## Abstract

**Background:** Neoadjuvant systemic therapy is offered to selected women with large and/or highly proliferative operable breast cancers. This option adds further complexity to an already complex breast cancer treatment decision tree. Patient decision aids are an established method of increasing patient involvement and knowledge while decreasing decisional conflict. There is currently no decision aid available for women considering neoadjuvant systemic therapy.

**Objective:** We aimed to develop a decision aid for women diagnosed with operable breast cancer and considered suitable for neoadjuvant systemic therapy, and the protocol for a multicenter pre-post study evaluating the acceptability and feasibility of the decision aid.

**Methods:** The decision aid was developed through literature review, expert advisory panel, adherence to the International Patient Decision Aid Standards, and iterative review. The protocol for evaluation of the decision aid consists of the following: eligible women will undertake a series of questionnaires prior to and after using the decision aid. The primary endpoint is decision aid acceptability to patients and investigators and the feasibility of use. Secondary endpoints include change in decisional conflict, participant knowledge, and information involvement preference. Feasibility is defined as the proportion of eligible participants who use the decision aid to help inform their treatment decision.

**Results:** This study has recruited 29 out of a planned 50 participants at four Australian sites. A 12-month recruitment period is expected with a further 12-months follow-up.

**Conclusions:** The decision aid has the potential to allow patients with operable breast cancer, who have been offered neoadjuvant systemic therapy, decreased decisional conflict, and greater involvement in the decision. If this study finds that an online decision aid is feasible and acceptable, it will be made widely available for routine clinical practice.

**Trial Registration:** Australian and New Zealand Clinical Trials Registry ACTRN12614001267640; <http://www.anzctr.org.au/TrialSearch.aspx?searchTxt=ACTRN12614001267640&isBasic=True> (Archived by WebCite at <http://www.webcitation.org/6gh7BPZdG>)

**KEYWORDS**

breast neoplasm; decision aid; neoadjuvant; chemotherapy; protocol

## Introduction

Neoadjuvant systemic therapy (NAST) has become a routine treatment option for selected women with operable breast cancer, endorsed by international guidelines [1, 2], patients [3], doctors [4], and breast cancer advocates [5]. We estimate that at least 20% of patients with breast cancer might benefit from NAST; however, this rate varies among clinicians [6]. It has the advantages of down-staging some larger tumors from mastectomy to lumpectomy [7], providing prognostic information depending on the degree of tumor response [8], and facilitating translational research for early biomarkers of response [9]. In tumors with higher rates of proliferation such as triple negative and HER2 (human epidermal growth factor receptor 2)-positive, pathological complete response is considered a surrogate outcome for the approval of novel therapies [10]. Additional potential benefits include additional time for surgical decision making, genetic testing, and downstaging of the axilla [11]. Overall survival and disease-free survival are equivalent following either neoadjuvant or adjuvant systemic therapy with appropriate local therapy [12]. Despite these advantages, NAST is not frequently used for women with operable disease, with one Australian study reporting an estimated rate of 2.75% [4], and in the United States 3.8% [13]. Possible reasons for this low rate of NAST use include the need for changes in workflow practices, patient expectation for upfront surgery, patient lack of awareness of NAST, and lack of available clinical trials [6]. Potential disadvantages to NAST include the loss of detailed pathology to guide multidisciplinary management; the (low) potential to delay surgery in patients who do not respond to NAST; and reduced time between surgery and radiotherapy, which may impact on breast reconstruction outcomes [4].

In a series of semistructured interviews conducted by our group, women with breast cancer expressed interest in NAST, for down-staging, prognostication, and to allow additional time to plan surgery [3]. However, they were not able to be as involved as they would like in the decision to receive NAST rather than adjuvant systemic therapy. They reported a lack of information, meaning that they did not feel adequately informed about the options available. They felt that clinicians tended to direct them toward one option, rather than their preference of shared control. This skewed distribution of decisional control was echoed in a survey of 207 Australian and New Zealand breast cancer specialists, where the majority of clinicians directed the decision about whether NAST would be given for operable breast cancer. This study, using an adaptation of the Control Preferences Scale [14], found that no clinicians reported that their patients made the final decision about NAST [15]. This indicates a mismatch between patient wishes and the experience of shared decision making [16], and suggests that strategies are required to better involve patients in the decision about NAST.

Women with early stage breast cancer typically desire involvement [17] and decisional control over their treatment [18]. Those who are at least as involved as they wanted experience better decision-related outcomes including consultation satisfaction, satisfaction with decision making, perception of clinician-shared decision-making skills, and decreased decisional conflict [18]. Being involved in decision making about breast cancer is associated with improved quality of life up to 10 years postdiagnosis [19]. However, it may be particularly difficult to engage women in decisions about NAST due to the complexity of the decision, distress from breast cancer diagnosis, perceived urgency, and an expectation that surgery will be the first treatment offered [3]. Patients may also want to proceed with up-front curative surgery in the hope that chemotherapy, which is seen as toxic and intrusive [20], may be avoided entirely.

Patient decision aids (DA) are an established method to improve the quality of shared decision making. Patient decision aids for treatment decisions have been shown to decrease decisional conflict, increase knowledge about options, improve risk perception, and improve patient-practitioner communication [21]. Decision aids are particularly suited to decisions where the various risks and benefits of the alternative treatment options may be valued differently by different individuals [22]. The choice between NAST and conventional sequencing (surgery followed by chemotherapy) is such a decision. In a systematic review of decision aids for patients with early stage breast cancer, we could not find any reports of a decision aid for NAST [23]. In our Australian survey, 86% of breast cancer specialists expressed interest in using a decision aid for women with operable breast cancer who are offered NAST. Women who were interviewed endorsed the development of a NAST DA and expressed a preference for a tool in print form that was accessible from a trusted source. In this paper, we describe the development of such a DA and the protocol for a study that will evaluate that DA.

## Methods

### Decision Aid Development

A DA (see [Multimedia Appendix 1](#)) was developed based on a literature review and then refined in an iterative process by an expert advisory panel comprising medical oncologists, breast surgeons, a psycho-oncologist, consumers, a breast care nurse, and a breast cancer advocacy organization representative according to the systematic process described by Coulter et al [24]. A skilled consumer advocate with personal experience of breast cancer reviewed the decision aid on multiple occasions and provided constructive advice. The structure of the DA was based on the International Patient Decision Aid Standards Collaboration statement, to include a balanced description of adjuvant and neoadjuvant therapy, including advantages and disadvantages, outcome probabilities for each option, graphics, and a values clarification exercise. The DA was then circulated

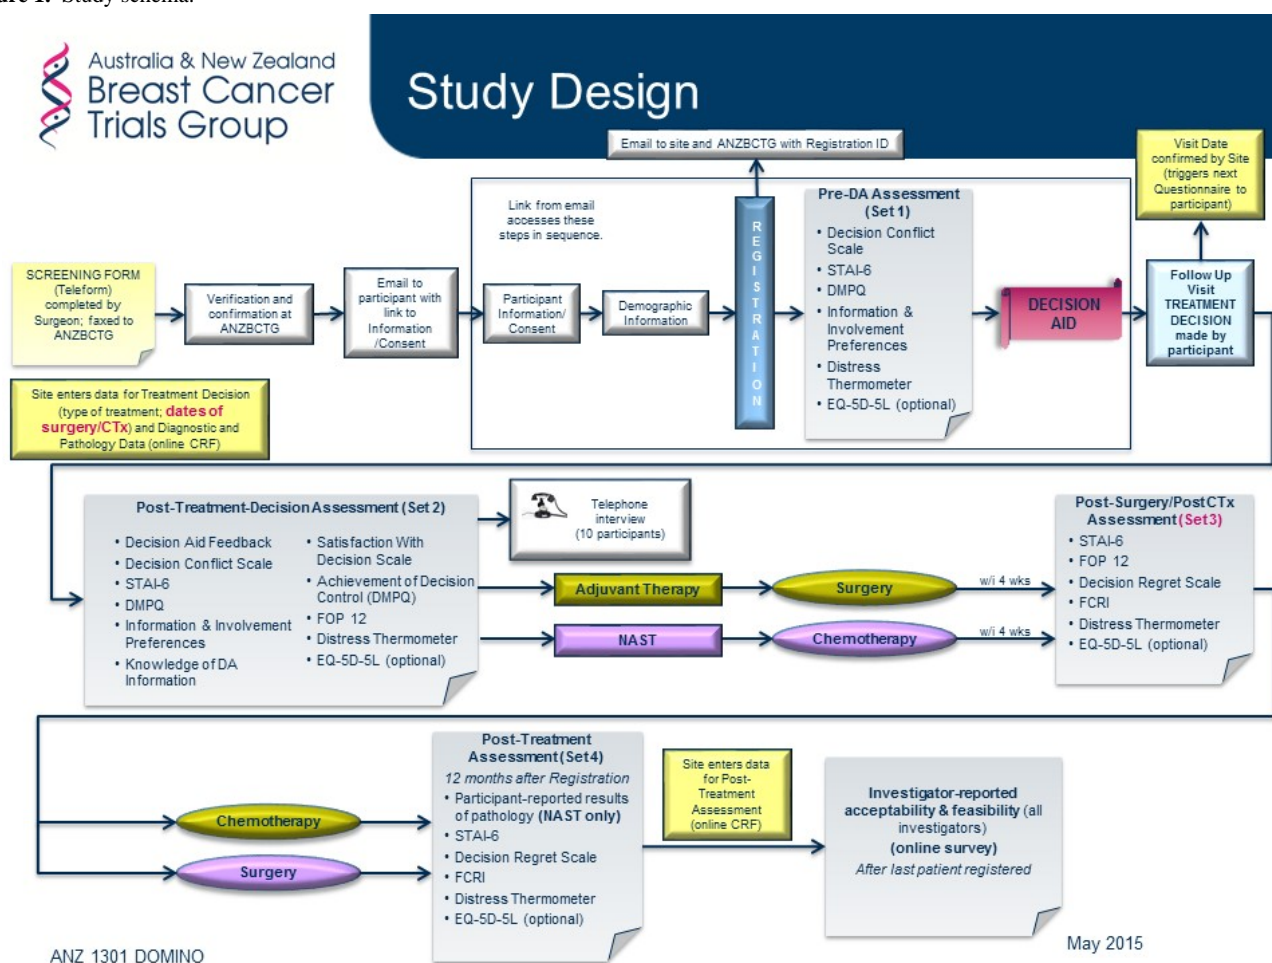

to an additional stakeholder group with similar composition to the first, who had not seen the DA, for further refinement. It was then professionally formatted in portable document format (.pdf) to be downloadable and printable in either color or black and white.

The final DA includes an introduction, brief general information about breast cancer and the treatments used, explanation of the options for the timing of chemotherapy and surgery, the advantages and disadvantages of neoadjuvant and adjuvant therapy, a values clarification exercise, a page for notes, a glossary, and information about where to find additional resources. Using the readability statistics package embedded in Microsoft Word, the decision aid has a grade 10 Flesch-Kincaid readability level. The introduction is necessary for newly diagnosed breast cancer patients to understand basic concepts about treatment modalities because they may not have received other written general information at the time that NAST is being discussed. A diagram represents the options of either chemotherapy followed by surgery or surgery followed by chemotherapy. Radiotherapy (if indicated), HER2-directed therapy (if HER2 positive), and endocrine therapy (if estrogen [ER] and/or progesterone receptor [PR] positive) follow in the flow diagram in [Multimedia Appendix 1](#). The diagram is designed to demonstrate that treatment duration is expected to be similar with either option.

Key components of risk are presented using visual, numeric, and narrative formats with appropriate labeling, tailored to individual tumor characteristics [25]. The likelihood of a pathological complete response is presented according to breast cancer subtype: ER/PR (hormone receptor [HR]) positive, HER2 negative; HR positive, HER2 positive; HR negative, HER2 positive; and HR negative and HER2 negative (triple negative [TNBC]). The probability of remaining alive and free of breast cancer at 5 years is presented, based on whether a pathological complete response was achieved, or not. These estimates are based on a meta-analysis of neoadjuvant clinical trial results reported by von Minckwitz et al [26] and Cortazar et al [8]. A 1000-dot diagram, with each dot representing one patient, illustrates the likelihood of tumor progression (3%) or becoming inoperable (0.3%) on neoadjuvant chemotherapy, based on a case series by Caudle et al [27].

The values clarification exercise in this DA is a diagram with statements about advantages and disadvantages of either option [28]. Patients can nominate how important each factor is to them and then make a mark on a linear analogue scale to show which option they prefer and how strong their view is. Patients are encouraged to discuss their options with friends, family, and other health professionals if they wish. The final decision is made at a follow-up visit with their surgeon or medical oncologist.

**Figure 1.** Study schema.

## Evaluation of Decision Aid

ANZ1301 is a multicenter study using a pre-post design to evaluate the acceptability and feasibility of the decision aid (Figure 1) described above. The project is being led by the Australia and New Zealand Breast Cancer Trials Group (ANZBCTG) in collaboration with the Psycho-oncology Co-operative Research Group. It is funded by an HCF Research Foundation grant with central trial coordination by the ANZBCTG. All four sites have received ethics approval from the Hunter New England Local Health District Human Research Ethics Committee, under the Australian National Mutual Acceptance multicenter ethics scheme.

## Study Participants

### Clinicians

In total, 26 clinicians from four ANZBCTG sites have been recruited to identify women eligible for the DOMINO (DecisiOn MakIng about NeOadjuvant) study. Participating sites are Calvary Mater Newcastle, Waratah, NSW; The Breast and Endocrine Center, Gateshead, NSW; The Mater Hospital, North Sydney, NSW; and Royal Melbourne Hospital, Parkville, VIC. Patients are screened at those four sites and in the private practices of associated clinicians. All participating clinicians and site study personnel receive training on the online system developed for this study.

### Patients

Patients are eligible to participate in the DOMINO study if they are female and aged over 18 years; have a histological diagnosis of invasive breast cancer; have an operable invasive breast tumour; are considered appropriate for neoadjuvant systemic therapy (NAST) with curative intent using chemo- and/ or endocrine therapy; are able and agree to access study information via the Internet; are able to comply with the study procedures for the duration of the study; and give voluntary, informed consent.

Patients are ineligible if they are expected to receive fewer than 3 months of NAST; have a hearing or other impairment that would preclude a phone interview; are unable to access the Internet using a laptop or desktop computer, or do not have an active email address with which to participate in the study; have insufficient English language skills for participation in online surveys and oral interviews; have inflammatory, metastatic, or inoperable breast cancer; or have a medical or psychiatric condition that precludes informed consent or prevents adherence to study procedures.

## Study Design

### Screening

Potentially eligible patients are identified during the planning of their initial treatment strategy at participating Australian sites during multidisciplinary meetings and at surgical and medical oncology appointments. Patients are approached by their clinician during their appointment to consider receiving additional information about the DOMINO study via a Web link that is sent to the patient via an auto-generated email. At the time of the initial offer of study participation, patients are

asked to indicate written consent on a screening form for their personal information (name, email address, and telephone number) to be provided to the ANZBCTG. A Web link to the study consent page and questionnaires is then sent to them by email. Patients who consent to share personal information are provided with a copy of their signed screening consent form along with study-specific written information about their breast cancer. This information is intended to aid understanding of their diagnosis when using the decision aid. Clinicians are required at this time to record details regarding the primary reason for NAST, as well as an opinion of the patient's current distress levels and information preferences. The completed screening consent form is sent via Teleform (Hewlett Packard) fax to the ANZBCTG to be verified, and email contact with the patient is established.

If the patient does not consent to share personal information, the clinician records information on the screening consent form so a log can be kept of each patient who is ineligible and screened out, eligible but not offered participation, and offered participation but declines. The number of patients who consent to screening but do not participate in the study will also be recorded. Screening data will be used to describe feasibility of DA use.

### Registration

Patients are registered to the study through the following process. The screening form is received at the ANZBCTG for validation and confirmation of eligibility criteria. Patients who consent to release their details on the screening form receive an automatically generated email. These patients are now considered eligible for the DOMINO study. Patients who access, read the online DOMINO Information Statement and Consent page, and agree to participate in the study are redirected to a series of demographic questions. On submission of responses to demographics and consent, patients are considered registered to the study. Patients at this stage are also given the opportunity to opt in to a telephone interview. Eligible patients have a 6-week window in which to view and agree to participate in the DOMINO study before being considered a screen failure. We aim to register 50 patients to the DOMINO study.

### Electronic Communication Processes

At the point of registration, patients are requested to enter a password to access the DOMINO website. Thereafter, an individual's username is defined by their email address.

Site trial coordinators input dates of patient appointments and projected treatment completion dates, which are then used to calculate and trigger all communication with the patient and reminders to site coordinators. Pre-designed patient and site coordinator emails are sent automatically at specific timepoints, as guided by information entered by sites as to the treatment decision (either NAST or surgery), to patients. A reminder email is sent to the patient if the survey remains unsubmitted 3 calendar days after the initial email. If after an additional 2 calendar days a patient has not submitted a questionnaire, an automatically generated email is sent to the ANZBCTG study coordinator prompting a telephone call to the patient. Site study coordination staff are sent automatically generated emails

prompting completion of data via the online system or informing them of their patient's submission of a questionnaire.

## Outcome Measures

### Primary Outcomes

DA acceptability is the first outcome. It is defined as at least half of patients considering the DA useful for their decision and at least half of clinicians indicating that they would use the DA in their routine clinical practice. Acceptability will be assessed using a single question from the DA feedback questionnaire developed by Juraskova et al [29] about whether the patient considered the DA useful for their decision. This questionnaire also measures general satisfaction with the DA.

Feasibility of DA use will also be assessed as an outcome. We define it as at least half of patients who were offered participation in the study accessing the DA, and at least half of those who access the DA stating that they read it.

### Secondary Hypotheses and Outcome Measures

We hypothesize that with use of the DA the Decisional Conflict Scale score will decrease [30]; knowledge about NAST, using a custom-designed questionnaire, will increase; information and involvement preference will increase [31]; agreement between preferred and achieved decision control will be high, based on an adaptation of the Control Preferences Scale to include achieved control [14]; and the Control Preferences Scale score will increase [14]. Further, there will be no change in cost of health care delivery or in the 6-item State-Trait Anxiety Inventory score [32]. Fear of cancer progression will be unchanged while receiving neoadjuvant therapy [33]; the Decisional Regret score after chemotherapy and after surgery will be low [34]; fear of cancer recurrence score will be low [35]; distress thermometer score will decrease [36, 37]; satisfaction with decision score will be high [38]; and there will be no change in outcomes between those who decided to receive neoadjuvant chemotherapy with those who decided not to have neoadjuvant therapy.

### Exploratory Hypotheses

Correlation will be good between baseline investigator assessment of participant information and involvement preference and participant report of DA acceptability. Correlation will be good between high baseline participant information and involvement preference and high acceptability of DA to participants. Correlation will be good between baseline investigator assessment of distress and participant report of distress. Participants will be willing to complete the EuroQol 5-Dimensions (EQ-5D-5L) questionnaire, a health utility measure.

### Knowledge Questionnaire

A custom-designed 7-item knowledge questionnaire has been developed based on the content of the DA to test recall and comprehension (see [Multimedia Appendix 2](#)). Questions were taken from information throughout the DA. The number of correct responses will be transformed to a score out of 100.

## Demographic, Tumor, and Treatment Information

The following demographics will be recorded: age, marital status, level of education, health insurance, occupation, and native language. Tumor characteristics consist of tumor size, nodal status, estrogen/progesterone receptor, HER2 amplification, and grade. Investigations and treatment received include duration of chemotherapy, radiotherapy, surgical procedure(s) performed, biopsies, and imaging performed.

### Telephone Interview

Participants will be asked to participate in a semistructured interview using a pre-planned interview guide, to gain a deeper understanding of their attitude toward the utility and acceptability of the DA. Participants are asked at the time of consent to tick a box indicating their willingness to be contacted for an interview. Interviews will undergo immediate initial analysis and will be conducted until thematic saturation is reached, defined as no new major themes in three consecutive interviews. Further rounds of analysis will be conducted in an iterative fashion after all interviews are complete. Interviews will be recorded, transcribed verbatim, and analyzed using qualitative methodology. Qualitative descriptive methodology will be used, as is appropriate when lived experience, views, and preferences are the target of investigation, and there are little existing data available. This method can be used to gain a rich description of an experience, founded in existing knowledge and interpreted in the context of the clinical experience of the research group [39].

### Clinician Questionnaire

After 50 patients have completed their post-DA questionnaire, all clinicians will receive an electronic questionnaire. The questions include specialty (surgeon or medical oncologist), intent to use the DA in routine clinical practice, patient selection for DA use, effect on consultation duration and number, apparent effect on decision making, and comments on content. The DA will be considered acceptable to clinicians if more than 50% report that they would use the DA in routine clinical practice.

### Questionnaire Administration

A series of validated questionnaires where available, and custom designed where a questionnaire is not available, are presented to patients at four timepoints before and after access to the decision aid (see [Table 1](#)). Prior to access to the decision aid, patients are asked to report demographics and to complete 6 questionnaires that address decisional conflict, decision-making preference, information and involvement preferences, anxiety, distress, and an optional health economic instrument.

At the completion and submission of the first set of questionnaires, patients are able to access an electronic copy of the decision aid. This document can be printed, saved, and accessed by a patient at any stage of the study by logging in to the DOMINO website. Patients are asked to complete and read the decision aid prior to attending their next appointment with their clinician, at which time a decision regarding treatment may be made. At this visit, the clinician refers to the decision aid and asks whether the patient has any questions about it. After the attendance at an appointment where a decision was made regarding treatment and specific data have been entered

by the site, the patient receives an autogenerated email informing them that a second set of questionnaires is available for completion. Questionnaires at this timepoint ask the patient to reflect on the information provided in the DA and its role in their treatment decision. Patients who do not submit both questionnaire sets 1 and 2 will be replaced to ensure that pre-post outcomes are recorded for 50 patients.

Based on treatment details supplied by the site trial coordinator about treatment option chosen and date of completion, an email link to questionnaire set 3 is sent to the patient. This questionnaire is to be completed after the initial treatment

strategy of either chemotherapy or surgery. It is expected that most participants will then proceed with surgery or systemic therapy respectively as their subsequent treatment strategy. This assessment aims to determine the effect of the first treatment strategy on decision-related outcomes, without the influence of the alternative strategy.

Questionnaire set 4 is answered 12 months after registration, to investigate longer-term outcomes including anxiety, distress, regret, and recollection of pathology results. This is the last questionnaire, and participants complete their study involvement at this time.

**Table 1.** Questionnaire content according to assessment timepoint.

	Pre-DA assessment	Posttreatment decision assessment	Postchemo assessment (NAST) <sup>a</sup>	Postsurgery (non-NAST) <sup>b</sup>	Posttreatment assessment <sup>c</sup>

<sup>a</sup>Postchemotherapy, before surgery.

<sup>b</sup>Postsurgery, before adjuvant chemotherapy.

<sup>c</sup>12 months (+/- 1 month) after registration.

## Statistical Analysis

A sample size of 50 participants is planned. The primary analysis will include all registered patients and clinicians as two separate cohorts. The proportion of patients and investigators who consider the DA acceptable will be reported with 95% exact confidence limits. The primary outcome will be considered positive if more than half of patients and clinicians consider the DA acceptable, and feasible if more than half of eligible patients who are offered participation register and subsequently use the DA. Assuming a sample size of 50 participants, the primary outcome of percentage of participants finding the DA acceptable can be estimated to within  $\pm 15\%$  based on 95% exact confidence limits. To ensure that the lower 95% one-tailed exact confidence limit is greater than 50%, at least 32 of the 50 participants will

need to indicate DA acceptability. Although the study is not powered to test the secondary hypotheses, there is 80% power to detect a change of at least 0.40 standard deviations from the pre- to post-DA assessments using a two-tailed *t*-test with  $\alpha=0.05$  and a sample size of 50 participants.

Changes in secondary outcome measures from the pre-DA assessment, including decisional conflict, information preference, anxiety, distress, and fear of progression, will be evaluated using repeated measures analysis of covariance (ANCOVA). All outcomes will be described using mean and standard deviation for continuous measures and frequency for categorical outcomes. If data are skewed, median and interquartile range will be reported and the appropriate linearizing transformation will be used. Analyses will be

performed unadjusted and adjusted for age, level of education, information preferences, and tumor characteristics (size, grade, node involvement, ER/PR/HER2). Agreement in decisional control before and after using the DA, and between preferred and actual control, will be assessed using a weighted kappa statistic with McNemar test. Knowledge will be reported as mean proportion of items correct with standard deviation. Cost will be recorded using Australian Medical Benefits Scheme item numbers and Pharmaceutical Benefits Scheme prices, and a comparison made between those who receive surgery first and those who receive systemic therapy first.

### Missing Data

Patients are encouraged to complete all questions but are not compelled to enter responses to any of the individual questions within each set of questionnaires and can submit responses with blank fields. Prior to questionnaire submission, patients will receive a prompt informing them that not all questions have been answered and to amend if they wish. During the study, levels of missing data are being monitored. If data completion rates drop below 70%, remedial action will be taken. An analysis of missing data will be completed at the end of the study.

## Results

The study is currently recruiting at four Australian centers. As of February 2016, 29 of the planned 50 participants have been registered to the study. Recruitment is expected to be complete in mid-2016, with early results available late 2016.

## Discussion

### Principal Considerations

This study intends to evaluate the acceptability and feasibility of a DA for women with operable breast cancer who have been offered NAST. It is designed as a single arm pre-post study to allow all participants access to the intervention. The population of Australian women who currently receives NAST is relatively small, limiting the feasibility of a larger, randomized controlled trial with comparative outcomes. However, the proportion of patients receiving NAST in Australia and New Zealand is expected to increase as a result of increased awareness, availability of neoadjuvant clinical trials, and from the results of ongoing neoadjuvant and post-neoadjuvant trials.

The study primary endpoints are pragmatic. We expect that some participants will not find the DA beneficial, based on their decision-making style and information-seeking behavior. However, we hypothesize that the number who find it helpful in their decision-making process will be greater than the number who do not find it useful. Because DAs have variable use across centers and individual clinicians [40], feasibility was included as an endpoint. A screening log is designed to quantify the number of patients who are seen at recruiting sites who are candidates for NAST for operable breast cancer; are eligible for the study; are offered study participation; accept study participation; and go on to access the DA. This will identify the proportion of eligible patients who are not offered participation (clinician feasibility) and the proportion of eligible patients who do not access the DA after being offered it (patient feasibility).

Acceptability will be assessed using direct questions to patients and clinicians.

Outcome measures were selected based on the availability of valid, reliable questionnaires that assess outcomes relevant to decision making in the context of a decision aid. In a systematic review of the quality of measures to test the effectiveness of decision support strategies, the Decisional Conflict Scale and the Control Preferences Scale satisfied the largest number of quality criteria [41]. These are commonly used measures of DA effectiveness [21, 42]. Knowledge assessment necessitates a custom-designed questionnaire. The Fear of Progression questionnaire is suited to the neoadjuvant setting where the primary cancer is present and has the potential to impact on psychological and physical domains [33]. The Information and Involvement Preferences questionnaire was included to determine the information needs of patients and to correlate the result with patient and clinician acceptability. The EQ-5D-5L is a health economic utility measure [43] and was included as an optional measure to determine patients' willingness to complete this additional questionnaire. If patients are willing to complete it, then it will be considered for future comparative studies as a health economic measure. Satisfaction with decision is of interest as an acute measure to be assessed after the decision has been made, but prior to experiencing the consequences of the decision [34]. Decision regret is a longer-term outcome measure, to be assessed after the consequences of the decision have been experienced [38].

Increased anxiety is associated with both more effective decision strategies and stressful health interventions, so is not a good measure of the benefit of DA use [44]. Anxiety therefore is not expected to decrease as a result of a DA, but nor should it increase and therefore anxiety has been included as a safety measure [21].

Decision aids are most beneficial if endorsed by a clinician at the time they are offered to the patient and referred to after the decision has been made [45]. This decision aid is introduced at a time when patients have recently been diagnosed with breast cancer and are faced with a number of complex decisions that are influenced by a variety of sources including clinicians, family, and the media [46, 47]. Patients are identified as suitable for the decision aid by their doctor (usually a surgeon) and are generally referred to a medical oncologist to discuss systemic therapy. The decision aid is suited to this situation as there is often a period of several days (or more) before an available appointment with a medical oncologist. If the decision aid is effective, the patient will be more prepared to be involved in the decision when they come to the medical oncologist. Balancing the provision of complex information with adequate readability proved difficult, as demonstrated by a higher Flesch-Kincaid grade than would be ideal.

Decision aids have been shown to have a variable effect on treatment choices [21]. For selected treatment decisions, some patients change their preferred treatment after a DA, but for others decision aids have been shown to have a neutral effect. We anticipate that study patients will not change their decisions after accessing the DA, as decisions such as this tend to be made based on a number of information sources [48].

If shown to be feasible and acceptable, the DOMINO decision aid has the potential to be offered to patients as part of routine clinical practice. There is good evidence for the efficacy of decision aids that are designed according to international standards [22,24]. Thus, a randomized controlled trial is not considered a prerequisite for dissemination. Clinicians who enroll participants in this study will be asked whether they would continue to use the decision aid as part of routine practice, as an indicator of perceived implementability.

## Conclusion

Use of the DOMINO decision aid has the potential to decrease decisional conflict, increase knowledge, and increase patient

involvement in women who have been offered NAST. Increased involvement in decisions by women with breast cancer is associated with improved decision-related outcomes [18] and long-term quality of life [19]. Neoadjuvant clinical trials are an established drug development pathway, and the decision aid may allow better understanding of the rationale behind neoadjuvant therapy. The patient may then be able to be better informed about the trial. It may also assist clinicians who are introducing neoadjuvant systemic therapy into their practice but have not yet become confident addressing the concept with their patients.

## Acknowledgments

We thank the Australia and New Zealand Breast Cancer Trials Group Supportive Care Subcommittee and Scientific Advisory Committee for scientific input and the Trials Coordination Department for protocol development. Newton Green Technologies developed the database, online questionnaires, and electronic case report forms. The ANZ1301 DOMINO study is funded by an HCF Research Foundation grant and by the Breast Cancer Institute of Australia.

NZ is supported by Sydney Catalyst and the Hunter New England Local Health District. FB is supported by the Friends of the Mater Foundation.

## Authors' Contributions

NZ, PB, JC, CD, and FB conceived the study and refined the design. All authors developed the protocol. NZ and FB will contribute patients and data. EH will coordinate the study centrally. NZ and EH drafted the manuscript. All authors have reviewed and approved the manuscript prior to submission.

## Abstract

**Background:** Women are disproportionately likely to assist aging family members; approximately 53 million in the United States are involved with the health care of aging parents, in-laws, or other relatives. The busy schedules of “sandwich generation” women who care for older relatives require accessible and flexible health education, including Web-based approaches.

**Objective:** This paper describes the development and implementation of a Web-based health education intervention, The Sandwich Generation Diner, as a tool for intergenerational caregivers of older adults with physical and cognitive impairments.

**Methods:** We used Bartholomew’s Intervention Mapping (IM) process to develop our theory-based health education program. Bandura’s (1997) self-efficacy theory provided the overarching theoretical model.

**Results:** The Sandwich Generation Diner website features four modules that address specific health care concerns. Our research involves randomly assigning caregiver participants to one of two experimental conditions that are identical in the type of information provided, but vary significantly in the presentation. In addition to structured Web-based assessments, specific website usage data are recorded.

**Conclusions:** The Sandwich Generation Diner was developed to address some of the informational and self-efficacy needs of intergenerational female caregivers. The next step is to demonstrate that this intervention is: (1) attractive and effective with families assisting older adults, and (2) feasible to embed within routine home health services for older adults.

intergenerational relations; health education; caregivers; intervention studies; Internet

## Introduction

**Background**

Researchers are faced with minimal operational guidance when attempting to develop complex interventions to reduce the gap between clinical evidence and behavioral practice [1]. There is, however, a growing recognition that behavioral-health interventions should be grounded upon a solid theoretical

framework [2]. Not only are theory-based interventions more likely to be effective, they can also provide an understanding of causal pathways for change [2]. Unfortunately, although there are numerous behavioral-health theories to draw upon, it is challenging to translate these theories into practical interventions [2,3].

In an effort to address these issues, Bartholomew [4] developed an Intervention Mapping (IM) protocol that provides a process

for developing theory-based health education programs. In IM, researchers use these six iterative and reciprocal tasks to create their interventions: (1) assessing the problem, (2) specifying program objectives, (3) identifying theory- and evidence-based behavior change methods, (4) creating the intervention, (5) planning the implementation, and (6) planning the evaluation [5]. In this article, we describe the development of our *Sandwich Generation Diner* intervention for intergenerational caregivers within the context of the IM framework.

## Intervention Mapping Step 1: Assessing the Problem

### *Prevalence and Correlates of Medication Nonadherence in Older Adults*

Older adults have more chronic medical conditions and a corresponding higher rate of medication use, spending three times the national average for prescription drugs [6]. Although some do an excellent job of managing their medications, a significant number have difficulty with this task. Medication mismanagement and errors may have dire consequences for seniors, including a higher risk for falls, delirium, excess disability, hospitalizations, and death [7].

### *The Role of Family Involvement in Medication-Related Behaviors*

Many older adults have close reciprocal relationships with younger members of their family, and due to physical or cognitive limitations, receive assistance with health care visits and medication management. There are an estimated 3.3 million older adults in the United States who receive assistance with both physician visits and prescribed medications, and these are a high-need group [8]. More than 75% of this population require aid with mobility, self-care, or household activities, and approximately 60% have possible or probable dementia. Involvement by a family care partner typically persists over time, and is more likely to be a younger female family member rather than a spouse [8]. Women make approximately 80% of health care decisions for their families and are more likely than men to be the caregiver when an older family member is ill [9]. Although caring for an older relative may have negative impacts on women's mental and physical health, caregivers often view their role as deeply meaningful [10].

### *Health Education for Intergenerational Caregivers*

Few community-based health education programs offer support explicitly targeting intergenerational caregivers [10-12]. Those that are available have significant limitations. Community-based programs are often inaccessible or burdensome due to the care recipient's need for ongoing supervision. In-home programs can affect a number of care outcomes, but also include challenges such as the cost of individualized services and staff travel. Psychoeducational groups may be helpful, but they require participants to travel to the program. Consequently, the "sandwich generation" women who care for older relatives require more accessible and flexible health education approaches than is generally available.

## Intervention Mapping Step 2: Specifying Program Objectives

### *Web-Based Health Education*

Technological advances have created new opportunities for reaching consumers through Web-based and other distance-based health education and support [13-15]. The Internet has become an important source of health information. Eighty percent of internet users, and 59% of the US population, look on the Internet for health information [16]. The proportion of adults aged 65 and older who use the Internet to search for information has grown to 53%; of these, 70% report using the Internet daily [17]. As providers continue to adopt eHealth technologies, the range of activities for consumers to participate in their health care continues to expand and includes everything from engaging in condition-specific discussions to entering information in personal health records [18]. Not only does participating in Web-based health care programs provide clear benefits in terms of wellness, it can also result in increased motivation and self-efficacy for managing care [19].

### *Receipt of Grant Award*

Our team has had a long history of developing eHealth interventions including an interactive public education exhibit, continuing education courseware, and smartphone apps [20,21]. These efforts, along with our experience developing video-based interventions for dementia caregivers [14,15,22] led to an award from the authors' university.

The primary aims for our project were to: (1) increase caregivers' knowledge and use of effective medication management strategies, (2) decrease medication-related hassles perceived by women caring for an older relative, and (3) decrease rates of adverse medication-related events for older care recipients. We assembled a diverse work group from units on campus (ie, Psychological Sciences, Gerontology, and the Missouri Institute of Mental Health) as well as a community advisory board and an interdisciplinary panel of consultants to assist with study content and dissemination.

## Methods

### Intervention Mapping Step 3: Identifying Theory- and Evidence-Based Behavior Change Methods

In their meta-analysis of the features of effective Web-based health promotion interventions, Lustria et al [13] describe the importance of grounding programs in empirically supported theories of change. Davis and colleagues [2] argue that many of these theories provide little guidance regarding how to translate underlying concepts into practical interventions. Bandura's Social Cognitive Theory (SCT) [23] is a notable exception. Bandura states that learning occurs in a social context and is shaped by reciprocal relationships between the person, environment, and behavior. SCT involves a heavily agentic perspective, in which individuals are seen as goal-directed and exert intentional influence over their functioning; these intentional actions then impact the course of events. A number of principles are incorporated within this theory, including reciprocal determinism (interaction of person, environment, and

behavior), behavioral capacity (actual ability to perform a behavior through knowledge and skills), observational learning, reinforcements, outcome expectations, and self-efficacy [23]. The construct of self-efficacy is an important facet of SCT, and refers to beliefs in one's ability to execute courses of actions to manage situations important within a specific life domain. In Bandura's theory, self-efficacy beliefs influence whether coping efforts will be initiated, how much effort will be invested, how long effort is sustained in the face of aversive experiences and obstacles, and affect vulnerability to emotional distress. Self-efficacy beliefs can be shaped by various means including mastery experiences, social observation, and social persuasion [24].

In the area of aging, the model has been applied to understanding dementia family caregiving [25] and medication adherence [26]. When individuals face health-related caregiving challenges, those with low self-efficacy focus on negative aspects of the situation (eg, personal deficiencies, task difficulties). In essence, they "lose heart." This focus on negative cognitions reduces motivation to initiate an activity, impacts task persistence, and leads to negative affective states, which then perpetuates the cycle [27].

Because Bandura argues that self-efficacy can be improved via social observation, many interventions attempt to promote behavior change by increasing self-efficacy through observational learning of similar others. These interventions often use dramatic enactments of scenarios that the target audience may face in their daily lives. By identifying with and watching others successfully master challenges, viewers gain an improved sense of their own mastery. Using this model, researchers have successfully used serial radio dramas to improve human immunodeficiency virus outcomes [28,29]. Our own work has demonstrated the benefits of video-based stories for improving knowledge of substance abuse [30].

Based on this prior validation, we chose to ground our current intervention on Bandura's SCT, with a particular focus on influencing the caregiving self-efficacy beliefs of intergenerational caregivers. We incorporated a number of elements of SCT, while aiming to: (1) acknowledge the importance of social context by distinguishing among skills needed in different caregiving situations, (2) influence behavioral capacity through instruction in specific health care management and interpersonal communication skills, (3) foster observational learning through serial video narratives of caregivers, and (4) enhance self-efficacy beliefs by developing story lines that show characters mastering progressively more challenging situations. We hypothesized that individuals who viewed true-to-life vignettes of individuals successfully overcoming difficulties providing care for their elderly family members would demonstrate improved outcomes as compared with individuals who received information presented in a more didactic format.

## Intervention Mapping Step 4: Creating the Intervention

### Content Outlines

We began our development efforts by creating detailed content outlines of the information we wanted to convey to our target audience. We had a team of expert consultants including pharmacists and nurse practitioners, as well as social work, psychology, and public health professionals consult with us about the most common difficulties associated with health care and medication management in older adults. We cross-referenced these content areas with existing behavioral health literature regarding best practice guidelines. We then included the overlapping recommendations as final content to be included in the intervention script, making sure to couch them within the context of social cognitive theory (eg, selecting situations identified as common challenges, developing the vignettes to show an increase in challenge/difficulty over the narrative, linking the behaviors of the characters to specific skills, having the characters demonstrate mastery at the end). This process resulted in the creation of four subject areas: (1) medication management, (2) recognizing and responding to alterations in cognition (delirium and dementia), (3) managing health care appointments and communication with providers, and (4) communication and planning strategies for family members.

### Development of Creative Approach

With the content clearly articulated, we were ready to develop the overarching creative approach for our intervention. In past work, we discovered that developing an underlying story or metaphor to convey our content helped to increase participant engagement. For example, in one of our early educational programs designed to teach students about the biology of addiction, we embedded our learning objectives within a narrative story about aliens coming to Earth to learn how to play basketball [31].

For the current intervention, we needed to develop a creative approach that would not only engage our target audience (middle-aged women caring for elderly family members), but would also reflect a diverse set of demographic characteristics. During a series of brainstorming sessions, we finally settled upon the idea of our intervention taking place in a diner with a wise and seasoned waitress serving as the primary character. Through interactions with her various customers, viewers would be able to see various health care challenges being overcome.

### Script Writing

It was only after the content and creative approach were finalized that we were able to begin writing the intervention's scripts. For each of the four content modules, we structured the story to evolve over the course of five separate vignettes. Each story began with the waitress character introducing the primary dilemma the characters were facing. Then, in each subsequent vignette, the characters demonstrated a growing sense of efficacy in their ability to solve the problems they were having while caring for their family members. In order to increase the likelihood of participants watching the vignettes, each is less than 4-minutes long.

## Review of Intervention Plans

When the scripts for each module were completed, we engaged in a second round of expert consultation. Once again, we used our interdisciplinary approach to discuss the relevance, use, and goals of this portion of our intervention. After completing suggested modifications to the script, we presented it to a small group of selected “beta testers.” These individuals were lay persons unaffiliated with the intervention who we asked to review the scripts for readability and clarity of the dialogue. We incorporated this group’s suggestions into the final script.

## Content Acquisition

After completing the scripts, we then created detailed storyboards for our Web-based intervention. Following these specifications, we produced custom graphics for the program’s logo and interface. In this way, we were able to “brand” our intervention with an engaging appearance and name – “Sandwich Generation Diner.” We used these graphics for all materials associated with the intervention (eg, marketing pieces, downloadable files, etc).

The scripts themselves called for a number of characters across a broad set of demographic characteristics. Through advertisements on local actor’s message boards, word of mouth, and notes to previous actors we had worked with in the past, we assembled a pool of candidates to appear in our production. We then used a series of phone and live auditions to settle upon the final cast.

In order to improve the authenticity of our production, we placed a special emphasis on finding the perfect location at which to shoot our videos. We eventually arranged with the management of a local diner and were able to use their space for eight, after-hours sessions during the course of a single month. In addition to providing us authentic props, the management also cooked us the food that was specified in the script.

We asked the actors to memorize their lines; prior to shooting each scene, we had them run their lines in place. This procedure reduced rehearsal time and facilitated the production process. For each scene, we recorded both wide and close-up shots. Although this process required the actors to deliver their lines multiple times, it also provided us with multiple options for editing the final footage.

## Coding

Because we wanted to roll out our intervention to participants across the course of a month, we needed to develop a solution that allowed for flexibility in the way our content would be displayed and delivered. In the end we chose to create a WordPress site and assigned all participants a unique login. By using the s2Member plug-in, we were able to code the site in such a way that it would modify its display according to the credentials we assigned each user. This procedure allowed us to set user’s access levels in terms of being part of the control or experimental condition and how far along they were in the intervention protocol. Each week, we increased the participants’ access level so that they would automatically see subsequent portions of the intervention.

## Results

### Program Description

Regardless of experimental condition to which they were assigned, all participants log onto our site and are automatically presented with the appropriate content based on their user credentials. By manipulating user’s access levels in the website’s control panel, we have been able to sequentially roll out the intervention across 4 weeks (Phase I) and test impact of accessing all intervention materials at once (Phase II). To encourage viewing of our materials, we send weekly reminder emails to the participants.

The overall appearance of our site is largely the same for participants in both the Narrative Vignette and Comparison Didactic conditions. See [Multimedia Appendix 1](#) for a screen shot of our site’s main menu. After clicking on one of the primary content areas, participants are presented one of the submenus illustrated in [Multimedia Appendix 2](#). Although participants in both groups have access to the didactic portable document format (PDF) informational sheets (see [Multimedia Appendix 3](#)) and talking head expert videos (see [Multimedia Appendix 4](#)) presented in the left column, only participants in the Narrative condition have access to the scripted vignettes (described above and illustrated in [Multimedia Appendix 5](#)). Although all links are visible throughout the entire intervention period, we sequentially enable them throughout the course of an individual participant’s 4-week trial. Participants are free to choose to view the information in any order and spend as much or little time on the site as they would like.

### Health Education Content

In keeping with the self-efficacy literature, we developed storylines consistent with common situations and needs of intergenerational female caregivers. Actors were selected who represented our target demographics for this study.

### Managing Medications

This content area includes a discussion of adverse events linked to medications (eg, falls, delirium, nursing home placement, negative health outcomes), and provides information about the most effective ways to manage scheduling of doses and refills. This module also includes psychoeducation about the role a pharmacist can play in medication management problem solving, as well as a list of basic and advanced questions that can be used to help improve medication management and organizational skills. The module also provides further information about the benefits of assessing interaction effects of over-the-counter medications with prescriptions that the care recipient already takes. The module highly encourages consultation with pharmacy staff.

### Signs of Confusion

Given that caregivers of older adults with undiagnosed cognitive impairment may not know how thinking abilities relate to medication management, this content area provides participants with information about the signs and symptoms of delirium and dementia, as well as ways to distinguish the two. Caregivers are given information about the high rates of undiagnosed

delirium and dementia in community-dwelling older adults and the benefits of medical evaluation and diagnosis. The module also presents information about the process for obtaining a diagnosis for a progressively dementing neurocognitive illness, including material about brief cognitive screens and neuropsychological testing.

### **Health Care Visits**

This content area provides caregivers with information about how to prepare for health care visits that they attend with their loved one. Caregivers are given a list of example questions they can ask medical providers about current medications, newly prescribed medications, over the counter medications, and side-effects. This module also addresses legal and Health Insurance Portability and Accountability Act (HIPAA) barriers to full communication between family members and health care professionals. The content area explains the need for signed releases on file in the patient's chart to allow these conversations and provides an example of a nationally available form for durable power of attorney for health care, named "Five Wishes."

### **Talking Together**

This content area focuses on developing communication skills between the caregiver and care recipient. Caregivers are given instruction on how to use basic communication strategies such as eye contact, tone, and "I" language. This module also provides examples of medication-related conflict between the caregiver and care recipient, and offers suggestions for effective communication strategies when negotiating these disagreements. In addition, caregivers are encouraged to use these communication skills when discussing potentially conflictual topics such as housing, financial planning, driving, and health care plans. This module also addresses legal and HIPAA requirements for full communication between family members and health care professionals.

## **Intervention Mapping Step 5: Planning the Implementation**

Our goal is to demonstrate that this intervention is (1) attractive and effective with families assisting older adults enrolled in home health care (a medically vulnerable population), and is (2) feasible to embed within routine home health services for older adults. We aim to evaluate the intervention's impact on family-clinician communication and reported caregiving self-efficacy and role overload. The original funding source (an internal grant from the investigators' university) supported the development of the Web-based intervention and collection of pilot data.

## **Intervention Mapping Step 6: Planning the Evaluation**

We first developed a preliminary evaluation with a community sample. Initial pilot data supporting the intervention will be valuable in developing collaborative relationships with health care agencies and systems serving older adults.

### **Participants**

Adult women providing informal care to an older adult are recruited through print advertisements placed in health care and community locations throughout a large Midwestern city, and

through study announcements posted on social media. Interested individuals are directed to a brief Web-based screening survey.

### **Intervention Procedure**

We email eligible participants who consent to the study a longer preintervention survey. Upon completion of the preintervention survey, we randomly assign participants to either the Narrative Vignette or Comparison Didactic condition. We use block randomization to balance dementia caregivers and nondementia caregivers across study conditions. After randomization, we email participants with their unique login and password along with instructions for using the website. We also instruct them not to allow anyone else to log in to the website using their credentials.

During the 4-week intervention period, we send participants weekly emails. At the end of their trial, we send participants a postintervention assessment survey, and a 1-month follow-up survey. We then conduct a brief phone interview to collect qualitative data. For participants who had been in the Comparison Didactic condition, we then allow them to have access to the narrative vignettes. Finally, 6 months after completing the intervention, we invite participants to complete another brief follow-up Web-based assessment.

Participants complete Web-based assessments at preintervention, postintervention, 1-month follow-up, and 6-month follow-up. We collect descriptive information about the participant's caregiving situation and demographic information about the caregiver and care recipient. Measures include medication risk [32], falls, and the Centers for Disease Control Healthy Days for the care recipient [33], caregiving medication administration hassles [34], role overload [35], self-efficacy beliefs [25], and family-health care provider communication [36]. We gather qualitative data about project feedback via a brief phone interview 1 month after completing the intervention. Participants receive US\$25 gift cards after completing each of the assessments. Participant's website usage is automatically tracked including information about the dates and times of website use and any downloads of Web-based material over the study period.

We are presently in the data collection phase of this process, and initial participant characteristics and satisfaction ratings are promising. Caregiver participants (N=137) are ethnically diverse at 31% (43/137) non-White compared with 26% of US residents being non-White. Participants predominantly care for a frail parent, with 85% (117/137) being a daughter or daughter-in-law of the older adult. Caregivers engaged in significant medical management tasks for older adults with a number of chronic and comorbid health conditions. Participants reported satisfaction with the intervention (mean=5.65, standard deviation=.97) on a 7-point scale with a score of 7 being most satisfied.

## **Discussion**

### **Summary**

We developed and are currently evaluating an eHealth intervention (in a randomized trial format) for female intergenerational family caregivers actively involved with the health care of an older relative. Both conditions are designed

to improve medication management and related health care behaviors in informal caregivers of older persons with physical and/or cognitive impairments. The didactic comparison condition contains a series of downloadable PDF “Handouts” with information about managing medications, attending a health care visit, causes of confusion in older adults, and communication with the older family member. Each section includes one video of an expert providing information in traditional didactic voice. The narrative vignette condition includes the same content as above, with additional serial Web episode storylines that show caregivers interacting with their loved one, and problem solving concerns in each of the aforementioned domains.

### Program Strengths

Strengths of our program include a solid conceptual grounding of the intervention within self-efficacy theory [27], and creation of a flexible Web-based format that allows caregivers to explore health education content areas of most interest to them. We also believe that targeting intergenerational caregivers involved in medication management for older adults is novel and justified, given the literature describing differences between spousal caregivers and adult children in levels of frustration with these types of tasks [37]. Many studies show that caregivers have increased time constraints when compared with similar noncaregiving individuals [10]; the Web-based availability of our intervention materials may decrease the time investment necessary for caregivers to obtain aid [12].

### Limitations and Lessons Learned

Because this study occurs over a relatively brief period (1 month), future research may benefit by extending the amount of follow-up contact and assessment points. This study has not implemented specific strategies to improve access for caregivers who are lower income or who demonstrate lower educational attainment. Such individuals generally have limited access to technological resources or may show lower general engagement with health care and health-related interventions. Future studies may explore the current barriers to technological access and eliminate these by providing other avenues to Internet resources (ie, library cards or rented tablets).

### Conclusions

The *Sandwich Generation Diner* has been developed to address some of the informational and self-efficacy needs of intergenerational women caregivers. Within the IM framework, development of the *Sandwich Generation Diner* intervention involved: (1) assessing the problem, (2) specifying program objectives, (3) selecting an overarching theoretical model, (4) creating the intervention, (5) implementing the intervention, and (6) evaluating the intervention. Bandura’s self-efficacy theory [27] provided the overarching theoretical model. The integration of serial narrative vignettes with multimedia resources is intended to result in a rich and meaningful intervention. We look forward to completion of the ongoing efficacy trial to evaluate the extent that we have accomplished these aims.

## Abstract

**Background:** The annual number of new human immunodeficiency virus (HIV) infections among men who have sex with men (MSM) has risen in the United Kingdom and, of those who are HIV positive, the proportion undiagnosed is high.

**Objective:** The prospective AURAH2 study aims to assess factors associated with HIV acquisition among MSM in the United Kingdom and to investigate changes over time within individuals in sexual behavior and HIV-testing practices.

**Methods:** AURAH2 is a prospective study among MSM without diagnosed HIV, aiming to recruit up to 1000 sexually active MSM attending sexual health clinics in London and Brighton in the United Kingdom. Participants complete an initial paper-based questionnaire, followed by online follow-up questionnaires every 4 months collecting sociodemographic, health and behavioral data, including sexual behavior, recreational and other drug use, HIV testing practices, and pre-exposure prophylaxis use, over a planned 3-year period.

**Results:** The study is ongoing.

**Conclusions:** The results from AURAH2 study will provide important insight into established and emerging risk behaviors that may be associated with acquisition of HIV in MSM in the United Kingdom, changes over time within individuals in sexual behavior, and information on HIV testing practices. These data will be crucial to inform future HIV prevention strategies.

## Introduction

### Background

In 2014, the number of men who have sex with men (MSM) that were newly diagnosed with human immunodeficiency virus (HIV) continued to rise with 3360 new diagnoses in the United Kingdom [1]. Currently, there are an estimated 43,500 MSM living with HIV, of whom around 16% are undiagnosed [2]. It is thought that MSM unaware of their HIV infection disproportionately contribute to onward transmission (60-82% of new transmissions come from people not diagnosed [3,4]) and that delay in diagnosis and treatment is associated with increased risk to health [5]. HIV prevention approaches have historically focused on condom use, which, if correctly and consistently used, is a reliable and established method to reduce transmission [6]; however, consistent condom use is difficult to achieve [7,8]. There is a clear need for improved HIV prevention and testing strategies targeted at HIV negative MSM to reduce the number of new HIV infections and increase HIV testing rates.

The AURAH study was a cross-sectional questionnaire study that collected data from 2013-2014 in a large sample of HIV-negative patients attending Genito-Urinary Medicine (GUM) clinics in the United Kingdom with a focus on two populations: black Africans and MSM [9]. It used a self-completed questionnaire to assess knowledge of and attitudes to HIV transmission risks and the role of antiretroviral therapy (ART), and to assess the prevalence of medical and psychological symptoms (eg, depression and anxiety), quality of life, lifestyle factors (eg, drug and alcohol use), and possible links to sexual risk behaviors. The AURAH2 study will build on the work of the AURAH study and is the first large prospective observational study of MSM in the United Kingdom. It will provide longitudinal data on HIV transmission risk in a group of HIV negative (at enrollment) MSM using online questionnaires for data collection over a 3-year period. It will collect baseline socioeconomic, health and lifestyle information (including recreational drug use and chemsex) with longitudinal information on sexual activity, HIV testing, sexual behavior, and occurrence of new HIV infections among UK MSM.

Understanding attitudes of HIV negative or undiagnosed MSM towards condomless sex with individuals of unknown HIV status, and examining risk behavior in the context of psychological or general health status, history of sexually transmitted infection (STI), alcohol and drug use, could elucidate reasons for the observed ongoing HIV transmission among the UK MSM population. Studies have consistently found associations between increased sexual risk behavior, such as condomless anal sex and group sex [10-13], with recreational drug use, and longitudinal data has highlighted the bi-directional relationship between sexual pleasure and drug use [14]. Longitudinal data from Australia has demonstrated an association between drug use and increased risk of HIV infection, in particular the use of oral erectile dysfunction medication in combination with methamphetamines to enhance sexual pleasure [12], and similar evidence was recently reported from a US study that showed a clear link between increased

sexual risk behavior and starting methamphetamine use [15]. Although not a new concept in the United States [16-18], a recent UK report on "chemsex" [19], which is defined as the use of certain sexually disinhibiting recreational drugs for facilitating or enhancing sex, has highlighted a need for more research into behaviors that put MSM at high risk of HIV and STI acquisition as a public health priority. Longitudinal data on recreational drug use, chemsex and associations with high risk sexual behaviors, such as group sex, in HIV negative or undiagnosed MSM would provide valuable insight into potential causes for the observed increases in HIV and STI acquisition among MSM in the United Kingdom.

Reducing the large proportion of MSM with undiagnosed HIV that potentially contribute to onward transmission of HIV is a public health priority [20], and data from HIV-negative or undiagnosed MSM in the United Kingdom are currently needed to inform and develop better provision of HIV testing options. Despite high coverage (86%) of HIV testing among MSM attending sexual health clinics [21], generally the frequency of HIV testing among UK MSM remains low (estimated 30% never tested, 75% not in past year) [4], and alternative ways to test for HIV, other than through sexual health clinics, are urgently required [1]. HIV self-testing (HIVST) was made legal in the United Kingdom in April 2015 [22] and is defined by the test being collected, performed, and interpreted in private by the individual who wants to know their HIV status [23]. HIVST has the potential to alleviate some of the perceived barriers to other forms of HIV testing, such as stigma, discrimination, and inaccessibility of health services [24], due to the environment the test is performed in, which may encourage more people to test. Increased HIV testing and resulting diagnoses could have prevention benefits if newly diagnosed men are more likely to use condoms and have fewer sexual partners after diagnosis [25,26]. However, it is not known whether the availability of HIVST will increase the diagnosis rates of HIV in the United Kingdom. The AURAH2 study will seek to collect information on the acceptability and uptake of HIVST as it becomes more widely available.

The expansion of HIV testing options is also of particular relevance since it was demonstrated that HIV transmission is preventable through ART in 2011 [27]. Evidence that ART greatly reduces onward sexual transmission of HIV in MSM [28], as well as heterosexuals [27,29], was demonstrated through the interim results of the PARTNER study [28]. Furthermore, the concept of treatment as prevention (TasP) has been widely explored as an HIV prevention strategy and is recommended in the British HIV Association's treatment guidelines to prevent onward transmission [30]. However, access to and uptake of ART is dependent on a person knowing their HIV status and, in the United Kingdom, research has shown that although widespread ART coverage among MSM at a population level may reduce HIV infectivity, it is unlikely to reduce the number of HIV transmissions in the absence of increased coverage and frequency of HIV testing [31]. There is some evidence that sexual risk behavior declines after an HIV diagnosis, as it has been demonstrated that behavior is modified to prevent onward transmission [25,26]. However, this has not been explored in the context of TasP, and little is known regarding changes in

sexual behavior during primary HIV infection (a period characterized by very high infectiousness) and on the variability in sexual risk behavior over time at an individual level (eg, the duration of periods of very high risk). There are cohort studies of MSM that provide some information on these issues from Europe, the United States, and Australia [32-35]; however, there have been no follow-up studies among individuals at risk of HIV infection in the United Kingdom, which the AURAH2 study will seek to address. The role of TasP is also critical in HIV-negative MSM's sexual decision making and risk reduction behaviors and, as yet, is largely unexplored among UK HIV-negative MSM. Further investigation is needed, particularly in light of TasP, into the risk reduction strategies that HIV negative or undiagnosed MSM utilize at a community level [36], such as sero-sorting (choosing a partner of believed sero-concordant status), negotiated safety (condomless sex with a sero-concordant main partner), strategic positioning (choosing a different sexual position or practice depending on the sero-status of a partner), and withdrawal (in which the negative partner is receptive during intercourse but without ejaculation by his partner) [37]. To investigate the role of TasP in sexual decision making and risk reduction strategies, the AURAH2 study will collect data to inform on these themes, including information on knowledge of an HIV-positive partner's viral load. Collection of longitudinal data will help describe the sexual behaviors and risk reduction strategies among HIV negative MSM and assess the extent to which patterns of sexual behavior and condomless sex change over time within individuals. This information will play a key role when developing effective, targeted HIV prevention strategies.

A further significant development for HIV prevention strategies that the AURAH2 study will provide information on is pre-exposure prophylaxis (PrEP), which has been used as an HIV prevention tool for HIV-negative men in the United States since 2012 [38]. Although PrEP is not currently available on the UK National Health Service (NHS), generic formulations have been increasingly available via websites. In 2015, the results from the UK PROUD study [39] and the French IPERGAY study [40] demonstrated that daily [39] and "on demand" [40] dosing of Truvada, the antiretroviral tablet used for PrEP, reduced the risk of HIV acquisition in HIV-negative men by 86%. There has been increasing community [41] and clinical [42] pressure to make PrEP available through the NHS. New PrEP websites that have been developed by activists [43,44] acknowledge the potential to access PrEP in a number of different ways that include ordering it online, which may challenge how the access and uptake of PrEP is monitored and may lead people to obtain PrEP without the appropriate counselling and follow-up [42]. Self-reported changes in attitudes, access to, and use of PrEP and factors associated with PrEP use by HIV negative men in the United Kingdom will be vital to inform policy and inform on acceptability and uptake of PrEP in sexually active HIV-negative gay men.

The landscape of HIV prevention is changing as concepts such as TasP and PrEP are introduced, and advances in HIV testing technologies potentially make testing for HIV more accessible. In conjunction with evolving HIV prevention strategies, emerging patterns in lifestyle choices that affect sexual behavior

are important to consider if current and effective HIV prevention interventions are to be designed and implemented. The information provided by the AURAH2 study will contribute to the understanding of the social, psychological, and health-related factors that are linked to high-risk sexual behaviors that potentiate transmission of HIV. The study will provide data highly relevant to HIV prevention efforts among MSM and will help inform national policies aimed at reducing HIV incidence and increasing HIV testing in the United Kingdom.

## Study Aims and Objectives

The aim of the AURAH2 study is to evaluate the incidence and predictors of new infections among HIV-negative MSM at risk of acquiring HIV and to assess changes over time in risk behavior and testing practices within individuals.

The detailed study objectives are to assess:

### 1. In MSM without diagnosed HIV:

(i) the prevalence and correlates of specific sexual behaviors, including numbers of condomless sex partners, condomless sex with casual partners and partners of unknown HIV status, insertive/receptive condomless sex, and other specific higher-risk sexual activities such as group sex and chemsex

(ii) the number of condomless sex partners before, during, and after the estimated period of primary HIV-infection and time of HIV diagnosis in men who become infected during the study, as well as correlates of within-person changes in sexual behavior

(iii) the frequency and type of HIV testing accessed over time (sexual health clinic, self-testing, general practitioner, surgery, hospital, other)

2. The extent to which baseline demographic, socioeconomic, and health and lifestyle factors (including recreational drug use and chemsex) are predictive of subsequent levels of condomless sex, incident HIV infection, and HIV-testing behaviors

3. The association of attitudes to HIV transmission, disclosure, treatment, and prognosis, with high-risk sexual behaviors, HIV-testing behaviors, and subsequent HIV acquisition

4. The associations of participant characteristics, sexual behavior, and attitudes with reported use of, and willingness to consider use of, post exposure prophylaxis (PEP) and PrEP

## Methods and Design

### Study Design

AURAH2 is a prospective cohort study of UK MSM not diagnosed with HIV. Baseline information is collected on each participant through the AURAH study paper questionnaire [9], which is completed during a sexual health clinic attendance. Follow-up questionnaires are made available online every 4 months through the study website and consist of two brief and one extensive questionnaire per year. Online follow-up will continue for up to 3 years from the time a participant joined the study during the recruitment period in 2015.

## Population and Setting

HIV negative or undiagnosed MSM adults attending sexual health clinics at three sites in the United Kingdom for STI screening or HIV testing are eligible to take part in the study. The three clinical sites are as follows: The Mortimer Market Centre, London; 56 Dean Street Clinic, London; and the Claude Nicol Centre, Brighton.

These three clinical sites were chosen based on their ability to provide access to large numbers of MSM attending sexual health services and previous successful collaboration with the researchers for the AURAH study [9]. During the AURAH study recruitment process, the three sites demonstrated their ability to provide a broad sample of homosexually active men, including gay, bisexual, and non-gay identified MSM.

The eligibility criteria to join the study is (1) self-reported HIV-negative, (2) self-defining as MSM, (3) being aged 18 years or over, (4) attending or having previously attended for routine STI or HIV testing in the study clinics, and (5) willing to be contacted for longitudinal follow-up for up to a 3-year period.

## Sample Size

The sample size calculation was based on our objective to assess within-person changes in sexual behavior after receiving an HIV diagnosis. This outcome is more constrained by power than others because it relies on comparisons of participants within the group who are infected with HIV during follow-up. For sexual behavior classified as whether or not a man reports >3 condomless sex partners in the past 3 months, 85 new HIV diagnoses would be needed to detect, with 80% power and 5% significance level, the following changes: 17 (20%) men newly diagnosed switching from >3 to ≤3 condomless sex partners pre to post diagnosis, and 4 (5%) men newly diagnosed switching from ≤3 to >3 condomless sex partners pre to post diagnosis. With 1000 HIV-negative men initially enrolled in the study sample, assuming an annual HIV incidence of 4% (for high-risk MSM) and a dropout rate of 15% per year, 96 new HIV infections would be expected to accrue over a 3-year period. This sample size of 1000 should provide adequate power for the other objectives.

## Recruitment

Participants are recruited to the AURAH2 study through two separate recruitment routes. The recruitment route 1 group consists of HIV negative or undiagnosed MSM who were (1) enrolled in the AURAH cross-sectional study [9] from the three clinics detailed above during targeted recruitment of MSM (until March 2015) and (2) who had indicated interest in future follow-up on the AURAH study consent form. An email invitation to participate in the AURAH2 study was sent to this group from the AURAH2 study website in March 2015. Participants who joined the AURAH2 study from AURAH were assigned the same study number in their online follow-up as their original AURAH study number so that online follow-up could be linked to responses in the original cross-sectional study.

The recruitment route 2 group consists of HIV-negative or undiagnosed MSM who are prospectively recruited in person

through the three clinic sites from March 2015 until December 2016. This group is directly consented into the AURAH2 study in their sexual health clinic and completes the baseline AURAH paper questionnaire during their clinic attendance. Online registration with the study website using a personal smartphone or iPad is explained during the consent procedure, or participants are contacted within 2 weeks with an email invitation to register.

## Consent

Consent for the study is gained through two mechanisms, according to the recruitment route. Participants from recruitment route 1 (contacted in March 2015) were required to complete an online consent form for the AURAH2 study. This was presented to them on the study website after they had read the online patient information sheet and prior to registration.

Consent for participants via recruitment route 2 is obtained at study enrollment in the clinic setting via a paper-based information sheet and consent form. Participants recruited through recruitment route 2 do not need to complete an additional online consent form as information on the AURAH2 study is provided in the Patient Information Sheet. In both consent processes, participants are (1) made aware of the study aims, (2) made aware that participation means they are expected to complete brief online questionnaires about sexual behavior and HIV testing on a regular basis over a 3-year period, (3) asked to provide their email address and mobile phone number and consent to receive reminders to complete the online questionnaires via email and/or text message, but are also told that there will be a maximum of two reminders by email followed by one text message if they do not respond, (4) asked to provide their full name and date of birth and made aware that this information will be used to link with matching data in UK national clinical databases including the national HIV/AIDS Reporting System (HARS) database (see clinical data), (5) made aware that results of any HIV test results from the day they joined the study, or that they self-report during the study period (up to 3 years), will be recorded and stored securely and separately from the study questionnaire, (6) made aware that they can withdraw from the study at any point and ask for their personal data to be deleted and that this will not affect their care at their GUM clinic, and (7) advised that should they wish to withdraw from the study they should send an email to a specified contact address to make this request.

## Online Registration Procedure

Participants are sent a maximum of three “invitation to register” messages via the study website (see below). The first contact is an email containing an individualized link, which, when selected, allows the recipient to register an account with the study website. A second similar reminder email is sent a week later to participants who have not registered, and finally a text message is sent a week after the second email (if a mobile phone number was provided during the consent procedure). In each email, participants are provided with information on how to opt out of the study and any further contact. Participants who do not register within 1 week after the two reminder emails and a text message have been sent are removed from the study lists and not contacted further.

## Website Design and Features

The AURAH2 website was designed to provide full information on the study to the general public and the study participants. The home page provides a login box that allows only registered participants to gain access to the study questionnaires by entering a username and password. Once a participant has registered and completed the first online questionnaire, automated reminder emails are sent every 4 months when follow-up questionnaires are due. Each reminder email informs the participant that a questionnaire is due for completion and contains a link to the study website homepage to login and access a questionnaire. The message also contains information on how to receive a username and password change prompt if login details have been forgotten. If a participant does not log in and complete a questionnaire, a second automated reminder email is sent 1 week after the initial email, and a final reminder is sent by text message a week later. If a participant does not log in and complete a questionnaire after the third reminder, no further contact is made until the next questionnaire is due, 4 months later.

The secure website provides facilities for content management including the ability to change information pages and add new items and details of study publications. The administration pages are accessible only to user accounts controlled by the study coordinator and data manager. From the administration pages of the website, the “invitation to register” and follow-up messages are managed and the status reports and questionnaire results data can be securely downloaded on a regular basis.

## Study Questionnaires

### Baseline Data

Extensive baseline data are collected through the pen-and-paper AURAH baseline questionnaire, details of which have been published elsewhere [9]. The questionnaire gathers detailed

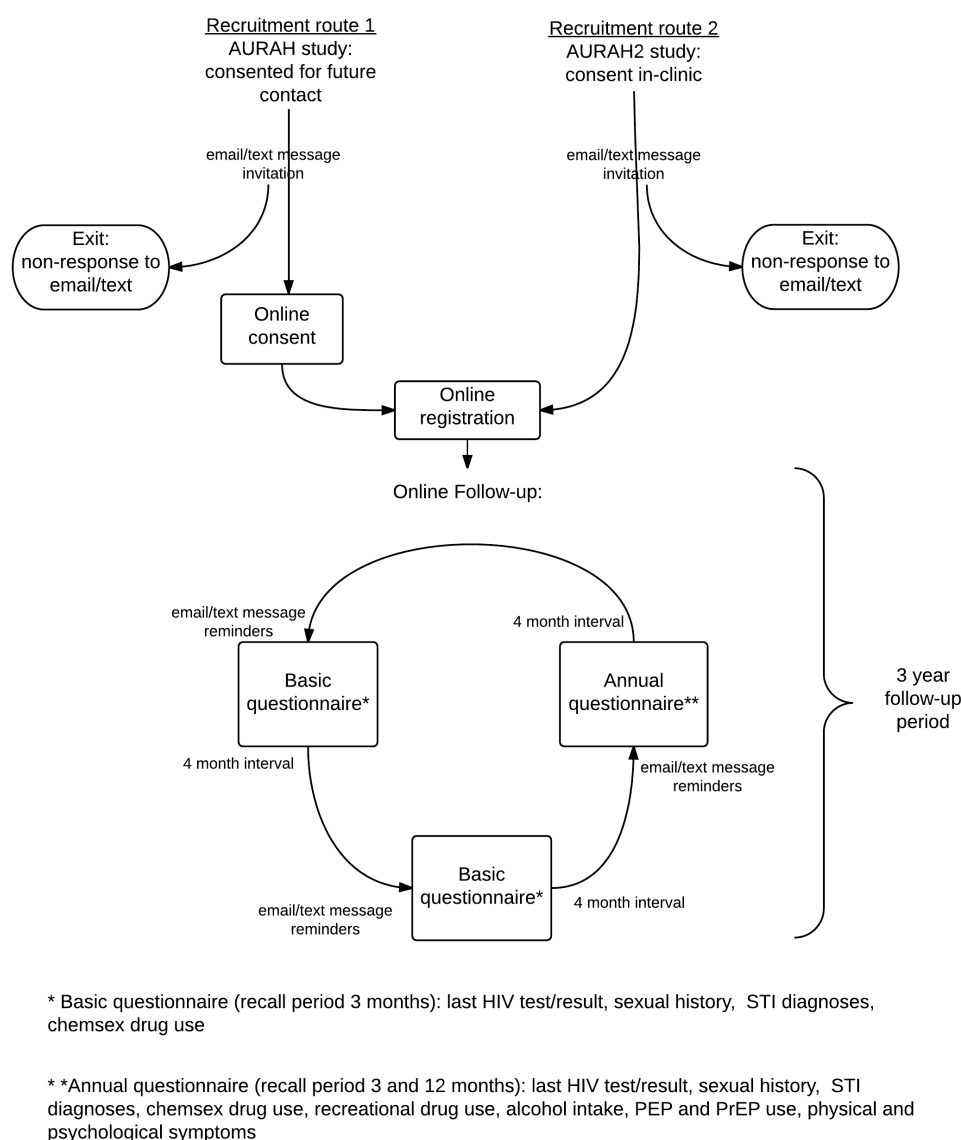

information on demographics, socioeconomic factors, physical and psychological health and well-being, knowledge and understanding of HIV and antiretroviral treatment, lifestyle factors (smoking, alcohol, and recreational drug use), HIV testing, knowledge and use of PEP, and sexual behavior. Both recruitment routes use the baseline AURAH questionnaire for initial data collection, which takes approximately 20-25 minutes to complete.

### Online Questionnaires

Online data collection every 4 months will be ongoing until 2018. It consists of a brief online questionnaire that assesses sexual risk behavior, HIV testing history, self-reported STIs, and use and frequency of chemsex drugs from the preceding 3 months. The basic 4-monthly online questionnaire takes approximately 5 minutes to complete. A more detailed questionnaire is undertaken on an annual basis that includes the information collected in the 4-month questionnaire and additional information on use of HIV testing preferences, PEP and PrEP, physical and psychological symptoms, and attitudes to HIV transmission. The annual online questionnaire takes approximately 20 minutes to complete.

Each online questionnaire commences with a question on the most recent date and result of a participant’s previous HIV test. If a participant consistently reports negative HIV test results or “not tested,” then the questionnaires remain specific to an HIV negative or unknown status. However, if a participant reports a positive HIV test result, the questionnaire is programmed to collect information on the number of partners, sexual behavior, and recreational drug use pre and post diagnosis. At each subsequent login, an HIV-positive participant will complete questionnaires that are similar to the HIV-negative participants, but tailored to reflect the HIV-positive sero-status of the participant. A flowchart to demonstrate recruitment from clinic to the online questionnaire sequence is shown in [Figure 1](#).

**Figure 1.** Flowchart of AURAH2 recruitment and questionnaire sequence.

## Clinical Data

The result of any HIV test taken in clinic at the same time as the baseline questionnaire completion is stored as part of the study records. At each online follow-up questionnaire, participants are asked to self-report the result of their most recent HIV test and any diagnosed STIs. At the end of the study period, in collaboration with Public Health England, data will be checked against corresponding records and data in national clinical databases such as HARS, the Genitourinary medicine clinical activity dataset (GUMCAD), and the Office for National Statistics. The linkage of the AURAH2 data to these databases will provide confirmation on the self-reported HIV status of participants as well as identify any new HIV diagnoses that have not been self-reported through the questionnaires.

## Data Processing and Security

Baseline paper questionnaires completed in clinic are collected by the study nurses and transferred regularly to the study management center via registered post or collected in person

from the clinic sites by the study researchers. At the study management center, the original paper questionnaires are stored securely in locked cabinets. Baseline questionnaires are identifiable only by an assigned study number to maintain confidentiality, and participant details linked with the study number are collected in a separate study log. The study log is maintained securely and updated daily at each clinical site. The study log contains study numbers, clinic identifiers, and details of consent status for all patients invited to participate in the study, whether or not HIV and other STI tests had been done, and the result of any HIV test. Contact details of participants are also entered in the log. A copy of the study log (with contact details removed for non-consenting participants) is transferred on a regular basis to the study management center using the NHS mail system, which is approved by the Department of Health for the purpose of sharing personal identifiable information and sensitive information.

Baseline questionnaires are digitized at the management center using the REDCap data capture system for secure double data entry. The study website is hosted in a secure data center and

network environment, and the online questionnaire response datasets are directly downloaded to encrypted data drives at the study management center on a monthly basis. Linkage to Public Health England's datasets will be done at the end of the study using limited participant identifiers: surname Soundex, sex, and date of birth.

The final resulting study datasets, including scanned images of the questionnaires, are stored on the University College London Data Safe Haven, which is a secure technical solution for storing, handling, and analyzing identifiable data. This has been certified to the ISO27001 information security standard and conforms to the NHS Information Governance Toolkit.

The contact details of any participants who did not join the AURAH2 study after the email invitations from recruitment route 1 were removed from the study records 1 month after their final email reminder or the text message had been sent (if provided). All AURAH2 participants contact details will be erased from the study database 6 months after the completion of the study.

### Ethics Approval

The research protocol and all versions of the study documents (information sheet, consent form, questionnaires, and versions of the online questionnaires) were approved by the designated research ethics committee (NRES committee London-Hampstead, ref: 14/LO/1881 in November 2014). Based on these documents, the study subsequently received permission for clinical research at the three participating National Health Service sites: Chelsea and Westminster NHS Foundation Trust, Central and North West London NHS Foundation Trust, and the Brighton and Sussex University Hospitals NHS Trust.

## Results

Data collection commenced in March 2015 and is ongoing until March 2018. Initial results from analysis of the baseline questionnaires are expected in 2016, and results from longitudinal data are expected in 2018.

## Discussion

### Principal Considerations

The AURAH2 study will provide important longitudinal data on sexual risk behavior, HIV testing habits, and risk factors for ongoing transmission of HIV in UK MSM who were HIV negative at entry to the study but who are at risk of HIV infection. It uses a novel approach to data collection by combining paper-based questionnaires collected in the clinic setting and online follow-up questionnaires that participants access at their convenience. We applied a short recall period of 3 months in the questionnaire responses to maximize self-report accuracy and diminish recall bias [45] and to better capture within-person changes over time in sexual behavior. The request to complete questionnaires was sent on a 4-monthly basis to decrease the study burden for the participant and reduce attrition during the long follow-up period. The online recall period is reflective of the timeframes that are used in the paper-based questionnaires and is closely aligned to the frequency of survey

completion in an attempt to capture ongoing and new behavioral information. The Internet has been increasingly used as a tool with which to collect survey data as it offers a low-cost, flexible, and fast way to collect data while reducing participant burden [46], and Internet surveys have been shown to be an acceptable method in researching MSM at risk of acquisition of HIV [47].

A similar study to AURAH2 is currently being conducted in the United States, using online follow-up over a 3-year period in a sample of 1000 gay and bisexual men who will complete self-administered HIV/STI tests and online surveys [48], which may offer comparisons of survey response rates and attrition over the 3 years. Despite some design differences, notably in recruitment routes (ie, the *One Thousand Strong* study recruited in partnership with a marketing firm via email invitation as opposed to face to face in sexual health clinics) and methods (ie, AURAH2 does not use biological methodologies for HIV/STI tests [48]), both studies will demonstrate the feasibility of using the Internet to engage MSM in online data collection and contribute substantial insight into sexual risk behavior and HIV testing. Longitudinal online follow-up in the HIV negative or undiagnosed population has not been widely explored among MSM in the United Kingdom but will be key to understanding how individual sexual behaviors change over time. The annual Gay Men's Sex survey "Vital Statistics" has been successfully conducted among participants since 1993, although the survey is a one-off online survey [49], as opposed to the follow-up and retention of the same group of individuals over time. The AURAH2 study will provide valuable insight into the feasibility of recruiting and retaining MSM in a study that requires regular ongoing follow-up over a period of 3 years using the Internet as a tool for data collection.

### Limitations

A recognized limitation of the study is the restricted recruitment of MSM from attendance at GUM clinics, which may not be reflective of the wider MSM population, and in particular from the two clinics (56 Dean Street and the Mortimer Market Clinic) that provide services for patients seeking support for drug use. However, recruitment is from the general clinic attendees, not from specific drug use services. Although the majority of MSM in London do appear to be engaged with GUM sexual health services [50], there is less information on engagement with these services in the rest of the United Kingdom, so recruiting from a site outside London will allow some comparison. Recruitment through GUM clinics was essential for this study so that the self-reported HIV test results of participants could be confirmed with UK national clinical HIV databases (in collaboration with Public Health England) and so that the study sampling frame was clearly based on MSM who had attended a sexual health clinic. Recruitment online or through other settings could have potentially provided larger numbers of anonymous participants but would have been limited by the inability to confirm HIV status during or at the end of the study period due to participant anonymity.

We identify a further limitation of the study in the lack of recruitment from clinical sites outside two major cities that have large gay communities. It is recognized that this will limit the study's generalizability given the potential differences in

lifestyle, HIV testing opportunities, and access to sexual health services between urban and rural settings. Future studies might address this issue using the Internet or other digital platforms to enroll participants so that a broader sample of MSM from across the United Kingdom could be included.

## Conclusion

Evidence that HIV incidence is increasing among MSM in the United Kingdom [1] indicates a clear need for ongoing research in this group. The AURAH2 study will provide detailed longitudinal data on the incidence and predictors of new infections among HIV-negative MSM at particular risk of HIV infection and will further provide some of the first data on emerging behaviors such as chemsex that have raised concern

for sexual health and well-being among MSM, as well as interest and uptake of PrEP and expanded HIV testing options for this group. The study completed recruitment of participants in March 2016, and it is hoped that the wide range of topics explored by the AURAH2 study renders results that will help improve a variety of targeted health promotion strategies that are specific to the men that need them. The study will be highly relevant to HIV prevention efforts among MSM, and it is planned for the data to feed into a mathematical model that simulates different scenarios to inform prevention strategies [4,51,52]. The results of the study will also inform national policies aimed at reducing HIV incidence and increase HIV testing in the United Kingdom in this population.

## Acknowledgments

This paper summarizes independent research funded by the National Institute for Health Research (NIHR) under its Programme Grants for Applied Research Programme (Grant Reference Number RP-PG-1212-20006). The views expressed are those of the authors and not necessarily those of the NHS, the NIHR, or the Department of Health.

We would like to thank all the study participants for their time and effort. We gratefully acknowledge the three participating sites and the contributions and efforts of the following at each site:

## Abstract

**Background:** Hypertension guidelines recommend ambulatory blood pressure (ABP), central aortic pressure (CAP), and pulse wave velocity (PWV) as parameters for estimating blood pressure (BP) control and vascular impairment. Recent advances in technology have enabled devices to combine non-invasive estimation of these parameters over the 24-hour ABP monitoring. However, currently there is limited evidence on the usefulness of such an approach for routine hypertension management.

**Objective:** We recently launched an investigator-initiated, international, multicenter, observational, prospective study, the Vascular health Assessment Of The Hypertensive patients (VASOTENS) Registry, aimed at (1) evaluating non-invasive 24-hour ABP and arterial stiffness estimates (through 24-hour pulse wave analysis, PWA) in hypertensive subjects undergoing ambulatory blood pressure monitoring (ABPM) for clinical reasons; (2) assessing the changes in estimates following treatment; (3) weighing

the impact of 24-hour PWA on target organ damage and cardiovascular prognosis; (4) assessing the relationship between arterial stiffness, BP absolute mean level and variability, and prognosis; and (5) validating the use of a 24-hour PWA electronic health (e-health) solution for hypertension screening.

**Methods:** Approximately 2000 subjects, referred to 20 hypertension clinics for routine diagnostic evaluation and follow-up of hypertension of any severity or stage, will be recruited. Data collection will include ABPM, performed with a device allowing simultaneous non-invasive assessment of 24-hour CAP and arterial stiffness (BPLab), and clinical data (including cardiovascular outcomes). As recommended by current guidelines, each patient will be followed-up with visits occurring at regular intervals (ideally every 6 months, and not less than once a year depending on disease severity). A Web-based telemedicine platform (THOLOMEUS) will be used for data collection. The use of the telemedicine system will allow standardized and centralized data collection, data validation by experts and counseling to remote centers, setup and maintenance of the Registry, and prompt data analysis.

**Results:** First follow-up results are expected to be available in the next 2 years.

**Conclusions:** The results of the VASOTENS Registry will help define the normalcy thresholds for current and future indices derived from 24-hour PWA, according to outcome data, and will also provide supporting evidence for the inclusion of this type of evaluation in hypertension management.

**Trial registration:** Clinicaltrials.gov NCT02577835; <https://clinicaltrials.gov/ct2/show/NCT02577835> (Archived by WebCite at <http://www.Webcitation.org/6hzZBKY2Q>)

## KEYWORDS

blood pressure telemonitoring; arterial stiffness; pulse wave velocity; augmentation index; central aortic pressure; hypertension

## Introduction

### Literature Review

Central aortic pressure (CAP) and pulse wave velocity (PWV) are independent predictors for the development of cardiovascular (CV) diseases [1-3]. Due to the large amount of epidemiological evidence for its predictive value for CV events, carotid-femoral PWV is currently highly indicated and useful for stratification of total CV risk, and considered the “gold standard” measurement of arterial stiffness [1,4,5]. Pulse-wave analysis (PWA), including evaluation of CAP, and Augmentation Index (AIx), may also provide additional information concerning wave reflections and may be useful for risk stratification and evaluation of the effectiveness of treatment, but more evidence is needed before recommending the routine clinical use of these vascular indices [1,5].

The most widely adopted methods for evaluating pulse waveforms are those based on applanation tonometry and transfer functions [1,6,7]. Notwithstanding the consistent evidence for superior and independent prognostic value, with respect to conventional office BP of either indices of central hemodynamics and stiffness assessed in controlled office condition at rest [2,3,8,9], currently there are no studies that evaluated the long-term predictive ability for CV events of vascular indices (ie, PWV, AIx, and CAP), measured in dynamic conditions over the 24-hours by ambulatory blood pressure monitoring (ABPM). However, some incomplete evidence is available from cross-sectional studies. For example, in 629 patients with diabetes, 24-hour aortic systolic blood pressure (SBP) was higher than in the 86 control patients, and increased with diabetic complications, being more strongly associated to complications than peripheral 24-hour SBP [10]. In the SAFAR Study [11,12], both 24-hour aortic and brachial SBP were superior to conventional office BP measurements in predicting

BP-related cardiac damage (left ventricular hypertrophy and left ventricular diastolic dysfunction) in 230 subjects (75% having arterial hypertension). In the same study, 24-hour ambulatory central SBP was also more closely associated with left ventricular hypertrophy than 24-hour ambulatory brachial SBP. With respect to arterial stiffness, Aissopou et al [13] found that ambulatory aortic PWV, estimated by an operator-independent method, provided additional information to carotid-femoral PWV regarding the association of arterial stiffness with the retinal vessel calibers. Elsurer and Afsar [14] found that in 339 hypertensive patients with chronic kidney disease, serum uric acid was significantly correlated with both 24-hour PWV and AIx. However, serum uric acid was independently associated with AIx only. Maloberti and colleagues [15] studied 19 children with Williams-Beuren syndrome, a genetic disorder involving the elastin gene and adversely affecting arterial function and found that sick children showed higher heart rate and AIx values at night than age-matched controls, suggesting an abnormal sympathetic cardiovascular control and an increase in small arteries resistance. The limited evidence from the literature is completed by two longitudinal studies. The Ambulatory Central Aortic Pressure (AmCAP) study described a significant CAP lowering effect on both day-time and night-time with a 12-week treatment based on either aliskiren (300 mg) or telmisartan (80 mg) administered once-daily [16]. Interestingly, this study also showed relatively higher values of nocturnal aortic than brachial BP. Karpetas et al [17] and Koutroumbas et al [18] showed a gradual interdialytic increase in ambulatory CAP and AIx, and to less extent in PWV, in 153 patients with end stage renal disease treated with dialysis.

There is previous evidence that non-invasive assessment of 24-hour arterial stiffness and central hemodynamics in daily life conditions measured by the device used in this study (BPLab device, BPLab GmbH, Schwalbach am Taunus, Hessen,

Germany) may help in assessing the arterial function impairment in hypertensive patients. We recently showed larger 24-hour CAP and peripheral AIx values in 661 patients with hypertension compared to 142 normotensive controls [19]. In a subgroup of 137 patients with hypertension, a significantly positive correlation was found between 24-hour PWV and left ventricular mass index (LVMI) [20]. In another study, Kuznetsova et al [21] provided age- and gender-specific reference diagnostic values for 24-hour PWV, AIx, and CAP in 467 normotensive volunteers. Minyukhina and colleagues [22] observed a reduction in 24-hour PWV one week after kidney transplantation in 41 patients with end-stage renal disease, with a return to pre-transplant values after 20 weeks. Finally, in another study the combination of hypertension and chronic obstructive pulmonary disease was associated with an increased ambulatory peripheral and central aortic pressure, while this was not the case for isolated essential hypertensive subjects and normotensive controls [23].

## Rationale

Recent advances in technology enabled devices to combine non-invasive estimation of CAP and arterial stiffness in ambulatory conditions over the 24-hours, based on the oscillometric method [24-28]. Such techniques are affordable and may allow a comfortable, accurate, repeated, and prolonged estimation of arterial stiffness and central hemodynamics over the 24-hours in daily life conditions by ABPM. Recent studies seem to indicate reliability and feasibility of ambulatory arterial stiffness and hemodynamics evaluation based on analysis of brachial oscillograms [8,29,30]. However, at present, there is limited evidence on the clinical usefulness of such an approach and much has to be done to prove its actual benefit in the daily clinical management of hypertension. In particular, there are very few data on the long-term prognostic and clinical value of 24-hour ambulatory CAP and arterial stiffness estimation, since most studies performed so far were not sufficiently long lasting or had a cross-sectional design [11-23]. At the moment, some associations with CV complications have been demonstrated for 24-hour CAP, but not for PWV and AIx. In addition, since different algorithms are used by the different ambulatory devices, non-invasive estimation of central hemodynamics and arterial stiffness appears to be device- and/or technique-dependent, and thus results obtained with one or the other device cannot be easily confronted and interpreted.

To provide further insight on the matter, we created a large database (or registry) of ABPM recordings obtained with the BPLab monitor, which is able to determine CAP, PWV, and AIx, over the 24-hours, based on a clinically validated technology of PWA of oscillometric BP measurements [26-28]. The choice of this device was made not only because of its proved accuracy and clinical reliability, but also because of its compatibility with the Web-based telemedicine platform THOLOMEUS (Biotechmed Ltd., Somma Lombardo, Varese Italy) [31], which enables easy data collection and communication within such a large worldwide network of study centers.

This paper summarizes the study protocol (final version, dated 20/02/2015, available as an online supplement to this paper)

([Multimedia Appendix 1](#)) that has been prepared following the recommendations contained in the SPIRIT statement [32], the most appropriate checklist for the publication of protocol papers of observational, non-randomized, prospective studies in the initial stage ([Multimedia Appendix 2](#)).

## Study Objectives

The VASOTENS (Vascular health Assessment Of The Hypertensive patients) Registry aims at evaluating the clinical value and the prognostic impact of 24-hour ambulatory non-invasive estimation of arterial stiffness and central hemodynamics by PWA in patients with hypertension undergoing an ABPM for clinical reasons in hypertension clinics. Specific study objectives include (1) the evaluation of 24-hour PWV, AIx and CAP in hypertensive patients over consecutive ABPMs performed at regular intervals, as recommended by current guidelines, for a minimum of 2 years (main study objective); (2) the evaluation of the changes in BP and arterial stiffness estimates following treatment initiation or modification, according to current guidelines; (3) the assessment of the impact of non-invasive arterial stiffness estimation on cardiac, vascular and renal damage and patient's CV prognosis (fatal and non-fatal events); (4) the definition of the normal thresholds for PWV, AIx and CAP, in hypertensive patients, according to outcome data; and (5) the definition of the relationship between arterial stiffness, BP absolute level and BP variability, and outcomes.

The outcome-based results provided by the VASOTENS Registry will help establish a worldwide network of certified centers performing ambulatory PWA and will help validate and foster the use of the 24-hour PWA electronic health (e-health) solution for hypertension screening and follow-up. Ultimately, the study-based evidence of the clinical relevance of 24-hour non-invasive central arterial stiffness and hemodynamics assessment may help favor the inclusion of such evaluations among the standard procedures made available in hypertension centers, as well as practical recommendations for improving hypertension management and control.

## Trial Design

The VASOTENS Registry is an international, multicenter, observational, non-randomized, prospective study.

## Methods

### Study Setting

A minimum of 20 hypertension centers will be involved worldwide, each providing at least 100 participants, in order to allow recruitment of a sufficiently consistent sample size able to demonstrate the study objectives. A list of participating centers grouped by countries is shown in [Multimedia Appendix 3](#). Initially, hospitals from Italy and Russia will be enrolled because of their proximity to the study coordinators. Attempts will be made to select investigators among active members of international and national hypertension societies, including membership in the bodies specifically dedicated to blood pressure and arterial stiffness measurement. This will ensure high quality standards of data collection and facilitate the dissemination of information on the project and its findings.

## Eligibility Criteria

Participants referred to the study centers for routine diagnostic evaluation of hypertension or established hypertensive patients will be eligible for inclusion in the study. Individuals fulfilling

eligibility criteria ([Textbox 1](#)), whose data are contained in existing databases collected by the participating centers, and who are regularly followed-up at the center will have priority for enrolment.

**Textbox 1.** Study eligibility criteria.

### Criteria

- Inclusion criteria
  - Male and female
  - Age  $\geq 18$  years
  - Participants referred to routine diagnostic evaluation for hypertension of any severity or stage, or established hypertensive patients
  - Good quality ABPM performed for clinical reasons with a BPLab device
    - Availability of individual measurements for ABPM on a bpw file (BPLab format)
    - Data directly uploaded on the telemedicine platform of the study
  - Availability of basic clinical information (see [Textbox 2](#))
  - Availability of a signed informed consent form
- Exclusion criteria
  - Age  $< 18$  years
  - Atrial fibrillation, frequent ectopic beats, second or third degree atrioventricular blocks, or other conditions which might make difficult or unreliable the automatic BP measurement with the oscillometric technique
  - Upper arm circumference  $< 22$  cm
  - Pregnancy

However, naïve hypertensive participants will also be enrolled, provided that an ABPM is required for evaluating their potential hypertension status, according to current recommendations [5,33]. Once enrolled, participants will be visited every 6 or 12 months at the study centers (dependant on disease severity) for a minimum follow-up of 2 years, and submitted to the procedures detailed in the next sections.

## Study Procedures

The project will not involve any type of diagnostic evaluation or pharmacological intervention and the investigators will be free to manage the patients included in the Registry according to the requirements of clinical practice and current guidelines

[5]. However, as guidelines recommend, each patient will be followed-up with visits occurring at regular intervals: ideally every 6 months, and not less than once a year, for a minimum follow-up of 2 years. The investigators will also be free to use the information yielded by the ABPM tests for the clinical management of their patients. At each study visit, an ABPM by the BPLab device will be performed and patient's clinical data, such as family history, anthropometric data, habits, past and current diseases, therapies, office BP, and laboratory tests, including evaluation of target organ damage, will be collected and entered on the electronic case report form (e-CRF) located on the study website. A detailed list of the clinical data to be collected during the study is itemized in [Textbox 2](#).

**Textbox 2.** Basic demographic and clinical information to be collected during the study.

## Demographic and clinical information

- Age
- Gender
- Height (cm)
- Weight (kg)
- Ethnicity
- Superficial distance between jugulum and symphysis (surrogate of aortic length; cm)
- Waist circumference (cm)
- Smoking status
- Alcohol drinking
- Coffee or tea drinking
- Dyslipidemia (yes/no and indication on treatment)
- Diabetes (yes/no and indication on treatment)
- Diagnosis of hypertension (yes/no and indication on treatment)
- Family history of premature CV disease
- Medical history with particular regard to previous and/or concurrent CV diseases
- Office BP (mmHg) and heart rate (bpm) obtained in the same treatment condition as ABPM
- Electrocardiogram (ECG) indication on left ventricular hypertrophy, Sokolow–Lyon and Cornell index)
- Left ventricular mass index (LVMI, as  $\text{g}/\text{m}^2$ ) at echocardiogram
- When available, diameter of the aorta (aortic annulus, root and sinotubular junction, in cm) and/or cardiac output (as L/min), assessed by the echocardiogram
- Intima-media thickness (IMT, mm) at carotid ultrasonography
- When available, ankle-brachial index
- Microalbuminuria (as mg/24h) or albumin-creatinine ratio (mg/g), and serum creatinine (g/dL), with subsequent calculation of estimated glomerular filtration rate (eGFR) by the Cockcroft–Gault equation
- When available, PWV (m/s), Aix (%), and CAP (mmHg) taken during the office visit with a validated device different from the BPLab device (eg, Sphygmocor or Complior)

**Ambulatory Blood Pressure Monitoring**

Twenty-four hour ABPM will be performed with the BPLab device, which has been found to be accurate for estimation of both BP and vascular indices in properly conducted validation studies [26,27,34–36]. A description of the technique used to non-invasively assess central hemodynamics and arterial stiffness by the BPLab device is detailed in a separate section.

Current guidelines will be followed for proper recording performance [33,37,38]. In order to reduce patient's discomfort and to ensure a reliable minimum number of BP measurements for the subsequent data analysis (particularly for the evaluation of BP variability), the device will be programmed to measure BP at least every 20 minutes during the day (providing a minimum of 3 readings per hour) and at least 30 minutes during the night (providing a minimum of 2 readings per hour). Whenever possible, recordings will start between 8 am and 11 am, in order to standardize data collection and comparisons. The monitoring cuff will be placed on the non-dominant arm, the lower edge 2 cm above elbow bend, with the bladder centered on the upper arm, to ensure uniform compression and

decompression during inflation and deflation. In order to allow the proper evaluation of PWV, the length of the aorta will be derived by measuring the distance from the sternal notch (jugulum) to the upper edge of the pubic bone (symphysis). In the case of obese patients, this superficial morphological distance will be adjusted by using the frontal projection in standing position. Up to 2 BP test readings will be triggered manually before the device is activated for automatic measurements in order to test its proper functioning. Two sequential conventional (office) BP and heart rate readings will also be taken in the sitting position at the time of ABPM placement (with the same BPLab device or with a validated automatic or manual BP measuring device), and recorded on the e-CRF. Patients will be instructed to keep the arm still and to avoid any movement during each automatic BP measurement. Patients will be free to attend to their usual daily activities during ABPM (avoiding strenuous exercise). They will have to complete a diary in which daily activities (ie, time of sleeping, time of meals) will be reported together with the time of occurrence of unusual events or poor night sleep quality. The patient will come back to the outpatient clinic on the second

day of the recording (after at least 24 hours) to remove the monitor. Shortly after device removal, the recording will be downloaded to a computer using the telemedicine Web platform of the project. The investigator will obtain the results from the Web-based analysis software and verify each recording for compliance with quality criteria (see below for details). In case of a bad quality recording the investigator will have to repeat the recording as soon as possible, preferably within 2 days.

### Pulse-Wave Analysis

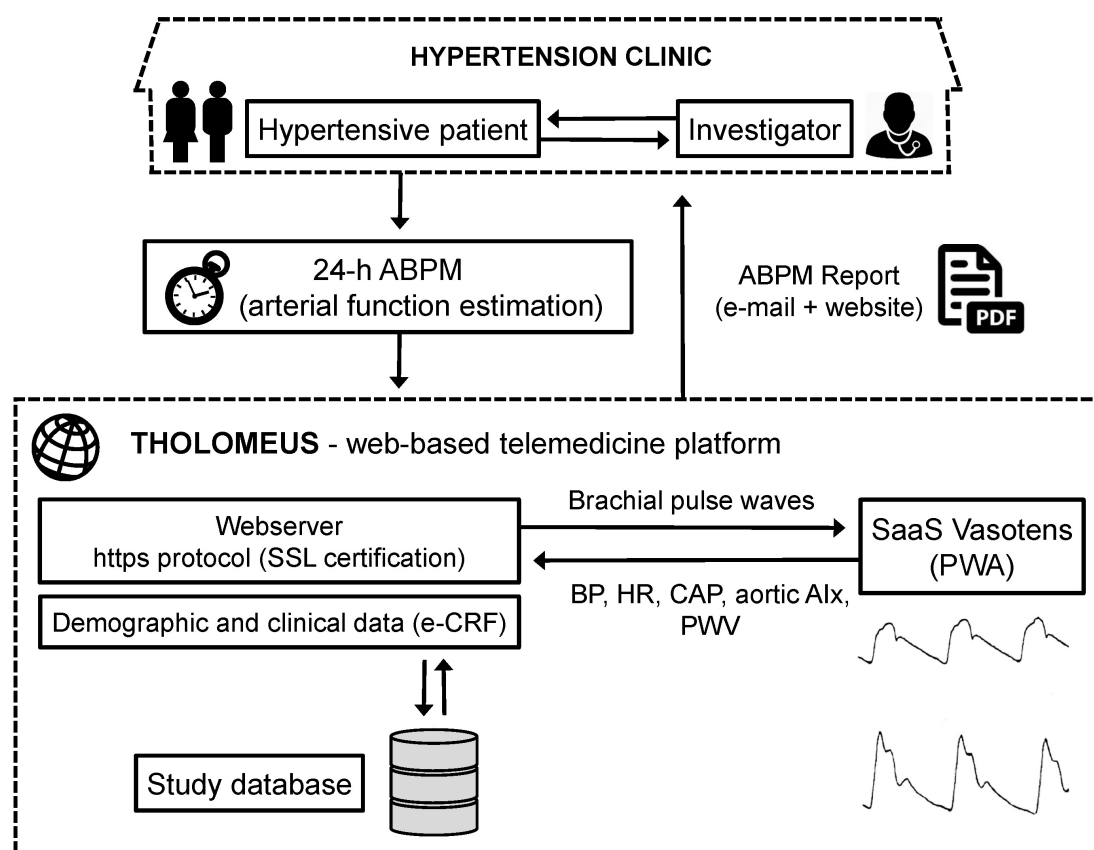

The oscillometric BPLab device will also allow measurements of ambulatory arterial stiffness and central hemodynamics by recording pulsatile pressure changes at the brachial artery level. Briefly, during BP measurement, the pressure waveforms in the cuff are recorded during a step-by-step deflation and then digitalized and stored in the device memory. When data are uploaded on the Web-based telemedicine platform, the software processes the signal using proprietary mathematical algorithms. These are based on a specially developed hemodynamic model to get the PWV and transfer function that utilizes a modification in a certain frequency range within the acquired pulse signal to derive the aortic pressure wave, and thus to assess CAP and AIx. A detailed description of the methodology may be found elsewhere [26,28,30]. As aforementioned, the accuracy of the BPLab device for the assessment of vascular indices has been validated in studies against a non-invasive gold standard [26,27].

### Web-Based Telemedicine Platform

Data contained in existing electronic databases or data of newly enrolled subjects fulfilling the inclusion criteria will be uploaded

and entered on the study website. These data will include ABPM measures (peripheral or brachial BP, CAP, and arterial stiffness) obtained with a BPLab device and clinical data. Data collection will be ensured by a certified Web-based telemedicine platform (THOLOMEUS, Biotechmed Ltd., Somma Lombardo, Varese Italy) available on the Tholomeus website [31]. The choice of using an e-health tool for study management is based on the potential of such a solution to allow standardized and centralized data collection, prompt data validation and analysis, effective study monitoring and auditing, easy and real-time distribution of software updates, and bug corrections. It will also help provide advanced screening options for the patients with hypertension through a worldwide network of expert centers connected together. ABPM data will be uploaded on the website as bpw files (original file format of the standard analysis software of BPLab device, for centers already using such software) or by plugging the ABPM device to the computer through a *Universal Serial Bus* (USB) cable. ABPM data will be transmitted to the website and analyzed in real-time with production of an electronic report (as an Acrobat Reader pdf file) sent by email to the investigator and simultaneously published on the user-restricted area of the website. The Web-based telemedicine platform is complemented by an e-CRF, which will allow entering main patient's clinical data into the study database. Access to the website and e-CRF will be granted through authentication with username and password according to local data protection and privacy regulations. A schematic diagram of the workflow of the Web-based telemedicine platform is shown in Figure 1.

**Figure 1.** Workflow of the THOLOMEUS Web-based telemedicine system used in the VASOTENS Registry.

## Ethics

The study will be conducted according to Good Clinical Practice guidelines and the Declaration of Helsinki [39]. The data collection will start in each center only after approval or notification (depending on local laws) of the study protocol and amendments (if any) by the independent ethics committees of the centers. All participants meeting inclusion criteria and not meeting exclusion criteria will be fully informed about the study design and purposes, and asked to give a written informed consent if willing to participate. All patient-related information is subject to medical confidentiality and to the local data protection acts. Data will be pseudonymized before any aggregate analysis. This means that main data useful to identify the patient will be replaced with a unique number and thus the patient's identity will not be disclosed to third parties, except the promoter.

## Data Quality Control

Given its observational nature, no formal monitoring of the study is foreseen for this study. However, electronic data verification will be done remotely by a data manager who will get in touch with the investigators and, when needed, will ask the investigator to correct the erroneous data or complete missing data on the e-CRF. The investigator will be required to verify and check that the information provided on the e-CRF is as precise and accurate as possible. The procedures for data monitoring and verification will be ensured by the presence of logical checks and range (defined a priori) for the different variables and by automatic identification of inconsistencies by the e-CRF used to manage the database. The controls and related corrections will be made on the e-CRF directly by the investigator on the website. Since no standardized or centralized analysis of laboratory tests will be done, except for ABPM, particular attention will be dedicated to check the congruency

of data collected through ultrasonography, ECG, and biochemistry.

## Dissemination Activities

An important part of the study-related activities will be aimed at disseminating the knowledge on the correct use of ambulatory CAP and arterial stiffness estimation in clinical practice and in research, and thus at achieving a possibly standardized and widespread use of this integrated technology. Manuscripts reporting main study results and documents embedding specific recommendations on the use of the technique will be developed. All publications related to the study results will be prepared by the study coordinators with the support of the scientific committee and will include any investigator significantly contributing to the success of the study. A complete list of investigators will be provided at the end of each manuscript. The original study protocol (with appendices) can be downloaded from, and any future study results will be published on the VASOTENS study website.

## Statistical Methods

### Primary Outcome Measures

The primary study endpoint will consist of the calculations of the average 24-hour values of PWV, CAP, and AIx during the study. The main time points will be the baseline versus the end of the study, corresponding to 2 years following enrolment, but averages will be computed for each study visit occurring during the follow-up.

### Secondary Outcome Measures

The endpoints considered secondary study variables and evaluated according to the same timeline applied to the primary outcome measures are shown in [Textbox 3](#).

**Textbox 3.** Secondary outcome measures.

#### Outcome measures

- Average 24-hour brachial (or peripheral) SBP and DBP
- 24-hour brachial SBP and DBP variability estimated by:
  - Unweighted standard deviation: the standard deviation of 24-hour mean value of brachial SBP and DBP [40]
  - Weighted standard deviation: the standard deviation of the average of all brachial SBP and DBP values during day-time and night-time, with weights corresponding to the duration of day-time and night-time [41]
  - Average real variability (ARV): the mean of the successive absolute differences between adjacent brachial SBP and DBP values over the 24-hours [42]
- Cardiac damage, defined by the presence of cardiac hypertrophy, as determined by echocardiography (LVMI >115 g/m<sup>2</sup> in men and >95 g/m<sup>2</sup> in women according to the recommendations of the American Society of Echocardiography) [43,44] or ECG (Sokolow-Lyon index >3.5 mV + R in aVL >1.1 mV or Cornell voltage duration product >244 mV\*ms) [5]
- Vascular damage, defined by the presence of carotid wall thickening or plaque (intima media thickness, IMT >0.9 mm) at ultrasonography and, if available, by an ankle-brachial index (ABI) <0.9 [5]
- Renal damage, defined by microalbuminuria (30-300 mg/24 h) or albumin-creatinine ratio (30-300 mg/g) (preferentially on morning spot urine) or reduced estimated glomerular filtration rate (eGFR <60 ml/min/1.73 m<sup>2</sup>) [5]
- Cardiovascular fatal or non-fatal events: death or hospitalization for congestive heart failure, myocardial infarction, angina, stroke or cerebrovascular accident, renal failure, or other cardiovascular diseases

## Sample Size

Given the observational nature of the study and the lack of precedent studies with a similar design and objectives, it is difficult to define a proper sample size. According to the number of subjects enrolled and followed-up in previous cross-sectional or prospective trials [10,11,14-21], and considering the number of participants usually needed to collect a sufficient number of clinical outcomes in longitudinal population studies based on ABPM [45], a minimum number of 2000 participants has been considered for the present study. Ideally, such a sample size will be able to provide consistent outcome-based information on the clinical relevance of 24-hour PWA.

## Statistical Analysis

Analysis will be performed on all participants with valid ABPM recordings at study entry and during the follow-up. Principal derived ABPM variables and arterial stiffness measures will be immediately calculated once the data will be uploaded on the website and their quality verified. Analysis of 24-hour recordings will be preceded by removal of artifacts according to previously described editing criteria [37,38]. Valid recordings will be considered those with (1) an interval between measurements not exceeding 30 minutes during the whole 24-hours; (2) a recording duration of at least 24-hours; (3) at least 70% of expected number of readings; and (4) at least 20 valid readings during the day-time and 7 during the night-time. Average brachial and central SBP and DBP, and arterial stiffness indices (PWV and AIx) will be computed by averaging all the individual readings over the 24-hours, and separately for the day-time and night-time subperiods, and for each hour of the recording. Measures of BP variabilities (unweighted standard deviation, weighted standard deviation and ARV) will also be computed based on individual readings. Other ABPM variables of interest (eg, nocturnal BP fall, morning surge, etc) will be subsequently defined in the framework of sub-analyses based on the Registry data and calculated according to procedures specifically defined.

Basic descriptive statistics will be provided for all variables with calculations of absolute and relative frequencies for categorical variables and calculation of average value, standard deviation, and minimum and maximum for continuous variables. The relationship between BP and arterial stiffness estimates, and organ damage and prognosis will be evaluated by appropriate parametric or non parametric tests, depending on the type of data distribution (normal or non-normal). The occurrence of any cardiovascular event during the study will be evaluated by the Kaplan-Meier method. Time-to-event curves will be drawn and the survival analysis will be performed according to the Cox proportional hazard model to analyze predictors of outcomes. Data management and analysis will be carried out by SPSS for Windows version 20. A  $P < 0.05$  will be considered as the minimum level of statistical significance.

## Results

Enrolment of patients in the first study centers started in October 2015. The first data analysis is expected to be performed by the end of 2017 or early 2018.

## Discussion

The VASOTENS Registry is an international, multicenter, observational, non-randomized, prospective study devised to evaluate the clinical impact and usefulness of 24-hour PWA for hypertension management.

### Expected Contributions

With respect to all of the studies briefly reviewed in this paper, our Registry may offer, for the first time, the possibility to shed light on the role of 24-hour ambulatory central hemodynamics and stiffness as predictors of cardiovascular outcomes. The study results may help determine whether the clinical value of ABPM might be further increased by incorporating information on ambulatory CAP and stiffness. The results of the VASOTENS Registry will help define the normalcy thresholds for current and future indices derived from 24-hour PWA, according to outcome data. They will also provide supporting evidence for the inclusion of such evaluations in recommendations on hypertension management and its possible impact on the general population health state. Thanks to this study, an important lack of knowledge will be worked-out and the foundation for future studies with a more robust design could be hopefully laid.

### Limitations

The non-randomized uncontrolled nature of the study and the rather wide selection criteria may increase the risk of obtaining heterogeneous and poorly powered results. In addition, the fact that patients will be recruited in hypertension centers may result in a potential selection bias: the sample being unrepresentative or not fully representative of the general population of patients with hypertension. Despite these important limitations, we think that since the study is carried out in a real-life setting and that it is a longitudinal long-term outcome-driven study, it represents an important added value.

### Dissemination Strategy

An important component of this study is disseminating the knowledge on correct use of ambulatory CAP and arterial stiffness estimation and to help create an e-health network for a standardized and widespread use of this hypertension screening tool. In order to achieve this, apart from data collection, several disseminating activities are required. An exchange of knowledge between participating centers will be achieved by the cooperation of investigators in preparing a possibly unified methodology of ABPM data collection and analysis and by jointly addressing methodological issues that may arise during the project. Data collected in the Registry will foster the performance of studies aimed at optimizing a possible clinical application of non-invasive ambulatory arterial stiffness estimation. The study will help provide instructions on appropriate ambulatory arterial stiffness monitoring methodology to other physicians, particularly to intermediate level centers, not necessarily experts in ABPM use and arterial stiffness determination. A major task of the consortium will be to provide these participants with accurate information on correct methodology and interpretation of such data, in order to support them in case of difficulties and to monitor the

correctness of the use of the methodology in these centers during the project. The study findings will favor preparation of specific recommendations on the use and clinical application of ABPM integrated with arterial stiffness evaluation. The study will also ensure cooperation between international and national scientific societies in the area related to ABPM and arterial stiffness monitoring. This will facilitate the dissemination of information on the project and its findings and will also allow an interaction with writing committees involved in the preparation of guidelines pertinent to this area

## Conclusions

The results of the data collected at baseline and during regular follow-up of hypertensive patients in the VASOTENS Registry will help define the normalcy thresholds for current and future indices derived from 24-hour PWA, according to outcome data. They will also provide supporting evidence on the clinical usefulness of such a technological approach, based on telemedicine, for the screening and follow-up of the vascular function status of the patients with hypertension.

## Acknowledgments

This is an investigator-initiated study, endorsed by the Russian and Italian Societies of Hypertension. The study coordinator, Italian Institute of Telemedicine, is the promoter and main sponsor of the study, and makes available its resources and facilities for conducting the trial. BPLab GmbH provides the ambulatory blood pressure devices, and Biotechmed Ltd provides the Web-based telemedicine platform used for data collection, at no cost. These funding sources had no role in the design of the study and will not have any role during its execution, analyses, interpretation of the data, or decision to submit results. For this study, no additional funding source is available.

## Authors' Contributions

SO conceived the study and defined the study design with INP. SO and INP wrote the protocol. SO, INP, GP, and ANR contributed to refinement of the study protocol. All authors approved the final manuscript.

## Conflicts of Interest

SO is scientific consultant of Biotechmed Ltd. The other authors do not declare any conflicts of interest.

## Abstract

**Background:** The need for documentation in cartilage defects is as obvious as in other medical specialties. Cartilage defects can cause significant pain, and lead to reduced quality of life and loss of function of the affected joint. The risk of developing osteoarthritis is high. Therefore, the socioeconomic burden of cartilage defects should not be underestimated.

**Objective:** The objective of our study was to implement and maintain a registry of all patients undergoing surgical treatment of cartilage defects.

**Methods:** We designed this multicenter registry for adults whose cartilage defects of a knee, ankle, or hip joint are treated surgically. The registry consists of two parts: one for the physician and one for the patient. Data for both parts will be gathered at baseline and at 6-, 12-, 24-, 36-, 60-, and 120-month follow-ups.

**Results:** To date, a wide range of German, Swiss, and Austrian trial sites are taking part in the German Cartilage Registry, soon to be followed by further sites. More than 2124 (as of January 31, 2016) cases are already documented and the first publications have been released.

**Conclusions:** The German Cartilage Registry addresses fundamental issues regarding the current medical care situation of patients with cartilage defects of knee, ankle, and hip joints. In addition, the registry will help to identify various procedure-specific complications, along with putative advantages and disadvantages of different chondrocyte products. It provides an expanding large-scale, unselected, standardized database for cost and care research for further retrospective studies.

**Trial Registration:** German Clinical Trials Register: DRKS00005617; [https://drks-neu.uniklinik-freiburg.de/drks\\_web/navigate.do?navigationId=trial.HTML&TRIAL\\_ID=DRKS00005617](https://drks-neu.uniklinik-freiburg.de/drks_web/navigate.do?navigationId=trial.HTML&TRIAL_ID=DRKS00005617) (Archived by WebCite at <http://www.webcitation.org/6hbFqSws0>)

**KEYWORDS**

ankle joint; cartilage defect; chondral defect; hip joint; knee joint; patient registry

**Introduction**

Isolated cartilage defects are common orthopedic disorders in middle-aged patients that are typically associated with pain, reduced quality of life, and loss of function of the affected joint [1,2]. In fact, chondral defects have been described in 34% to 62% of knee arthroscopies [3-6]. They tend to progress to osteoarthritis, as spontaneous healing is rare, and can therefore be considered a potential risk factor or precondition for joint degeneration [7].

As of 2008, nearly 27 million US adults aged 25 and older have clinical osteoarthritis [8]. Osteoarthritis is the fourth most frequent cause of hospital admission in the United States and the leading cause of joint replacement surgery [9]. In 2009, in the United States 905,000 knee or hip replacements were conducted, resulting in treatment costs of US \$42.3 billion [9]. In sum, osteoarthritis is one of the major causes of global disability and is a socioeconomic burden that will most likely soon become a substantial problem for global health systems [10,11]. Therefore, it is very important to cure cartilage defects in the first place.

Concerning cartilage repair techniques, several therapies have been established, which can be divided into two major groups: bone marrow stimulation techniques and transplantation techniques [12,13]. Despite the fact that the number of randomized controlled trials (RCTs) on cartilage repair has increased significantly over the years, RCTs aim only at direct comparison between two surgical procedures, such as the comparison between arthroscopic microfracturing and autologous chondrocyte implantation [14-18]. In addition, only a highly selected patient population is considered in these trials. Real-life clinical data are hardly ever considered.

The group of Engen et al [11] published a study on this issue and came to the final conclusion that only approximately 4.5% of patients with cartilage defects are represented by RCTs. Jakobsen et al [19] stated that promising results of cartilage repair studies have to be interpreted carefully due to their low methodological quality. Against this background and based on the fact that some scientific questions, such as a detailed analysis of surgical complication, and the influence of sex, overweight, and other factors, cannot be investigated in RCTs, many experts think that RCTs should be supplemented by well-designed observational studies [20-24]. Thus, we have initiated this multicenter patient registry to 1) systematically describe the current medical care situation of patients undergoing surgical treatment of their cartilage defect, 2) compare competing cartilage therapies regarding their outcomes, procedure-specific complication rates, and symptom relief by collecting real-life clinical data, 3) identify putative advantages and disadvantages of various chondrocyte products in daily clinical care, 4) develop new hypotheses on cartilage repair techniques as a basis for future RCTs and to test outcomes of former RCTs in a larger

and more representative population, and 5) evaluate the efficiency and safety of surgically treated cartilage defects of knee, hip, and ankle joints, independent of strict patient characteristics or surgical procedure.

Here we describe the study design and layout of the German Cartilage Registry, which is to our knowledge the first patient registry for this indication worldwide.

**Methods****Study Design**

The German Cartilage Registry is an observational and international multicenter registry that was initiated by the *Arbeitsgemeinschaft Klinische Geweberegeneration* (Working Group Clinical Tissue Regeneration) of the German Society for Orthopaedics and Trauma (DGOU) in 2013. It is a purely scientifically motivated project and as a consequence independent of the interests of industrial partners. The study is conducted in accordance with the Declaration of Helsinki and registered at [germanctr.de](http://germanctr.de) (DRKS00005617).

The registry investigates the efficiency and safety of surgical treatment of cartilage defects in patients under real-life conditions. In October 2013, the assessment started with the documentation of cartilage defects of the knee. The modules for cartilage defects of the ankle and hip joint were implemented 1 year later.

**Ethics Approval**

Depending on individual state's law, investigators consult the responsible ethics committee before starting the study at their site. At their request, investigators are supported by the Clinical Trials Unit (CTU; Medical Center - University of Freiburg, Freiburg, Germany) in preparing the essential documents for submission (first approval in Freiburg on March 13, 2013, internal number 105/13). So far, 33 ethics committees have welcomed the implementation of the German Cartilage Registry in their jurisdiction.

After consulting the ethics committee, investigators are allowed to take part in the German Cartilage Registry.

**Study Population**

All patients aged  $\geq 18$  years who meet the following criteria are eligible to take part in the German Cartilage Registry: 1) they have had surgical treatment of cartilage defects of a knee, ankle, or hip joint at a participating site, 2) they have given written informed consent, 3) they have a personal email address.

**Procedure and Data Collection**

Only after the patient has signed the written informed consent the investigator is allowed to register the patient in the database. We recommend that this registration procedure takes place immediately after the surgery is completed. Thus, the investigator can type in the following mandatory baseline data

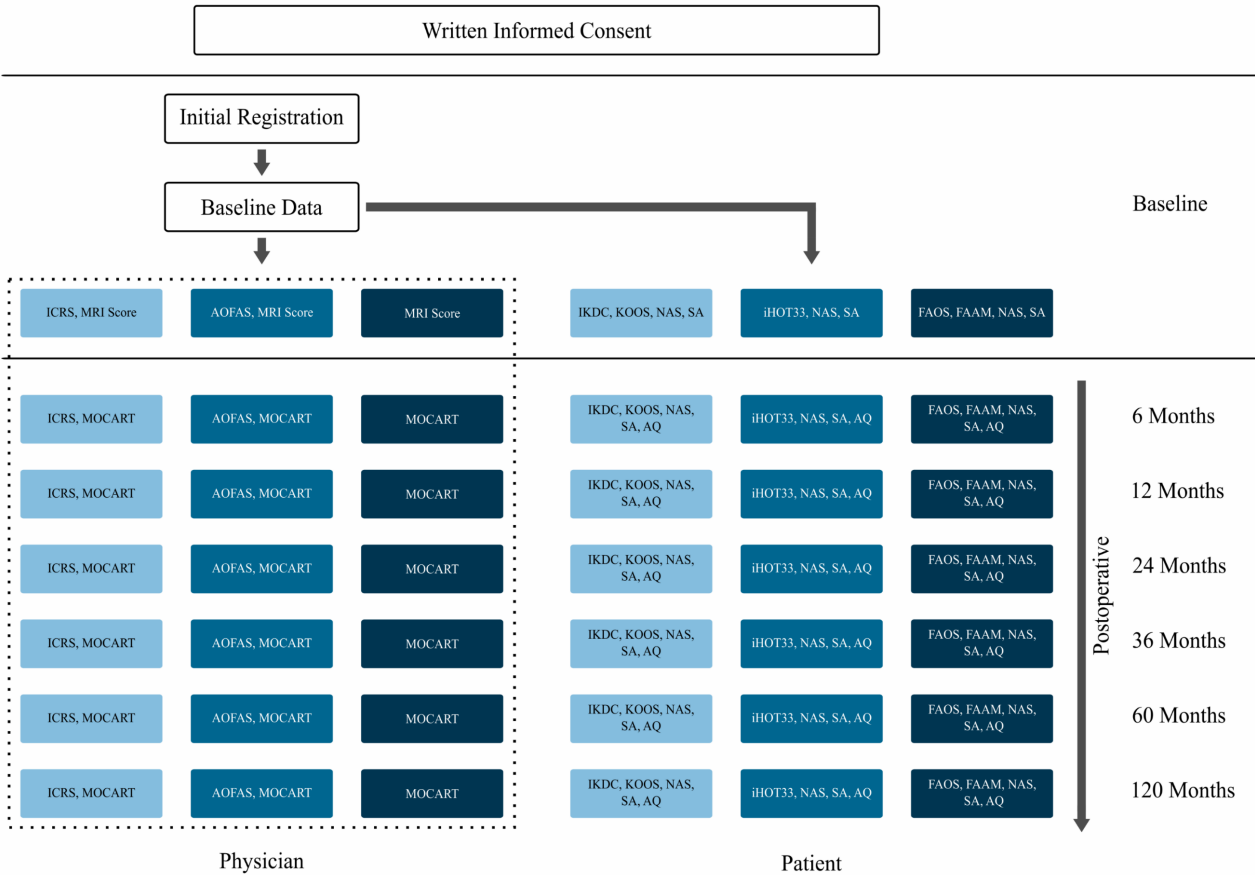

at the same time: initially, the date of surgery, the patient’s identification, and the patient’s email address to generate a new case; and subsequently, basic information concerning patient history and treatment technique. In the course of 6-, 12-, 24-, 36-, 60-, and 120-month follow-ups, the physician can document further optional data.

The day following initial data entry by the physician, the patient automatically receives an email inviting him or her to fill in a questionnaire for baseline data. Additionally, the patient receives an invitational email at 6-, 12-, 24-, 36-, 60-, and 120-month follow-ups to complete the questionnaire. If the patient does

not complete the form within a given time limit, an email reminder is sent automatically. If the patient still does not fill in the questionnaire, the trial site seeks personal contact. [Figure 1](#) shows the flow chart of the German Cartilage Registry in detail, naming all deployed questionnaires. Light blue represents all questionnaires that are used in the knee part, medium blue shows the questionnaires deployed in the hip part, and dark blue displays all questionnaires used in the ankle part of the German Cartilage Registry. Completion of the questionnaires shown in the dotted box is optional. Answering all other questionnaires is mandatory.

**Figure 1.** Flow chart of the German Cartilage Registry and questionnaires deployed to physicians and patients. AOFAS: American Orthopaedic Foot & Ankle Society; AQ: additional questions; FAAM: Foot and Ankle Ability Measure; FAOS: Foot and Ankle Outcome Score; ICRS: International Cartilage Repair Society; iHOT33: International Hip Outcome Tool-33; IKDC: International Knee Documentation Committee; KOOS: Knee injury and Osteoarthritis Outcome Score; MOCART: magnetic resonance observation of cartilage repair tissue; MRI: magnetic resonance imaging; NAS: numeric analog scale for pain description; SA: sports activities.

Instruments

The German Cartilage Registry consists of two parts: one for the physician and one for the patient. At baseline, the physician section includes mandatory information on patient-specific characteristics (age, sex, smoking behavior, weight and height, as well as varus or valgus malalignment), the preliminary operation(s), all surgical procedures performed on the injured joint (including defect-specific characteristics), and therapy characteristics.

Furthermore, the physician can fill in a premagnetic resonance imaging score (similar to the magnetic resonance observation of cartilage repair tissue, or MOCART, score), as well as joint-specific scores, such as the International Cartilage Repair

Society (ICRS) score (equal to International Knee Documentation Committee, IKDC, objective score) for the knee joint and American Orthopaedic Foot & Ankle Society (AOFAS) for the ankle joint [25,26]. Investigator’s data entry at 6-, 12-, 24-, 36-, 60-, and 120-month follow-ups is optional. But there is the opportunity to document joint-specific scores, such as MOCART [27,28], AOFAS, and ICRS (see [Figure 1](#)).

At all times, the patient’s questionnaire consists of a numeric analog scale for pain description, a few questions about sports activities, and joint-specific, validated, and standardized instruments, such as IKDC subjective score and Knee injury and Osteoarthritis Outcome Score (for the knee part) [29-33], International Hip Outcome Tool-33 (hip part) [34,35], Foot and

Ankle Outcome Score, and Foot and Ankle Ability Measure (ankle part) [36-38]. At 6-, 12-, 24-, 36-, 60-, and 120-month follow-ups, 3 additional questions ask about the patient's satisfaction with the surgical treatment at baseline and further surgeries (see Figure 1).

### Data Entry

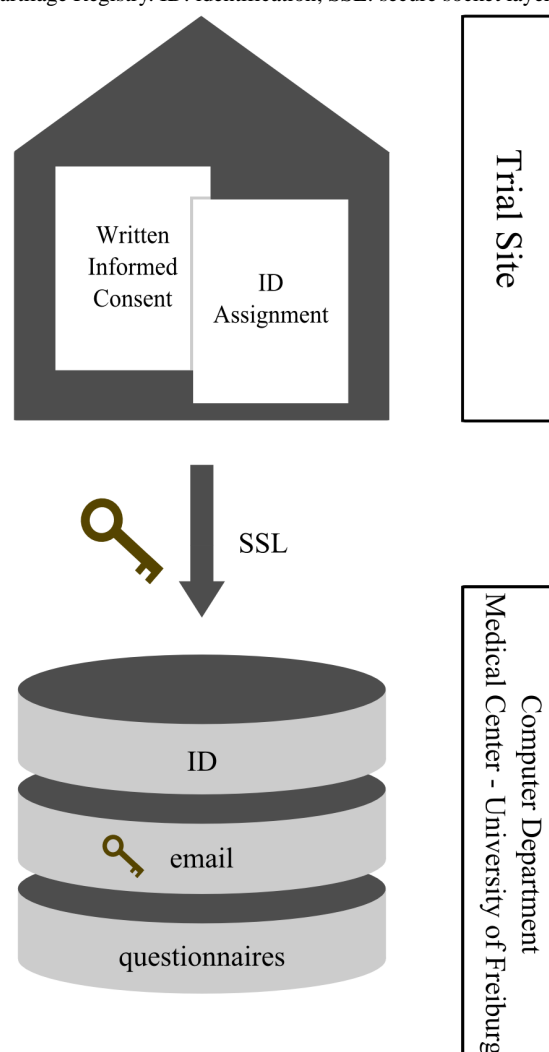

The Web-based remote data entry system called RDE-LIGHT was developed by the CTU of the Medical Center - University of Freiburg as an electronic data entry interface and data management system for clinical studies and other projects in clinical research. Data are collected paperless and directly on site via an Internet browser. The RDE-LIGHT system displays the questionnaires in a structured view in the main window, indicating the status of the questionnaires as traffic light colors. Questionnaires are based on HTML. RDE-LIGHT is available in various languages and validated according to GAMP 5 (ISPE, Tampa, FL, USA). Furthermore, it fulfills all requirements of good clinical practice.

The RDE-LIGHT system applies established security standards such as cryptographic security protocols (secure socket layer/transport layer security), user authentication protocols, and authorization concepts. For example, investigators can access data only of their own site, while the system denies

unauthorized access. Data transfer to the database is encrypted and secured. The server is located in the Medical Computer Department of the Medical Center - University of Freiburg, with strict access control. Hence, common concepts of data protection are implemented. Changes to the database and the underlying system are logged, saved, and archived regularly to ensure end-to-end tracking.

When working with personal data, the CTU encourages involved researchers to use pseudonyms to prohibit the identification of their patients. The patients' names and contact details (email address) will be kept confidential and are available to the research team only for contact purposes. Any data presented publically will ensure participants' anonymity. In order to be able to automatically send emails to the patients when new questionnaires have to be completed, it is necessary to access the patients' email addresses in the system's database. As the email address is part of the patients' personal information, it is stored in an encrypted way in the database using password-based encryption with MD5 and Triple Data Encryption Standard. Figure 2 illustrates the data storage location and clearly shows that the email addresses are separated from the physicians' and patients' questionnaires, as well as the patients' identification, in a well-protected way.

**Figure 2.** Data storage location for the German Cartilage Registry. ID: identification; SSL: secure socket layer.

## Statistical Analysis

After approval from the *Arbeitsgemeinschaft Klinische Geweberegeneration* (Working Group Clinical Tissue Regeneration), every participating physician is allowed to publish the full set of anonymized data available at that time. Data will always be prepared by an experienced biostatistician of the CTU. We are planning several descriptive analyses concerning the structure and composition of the registry. Analyses will be done by first specifying several different research questions (eg, efficacy of certain therapies in real-life datasets) and prespecifying inclusion criteria for these specific questions. Independently, every investigator is allowed to download his or her own data set for anonymized statistical evaluations. However, it is important to keep in mind that registry data need special care in the analysis, as populations are unbalanced and several sources of bias can be present, such as in confounding variables. Therefore, the results must be interpreted very carefully.

## Quality Assurance

The registry is being implemented and maintained by the CTU of the Medical Center- University of Freiburg. The CTU is

member of the network of coordinating centers for clinical trials in Germany [39] and offers profound expertise in all areas of clinical trial planning, conduct, and analysis, in both universities and industry. The CTU is involved in about 250 trials a year.

Skilled and experienced staff of the CTU offer email and telephone support for any emerging problems. Additionally, documents, user manuals, and Web-based instructions via video may help to assist physicians and other personnel at the site. A query management system helps to identify patients and physicians who did not fill in the mandatory questionnaires.

## Results

At time of data collection for this paper, 100 German trial sites and 5 trial sites in Austria and Switzerland are taking part in the German Cartilage Registry. Among these are university medical centers and private hospitals, doctors' surgeries, and outpatient surgical centers. As of January 31, 2016, a total of 2124 patients have been registered (see Figure 3) and the first clinical results have been published [40-42].

**Figure 3.** Total number of patients in the German Cartilage Registry as of January 31, 2016.

## Discussion

The primary aim of this multicenter registry is to assess the efficiency and safety of surgically treated cartilage defects of knee, hip, and ankle joints and to subsequently provide future patients with their best treatment option. Therefore, we are collecting as much valuable information as possible on a preferably heterogeneous group of people who have been treated in day-to-day clinical practice.

In the following section we highlight the strengths of the German Cartilage Registry and discuss the known limitations to this project.

### Complementing Data from RCTs

In recent years, there has been a focus on RCTs in cartilage repair, since they still are the highest level of clinical research [43]. Nevertheless, due to strict inclusion and exclusion criteria, study populations in many RCTs do not completely represent clinical routine and the entire population of patients with cartilage defects. In fact, the number of patients who are eligible

for RCTs in the field of cartilage defects is estimated to be only around 4.5% [11]. Hence, the vast majority of patients are not represented by RCTs, since they do not qualify for different reasons, such as an increased body mass index or concomitant pathologies. In addition, important patient-related factors such as smoking and being overweight have been proven to significantly influence the outcome of cartilage repair techniques, but they cannot be analyzed by RCTs for methodological reasons [44-46]. This also applies to pathology-related parameters such as the influence of defect size or detailed defect location [46]. Furthermore, concomitant pathologies are considered to be exclusion criteria in most RCTs but are frequently present in cartilage repair patients. All of these factors underline the necessity of not exclusively relying on findings of RCTs, but to complement the results of RCTs with data from well-designed observational studies (eg, registries), and, therefore, to reassess findings of RCTs in daily clinical use.

### Selection Bias

Due to organizational or other limitations, we cannot guarantee that every single patient with a surgically treated chondral defect of a knee, hip, or ankle joint will be documented in the system. For instance, for small- or medium-sized medical health

providers, the additional workload for data input may seem too high. But we tried to keep the administrative effort as small as possible by allowing the physicians to register a patient immediately after surgery has been completed, although the first patient questionnaire refers to the complaints before surgery. In this way, the physician can record all mandatory data at once. Furthermore, we tried to include as many patient characteristics as possible that are thought to affect outcomes.

### Data Quality

No onsite clinical monitoring is provided to assure the quality of entered data, and the respective sites are solely responsible for data input. Nevertheless, quality parameters need to be established and carefully applied. For instance, we have to observe the follow-up rate, which is crucial in any type of clinical research. Therefore, a validation study of recorded data will have to follow.

### Expansion of the Registry

Additional sites in German-speaking countries, namely Austria and Switzerland, have already been affiliated and others will be approached to join the registry.

Further information is available on the KnorpelRegister website [47].

### Acknowledgments

We thank all participating sites and the Arbeitsgemeinschaft Klinische Geweberegeneration (Working Group Clinical Tissue Regeneration) of the German Society for Orthopaedics and Trauma who have contributed to the successful implementation of the German Cartilage Registry. Special thanks to Deutsche Arthrose-Hilfe e.V. and Stiftung Oskar-Helene-Heim, who supported this registry financially.

The article processing charge was funded by the German Research Foundation (DFG) and the Albert-Ludwigs University Freiburg in the funding program Open Access Publishing.

### Conflicts of Interest

None declared.

## Abstract

**Background:** The European eHealthMonitor project (eHM) developed a user-sensitive and interactive Web portal for the dementia care setting called the eHM Dementia Portal (eHM-DP). It aims to provide targeted support for informal caregivers of persons with dementia and professionals.

**Objective:** The objective of this study was to assess the usefulness and impact of the eHM-DP service in the dementia care setting from two user perspectives: informal caregivers and professionals.

**Methods:** The evaluation study was conducted from June to September 2014 and followed a before-after, user-participatory, mixed-method design with questionnaires and interviews. The used intervention was the eHM-DP: an interactive Web portal for informal caregivers and professionals that was tested for a 12-week period. Primary outcomes for caregivers included empowerment, quality of life, caregiver burden, decision aid, as well as perceived usefulness and benefits of the eHM-DP. Primary outcomes for professionals involved decision aid, perceived usefulness, and benefits of the eHM-DP.

**Results:** A total of 25 informal caregivers and 6 professionals used the eHM-DP over the 12-week study period. Both professionals and informal caregivers indicated perceived benefits and support by the eHM-DP. In total, 65% (16/25) of informal caregivers would use the eHM-DP if they had access to it. Major perceived benefits were individualized information acquisition, improved interaction between informal caregivers and professionals, access to support from home, and empowerment in health-related decisions (PrepDM Score: 67.9). Professionals highlighted the improved treatment and care over the disease course (83%, 5/6) and improved health care access for people living in rural areas (67%, 4/6). However, there was no improvement in caregiver burden (Burden Scale for Family Caregivers) and quality of life (EuroQol-5D-5L) over the study period.

**Conclusions:** Our study provides insight into the different user perspectives on an eHealth support service in the dementia treatment and care setting. These results are of importance for future developments and the uptake of eHealth solutions in the dementia domain and reinforce the importance of early user involvement. Turning to the primary target of the eHM-DP service,

our findings suggest that the eHM-DP service proved to be a valuable post-diagnostic support service, in particular for the home-based care setting. Further research on a larger scale is needed to enhance the implementation in existing health care infrastructures.

## KEYWORDS

eHealth; web portal; decision aid; personalized support; dementia; Alzheimer's disease; informal caregiver; medical professional

## Introduction

Planning for the treatment and care provision of increasing numbers of persons with dementia (PwD) and their informal caregivers has become an urgent global health service task. Need for care in dementia starts early and increases with disease severity, affecting multiple dimensions such as medical treatment and care, support for household, financial, and social activities, up to almost constant supervision in the severe stage. Thus, dementia has a high impact on PwDs, families (informal caregivers), and health care systems [1]. On average, 70% of persons with dementia are cared for at home. In particular, spouses and children provide extensive care and communicate with professionals, while facing many challenges. They often suffer from higher physical and emotional burden [1-7] in contrast to informal caregivers caring for a person without dementia [8]. In addition, the personal burden of informal care is one of the main reasons for nursing home transfers [9,10]. Given that there is currently no cure for dementia, care concepts and services that provide assistance for persons with dementia are essential. Although several support services exist, they are highly underutilized. Brodaty et al [11] identified the following four major reasons for non-use of support services: caregivers do not perceive the need of the services, reluctance to use the services, the service characteristics, and the lack of information regarding the availability of support services. A recent review highlights the importance of tailoring support services to the needs of caregivers as well as improving access to services [12]. Against this background and due to the projected increase in the number of PwD worldwide [13], there is an urgent need for cost-effective support services for informal caregivers. In this context, several studies highlight the potential of eHealth services, due to the increasing availability of Internet access and the benefit of flexibility, facilitated accessibility, and personalization of the service [14-19].

Therefore, the European eHealthMonitor project (eHM) developed a user-sensitive and interactive Web portal for dementia care: the eHM Dementia Portal (eHM-DP). By providing information and access for local support services from home and information that is tailored to the needs of the users, the eHM-DP aims to increase the use of support services. It aims to provide targeted and personalized support for both informal caregivers of persons with dementia in a home-based care setting and professionals [20]. Especially during the course of the disease, medical professionals play an important role with regard to treatment and care for the PwD and communication with informal caregivers is crucial in order to provide the appropriate treatment and care.

Currently, the majority of Internet-based, supportive interventions for informal caregivers in dementia are websites or specific educational programs. A recent review identified six (of 14) interventions that included a professional [21]. However, only a minority of studies that were identified in two recent reviews [21,22] were similar to the eHM-DP with respect to provision of context-sensitive information [23,24] or interaction functionalities [25-27]. In comparison, the eHM-DP is unique by combining individualized (need-tailored) information and interaction functionalities for both informal caregivers and professionals. Overall, the eHM-DP differs from previous eHealth service solutions for informal caregivers of PwD by a combination of seven major aspects, which were identified based on current reviews [21,22] and the involvement of users in the initial development of the program: (1) interactive and personalized portal with own account, (2) computerized communication between professionals and informal caregivers, (3) tailored support services according to user-specific entries in caregiving diaries, (4) focus on caregiver empowerment and decision aid, (5) the perspectives of medical professionals, (6) provision of individual and longitudinal data about the home-based care setting and course of the disease of the PwD (ie, symptoms, medication, well-being), and (7) provision of individual and longitudinal data of caregiving tasks and caregiver burden. A further advantage of the eHM-DP is the professionals' access to information from health care parameters of PwDs and caregiver burden of informal caregivers.

The purpose of this study was to assess the usefulness and impact of the eHM-DP. The focus was on perceived usefulness that was assessed by the attitude toward using, perceived benefits, concerns, and recommendations of informal caregivers and professionals. In addition, the impact on informal caregivers (quality of life, caregiver burden) was explored.

## Methods

### Description of the eHM Dementia Portal

We designed a Personal eHealth Knowledge Space (PeKS) as an aggregation of all knowledge sources relevant for the provision of individualized personal eHealth services, featuring individualized support and a personalized Web portal that enables interactions with professionals.

Findings of a recent review from Boots et al [22] indicated that multicomponent interventions, combining tailored information with interaction, are the most promising. The technical design of the eHM-DP was realized by service-oriented architecture based on the open source Web platform, Liferay; modeling and semantic knowledge engineering methods; and multiagent systems (MAS) [28,29]. Based on the aforementioned

technologies and a rapid and iterative design process between technical and medical partners, the caregivers' needs were integrated based on (1) a caregiver focus group, (2) interviews with three medical professional experts in the field, and (3) reviews of current scientific literature [2,3,5,21,22,30-33]. Based on these findings, we decided to involve two important professional groups within the eHM-DP: medical and social professionals. Whereas medical professionals are important for medical treatment and care for the PwD (focus on PwD), social professionals from caregiver counseling institutions take care of the caregiving situation and informal caregivers needs (focus on informal caregivers). The eHM-DP aims to provide access to relevant and comprehensive information for both professional groups in order to improve treatment and care and to prevent caregiver burden.

Before the final implementation and evaluation in a field trial, the eHM-DP was piloted in a pretest by 31 informal caregivers and 11 professionals [34]. Based on the pretest findings, the eHM-DP was revised. Major revisions were made on the following aspects: improved interaction functionality for communication between informal caregivers and professionals, the possibility for professionals to list patients based on priority levels (eg, worse health status), a revision of the medication plan, a print option for diaries and design aspects.

In the evaluation study, user access to the eHM-DP was realized via a customizable personal account for informal caregivers and professionals. Thus, the provision of individualized support services by means of a user-specific profile and user-specific diary entries (by informal caregivers) were enabled. This is important, as caregiver needs are multifaceted and complex in nature [16]. There are four major roles that are relevant for the eHM-DP:

1. Informal caregiver with own user account: provision of information about medical data and health status (symptoms, well-being) of the PwD (external assessment) as well as about their own caregiving situation and well-being (caregiver burden).
2. Person with dementia without personal eHM-DP account: PwD is not directly involved in the eHM-DP, but is indirectly via external assessment from informal caregivers and recommendations/advice from medical and social

professionals with the aim to improve treatment, care, and well-being for the PwD.

3. Medical professional with personal eHM-DP account: acquisition of "hard-to-access" information about the PwD (improved decision making, improved treatment and care), timely reactions to health status changes of the PwD via the eHM-DP or directly.
4. Social professional with personal eHM-DP account: acquisition of "hard-to-access" information about the caregiving situation (prevention of caregiver burden), timely reactions to health status changes of the informal caregiver via the eHM-DP or directly.

The eHM-DP is personalized and interactive and provides two major functionalities (see Figure 1): (1) interactive and individualized provision of information and knowledge, and (2) communication with domain experts in dementia. First, the portal provided individualized, timely, and situation-specific information to informal caregivers and professionals based on an individual registration profile as well as the electronic diary entries provided by informal caregivers (ie, caregiving diary, course-of-disease diary about PwD, medication diary about PwD). Informal caregivers received tailored information consisting of approved guidelines and documents (eg, factsheets of German Alzheimer Association, Ministry of Health, local dementia institutions/groups) and of recommendations from professionals via the message functionality of the eHM-DP. Second, the eHM-DP sought to facilitate and enable close communication and interaction between informal caregivers and professionals. Thus, its aim was to empower informal caregivers and prevent caregiver burden as well as to improve treatment and care for the PwD. From the perspective of professionals, the eHM-DP facilitated information acquisition of individual "hard-to-access" information and sought to improve the management, treatment, and care for PwDs (based on diary entries from caregivers about symptoms and medication of the PwD) and the well-being of informal caregivers (based on diary entries from caregivers about the caregiving situation and caregiver burden). Based on these individual diary entries provided by informal caregivers as well as specific questions (free text), professionals were informed by the eHM-DP (eg, alerts) and were able to provide support either via the portal (messaging feature) or directly (appointment, telephone call).

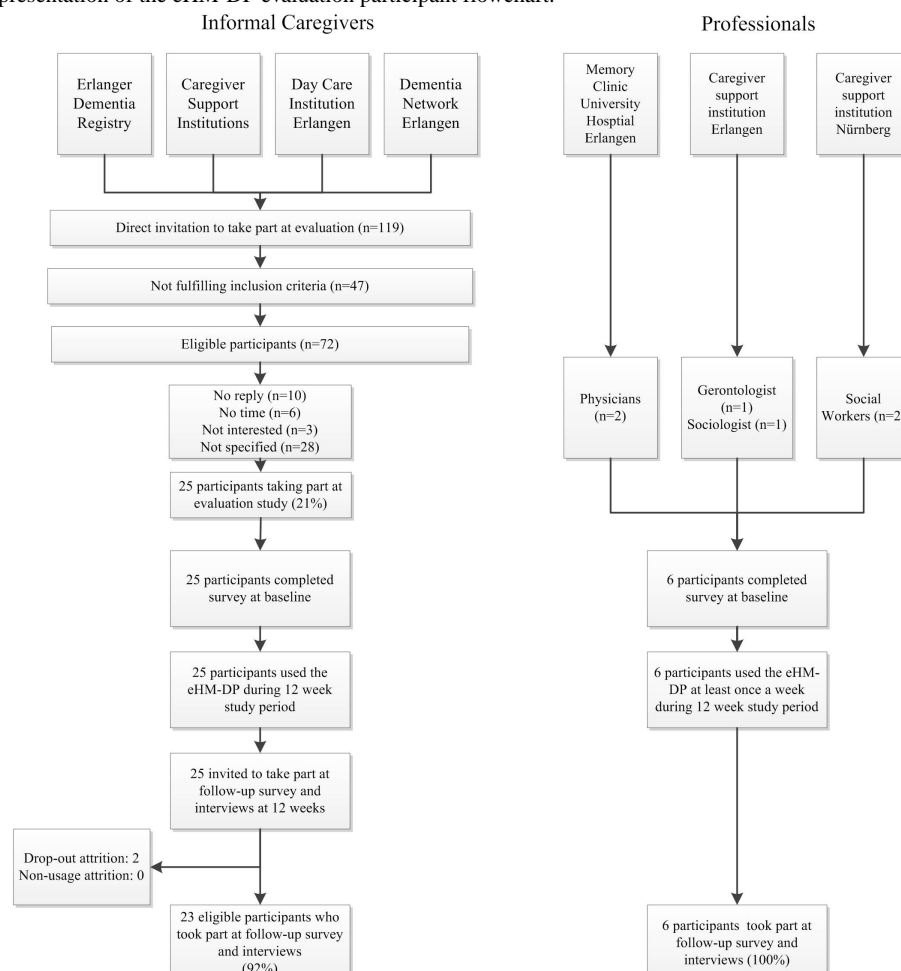

**Figure 1.** Schematic representation of the eHM-DP.

### Participants and Evaluation Design

The Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online TeleHealth (CONSORT-EHEALTH) provided guidance for the development of our evaluation [35]. According to Eysenbach [35], these guidelines may also be used for other evaluation methods. Our evaluation study sought to assess the usefulness and impact of the final implementation of the eHM-DP in order to optimize the platform before starting a large-scale randomized controlled trial. This is in agreement with previous studies, which emphasized the need to conduct early evaluation studies such as “proof-of-principle-studies” before the realization of studies on a larger scale [36].

Our study was conducted from June 1-September 30, 2014, and followed a before-after study with 12-week follow-up to investigate the eHM-DPs impact on informal caregivers and professionals. Study participants accessed the Web portal from home (informal caregivers) or from their workplace (professionals) and used the Web portal at least once a week over the 12-week study period. A convenience sampling strategy was used to recruit study participants: informal caregivers, medical professionals, and social professionals. Informal caregivers were recruited from a Hospital Memory Clinic, a

district hospital, and two caregiver support institutions from the metropolitan region of Erlangen-Nürnberg. Eligibility criteria included (1) primary responsibility as an informal caregiver for a person with dementia (International Statistical Classification of Diseases and Related Health Problems, ICD-10, F00-F03) who is living at home, (2) is aged over 18 years, (3) is able to speak, read, and write German, and (4) has Internet access from home. In addition, 2 medical professionals were recruited from a Hospital Memory Clinic and 4 social professionals from caregiver support institutions. The participant flowchart (see Figure 2) describes the recruitment and inclusion process in detail. The evaluation study was approved by the local ethics committee of the Friedrich-Alexander University Erlangen-Nürnberg (Germany). All study participants were informed about the objectives and the scope of the study and gave written, informed consent for participation. Data were collected confidentially in written face-to-face interviews by trained interviewers. Personal contact data (ie, name, address, institution) were used only for the second contact (follow-up interview) and related questionnaires were coded based on an identification number. The data analysis and interpretation were based on two separate datasets (informal caregivers and professionals) and conducted confidentially by 2 independent researchers.

**Figure 2.** Schematic representation of the eHM-DP evaluation participant flowchart.

## Procedure

The eHM-DP was introduced to study participants by trained persons according to the Standard Operating Procedure of eHealthMonitor's evaluation [37]. The content of the introduction included a detailed explanation of all the features and functionalities of the eHM Portal and was supported with additional materials, such as videos and written information material. Support for study participants was provided throughout the whole study period (ie, telephone help desk, email). The non-usage attrition (discontinuation of services) [38] was minimized by "push" factors such as reminders and telephone calls.

## Measures

A user participatory research design based on a mixed-method approach was applied to investigate the different user perspectives of the eHM-DP at baseline and follow-up (after 12 weeks). This approach has been recommended in previous reviews and studies on eHealth interventions [21,39,40]. The questionnaire was developed according to our research questions and consisted of instruments assessing the perceived usefulness of the eHM-DP with regard to decision aid, the attitude toward using it, perceived benefits and concerns, as well as recommendations of both informal caregivers and professionals. In addition, the impact on informal caregivers' quality of life and burden was explored.

Further, sociodemographic data as well as informal caregivers' eHealth literacy, using the eHEALS scale [41], and needs, using the Carers' Needs Assessment for Dementia (CNA-D) [30], were assessed at baseline.

## Quantitative Measures

### Usefulness: Empowerment (Informal Caregivers)

The empowerment of informal caregivers was assessed via 13 relevant categories of the CNA-D instrument and rated on a 5-point Likert scale (1=strongly agree to 5=not agree at all). Although the CNA-D was designed to assess carers' needs, its relevant areas of need were chosen to assess whether the eHM-DP contributes to address these needs and is able to empower caregivers in these specific areas of need.

### Usefulness: Decision Aid (Informal Caregivers, Professionals)

The "Preparation for Decision Making Scale" (PrepDM) [42] was used to assess the informal caregivers' and professionals' perception of the eHM-DP with regard to decision support. Based on 10 items, the preparation for decision making is rated on a 5-point Likert scale (5=a great deal, 1=not at all). The score ranges from 0 (no perceived preparation for decision making) to 100 (highest perceived level of preparation for decision making).

**Usefulness: Attitude Toward Using (Informal Caregivers, Professionals)**

The attitude toward using the eHM-DP was assessed via the item “I think that eHM is a good concept” and intention to use via the item, “If I had access, I would use eHM.” Both were rated on a 5-point Likert scale (1=strongly agree to 5=not agree at all). In addition, users were asked about the frequency of use of the eHM-DP.

**Usefulness: Perceived Benefits (Informal Caregivers, Professionals)**

The benefits for each user group were assessed via specific items that were rated on a 5-point Likert scale (1=strongly agree to 5=not agree at all). The questionnaire items were derived from current literature as well as pretest results of the eHM-DP [34].

**Impact: Quality Of Life (Informal Caregivers)**

Health-related quality of life was measured via the EQ-5D-5L instrument [43], which captures five dimensions: mobility, self-care, activity, pain, and anxiety. The labels for each of the dimensions are no problems, slight problems, moderate problems, severe problems, and unable to/extreme problems. Utility values range from 1 (best possible health) to 0 (worst possible health).

**Impact: Caregiver Burden (Informal Caregivers)**

Caregiver burden was assessed via the short form of the Burden Scale for Family Caregivers (BSFC) [44], which measures the subjective caregiver burden of informal caregivers. It consists of 10 items rated on a scale (3=strongly agree, 2=agree, 1=disagree to 0=strongly disagree). The score ranges from 0-30 (0-9: low burden; 10-20: moderate burden; 21-30: severe burden).

**Qualitative Interviews**

In addition to the quantitative data, the perceived usefulness was explored through a semistructured interview focusing on users' experiences in terms of perceived benefits, major concerns, and further desired functionalities and improvements. The rationale was to assess the impact on users' perception of the eHM-DP. The semistructured, written interviews lasted approximately 60 minutes. All interviews were performed by

a trained interviewer (3 interviewers were involved in the study) at baseline and follow-up. Interviews were conducted either at the study participants' home (informal caregivers) or at work (professionals).

**Data Analysis**

Descriptive analysis methods for quantitative data were applied using SPSS Statistics 21.0 software. Paired sample *t* tests were used to analyze changes in caregiver burden and quality of life from baseline to 12 weeks. Written qualitative data was captured electronically and structured by the method of an inductive category development according to Mayring [45]. The summary content analysis technique was applied in order to reduce the material to core contents or aspects. Therefore, the following steps were applied: (1) paraphrasing of content-bearing text passages, (2) generalization to the required level of abstraction (category definition), (3) first reduction through selection, and (4) second reduction [45]. At the end of this reduction phase, exact checking took place to ascertain whether the new statements collated as a category system still represent the base material. An intercoder check by 2 coders was performed to assure quality of the data analysis. The software MAXQDA was used to conduct the content analysis.

## Results

**User Statistics**

A total of 119 informal caregivers were invited to take part in the evaluation study. Of those, 47 (39.5%) did not meet the inclusion criteria (eg, no Internet access), and 25 (35%) of the 72 caregivers who were qualified for the study were interested in taking part in the study. The main reason for non-participation was “no time,” which often was due to the fact that informal caregivers were already stressed by the caregiving situation. This fact has to be taken into account when interpreting our conclusions and when planning further studies in the field. Informal caregivers were aged 29-80 years. Mean age was 58 years (SD 13.0, median 61 years) and almost half (48%, 12/25) of informal caregivers were female. Informal caregivers were mainly spouses (44%, 11/25) or children (36%, 9/25) of the PwD. Table 1 provides detailed information for the 25 informal caregivers.

**Table 1.** Informal caregivers' characteristics (N=25).

	Participants, n (%)	Median; Min, Max
<b>Age</b>		Median 61; min=29, max=80
Time caring for PwD (years)		4 (3); min=1, max=12
<b>Sex</b>		
Female	12 (48)	
Male	13 (52)	
<b>Relationship to PwD</b>		
Spouse	11 (44)	
Child	9 (36)	
Relative	5 (20)	
<b>Living situation</b>		
Living together with PwD	14 (56)	
Living NOT together with PwD	11 (44)	
<b>Living area</b>		
Urban	16 (64)	
Rural	9 (36)	
<b>Professional status</b>		
Full-time employed	9 (36)	
Part-time employed	4 (16)	
Retired	10 (40)	
Other	2 (8)	
<b>Caregiver burden</b>		
Low	11 (44)	
Moderate	8 (32)	
Severe	6 (24)	

At baseline, the health information source "Internet" was rated as "very important" by 48% (12/25) and as "important" by 24% (6/25) of informal caregivers. It is rated as the second most important information source (mean 2.0, SD 1.2), directly after the personal contact to professionals (mean 1.8, SD 1.1) (see [Figure 3](#)). eHealth literacy competence at baseline was measured by the eHEALS Scale [41] and indicated a mean value of 19.9 (SD 9.0) on a scale from 8-40. On average, 37% of informal caregivers expressed needs for one of the 18 categories of the

CNA-D instrument. The mean value for the number of reported needs is 6.6 (SD 5.3).

Mean age of professionals was 43 years (SD 13.2; min=31; max=58) and half of them were female (3/6). In total, 29 study participants (23 informal caregivers and 6 professionals) took part in the follow-up study (two drop-out attritions within the group of informal caregivers; reasons: 1 PwD died, 1 informal caregiver was sent to hospital) [38].

**Figure 3.** Importance of information sources for health-related aspects.

## Quantitative Findings

### Usefulness: Empowerment (Informal Caregivers)

The empowerment of informal caregivers was assessed via 13 relevant categories of the CNA-D instrument (see Figure 4).

**Figure 4.** Empowerment via the eHM-DP (Informal caregivers, n=23).

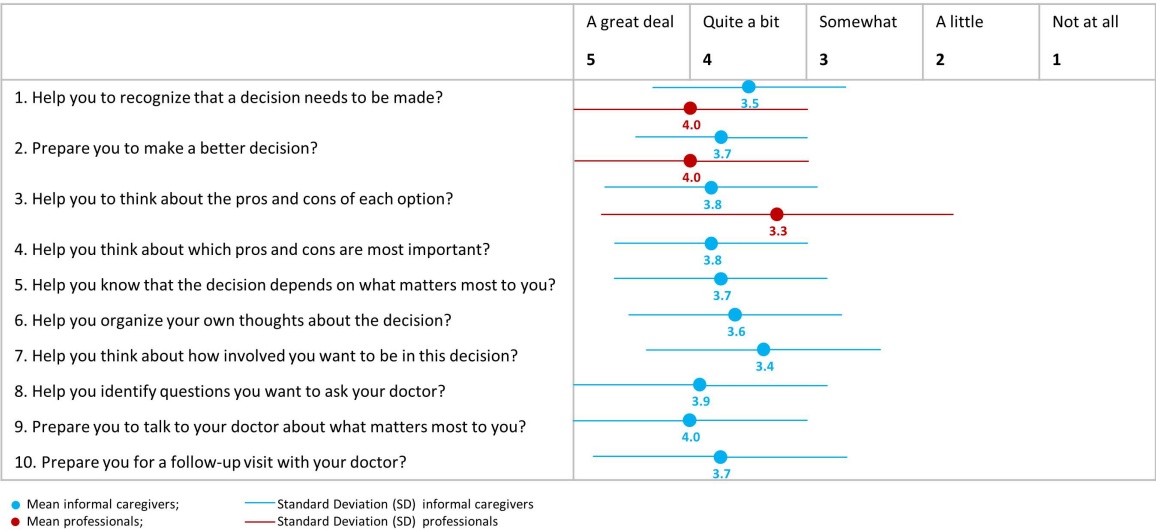

### Usefulness: Decision Aid (Informal Caregivers, Professionals)

The score of 67.9 (min=38.9; max=100.0) of the PrepDM instrument indicates the perceived decision aid of the eHM-DP for informal caregivers. Highest decision support was perceived for “Prepares me to talk to my doctor about what matters most

The most perceived empowerment was received via information acquisition for several topics (disease, local services, treatment, caregiving activities, and communication strategies). About a third agreed that the eHM-DP contributed to fewer worries about the disease or to less caregiver burden.

to me” (mean 4.0, SD 1.0), followed by “Helps me to identify questions I want to ask my doctor” (mean 3.9, SD 1.1). Professionals pointed out that eHM-DP specifically helps them to recognize that a decision has to be made (mean 4.0, SD 1.0) and prepares them to make a better decision (mean 4.0, SD 1.0). Figure 5 illustrates the perceived decision support of the eHM-DP.

Figure 5. Preparation for decision making by the eHM-DP service.

Usefulness: Attitude Toward Using (Informal Caregivers, Professionals)

Two thirds (65%, 15/25) of informal caregivers indicated that they would use the eHM-DP service if they had access to it. In total, 83% (19/25) of caregivers and 67% (4/6; 2 medical professionals, 2 social professionals) of professionals think that eHM-DP is a good concept. Further, 2 social professionals were not convinced that eHM-DP is a good concept; however, they suggested further functionalities that would make the eHM-DP unique for them (eg, involvement and connection of all relevant stakeholders within the dementia treatment and care process via the eHM-DP). With regard to the informal caregivers' frequency of use, 22% (5/25) indicated 2-3 times per week, 57% (13/25) weekly, and 13% (3/15) monthly. Half of the professionals prefer to use the eHM-DP at least once a week.

Usefulness: Perceived Usefulness (Informal Caregivers, Professionals)

Although there were no pre-post changes in quality of life, the user-specific questionnaires suggest that over half of the informal caregivers perceived an improvement of their individual situation (see Figure 6). Over one third highlighted an improvement in communication with professionals (especially from home), the provision of individualized information, an overview about course of the disease (symptoms, care), as well as the information acquisition from home. In

addition, the provision of information about local support opportunities, the improved individual situation as an informal caregiver and the competence-building in dementia were mentioned. A resulting consequence for 26% (6/25) of informal caregivers is a reduction of caregiver burden. From the perspective of professionals, the eHM-DP contributes to an improved medical treatment of the PwD (83%, 5/6) and improved compliance (50%, 3/6). One major aspect that contributed was the provision of "hard-to-access" information (home-based care setting, symptoms over disease course). This resulted in faster response time to status changes and thus also to a reduction of caregiver burden (50%, 3/6), and overall improved interaction with informal caregivers (33%, 2/6). A third aspect that is highlighted is the improved access to support, especially for mobility-impaired persons and for people living in rural areas (67%, 4/6). In addition, professionals indicated that eHM-DP contributes to active medical decision making for PwD and informal caregivers, timely reaction to changes in the disease course (67%, 4/6), as well as the prevention of the deterioration of the disease (50%, 3/6).

Overall, medical professionals emphasized the possibility of timely reactions to status changes, whereas social professionals highlighted the improved access to care and support for caregivers who are living in rural areas. Both groups showed a high level of consistency with regard to an improved medical treatment of the PwD.

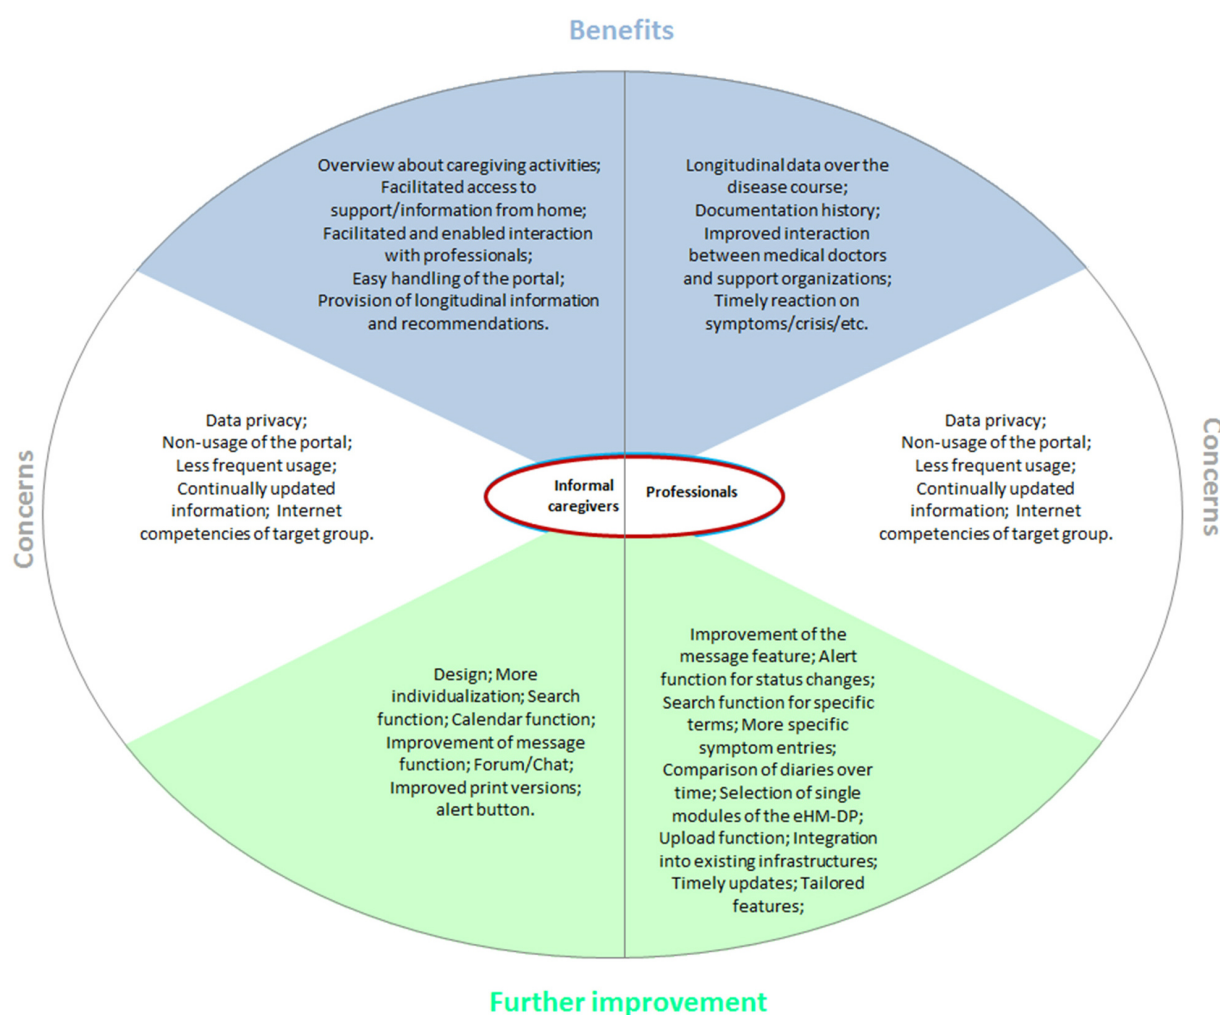

**Figure 6.** Perceived usefulness of the eHM-DP.

### ***Impact: Quality of Life and Caregiver Burden (Informal Caregivers)***

After 12 weeks of eHM-DP usage, there were no improvements on primary informal caregiver outcomes (BSFC and EQ-5D-5L).

### **Qualitative Findings**

The content analysis of the 29 interviews (23 informal caregivers and 6 professionals) resulted in 18 categories across three domains (ie, perceived benefits, concerns, further improvement), which are presented below (see [Figure 7](#)).

**Figure 7.** Results of qualitative content analysis: Benefits, concerns, improvements.

### ***Perceived Benefits (8 Categories)***

Informal caregiver reported the following five major benefits: saved time, 24-hour access, facilitated communication with professionals, easily operated portal, and overview about individual caregiving activities.

A major benefit for informal caregivers was saved time (eg, communication with professionals from home, provision of individualized information), which was predominantly expressed by employed informal caregivers. Another perceived benefit was 24-hour facilitated access to support and information, due to access from home or work. A further perceived benefit resulted from the facilitated and increased communication with professionals. In addition, the overview about individual caregiving activities resulted in increased awareness of personal tasks and support areas. The easily operated portal also accounted for frequent use from users.

For the professionals, the following four major benefits were identified: provision of longitudinal data over the disease course, documentation history, improved interaction between professional institutions and support organizations, and timely reaction to status changes.

Provision of longitudinal data over the disease course and documentation history were essential and beneficial factors of the eHM-DP. In addition, the professionals mentioned an improved interaction between professional institutions and support organizations. The latter factors contributed also to an improved and faster response time to behavioral symptoms, adverse events, or crisis.

### ***Concerns (4 Categories)***

We identified the following categories: concerns of data privacy, risk of non-usage of the portal, assurance of provision of up-to-date information, and insufficient Internet competence of informal caregivers. Both informal caregivers and professionals expressed concerns about data privacy (eg, who will access the entered data?). In addition, they mentioned the risk of non-usage or insufficiently frequent usage, which is the precondition to realize the eHM-DP's benefits and interaction between both sides. Further, they emphasized that all provided information has to be up to date and professionals stated that the target group of informal caregivers is hard to reach and often has less competence with the Internet.

### **Further Improvement (6 Categories)**

The following categories for the domain “further improvement” were identified: improved design of the portal, more specific individualization of the portal, further functionalities, improvement/extension of specific functionalities, selection of certain functionalities of the portal for professionals, and integration of the eHM-DP into existing infrastructures.

Informal caregivers reported the following comments for further improvements. First, they suggested an improved design of the eHM-DP (eg, the presentation of tables and graphs, the main menu, the selective use of colors, or the presentation of videos). In addition, they emphasized the need for even more specific individualization of the eHM-DP (eg, according to the caregiver status to the patient [spouse or child] or for specific topics). The possibility of searching for specific terms, information about local events (eg, based on a calendar), print version for whole diaries, and the integration of an alert button were warranted. Further, the need to improve the message feature for communication with professionals was expressed by both informal caregivers and professionals (eg, display of a message history, read confirmation). In addition to the interaction with professionals, informal caregivers wanted to have an integration of a forum or chat for informal caregivers themselves.

The professionals mentioned the benefit of an improved alert function for status changes of the patient or caregiver, which helps them react in a timely fashion to status changes. In addition, the possibility of making more specific symptom entries and caregiving entries within the diaries and the integration of a search functionality for specific terms was expressed. Professionals would also benefit from the option to compare diary entries (over time). A selection of single modules of the eHM-DP service would help professionals choose the most important functionalities of the service and tailor the eHM-DP features and modules to specific professions (eg, physician, caregiver counseling institution, psychologists, care service). Also the possibility of uploading specific documents like blood parameters or diagnostic findings would facilitate patient management.

Finally, the need for integration of the eHM-DP into existing software infrastructures as well as the need for timely updates of provided information was highly warranted.

## **Discussion**

### **Principal Findings**

This study describes the perceived usefulness and impact of a personalized eHealth service (eHM-DP) that aims to support informal caregivers and professionals in the dementia treatment and care setting. Our results reveal that the eHM-DP is promising in addressing needs of both informal caregivers [2,3,30,31,33] and professionals [32] in the dementia treatment and care setting. Those were addressed by five major factors: individualized information acquisition, decision support, facilitated access to care and support infrastructures, interaction between professionals and informal caregivers, and provision of longitudinal data about the disease course and medication history (“hard-to-access” information). Although pre-post

changes in caregiver burden (BFSC) and quality of life (EQ-5D-5L) for informal caregivers were not observed, the perceived usefulness of the eHM-DP and qualitative interview data of both study participant groups are encouraging. They indicated perceived benefits and a positive impact of the eHM-DP with respect to increased knowledge in certain topics (PrepDM, CNA-D), as well as the facilitated interaction with professionals. These results are also evident in a recent review from Boots et al (2014) [22], concluding that multicomponent interventions that combine tailored information with interaction are the most promising approaches [22].

One factor that contributed to these results is that both user groups have been involved early in the development process of the eHM-DP, which has proven to be valuable in previous studies [46-48]. Further, the combination of comprehensive information provision within the eHM-DP of informal caregivers and of PwDs was relevant for tailoring information and support.

From the perspective of professionals, the eHM-DP provided benefits for improved medical treatment of dementia patients, improved compliance, and interaction with informal caregivers. Although no significant changes in the reduction of caregiver burden were measured, half of the professionals considered that the eHM-DP is able to reduce caregiver burden. The latter aspects are encouraging with regard to the reduction of hospitalizations and institutionalizations (positive health economic impact), as especially caregiver burden is one of the main predictors for nursing home referrals [9,10,49]. A major factor that led to these perceived benefits was the timely provision of “hard-to-access” information (eg, home-based care situation, symptoms over disease course, medication, subjective informal caregiver burden, health status of informal caregiver and PwD). This is a major advantage as informal caregivers are often the only information source for professionals at (regular) checkups but are not able to provide quantified long-term details. However, professionals expressed doubts about whether the informal caregivers would be motivated to use the eHM-DP regularly. This concern could not be confirmed within our study; however, participants were reminded and motivated to use the eHM-DP. The physicians from the memory clinic mainly benefited from the course of disease diary with timely, quantified, and longitudinal information about cognitive status, activities of daily living, mood, behavioral symptoms, and social behavior, followed by the medication diary with information of all medications and reported side effects. This is especially important because PwDs are often elderly persons with more than one disease who are in contact with several physicians [50]. The latter diaries enable an overview of all prescriptions, side effects, and comorbidities of the PwD. In contrast to physicians, caregiver counseling institutions emphasized the comprehensive (PwD and informal caregiver status, needs) and timely information provision that helps prevent caregiver burden and provides additional benefits (eg, optimized counseling, improved accessibility for target group) to the usual face-to-face support. The eHM-DP provided them additional and timely insight into actual carers’ needs and, thus, contributes to prevention of caregiver burden and early crisis intervention. This is crucial, as informal caregivers often wait until a crisis situation occurred or they become exhausted before seeking

support [51]. Regular contact with professionals can help prevent such crisis situations.

From the perspective of informal caregivers, the provision of individualized information for the specific care situation of the informal caregiver contributed to caregiver empowerment. The importance of tailoring information to informal caregivers' needs was highlighted in previous studies [21,23,33,52,53]. Within the eHM-DP, modifying information based on the symptoms and status of the PwD, in addition to informal caregivers' health status and needs, proved to be important for individual information provision and interaction with professionals. In addition to provided information from the eHM-DP, professionals gave individual recommendations based on diary entries via the portal message feature. A number of the informal caregivers reported that information about specific topics triggered reflection about their own caregiver role and situation and, thus, provided a useful decision aid. In contrast to experienced caregivers, "new" caregivers of recently diagnosed PwDs reported a high perceived benefit with regard to individual information acquisition.

Overall, a recent review indicated that informal caregivers often receive little or unclear information about dementia, especially after the diagnosis disclosure [54]. This leads to another determinant that contributed to empowerment of informal caregivers: the facilitated access to information and support. It is evident that the accessibility of services is a major predictor for its utilization [11,55]. The overall empowerment of informal caregivers via knowledge acquisition about local support options is crucial, as the lack of knowledge about existing services and dementia infrastructures contributes to one of four major reasons for non-use of services [10]. The eHM-DP contributes to increased autonomy in the sense of awareness and offers the chance to choose between different support services as demonstrated by Schüz et al [56]. In particular, informal caregivers from rural areas, non-mobile informal caregivers or full-time employed informal caregivers emphasized the facilitated interaction and information acquisition from home. In addition, it can reach informal caregivers, who are either not motivated (eg, persons who do not want to travel to the next town) or not able to use (eg, no public transport) traditional services like caregiver counseling. This is especially true for people living in rural and remote areas [18,51,57]. These findings are in line with previous studies, where time constraints, transportation, and health issues have been identified as predictors for non-participation in face-to-face support services [12,51].

## Limitations

Although the findings of our study provided essential insight into the usefulness of eHealth support services for informal caregivers of PwD and professionals, some limitations need to be considered. Our study confirmed that introducing eHealth services to elderly people is challenging, as computer competencies and Internet access are important prerequisites, which narrows the potential number of study participants. The objective was to conduct a comprehensive proof of principle study with a demonstrator in order to improve the eHM-DP before evaluating effects on a larger scale and in a (randomized)

controlled group design. This approach has been recommended in previous studies [36]. However, the fact that no control group was included is a limitation and the realization of a controlled study is needed. The first limitation was the small sample size of study participants. The convenience sample had rather lower levels of caregiver burden, which has to be taken into account when interpreting results for further studies on a larger scale, as well as the reach of the intervention. Additionally, the positive feedback of the eHM-DP from 83% of caregivers may be overestimated due to the convenience sample that agreed to take part in the study.

Another limitation is the short 12-week study period, which likely explains the non-significant changes in quality of life and caregiver burden. Furthermore, an apparent discrepancy between the non-significant pre-post outcome measures (BSFC, EQ-5D-5L) and the positive results on perceived usefulness of both user groups is present. This can be explained by the small number of study participants and the testing period of 12 weeks. However, an advantage of our study is the focus on post-outcome measurements and qualitative interviews (mixed-method design) that provided promising results for the eHM-DP service and emphasizes the need for further controlled studies on a larger scale.

## Future Directions

Our study contributes to scientific research by providing insight into the different user perspectives of eHealth support services in the dementia treatment and care setting. These results are crucial for future developments and the use of eHealth solutions in the dementia domain and reinforce the importance of early user involvement. The perceived benefits and willingness to use the system combined with an increasing number of adults who use the Internet regularly, emphasizes the potential of personalized and Web-based support services for informal caregivers. This is especially true for our aging societies and limited expenditures for health care services.

Based on our findings, the following aspects are decisive for implementing eHealth services in the dementia treatment and care context: a comprehensive introduction into the eHM-DP with all its functionalities, the provision of informational material and the provision of a contact person for seeking advice or help. These aspects proved to be important to ensure competent handling of the eHM-DP service. In addition, the latter aspects are suitable for addressing concerns of both study participants (non-usage of the portal, Internet competencies of target group, data privacy). Furthermore, the provision of technical support is essential, in particular for participants with low computer competence. In the future, the introduction and support could be provided by, for example, the professional organization itself or by trained, voluntary caregivers. The use of reminders (eg, messages, phone calls) to use the eHM-DP has proven to be valuable.

Another important success factor of the eHM-DP is the facilitated and enabled computerized interaction between informal caregivers and professionals. Future developments of the eHM-DP should concentrate on linking more than one stakeholder via the eHM-DP (eg, informal caregiver, social worker, physician, professional caregiver) because a

well-functioning, interprofessional, and interorganizational communication in dementia care is important [58]. Overall, further controlled studies on a larger scale, focusing on cost-effectiveness and usability are crucial to embed the eHM-DP into existing health care infrastructures. In addition, the future eHM-DP development should exploit potential synergy effects between existing systems with similar intentions, such as InformCare [59] as well as complementary systems such as Ambient Assisted Living (AAL)-systems (eg, ALLADIN [60]), educational online courses (eg, Mastery over Dementia [61]), or chatrooms (eg, ALZConnected [62], ANKER [63]).

In particular, different priorities and needs of professional organizations (eg, hospitals versus counseling institutions or professional caregivers) have to be considered carefully.

Valuable tips for professional organizations were already provided in the results section. In addition, more research with regard to different informal caregiver types (eg, according to gender, relationship to PwD, employment status, rural areas, and ethnicity) and related needs is necessary. This was also emphasized in the qualitative study results, where informal caregivers expressed the wish for more individualization.

Turning to the primary target of the eHM-DP service, our findings suggest that the eHM-DP service proved to be a valuable post-diagnostic eHealth support service for the home-based care setting. It revealed several benefits for families (informal caregivers), professionals, and health care systems, which are the basis for further studies and future health care policy planning in dementia.

## Acknowledgments

We express our special thanks to all family caregivers who contributed to this study by giving their opinions and ideas to the design and functionalities of the eHM-DP. The staff of the regional offices of the Alzheimer's Society, caregiver counseling services (S Engel, V Stein, C Lottes, A Ober, HD Mückschel, B Kuhn, B Lischka, P Mönius-Gittelbauer, H Volkmann), and the Memory Clinic of the University Hospital Erlangen are also acknowledged for their support.

Furthermore, we express special thanks to V De La Rosa and B Häupler for several revisions to the manuscript. Finally, we would like to express our thanks to all the eHealthMonitor consortium partners.

This study was financed by the European Commission, FP7-project eHealthMonitor (ID 287509) and supported by the Emerging Fields Initiative (EFI), Project Human Rights in Healthcare, of the Friedrich-Alexander-University Erlangen-Nürnberg.

This work was performed in partial fulfillment of the requirements for obtaining the degree "Dr. rer. biol. hum." for author SS.

## Authors' Contributions

SS designed the study; coordinated, prepared (interviewer training), and organized data collection; and was responsible for the statistical design and data analysis (qualitative and quantitative study) as well as for the preparation of the manuscript. SS, VM-S, and MS were responsible for the data collection and interviews and contributed to data preparation and analysis (qualitative and quantitative data). MS and LG were responsible for designing the study from the perspective of a medical technician with a focus on the relationship between technical features and perceived benefits. Both gave important tips for interpretation and discussion of study results. HK was responsible for the development of Sematic Infrastructure of the eHM-DP and the description of the technical infrastructure. EG and JM contributed to the pilot study by providing expert advice from the perspective of a professional in the dementia care setting and gave important hints for interpretation and discussion of study results. The eHM project coordinator SK was responsible for the development and provision of the eHM-DP demonstrator and gave important advice for the realization of the study and discussion of the study results from a technical perspective. PK-R supervised and designed the study. All authors have read the paper and contributed to the discussion of the study results.

## Abstract

**Background:** Parents often turn to the Internet to seek health information about their child's diagnosis and condition. Information, support, and resources regarding pediatric neurosurgery are scarce, hard to find, and difficult to comprehend. To address this gap, a pediatric nurse practitioner designed a website called the Neurosurgery Kids Fund (NKF). Analyzing the legitimacy of the NKF website for parents seeking health information and fulfilling their social and resource needs is critical to the website's future development and success.

**Objective:** To explore parental usage of the NKF website, track visitor behavior, evaluate usability and design, establish ways to improve user experience, and identify ways to redesign the website. The aim of this study was to assess and evaluate whether a custom-designed health website could meet parents' health information, support, and resource needs.

**Methods:** A multimethod approach was used. Google Analytic usage reports were collected and analyzed for the period of April 23, 2013, to November 30, 2013. Fifty-two online questionnaires that targeted the website's usability were collected between June 18, 2014, and July 30, 2014. Finally, a focus group was conducted on August 20, 2014, to explore parents' perceptions and user experiences. Findings were analyzed using an inductive content analysis approach.

**Results:** There were a total of 2998 sessions and 8818 page views, with 2.94 pages viewed per session, a 56.20% bounce rate, an average session duration of 2 minutes 24 seconds, and a 56.24% new sessions rate. Results from 52 eligible surveys included that the majority of NKF users were Caucasian (90%), females (92%), aged 36-45 years (48%), with a university or college degree or diploma (69%). Half plan to use the health information. Over half reported turning to the Internet for health information and spending 2 to 4 hours a day online. The most common reasons for using the NKF website were to (1) gather information about the 2 summer camps, (2) explore the Media Center tab, and (3) stay abreast of news and events supported by NKF. Parents were unanimous in reporting that the NKF website was pleasing in color and design, very easy to use and navigate, useful, and that they would continue to access it regularly.

**Conclusions:** Parents perceive the NKF website to be useful and easy-to-use in meeting their health information needs, finding social support, and learning about resources relevant to their child. A custom-designed website can be used to augment parents' health information needs by reinforcing, supplementing, and improving their understanding of their child's medical needs.

(JMIR Res Protoc 2016;5(2):e55) doi:[10.2196/resprot.5156](https://doi.org/10.2196/resprot.5156)

**KEYWORDS**

Pediatric; neurosurgery; website; evaluation; parents; children; Google analytics; Internet health information needs; knowledge translation.

## Introduction

Children who require neurosurgery are a unique population with highly specialized medical needs. Information, support, and resources regarding pediatric neurosurgery are scarce, hard to find, and difficult to understand. Furthermore, connecting with other parents or caregivers whose children are also affected by neurosurgical conditions or illnesses can be even more difficult given the rarity of these diagnoses. Studying the impact and legitimacy of using a custom-designed website, the Neurosurgery Kids Fund (NKF) [1], to support parents' health information needs—as well as their social and support needs—is imperative in bridging these gaps.

Searching for information on the Internet is a common first step for parents to gain knowledge about a child's diagnosis, prognosis, treatment, and support options [2-4]. Once considered passive receivers of care, patients today are active consumers of health care who want to be involved in decision making, in managing their own health care, and in deciding how to mitigate risk factors and complications [5]. eHealth, the use of the Internet as a source of health information, offers many benefits, including data that complements the physician's information, anonymous health information seeking, information exchange, community support, and empowerment in seeking help for and understanding of medical conditions [6]. People use online health information as a source of knowledge for many reasons. These reasons may include: getting immediate answers; learning about the diagnosis, treatment options, and prognosis; supplementing the physician's information; finding support; and sharing with others who have similar experiences [2,6-11]. Parents of sick children report using the Internet to find health information because they worry about their child's health, feel rushed and received limited guidance or advice from doctors, seek convenience and accessibility, and need to connect with others in similar situations [11].

Up until now, knowledge translation efforts have largely focused on ensuring that health care professionals use the latest research to inform their practice; however, initiatives that target health care consumers (eg, parents) can inform parental decision making, expectations, and shape their treatment outcomes [7,12,13]. Parents now have access to what was once privileged health information, potentially changing their understanding of their child's medical condition, treatment options, medical decision-making, and relationships with health care providers [13]. Knowledge translation in child health is unique given family-centered care and the extent and level of parental involvement [14]. It is important to examine knowledge translation interventions such as websites that are developed specifically for parents to address health information needs and to provide resources and support tools (Appendix 1).

Crutzen, Roosjen, and Poelman argued that in contrast to self-reported exposure measures, tracking user behavior (eg, via dedicated software such as Google Analytics [15]) is independent of visitor's memory, interpretation, or social desirability and when combined with qualitative methods, such as interviews, can yield a fuller and richer picture [16]. In Google Analytics, each visitor to the NKF website brings along

his own set of data that can be collected, measured, analyzed, and reported and is an effective website evaluation tool guided by an analyst [17]. Similarly, Wilfert asserted that Google Analytics yields only statistical data but when paired with qualitative methods, a narrative unfolds with storylines including “how people got to the site, what they searched for when they were there, what they looked at, and what they did not” [18].

## Methods

### Design

This study used a multimethods approach including both quantitative and qualitative designs. Firstly, Google Analytics, a sophisticated Web analytics service, was employed to collect statistical data about NKF usage behavior. Secondly, a 20-question online survey questionnaire directed at parents about the usability of the NKF website was designed and collected using determinants of the technology acceptance model (TAM) [19,20]. Lastly, a focus group interview with parents about their experiences using the NKF website was conducted to augment the Google Analytics and online survey questionnaire data. The Google Analytics reports and online survey questionnaire results were used to inform and direct the focus group interview. Distinctions between usability and user experience are needed because the former is the ability of the user to use the website to carry out a task successfully (eg, used the NKF website to meet the health information needs addressed in the survey) and the latter takes a broader look at the individual's interaction with the website, as well as the thoughts, perceptions, and experiences that results from that interaction (eg, reported during the focus group) [21]. Usage refers to the ways a website is used (eg, number of users, number of page views, time spent on page, etc). However, it is noteworthy that usability influences user experience.

Ethical approval was obtained from the University of Alberta Health Research Ethics Board. Consent was not required for Google Analytics as it is an embedded Web tool that collects anonymous grouped data. Participation in the online survey questionnaire and focus group interview was voluntary and signed consent was obtained for the focus group.

### Sampling

Recruitment was targeted at parents who have children, aged 0 to 16 years, who have undergone neurosurgery at the Stollery Children's Hospital in Edmonton, Canada. Parents also had to be familiar with the NKF website for inclusion in the online survey questionnaire and focus group interview. Purposeful sampling was used in the focus group to ensure a breadth of age (for both the child and parent); parental education level; their usage of mobile devices, tablets, and/or computers; and their child's neurosurgical diagnosis. Parents were excluded from the study if their English fluency prevented them from completing the survey or conversing in the focus group.

### Data Collection

Methodological triangulation was used and 4 sources of data collected: (1) Google Analytics reports, (2) online survey questionnaire results, (3) focus group interview with parents, and (4) field notes. Survey and focus group data were uploaded

and kept secure in the Health Research Data Repository of the Faculty of Nursing at the University of Alberta. First, the Google Analytics data collection and analysis were conducted for the Web analytic and survey phases. With these results, revision of guiding questions for the focus group interview was performed. Google Analytics reports about NKF website usage were obtained from April 23, 2013, to November 30, 2013. This Web analytic tool uses client-sided data collection, called “page-tagging,” to collect raw data from the user’s browser. Google Analytics turns that raw data, or statistical numbers, into meaningful and usable information. Using a Web analytic tool, such as Google Analytics, removes bias and ensures speed, rigorous structure, and that an abundance of data can be collected [9,22].

The survey consisted of 20 multiple-choice and check-box questions with principals of the TAM underpinning the framing of the questions. The survey was developed after a review of the literature and piloted with 12 parents to ensure content validity and reliability. Developed by Davis, the TAM suggested perceived usefulness and perceived ease of use to be fundamental determinants of system use [19]. To summarize, a system, such as using a website, is more likely to be accepted and used if it is perceived to be useful and easy to use. Questions focused on the usability of the NKF website, namely: how parents seek health information; how and why they accessed the NKF website; whether their information, support, and resources needs were met online; if they discussed any health information found online with their health care provider; and the website’s perceived ease of use and usefulness. In addition, demographic data about the parents were collected including age, gender, ethnicity, location of residence, highest level of formal education, and computer usage.

A semistructured interview guide (Appendix 2) was used in the focus group, which lasted approximately 60 to 90 minutes and asked 4 parents about their experiences using the NKF website and its usability. The interview was recorded in real-time by a court reporter [23]. Benefits to using a court reporter to transcribe the focus group interview verbatim include increased data accuracy, timeliness, preserving confidentiality, and affordability [23]. Transcript-based data collection and analysis represents the most rigorous and time-intensive mode of analyzing focus group data [24]. The transcribed interview was cleaned by comparing the audio-recording with the transcript. Any identifiable information in the transcript was removed to preserve anonymity. Field notes were also obtained before, during, and after the interview to capture the context in which the data was collected. The field notes were reflected on during the data analysis to help situate when and how the responses were elicited (eg, nonverbal expressions or linguistic patterns).

## Data Analysis

Usage data for the NKF website was analyzed using the Audience, Acquisition, and Behavior reports from Google Analytics. The Audience report offers an overview of the time period selected, including the number of sessions logged, number of users, percentage of new sessions, number of page views, average session duration, bounce rates, number of pages per session, and location and languages used by the user. Reports

about what type of browser and operating system were used and a mobile device overview and breakdown were analyzed. The Acquisition report examines how a user arrived at the website, which can reveal their purpose for visiting the website. Traffic analysis examines how well a website is supporting users who come to the site with specific information. Subheads of channels and mediums, all traffic sources, all referrals, and keywords were identified as metrics in this study. Lastly, the Behavior report offers information about what the user actually did when they arrived on the site; data about landing page, time spent on each page, the number of page views, and the percentage of exits and what page they exited from were analyzed.

Survey data were collected and entered into SPSS Statistics version 21 (IBM) from a text file and uploaded into a secure data repository. Data were verified for accuracy and cleaned. Seventy-four surveys were completed. Of those, 21 respondents were not parents or primary guardians of children with neurosurgery and 1 respondent indicated English was a second language with poor fluency; therefore, those surveys were excluded from this study. A total of 52 surveys were used in data analysis. Data were coded and descriptive data were computed for all variables.

The focus group interview data were analyzed using an inductive content analysis approach to address the purpose of the study [25]. The transcript was read as a whole several times and concepts, patterns, and themes were identified. With further immersion in the data, a coding system was developed and subsequent grouping and categorizing of the data into the recurring themes was performed. New codes and themes emerged throughout the analysis period and the data were continuously reexamined. The qualitative analysis software program NVivo 10 (QSR International) was used to assist with data management and analysis. In addition, a classic analysis strategy was used to make analysis a visual and concrete process [26].

Credibility was achieved in this study with methodological triangulation between the quantitative and qualitative data [27,28]. Both qualitative and quantitative methods were used together in an iterative process with neither method being weighted superior to another method [27]. Triangulation also allowed for the use of new research methods, Web analytics, to balance with the other methods in this study.

Credibility of the data was further achieved with transparency using an audit trail of all methodological processes. Reliability was achieved with the audit trail such that the results of this study could be replicated. Equivalence and internal consistency criterion were met because there was 1 researcher who was the only moderator and coder of the focus group data. Validity was enhanced with method triangulation because 2 or more methods demonstrated the same results and strict adherence to principles of qualitative research were followed. Field notes were reviewed to ensure that the findings were reflective of the focus group interview and not a reflection of any personal biases [10].

## Results

### Google Analytics Reports

#### Audience Report

For the first 6 months after the NKF website was launched, 2998 sessions and 1686 unique users were logged, with 56.27% (1687/2998) returning visitors. There were 8818 page views with an average of 2.94 pages viewed per session. The site bounce rate was 56.20% and the average session duration was 2 minutes 24 seconds. Using IP addresses to track and measure where a user is located, 90.23% users were from Canada (85.55% were from Alberta with 50.35% of them located in the Edmonton area). The remaining users were from: United States (172/2998, 5.74%), United Kingdom (35/2998, 1.17%), India (15/2998, 0.50%), Australia (8/2998, 0.27%), Ukraine (6/2998, 0.20%), and Philippines, Saudi Arabia, and South Africa (5/2998, 0.17%). The majority of users (2971/2998, 99.11%) viewed the NKF website in English. The remaining users accessed the website in French, German, Mandarin/Cantonese, or Arabic.

Users from the Philippines had the longest average session (4 minutes 5 seconds), followed by Canada (2 minutes 33 seconds) and the United Kingdom (1 minutes 28 seconds). Apple's Safari browser was the most frequently used (1354/2998, 45.16%), followed by Internet Explorer (690/2998, 23.02%), Chrome (360/2998, 12.01%), Safari (app version; 241/2998, 8.04%), Mozilla Firefox (183/2998, 6.10%), and Android (117/2998, 3.90%). The majority of NKF website users (1628/2998, 54.30%) accessed the site using desktop or laptop computers. Mobile users accounted for 31.05% (931/2998) of all sessions and tablet users logged 14.64% (439/2998) of all sessions. Mobile users had the highest bounce rate with 68.74%, whereas computer and tablet users showed bounce rates of 50.06% and 52.39%, respectively.

#### Acquisition Report

Direct traffic accounted for 42.56% (1276/2998) of total visits to the NKF website. Organic search traffic using Google yielded 32.52% (975/2998) of users. Bing generated only 1.37% (41/2998) of users, and Yahoo brought only 1.03% (31/2998) of users to the NKF website.

Referral traffic accounted for 22.41% (672/2998) of the sessions. Average session duration for referral traffic was 2 minutes 5 seconds, with 2.82 pages viewed per session and a bounce rate of 54.76%. Of significance is that 24.67% (416/1686) of new users to the NKF site were acquired via referral sources. When mobile devices and tablets are combined, 70.09% (471/672) of all referrals were generated from Facebook, with a 50.41% bounce rate and an average of 3.25 pages viewed per session.

Since the NKF does not have any paid AdWords with any search engine company, only organic inbound keywords were analyzed. Organic search traffic yielded 1050 sessions, with an average session duration of 2 minutes 28 seconds, 3.03 pages viewed per session, and a 54.10% bounce rate. Variations of search terms "pediatric," "neurosurgery," "kids," and/or "fund" accounted for 12 of the top 20 organic inbound keyword

searches, or 24.86% (261/1050) of sessions. Of note, 48.48% (509/1050) of all sessions did not provide a keyword—this traffic arrived via a referral, used the URL directly, or had bookmarked the NKF website. The highest average session duration, using "www.neurosurgerykids.com" as a keyword, was 9 minutes 12 seconds, a significant outlier. The remaining top 8 keywords were related to specific fundraisers or events that were happening at that time. Only 1 medical term, "arachnoid cyst," was included in the top 20 organic keyword searches. One search included the name of a pediatric neurosurgeon from the Stollery Children's Hospital.

#### Behavior Report

The All Pages report for the NKF site illustrated a fairly typical distribution of the top 10 page views—the Homepage was the most viewed with 21.05%, followed by other pages that can be accessed from the Homepage with one-click buttons: About NKF (9.55%), Media Centre (7.62%), Join the Community (3.62%), Events (3.40%), Just for Kids (2.98%), Donate (2.88%), and Hope Stone (2.82%). The Media Centre's subcategories of photographs and videos of children attending the NKF Camp or other events garnered the lowest bounce rate (23.53%) on the NKF website.

The NKF Homepage was the top-landing page with 52.97% (1588) of all sessions. Noteworthy are 3 landing pages that are buried further into the NKF site, which each garnered a number of sessions—arachnoid cyst (66), Just for Kids (47), and Hope Stone (45). The NKF website did not have any significant outliers in the time spent on pages when combined with page views and unique page views. The range difference between page views and unique page views was 14%-38%. The Donate page attracted 216 page views, with 92 of those being unique, and users spent a lot of time there (2 minutes 37 seconds); however, the bounce rate was 85.87%.

#### Online Survey Questionnaire

Demographic data and computer usage data were collected for 52 parents of children who have undergone neurosurgery. All participants resided in Alberta and a majority were Caucasian (47/52, 90%), female (48/52, 92%), aged 36-45 years (25/52, 48%), and had a university or college degree or diploma (36/52, 69%). Ninety-six percent of parents (50/52) reported accessing the Internet from home and 52% (27/52) spent approximately 2 to 4 hours a day online, with 21% (11/52) going online less than an hour a day and 25% (13/52) surfing the Internet for 5 or more hours a day.

A total of 42% (22/52) of parents reported that accessing health information on a computer as "very easy." This was followed by 25% (13/52) and 21% (11/52) who said it was "somewhat easy" or "neither easy nor difficult," respectively. Only 7.7% (4/52) of parents found accessing health information online to be "somewhat difficult"; however, no parents reported it being "very difficult."

Several health information resources were reportedly used by parents. Ninety-eight percent of parents (51/52) reported relying on health care providers for their health information, followed by 77% (40/52) getting information from family and/or friends and 60% (31/52) going online to health websites. In addition,

one-third (16/52, 31%) of the sample accessed medical journals and another third (18/52, 35%) reported favoring print media to supplement their health information search. One-fifth (19%, 10/52) of parents reported using TV or radio programming. Almost half (24/52, 46%) of the parents found reading health information on a computer compared to a book or pamphlet to be very easy, with 25% (13/52) saying it was somewhat easy, 21% (11/52) reporting it to be neither easy nor difficult, and 8% (4/52) stating it was somewhat difficult.

When parents were asked how they came to learn about the NKF website, 69% (36/52) responded that they learned about the NKF website from medical staff at a clinic or hospital visit, followed by 37% (19/52) hearing about it from family and/or friends, and 14% (7/52) came across it from an Internet search. Two respondents learned about the NKF site via Facebook or a local television or radio program.

Reasons why parents visited the NKF website included: to find more information about Camp Everest and L'il Everest Camp (67%, 35/52), to learn about upcoming media events and news related to the NKF (40%, 21/52), to check out the site in general (33%, 17/52), to find more health information about their child's diagnosis or condition (23%, 12/52), to find social support and resources (21%, 11/52), to get their child a Hope Stone (17%, 9/52), and to make a donation (14%, 7/52).

Parents were also surveyed on how or if they planned to use the health information specifically found on the NKF website. Half of the parents (26/52) have discussed or plan to discuss the health information found on the NKF site with their child's physician, nurse practitioner (NP), or other medical personnel involved in their child's care. Six percent (3/52) of parents reported looking for health information from other sources. One-third (17/52) of the sample will discuss findings with family and friends and have contacted, or plan to contact, a support group. Further, survey results found that approximately 20% (10/52) stated that the health information found on the NKF website may influence future health decisions for their child and has improved their understanding of their child's condition, surgery, or illness. The majority of parents (58%, 30/52) strongly or somewhat agreed that the health information found on the NKF website added to information from their child's physician,

NP, or other medical personnel, with 19 (37%) neither agreeing nor disagreeing and 2 (4%) strongly or somewhat disagreeing.

The survey examined parents' perceptions about the ease of reading and understanding health information on the NKF website. Results found that approximately two-thirds of the parents (65%, 34/52) found the NKF website to be very easy to read and understand. Twenty-one percent (11/52) reported the website as "somewhat easy" followed by only 12% (6/52) who found it "neither easy nor difficult." Only 1 parent (2%, 1/52) found the NKF website to be "somewhat difficult" to read and understand. Parents were also asked about their "favorite" part(s) of the NKF website and were allowed to give multiple responses (Table 1). Overwhelmingly, the NKF website was used to find more information about the 2 summer camps. Health information and Canadian content appealed to a large number of respondents. Supportive resources were reportedly also popular reasons to access the website. Please note percentages do not sum to 100% because of multiple responses.

### Focus Group

Of the 4 parents in the focus group, all were mothers with a child who had undergone neurosurgery a minimum of 2 years ago. The mothers' ages ranged from 35 to 44 years, 2 had university or college degrees, and all had high school diplomas. Three self-reported their computer literacy as proficient and 1 described it as poor. All had familiarity with and used mobile phones and tablets regularly, and all of their children had attended Camp Everest. The focus group took place in a room with audiovisual equipment, and the NKF website was loaded and "surfing" throughout the session.

### User Experience

Parents were asked to describe their experiences about where and how they began searching for information about their child's neurosurgical diagnosis. All 4 of the parents strongly responded that they were reluctant to search online for mainly 2 reasons: (1) the timing of their child's illness was a chaotic time and "when you're in the hospital, it's all very overwhelming" so searching online for information was not a priority. One parent reported not accessing it "until I was ready to go and do that," further illustrating the impact of timing. This sentiment was further supported by the other parents in the focus group (Table 2).

**Table 1.** Parents' favorite part(s) of the Neurosurgery Kids Fund website.

	Frequency n (%) <sup>a</sup>
Camp Everest and L'il Everest Camp information	41 (78.8)
News and events	34 (65.4)
Hope Stones	26 (50.0)
Social support and resources	23 (44.2)
Ease of use	22 (42.3)
Health information	21 (40.4)
Canadian content	19 (36.5)
Attractiveness, design, and layout	17 (32.7)
Donation information	15 (28.8)
Join the Community page	13 (25.0)

<sup>a</sup>Percentages do not sum to 100% because of multiple responses.

**Table 2.** Concepts and examples of parental experience using, or not using, the Internet.

Concept	Parent	Experience
Timing at acute phase of illness	Parent 2	"We were thrown into it ... so you don't have any time to do any research ... so when that's all happening and you're bringing in a priest to give someone last rites, you're not really thinking about a computer, see, and I would never read ... when you had that thing up about trauma and stuff, I've already lived that nightmare, so I wouldn't want to read that because I've already lived it, so I would never click that right now because I already know what it is (shaking her head, voice low and controlled, and pointing at the NKF screen)."
	Parent 3	"It was boom, boom, boom ... everything happened at a very fast rate.... I remember [a nurse] saying going onto the NKF group, but I didn't go home immediately and do it. I mean it, it sat there for a bit until I was ready to go and do that (arms gesturing dramatically in the air)."
Timing at chronic phase of illness	Parent 1	"Because he was born so early ... we [searched online] later, before you had this [NKF website] set up."
	Parent 2	"Because [our child] is pretty stable right at this moment."
	Parent 3	"[Now] we're okay; we're in that stage of our lives where, you know, there's nothing for us to do [like search online]. We have the support that we need."
	Parent 4	"I think for us, just because [our child] has been stable for so, so long that really I go on here mostly about camp.... I know we've been blessed so far that—touch wood—you know, we're not really going in for a lot of medical stuff."
Influence of medical staff	Parent 2	"[Physician B] was very adamant. Don't you dare touch that Internet, do not look at that—you listen to what I say, I'm the boss, and this is the way it's going to run (other parents nodding)."
	Parent 3	"Well, I remember both [Physician A and Physician B] saying don't Google it ... we were directed by [a nurse]. And the doctors saying don't go really anywhere (all other parents nodding)."
	Parent 4	"When we did research, it was basically only [Physician C]."

The second reason reported in the focus group for how or when these parents searched online for health information was that 3 of the 4 parents were advised by a physician or nurse to avoid using the Internet. Two mothers explain:

*So when that's all happening and you're bringing in a priest to give someone last rites, you're really not thinking about a computer. [Physician B] was very adamant, "Don't you dare touch that Internet, do not look at it, do not—you listen to what I say, I'm the boss, and this is the way it's going to run." [Parent 2]*

*I remember both [Physician A and Physician B] saying don't Google it. [So later when searching online], I remember typing it in and feeling guilty about it. I just wanted the definition ... I just wanted to know what the words meant.... [Parent 3]*

Despite receiving cautionary warnings from their health care professionals, most of the parents reported going online eventually when their child was in stable health. Parents reported that they typed in a keyword, such as "VP shunt," "cerebral palsy," or "third ventriculostomy" into a browser. One parent described also using a "big encyclopedia book of brain and thinking, well, it doesn't really have what I'm looking for." One

participant (with poor self-reported computer literacy skills) did not seek information on the Internet about her son's diagnosis because "I've already lived that nightmare."

All parents reported hearing about the NKF website by "word of mouth" from staff. All parents reported that the webpages were easy to navigate, "colorful, inviting, and joyful," and even the non-tech parent said, "I'm not a computer person ... I can just click that right there on the front, and that's what I like." All reported accessing the NKF website on their mobile phones without any difficulties, but when they wanted to read or explore the website at length, they used their home computers. One parent made many positive references to using her mobile phone to follow the NKF's news and events via social media (eg, Twitter, Facebook). Difficulties on the website included the some technical errors (eg, not receiving a confirmation for registration into Camp Everest) and broken links (eg, brain tumor information page reported only an error message). Another parent agreed with the problem of broken links and also mentioned that some pages are not updated regularly. Parents described these 2 reasons for why the "medical conditions" pages were among the pages with the fewest page views. Findings from the Google Analytics data identified that the Community Resources page was infrequently viewed and used. Following up with parents on this identified some potential reasons for low page views and infrequent usage. Parents reported they did not know it existed, did not see the link, or had never visited the webpage. One parent questioned, "Is that the best name for it?" This led into discussion among the parents with a resolution that "Community Funding Support Resources" would more accurately describe the content.

Participants consistently used language of "safe" and "credible" when discussing the NKF website. The parents expressed feelings of "fear" and "mistrust" surrounding what they may find on the Internet and thus preferred to place their trust in their primary care providers (and the NKF website) to mediate the health information they received. This sense of legitimacy of the information on the NKF website is described by 2 parents:

*This [NKF website] is a verifiable source ... [said to be safe by other parents] ... definitely ... so they've kind of [sifted] out some of it so it isn't this flukey, you know, therapy or surgery or doctor. Yeah, I felt safer ... and if the doctors are telling parents not to Google it, if they are able to say, "Yeah, this is a*

*verifiable source," you know (other parents nodding in agreement). [Parent 1]*

*[T]his is a safer place ... definitely more ... yeah, it's credible ... I had just the right information.... Here, I felt like, again, it's been—someone's already, you know, looked at it and thought, "This is right, this is perfect for what our parents are going to hear or read or see," and I'd feel safer if it was through [the NKF website]. [Parent 3]*

Parents also expressed fear surrounding accessing the Internet in search of health information and finding upsetting stories or poor outcomes:

*I would never read ... about trauma and stuff, I've already lived that nightmare, so I wouldn't want to read that because I've already lived it, so I would never click that right now because I already know what it is. [Parent 2]*

*I try and stay clear of reading other people's stories or surgeries or mishaps or things like that or what went wrong, all that kind of things that you're going to find. [Parent 3]*

### **Join the Community Tab**

The NKF website is enabled with its own password-protected social network webpage called "Join the Community," which is designed to function and serve as a forum or blog for parents, caregivers, and their children. By requiring them to register their minor children, parents give consent for their children to use it. Despite the Join the Community tab being on the home page, with one-click access, it was a seldom viewed and utilized feature of the NKF website. Parents were directed to the Join the Community tab for discussion and only 1 parent reported previously using it. The parent placed a message on the dashboard, never received a response, and thus abandoned it altogether. The parents cited reasons such as technical difficulties or unawareness as reasons for not using the Join the Community webpage.

Parents also described preferring to have an additional tab on the NKF homepage that is just for their children, "because I'd love for her to connect outside of camp with some of these kids." When informed that this was the intended purpose of the Join the Community page, parents collectively identified hesitance in using it (Table 3).

**Table 3.** Parental opinion about having a blog or forum as a source of support parent-to-parent or just for the children.

Source of Support	Parent	Opinion
Blog or forum as a source of support for parent-to-parent	Parent 3	“If somebody was going through a similar situation, you could offer that I’ve been there, and you give ... so even though it may not pertain to you, because right now [your daughter] is doing well and you already lived with it, as somebody else new comes, too, you could pop in and say ... where you need to connect with others and chat.... (looking at parent 4)”
	Parent 4	“Yeah. I’d be very happy to be able to say to somebody, ‘Hey you can get through this.’ In fact, I went and did a talk at the [hospital] and it felt good to do it, sort of give some hope back, I guess ... I know when I was going through it, I was pretty much a wreck....”
Blog or forum as a source of support just for the children	Parent 1	“If you had a tab for adults and a tab for kids, I think would be better you know ... just letting them go into their own site. I just think ... if a parent is asking a question about something that maybe a parent doesn’t want their child to see, you know, like something went wrong ... if the kids amongst themselves want to talk about, ‘hey, this is what I did,’ you know, that’s different than coming out of our fear as parents.... [If the kids have their own site] ... so they’re not seeing the kind of ... I think it would be better, you know?”
	Parent 3	“I think you have to get the kids involved with it, too. I showed him all of the pictures. I think the pictures really helped ... but I was hoping that there could be a little bit more of that ... because this is a safer place.”
	Parent 4	“I think I wonder about whether you want the kids—like, I kind of think sometimes the kids should almost have a different area than the adults for some of that stuff.”

The parents wanted a “safe” place to connect with other parents, or to ask a question, and they wanted their children, who are often too young or vulnerable to go online seeking peer support (eg, Facebook) to have a different tab to ensure a completely distinct and separate forum. One parent explains:

*[My son] is absolutely terrified of needles, so if a parent is talking about “In this procedure you have to get this many needles” kind of thing ... [my son is] not having to read that.... If the kids, amongst themselves, want to talk about, “hey, this is what I did,” that’s different than coming out of our fear as parents. [Parent 1]*

When prompted, the parents elaborated further:

*If you had a tab for adults and a tab for kids ... I think it would be better you know ... just letting them go into their own site.... I just think—so the kids—if a parent is asking a question about something that maybe [another] parent doesn’t want their child to see, you know, like something went wrong ... so they’re not seeing that kind of stuff.... I think would be better, you know? [Parent 1]*

*I think you have to get the kids involved with it, too. I showed [my son] all of the pictures. I think the pictures really helped ... but I was hoping that there could be a little bit more of that, because this is a safer place. [Parent 3]*

*I think I wonder about whether you want the kids—like, I kind of think sometimes the kids should almost have a different area than the adults for some of that stuff. [Parent 4]*

## Discussion

This study contributes to the literature demonstrating the legitimacy of using an online health website, Neurosurgery Kids Fund, for supporting parents seeking health information and fulfilling their social and resource needs. This study found that the health information found on the NKF website contributed

and improved parents’ understanding of their child’s neurosurgical illness or condition. Themes not formally considered, such as how the timing during their child’s illness trajectory, parents’ fear of searching online, the context of what was being searched, and the influence of health care provider’s advice against online surfing were illuminated. The NKF website also serves as a single portal for meeting children’s and their parents’ support and resource needs in an accessible, attractive, and user friendly method that is easy to read and comprehend. Several studies have found that the Internet is a popular and efficient mode for distributing health information and offering social support because it is interactive, user controlled, offers anonymity, and is available around the clock [2,4-6,8,25]. In 2010, 8 out of 10 Canadian households (79%) had access to the Internet, with the second highest rate being in Alberta at 83% [29]. Among those, 70% of Canadians reported searching for medical or health-related information online [29].

### Parents’ Approaches to Searching the Internet

In this study we found that parents are increasingly accessing the Internet, particularly health websites, in search of health information, support, and resources. Hand et al [30] found that 83.4% of parents reported going online in search of information regarding their child’s health. DeLuca et al [2] and Kurup et al [31] found that parents are increasingly consulting other sources, mainly the Internet, even before visiting a health care professional. Parental usage of health websites for getting immediate answers; learning about the diagnosis, treatment options, and prognosis; adding to what the physician has explained; finding support groups; and sharing with others having similar experiences is well documented in the literature [2,5,11,13,25,30,32].

While the marrying of Web analytic, survey, and interview data created a picture of NKF website use, it can potentially lead to more confusion and questions. For example, both the Google Analytics and focus group data revealed that the Medical Conditions information pages (eg, hydrocephalus, achondroplasia) on the NKF website were less frequently visited compared to other pages (eg, Hope Stone, NKF News and Event

, Media Centre). In contrast, the survey results reported that almost 25% of the parents visited the NKF website in search of health information and 40% of the surveyed parents rated it as one of their favorite parts. Inconsistencies in the findings can be perceived as a strength using methodological triangulation because it provides an opportunity to capture an unexpected new concept or theme [27]. Careful collection and insightful interpretation guided the concepts of timing and sample as potential reasons for the inconsistency in this study's findings. The Google Analytics data was collected during the first 6 months after the website was launched and included data about anyone in the public accessing the site (eg, not parents with a sick child). For these visitors, digging deeper into the health information pages may not have held any relevance, and thus they avoided those pages. All the parents in the interview had children who had been diagnosed some time ago, described how they were more in the "chronic" phase in their child's illness trajectory, and thus their health information needs were already met. In addition, the sample size was small and therefore these parents' perspectives may not be representative of all NKF users. This example justifies why it is important to combine Google Analytics reports with other qualitative methods.

During the focus group, the parents explained not using the Internet to search for health information, primarily because their child's neurosurgical diagnosis came during the acute phase of the illness—a time when life-saving decisions are needed in a very stressful situation. The parents in the focus group further described being overwhelmed and fearful, not wanting to relive the "nightmare," and that the fear and uncertainty of their child's health outweighed their desire to go online. Similarly, DeLuca et al found that parents wanted to learn about the medical condition, but were too anxious to directly search the Internet because of fear, further fueling their anxieties, or the potential for obsessing over negative content [2]. In contrast, Tuffrey and Finlay's 2002 research involving parents of pediatric outpatients had a generally positive attitude toward the Internet and 88% felt that doctors should suggest suitable websites to parents [32]. Another study found that most people (72%) believe that all or most of the health information on the Internet is credible [33].

### Is Internet Health Information Seeking Context Dependent?

Gage and Panagakos's 2012 study proposed that the type of health issue (eg, life-threatening condition versus routine health information) being confronted may be a critical dimension in understanding how, when, and why parents use the Internet as a source of health information [12]. A study involving patients before and after cardiac surgery, found that only 21% of the patients had used the Internet for health information [34]. Conversely, Chisolm found that health crises were consistent predictors of increased Internet use by patients for health information [35]. Knapp et al similarly stated that 76% of parents of children with life-threatening illness used the Internet for medical information [36]. Further, DeLuca et al found that nearly every parent acquired online information in the first hours and days after learning of the referral to a genetics specialist [2]. Despite the parents in our focus group describing cautious use of the Internet for neurosurgical information, 60% of the surveyed parents reported using websites for health information,

which is comparable to the Canadian national average of 70% [29].

### Influence of Health Care Providers on Parents' Health Information Seeking

Similar to the DeLuca et al 2012 study, some of the parents in this study were advised against seeking medical information on websites by their child's health care providers [2]. The literature is replete with reasons why health care providers may be cautious about referring their patients to the Internet as a health resource: it may be inaccurate, unreliable, possibly even dangerous, has not been critically appraised (ie, peer reviewed), or may even be threatening to the image of the primary care provider [12,37,38]. However, as Nichols and Oermann stated, caution may well be advised when using the health information received on the Internet because of the unregulated nature of the medium, potentially giving way to obsolete and inaccurate information [39].

This study found that 98% of parents with a sick child prefer to receive specific health information from a trusted health care provider rather than on the Internet, and other studies found similar findings [2,6,7,40]. Similarly, Gage and Panagakos cited that during the highly emotional period following a diagnosis, parents may not want to be empowered through the Internet, but prefer to transfer some of the burden of decision-making to a trusted health care professional [12]. Knapp et al found that parents were more likely to trust information from a health care provider versus the information they located from Internet sources [36]. AlSaadi found that 68% of parents used health care providers as their main source of health information, although 79% of these same parents also reported using the Internet to gain information on their child's health [8]. However, what is unique about the NKF website is that this information is created and provided by health care professionals.

### Parents' Usage and Experiences Using the NKF Website

The results of this study showed that it is more common to seek health information on the NKF website among young to middle-aged Caucasian women who have higher levels of education and direct access to the Internet at home. Similar characteristics have been found in many other studies and have been dubbed the "digital divide" [6,7,31,41,42]. With the increasing ubiquity of mobile devices and tablets, this socioeconomic disparity may be negligible in the near future. Glynn et al dubbed the burgeoning use of mobile wireless communication devices as a subsection of eHealth called mHealth [6]. In this study, parents reported that being able to access the NKF website on their mobile devices or tablets (at their child's bedside) day or night was a vital source of information and support.

In this study, 40% of the parents reported using the NKF website for health information. Despite 60% of the parents in this study reporting that the NKF health information added to their knowledge, only 20% reported that it may influence their medical decision making. Similarly, Glynn et al found that 29.1% of parents felt that the health information found online would influence the treatment decisions for their child [6]. In

contrast, another study found that 68% of patients reported that the health information received online impacted their medical decision making [33]. However, 50% of the parents who received health information on the NKF website had discussed, or planned to discuss, their findings with their health care providers as compared to 34% of parents in another study [32]. Glynn et al similarly found that over half of the parents in their study had discussed, or intended to discuss, health information with their surgeon [6]. Only 6% of the parents in this study reported looking for health information elsewhere other than the NKF website. One of the parents in the focus group stated that the health information on the NKF website has been “verified” and is “just right for what our parents need.” Other studies found that some of the information available on the Internet is too technical in nature and not easily understood by the layman [2,8].

### Evaluating the NKF Website’s Usability

MacCulloch et al stated that website quality and presentation are critical elements in order for a website to be used effectively [43]. The findings demonstrated that the NKF website’s usability was evaluated to be: very easy to use, very easy to read and understand, informative, attractive, colorful and inviting, and easy to navigate. The parents reported the NKF website to have great “responsiveness,” meaning the dimensions were able to “flex” to the device (eg, mobile phone, tablet) being used—despite the Google Analytics reports indicating a high bounce rate for mobile phone users. When examined further, it was found that when parents used their mobile phones, it was mostly for quick fact finding, such as an address or contact information, or they were “on the go” and didn’t have time to graze on the NKF website.

Findings in this study suggest that the NKF website is congruent with the underpinning premise of TAM, which is that a website is more likely to be accepted and used by parents if they perceive it to be useful and easy to use [19,20]. However, some technical errors or broken links were identified by the parents; addressing these points and maintaining current updates can improve NKF usability and usage. Pew Internet and American Life found that 37% of users will leave a website if there are inadequate updates [33]. It is encouraging that 94% of the parents found what they were looking for on the NKF website, thus suggesting good usability. Ninety-two percent of parents plan to use the NKF website in the future, suggesting a good user experience.

### Parents Use of the Internet and NKF Website for Social Support and Resources

One of the most prevalent themes to emerge out of the collected data was the use of the NKF website for social support, connecting with peer parents, and resources. Plantin and Daneback found that using the Internet to establish connections with others in similar situations is of particular importance for parents whose children have serious medical conditions [7]. Google Analytics revealed that 6 of the top 7 landing pages were “social-related” pages. MacCulloch et al found a strong endorsement from the parents in their study for an online peer-based support network [43]. Similarly, Holtslander et al found in their study involving parents with diabetic children, that when parents can share experiences, it may more rapidly

enable parents to achieve “normalization” following a life-altering diagnosis [44]. Results in this study revealed that 67% of parents reported using the NKF website for socially-related information and support—accessing Camp Everest and L’il Everest Camp information and parents “staying on top of things” by tracking the NKF’s News and Events (eg, fundraisers, parties, social gatherings)—and 70% arrived at the site via Facebook (another social gathering webpage).

### Study Limitations

There was only 1 focus group and the sample size was small (eg, 4 participants), however, parents brought a range and depth of experiences about having a child with neurosurgical concerns and their health information, support, and resource needs. The findings from the combined data of the Google Analytics, online survey questionnaire, focus group, and field notes were similar, indicating the main issues were identified (eg, theoretical saturation was met). The sample was predominantly mothers and, therefore, the relevance to fathers may be inappropriate. In future studies, health information should be clearly defined because it may mean different things to different people. Strict adherence to criteria for ensuring qualitative research trustworthiness increased confidence in the findings. There is a small potential for a margin of error in the Google Analytics data because all crawlers were granted access to the NKF website. In the future, to refine exploring only parents’ usage, a robot.txt file should be encrypted in the NKF website. The data were also collected over a relatively short period of time. Findings of website usage and experiences among parents of children undergoing neurosurgery may not be generalizable given the NKF website is targeted to the Edmonton, Alberta, region.

### Conclusions

There is a lack of research about the specific health information, support, and resource needs of parents with children undergoing neurosurgery. There is even less known about when they seek health information online, what health websites they are visiting, how useful the information was or was not, how e-literate they are, and, especially, why they are visiting the health websites that they do [14]. This study aimed to assess and evaluate whether a custom-designed health website could be used to meet parents’ health information, support, and resource needs. From this study, the majority of parents felt that the NKF website is credible, useful, and informative. Key findings that impacted whether parents sought online health information included the timing during the child’s illness, the context of the information being sought, and the impact of cautionary advice from their health care providers. However, after visiting the NKF website, many parents reported that the health information improved their understanding of their child’s condition, surgery, or illness. Other parents found the website to be a portal for joining the “NKF family” and for connecting with other parents for support and shared experiences.

Utilizing data and findings from this study, modifications to the NKF website will include expanding on specific health information and adding pictures related to neurosurgical diagnoses, equipment, treatment options, interventions, and prognoses provided by their own pediatric neurosurgeons,

pediatric nurse practitioners, and allied health care providers involved in the care of this pediatric neurosurgical population. Blogs, video posts, and messaging designed by the health care team at the Stollery Children's Hospital will be encouraged. These blogs, posts, and messages would reflect the 98% of parents who report relying on their direct health care providers for needed health information.

Additional modifications to the NKF website should be targeted at the support services and resources offered by the NKF including both L'il and Camp Everests, Hope Stones, and splitting the Join the Community pages between parents and children. These modifications would include more detailed explanation of the mission and purposes of the camps, eligibility, accommodations to the children's specific health care needs, and qualifications of the camp counselors. More attention to the Just for Kids page will be outlined on the homepage explaining its purpose, target audience, and its safety measures to protect identity and confidentiality to the end users. Over

40% of parents also accessed the NKF website to stay abreast of news and events; therefore, keeping information updated, accurate, and informative will be stressed. From a technical standpoint, the NKF website should be monitored more closely and regularly for correct linkages and active pages.

The method of health care delivery is being transformed by the ubiquity of the Internet and the newly empowered, computer-literate public is making a claim in becoming partners in managing their own health. Such changes have the potential to bring about positive outcomes, such as improved medical decision making, increased efficiency in the clinic or hospital appointment, and strengthening the relationship between primary health care providers and the patient's parents. The time is now for the health care profession to respond to the "Internet-informed" parent by guiding them to reliable health information websites, giving them a "health website prescription," and collaborating with them in obtaining and analyzing the information received.

## Abstract

**Background:** The Internet should be suitable for delivery of interventions targeting young cancer patients. Young people are familiar with the technologies, and this patient group is small and geographically dispersed. Still, only few psycho-educational Web-based interventions are designed for this group. Young cancer patients consider reproductive health, including sexuality, an area of great importance and approximately 50% report sexual problems and fertility-related concerns following cancer treatment. Therefore, we set out to develop a self-help Web-based intervention, Fex-Can, to alleviate such problems. To improve its quality, we decided to involve patients and significant others as research partners. The first 18 months of our collaboration are described in this paper. The intervention will subsequently be tested in a feasibility study followed by a randomized controlled trial.

**Objective:** The study aims to describe the development of a Web-based intervention in long-term collaboration with patient research partners (PRPs).

**Methods:** Ten former cancer patients and two significant others participated in building the Web-based intervention, using a participatory design. The development process is described according to the design step in the holistic framework presented by van Gemert-Pijnen et al and evaluates the PRPs' impact on the content, system, and service quality of the planned intervention.

**Results:** The collaboration between the research group and the PRPs mainly took place in the form of 1-day meetings to develop the key components of the intervention: educational and behavior change content, multimedia (pictures, video vignettes, and audios), interactive online activities (eg, self-monitoring), and partial feedback support (discussion forum, tailored feedback from experts). The PRPs influenced the intervention's content quality in several ways. By repeated feedback on prototypes, the information became more comprehensive, relevant, and understandable. The PRPs gave suggestions concerning the number of exercises and pointed out texts and pictures needing revision (eg, experienced as normative or stereotypical) to increase the

persuasiveness of the program. The system quality was improved by PRPs' feedback on design, technical malfunctions, and navigation on the website. Based on feedback about availability of professional support (technical problems and program content), the organization for support was clarified, which increased service quality. The PRPs also influenced the research project on an overall level by suggesting modifications of inclusion criteria for the RCT and by questioning the implementation plan.

**Conclusions:** With suggestions and continuous feedback from PRPs, it was possible to develop a Web-based intervention with persuasive design, believed to be relevant and attractive for young persons with cancer who have sexual problems or fertility distress. In the next step, the intervention will be tested in a feasibility study, followed by an RCT to test the intervention's effectiveness in reducing sexual problems and fertility distress.

## KEYWORDS

adolescent; clinical trial; Internet; neoplasms; online systems; patient participation; technology; telemedicine; young adult

## Introduction

There is a need for psycho-educational interventions adapted for adolescents and young adults with cancer [1,2]. Web-based interventions are presumed to be a useful mode to deliver such interventions as young people are well accustomed to the technologies [1] and the patient group is relatively small and geographically dispersed. The Internet has proven to be effective for both delivery of information [3,4], support [5,6] and psychological treatment [7] for a wide range of health problems; such delivery is known as eHealth [8]. However, Internet interventions also face problems such as high dropout rates and non-usage during the test phase as well as after implementation [9,10]. Collaboration with patients in the development of Web-based interventions has been suggested to make the technology more attractive and user friendly, thereby improving uptake and impact of the intervention [10].

### Patient and Public Involvement

Patient and public involvement in research [10] is regarded as an integral part of good scientific practice [11] and is increasingly requested from research funders. A recent systematic review showed that patient and public involvement has beneficial effects on all stages of the research process [12]. Different approaches to involvement exist. Consultation is when end users are asked for their views and these views are used to inform decision making. Collaboration involves active, ongoing partnership with end users where both collaborating parties share decisions about the research. In user-controlled research, the end users rather than the professionals have the power and the initiative to carry out the research. Long-term collaboration with end users has been proposed to increase the relevance, quality, and validity of eHealth interventions [13,14]. Still, patient and public involvement has, with few exceptions [9], been limited to the consultation level and involved end users only on single occasions [15-17]. Patient and public involvement has seldom been applied in the development of Internet interventions to be tested in randomized controlled trials (RCTs) [12]. In this study, a collaboration level of patient and public involvement was used, in preparation for a subsequent RCT.

### The Fertility and Sexuality Following Cancer (Fex-Can) Project

Previous studies from our research group [18-20] and others [21] have shown that adolescents and young adults diagnosed with and treated for cancer have concerns about fertility and sexuality. It is also well known that sexual problems and reproductive issues often are neglected in clinical care [22,23] and that care providers lack training for such discussions [22,24]. Meta-analyses have found Web-based interventions to be effective in the areas of sexual [25] and reproductive health [26]. Based on the above findings, we set out to develop a self-help Web-based intervention, Fex-Can, to alleviate sexual problems and fertility-related distress in young people treated for cancer.

The effectiveness of the intervention will be evaluated in an RCT embedded in a nationwide cohort study directed towards individuals aged 16-40 in Sweden with selected cancer types, 1 year post-diagnosis. During 1 year, potential participants will be identified through national cancer registers and invited to participate in the cohort study. After consenting, participants will complete standardized questionnaires measuring sexual function and fertility distress (online or paper version). Those rating high levels of sexual dysfunction and/or fertility distress at baseline will be invited to participate in the RCT (closed user group trial) with two arms, testing the Fex-Can intervention versus control group. The Regional Ethical Review Board in Stockholm has approved the study. In Sweden, health care is mainly tax-funded and all Swedish citizens receive health care at limited costs [27]. The project, including development of the intervention followed by a feasibility study and an RCT, is financed by research grants. If the intervention is shown to be effective, it is planned to be implemented in regular care.

### The Holistic Framework for Development of eHealth Technologies

This study is based on the holistic framework for developing eHealth technologies by van Gemert-Pijnen et al [10] and focuses primarily on the design step of the model, that is, the co-creative participatory process of building the Web-based intervention. An essential principle in this framework is end users' involvement throughout the development process. End users in this study were represented by former cancer patients

and significant others, hereafter referred to as patient research partners (PRPs), who participated in repeated evaluation cycles of the eHealth technology. According to theory, the quality of an eHealth intervention can be evaluated on three different levels: content, system, and service quality [10,28]. Content quality includes creating information that is understandable, meaningful, and persuasive. System quality means that the technology is safe, user-friendly, and easy to manage. Service quality entails providing an e-service that is adequate and reliable, that is, providing prompt and empathetic support to participants regarding technical and general issues.

The study aims to describe the development of a Web-based intervention in long-term collaboration with PRPs.

## Methods

### Recruitment of Patient Research Partners

The PRPs were recruited from a previous study investigating sexuality and fertility among childhood cancer survivors [18], and through cancer nurse navigators at a university hospital. The research group set out to recruit women and men, aged 16-40, who had undergone cancer treatment for any of the cancer types selected for the planned RCT. In addition, we wanted to recruit a few significant others (partners or parents of young patients). In total, 13 PRPs were recruited—11 individuals previously diagnosed with cancer (2-9 years earlier) and 2 mothers of teenagers who had undergone cancer treatment agreed to participate in a 5-year long collaboration. The PRPs were all born in Sweden but lived in different parts of the country. All were fulltime working or studying with a majority having a university degree. The former patients were 7 women and 4 men, aged 20-41, and included singles as well as partnered individuals of whom 2 had children and 1 became a parent during our collaboration. The following cancer diagnoses were represented: Hodgkin lymphoma (n=5), tumors of the central nervous system (n=2), breast cancer (n=2), testicular cancer (n=2), cervical cancer (n=1), and Ewing sarcoma (n=1). One PRP (former patient) decided to leave the collaboration after attending one meeting, while the other 12 PRPs remained in the group.

The PRPs had a status of research partners rather than research participants and were paid for their participation in project meetings and time working with assignments. Additionally, PRPs were reimbursed for travel expenses and if needed, accommodation, as some traveled to meetings from distant places in Sweden.

### Project Management

The research group included researchers, health care providers, and a project coordinator with academic backgrounds in medicine, psychology, psychiatry, sociology, nursing, and arts. Their clinical backgrounds included primary care, psychotherapy, and counseling in cancer care and sexually transmissible infections, respectively. The composition of the research group altered during the 18-month period described, with an average of 6-7 researchers present at each meeting with the PRPs. The researchers had weekly project management meetings and regular contact with a network of professional collaborators including physicians and nurse practitioners in cancer and reproductive care, and sexual therapists. The research group was responsible for managing the collaboration with the PRPs, including strategic and logistic planning of meetings with PRPs. The researchers were also responsible for documenting and implementing PRPs' ideas and for decisions regarding the scientific process.

A software company was contracted to build the Fex-Can Internet portal. Additionally, we collaborated with a Web designer, an illustrator, and a photographer. One of the research group members was responsible for contacts with the software company, and another team member acted as main contact person for the PRPs throughout the process.

### Forms for Collaboration

The collaboration mainly took place in the form of 1-day meetings. Efforts were made to establish a trustful collaboration between the researchers and the PRPs. All meetings included a joint lunch for all involved PRPs and researchers at the expense of the project.

During the first meeting, the forms for collaboration between researchers and PRPs were agreed upon. Different forms of collaboration were discussed, for example, Web-based discussion forums for different age groups, video conferences, or physical meetings. The PRPs preferred to have meetings in person on a regular basis as 1-day get-togethers during weekends (PRP meetings), while communication between these meetings was to be carried out by email. The 1-day meetings included plenary (see Figure 1) and small group discussions as well as individual assignments. At subsequent meetings, the forms for collaboration were revisited and PRPs were asked if they wanted to continue to work in the same way. This procedure generated four additional PRP meetings within the design step; PRPs attended a median of four of the total five PRP meetings.

**Figure 1.** Plenary discussion at PRP meeting.

## Documentation

The results in this article are based on several sources of data. First, notes were taken by 2 members of the research team during each 1-day meeting with the PRPs. These notes covered all topics discussed and all opinions raised by the PRPs. The notes were compiled and presented at research group meetings when the notes were adjusted according to the impressions of all research group members. Minutes from all meetings, together with notes from contacts with PRPs between meetings were continuously compiled into a log book. Second, all researchers met directly after each 1-day meeting with the PRPs and reflected upon their impressions throughout the day. These reflections were added to the log of the collaboration with the PRPs. Third, the notes from previous meetings were also discussed with the PRPs to check that their opinions had been correctly understood. Fourth, the PRPs gave confidential feedback on content, layout, and functionality on some of the modules of the intervention directly into the Fex-Can portal.

The results in this article are based on this documentation and will be presented according to the quality criteria suggested by the holistic framework by Gemert-Pijnen et al [10]: content, system, and service quality. Furthermore, the process of building the intervention will be described, as well as the PRPs' impact on the overall research project.

## Predefined Components of the Web-Based Intervention

Some features were planned to be included in the intervention, prior to the recruitment of patient research partners. According to key components for Internet interventions defined by Barak

[29], these features were educational and behavior change content, multimedia (eg, pictures, video vignettes, and audios), interactive online activities (eg, self-monitoring), and partial feedback support (eg, discussion forum, tailored feedback from experts). The behavior change content was intended to convey a balance between problem solving (change) and acceptance strategies, including mindfulness. An aim was to affect participants' autonomy (sense of control over one's life), competence (perceived efficacy), and relatedness ("I am not alone with these problems") [30]. However, details of the intervention were not planned and an objective for the collaboration was to let the PRPs have an impact on the composition of the content and structure of the intervention, to make it more relevant and attractive for users.

## Results

### Building the Intervention

In the first meeting, PRPs received information about the aims and framework of the planned study, and basic ethical principles in research. We also spent time on getting to know each other; the PRPs and the researchers introduced themselves and the PRPs shared their "cancer story." For the second meeting, a mock-up of the Fex-Can Internet portal was created, based on existing knowledge regarding Web-based interventions, and presented to the PRPs. The mock-up suggested content divided into different modules and other functions such as expert and discussion forums. After discussing the planned set-up of the intervention, a prototype was produced for the following meeting. The researchers refined the Fex-Can intervention

several times and the revised versions were discussed at meetings so that the PRPs were able to contribute to the process. Working materials, such as topic-relevant websites, suggested contents of specific modules, and access to different preliminary versions of a module, were mailed to the PRPs to be read before scheduled meetings. The Fex-Can intervention came to include

several features organized in subsequent modules and divided in two streams: fertility and sexuality. Examples of two module overview webpages are presented in Figures 2 and 3. The following paragraphs describe how the PRPs had an impact on the intervention's content quality, system quality, service quality, and overall project.

**Figure 2.** Example of module in the fertility stream of the intervention.

KAPITEL > ATT HANTERA ORO

## Att hantera oro

Att känna oro är normalt, det är kroppens sätt att signalera till dig att något behöver uppmärksammas. Ibland kan man dock känna så mycket oro att den blir ett hinder i livet. På kommande sidor kommer du att kunna läsa om vad som händer när man blir orolig och vad man kan göra för att kunna hantera sin oro.

Olika sorters funderingar och oro efter en cancersjukdom är helt begripliga eftersom man fått erfara att inget kan tas för givet och att man bör hålla sig uppmärksam. Funderingar och oro om det som är viktigt för en är helt naturligt för oss människor. I det här programmet handlar det om oro som gäller möjligheten att kunna få barn i framtiden. Vi vill förmedla att det både är helt naturligt att känna oro och att du kan göra något åt det.

VAD HÄNDER I KROPPEN VID ORO?

ÄR DET ORO JAG KÄNNER?

SITUATION, TANKE, KÄNSLA, KROPP, HANDLING

OLIKA SÄTT ATT HANTERA SIN ORO

MINSKA SÄRBARHET FÖR ORO GENOM ATT TA HAND OM DIG

MEDVETEN NÄRVARO

OROSTID OCH OROSFRIA ZONER - TVÅ BRA TEKNIKER FÖR ATT HANTERA ORO

Fex-Can är ett forskningsprojekt som genomförs av Karolinska Institutet © 2015

KAPITEL FÖR LITE LUST TILL SEX

## För lite lust till sex

**VÄLKOMMEN TILL LUSTMODULEN**

Här beskrivs modulens innehåll

**HUR KAN EN CANCERBEHANDLING PÅVERKA SEXLUSTEN?**

På den här sidan beskrivs på vilket sätt cancer och dess behandling kan påverka sexlusten.

**ÖKA FÖRUTSÄTTNINGARNA FÖR ATT KÄNNA LUST**

Den här sidan handlar om hur man kan förbättra förutsättningarna för att uppleva sexlust.

**ÖVNING 1. RUSSIN - EN PROVA-PÅ ÖVNING I MEDVETEN NÄRVARO**

Den här övningen ger en introduktion till medveten närvaro. Genom att öva upp din förmåga till medveten närvaro kan du lättare komma i kontakt med dina lustkänslor.

**ÖVNING 2. TRÄNA DIN BÄCKENBOTTEN**

Med bäckenbottenträning kan du öka känsligheten i din bäckenbotten och motverka inkontinens.

**ÖVNING 3. UTFORSKA DINA FANTASIER**

I den här övningen ska du gå på en resa tillbaka i tiden till dina tidigare sexuella fantasier som kan vara en inspirationskälla till hur du kan hitta och locka fram din sexlust även i framtiden.

**ÖVNING 4. UTFORSKA BERÖRING PÅ EGEN HAND**

Den här övningen ska hjälpa dig att våga röra vid dig själv och känna efter hur det är att pyssla om din kropp på ett kärleksfullt sätt.

**ÖVNING 5. UTFORSKA BERÖRING TILLSAMMANS MED EN PARTNER**

Den här övningen går ut på att göra en upptäcktsfärd på den andras kropp och låta din partner göra en upptäcktsfärd på din kropp.

### Patient Research Partners' Impact on Content Quality

During the first meetings, the PRPs expressed an overall concern that information on the website could cause emotional distress, especially in relation to information on risks of infertility and relapse of disease. At the same time, the importance of offering accurate and evidence-based detailed information was underscored. The views of what kind of information might be perceived as distressing differed within the group of PRPs. Following further discussion, we agreed that the Fex-Can intervention would convey a hopeful and encouraging attitude

and present examples and strategies for dealing with problems, that is, it would be empowering. The PRPs wanted information on the website to be tailored to meet participants' diverse needs regarding the amount of information, which made us organize the information on several levels, where participants have the option to read extended text.

The PRPs wished for the intervention to include more facts on sexuality and fertility related to side effects of specific cancer treatments as well as information about what side effects or symptoms were to be expected. All of this was added.

Furthermore, the PRPs stressed the importance of including content related to bodily changes or body image in the sexual stream of the Fex-Can, which resulted in the addition of a separate module focusing on this aspect.

The PRPs shared their opinions about what types of exercises they thought should be included and how much time participants would be willing to spend on an exercise. They thought there were too many exercises and recommended us to carefully select a reduced number to be included and present all of them as optional. In particular, the included mindfulness exercises were debated since some PRPs were skeptical and questioned if the technique was evidence-based. After being presented with facts about the effects of such exercises followed by thorough discussions, the PRPs were supportive of including mindfulness in the Fex-Can intervention. Furthermore, PRPs appreciated that some misconceptions about mindfulness were disentangled on the website. In later versions of the intervention, the PRPs expressed that the included exercises appeared useful and reliable.

Another issue stressed by the PRPs was the importance of using an inclusive, easily comprehensible language matching a broad group of end users, including individuals with cognitive difficulties (common when diagnosed with brain tumors). A challenge was to use language without jargon, neither too colloquial, nor too formal. The PRPs stressed this necessity during earlier stages of working with the texts and expressed their satisfaction with the comprehensibility of the texts in the later versions of the website, indicating that a well-balanced language level had been established.

The PRPs emphasized that the content of the program should communicate an awareness of participants' cancer experience. One part of this was the PRPs' wish that the program should include other cancer patients' stories to increase relatedness to others, for example, "I'm not the only one having these problems." The researchers asked if the PRPs were willing to share their own stories (in text or as videos), which 5 agreed to do. The importance of choosing appropriate photos for the website was also emphasized by the PRPs. The photos should be representative also for participants who were still under treatment and troubled by side effects, for example, include persons with visible signs of cancer treatment such as hair loss, overweight/underweight, and scars.

In order to persuade participants in the intervention to stay in the program, the researchers suggested that a new module would be introduced every 2 weeks for participants in the intervention. This was supported by the PRPs who thought participants would be curious to see the next module. The PRPs also supported the idea that participants would receive feedback on what they had done so far in the program. Based on this, a timeline was included on the opening page of the intervention to visualize the progression of time during the 12-week program. Following suggestions made by PRPs to increase active participation in the intervention, weekly email reminders were also added as a feature in the program. Another topic discussed was the possibility of including quizzes in the program since they are interactive and have the potential to increase a sense of progressing. However, since some of the PRPs perceived such

quizzes as stressfully competitive, quizzes were not included in the program.

A way to increase social dynamics in the program was to incorporate a discussion forum in the intervention as well as a counseling feature in the sexuality stream of the intervention, which also was supported by the PRPs. The feasibility of having a discussion forum with participants in such a wide age span as 16-40 years was thoroughly discussed, since persons of different ages might think differently about fertility and sexuality. After reflecting on advantages and disadvantages of dividing the forum into age groups, it was decided to keep one discussion forum but to create discussion threads for different age groups.

The PRPs emphasized that text and pictures included in Fex-Can should not be overly normative when relating to sexual problems and fertility distress. This includes addressing a diversity of sexualities, ethnicities, relationships, and ways of building a family instead of exclusively presenting white heterosexuals in monogamous relationships having biological children of their own. Initially, PRPs expressed that the intervention focused too much on couples and did not give enough attention to the potential problem of finding a partner. Therefore, the intervention was developed to better reflect the situation of singles, and a module on "How to meet a partner" was included in the sexual stream of the intervention.

### **Patient Research Partners' Impact on System Quality**

The layout of the website was frequently discussed with the PRPs. They stressed that young people have high expectations on a website and that a design that is perceived as unprofessional would risk increasing participant dropout of the RCT. Researchers and PRPs agreed on the idea that the website should have a responsive design, that is, it should adapt its layout to various devices such as computers, smartphones, or tablets. PRPs also considered the Web address/domain to be an important factor that should communicate a rigorous and valid source, preferably university-based. The PRPs recommended using a more professional design than the first mock-up and suggested using a light background color, black text with classic font, and header in Karolinska Institutet's promotional color. Furthermore, they wanted pictures to be included only if they had a function related to the text and not merely for esthetic purposes. A Web designer was consulted to make a neater layout with a uniform style and a better structure throughout the intervention, since the PRPs repeatedly stressed that the website was difficult to navigate. During the entire development process, the website had several technical malfunctions, which were pointed out by the PRPs. These problems were continuously adjusted in collaboration between the project coordinator and the software developer.

### **Patient Research Partners' Impact on Service Quality**

The PRPs repeatedly stressed that technical malfunctions on the website were very frustrating. This increased the researchers' awareness of the importance of almost instant support when intervention participants experienced technical problems. A plan for implementation of technical support within the intervention was added.

PRPs had objections to the suggested rules for the planned discussion forum. The PRPs expressed concerns regarding our plan to check all postings before they were published to prevent inappropriate texts and topics. This was believed to negatively affect the communication in the discussion forum because participants would lose interest if postings were delayed. Therefore, we decided that postings would be instantly visible in the forum but the researchers would be responsible for continuously checking for (and deleting) potentially inappropriate postings (or comments) within every 24 hours. Further, the PRPs stressed that replies to postings in the feature “ask an expert” should not take too long. Therefore, it was decided that the researchers would be responsible for the contact with external experts to make sure postings were replied to within 3 workdays. Likewise, it would be problematic if other website functions would not work properly. A Web-based support (e-service) was added within the program, where participants could ask researchers any type of questions (technical, content, and/or how to use the partial feedback support) via mail and get a fast reply. This e-service was planned to be given by someone from the research group who would understand and know all parts of the intervention and would be able to give this e-service in an emphatic way. Furthermore, a telephone support run by research group members was planned to be available for the website.

## **Patient Research Partners’ Overall Impact on the Research Project**

### ***Naming the Project***

After thoroughly discussing the purpose of the intervention, most of the PRPs did not appreciate the initial name of the project (“Life Interrupted”). They thought that the program should focus on moving forward in life rather than on the interruption in life that a cancer diagnosis might constitute. Several suggestions were discussed between the researchers and the PRPs, resulting in the more neutral name “Fex-Can, Fertility and sexuality following cancer”.

### ***Plan for Evaluation and Implementation***

In the beginning of the collaboration, the PRPs emphasized the need for the program to improve the care of cancer patients. They expressed that they would have appreciated access to such a program during and after their own cancer treatment, whether they had problems or not. Therefore, they thought the program should be available for anyone with a cancer experience, and not offered only to those with sexual problems and fertility distress. The reasons for conducting an RCT before making the intervention available to unselected patient groups were explained (by the researchers) and accepted. Furthermore, we explained that if the intervention showed to be effective in reducing sexual problems and fertility-related distress, the goal was to collaborate with health care services to implement the program into regular care. Regarding the RCT testing, PRPs questioned why the Fex-Can intervention would be available only for study participants at baseline (1 year after diagnosis). They argued that problems could occur later during the planned follow-up period and suggested that the intervention should be made available to those with sexual problems or fertility distress in connection to late follow-ups (3 and 5 years after diagnosis).

This promising suggestion will be taken into consideration in the RCT phase of the project. Other issues of value for implementation were identified, and it may be possible to address them throughout the development process (eg, ways to avoid dropout).

### ***Input on Outcome Measures***

The questionnaire measuring fertility distress, Reproductive Concerns After Cancer [31], which was one of the primary outcomes of the Fex-Can program, was discussed with the PRPs. Several items raised concern among the significant others about the risk of evoking worries, especially among participants in young ages (16-17 years). Based on this, we conducted additional cognitive interviews with 4 adolescents who had been treated for cancer to verify the acceptability of the measure among the youngest respondents.

## ***Discussion***

### **Principal Results**

This study aimed to describe a co-creative process in the development of a self-help Web-based intervention to alleviate sexual problems and fertility-related distress in young cancer patients. The ultimate goal for patient and public involvement in research is to get another perspective on research projects by taking the PRPs’ lived experience into account [11] and getting new insights [32], which will result in more relevant interventions. We believe that our collaboration with 12 PRPs accomplished this goal and that both the demands of the PRPs and the needs of the study have been met in the development of the intervention, as stressed by van Gemert-Pijnen et al [10]. The input from the PRPs contributed to making the content of the Fex-Can intervention meaningful, relevant, and understandable. Furthermore, PRPs addressed the importance of an inclusive, diverse imagery and of creating a professional layout and persuasive design, and to improve support systems included in the intervention. The PRPs also affected the research project on an overall level by participating in naming the project, suggesting changes in the follow-up, and by questioning the implementation plan.

The co-creative process comprises bringing together researchers and stakeholders, exchanging ideas, and interacting to improve research [11]. This project is unusual as it from the start aimed to establish a long-term collaboration over 5 years, with a PRP group of considerable size in contrast to the more common set-up with multiple participants at a single event [15,16] or one or two participants on multiple occasions [9]. The recruitment procedure [13,33] proved to be successful, with high attendance at meetings and only one person dropping out from the collaboration. The PRPs themselves described that their main motive for commitment in the project was a wish to help others in a situation similar to the ones they had experienced themselves when diagnosed with cancer. They also expressed that they appreciated sharing their experiences with people in the same age group, as described in other studies of young cancer patients [34].

We believe that our careful preparation and set-up of the collaboration created beneficial circumstances for PRPs to have

a real impact on the project [12,32] for four main reasons. First, we allocated one person in the research group for all contacts with the PRPs and invested time getting to know each other. This procedure contributed to an environment that facilitated a positive and committed collaboration that may be especially important for younger PRPs, who otherwise might be too shy to express their opinion in a group [13]. Second, the involved researchers early on reflected on and discussed their expectations and perceptions regarding the roles of the PRPs in the project. We expected that a successful collaboration would require commitment, openness, and flexibility in the research group, where the PRPs were seen as experts on the patient perspective. However, this did not imply the incorporation of all PRP ideas. In cases when there was disagreement between researchers and PRPs, the researchers argued their points and clarified their view in order to achieve a common standpoint. Third, we compensated the PRPs for their time and expenses and also served food and drinks, which has been reported to increase PRPs' feelings of being important for the project [33]. Fourth, in contrast to the common procedure when researchers are solely responsible for decisions on forms of collaboration [10], researchers and PRPs reached a common agreement on how meetings were to be organized in the Fex-Can study, even though the researchers decided on the agendas.

One of the main advantages of the long-term co-creative process was the possibility to, in an iterative way, fine-tune the Internet intervention through the PRPs' repeated feedback on aspects that had been adapted following their earlier suggestions. The collaboration with PRPs was also timesaving for the researchers. Prompt confirmation of ideas and solutions that were well functioning enabled further development of these without delay, and weaker solutions could likewise be adjusted or discarded promptly. This made the researchers more confident in their work, and fewer parallel versions of layouts and contents had to be produced when existing versions were approved by the PRPs. Furthermore, when the PRPs saw that their feedback was incorporated in the program, they expressed satisfaction that their impact was valued, which further increased their motivation to participate. Another advantage of such a long-term collaboration was that the PRPs were able to contribute more as their understanding of the intervention's intention grew. In addition, the researchers and the PRPs became more equal partners over time, and the researchers relied more on the PRPs who became indispensable in the project.

## Limitations

This study is novel in many ways and some methodological limitations should be mentioned. A problem with a long-term collaboration might be, as has been discussed elsewhere [35,36], that the PRPs become "professional" patients, who incorporate the researchers' views and alienate themselves from the target group. As the relationship between researchers and patients is asymmetrical [35], patients' experiential knowledge and input might also be unintentionally overruled [37]. However, the PRPs were encouraged to express their opinions during the meetings and all PRPs did so, including expressing divergent opinions and questioning ideas from the researchers. The PRPs often referred to how they would have reacted 1 year after their cancer, clearly identifying themselves with future users of the

intervention. The meetings were held 2-3 times per year and the PRPs outnumbered the researchers in all discussions, limiting the risk that PRPs became "professional" patients. An opposite problem might be that researchers let the PRPs' ideas and suggestions run the project without being critical. However, we strived to create a balance between new ideas and methods known to be effective.

Further, the PRPs were not recruited based on their level of problems in the areas targeted in the intervention (ie, sexual problems and fertility distress). Therefore, it was not known if individuals with high levels of problems/distress were adequately represented, thus possibly limiting representativeness. We are also aware of the lack of heterogeneity in the PRP group, as most of them were well educated and there seemingly was a lack of diversity in ethnicity and sexual orientation. The characteristics of the PRPs may therefore have contributed to less variety in expressed opinions. However, the perspectives of different groups of future users were often brought up by the PRPs, who argued that the intervention must suit users with, for example, different sexual orientations. Furthermore, the research team's composition was mixed regarding country of birth and sexual orientation, which may to some degree have broadened the perspectives represented. In other aspects the PRP group was heterogeneous in that it included men and women of different ages, both singles and those living with a partner, from different parts of the country. An important limitation is, however, that this study is based on the researchers' views of the co-creative process, with only indirect reports from the PRPs and no independent assessment of the collaboration process.

When individual PRPs expressed conflicting viewpoints the researchers sometimes found it difficult to know whom they should listen to. There is a risk that those who talk loudly or eloquently receive more attention or that researchers pay attention to comments that are close to their own opinions. We tried to avoid this in several ways, for example, by letting PRPs give feedback on the mock-up and early versions of the website confidentially by writing comments online and by discussing topics in small groups to facilitate expression of opinions. Another way of equalizing power relations between the collaborating parties was to strive for researchers to be in the minority in all discussions. Finally, several of the researchers had training in counseling and were used to encouraging other persons, which we believe contributed to a sensitive and constructive discussion climate at collaboration meetings.

## Conclusion

A long-term collaboration between researchers and a committed group of patient research partners contributed substantially to the development of a self-help Web-based intervention. With suggestions and continuous feedback from PRPs, it was possible to develop a Web-based intervention believed to be relevant and attractive for young persons with cancer having sexual problems or fertility distress. The collaboration with PRPs will continue in the following steps of testing the Fex-Can intervention. The intervention will first be tested in a feasibility study with cancer patients, where PRPs will participate in the interpretation of results. The effectiveness of the intervention

will thereafter be tested in an RCT targeting a nationwide cohort of adolescents and young adults with problems and distress related to sexuality and fertility after cancer.

## Acknowledgments

The study was supported by grants from the Swedish Childhood Cancer Foundation, the Doctoral School in Health Care Sciences at Karolinska Institutet, the Cancer Research Foundations of Radiumhemmet (121242), the Swedish Cancer Society (2010/877), the Vårdal Foundation, and the Swedish Research Council for Health, Working Life and Welfare.

## Abstract

**Background:** Despite improvements in treating psychosis, schizophrenia remains a chronic and debilitating disorder that affects approximately 1% of the US population and costs society more than depression, dementia, and other medical illnesses across most of the lifespan. Improving functioning early in the course of illness could have significant implications for long-term outcome of individuals with schizophrenia. Yet, current gold-standard treatments do not lead to clinically meaningful improvements in outcome, partly due to the inherent challenges of treating a population with significant cognitive and motivational impairments. The rise of technology presents an opportunity to develop novel treatments that may circumvent the motivational and cognitive challenges observed in schizophrenia.

**Objective:** The purpose of this study was two-fold: (1) to evaluate the feasibility and acceptability of implementing a Personalized Real-Time Intervention for Motivation Enhancement (PRIME), a mobile app intervention designed to target reward-processing impairments, enhance motivation, and thereby improve quality of life in recent onset schizophrenia, and (2) evaluate the empirical benefits of using an iterative, user-centered design (UCD) process.

**Methods:** We conducted two design workshops with 15 key stakeholders, followed by a series of in-depth interviews in collaboration with IDEO, a design and innovation firm. The UCD approach ultimately resulted in the first iteration of PRIME, which was evaluated by 10 RO participants. Results from the Stage 1 participants were then used to guide the next iteration that is currently being evaluated in an ongoing RCT. Participants in both phases were encouraged to use the app daily with a minimum frequency of 1/week over a 12-week period.

**Results:** The UCD process resulted in the following feature set: (1) delivery of text message (short message service, SMS)-based motivational coaching from trained therapists, (2) individualized goal setting in prognostically important psychosocial domains, (3) social networking via direct peer-to-peer messaging, and (4) community “moments feed” to capture and reinforce rewarding experiences and goal achievements. Users preferred an experience that highlighted several of the principles of self-determination theory, including the desire for more control of their future (autonomy and competence) and an approach that helps them improve existing relationships (relatedness). IDEO, also recommended an approach that was casual, friendly, and nonstigmatizing, which is in line with the recovery model of psychosis. After 12-weeks of using PRIME, participants used the app, on average, every other day, were actively engaged with its various features each time they logged in and retention and satisfaction was high (20/20, 100% retention, high satisfaction ratings). The iterative design process led to a 2- to 3-fold increase in engagement from Stage 1 to Stage 2 in almost each aspect of the platform.

**Conclusions:** These results indicate that the neuroscience-informed mobile app, PRIME, is a feasible and acceptable intervention for young people with schizophrenia.

## KEYWORDS

schizophrenia; mobile app; smartphone; motivation; technology-based intervention; social networking; coaching; negative symptoms; quality of life

## Introduction

Schizophrenia is associated with significant psychosocial impairments, which lead to poor quality of life [1,2]. Recent data suggest that negative symptoms, and amotivation in particular, are the single most important factor affecting functional disability in schizophrenia [3,4]. Recent cognitive neuroscience research demonstrates that motivational deficits in schizophrenia are characterized by impairments in reward prediction, maintenance of rewarding experiences to guide future behavior, and a reduction in higher effort allocation to obtain rewarding experiences [5-8]. The likelihood to anticipate experiences to be less rewarding and more effortful leads to significant functional impairments. Yet, some aspects of reward processing for individuals with schizophrenia may be preserved, such the degree to which reward experiences are perceived as pleasurable in the moment. Findings suggest that individuals with schizophrenia demonstrate intact hedonic experiences, as evidenced by subjective reports of in-the-moment positive emotion [6,9,10], self-reported arousal similar to healthy comparison subjects [11], and intact hedonic experiences in social contexts [11]. While it appears that the ability to experience pleasure from rewarding experiences is intact, individuals with schizophrenia are more likely to be alone and endorse a preference to be alone while in the company of others, relative to healthy subjects [11], which suggests that the in-the-moment experience of pleasure may not be motivating future social interactions. Given the progress we have made in understanding the complexity of reward processing deficits in schizophrenia and how they might influence motivated behavior, it is time to translate these findings into enhancements of traditional treatments and/or developing novel approaches.

Current gold-standard treatments for individuals with schizophrenia include atypical antipsychotic medication and psychotherapy, with cognitive behavioral therapy (CBT) as one of the most effective behavioral treatments. These approaches are particularly effective at treating the positive, psychotic symptoms, but they do not adequately treat the negative symptoms [12,13]. While some of this may be due to problems with engagement and/or cognitive deficits, which limit the degree to which the skills may be used in real-world settings, the evidence suggests that the current gold-standard treatments do not lead to clinically meaningful improvements in motivated behavior, negative symptom severity, functioning, and quality of life [12,13]. Negative symptoms in schizophrenia, including social withdrawal, limited affective expression, and decreased drive to engage in motivated behavior, pose significant challenges to traditional treatment approaches that require patients to attend in person sessions and make use of the

treatment in real-world contexts [14]. As such, it is not surprising that treatments that use compensatory strategies, such as environmental supports and reinforcement in simulated contexts (cues, reminders, and reinforcement), may be more effective in treating negative symptoms and improving psychosocial functioning, than traditional approaches [15-19]. What this suggests is that treatments that target negative symptoms, may benefit from using strategies that bypass cognitive impairments and deliver environmental supports in real-world contexts that directly motivate individuals with schizophrenia to engage in more rewarding experiences.

The rise of digital health technology presents an opportunity to develop novel treatments that may circumvent the motivational and cognitive challenges observed in schizophrenia. Further, a mobile approach delivered in real-time and in real-world settings, may support the retention, reinforcement, and transfer of intact in-the-moment hedonic experiences to future behavior. Mobile interventions may be accessed with greater frequency than traditional psychotherapy approaches and briefer therapeutic interactions might require less effort and have a greater therapeutic benefit. Indeed, several research groups are taking advantage of technology to deliver behavioral treatments to individuals with schizophrenia [20,21].

These considerations led us to harness digital technology and translate current knowledge on reward processing deficits in schizophrenia into an intervention to improve motivated behavior in the early phases of the illness. We thus designed and developed a Personalized Real-time Intervention for Motivational Enhancement (PRIME), a mobile app treatment that delivers text message (short message service, SMS)-based motivational coaching from trained therapists; individualized goal setting in prognostically important psychosocial domains; and social networking via direct peer-to-peer messaging as well as a community “moments feed” to capture and reinforce rewarding experiences and goal achievements. PRIME was designed with a systematic user-centered design process that included the involvement of individuals with schizophrenia, family members, treatment providers, and research experts. The purpose of this report is two-fold: (1) to evaluate the initial feasibility and acceptability of implementing the PRIME intervention to individuals who were recently diagnosed with schizophrenia, and (2) to evaluate the empirical benefits of using an iterative, user-centered design (UCD) process to develop a digital intervention for individuals with schizophrenia.

## Methods

### User-Centered Design Process

UCD, also referred to as human-centered design, is a process for gaining insight into the needs of end-users, creating novel approaches to meet those needs, and delivering solutions that are optimized for specific contexts [22,23]. Our team worked in collaboration with IDEO, a design and innovation firm, to develop our design strategy and implement the UCD process. Over a 4-week period, we conducted two design workshops with 15 key stakeholders (young individuals with a schizophrenia-spectrum disorder, family members, treatment providers, and research experts), and conducted a series of in-depth, 1:1 in-person interviews with six young people with schizophrenia-spectrum disorders.

The 1:1 interviews included several exercises focused on gaining a better understanding of the values that drive participants to improve their lives. During the initial design workshop, key stakeholders generated 12 potential values that would improve quality of life, including: (1) feel part of a group, (2) be a role model, (3) deepen my relationships with family and friends, (4) have a partner/boyfriend/girlfriend, (5) feel energized, (6) feel appreciated when I achieve a goal, (7) feel a sense of progress, (8) feel productive, (9) remember positive moments, (10) feel happy, (11) feel “normal”/not like I am ill, and (12) feel a sense of control over my future. During the 1:1 interviews, participants discussed whether those values were personally relevant and ranked them in order of importance. While most of the values were important to participants, the top two priorities for participants were to feel a sense of control over my future and deepen my relationships with family and friends. This is in line with self-determination theory (SDT) [24], which emphasizes relatedness, autonomy, and competence as essential values that drive intrinsically motivated behavior. The SDT framework has been used to understand motivated behavior in schizophrenia, such as supporting the motivating role of relatedness [25], the importance of autonomous choices in engaging in health-promoting behaviors [26], and competence in driving reward learning [25,27]. We therefore explicitly integrated principles of SDT into the overall design structure of the app.

Another objective of the interviews was to evaluate each feature of the app. For instance, we used experiential strategies such as prototyping specific features and presenting potential paper mockups of the app. An example of a prototyping exercise was to invite participants to use their mobile phones to take photos of positive moments in their life. Our team was interested in developing a feature that prompted participants to capture rewarding experiences and share those experiences among peers and coaches. When participants came in for their interviews, we reviewed their photos and evaluated the subjective experience of engaging in this type of activity. Notably, in

addition to participants reporting that they enjoyed the process of taking the photos, they also became much more affectively expressive, talkative, and overall more engaged during this portion of the interview, suggesting that this feature would be well received and that participants enjoyed the opportunity to communicate nonverbally through pictures.

Lastly, we presented paper mockups of the app, which enabled our team to evaluate the design, flow, and functionality of particular features. An example of how this significantly influenced the final design of the app was observed during the evaluation of the goal-setting feature. Participants were shown two options of how a user might navigate the goal-setting feature. In one case, participants were shown a “daily challenge” option that was highly customizable and in the other case, the feature was prepopulated with personalized content and a simplified interface. While we expected that our participants would prefer a more customizable option, the degree of complexity and effort required to navigate a customizable experience was undesirable, as almost all the users preferred simplicity to customization. This subtle, yet highly important preference significantly influenced the design of this feature.

The UCD approach ultimately resulted in the first iteration of PRIME, a mobile app intervention aimed at improving motivation and functioning in people with recent-onset schizophrenia-spectrum disorders. With PRIME, participants join a supportive online environment where they can select and document progress on small, self-determined goals in four key domains that have been shown to be significantly associated with better quality of life: (1) health/wellness [28,29], (2) social relationships [30], (3) creativity [31], and (4) productivity [32]. PRIME provides users with motivation coaches: Masters-level clinicians who use evidence-based “microinterventions” drawn from CBT, mindfulness, and psychoeducation to help participants overcome the daily obstacles that hinder goal progress and PRIME engagement. Additionally, the PRIME community provides a platform for users to interact with one another. Users may send messages directly to each other and can also capture and share positive moments in their daily life with the community. Importantly, the PRIME app also includes a unique tone. Our participants noted during the design process that existing mental health apps and treatment approaches overly emphasize illness, and as such, IDEO suggested an approach that focused on a more casual, friendly, nonstigmatizing tone. Examples include the overall “look” of the app, which feels like a mainstream social media app, rather than a clinical tool, and the language used in the automated responses to completed challenges (ie, “You’re basically amazing. Way to rock that challenge!”). This approach is in line with the recovery model of psychosis, which emphasizes a collaborative, reinforcing and strengths-based approach [32,33]. The final design and screenshots of the PRIME app are shown in Figure 1.

**Figure 1.** Screenshots of the three primary features of PRIME (from left to right): Goals (goal-setting), Community (Text-based motivational coaching), and Moments (social networking and community feed).

### Procedures: Using an Iterative Design Process to Improve PRIME Feasibility and Acceptability

Importantly, and unlike what occurs in traditional psychotherapy randomized control trials (RCTs), the PRIME development and evaluation process was iterative and consisted of two stages. In Stage 1, our first iteration, we enrolled 10 participants to evaluate initial feasibility and acceptability. The results from the first 10 participants were then used in Stage 2 to inform the next iteration of PRIME to be tested in a RCT, during which participants were randomized to either receive PRIME or a wait-list/treatment as usual control condition. Participants in both stages were encouraged to use the app daily with a minimum frequency of 1/week over a 12-week period. The same assessment schedule was used for both stages and included clinical evaluations at baseline, 12-weeks, and a 3-month follow-up assessment. Outcome evaluators in the RCT are blind to condition. The RCT is ongoing and as such, we only report the feasibility results of the Stage 1 participants and the first 10 randomized participants from Stage 2. Participants were compensated for their time to complete study-related assessments (US\$20/hour), but were not paid for their participation in the intervention.

### PRIME Protocol

Once participants completed their baseline assessments, participants were either provided with an Apple iPhone 5C with PRIME already installed or a study coordinator installed PRIME on their own personal iPhone. Participants initially met with an assigned “motivation coach” for a “set-up session.” The purpose of the set up session is to orient participants to the app and to

discuss goals the participant would like to achieve by using PRIME. The first time participants sign in to the app, they are guided through a process of creating a user profile. Participants create a user name, upload a profile picture, select their interests, goals, symptoms, and write a short bio. Goals and interests are categorized in the domains of health/wellness, social, productivity, and creativity. Participants are given the option to make their profile “private” or “public” to the PRIME community. If users select private, their peers will not be able to see their profile or posts to the community feed. However, coaches will be able to view their profile and posts in a Web-based “backoffice.” Participants are informed of the privacy practices in the app and encouraged to be respectful of their peers’ privacy.

Once the user is set up with his/her profile, the participant may select from prepopulated, personally tailored “daily challenges,” associated with a participant’s stated goals. For instance, if a participant endorsed “working out” as an interest and a goal of “feeling healthier,” the participant will be shown a daily challenge of “Spend X number of minutes working out today.” The participant may select the amount of time spent engaging in that daily challenge and set an alert to remind him/her to work on that particular daily challenge. Once a participant has completed their challenge, they have the option to post the goal achievement to the community or to their own private feed (also viewable to coaches in the backoffice). Participants are also encouraged to post spontaneous, positive moments in their life to encourage reinforcement of rewarding experiences. The daily challenge and spontaneous moments are displayed on the PRIME community feed and the participants’ “My PRIME”

feed. Assigned coaches explain their role and immediately engage the user in a text-based chat about the participant's goals. For the Stage 1 participants, the coaches explained to their participants that they would reach out to them 1/week, but that the participants could message them at any time they would like help working on a goal or anything that might interfere with goal achievement. Based on use patterns and feedback from participants (reported below) the protocol was changed and coaches now explain that they will reach out to the user on "most days" (on average 4 days per week), but will modify the frequency depending on the user's preference, clinical issues, and degree of overall progress toward goal achievement. Participants are also shown the option to view their peers' profiles and shown how to message with them directly. Other opportunities for social interaction include "liking" or commenting on moments posted to the PRIME community feed.

### ***PRIME Coach Training***

The coaching staff currently consists of six Master's level clinicians who are experienced delivering CBT to patients in community practice settings. Coaches are trained over a 2-hour session using the PRIME treatment manual, which orients coaches to the clinical population, evidence-based approaches to managing symptoms, including CBT, psychoeducation, and mindfulness techniques, and suggested tone/approach to match the overall tone of the app. Due to the text-based modality of coaching, the manual discusses suggested adaptations, such as emphasizing more behavioral strategies during asynchronous interactions, delivering Web-based resources, such as short

videos or websites providing psychoeducation about schizophrenia or other distressing symptoms, cognitive strategies, activity planning, and other behavioral suggestions. After an initial training, coaches "round" on their participants during a weekly meeting with the principal investigator and coaching team to review cases and troubleshoot potential challenges.

### **Participants**

A total of twenty people (10 in the Stage 1 group and 10 in the Stage 2 group) met Diagnostic and Statistical Manual-IV-TR (American Psychiatric Association, 2000) criteria for a schizophrenia spectrum disorder: schizophrenia (n=13), schizophreniform (n=2), or schizoaffective disorder (n=5). Participants were recruited from the Early Psychosis Clinic at University of California, San Francisco as well as other community-based treatment providers in the San Francisco Bay Area. In addition to local recruitment, several participants (n=3) living outside of California were remotely enrolled from Texas, Maryland, and North Carolina. Participants were between the ages of 16 and 30 and in their early course of illness, defined as being within the first 5 years of formal diagnosis. In addition, participants had no history of neurological disorders or serious head trauma, were fluent in English, had an estimated intelligence quotient (IQ) > 70, and did not meet criteria for a substance dependence disorder within the past 6 months. Demographic information, such as age, years of education, as well as use of treatment resources (eg, therapy, psychiatric services) can be found in [Table 1](#).

**Table 1.** Demographic and clinical characteristics.

	Stage 1 (n=10) Mean (SD)	Stage 2 (n=10) Mean (SD)	<i>t</i> or $\chi^2$ ( <i>P</i> )
Age (years)	23.40 (2.6)	23.30 (3.7)	.95

<sup>a</sup>Wechsler Test of Adult Reading.<sup>b</sup>Positive and Negative Syndrome Scale.<sup>c</sup>Role Functioning Scale.<sup>d</sup>Quality of Life Scale-Abbreviated.

## Clinical and Interview-Based Assessment

Trained interviewers confirmed diagnoses using the Structured Clinical Interview for the Diagnostic and Statistical Manual-IV [34]. We assessed positive and negative symptoms using the positive and negative syndrome scale (PANSS) [35]. Functioning in the areas of work, self-care, family, and social was assessed with the role functioning scale (RFS) [36]. Quality of Life was assessed with the quality of life scale - abbreviated (QOL-A) [37]. See Table 1 for symptom, functioning, and quality of life characteristics. We estimated full-scale IQ with the Wechsler Test of Adult Reading (WTAR). For remote participants, the clinical and interview-based assessment was conducted via FaceTime or Skype.

## Assessing PRIME Acceptability

We assessed PRIME acceptability during an exit interview where participants rated their satisfaction with the specific

features of PRIME, such as the ability to interact with peers and the different goal categories, on a 1 (not at all) to 10 (very much) scale. We also assessed retention in the trial as a measure of acceptability.

## Assessing PRIME Feasibility

To evaluate feasibility, we assessed the following: login frequency (average number of days logging in per week), average number of challenges completed (both overall and by individual challenge category), challenge completion percentage, and the average number of peer and coach interactions. Interactions included direct messaging on PRIME as well as commenting on and liking content posted to the community moments feed. To further understand how participants were engaging with the PRIME platform, we evaluated user metrics, such as active use (ie, while logged in, any type of interaction with coaches and/or peers, posting spontaneous or goal achievement moments) versus passive use (logging in, but not

engaging with peers or coaches or posting content onto the moments feed), the degree of social reciprocity (ie, initiating interactions and the ratio of initiated interactions to responsive interactions) from peer-to-peer and coach-to-peer interactions.

### Data Analysis Plan

We examined whether any demographic variables were related to symptoms or functioning in the overall sample, and whether any demographic variables, symptoms, or functioning were related to PRIME use by conducting zero-order correlations. We also investigated any group differences (Stage 1 vs Stage 2) in demographic variables, symptoms, and functioning by conducting independent samples *t*-tests for continuous variables and chi-square tests for categorical variables. To examine initial acceptability of PRIME, we compared the average ratings for each group from the PRIME exit interview for overall satisfaction as well as the most and least popular PRIME features using independent samples *t*-tests. Furthermore, we also reviewed qualitative feedback from the PRIME exit interview.

To investigate initial feasibility of PRIME, we examined descriptive statistics for the following PRIME metrics: login frequency, challenges completed, peer and coach interactions, and active use rate. To understand participants use of PRIME on a daily basis, we computed a variable that represented how often participant's actively used PRIME, which we called the active use rate. To do this, we added together the average number of challenges completed, peer, and coach interactions and divided this total by the number of weeks the participant had access to PRIME. Thus, a value of 2.3 would mean that a participant was active on PRIME 2.3 times/week. Passive use was defined as logging into the app, but not posting a moment, completing a challenge or interacting with peers or coaches. Thus, a participant may login to the app 4 days/week, but actively engage with the features of the app 2 days/week.

In addition to examining the total number of coach and peer interactions, we also calculated the degree to which participants initiated interactions, relative to received interactions as an indicator of engagement. For instance, a ratio of 3:1 for peer-to-peer interactions would mean that for every three times a user sent a message, the peer received one message, which suggests that the user is more proactively engaging in interactions. For both PRIME acceptability and feasibility, we tested the effectiveness of our iterative design process by comparing the Stage 1 and Stage 2 participants using independent samples *t*-tests, correcting for multiple comparisons.

## Results

Participant demographics are reported in Table 1. Participants in the Stage 1 group had a significantly longer duration of illness than the Stage 2 group. However, neither this nor any other

demographic variable was related to symptoms or functioning in either group, nor were symptoms and functioning related to PRIME use in the two groups.

We also assessed participant digital health use (eg, health-related mobile app usage) over the past month. In terms of digital health resource usage, 75% (15/20) reported owning a smartphone. We then asked participants whether they used digital health apps in their daily lives. Overall, participants reported low levels of digital health use, with the most used applications falling in the categories of increasing exercise and fitness (5/20, 25%), improving relaxation (3/20, 15%), and improving mood (2/20, 10%). Only one of the 20 participants reported using digital health resources for managing weight or alcohol use. In comparison, 95% (19/20), reported using a social media platform (e.g. Facebook, Twitter), with 50% (10/20) also using social media for sharing photos and music. Participants in Stage 1 reported using social media apps daily and participants in Stage 2 reported social media use "more days than not."

### PRIME Acceptability

To date, all of the participants were retained in the trial. Mean overall satisfaction with PRIME for the entire sample, as rated during the exit interview administered at the 12-week post-assessment, was 8.00 (standard deviation (SD): 2.0). The difference between the two groups was not significant (Stage 1: mean: 7.25, SD: 2.3; Stage 2: mean: 8.86, SD: 1.2). Some of the comments made by participants when asked about how PRIME influenced their lives included:

*There's nothing like it out there*

*It was a good chance to be more social, meet other people, and see what they're like.*

*Definitely getting to do more, not chores, but be more active. Motivation to do more stuff, achieve more goals, and be more social.*

The most popular PRIME features for both groups were the ability to comment on other user's posts (mean: 8.53, SD: 1.9) and the least popular PRIME feature was the ability to view coach profiles (mean: 7.33, SD: 2.7).

### PRIME Feasibility

PRIME use data (login frequency, challenge completion, and interactions) for the participants in both stages are shown in Table 2. Overall, participants logged into PRIME approximately every other day, with the Stage 2 sample logging in at a slightly higher frequency. Over a 12-week period, participants were highly engaged in the platform, with 177 direct messages sent from participants to coaches in the Stage 1 sample and 955 sent from participants to coaches in the Stage 2 sample ( $P=.04$ ;  $d=1.02$ ). In terms of peer-to-peer interactions, participants initiated interactions with each other 97 times in the Stage 1 sample and 151 times in the Stage 2 sample ( $P=.49$ ,  $d=.23$ ).

**Table 2.** PRIME usage data for the overall sample as well as both the Stage 1 and Stage 2 groups.

	Stage 1	Stage 2	
	Mean (SD)	Mean (SD)	<i>p</i> , <i>d</i> [95% CI]
Login frequency (average logins per week)	3.51 (1.8)	4.69 (1.4)	.13, .73 [-.20 to 1.60]
Challenge completion rate (%)	84.48 (18.4)	85.35 (15.3)	.91, .05 [-.83 to .93]
Average number of user-initiated peer interactions			
Comments	7.70 (6.4)	9.50 (10.1)	.68, .21 [-.67 to 1.08]
Likes	11.80 (11.9)	24.00 (20.6)	.12, .73 [-.21 to 1.60]
Messages	9.70 (8.8)	15.10 (22.5)	.49, .32 [-.58 to 1.18]
Total	29.20 (21.1)	48.60 (44.3)	.23, .56 [-.36 to 1.43]
Average number of user-initiated coach interactions			
Comments	7.80 (7.0)	12.90 (14.5)	.33, .45 [-.46 to 1.32]
Likes	4.40 (4.9)	10.00 (12.3)	.20, .60 [-.06 to 1.47]
Messages	17.70 (22.9)	95.50 (105.8)	<b>.04<sup>a</sup></b> , 1.02 [.05 to 1.90]
Total	29.90 (31.6)	118.40 (105.9)	<b>.02</b> , 1.13 [.15 to 2.02]
Challenges completed			
Overall	18.40 (14.5)	20.40 (18.2)	.79, .12 [-.76 to .99]
Health/wellness	6.80 (5.7)	7.80 (9.1)	.77, .10 [-1.47 to .49]
Social	3.20 (1.8)	4.40 (3.9)	.39, .40 [-.51 to 1.26]
Creativity	4.50 (4.7)	4.40 (3.7)	.96, -.02 [-.85 to .90]
Productivity	3.90 (5.7)	3.80 (3.6)	.95, -.02 [-.86 to .90]
Active engagement rate (average times active per week)	3.87 (2.7)	11.17 (9.4)	<b>.03</b> , 1.06 [.08 to 1.94]

<sup>a</sup>Bold Values indicate statistically significant results.

Participants in both groups completed an average of approximately 1.5 challenges per week, with the Stage 1 sample completing slightly more than the Stage 2 sample. For both groups, health/wellness challenges were the most popular at approximately one challenge completed per week, followed by creativity challenges, social challenges, and productivity challenges of which participants completed approximately 1 every 2 weeks. Challenge completion percentage was high for both groups (>16/20, 80%), suggesting that participants had little difficulty completing the challenges that they set. Participants had approximately two interactions with coaches and two interactions with peers each week. Participants in the Stage 2 sample tended to have more interactions with coaches

and peers than those in the pilot group. The Stage 1 group, on average, was active on PRIME approximately 4 times/week. This rate almost tripled for the Stage 2 group at a little over 11 times/week (see Table 2). The degree to which participants reciprocated interactions initiated by a peer or coach user is shown in Table 3. The ratios reflect a higher degree of reciprocity in peer interactions than coach interactions. Yet, the Stage 2 participants were much more responsive to coach interactions than the Stage 1 participants (see below for a description of the change in the coaching strategy). Real examples of peer to peer and coach to peer interactions are shown in Textboxes 1 and .

**Textbox 1.** Examples of peer to peer interactions.

John: Hey the doctors said I should connect with you because you have some good insights about the diagnosis. What do you think about it?

David: Hey bud, sorry about the delayed response. Thanks for reaching out. I think this disease is definitely a huge challenge that we all sort of have to face. But I think its a type of challenge that can be overcome. When I first got the diagnosis, I was a wreck. Depression as well as an onslaught of negative symptoms... I think it's important to slowly get ur life back together step by step. As u progress, u will realize things really are not all that bad and that this disease is just one of the bumps in life that u will have to overcome.

John: I agree, it's just another challenge. How do you deal with your negative symptoms?

David: It takes time. Therapy helped. Also a goal orientated attitude is important. Gotta realize that u r no different than someone without the disorder after proper medical treatment.

**Textbox 2.** Examples of and coach to peer interactions.

Coach: Hey [participant's name]! I noticed you haven't completed any challenges or posted any moments recently. What have you been up to?

Participant: Playing video games. I haven't been up to it lately. Is there a way I can fight through this? Laziness or whatever it's called? How do you complete your goals in life? I feel stagnant more depressed and less motivated. I feel like this because I have low self esteem. So I play video games to distract myself and get lost. Doing much seems unrealistic.

Coach: I'm sorry to hear that you haven't been feeling great recently. Feeling blue happens to us all from time to time, and luckily there are some ways to combat feeling this way. One thing that might help is trying to be active. I know it's hard when you feel this way, but even something as simple as going for a walk can help. When you feel this way, do you notice that you are having negative thoughts as well?

Participant: Yeah ok Coach thank you. I love being active, working out, cleaning, walking my dogs, doing hw, cooking. These things help me focus.

Coach: Do you notice feeling different? Sometimes it helps to take a step back and realize all that you have accomplished. You have worked very hard over the past 2 months and have made good progress. I am proud of you and hope that you feel proud as well.

Participant: Thank you so much you are right I have!!! I feel like I'm not going to be so harsh on my self and I feel like being more active!

Coach: Self-compassion is important as being too hard on yourself can make you feel down. Next time you think you are being hard on yourself, try writing down some things you recently accomplished. Or, you can write down evidence for and against the thoughts you are having. I have used both approaches and they both work!

Participant: Okay thank you so much. I'm going to try and write down some recent accomplishments and find evidence against being too hard on myself.

Coach: Great to hear! Let me know how it works. Maybe you can complete a challenge this weekend.

## Iterative Design Process Results: Shifting the Coaching Strategy and Tone

The feasibility and acceptability results from the Stage 1 participants, reported above, for the most part demonstrated that the intervention was well tolerated, yet feedback from individual participants coupled with an examination of their use patterns suggested we should modify our approach to motivation coaching. For instance, one participant felt that it seemed that the coaches were working "off of a script," which made it hard for her to connect with her coach, stating:

*It felt like every time [my coach] posted something, she was fitting me inside this box. Instead of having a normal conversation like "Hey what's up, how are midterms", they followed a script.*

Still, others found the coaching to be very helpful, with one participant stating:

*It was great! I think the coaches were very, very, very supportive and they did as much as they could to help me participate and be active in the community. They helped me manage my stress and take on everyday life and they did a good job.*

Another key observation during the first iteration was the low response rate to coach initiated interactions (Table 3), with less than half of the messages sent by coaches receiving a response

from participants. The ratio of coach to participant responses was 12:1 for the pilot participants. This led to the following changes in Stage 2: (1) we increased the frequency of the interactions initiated by motivation coaches from once a week to an initial 5 days/week followed by a decreased frequency over time, based on the preference of the participant and their clinical needs, (2) decreased the amount of content in each message, and (3) personalized the messages and adopted a more casual tone that reflected the tone recommendations by IDEO. For example, instead of sending a lengthy, once per week message, coaches would instead send a brief message most days per week, checking in with their participant (eg, "Hi there! I'd love to see you work on your goal to exercise more. How about going for a walk today?"). By initiating almost daily contact, we sought to increase overall engagement with PRIME and to facilitate more frequent interactions with coaches and among peers. By decreasing the amount of content in each message, we aimed to reduce the cognitive load for participants and make it easier to respond to messages. The data suggest that this change may have led to increased engagement as evidenced by a 2- to 3-fold increase in the following usage patterns between Stage 1 and Stage 2: number of logins (3.51 days/week to 4.69 days/week), overall peer and coach interactions (peers: from 29.20-48.60 ( $P=.23$ ,  $d=.56$ ); coaches: from 29.90-118.40 ( $P=.02$ ;  $d=1.13$ )), active use rate (~4 times/week to ~11 times/week; see Table 2), and the degree of coaching interaction reciprocity (Table 3).

**Table 3.** Initiated to received coaching and peer interaction rate for Stage 1 and Stage 2 groups.

	Stage 1 Mean	Stage 2 Mean	<i>P, d</i> [95% CI]
Coach interaction (ratio of interactions initiated by coaches to received)			
Comments	10.88:1	8.16:1	.44, -.37 [-1.24 to .53]
Like	44.40:1	24.17:1	.19, -.65 [-1.52 to .27]
Messages	5.17:1	1.87:1	.07, -.87 [-1.75 to .08]
Overall	12.23:1	3.37:1	.01 <sup>a</sup> , -1.35 [-2.26 to -.33]
Peer interaction (ratio of interactions initiated by peers to received)			
Comments	1.68 : 1	1.89 : 1	.81, .12 [-.77 to .99]
Like	2.06 : 1	0.98 : 1	.42, -.41 [-1.28 to .49]
Messages	1.10 : 1	1.03 : 1	.65, -.20 [-1.07 to .69]
Overall	1.17 : 1	1.25 : 1	.84, .10 [-.78 to .97]

<sup>a</sup>Statistically significant result.

## Discussion

### Principal Findings

The results from this study demonstrated that the cognitive neuroscience-informed mobile app, PRIME, is a feasible and acceptable intervention for young people with schizophrenia. Over 70% (14/20) of our participants reported owning a smartphone and 95% (19/20) reported using social media, suggesting that using a smartphone-based, social networking platform to deliver an intervention would be an acceptable treatment modality for this population. The overall satisfaction with PRIME was relatively high, as reflected in the satisfaction ratings endorsed in the exit interview as well as the current 100% (20/20) study retention rate. The PRIME use data demonstrated a high degree of engagement with this digital treatment platform. Participants used the app, on average, every other day, and were actively engaged with its various features each time they logged in. Qualitative feedback from participants was overall positive, and the critiques of the platform during Stage 1 were used to guide refinements for Stage 2 (ie, the coaching strategy). A common theme in the feedback from participants was the positive experience of social support from coaches and their peers. This was also reflected in the total number and frequency of interactions and degree of reciprocity the participants exhibited with their coaches and peers. The quality of the interactions, as reflected in the provided examples, was also impressive given the entirely text-based messaging format.

The increase in various metrics of engagement between Stage 1 and Stage 2 participants, suggests that the integration of user feedback to influence the refinement of the intervention was successful. The changes we made in response to this user-centered, iterative approach led to a 2- to 3-fold increase from Stage 1 to Stage 2 in use of the app (ie, logins), greater active use (engagement with features), a significantly greater number of social interactions with peers and coaches and improved ratios of reciprocal interactions with coaching. While the changes we made were focused on the text-based coaching,

these simple changes appeared to generalize to greater engagement in almost every aspect of the platform. Taken together, this suggests that the development of mobile digital interventions should continuously incorporate user feedback and adopt refinements to meet the needs of the population. This is in line with conclusions from the Agency for Healthcare Quality Improvement, which recently highlighted that the success of new technology-based interventions hinges on incorporating user feedback in design and implementation [38].

### Limitations

This study has several limitations. First, our sample size is relatively small, which limits the generalizability of the results. However, the tradeoff for using a small sample size in Stage 1 was that we were able to very quickly evaluate the feasibility of the app and refine the platform for use in Stage 2. Another limitation of this feasibility study is that our participants were all in the early phase of schizophrenia and therefore the results of the study are likely not representative of the larger population of those with persistent schizophrenia. We decided to focus on designing the intervention to treat young patients early in their course of illness based on numerous findings promoting the benefits of early intervention [39,40]. By designing an intervention specifically for use with this population we are aiming to significantly improve the course of illness by improving functional outcome during a critical period.

### Conclusions

With the proliferation of digital technology-based interventions to address mental health issues, it is encouraging to learn that a mobile app-based treatment is feasible, tolerable, and acceptable to young people with schizophrenia. Indeed, several other research groups have developed novel digital technologies to improve outcome for individuals with schizophrenia, often emphasizing CBT approaches for positive symptoms and focusing on people with persistent illness [29,41]. In addition, the existing digital treatment tools have not been developed with an explicit cognitive neuroscience rationale, have not focused on the needs of recent onset individuals, and have not included a social network with peers or mental health coaches

[21]. The results of our feasibility study seem to suggest that the delivery of a smartphone mobile app intervention that includes several opportunities for social engagement and to share goal achievements within a recovery-oriented framework is a desired treatment modality for young people with

schizophrenia. The goal of our ongoing RCT will be to explicitly examine the degree to which the focus on targeting reward processing impairments and enhancing motivated behavior will lead to improved functional outcome in this population.

## Abstract

**Background:** Weight gain and its related illnesses have become a major public health issue across the world, with Saudi Arabia and other Gulf countries seeing dramatic increases in obesity and overweight, and yet there is very little information on how to intervene with this demographic due to cultural and linguistic barriers. As the use of smartphones and apps has also increased in the region, information communication technologies could be a cost-effective means of facilitating the delivery of behavior-modification interventions directly to the target population. Although there are existing apps that offer lifestyle-modification tools, they do not give consideration to the evidence-based practices for weight management. This offers an opportunity to create an Arabic language weight loss app that offers localized content and adheres to evidence-informed practices that are needed for effective weight loss.

**Objective:** This paper describes the process of developing an Arabic weight loss app designed to facilitate the modification of key nutritional and physical activity behaviors among Saudi adults, while taking into consideration cultural norms.

**Methods:** The development of the Twazon app involved: (1) reviewing all available Arabic weight loss apps and compared with evidence-based practices for weight loss, (2) conducting a qualitative study with overweight and obese Saudi women to ascertain their preferences, (3) selecting which behavioral change strategies and guidelines to be used in the app, (4) creating the Saudi Food Database, (5) deciding on graphic design for both iPhone operating system and Android platforms, including user interface, relational database, and programming code, and (6) testing the beta version of the app with health professionals and potential users.

**Results:** The Twazon app took 23 months to develop and included the compilation of an original Saudi Food database. Eight subjects gave feedback regarding the content validity and usability of the app and its features during a pilot study. The predominant issue among the group was the lack of information explaining how to use the app. This has since been resolved through the implementation of a tutorial. No other changes were required to be made.

**Conclusions:** Information communication technologies, such as smartphone apps, may be an effective tool for facilitating the modification of unhealthy lifestyle habits in Saudi; however, consideration must be given to the target population, cultural norms, and changing trends in the global market. The effectiveness of the app will be better determined during a 6-month intervention with 200 overweight and obese Saudi women.

weight loss; smartphone; mobile apps; Arabic; obesity

## Introduction

Obesity and overweight in the Saudi adult population has increased dramatically for both men and women, respectively; however, due to the cultural limitations and inaccessibility to physical activity, there is a predominant effect on the female population. Recent studies show that the rate of obesity and overweight in women has increased from 26.6% in the mid-1990's to 33.3% in a national survey conducted in 2013 [1,2]. This is supported by the World Health Organization's report published in 2014, which indicates that obesity has increased worldwide by more than 50% since 1980. This worldwide increase, paired with the statistical increase in Gulf countries, makes the prevalence of obesity a major public health issue in Saudi Arabia [3,4].

Certain local issues have contributed to the current and projected increase in the prevalence of overweight and obesity. These include aspects such as climate making it substantially harder to be physically fit [5], and the growing popularity of western fast foods resulting in a change in diet [6]. Additionally, the lack of nutritional and proportional information for regional dishes makes it difficult for locals to identify caloric content of meals [7]. Furthermore, cultural aspects relating to the status of women may also contribute to the higher prevalence of overweight and obesity in women specifically. These include high birth rate, and cultural restrictions that require women to stay inside the home, be accompanied by a male to go outside, and seek permission from family members to engage in physical activity [8]. Currently, the most popular method to lose weight among Saudi is gastric and bariatric surgery, as it is considered to be the fastest and most effortless method regardless of the risks associated with it [9].

Smartphone and app usage has shown exponential growth in Saudi Arabia in recent years ranking it third in smartphone usage in the world [10], with a penetration rate of 73% as of 2014 [11]. Saudi Arabia also has the highest-ranking Twitter usage in the world [12]. Cultural restrictions make it easier, for women especially, to express themselves socially and publically in a virtual environment through the use of smartphone technology. There is evidence that women are using websites and apps such as Instagram, Facebook, and Twitter to initiate home-based businesses [13] and participate in social solidarity [14].

The increasing ubiquity of these technologies therefore created an opportunity for the development of an Arabic app to be used as an appropriate tool to treat and prevent obesity in this population. To inform this development, two important aspects were investigated. First, Saudi Arabian women were consulted about their use and needs for a weight loss app [15]. Although women in Saudi Arabia reported using weight loss apps, they highlighted language barriers and cultural insensitivity, making recommendations for the development of a culturally sensitive

Arabic weight loss app [15]. Second, it was important to ascertain whether there were any effective weight loss apps already available, specifically Arabic apps as recommended by the Saudi women. Although there was evidence available that English apps [16,17] fail to comply with evidence-informed practices for weight management, there was a paucity of evidence for Arabic apps. Screening of Arabic weight loss apps confirmed that they also did not comply with evidence-informed practices for weight management [18]. The development of an Arabic weight loss app including evidence-informed practices for weight management was therefore justified.

This article sets out to elaborate on the steps taken in the development of the Twazon app and tools included, the challenges that were faced, and the insights gleaned from the process.

## Methods

### Description of 'Twazon'

The Arabic name, Twazon, means balance, which refers to the balance of dietary intake compared with energy expended through physical activity. The name and logo were developed through consultation with the community, including participants from the initial focus group discussions.

The use of the app begins with membership and social networking features. The user is required to complete a "5-step" registration process that allows them to use their email, Facebook, or Twitter accounts when signing in or out of their Twazon account. The process begins with the input of basic, required information such as name/nickname, gender, age, height, current weight, waist circumference, current health status, pre-existing diseases, and physical activity status. After submitting this information, the app provides the user with their ideal weight goal and the date by which this weight can be achieved by reducing the user's daily caloric intake by 600 [19]. An optional tutorial presents the user with instructions on how to use the app.

There are many different theories that guide health promotion interventions. The social cognitive theory [20] forms the theoretical base of this application as it considers the importance of the social system in relation to the behavior of the individual, as well as the value of self-efficacy and self-regulation. It is considered a dynamic interaction between personal factors, behavior, and environment and confirms the importance of observational learning, which is based on observing others' experience or results [20].

The Twazon app includes various tools to address evidence-informed practices for weight loss interventions as identified and used for screening of Arabic apps [16] (Table 1), and based on recommendations provided during the focus group discussions with overweight and obese Saudi women [15].

**Table 1.** Tools in Twazon addressing evidence-informed weight loss practices.

Practice	App Information
Weight assessment and goal setting	Assesses weight by calculating body mass index and waist circumference  Allows users to set their ideal weight, and sets a target date for achieving the weight loss goal Calculates the number of calories needed daily based on their target weight Recommends a decrease of at least 600 calories consumed per day in order to achieve weight loss goal
Healthy diet	Recommends daily servings/portions of all foods and beverages, including 6 cups of water per day Recommendations given according to healthy lifestyle self-assessment score Provides a customized healthy food palm based on the user's intake report Recommends the reading of labels and describes how to properly read labels Offers some suggestions for healthy food options in place of unhealthy food items. Allows users to correct a poor meal/diet as an education tool for menu planning Tips will be sent if the intake/activity ratio is off-balance according to healthy lifestyle self-assessment score
Physical activity	Recommends a minimum of 30 minutes of physical activity three times a week and allows users to assess their physical activity every 2 weeks  Tips will be sent if the amount of physical activity is low Recommends taking at least 10,000 steps and provides a pedometer that tracks the daily number of steps
Self-monitoring	Allows users to track their daily food (calories) and water intake, and number of servings per food group, every 2 weeks  Allows users to self-assess their physical activity, every 2 weeks Provides a weight loss tracker that informs user of current weight loss toward their goal weight (kg)
Social support	Provides an app-specific message board allowing users to privately share experiences, weight loss goals achieved, and photos with other users  Allows users access to social networking services such as Twitter

## Evidence-Informed Weight Loss Practices

### *Weight Assessment and Goal Setting*

Users will be able to assess their current weight goals by providing physical and lifestyle information. The app calculates the current body mass index and ideal body weight based on the formula from Lemmens et al [21]. The app will provide a realistic goals setting feature with a target weight loss of 0.5 to 1 kg (1-2 lb) a week [19] and will encourage modest loss of initial weight (5%-10%) as it is significantly correlated with meaningful changes in chronic disease risk [22]. The app will calculate the duration (days) required for the weight loss, enabling users to set appropriate and realistic goals. The app will also provide a daily caloric intake goal by calculating the daily calories needed based on the ideal weight with a recommended daily decrease of 600 calories less than current consumption.

### *Healthy Diet*

The app also includes a healthy lifestyle self-assessment score. Users will be prompted to complete the self-assessment every 2 weeks to track their level of achievement. As several studies have shown that there is a link between increasing consumption of a Mediterranean diet and lowering obesity rate [23,24], this self-assessment tool was developed using the Mediterranean diet assessment tool [25], however the alcohol question was excluded as alcohol intake is forbidden in the Saudi culture. Four additional questions were included based on the Saudi Healthy Food Palm guide [26] (Figure 1).

The additional questions cover aspects of dairy and whole grain consumption as well as daily physical activity. The healthy lifestyle self-assessment is therefore scored out of 17 and each question is linked to the relevant part of the Healthy Food Palm. Each question asks for the level of intake of a specific food/food group and this response is then used to calculate whether this is within the recommended levels or not (Textbox 1).

**Textbox 1.** Lifestyle self-assessment questions

## Vegetables:

- Are  $\geq 2$  servings (of 200 g each) of vegetables eaten each day?
- Are pasta, vegetable, or rice dishes flavored with garlic, tomato, leek, or onion eaten  $\geq 2$  a week?

## Fruits:

- Are  $\geq 3$  servings of fruit (of 80 g each) eaten each day?

## Oils:

- Is olive oil the main culinary fat used?
- Are  $\geq 4$  tablespoons of olive oil used each day?
- Is  $< 1$  serving (12 g) of butter, margarine, or cream eaten each day?

## Sugar:

- Is  $< 1$  serving (330 ml) of sweet or sugar sweetened carbonated beverages consumed each day?
- Is  $< 3$  servings of commercial sweets/pastries eaten each week?

## Meat and beans:

- Is  $< 1$  serving (100-150 g) of red meat/hamburgers/other meat products eaten each day?
- Are  $\geq 3$  servings (of 150 g) of legumes consumed each week?
- Are  $\geq 3$  servings of fish (100-150 g) or seafood (200 g) eaten each week?
- Is  $\geq 1$  serving (of 30 g) of nuts consumed each week?
- Is chicken, turkey, or rabbit routinely eaten instead of veal, hamburger, or sausage?

In addition to the 14-Item Mediterranean Diet Assessment above, these questions were added to the current assessment:

## Dairy:

- Are  $\geq 2$  servings of dairy products consumed each day? (One serving=one cup of milk or yogurt, three slices of processed cheese slices)
- Are low fat or skimmed milk products consumed instead of full fat?

## Bread and cereal:

- Are whole wheat grains consumed instead of refined grains?

## Physical activities:

- Do you do physical activity for 30 minutes or more three times a week or more?

The results of the assessment will be provided in a graphic format of the Healthy Food Palm guide and responses within recommended levels will turn the palm leaves green (Figure 2). For a full list of app prompts and feedback, see Supplementary Table 2.

A response below the recommended levels will prompt a notification to be sent to users with tailored tips based on the healthy food palm guidelines [26] as well as other international

government health websites [27-29]. The app will recommend daily servings or portions of all foods and beverages, including six cups of water per day as well as describe how to properly read labels (Figure 3). The app will offer some suggestions for healthy food options in place of unhealthy food items and allows users to correct a poor meal/diet as an education tool for menu planning (Figure 4). Tips will be sent if the intake/activity ratio is off-balance according to the healthy lifestyle self-assessment score.

Figure 1. The Healthy Food Palm.

Figure 2. Graphic display of results of the healthy lifestyle self-assessment score.

**Figure 3.** How to read food labels.**Figure 4.** Education tool for menu planning.

## Physical Activity

Energy expenditure is calculated using the Metabolic Equivalent of Task values based on The Compendium of Physical Activities, which provides a wide variety of sports and fitness activities as well as activities of daily living [30]. The Twazon app physical activity practice was created to ensure context validity to include only activities that Saudi women would be involved in (H. Al-Hazza, email communication, July 2014). Physical activities that are traditionally not available to most women such as tennis, running, or playing sport outdoors have been replaced with suggestions to do exercises at home or find support from others in order to find physical activities that are easily accessible by Saudi women. The app will recommend a minimum of 30 minutes of a physical activity selected from a provided list, at least three times a week. The app will also recommend taking at least 10,000 steps per day and will provide a pedometer that tracks the daily number of steps. It will also allow users to assess their physical activity every 2 weeks, sending tips if the amount of physical activity is low.

## Self-Monitoring

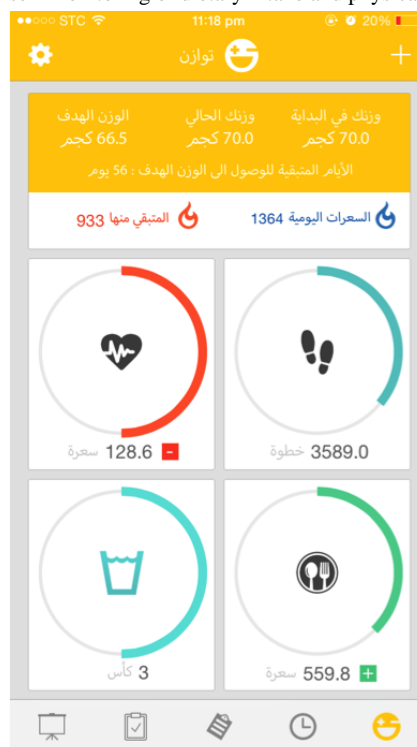

As there is a significant association between self-monitoring of both diet and physical activity and weight loss [31], the app will enable self-monitoring of daily energy (kCal) of food and drink consumed (in) and physical activity (out) as well as weight tracking. For the purposes of tracking the balance of calories (in vs out), the Twazon app includes customized databases for dietary intake (calories only) and physical activity. These databases will allow users to keep a daily food and physical activity diary. The home page, or dashboard, of the app will provide this information for easy access to tracking and goals (Figure 5).

The app will allow the users to monitor their weight progress including starting weight, current weight, and goal weight. The app allows the user to report the foods consumed daily and then calculates the equivalent amount of calories, providing the user with a number of calories remaining for the day. The dashboard will provide a system to track calories consumed, steps taken, water consumed, and physical activity. When a user exceeds

the number of calories required in a day for weight loss, consumes more servings of a particular food group, or does not practice the minimum amount of daily physical activity, they

will receive a notification informing them to engage in more physical activity.

**Figure 5.** 'Twazon' home page indicating daily self-monitoring of dietary intake and physical activity and goal tracking.

### Social Support

Twazon will encourage the user to connect to social networks to add social support, which has a positive effect on health behavior [32]. This allows participants to view other app users and their progress, post pictures, and share them on a variety of social networking services (eg, Instagram, Facebook, and Twitter) to facilitate real-time communication and peer support among participants. This was one of the major shortcomings identified in both English [16,17] and Arabic weight loss apps [18], and an aspect highly recommended for inclusion by overweight Saudi women during the focus group discussions [15].

### Customized Saudi Food Database

A Saudi food composition database was developed to provide the caloric information of more than 400-food item servings. This database was developed specifically for the app and compiled using multiple data sources. These include the Saudi food composition tables [33], the food composition tables for the Kingdom of Bahrain [34], the Kuwait food composition tables [35], the US food composition tables (ESHA Food Processor, version 10.8, nutrient analysis software), and the UK food composition tables [36]. If the calorie value was not available in the Saudi food composition tables, the international food tables were consulted in a relevant order. In the event that there was a complete lack of food composition data for specific traditional dishes (eg, falafel sandwich, yogurt cucumber salad), common recipes taken from restaurants were added by calculating the nutrient values of ingredients using the ESHA food processor program. As the current Arabic food databases

(Saudi, Bahrain, and Kuwait) measure food only in grams, average household measure portion sizes (cups, spoons) were calculated for each of the food items/dishes for which this information was not available. If a user consumes a product that is not found in the finished database, they are able to input the food item into a private database, which sends a notification to the administrator alerting them to update the database with the new product.

### Behavior Change Techniques

All system requirements were based on proposed features for and ideal weight loss app by the target group [15] as well as trying to include all aspects for evidence informed practices. As most weight loss apps tend to lack behavior change techniques (BCT), these were incorporated into this app using Michie's taxonomy [37] to code the techniques (Supplementary table 2 in Table 2). A total of 29 BCTs were included, related to goals and planning (4 codes), feedback and monitoring (4 codes), social support (3 codes), shaping knowledge (1 code), natural consequences (1 codes), comparison of behavior (2 codes), associations (2 codes), comparison of outcome (1 code), repetition and substitution (3 codes), comparison of outcomes (1 code), rewards and threats (1 code), regulation (1 code), antecedents (3 codes), and identity (1 code). An overview of the system requirements, BCTs, and associated features in Twazon App is provided in Supplementary Table 2.

## Results

### Testing the App

The Twazon app was piloted as a preliminary evaluation by two groups made up of experts in the field and potential users. These groups were asked to use the app for 5 to 7 days and give feedback and suggestions.

### Expert Testing

The group of Saudi health professionals included two physical activity specialists and three nutritionists/dietitians. They provided content validity by reading app info, tips, and goals set by the app, and so on, and verified that it was accurate based on their professional knowledge. They were given access to the app itself, as well as an attached document listing the app's content sent by email. Three professionals reviewed the app and reported that it met all necessary criteria and found the content to be valid and accurate. They approved the information given to potential users although they raised a few questions about the use of the palm tree as the food guide, using waist-to-hip ratio instead of waist circumference, the accuracy of the "energy-expenditure formula," and inquired about the relationship between the pedometer and the offline function.

### Potential Users Testing

The group of potential users included 10 overweight Saudi women over the age of 18. They were asked to input their personal data into the app, and then follow the goals set by the app including any physical activity recommended. They checked for usability, design satisfaction, and any problems in the app's system. In order to facilitate fast response times, their feedback was sent by WhatsApp. Five women submitted feedback on what they liked and disliked about the app. The majority of the users liked that the app raised awareness, and encouraged commitment and self-monitoring.

*...It made me realize that a lot of foods that I eat between meals, which I don't care about, have a great effect on increasing the calories."*

They also liked that it assigned a weight goal and calculated daily caloric intake, water consumption, and effort exerted.

*"What I liked in the application is that it calculates my steps, and water quantity, and how many calories I consumed; even the effort; it could calculate it."*

The Healthy Food Palm Tree was also beneficial to the users by identifying current health status.

*I liked the palm tree...I came to know my nutrition disorder through it unfortunately, and the need to adapt my eating and nutrition habits."*

The app's design and simplicity was also well received and the users enjoyed being able to add specific dishes as "favorites" and reference them in the future.

### Future Suggestions

Suggestions made included that they would like to be able to view the history of the previous day's food intake and activity, in addition to being able to "add forgotten meals" or activity. Moreover, the majority felt that the app needed to be even easier

and should offer a detailed explanation on how to use the app. A couple of the women wanted notifications on meal times and one woman mentioned "the need for the caloric information for certain fruits and juices." The results show that the usability of the app varies between potential users and this might be attributed to the different learning styles or technological literacy of users.

## Discussion

### Principal Findings

To our knowledge the development of previous Arabic weight loss apps has not complied with sufficient evidence-informed practices for weight management. The Twazon app differs from previous commercial Arabic weight loss apps in the following key areas: (1) it has been designed in collaboration with final users, (2) it complies with evidence-informed weight loss practices, (3) it provides social-network access, and (4) it includes a caloric content of Saudi local food.

The Twazon app, developed under the Android and iPhone operating system platforms, is a user-friendly, interactive app designed to track daily physical activity and food intake, and then provides customized advice to losing weight. The app took 23 months to build primarily because of the lack of information regarding household measurements of local foods [7]. During the creation of the local food databases, we reviewed the content of Arabic weight control apps and explored overweight Saudi women's opinions in order to design a smartphone app to fit their needs.

The Twazon app was tested in collaboration with the local community and health professionals. Three health professionals determined content validity and five potential users (overweight Saudi females) evaluated the app for usability.

Overall, the app was reviewed to provide accurate information and was reported to have helped several of the potential users identify and understand their weight loss goals. The app was found to be aesthetically pleasing in design and many of the features were user-friendly.

In order to better explain the functions of the app and its features, a tutorial that includes pop-up messages will guide the user through the general use of the app, identifying the most important points and steps. The lack of nutritional data for certain foods will be solved by a detailed explanation of use in the aforementioned tutorial as well as a constantly updated crowd-sourced admin-reviewed food data bank. The users will be allowed to input their favorite daily foods, and an administrative team will review these foods to see if they should be added to the official data bank. Notifications of mealtimes and the ability to view and modify your "history" are features that are currently being worked on, and will be made available to users in the future.

### Limitations

The Twazon app possesses some limitations such as: (1) it doesn't record the daily calories or activity into a history or backlog, (2) there is no meal planning available or recipes offered, (3) there is no professional support, (4) there is no

bar-code scanning feature available as of yet, (5) it cannot generate new tips 365 days a year, and (6) for clarification, the app cannot work offline. Finding solutions to these limitations and upgrading the app consistently will be necessary to encourage and maintain engagement.

### Strengths

The Twazon app is different from other available weight loss applications in that it applies the information found in evidence informed practices and focus group findings, allowing for the specific needs of overweight Saudis to be met through a localized and tailored approach. The Twazon app is currently the only app to provide household measurements for local foods and dishes, making it easier for the user to manage their portion

control. The app also offers recommended daily exercise that is culturally sensitive and suited to individual physical status. It also provides social networking features that allow users to connect and support each other. Based on the biweekly self-assessment, the users receive notifications that give tips about avoiding certain foods and increasing the intake of others.

### The Way Ahead

The effect of the app on weight loss will be examined in a 6-month pre-post intervention study with 200 overweight and obese women from Riyadh, Saudi Arabia. The primary endpoint will be the proportion of the group who lose at least 5% body weight.

## Abstract

**Background:** Osteoarthritis is highly prevalent and has enormous personal and socioeconomic impact. Enabling Self-management and Coping with Arthritic Pain through Exercise (ESCAPE-pain) is an integrated rehabilitation program that helps people understand how exercise can improve physical and psychosocial well-being. Unfortunately, its availability is limited. A Web-based version of the program could increase access for more people. Many Web-based resources are developed without end-user input and result in over-complex, unwanted, ineffective products with limited uptake.

**Objective:** The objective of this study was to codesign a Web-based version of ESCAPE-pain that people with chronic joint pain find engaging, informative, and useful.

**Methods:** To establish older persons' Internet use we conducted a postal survey of 200 people. To establish their opinions, likes or dislikes, and requirements for a Web-based version of the ESCAPE-pain program, we conducted two focus groups with 11 people who had participated in a program based on ESCAPE-pain and two with 13 people who had not. Information from the postal survey and focus groups was used to develop an online prototype website. People's opinions of the prototype website were gauged from thematic analysis of eight semistructured "think aloud" interviews.

**Results:** The survey response rate was 42% (83/200), of whom 67% (56/83) were female and mean age was 67 years. Eighty-three percent of the people had used the Internet, 69% described themselves as either very confident or confident Internet users, and 77% had looked online for health information. With regard to participating online, 34% had read a commentary or watched a video of someone else's experience of a health problem and 23% had tracked a health issue. Key qualitative themes emerged that included engagement, acceptability and usability, and structure and content of the program.

**Conclusions:** Older people use the Internet as a source of health information but have concerns about safe use and quality of information. Users require a credible website that provides personalized information, support, monitoring, and feedback.

**KEYWORDS**

osteoarthritis; exercise; self-care; web-based program; behavioral change; qualitative research; quantitative research

**Introduction**

Chronic joint pain, often labeled osteoarthritis (OA), is one of the most prevalent health conditions [1,2]. It compromises mobility and physical activity, increases the risk of developing comorbidity [3], reduces quality of life, independence [4,5], and makes people feel anxious and depressed [6]. The socioeconomic cost is high and the consequences associated with chronic joint pain will increase as people live longer, become less physically active, and obesity rates increase [2,7].

Evidence-based guidelines recommend exercise/physical activity, simple analgesics, patient information and advice about self-management, pain coping strategies, and maintaining appropriate body weight [8-10]. Unfortunately, only a small minority of people receive these interventions [11-13], whereas most people are prescribed long-term analgesics despite concerns about safety [14,15], effectiveness, costs [16], and unpopularity [17,18]. Others receive an inappropriately early referral for surgery.

Enabling Self-management and Coping with Arthritic Pain through Exercise (ESCAPE-pain) is a rehabilitation program that integrates information, advice, and self-management and coping strategies with an exercise regimen. The program incorporates behavioral change techniques (BCTs) [19] that challenge people's erroneous health beliefs about the harmful effects of physical activity on joint pain. It helps them to appreciate that exercise is safe and has wide physical and psychosocial benefits, which results in changes to their behavior by increasing physical activity levels to reduce pain and improve physical function [17,20,21]. ESCAPE-pain is more clinically effective and cost-effective than usual care [22-25] and popular with participants who have pain associated with knee OA [17,18]. Unfortunately, limited clinical resources (such as time, space, and funding) mean that relatively few clinical departments run the program. Therefore, innovative ways are needed to reach the large and rapidly increasing number of people who could benefit from the intervention.

Digital technologies (telemedicine, Web-based programs, mobile phone apps, and so on) are increasingly popular ways of enabling many more people to access information [26-28]. Adapting ESCAPE-pain as a Web-based program would increase access. However, programs are rarely developed with input from end users [29-31] and little consideration is given to the human-technological interaction or context [32]. The resulting products are often unwanted, unusable, "high-tech, low-impact" Web-based programs that users regard as irrelevant and overly complex. These Web-based solutions have poor uptake, lack effectiveness and adherence, and are often unsuccessfully implemented [26-29,33-36]. Adopting a user-centered approach when designing the program might improve the "fit" between human needs and the technology, improving uptake, implementation, and effectiveness [37]. We used quantitative and qualitative research methods, the principles

of persuasive technology, and human-centered design to discover what people considered important in the content and design of a Web-based version of the ESCAPE-pain program.

**Methods****Survey**

A postal survey was distributed to 200 people aged 50 years and older with chronic (>6 months' duration) knee, hip and/or back pain who had participated in a trial based on the ESCAPE-pain program in the West of England in the United Kingdom [38]. Of these trial participants, 100 were "experienced" (ie, had undertaken the ESCAPE-pain program, in order to understand what they found useful and necessary to be included in a Web-based program) and 100 people were "naïve" (ie, they had not participated in the program but had received a verbal description of the program's content and format) in order to understand the needs of a typical person taking part in the Web-based program. Demographic data and Internet use and experience of the participants were collected. The survey posed questions and invited comments about the format and content of the proposed Web-based resource and people's preferences [39] for features that may improve the effectiveness of Web-based interventions (text messaging, prompts, diaries, support forums, and so on) [37,40-42]. Descriptive analyses were used to describe the survey data.

**Focus Groups and One-to-One Interviews**

To gain a better understanding of people's (dis)likes, opinions, and preferences about the ESCAPE-pain program, how to engage people, and what the Web-based program needed to convey, four focus groups were conducted (n=24 participants in total). Table 1 provides further details of the participant characteristics. Two focus groups involved "experienced" people who had participated in the program (n=11), and two focus groups involved people "naïve" to the program (n=13). Participants were purposively selected from the survey based on characteristics of age, sex, duration and site of pain, and their use of and confidence in using the Internet. Focus groups comprised five to seven participants. The focus groups took place in university or hospital settings, facilitated by one of the authors (JP) using a topic guide (Multimedia Appendix 1), and lasted on average 94 minutes (range 84-105 minutes). Field notes were also taken.

The focus groups and interviews were recorded, transcribed, checked for accuracy, and anonymized, and emerging themes were identified using thematic analysis [43]. Transcripts from all focus groups were coded by JP. The first two focus group transcripts were independently coded by all the authors, who discussed the coding and initial emerging themes. The topic guide was amended to reflect the emerging themes, which was used in the following focus groups. The additional focus group transcripts were independently coded by DC.

**Table 1.** Focus group and interview participant characteristics.

Pseudonym	Sex	Age range (years)	Duration of pain (years)	Site of pain	Experienced or naïve to the ESCAPE-pain program	Confidence in using the Internet	One-to-one interview
John	Male	60-69	>10	Knee and back	Experienced	Very confident	No
Patricia	Female	60-69	>10	Hip and back	Experienced	Neither confident nor unconfident	Yes
Barbara	Female	60-69	1-5	Knee and back	Experienced	Very confident	No
Linda	Female	60-69	1-5	Hip and knee	Experienced	Very confident	No
James	Male	70-79	5-10	Knee	Experienced	Confident	Yes
Mary	Female	60-69	5-10	Multiple	Experienced	Confident	No
Carol	Female	60-69	>10	Multiple	Naïve	Confident	No
Richard	Male	60-69	5-10	Knee	Naïve	Confident	Yes
Betty	Female	70-79	>10	Back	Naïve	Neither confident nor unconfident	Yes
Edith	Female	70-79	>10	Multiple	Naïve	Neither confident nor unconfident	No
William	Male	70-79	5-10	Knee	Naïve	Neither confident nor unconfident	No
Charles	Male	70-79	<1	Knee	Naïve	Unconfident	No
Shirley	Female	70-79	>10	Knee	Experienced	Very confident	No
George	Male	50-59	1-5	Hands	Experienced	Very confident	No
Karen	Female	60-69	1-5	Knee	Experienced	Confident	Yes
Michael	Male	60-69	1-5	Knee	Experienced	Very confident	Yes
Susan	Female	70-79	5-10	Back	Experienced	Very confident	No
Gerald	Male	60-69	>10	Back	Naïve	Confident	No
Gary	Male	60-69	1-5	Knee	Naïve	Confident	Yes
Daniel	Male	60-69	5-10	Hip	Naïve	Confident	No
Donna	Female	60-69	5-10	Back	Naïve	Confident	Yes
Paul	Male	60-69	5-10	Knee	Naïve	Confident	No
Frank	Male	60-69	5-10	Back	Naïve	Very confident	No
Walter	Male	60-69	5-10	Knee and hip	Naïve	Very confident	No

## Prototype Website

The results of the survey and emergent themes from the focus groups were used to design a prototype website (see [Figure 1](#)). This had limited online function and offline material and resources, consisting of four external pages and four internal pages. The external pages included the following:

- “Home” page gave a brief overview of the ESCAPE-pain program and a Web-based promotional video explained the concept of the program.
- “About ESCAPE” explained the history of the program and its potential benefits, provided information about the website's contents, videos of participant endorsements and testimonials, and information of partner organizations.
- “Frequently Asked Questions.”

- “Contact Us” had a registration section and ways to contact the ESCAPE-pain team.

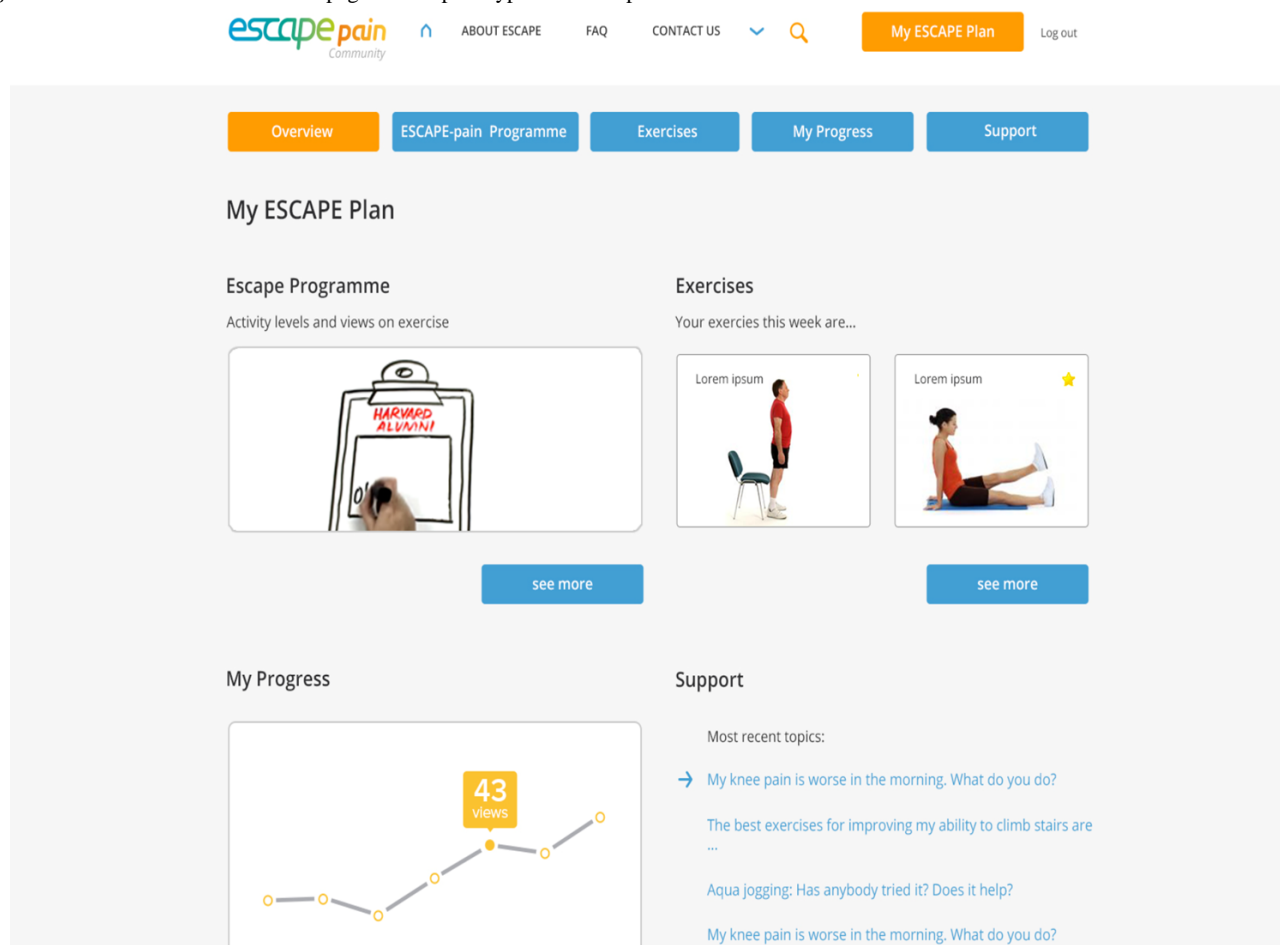

The internal pages consisted of the following:

- “My ESCAPE Plan” page provided an overview of the 12 modules that compose the program, such as physical activity, exercise, goal setting, action plans, pacing, drug management, diet, home exercises, understanding pain, pain management, and relaxation.
- “Exercise” consisted of a library of “easy,” “medium,” or “advanced” exercise videos suitable for people with joint pain, which they could watch and which provided instructions on how to perform the selected exercise.
- “My Progress” provided an example of how people could input data and view graphical feedback on the amount of

exercises they performed, as well as their activity levels, mood, and so on.

- “Support” provided an example of a forum where participants could join to discuss joint pain-related issues, with links to other Web-based resources.

**Figure 1.** A screenshot of the internal pages of the prototype ESCAPE-pain website.

### “Think Aloud” Semistructured Interviews

The prototype website was then tested by eight participants using semistructured interviews and a modified “think-aloud” technique [44]. The participants were purposively selected based on the key characteristics of age, sex, duration, site of pain, and their confidence in using the Internet. JP conducted the interviews at participants' homes, which lasted on average 107 minutes (ranging between 78 minutes and 142 minutes). Participants were shown the prototype Web-based version of ESCAPE-pain and asked questions using a topic guide developed from themes emerging from the survey and focus groups and features of the prototype website (Multimedia Appendix 2). Table 1 indicates those participants who were involved in the “think aloud” interviews.

The interviews were analyzed using a thematic analysis [43]. JP coded all the interviews, the first two interview transcripts were independently coded a second time by MH, DC, and NW, then each member coded two additional transcripts so that each interview was coded independently by three authors. The final themes were then mapped to the behavioral change taxonomy [19]. The findings from the focus groups and interviews are presented together.

### Ethics

Ethics approval was obtained from the National Research Ethics Service Committee South West-Central Bristol (Research Ethics Committee reference 11/SW/0053). All participants received information about the project and gave signed informed consent.

## Results

### Survey

The survey response rate was 42% (83/200). The demographics of the respondents reflect the demographics of people with OA, predominantly female (56/83, 67%), mean age was 67 years (range 53-84 years), over two thirds were retired and had pain in several joints for a prolonged time (Table 2).

Most respondents (71/83, 86%) had used the Internet, of whom 83% (59/71) used it daily and almost exclusively at home (99%). Most people felt confident or very confident using the Internet (49/71, 69%) with personal computers, tablets, laptops and/or mobile phones. Although more than three-fourths of the people used the Internet to search for information about health problems, few (14/71, 20%) had used this information to manage their condition (Table 3).

**Table 2.** Participant demographics.

Participant demographics		Survey (n=83), n (%)	Focus group (n=24)	Interviews (n=8)
<b>Sex</b>				
	Male	27 (33)	12	4

### Focus Groups and Interviews

From the focus groups and “think aloud” interviews, three key themes emerged that influenced people's use of the proposed

website ([Table 4](#)): (1) initial and sustained engagement with the website, (2) acceptability of a Web-based exercise-based self-management program, and (3) content/structure of the program.

**Table 4.** Features to encourage engagement with and improve effectiveness of a Web-based program mapped onto the behavioral change taxonomy [19].

Theme	Subtheme	Supporting quote	Taxonomy
Engagement	Credibility	<p>"...you go to sources that you know are genuine...For medical information I would always go to the NHS website..." Mary</p> <p>"...it's got to be recommended to you by a professional..." Paul</p> <p>"...I am very wary about the web and medical problems...but this is one that was recommended by the GP..." Daniel</p> <p>"...[research information] adds weight to the thing...communicates integrity I think it's a serious piece of work..." Donna</p> <p>"...not sponsored by drug companies..." Gerald</p>	<p>9 Comparisons of outcomes</p> <p>9.1 Credible source</p>
	Patient testimonials	<p>"...I think [patient testimonials] explained the purpose very well...it showed a good cross section of different people doing different exercises...I think I would be encouraged to pursue it further...Makes you realize that people can get good improvement. Yes that these are people who have been through the program and have found benefit and its much improved their quality of life...it makes you realize you are not alone..." Patricia</p> <p>"...I always skip over those sort of things..." John</p> <p>"...I don't actually I like reading other people's experiences because it somehow makes it feel more real you know...this is really flippant but if it's a recipe I have looked up on line and you know a hundred people have said oh yeah that was absolutely brilliant I will give it five stars or something then you think well great I'll do that..." Mary</p>	<p>6 Comparison of behavior</p> <p>6.1 Demonstration of the behavior</p> <p>6.2 Social comparison</p> <p>6.3 Information about others' approval</p>
	Social identification	<p>"...this program is designed for later life people isn't it? So it should have them in it I think. Not young people who can do it easily and no pain, but people who are actually finding it hard..." James</p> <p>"...I watched a little clip a couple of years ago because I had labyrinthitis and that was really awful and seeing this girl saying how she had experienced it and how she came through it and she was obviously ten time worse than mine..." Barbara</p>	
Acceptability and usability	Aesthetics	<p>"...something nice and bright that would attract you to the site, you know to attract you...very self-explanatory..." Betty</p> <p>"...plying a very positive image..." Gerald</p> <p>"...its plain and simple its not too fussy it tells you what you want to know..." Patricia</p> <p>"...well I think simplicity is the best thing...it's got to be interesting..." George</p> <p>"...big fonts, nice and clear, plain simple language, hasn't got thousands of links on it, asks intelligent questions and leads the user to the information you get to what you want within about 2 or 3 screens..." John</p> <p>"...[not] loads and loads of advertisement..." Richard</p>	
	Functionality	<p>"...something simple you know so people can just click in and find out what they want..." Betty</p> <p>"...easy to navigate through...navigation is the key..." Mary</p> <p>"...I am not going to spend hours trawling through stuff but if there's a star or something like that that says this that and it you know captures the attention because there is a need then you can go into that and it opens up the bit that you need..." Karen</p> <p>"...you don't want hundreds of links..." Richard</p> <p>"...one of the problems with links as well is that you link to something and that gives you a link to something else and before you know where you are you can't remember how you got there..." Carol</p>	

Theme	Subtheme	Supporting quote	Taxonomy
Content and structure of program	Registration	<p>"...oh not something you have to register for..." Barbara</p> <p>"...I hate that you have to put passwords in...and all that malarkey just get the flipping information..." Mary</p> <p>"...certainly not open an account because that always sounds like money to me..." James</p> <p>"...people ought to log on they should sign up I mean because I think it would help enormously the feeling of actually belonging to something..." Michael</p>	
	Technical capability	<p>"...my mother-in-law is 90 plus she has never switched a computer on she doesn't know how to use it...she will never use that web-site..." Gerald</p> <p>"...this problem of aged people and computers is going to drift away...maybe it's only a problem possibly for another 15 years..." Daniel</p>	
	Information and advice	<p>"...[information] needs to be in a visual form rather than a written form...an executive summary of the sequence rather than the detail of the sequence so you would read the executive summary and then get into the detail..." James</p> <p>"...if I got them at my bedside cabinet or pinned up on the fridge, I will always remember to do them..." Shirley</p> <p>"...for someone that's coming in and using it for the first time it would be nice to if its presented sequentially if someone's going back to it they want to go directly to there..." John</p>	<p>4 Shaping knowledge</p> <p>4.1 Instruction on how to perform a behavior</p> <p>7 Associations</p> <p>7.1 Cues/prompts</p>
	Exercise	<p>"...a nice little looped video wouldn't they, demonstrating the exercise..." John</p> <p>"...it's clear what the exercise is, and how it's going to benefit you, and what you might do wrong, and how that is going to affect you..." Linda</p> <p>"...how often should these exercises be done, and how many repetitions all the things that we had in the class that we went to..." Mary</p>	<p>4 Shaping knowledge</p> <p>4.1 Instruction on how to perform a behavior</p> <p>5 Natural consequences</p> <p>5.1 Information about health consequences</p>
	Personalized	<p>"...need for the website to be an individual's website...they can have you know their own diary, they can have their own records..." Michael</p> <p>"...it has to be personalized to you otherwise you know why do you bother to turn it on...it shows you what you have done so that you can when you have done something you can actually tick it and you get something to show you have done something...this is the goal setting... right so you have got your goal setting you are achieving so and so there's your action plan have you done it and is there something along the line that shows you, you have done something..." Gary</p> <p>"...if I was going to start my activity and exercise with it I would want the goal setting..." Donna</p> <p>"...set your target and get a little bit better each time you do it, or each week you do it, sort of build yourself up..." Betty</p>	<p>1 Goal setting and planning</p> <p>2 Feedback and monitoring</p> <p>3 Social support</p>

Theme	Subtheme	Supporting quote	Taxonomy
	Monitoring	<p>“...if there was sort of a little personal diary where you could say, ‘Tuesday did 10 of this and 15 of that,’ then maybe some monitoring person says, ‘well next week you should do 20 of those and 25...I would definitely want to monitor my progress...” Patricia</p> <p>“...you have got your exercises, you have got my progress. I like that because you can then monitor where you are and you have also got support...I can look at that and feel I have achieved...I like to see the chart because the progress bit like I did for my weight so I would like to see that you know because it would then tell me you know have you done them this week or haven't you done them...you can look to see well three months ago I could only do so and so ooh, look now I can do this so again its goal setting if you like, but I mean its yeah its moving forward all the time...” Gary</p> <p>“...I don't know whether I would monitor myself...” Betty</p>	<p>2 Feedback and monitoring</p> <p>2.2 Feedback on behavior</p> <p>2.3 Self-monitoring of behavior</p> <p>2.4 Self-monitoring of outcome behavior</p>
	Peer support	<p>“...a members site you can have a blog....so you could actually contact then talk to people with similar problems...” Gerald</p> <p>“...it could be interesting to see how they are getting on and support each other you know if they have had a down day or something has gone wrong sort of be able to be a bit supportive...I would like to be in contact with other people...to see how other people do the exercises it gives you a good idea of whether you are doing it right...[has she used forums?] very rarely...it was too time consuming...I wasn't sure that it was being any help for me...” Patricia</p> <p>“...you get somebody else's feedback on what they do to get rid of their knee pain in the morning. I mean it might not suit you, you could try it and if it doesn't suit you perhaps you could look for something else that would help you, do you know what I mean?...” Betty</p>	<p>3 Social support</p> <p>3.1 Unspecified</p> <p>3.2 Practical</p> <p>3.3 Emotional</p>
	Professional support	<p>“...you need some personal physio input to start with...you need to be doing that first set of exercises with a physio so you get direct feedback...eight weeks, or whatever it is, you can then go off and do it on the internet...not standing on its own as a substitute [for a face-to-face program]...” James</p> <p>“...I think I would want something personal...something more than just being told to go and look at a website...you want reassurances I guess so if you have been doing it for two months then nothing has happened then you actually want to know how long you should be doing the exercises...” Barbara</p> <p>“...I think it would be difficult to give people the confidence to accept [an Web-based program] as a sole treatment avenue...” John</p> <p>“...I would feel less confident about the information than if I had had some physical contact with doctor, physio something else beforehand and I think probably most people would think along those lines, you know, like your concerns about a replacement [for a face-to-face program] it doesn't feel that comfortable...” Linda</p> <p>“...websites that you can go on that there is literally somebody at the other end so you can type in a question and then you get an answer back...” Paul</p> <p>“...an email to say have you done your exercises this week...” Patricia</p> <p>“...I would need somebody who actually knew about pain and knew about exercise...” Michael</p>	<p>2 Feedback and monitoring</p> <p>2.7 Feedback on outcomes of behavior</p> <p>3 Social support</p> <p>3.1 Unspecified</p> <p>3.2 Practical</p> <p>3.3 Emotional</p>

## Engagement

Finding a health-related website usually results from a purposeful search for information about a specific health issue,

for example, joint pain. However, people are often skeptical and mistrustful of information they find online. In our study, people wanted to be directed to Web-based resources by a trusted “source” such as a health care professional [45] or

credible organization (ie, a statutory health body) [46-48]. They were mistrustful of commercial websites with advertisements, which they saw as promoting goods for financial gain with little regard to whether it will help the patient [46,47]. The website needed to capture people's attention visually, with content that was obviously relevant and created a positive association between the website and the health benefits it could bring [46,47]. Important determinants for engagement with the website were video testimonials of people discussing their experiences of participating in the program, with personal and social traits that potential users could identify with [46,47].

### Acceptability and Usability

In general, people thought a Web-based ESCAPE-pain program could be an effective way to help them self-manage their condition. However, they thought there were limitations to how well they could do this and wanted to know when to seek advice from a health care professional, especially in regard to the exercise regimen. Some people were willing to accept the Web-based program as a replacement for face-to-face contact, while others saw it as an adjunct to the supervised face-to-face program that would help them sustain benefit and motivation after completing the program.

Acceptability partly depended on people's technical ability in using Web-based resources. Regular Internet users, familiar with technology and using Web-based resources to manage a health condition, were most accepting of the proposed website. Infrequent users, unconfident in their ability to use the Web-based resource correctly, thought they were less likely to use the website.

The website had to be aesthetically pleasing, which was defined as simple, bright, attractive, and interesting. However, people's aesthetic preferences (ie, color schemes, layout, icons, dropdown menus, scroll bars, and so on) varied greatly and were frequently mutually exclusive.

Navigation around the website had to be easy and intuitive so people could find what they wanted quickly, and information had to be easy to understand and free from jargon and acronyms. Internal and external links needed to be working, obvious, self-explanatory, and up to date. The website also needed to be optimized to work on different devices (ie, laptop, mobile phone, tablet), platforms (ie, Android, iOS), and Web browsers.

### Content and Structure of a Web-Based ESCAPE-pain Program

People wanted information and advice tailored to their personal needs, which was easy to understand, was practicable, and brought tangible benefits [48]. To surmount the difficulties of individuals having different needs and preferences, they suggested each person could have "their own website" that stored personalized information and advice, allowed for creation and adjustment of personal goals, as well as monitoring and recording of progress and achievements. When it was suggested that people might need to register to use the website to its full potential (ie, monitor, record, and chart progress and enable provision of targeted personalized support) many people were uncomfortable [48]. Even if registration was free they thought it might be a barrier to some people using the website because

they would be suspicious about the reasons for registration. People also expressed concerns about the difficulty of remembering usernames and passwords.

In general, people who had "experienced" ESCAPE-pain thought a Web-based version should replicate the program. People "naïve" to ESCAPE-pain asked for broader information to explain their joint pain and how to cope with its effects. For example, they wanted to know about the following: why they get pain at night; home adaptations or assistive devices that might help them cope; what the "placebo effect" was; and the association between alcohol and joint pain. People also wanted information about the effectiveness of diet and complimentary medicines (ie, fish oils, food supplements, acupuncture) in preventing or relieving joint pain. They thought this might be best presented as a brief summary of essential information, educational videos, supplemented with printable leaflets for reference and linked to reputable external sources for more in-depth information [39].

When delivered face-to-face in a clinical setting, the educational sessions of ESCAPE-pain are presented in a specific sequence. However, people thought that online this would be very restrictive and cumbersome; they wanted easy access to relevant information when it was most appropriate rather than having to navigate through "irrelevant" information. For example, people wanted to find information about dealing with an exacerbation of pain when they were in pain without going through sessions discussing weight control and diet.

### Exercise

The ESCAPE-pain program focuses on the benefits that physical activity and exercise have on pain, mobility, and physical and psychosocial function. To achieve this, people undertake a progressive exercise regimen, starting off with simple exercises and gradually increasing both the number of repetitions and the quality of performance, while adding more challenging exercises as they improve. When delivered face-to-face, the exercises are supervised by an appropriately qualified professional. The Web-based program would necessitate participants to choose, perform, and progress their own exercise regimen. To achieve this, people thought they would need detailed information about exercises and exercising—how to choose appropriate exercises, how to perform them correctly, how many repetitions they should do, how often, what they should feel, and how they would know whether they were doing an exercise incorrectly or potentially causing harm. Videos showing people exercising with instructions on how to do them and how often were well received. Many people said they would be happy to try the exercise regimen, but some were concerned about performing the exercises without supervision and wanted to know when they should seek advice from a health care professional.

### Monitoring

Many people wanted to document their progress to evaluate the usefulness of the program. Monitoring was also seen as a good way to engage people with the Web-based program. However, views on what should be monitored, how, and when varied. Most people thought online diaries documenting levels of pain and physical activity would be essential. Mood and medication

were also suggested but considered less important. People who were more engaged with self-managing their condition wanted to monitor symptoms frequently, whereas others thought they would only likely monitor themselves occasionally, when reminded, or if it was compulsory. In some cases, monitoring was considered an intrusive burden requiring time, effort, technical ability, and appropriate hardware.

### Support

Another way of maintaining engagement and interaction with a website is by providing support. People were particularly keen to have some form of support from a health care professional (ie, physiotherapist, general practitioner) who could monitor progress, guide progression, reinforce health messages, and provide reassurance, motivation, and encouragement. Peer support through online communities (ie, forums, blogs) where people could share experiences to learn from and support other people with joint pain was seen as a positive feature, although users thought it would need to be moderated to prevent inaccurate and inappropriate postings.

### Discussion

Using persuasive technology and human-centered design we investigated what features help people discover, engage with, and benefit from a Web-based program to manage chronic joint pain. If endorsed by credible organizations, some participants would be happy to accept a Web-based program as an alternative to a face-to-face program, although others did not believe it could adequately replace a face-to-face program aiming to change entrenched beliefs and behaviors. To be effective, information needs to be easy to understand and personalized for each user. People want to monitor their progress, receive feedback and guidance from a health care professional, and learn from others with similar problems. Feedback on what this might entail and the way it would be delivered varied considerably, and could be mutually exclusive, but overall it needed to be simple to minimize burden and technical requirements and, above all, protect people's privacy.

Increasingly, older people use the Internet as a source of health information [49] and accept it as part of their management [39], especially if it supplements—rather than replaces—personal care [50]. However, few utilize online information to fully self-manage their condition, often doubting the accuracy of the online information and the motives of commercially sponsored websites [46]. Approval and endorsement by health care professionals, coupled with testimonials by people that users could identify with, are very influential in encouraging people to visit a website and convincing them to engage with it and implement online advice [46,47,50].

Pain is a ubiquitous, multifaceted problem that evokes unique and varied personal experiences and consequences. It often induces health beliefs that result in harmful behavior. For example, people with chronic joint pain commonly experience pain during physical activity. They erroneously surmise activity-related pain is harmful and reduce or avoid activities to prevent causing pain and harm—"fear-avoidance behavior." Unfortunately, fear avoidance results in muscle weakness that

can exacerbate pain, functional limitation, and disability [51,52]. Face-to-face behavioral change programs, such as ESCAPE-pain, incorporate BCTs to challenge these erroneous health beliefs and promote healthier behavior, namely, the role of physical activity in the management of chronic joint pain. Effective Web-based behavioral change programs need to incorporate the BCTs that make face-to-face programs effective [19,53-57].

Altering behavior involves several steps. First, people need to be convinced of the consequences of poor health behavior (inactivity) and good behavior (activity). They then need clear, unequivocal information and instructions about what (not) to do, demonstrations of how to perform specific exercises, how often, and what to expect. Knowing why and how to exercise helps form strong "implementation intentions" [58]. Unfortunately, good intentions are often not turned into action. Bridging this "intention-behavior gap" requires people to form "action plans" (which specify behaviors they want to perform, where, when, and how) and "coping plans," which raise awareness of their personal strengths, weaknesses, and situations that could undermine behavior and prepare a coping strategy to overcome these barriers [59-61]. Behavioral change is also facilitated if people self-monitor their behavior and compare it with what is expected of them (their level of physical activity compared with how physically active should they be) and this includes factors such as goal setting, feedback, and support of performance and progress [19,53,57]. Although information is usually provided in Web-based behavioral change programs, the incorporation of methods to help people construct intentions to change, such as goal setting, action plans, and interactive feedback and support, are more difficult and consequently do not often feature in many Web-based programs [56].

Our study highlights the importance of BCTs. Participants intuitively appreciated that they require in-depth, accessible information to explain and demonstrate why and how to exercise correctly. Additionally, users value self-monitoring and self-regulation, feedback, support, and encouragement, all of which can be personalized to each person's unique circumstances to make it effective and sustain engagement [55]. However, different people have varying preferences, which are often mutually exclusive. Achieving personalization is extremely difficult as it increases user time and effort burden, technical requirements, cost, and the need to register. These are features people identify as barriers to engaging with Web-based resources. Moreover, patient forums that are often advocated to facilitate health care professional and peer support [55] were rarely used by our survey respondents and the respondents in other studies [62,63].

### Strengths of the Study

The survey response rate (83/200, 42%) was reasonable and allowed us to recruit focus groups and interviewees representative of people with chronic joint pain. Using participants who were "experienced" to an ESCAPE-pain based program enabled us to understand what they considered important to convey and how to convey it, while using people "naïve" to the program enabled us to understand what more

“typical” people with no prior experience of the program would need in order to apply it.

### Limitations of the Study

Although participants were purposely sampled to reflect the wide opinions of people, only one person in the focus groups and none of the participants selected to test the website were unconfident about using the Internet. This means that Internet users lacking confidence were underrepresented. However, this did not have a significant impact on our findings because the prototype tested had limited functionality and was problematic even for experienced, confident Web users. Another limitation of the study was that the prototype website could only be displayed on a laptop or desktop computer, meaning it was

difficult for users who are familiar with other devices, such as tablets, to feel as confident when testing the website and giving their opinions.

### Conclusions

As more people live longer, and obesity and sedentary lifestyles increase, the prevalence of chronic joint pain will increase [1,2]. Web-based programs have the potential to reach the large number of people requiring help, but historically the uptake of, effectiveness of, and adherence to Web-based interventions are notoriously poor [64-66]. Persuasive technology and human-centered design and business modeling can inform the design and content of engaging, effective Web-based behavioral change programs.

### Acknowledgments

The authors would like to acknowledge our patient research partner Edith Anderson, all study participants, and Salaso, who developed the prototype website. We also acknowledge Arthritis Research UK for funding the study.

## Abstract

**Background:** Systemic Lupus Erythematosus (SLE) is a serious, complex, and chronic illness. Similar to most other chronic illness states, there is great interest in helping persons with SLE engage in their disease management.

**Objective:** The objectives of this study were to (1) develop the Lupus Interactive Navigator (LIN), a web-based self-management program for persons with SLE, and (2) test the LIN for usability and acceptability.

**Methods:** The LIN development platform was based on the results of preliminary comprehensive needs assessments and adapted from the Oncology Interactive Navigator, a web-based tool developed for persons with cancer. Medical researchers, writers, designers, and programmers worked with clinical experts and persons with SLE to develop content for the LIN. Usability and acceptability of the LIN was tested on individuals with SLE meeting American College of Rheumatology criteria, who were recruited from five Canadian SLE clinics. Participants were provided with access to the LIN and were asked to use it over a two-week period. Following the testing period, participants were contacted for a 30-minute telephone interview to assess usability and acceptability.

**Results:** The content for the LIN was subdivided into six primary information topics with interview videos featuring rheumatologists, allied health professionals, and persons with SLE. Usability and acceptability of the LIN was tested on 43 females with SLE. Of these, 37 (86%) completed telephone interviews. The average age was 43.6 (SD 15.9) years and disease duration averaged 14.1 (SD 10.8) years. Median time spent on LIN was 16.3 (interquartile range [IQR]:13.7, 53.5) minutes and median number of sessions was 2 (IQR: 1, 3). Overall, Likert ratings (0=strongly disagree; 7=strongly agree) of website usability and content were very high, with 75% scoring >6 out of 7 on all items. All participants agreed that LIN was easy to use, would

recommend it to others with SLE, and would refer to it for future questions about SLE. Very high ratings were also given to relevancy, credibility, and usefulness of the information provided. Overall, 73% of the participants rated all topics helpful to very helpful. Participants who reported more prior knowledge about SLE rated items regarding improvement in knowledge and helpfulness relatively lower than persons with less prior knowledge. Most participants commented that the LIN would be very useful to those newly diagnosed with SLE. Minor revisions were recommended.

**Conclusions:** This study furthers the understanding of the needs in the SLE community and delivers a unique eHealth tool to promote self-management in persons with SLE. The LIN was found to be highly acceptable in content and usability. The information provided on LIN may be most helpful for individuals with less experience with the disease, such as those newly diagnosed, indicating the need to tailor the content for persons with more SLE experience.

(*JMIR Res Protoc* 2016;5(2):e44) doi:[10.2196/resprot.4219](https://doi.org/10.2196/resprot.4219)

## KEYWORDS

Systemic lupus erythematosus; web-based eHealth tool; self-management; empowerment; usability; navigation

## Introduction

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease associated with multi-organ involvement and characterized by frequent flares. The unpredictable nature of the illness and complexity of treatment create serious challenges in disease management to persons with SLE and their health care providers [1]. Self-management interventions are essential to meet these challenges and they must be built on sound person-centered approaches and aimed at self-empowerment strategies. In chronic illness management there is an ever increasing need for patients to play more active roles in their health care, and work in partnership with their health care providers. However, for this to occur, patients need to be equipped with a technology that will provide them with appropriate information and accessible support tools. We used qualitative research methods to better define the information and support needs of persons with SLE and health care providers [2,3]. Oncology Interactive Navigator (OIN) is a web-based tool developed to build a sense of competence around living with cancer, support autonomy, and engage patients and families as partners in care. Based on the OIN and preliminary work in SLE, we developed the Lupus Interactive Navigator (LIN). The

LIN was designed to provide education and to support self-management in persons with SLE. This paper reports on the development of the LIN and the results of the testing of usability and acceptability of the LIN.

## Methods

### Development of the Lupus Interactive Navigator

The results of the needs assessments were organized into topic groups to form the basis of the *Table of Contents* and guide content development of the LIN. By adapting the OIN platform and approach, medical researchers, writers, designers and programmers worked with clinical experts and persons with SLE to outline the *Table of Contents* and write the first plain-language draft for the LIN. Required graphics and interview videos featuring rheumatologists, allied health professionals, and persons with SLE were produced to complement the written content.

The content for the LIN was subdivided into six primary information topics that were derived from the qualitative analysis of the results of our focus groups and surveys [2,3]. Each primary topic was subdivided with pull-down tabs for further elaboration on each topic (Table 1).

**Table 1.** Summary of LIN *Table of Contents*.

About Lupus	Symptom Management & Treatments	Accessing Healthcare	Support Services	Family, Friends & Work	Living Well With Lupus
What is Lupus	Symptoms of Lupus	Your Care Team	Community Services search tool to locate available lupus- support resources in close proximity to the user's postal code	Family & Lupus	Managing Stress & Fatigue
What Causes Lupus?	Medications to Treat Lupus	Communicating with Your Care Team		Lupus & Work	Getting Enough Sleep

A Lupus Diagnosis	Preventing and Managing Flares	Transitioning From Pediatric to Adult Care		Resources for Family Members & Friends	Depression
Prognosis	Monitoring Your Lupus	Accessing Care in Rural Areas			Overcoming the Emotional Hurdles of Lupus
Flares and Remissions	Complementary Therapies				Maintaining a Healthy Diet
Lupus & The Body	Other Therapies				Vaccinations
FAQs/ Myths	Clinical Trials				Pregnancy & Lupus
					Young People & Lupus

## Usability and Acceptability of the Lupus Interactive Navigator

### Participants

Individuals meeting the 1997 SLE American College of Rheumatology criteria [4] were recruited from five Canadian SLE clinics based in university health centers in Vancouver, Edmonton, Winnipeg, Montreal and Quebec City. Each center had obtained prior approval from their local research ethics board for this study. Consenting participants were provided information on how to access the LIN website and were asked to use their devices (computers, tablets, or mobile phones) to browse LIN over a two-week period. The number of log-ins and the duration of each session were recorded for each participant. Following the two-week testing period, participants were contacted for a 30-minute telephone interview to assess their opinions about the LIN and to identify areas for improvement.

### Telephone Interview

Content for the telephone interview was established following discussions with members of an expert panel including a rheumatologist, a psychologist, a nurse, the developer of the OIN, and an individual with SLE. The telephone interview consisted of a four-page document including (1) a script to be used as the introduction to each interview, (2) questions to assess demographics and participant characteristics, (3) Likert scales to rate website usability, content, and perceived helpfulness, and (4) open-ended questions to assess overall acceptability and

usability of the LIN and to provide recommendations and comments.

*Participant characteristics* included age, marital status, education, disease duration, and factors related to computer usage, including ease with using computers, time spent on the Internet, time spent searching for health information, and type of device used.

### Website Usability and Content

Likert scales were used to assess website usability and content quality and quantity. Participants were asked to rate 17 items on a 7-point Likert scale (0=strongly disagree; 7=strongly agree). Participants who scored items <3 were asked to elaborate. Scores equal to or >5 were considered moderate to strong agreements. Scores equal to or <4 were considered low to no agreement.

### Helpfulness

Participants were asked to rate each of the six topic sections using a 5-point Likert scale in terms of how helpful each section was to them (1=not at all helpful; 5=most helpful). Scores equal to or >4 were considered *helpful* to *very helpful*. Scores equal to or <3 were considered low to *not at all helpful*.

### Recommendations and Comments

Four open-ended questions were asked to further assess if there was information missing, and give participants the opportunity to comment on the overall experience and provide recommendations for improvement.

## Statistical Analyses

The data was transferred from the interview questionnaire to Microsoft Excel (2007). Means, medians, and percentages were calculated for continuous variables and percentages were calculated for categorical variables.

## Results

### Development of the Lupus Interactive Navigator

The LIN was constructed from a *Table of Contents* that was developed from the results of the prior focus group studies and surveys performed in preparation for this project [2,3]. An abbreviated *Table of Contents* is provided in Table 1, reflecting the topics that were prioritized by the focus groups and surveys. Figure 1 provides a glimpse of some of the web-based pages that persons with SLE can access once logged into the LIN.

Figure 1. Examples of LIN web pages.

### Usability and Acceptability of the Lupus Interactive Navigator

Forty-three women with SLE were recruited. Of these, six participants did not complete the two-week follow-up telephone interview (time constraints, 2; illness, 2; could not be contacted, 2). Thirty-seven (86%) completed the telephone interviews. Median time spent on LIN was 16.3 (interquartile range [IQR]: 13.7, 53.5) minutes and median number of sessions was 2 (IQR: 1, 3).

### Characteristics of Participants

Table 2 describes the characteristics of the study participants. The average age was 43.6 (SD 15.9) years, disease duration averaged 14.1 (SD 10.8) years, 57% (21/37) were married, and 86% (32/37) had completed post-secondary education. Weekly reported average Internet usage was 15.8 (SD 24.6) hours with 2.8 (SD 0.9) hours used for health information. Ratings for overall experience, website usability, and content are shown in Table 3.

**Table 2.** Participant characteristics (N=37).

	Mean (SD)	n (%)
Age (years)	43.6 (15.9)	
Disease duration (years)	14.1 (10.8)	
Gender (% female)		37 (100)
Marital status (% married)		21 (57)
Education (% post-secondary)		32 (86)
Comfort with computers (% comfortable to very comfortable)		27 (73)
Internet usage per week (hours)	15.8 (24.6)	
Health information searches per week (hours)	2.8 (0.9)	
<i>Preference for web searching</i>		
Personal Computer		24 (65)
Tablet		7 (19)
Mobile Phone		6 (16)

**Table 3.** Ratings of website usability and content based on 37 participants (1=strongly disagree; 7=strongly agree).

Statement	Mean (SD)	% equal to or >5
<i>Overall experience</i>		
I would recommend this website to others seeking information about lupus	6.8 (0.5)	100
Would go to this website if I had a question about lupus	6.2 (1.5)	89
My friends and family would benefit by accessing this website	6.0 (1.8)	89
<i>Website design</i>		
Easy to learn how to use the website	6.7 (0.6)	100
Easy to find information on this website	6.6 (0.6)	97
Easy to read information	6.6 (0.7)	100
Easy to use the website	6.6 (0.6)	100
<i>Content</i>		
Information was credible	6.6 (0.8)	97
Information was relevant	6.6 (0.7)	97
Information was useful	6.5 (1.1)	97
Satisfied with the amount of information	5.9 (1.6)	87
Improved knowledge about lupus	5.8 (1.6)	87
Improved knowledge about coping	5.4 (1.9)	78
Improved knowledge about resources	5.4 (1.8)	77
Will help me maintain better health habits	5.3 (1.7)	69
Improved knowledge about medications	5.0 (1.8)	68
Will be useful to help me prepare for next doctor's visit	5.0 (1.9)	67

### Overall Experience

All participants strongly agreed that they would recommend this website to other persons with SLE seeking information about SLE and 89% (33/37) would refer to it to answer their own future questions about SLE. Participants also agreed that family and friends would benefit from accessing the LIN.

### Website Usability

All items assessing website usability received *high to very high* ratings. All participants were in *high* agreement that the website was easy to learn and use.

### Content

Over 97% (36/37) of the participants were in *high to very high* agreement that the content was useful, credible, and relevant.

Additionally, 86% (32/37) of participants were satisfied with the amount of information provided. Ratings for items relating to gains in knowledge about lupus, coping, and resources were *high* (77-87%). Somewhat lower ratings were given for items relating to gains in knowledge about medications, helpfulness in maintaining good health habits, and preparing for clinic visits (67-69%). Participants stated that the reason for giving lower ratings was prior knowledge about these items. Participants with disease duration <5 years had similar ratings for these items as those with disease duration >5 years. However, there were only 11 participants with short disease duration in our sample.

### Helpfulness

Table 4 shows the ratings of helpfulness of each of the six major information topics provided in LIN. Overall, 73% (27/37) of the participants rated all topics *helpful* to *very helpful*.

Ratings of perceived helpfulness for each individual major topic varied across topics. The topic *About Lupus* (providing general information about SLE) was perceived as the most helpful (91%) and the topic *Support Services* (providing information about available resources) was considered least helpful (57%). Once again, lower ratings were given by those who reported prior knowledge about SLE than those with less prior knowledge (62% versus 86%).

All participants voiced enthusiasm about LIN and were eager to offer comments and recommendations to further improve this website. None of the participants reported any information missing from the content. However, 26 participants would have preferred more information about specific topics. Of these, the most frequently requested were: more information regarding current research about new medications for SLE (n=9); coping strategies including yoga, meditation, psychosocial, and complementary/alternative treatments (n=9); and adding more support resources on the resource locator for Manitoba and Alberta, including support groups and social workers (n=7).

Minor changes were recommended to improve appearance and usability of the LIN, including changes to font and facilitating drop-down menus. Recommendations to improve content included (1) more videos of physicians and youths, (2) more pictures of rashes and medications, (3) the addition of social networking tools such as a chat room or forum, (4) updates on research and new medications using podcasts, tweets, newsletters, or message boards, and (5) providing a link to show the source of the information provided in the LIN. These adaptations are being implemented.

Overall, the comments were very positive. The most frequent comment was that this website would be most useful to those newly diagnosed with SLE (n=10). Many participants spoke of looking forward to the completed version of LIN that would include a forum for discussion.

**Table 4.** Ratings of helpfulness of the LIN content across information topics based on 37 participants (1=not at all helpful; 5=most helpful).

Section topic	Median (IQR)	% equal to or >4
About Lupus	5 (4,5)	91
Friends, family, and work	5 (4,5)	76
Symptom management and treatment	5 (3,5)	72
Living well with Lupus	5 (3,5)	71
Accessing health care	4 (3,5)	68
Support services	4 (3,4)	57

### Discussion

Tailored web-based programs are becoming increasingly considered as a means of empowering individuals with chronic conditions with the tools and strategies needed to promote self-management. Our study furthers the understanding of needs in the SLE community, and allowed us to develop a web-based tool to build confidence, support autonomy, and empower persons with SLE toward self-management. As SLE is an uncommon yet important disease, this is also an important tool to support health providers caring for people with SLE.

There are a number of potential limitations of our work. First, the study participants were recruited from tertiary care centers and tended to be well educated, and thus may not be entirely representative of the full spectrum of persons with SLE. Second, participants were all females and we cannot generalize these findings to males, who represent 10% of the SLE population. Third, most participants had SLE for several years and their analysis of the LIN was affected by their own experience of

living with SLE for that period of time. Many participants mentioned the usefulness of the LIN for persons newly diagnosed with SLE. Several participants also perceived that the LIN would have been most useful at the time of their diagnosis, although they agreed that they still learned from the LIN and would continue to use it to answer questions in the future. This suggests that the LIN could provide different points of entry based on disease duration and experience. Lastly, accessibility of a web-based tool may be suboptimal in some geographic, demographic, or socio-economic groups. However, the LIN can be used from any mobile device such as a tablet or mobile phone.

We assessed the acceptability and usefulness of the LIN as a tool to improve empowerment and self-management in persons with SLE. These results support the value of using a multi-method design that included surveys, focus groups, an expert panel, and interviews when developing programs tailored to specific populations. It is important to acknowledge that tools such as the LIN require ongoing updates and development to

respond to new information and user feedback. Other sections which we are already considering for further development include a personalized *SLE Tool Box* which will offer links to an electronic *SLE Health Passport* (personal profile to monitor aspects of health, such as blood pressure), printable information sheets, links to clinical trials, and a forum for discussions relating to SLE.

All participants agreed that the website was easy to navigate and functioned well. The quality and quantity of content were also rated highly. No topics were reported to be missing. This suggests the value of involving patients in the design phase by identifying their needs and preferences when developing eHealth websites tailored to specific populations. Nine participants suggested adding more information about research on new medications for SLE and six participants asked for more information about yoga and meditation as coping strategies. To

address these needs, more information will be provided about ongoing research on SLE, and coping strategies delivered interactively via webinars with psychosocial experts are being considered.

## Conclusion

As chronic disease models of care evolve toward self-management, it is increasingly important to develop and validate tools that support providers and engage patients. The LIN is an example of such a tool. It was very well received by patients, and considered easy to navigate with sufficient quantity and quality of content. The information provided on the LIN may be most helpful for individuals lacking experience with the disease, such as those newly diagnosed. Our results suggest the need to tailor the content for persons with more SLE experience.

## Acknowledgments

We are thankful to all participants for their contributions in the telephone interviews for this study. We would like to acknowledge the contributions to the development of the content for LIN from our SLE patient collaborators, including Fern Davis, Wendy Singer, Claire Rodrigues, Ben Sherman, Miriam Gaudelli, and Elizabeth Vicente. We would also like to thank our colleagues from Health Care Providers, including Evelyne Vinet, Janet Pope, Monique Gignac, Lori Tucker, and Anne Cymet. We are grateful to: Kathryn Reimer, Vancouver, British Columbia; Asvina Bissonauth, Edmonton, Alberta; Mellissa Moyon, Winnipeg, Manitoba; and Alexandra GodBout, Quebec City, Quebec, for their help in coordinating the study, Jane Su for providing research assistance, and Julie Parrot for secretarial assistance.

This research was supported by Partnerships for Health System Improvement (PHSI) grant 238692 from the Canadian Institutes of Health Research (CIHR), with an in-kind contribution by Jack Digital Productions (JDP) and a partnership contribution to PHSI made by GlaxoSmithKline (GSK) Canada. Dr Fortin holds a Canada Research Chair in Systemic Autoimmune Rheumatic Diseases and is supported by Université Laval, Quebec, Canada.

## Authors' Contributions

All authors contributed to the conceptual framework of this paper as well as to the development of the content of the surveys with their own expertise as rheumatologist (Paul R Fortin), psychologist (Deborah Da Costa), nurse (Carolyn Neville), and developer of the Oncology Interactive Navigator (Murray Rochon). This effort was coordinated by Davy Eng. The analysis was done by Carolyn Neville. Interpretation of the data was done by Carolyn Neville and Paul R Fortin. All authors contributed to, reviewed, and approved the paper.

## Conflicts of Interest

Carolyn Neville, Deborah Da Costa, Christian Pineau, Antonio Aviña-Zubieta, and Davy Eng declare that they have no conflicts of interest. Murray Rochon has a patent copyright, trademark, and marketing rights with royalties paid to JDP and is the founder of JDP, a social innovation company that is a partner organization under the PHSI grant provided by CIHR for this work. As part of the mandate of this grant, corporations are asked to partner with researchers to help effect change in health systems. This alignment and collaboration is a criterion of the CIHR grant to extend the reach and application of innovation. JDP contributes funds and expertise to develop this tool, and retains rights to content, technology, dissemination, and licensing of the tool in all jurisdictions. Stephanie Keeling reports having participated in a Lupus Advisory Board for Eli Lilly. Paul R Fortin reports grants from the CIHR and an in-kind contribution from JDP during the conduct of this study, as well as other unrestricted funds from GSK Canada Inc., also as part of the PHSI CIHR grant partnership program. He also reports having participating on Lupus Advisory Boards for Eli Lilly, AbbVie and GSK.

## Abstract

**Background:** Chronic conditions are the leading cause of disability throughout the world and the most expensive problem facing the health care systems. One such chronic condition is osteoarthritis (OA), a frequent cause of major disability.

**Objective:** To describe the effect on joint pain for the first users of a newly developed Web-based osteoarthritis self-managing program, Joint Academy, and to examine whether these patients would recommend other OA patients to use the program.

**Methods:** Patients with clinically established knee or hip OA according to national and international guidelines were recruited from an online advertisement. A trained physiotherapist screened the eligible patients by scrutinizing their answers to a standardized questionnaire. The 6-week program consisted of eight 2- to 5-minute videos with lectures about OA, effects of physical activity, self-management, and coping strategies. In addition, exercises to improve lower extremity physical function were introduced in daily video activities. During the course of the program, communication between physiotherapist and patients was based on an asynchronous chat. After 6 weeks, patients were able to continue without support from the physiotherapist. Patients reported their current pain weekly by using a numeric rating scale (range 0-10; 0=no pain, 10=worst possible pain) as long as they were in the program. In addition, after 6 weeks patients answered the question "What is the probability that you would recommend Joint Academy to a friend?"

**Results:** The eligible cohort consisted of 53 individuals (39 women; body mass index: mean 27, SD 5; age: mean 57, SD 14 years). With the continued use of the program, patients reported a constant change in pain score from mean 5.1 (SD 2.1) at baseline to mean 3.6 (SD 2.0) at week 12. Six patients participated for 30 weeks (mean 3.2, SD 2.1). Overall, the patients would highly recommend Joint Academy to other OA patients, suggesting that the platform may be useful for at least some in the vast OA population.

**Conclusions:** Joint Academy, a Web-based platform for OA therapy, has the potential to successfully deliver individualized online treatment to many patients with OA that presently lack access to treatment.

## Introduction

Chronic conditions are the leading cause of disability throughout the world and collectively they represent the most expensive problem facing health care systems [1]. One prevalent condition among these noncommunicable diseases is osteoarthritis (OA), which is one of the leading causes of global disability [2]. Approximately 27 million individuals live with OA in the United States [3], estimated to cost US \$189 billion annually [4,5] highlighting the financial and societal burden attributed to OA.

Osteoarthritis primarily affects the elderly. The prevalence in the age group 60 years and older is 10% among men and 18% among women [6]. Ongoing demographic changes, particularly in developed countries, and a growing number of elderly individuals suggest that the number of people with OA will increase.

Like other chronic diseases, OA progresses slowly. Before individuals are eligible for total joint replacement (TJR) surgery, incubation time is some 10 to 15 years with increasing joint pain, decreasing function, and reduced quality of life. Accordingly, cross-sectional Swedish and UK data show that only 20% of the OA population qualifies for TJR in spite of debilitating symptoms [7-9]. For those in earlier stages of OA when the diagnosis should be based on clinical symptoms, the primary treatment is nonsurgical, based on exercise, information, and—in relevant cases—weight loss according to all international and national guidelines [10-13]. Unfortunately, this evidence-based treatment is not reflected in present OA management administered by the health care system [14]. Rather, joint pain is considered by health care professionals as a normal part of the aging process (ie, “wear and tear of the body”) and is therefore not manageable until TJR becomes an option. As a result, many suffering from OA are not aware of or offered well-established evidence-based nonsurgical treatment.

The Swedish national initiative “Better Management of Patients with OsteoArthritis” (BOA), a national quality registry and an evidence-based supported self-management program for patients with OA, was developed to facilitate the implementation of guidelines [9,14]. Of Sweden’s 9 million inhabitants, more than 50,000 individuals have participated in the BOA program between 2008 and 2015. Still, they represent less than 20% of people in need of treatment due to joint problems [9,14]. Thus, despite the systematic and thorough work put into BOA, most individuals suffering from OA have not yet received access to the program, which may be due to lack of health care resources or people having trouble fitting their schedule to primary care opening hours. Therefore, alternative methods are required to reach these individuals.

One appealing method that leverages technology into health care is digital therapeutics. In this context, digital therapeutics can be viewed as software functioning as “medication” that is delivered via the Web. This treatment focuses on behavioral changes with long-term improvements in contrast to the short-term gain of taking a pill or other interventions presently used in health care. A crucial point to achieve the effect of any treatment is compliance. Using digital therapeutics that utilize

the Internet to deliver cost-effective treatment around the clock has the potential to increase adherence. Allowing for people to administer their treatment at a suitable time point probably increases compliance and the likelihood of improved health and quality of life for patients with chronic conditions. An interesting and successful example is the translation of the Diabetes Prevention Program into an online treatment [15,16]. With respect to OA, we have developed Joint Academy [17], which is a digital platform for individuals with clinically verified OA. The platform is based on the BOA program [9,11,14]. It includes a Web-based patient interface that provides individualized exercises, a personal physiotherapist, peer-to-peer support, education about lifestyle and behavioral changes, and a physiotherapist interface that provides necessary information on the patient’s progress in the program for support and encouragement.

The aim of this pilot study was to describe the effect on joint pain for the first users of a newly developed Web-based OA self-managing program, Joint Academy, and to examine whether these patients would recommend other OA patients to use the program. Collectively, the objectives aimed at deciding (1) whether it seemed feasible to deliver Web-based OA treatment and (2) whether the results would support further development of the platform.

## Methods

### Patients and Study Design

Participants with knee or hip joint pain were recruited from an online advertisement on the home page of the Swedish Rheumatology Association during two weeks in January 2015. However, single patients were eligible for inclusion until December 2015. The potential participants were directed to a website where they were asked to create a user account and fill in a screening questionnaire. Participants were not compensated for their participation but were enrolled in the program at no cost.

A trained physiotherapist (CT) screened the questionnaires and, whenever relevant, asked additional questions to patients through their user interface. To be included, the physiotherapist ensured that described symptoms were in agreement with clinical OA according to national guidelines [9,11,14]. Exclusion criteria included chronic widespread pain or other, more severe diseases, such as inflammatory joint disease, cancer, sequel after hip fracture, or due to major trauma.

Participants were informed that the program lasts for 6 weeks. Included participants (referred to as patients subsequently) were asked to answer some demographic questions according to the International Consortium for Health Care Measurement (ICHOM) initiative as well as those in the BOA registry [9,14,18] and reported their current baseline of pain using the Numeric Rating Scale (NRS; range 0-10, 0=no pain, 10=worst possible pain). After 6 weeks, patients were asked “What is the probability that you would recommend Joint Academy to a friend?” (range 0-10, 0=not likely, 10=most likely). For this study, patients were not asked to specify what joint was affected by their disease.

## Description of the Intervention

The basis for Joint Academy is the Supported Osteoarthritis Self-management Program (SOASP) used in BOA. The BOA program consists of theory sessions held by a physiotherapist, sometimes in collaboration with an occupational therapist and an OA communicator (ie, a patient with OA who has been educated by the Swedish Rheumatology Association to talk about the daily experience of OA and good coping strategies including physical activity). After completing the theory sessions, patients can opt for an individually adapted and physiotherapist-supervised exercise program [14]. The SOASP content was based on existing evidence, national and international treatment guidelines, as well as patients' views, thoughts, and tolerability of treatment and exercise for OA. Patients in the SOASP rate their pain on a visual analog scale at baseline and again after 3 and 12 months.

The Joint Academy program that was used in this study started on Sunday and ran for 6 weeks. The program consisted of eight videos of 2- to 5-minute lectures about OA, effects of physical activity, self-management, and coping strategies. After each lecture, the patient took a quiz to confirm that the take-home messages of the lecture were correctly understood. Parallel to these lectures, four neuromuscular exercises were introduced to improve lower extremity physical function. Each exercise had 3 to 5 levels of intensity. The level of intensity was based on an algorithm taking into account individual progress and the patient's perceived ability to perform the exercise without exacerbating pain. The week's exercises and lessons (12-14 exercises, two lessons, and one pain report per week) were divided into daily packages and delivered in video format to the patient during the 6-week period by push email. In each email, there was a link to the embedded videos within the Web-based platform. These videos showed how to properly perform the exercises. The short video lectures also included key OA issues important for understanding the delivered treatment to be fully motivated for the exercises. Each package was designed to take no more than 5 to 15 minutes per day. After having performed an exercise, the patient registered it as complete. When needed, the patient was able to communicate

questions to the personal physiotherapist. This communication between the physiotherapist and patient within the Joint Academy platform was asynchronous and based on a chat during the 6-week program. To have a comparable benchmark over time, pain was always reported on Sundays and referred to the average pain during the week. An "active week" was defined as a week when patients reported their pain level. If a patient reported pain values for four consecutive weeks, skipped two weeks, and finally reported pain for three additional weeks, this was defined as seven active weeks in the program.

## Software Programming

The software was compatible with all platforms and worked on personal computers, tablets, and mobile phones. It was built as a single-page Web app with a responsive user interface to facilitate user experience. The Web app was connected to our proprietary back-end service for OA treatment. The back-end was built on the framework Ruby on Rails and the front-end on Angular JS.

## Statistical Analyses

The statistical analysis was performed using a longitudinal random effects model. A random intercepts and slopes model was fitted with using the restricted maximum likelihood approach and with the underlying assumption of an unstructured variance-covariance matrix and degrees of freedom estimated using Satterthwaite's method. The calculations were performed using the mixed command in Stata version 14.

## Ethical Consideration

Patients gave informed consent when entering the program.

## Results

The study cohort consisted of 53 individuals (39 women; body mass index [BMI] mean 27, SD 5; age mean 57, SD 14 years). Of these 53 patients, 36 (68%) registered their pain levels for 6 active weeks (Table 1). On average, patients needed 7 to 8 weeks to complete a 6-week active period (Table 1). During these weeks, patients received 113 activities in total, of which they performed a mean 83 (SD 13) activities.

**Table 1.** Study results summary.

Result	Number of active weeks					
	Baseline	6	12	18	24	30
Number of patients in program, n	53	36	19	12	9	6
Time to complete active weeks (days), mean (SD)		53 (18)	112 (53)	154 (32)	201 (39)	246 (49)
Activities per week, mean (SD)		14 (2)	13 (2)	13 (2)	14 (1)	14 (1)
NRS pain score, mean (SD) <sup>a</sup>	5.1 (2.1)	4.5 (1.8)	3.6 (2.0)	3.3 (2.5)	2.7 (1.7)	3.2 (2.1)
Change in mean NRS pain score vs baseline, %		-11	-28	-35	-47	-38
Patients with >15% improvement in NRS pain score, n (% of remaining patients) [19]		17 (47)	12 (63)	7 (58)	8 (89)	5 (83)

<sup>a</sup> Numeric Rating Scale: range 0-10.

We observed that 33 patients voluntarily continued using the program after 6 weeks utilizing the same weekly instructions

as in week 6, but without the support of a personal physiotherapist.

Furthermore, 19 patients (36%) voluntarily continued to exercise and report their pain level for a total of 12 active weeks. After 18 and 24 active weeks, there were 12 and nine patients remaining, respectively, and six patients completed 30 active weeks in the program (Figures 1 and 2, Table 1). The longest participating patient continued for a total period of 50 weeks (data not shown). Pain according to the NRS was markedly reduced over a 30-week period (Figures 1-3, Table 1). The mean weekly change in pain during follow-up was estimated to be  $-0.074$  (95% CI  $-0.118$  to  $-0.030$ ,  $P=.002$ ), which corresponds to a pain reduction of one unit every 14 weeks.

Figure 2 shows that baseline values were similar regardless of how long patients participated in the program (ie, patients engaged in the program for a longer time period did not have less severe pain at baseline compared to baseline values for patients who participated for a shorter period of time). There were no obvious demographic differences (ie, sex, age, BMI) between patients who were active for less than 6 weeks compared to those who were active for more than 6 weeks (data

not shown). At all weeks during the 30-week period, the mean pain score of the active patients was similar to the reported pain score of the patients that discontinued the program after that week (data not shown).

At week 6, 18 of the 36 active patients had a lower absolute value in pain score, eight were unchanged, and 10 had an increase compared to baseline. The mean NRS pain score for the 36 active patients changed from mean 5.1 (SD 2.1) at baseline to mean 4.5 (SD 1.8) (Table 1). Sixteen patients (68%) were classified as responders with an individual improvement of more than 1.5 in NRS pain score [19].

The NRS pain data showed that at weeks 6 and 30, 47% (17/36) and 83% (5/6) were responders, respectively (Table 1).

In all, 31 patients (five were lost due to technical reasons) answered the question “What is the likelihood that you would recommend Joint Academy to a friend?” The median score was 10 (range 6-10).

**Figure 1.** Mean NRS pain score for active patients (●) and number of patients (○) remaining in the program at each week. Due to decreasing number of patients during the course of the program, individual weekly changes may have a disproportional effect on the mean pain level.

**Figure 2.** Box plots of the NRS pain values (the horizontal line in the middle of each box indicates the median and the top and bottom borders of the box mark the 75<sup>th</sup> and 25<sup>th</sup> percentiles, respectively; the whiskers above and below the box mark the 90<sup>th</sup> and 10<sup>th</sup> percentiles; the black dots beyond the whiskers are outliers) at different time points. Baseline is baseline mean NRS for all 53 patients. For each subsequent time point, data are presented for those patients that participated in the program at the indicated time period (6 weeks: n=36; 12 weeks: n=19; 18 weeks: n=12; 24 weeks: n=9; 30 weeks: n=6). White boxes: baseline NRS; gray boxes: NRS after the indicated time period.

**Figure 3.** Spaghetti plot showing NRS pain. Each blue line represents a single patient. The red line represents change in mean pain over time for all 53 patients.

## Discussion

In this study, we demonstrate that Joint Academy, a Web-based platform for OA therapy, has the potential to successfully deliver individualized digital treatment to patients with clinical OA in the hip or knee. Many experienced an improvement in pain and would recommend the program to others. This is one of few exercise intervention studies following patients for a longer period of time [20,21]. This study shows similar pain improvement as those in previous face-to-face studies [13,14,22,23]. Furthermore, although a definitive cause relationship could not be established, the degree of improvement seems to be associated with duration of stay in the program. Although not designed to determine reasons for discontinuing the program, the study revealed that patients who discontinued the program within 6 weeks showed similar pain scores at baseline (Figure 2) compared to those that remained in the program. Of note, patients consecutively entered the program during the 12 months of recruitment meaning that not all patients had the opportunity to participate for 30 weeks and that the lower number of patients by time is not a true measure of compliance.

Even though several patients discontinued the program, results suggest that pain fluctuates over time (Figure 1). This is in agreement with the clinical profile of OA showing relapsing intervals of pain and impaired function. Another possible explanation for the fluctuating pain level may be that as patients improve (ie, their symptoms become less severe), they increase

exercise time and intensity. This suggests that patients may have similar or increased pain but, at the same time, they have increased physical function. Future studies will explore the relationship between pain and function by assessing physical function, which was recently included in Joint Academy.

In SOASP, patients rate their pain on a visual analog scale (VAS) at baseline and again after 3 and 12 months [13,14]. On average, the VAS pain score decreases by 10 points (from 48 to 38) and 12 points (from 48 to 36) for patients with hip and knee OA, respectively. These results are similar to the results reported at 12 weeks in this study (5.1 to 3.6) (Table 1) indicating that a Web-based means to deliver evidence-based health care to OA patients seems to work as well as the “analog” face-to-face predecessor.

In the United States, US \$40 billion per year is allocated to the more than 600,000 TJR operations conducted annually, making TJR one of the most expensive interventions today [4]. The number of TJRs is expected to increase by more than 100% by 2030 due to the increasing prevalence of OA in an aging population, together with the decreasing age of intervention for TJR in the baby boomer generation [24]. Without doubt, TJR is a very successful intervention when performed on the right patient at the right time point. However, recent studies have shown that many TJRs, as well as other surgical interventions in patients with OA, are often unnecessary and that indication for surgery is not well validated. For instance, a study that compared pre- and post-health care costs for OA patients that underwent a TJR in the United States showed that although the

total number of outpatient visits declined after surgery, the percentage of patients hospitalized after TJR increased. The result was a higher total cost during follow-up compared to before surgery [25]. In addition, TJR patients may need revision surgery (ie, a new prosthesis) and TJR is associated with an increased risk for adverse events compared to nonsurgical treatment [24]. Furthermore, 15% to 20% of the TJR population has sustained disabilities after surgery, which generates suffering, costly visits, and unnecessary diagnostics and treatments [26].

Another common operative procedure in middle-aged patients with knee pain is arthroscopy. In the United States alone, 400,000 arthroscopies are performed annually due to the popular belief that pain in the degenerative knee is caused by a meniscal tear [27-30]. As concluded by Katz and Jones [28], a reasonable initial strategy for these patients is physiotherapy rather than arthroscopy. This conclusion is supported by a recent study that contradicts the prevailing consensus that mechanical symptoms justify an arthroscopic intervention [31]. Furthermore, partial meniscectomy may be associated with increased risk of incident radiographic osteoarthritis [32]. That physiotherapy indeed has an effect, and that the results of this study shows similar effect, is further demonstrated by a recent Cochrane review [22] as well as results from the Danish GLA:D program, which is based on the BOA program [23]. The positive effect of exercise, weight control, and information can be explained by the biomechanical origin of OA as well as the importance of patients having accurate knowledge about their disease [22,33].

Two randomized controlled trials are of interest with respect to nonsurgical options to treat OA patients eligible for total knee replacement [34,35]. One of these studies showed that supervised exercise before surgery is associated with a faster postoperative recovery [34]. The second study compared knee TJR with a nonsurgical treatment program and showed substantial improvement in both groups with respect to most outcomes. However, only 26% of the patients who were assigned to receive nonsurgical treatment alone underwent total knee replacement in the year following the procedure [35]. That education and individually adapted exercise have the potential to reduce the need for TJR is further enforced by Svege et al [36].

To our knowledge, Joint Academy is the first platform to deliver digital health care to OA patients. The fact that the program may reverse the course of symptoms for some patients to the degree observed in the current study is very encouraging, suggesting that Joint Academy may be feasible at least for some OA patients. For the subgroup of the OA population volunteering for participation in this program, a pragmatic approach with 5 to 15 minutes of exercise a few days per week seemed sufficient to achieve significant results. Interestingly, the program motivated the patients to perform approximately 80 activities in a 7- to 8-week period. This suggests that Joint Academy may play an important role in OA treatment. In addition, Joint Academy may also increase equity in OA treatment by offering evidence-based health care for people living with clinical hip or knee OA in the developing world.

That a digital health program may have significant effects on health is also shown by the Prevent program targeting patients with prediabetes. By combining weekly theoretical lessons and individualized health coaching, patients lowered their body weight as well as their blood glucose levels [15,16]. The great advantage of a Web-based platform that works on personal computers, tablets, and mobile phones, is that it can be used wherever and at a time point of the patient's own choice, minimizing the interruption of daily life activities and the need for scheduled appointments at a clinic. This may be particularly relevant for patients in rural areas with limited access to and/or living far away from health care facilities as well as for working people who may find it difficult to allocate time for a visit to a primary care practice. In addition, Internet availability is increasing rapidly as the price of a basic mobile phone decreases. Ultimately, digital health care may save financial resources and increase quality of life for many people living with chronic diseases.

There are limitations to this study. This is a pilot study without a control group and with a small study population, especially at later time points, limiting the establishment of a definitive cause relationship between length of participation in Joint Academy and improvement in pain. However, patient attrition over time is not due to demographic differences between those patients who discontinued the program and those patients that continued the program. When using this study design, there is a risk that the cohort is not representative of the general OA population. However, both the OA pathology and the clinical disease patterns are similar around the world. The relative ease with which you can enter the study (eg, patients do not need to visit a general physician to have a diagnosis or a physiotherapist to perform the exercises), may result in a higher-than-average dropout rate. Alternatively, those signing up may be more motivated to change their present situation and/or have an interest in digital technology and, consequently, show better results. It can also be argued that patients that enroll in the program are currently experiencing an exacerbation in pain and, therefore, are more motivated than the average OA patient. However, this did not seem to be the case for all patients in this study. Patients that enrolled in Joint Academy had a baseline mean NRS pain of 5.1 (SD 2.1) meaning that the pain level of at least some patients was relatively low. Overall, we believe it can be argued that patients in the study cohort are well suited to be the future target group for digital OA management. Despite these limitations, the results encouraged us to further develop Joint Academy. In the current version, we have included extended assessments at inclusion and also during the course of the program. Furthermore, we have included a functional test, comorbidities, and additional demographics to enable an improved user definition in order to further individualize the program. With respect to the enormous OA population, we believe that Joint Academy has the potential to attract people who are more motivated by digital health than by visits to a primary care practice.

In conclusion, we demonstrate that Joint Academy, a Web-based platform for OA therapy, has the potential to successfully deliver individualized Web-based treatment to many patients with OA who presently lack access to treatment.

## Acknowledgments

Joint Academy has received financial support from Lund Innovation System.

## Conflicts of Interest

Jakob Dahlberg and Daniel Grahn are employees of Joint Academy. Carina Thorstensson is a part-time consultant of Joint Academy. Leif Dahlberg is a board member of Joint Academy.

## Abstract

**Introduction:** Sudden unexpected death in epilepsy (SUDEP) is possibly the most common cause of death as a result of complications from epilepsy. The need to educate and regularly review risk for all patients with epilepsy is paramount, but rarely delivered in actual clinical practice. Evidence suggests that education around SUDEP and modifiable risk variables translate into better self-management of epilepsy.

**Objective:** We aimed to develop and implement an eHealth solution to support education and self-management of risks, in epilepsy.

**Methods:** We undertook an innovation pathways approach, including problem identification, feasibility assessment, design, implementation, and marketing. People with epilepsy were provided a smartphone-based app (Epilepsy Self-Monitor, EpSMon), which translates the clinical risk assessment tool into an educational and self-monitoring platform, for the self-management of epilepsy.

**Results:** Results include the success of the marketing campaign, and in what areas, with an estimated reach of approximately 38 million people. EpSMon has proved a success in academic and clinical circles, attracting awards and nominations for awards. The number of users of EpSMon, after 3 months, turned out to be lower than expected (N=221). A 4-month trial of the app in use in the United Kingdom, and the success of the marketing strategy, point to necessary changes to the model of delivery and marketing, summarized in this paper. These include the marketing message, user cost model, and need for the availability of an Android version.

**Conclusions:** EpSMon has proven a success in respect to its reception by academics, clinicians, stakeholder groups, and the patients who use it. There is work needed to promote the model and increase its acceptability/attractiveness, including broadening the marketing message, increasing its availability, and reducing its cost. Future development and promotion of the tool will hopefully inform iterative design of its core features for a receptive audience and lead to increased uptake as it is launched worldwide in 2016.

## Introduction

### Background

Epilepsy is one of the most common neurological disorders globally affecting 5 to 40 people per 1000 population [1]. Epilepsy affects approximately 50 million people throughout the world. It has been estimated that 10% of the burden of brain and mental disorders in the world is caused by epilepsy. This calculation includes premature deaths and the loss of healthy life due to disability [2].

Sudden unexpected death in epilepsy (SUDEP) is the most important direct epilepsy-related cause of death [3]. SUDEP is possibly the most common cause of death as a result of complications from epilepsy, accounting for between 7.5% and 17% of all epilepsy-related deaths and [4] 50% of all deaths in refractory epilepsy [5]. Sudden death is 20 times higher in people with epilepsy (PWE) than the general population. Epilepsy is the 5th highest cause of life-years lost and the public health burden of SUDEP alone is estimated as second only to stroke among neurological conditions [6]. Forty-two percent of all deaths are considered avoidable [7]. Consequently, the National Institute for Health and Care Excellence epilepsy guidelines 2004 and 2012 [8] recommend discussion of SUDEP with newly diagnosed PWE. This is rarely delivered and until recently only 4% of PWE had a recorded SUDEP discussion [9].

There is robust evidence to suggest that knowledge relating to modifiable risk factors would help empower the patient to take responsibility toward his well-being in managing his condition [10-12]. Recent studies have shown that factors influencing SUDEP and other direct causes of epilepsy death overlap [13-15].

### Aim

Development of a patient-centered eHealth solution to reduce risk of SUDEP and educate PWE around risk. Utilization of quality improvement and iterative cycles of development to evidence the proposed solution.

## Methods

### App Conceptualization

In the conceptualization stage of a patient-administered eHealth alternative to the consultant-administered checklist, it was important to identify how this might fit alongside existing care pathways and where, if anywhere, a clear gap in service delivery was observed. Consultation was undertaken with a specialist national Epilepsy charity (SUDEP Action), a specialist general practitioner (GP) commissioning group in Cornwall, UK and both national academic and consultant specialists in epilepsy.

This steering group identified the removal of the primary care-based Quality Outcomes Framework financial support for

annual epilepsy reviews, provided by GPs, would likely translate into a significant reduction in epilepsy reviews in the community for patients not identified as at risk. A service pathway was drafted, which included an eHealth self-monitoring option, for patients to self-administer, which could act as a triaging tool alongside existing primary care models.

### Stepped-Care Model Approach

A rapid informal review of eHealth solutions delivered in other sectors revealed a range of options for support, including general education, risk-specific educational interventions, prompts to seek help, and automated triggering of community or secondary care service support. Against the current level of support for PWE with ongoing seizures, where it is currently their own responsibility to seek help when they perceive a need, the steering group perceived that support in the ability to identify when this need is present was most relevant. This is reinforced by earlier reported findings [16] in which coroner data for SUDEP-related deaths identified that only 20% of patients had sought medical contact with an epilepsy specialist in the period of 12 months prior to their deaths. The evidence indicated a 3-month high-risk period for people whose risk profile deteriorates, as identified by the checklist, and so the identified eHealth need was the provision of an informative risk assessment at prompted 3-monthly intervals.

### Technology Identification

The steering group assessed the potential risks and benefits of differing technologies to support this eHealth solution, including a systematic review of existing seizure detection methods [17]. Primarily, the goals of the project required ease of use, accessibility, effortless international dissemination, notification capabilities, and data collection capabilities (to support the ongoing development of the checklist). A mobile app was selected due to the ongoing surge of take-up of these devices (6.9 billion mobile phone prescriptions worldwide with a forecast of 5.6 billion smartphone subscriptions by 2019, Global mobile statistics report - 2014 [18]), the tendency for owners to carry their device at all times, the numerous notification options and the expansive range of data collection options including take-up and user retention data.

### App Design (EpSMon – Epilepsy Self Monitor)

The development of the App content was iterative, cycling on the basis of specialist input across a range of development themes: the consultant steering group, a patient-representative group (recruited by the charity), University information technology (IT) support services and patients of volunteer clinicians were repeatedly involved in providing feedback across a range of development stages, (summarized in [Figure 1](#))

A wire-frame (flowchart of screens, features, and server activity) was initially developed by a local University-based team who specialize in the development of apps for neurology and clinical services. Following this, a graphical representation mock-up

was produced providing, first versions of the graphics in situ in a functioning App and the final Beta version prerelease (a Beta version being the version that is tested for coding bugs, all other features assumed complete). The target users for this tool span all ages and demographics and so the development team strived to access a diverse feedback group.

Usability testing (public and patient involvement, PPI): explored and observed how users experienced and used the app naturally and across a series of identified tasks. This research was led independently by the charity (to be published separately), software team, and specialist clinicians in clinics with patients. Feedback was reviewed by the steering committee with design modifications to the app when deemed appropriate.

In order to generate the content of the app, the translation of the checklist into a self-administered tool, supported by educational material, was led by the charity in liaison with a specialist patient consultation group and specialist clinicians and academics in this field. This content was reviewed in the first version of the app, by volunteer patient representatives, with edit recommendations made when deemed appropriate by the steering committee. The steering committee decided upon a minimum governance standard for the project, requiring that the checklist be taken through an annual update, requiring ongoing reviews of the literature. An update cycle was undertaken during the build of the app and the app content was updated accordingly.

Once version 1 of the app was built, beta testing was completed for bugs in its functioning by all supporting partners, and a range of patient representatives who had registered to support this activity on a prerelease invitation hosted on the charity's website. Prior to release of the app to iTunes, the app's code, user policies, terms of use, data protection protocols, and security protocols (data encryption, secure transfer, etc) were all reviewed by an IT specialist and legal services provided by the University partner.

Given the heterogeneous characteristics of the potential user population, being any individual with epilepsy and so any age, sex, or race – speculations about user preference or accessibility to devices seemed uninformative beyond national update statistics. Rather, it was decided to aim to release the app to the most popular platforms (Apple and Android) with the aspiration to expand to provide to Windows phones if resources allow.

### Key Feature Selection

Following the iterative design process, the app was completed with a range of features that are supportive to patients, service delivery and future research. The features included represent the minimum required to rapidly meet identified user needs and research model of the project, with additional features to be considered in future updates.

It was considered valuable to develop capability to support users in self-triaging their need to seek clinical contact, following an assessment of risk. The translation of the checklist into a self-assessment provides a robust evidence-based self-triaging tool that identifies risk change across regular time intervals.

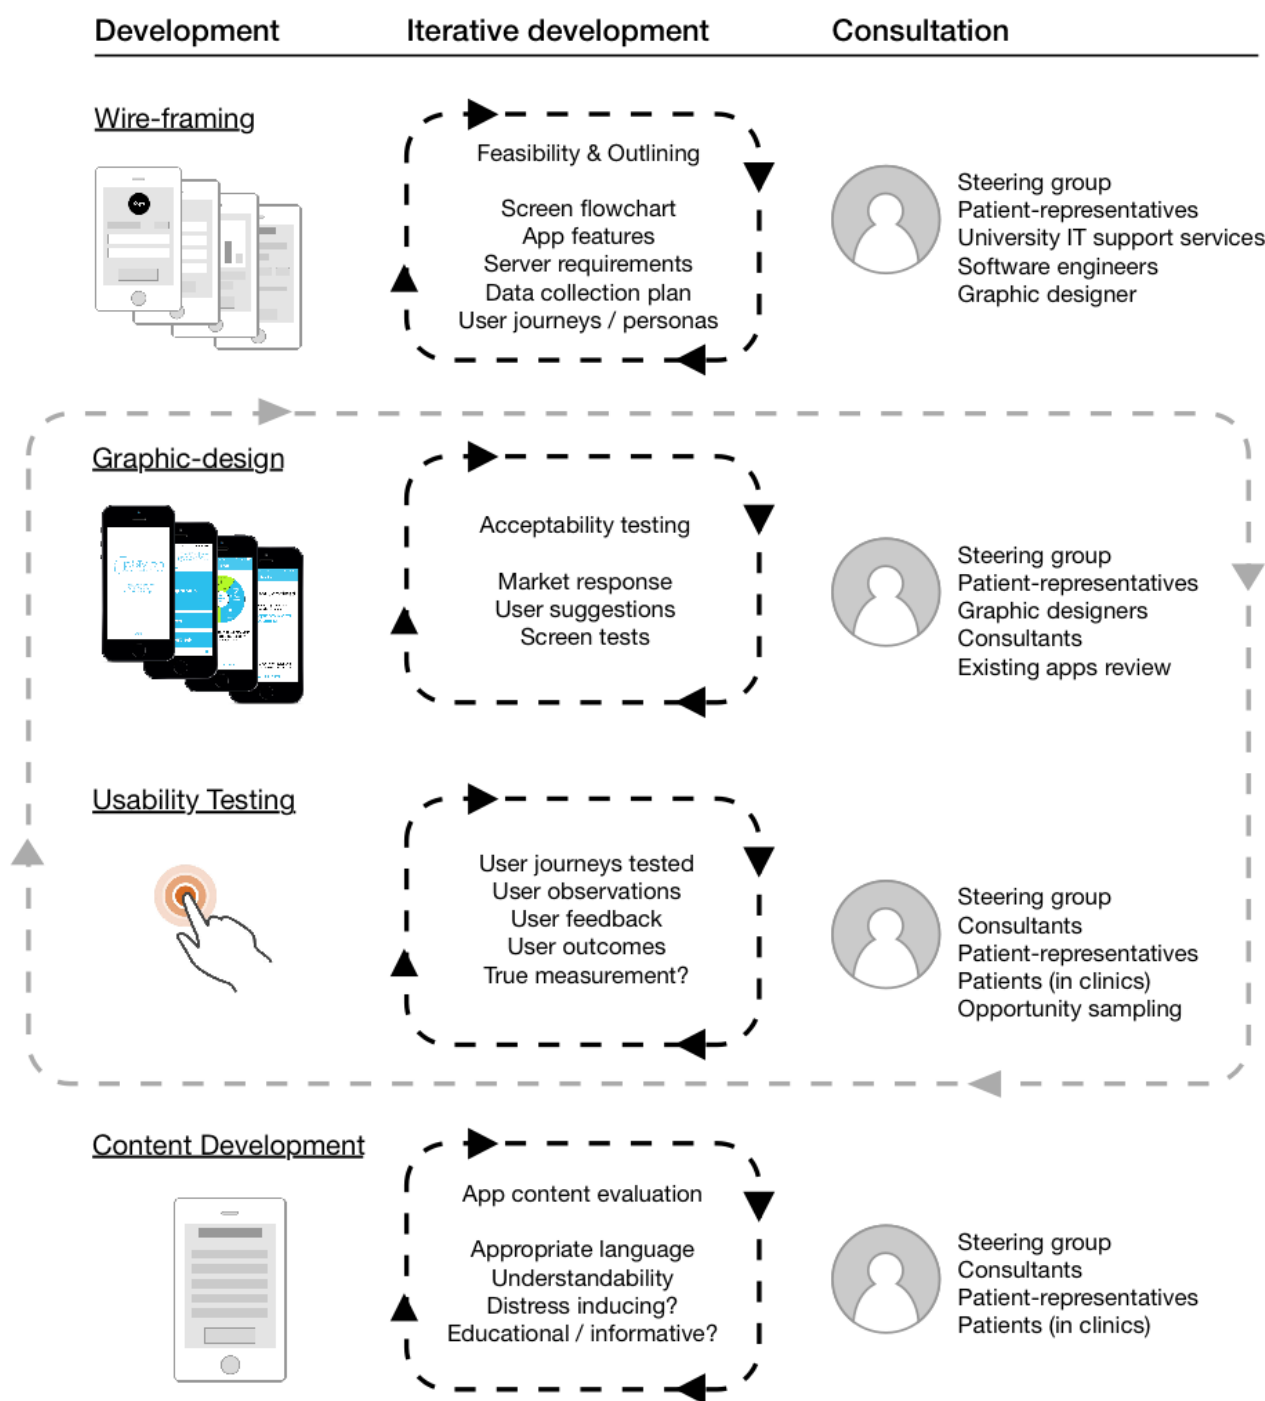

Rather than providing a binary health care approach, a stepped-care approach was designed into the app. EpSMon initially educates PWE around variables related to risk through regular exposure to the checklist. Secondly, succinct educational content is provided to support further queries around identified risk with the app designed to encourage access to this information. Finally, the app encourages contact with a GP when appropriate and queries whether this was adhered to at the next assessment. As an additional safety precaution, a telephone number is provided for people who are distressed or confused, direct to SUDEP Action.

Interventions in other disease areas frequently use a stratified approach, cutting off access to services at a particular percentage of risk of serious disease or death. The Checklist and EpSMon do not do this. The app replicates the checklist, in that it is designed to not include a cumulative score or percentage of risk so there is no cut off of risk, hopefully maximizing doctor and patient empowerment and risk-management. To maintain a quality risk-management and clinical governance approach, the app is designed to support research by consenting users into research and collecting data relating to user demographics, comorbidity, medication use (epilepsy, depression, and psychosis), risk profiles over time, and app usage.

### App Governance

After reviewing the government's criteria for app medical device registration [19], it was considered that EpSMon does not meet entry requirements. EpSMon does not diagnose, monitor, prevent, treat, or alleviate a disease. Although the tool is called a monitor, this is a reference to the tool supporting the self-report of user's perceptions about their current state that is used to prompt education or conversation with a clinician, no raw data is interpolated for clinical use. The app is not an alternative to standard treatment and nor does it interfere with or recommend any treatment plan, which is a stipulation (not met) for medical device status required by the Medicines and Healthcare products Regulatory Agency. It informs its users that the results are not to be considered as anything but suggestive. This position could change if the underlying questionnaire responses are developed into statistically weighted factors and the report process becomes more interpretative. This may also need further consideration when EpSMon is released to other countries, such as the United States.

While the safety checklist was developed for SUDEP, risk factors such as nonadherence and depression are relevant to epilepsy mortality generally. They bring a set of questions to the fingertips of doctors and patients that were developed from research on SUDEP. Many of the questions overlap with epilepsy mortality generally and the 2015 version of the Checklist agreed by a UK development group of experts includes the latest research on epilepsy fatality. These include questions on wellbeing as well as seizures. The Checklist will be reviewed annually to enable updating with evidence on fatality. A question on comorbidity has already been identified as an area for recommended inclusion in 2017. Country versions outside the United Kingdom will need additional information and country contextualization if there are no national guidelines in place.

**Figure 1.** Cycles of iterative development undertaken in creating EpSMon.

## Results

### Launching the Epilepsy Self-Monitor App

EpSMon was launched to iPhone (UK only) in July 2015 at a cost of £1.49 for life-time access. A strategic marketing communications campaign supported the launch of the app, with public relations support from all partner organizations. Coverage achievements included 5× regional television news reports (audience estimates unavailable), 7× regional radio reports (estimated 1.5 million audience), 27× national and regional newspaper articles (estimated 33.2 million audience), 625 Facebook likes, 424 shares, and 255 clicks to the website

(from a potential Facebook reach of 360, 000) and 110,300 'EpSMon' retweets and 14,900 mentions. In total, the marketing communications campaign attained an overall reach of approximately 38 million people.

A full-time support phone line was indicated in the app, provided by SUDEP Action. Very little activity has been generated, with contact mostly relating to enquiries for an Android version of the tool.

Releasing EpSMon has been a very positive experience with unanimous support from clinicians, academics, and patients who have had contact. It has received awards at the International League Against Epilepsy conference, mass media interest, and

two nominations to the Health Service Journal Innovation awards (HSJ) despite its infancy in respect to project duration. The almost nonexistent need for support, by users, encourages further expansion of the user base.

Since the launch, 221 users have downloaded the tool and registered, with 218 having assessed their risk. In addition, EpSMon has also been adopted into the National Epilepsy Commissioning Toolkit, alongside its parent checklist for clinicians. The app collects, with consent, users' age, sex, epilepsy diagnosis duration, seizure type, medications use, questionnaire responses, and app-use frequency data for all users. This data will be used to both better understand the existing user base, for purposes of further project delivery, and to support the research that will further develop the risk checklist's ongoing development.

### APP Modifications

The current user base, while modest, represents a test base for the project and has supported the identification of areas in which further work is needed. The first of these is cost. The introduction of a £1.49 fee was driven by a desire to test whether this would increase trust in the product, rather than a need to fund the project. Data indicates that 80% of visitors to the app download page do not purchase the app, which may be a consequence of this fee structure. The steering committee has chosen to remove this fee and to provide the app at no cost. This may, in addition, encourage GPs and other organizations to promote the tool without fear that there is a profit motive for the partners involved.

There is an imminent need to provide an Android version of the tool, based on feedback to the charity and the fact that 79% of smartphone ownership is Android [20]. This could translate into an immediate rapid uptake of EpSMon, especially in the context of this being provided at no cost.

The marketing campaign for EpSMon was built on earlier epilepsy work relating to safety, 'Safety in your pocket.' Feedback since the launch suggests that we may need to consider a multipronged approach. Marketing strategies are currently being explored, with potential but resistant users. A second marketing communications campaign is planned for mid 2016, with news of the app now being free and available for Android and new Apple users.

Discussions are underway with potential US supporters who can provide marketing support into a US market in early 2016. This will involve the bundling of a Spanish translation of the

tool. A translation proforma has been developed, which will be provided to a translation agency in the near future.

## Discussion

### Principal Findings

The development of EpSMon and its first phase of implementation has been successful. In only 4 months the tool has been adopted into the commissioning toolkit for the National Health Service and has been nominated as a finalist in two categories of the UK's prestigious HSJ. The project has also received recent prizes at the International League Against Epilepsy for best poster and best presentation. The reception from academics, clinicians, families, and users is to date unanimously positive and supportive.

The take up of the app has been modest, although this likely reflects a cocktail of challenges that will require a responsive and reflective approach, beyond the need for an Android version summarized above. The literature relating to SUDEP in many ways characterizes both community and clinical level denial or ignorance as to the need to monitor risk of death in PWE. Marketing to a potential user base who are unaware of, or disconnect from, the narrative of risk in epilepsy is a challenge. The EpSMon project will seek to engage with clinicians, who already appear very receptive, and user groups to develop marketing strategies that engage people in the community, GPs, and specialist clinicians. In addition, work is underway to embed EpSMon into standard advice practice of GPs, through research trials to demonstrate the efficacy of this approach and specialist GP e-training (expected implementation in spring 2016).

### Conclusions

Although this project appears U-centric, SUDEP is a global phenomenon. There is a higher prevalence of epilepsy in economically poorer and developing countries than economically developed countries [21]. In such poor countries, priority of safety and ignorance is rife. Presence of a cost-effective solution such as the app could save lives. The initiative toward making this app free to use, and housed within a research collaborative model, will hopefully invite opportunities to create impact in these contexts, through further development and uptake of EpSMon. Further usability research, academic publication of the tool's merits, and developments alongside a strong research strategy will hopefully further support the success of this project into the future and beyond the United Kingdom.

## Abstract

**Background:** The parenteral nutrient (PN) mixtures may pose great risks of physical, microbiological, and chemical contamination during their preparation, storage, distribution, and administration. These potential hazards must be controlled under high levels of excellence to prevent any serious complications for the patients. As a result, management control and traceability of any of these medications is of utmost relevance for the patient care, along with ensuring treatment continuity and adherence.

**Objective:** The aim of this study is to develop a mobile-based platform to support the control procedures and traceability services in the domain of parenteral nutrient (PN) mixtures in an efficient and nonintrusive manner.

**Methods:** A comprehensive approach combining techniques of software engineering and knowledge engineering was used for the characterization of the framework. Local try-outs for evaluation were performed in a number of application areas, carrying out a test/retest monitoring to detect possible errors or conflicts in different contexts and control processes throughout the entire cycle of PN. From these data, the absolute and relative frequencies (percentages) were calculated.

**Results:** A mobile application for the Android operating system was developed. This application allows reading different types of tags and interacts with the local server according to a proposed model. Also, through an internal caching mechanism, the availability of the system is preserved even in the event of problems with the network connection. A set of 1040 test traces were generated for the assessment of the system under various environments tested. Among those, 102 traces (9.81%) involved conflictive situations that were properly taken care of in this paper by suggesting solutions to overcome them.

**Conclusions:** A mobile oriented system was generated and tested in order to allow enhanced control and quality management of PN mixtures that is easy to integrate into the daily praxis of health care processes.

**KEYWORDS**

parenteral nutrition; quality control; process assessment; information management

## Introduction

Mixtures of parenteral nutrition (PN) enable intravenous delivery of essential nutrients to patients who cannot be fully fed orally. The PN mixture may contain more than 50 components with a high potential for physicochemical interaction among its ingredients, the bag, oxygen, temperature, and light. These interactions are potentially iatrogenic and, in some cases, may even compromise the patient's life [1,2]. Therefore, PN is considered a high-alert medication that must be controlled throughout its life cycle [3].

In such contexts, in order to minimize errors and problems in the procedures involved, clinical practice guidelines and recommendations for action are generated [4]. A properly defined protocol ensures a high degree of theoretical viability, quality, and safety of the intended process. Thus, it is possible to adapt the context to strict quality requirements of the health care environment and compliance, in the elaboration and control of PN, with current regulations [5].

The criterion that determines whether those goals are achieved is adherence to the protocol of the different operations performed by the agents involved. Thus, in this type of high-risk context, to ensure proper execution of the processes, it is mandatory to check that the protocols are being applied and the results are the expected ones. In line with this, certain time points and places within processes need to be monitored. These elements are known as control points (CP) and allow for verification of the defined requirements [6]. Additionally, depending on the probability of the event, and especially the severity of the potential damage, those CP that require special supervision, which are referred to as critical control points (CCP), should be identified [7].

At the CP, and especially the CCP, data records from the applied monitoring system are generated, which are known as traces [8]. Gathered traces allow explicit statement to be made about the states or interactions, or both, between the different elements involved in the various processes that are being carried out. A thorough and complete log of traces makes full awareness of the history, usage, or location of an entity possible. This ability is known as traceability [9].

In the context of PN, traceability makes following the movement of a mixture through all the stages of its life cycle possible. Specifically, traceability is aimed at determining with certainty which vendors and products are part of a PN mixture's composition (traceability back), tracking the PN in production time (internal traceability), and tracing the mixture once it is produced and distributed (traceability forward) [10]. Thus, an efficient system of traceability should be able to react quickly and appropriately to any quality risks identified or to hazards related to the safety of medicines.

Various technological proposals are focused on traceability, particularly in the logistics area [11]. But, unfortunately, this type of deployment is based on automatic recording from the temporary location of the product and cannot cover all immediate demands, requirements, and needs of comprehensive management control in a context such as that of the PN.

Nevertheless, mobile technologies are providing new solutions, based on comprehensive patient-focused care models, which make them very attractive for clinical care applications [12,13].

Having noted the benefits of a management and traceability platform for PN using mobile technologies, we proposed the design and implementation of a holistic service architectural framework to fill the gaps in traceability and to provide flexible and effective telematic mechanisms for monitoring PN in a health care setting. We describe a technology platform to support control procedures and traceability of PN mixtures in an efficient and nonintrusive way.

## Methods

### Models

We used a comprehensive approach combining software engineering and knowledge engineering techniques to characterize our framework. In particular, we generated three initial models to fully define the system from different perspectives. Together they provide a complete description of the solution. We tested these models [14], which are a business model (high-level description of conditions, agents, and general behavior of the platform); a semantic model (formalization of the knowledge within the system using technologies that facilitate automatic processing and interpretation of information); and a reference architecture (the definition of a framework for the development of a software solution).

### Business Model

The business model is intended to identify the basic features of the technological platform. This characterization offers a vision, not necessarily formal, of how the whole system works in this context.

To conduct this modelling, in addition to consulting the opinion of experts, we reviewed the available literature (science, technology, legal, etc) and generated different usage scenarios for analysis and validation.

By using this model, we were able to identify, manage, and freely modify on run time the data attached to CP, CCP, and the monitoring parameters associated with the entire life cycle of a PN mixture. We also labelled the elements involved in the context (pumps, filters, etc) with matrix barcodes (quick response, or QR, and data matrix codes) and near field communication (NFC) tags to identify them uniquely.

### Semantic Model

The semantic model formalized the proposed traceability mechanisms, which facilitated the analysis and automatic processing of the history of each PN mixture. In this sense, it was essential to establish a formal scheme that would describe the information in a way that would enable the efficient application of reasoning or complex queries.

This modelling allowed formal conceptualization of the universe of applications and of relationships, which would be easily readable and interpretable by machines. Having semantic support in the model enabled the application of advanced information technologies and added-value solutions and tools,

such as inference engines that perform logical reasoning (or make inferences). Such reasoning enabled us to extract new facts and knowledge and to answer specific and complex queries.

Following this line of reasoning, we defined an open and generic data model focused on the definition of common concepts (with their properties) for related scopes of the domain of interest: users, institutions, CP, CCP, services, and parameters to monitor, for example traces and context variables. This semantic model provided us with an abstract representation of the whole application domain. To this end, we generated specific internal vocabularies and, as much as possible, reused vocabularies that are widely accepted in the field of semantics (eg, friend of a friend, resource description framework schema).

Uniform resource identifiers (URIs) [15] univocally identify semantic concepts and entities. This usage is derived from the HTTP paradigm and makes it possible to reference resources. This feature allowed us to attach the URI of each element in the semantic model to the information on the label on each actual item. Thus, by reading a label, regardless of the agent involved, it was possible to directly access a representation of the information stored in the system for the specific entity.

### **Reference Architecture**

The next step in the comprehensive modelling of the system was to define a reference architecture that would provide a guide or framework for the development and final implementation of

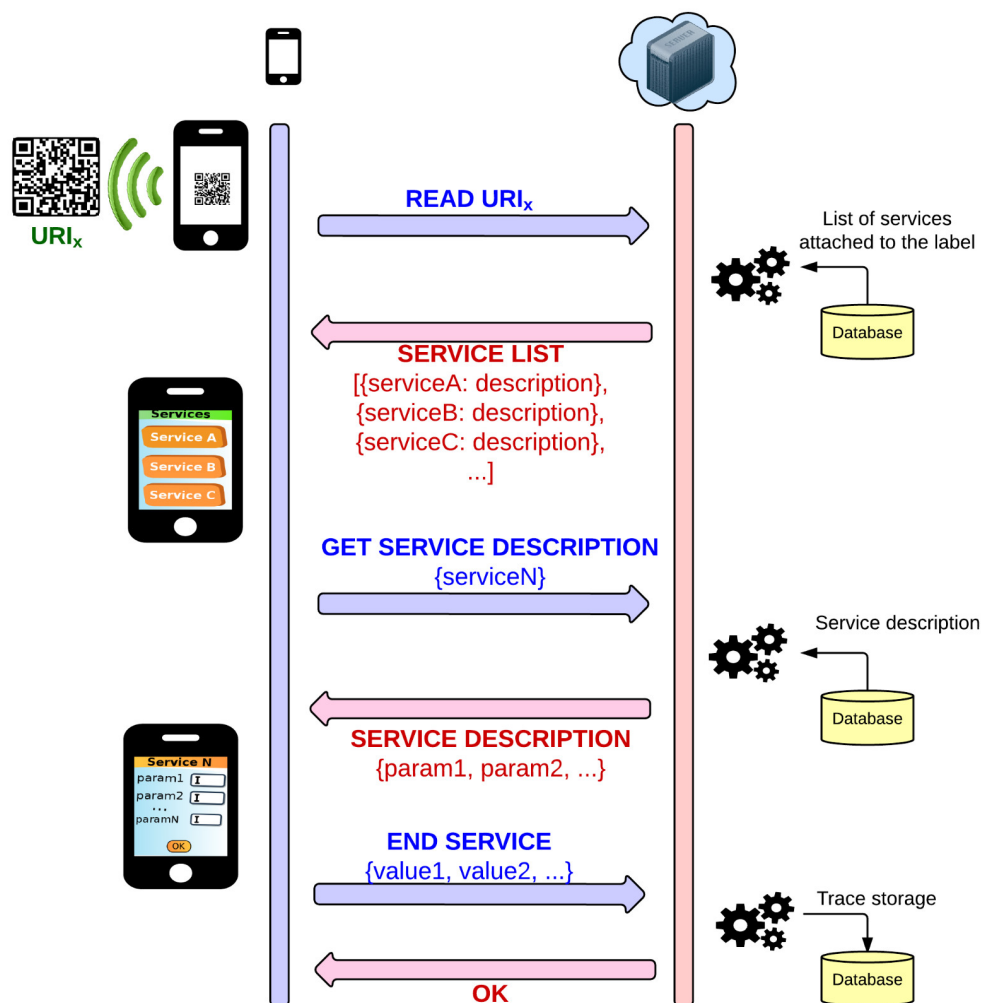

the software platform. In general, we used a client-server architecture. Thus, the business logic was hosted on servers accessible over the network and, as a result, the complexity of the agents was simplified.

In this methodology, the reference architecture is described from different perspectives that compose a comprehensive view of the platform. The aim is to be able to speak to the characteristics and peculiarities defined in the business model and the semantic modelling.

### **Client-Server Interaction**

To carry out a successful interaction with the frame of the proposal, the client (the software that runs on the end user device) and server must interact according to the established model. In particular, this interaction must be compliant with the model presented in [Figure 1](#). In this example, after reading the label on a PN bag, the client launches a request to the server. The server then responds with a list of services associated with the element depending on the requesting user and other related variables of context.

Afterward, the client must select the actual service to invoke using an on-screen interface. On selection, the server sends back a full description of the service under consideration. Using this description, the client software generates a form in the display with the parameters required by the service and that the user must provide. Finally, the values entered into the form are sent to the server according to the software interface and become a trace in the system.

**Figure 1.** Model representation of a regular interaction between client (software) and server.

### Reference Model

During the life cycle of a PN mixture, management and control of the traces may concern different institutions or companies (eg, pharmaceutical industry, hospitals, transport companies). Given the sensitive nature of the information processed, these organizations are compelled to store the information generated in its ecosystem under rigorous security measures to ensure compliance with legal and ethical regulations.

To achieve the required security levels, each organization may deploy its system locally according to its own standards of security. This decentralized scenario is achieved through the

use of specialized agents (running mobile apps for the final clients) that have the appropriate logic to establish direct connections with servers in their organizations.

By means of this modelling, different servers may record different traces throughout the life cycle of the product (see Figure 2). Consequently, if an unregistered user accesses the system, the central server is responsible for redirecting the request to the proper agent that possesses the requested information.

The central server acts, from the point of the client agent, as the single access point and coordinator for the existing local system. In this way, the fragmented system appears seamless to the user.

**Figure 2.** Reference structure for the different components and communication models.

### Modular Architecture

The architecture model for the server was designed following a modular approach. Thus, it was possible to divide the overall complexity of the system, and the logic layer was distributed according to the nature of each component. Figure 3 shows the high-level architecture of a server and different interfaces and management layers. We describe the main modules below.

### Open Information Provider

This provides a universal access point for public information about semantic records. In particular, it responds to HTTP requests on the URI that uniquely identifies the elements within the domain of the application.

### Tracking Application Programming Interface

This provides the functionality that is available for interaction with the specialized customer software. These features include services for discovering control services, accessing information about a concrete item, downloading service descriptions (eg,

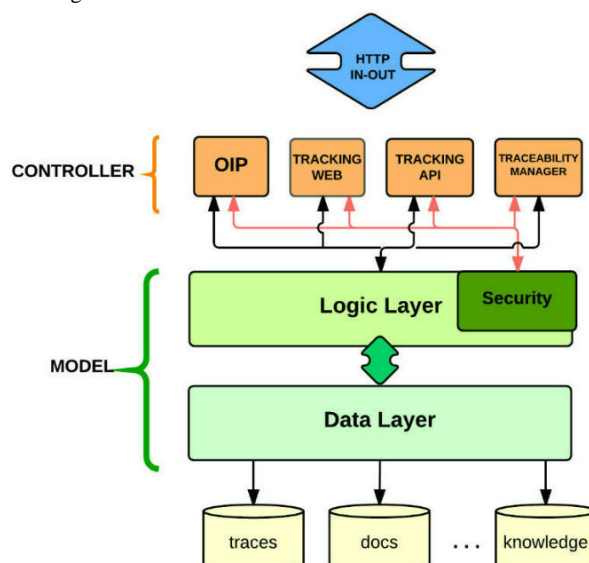

describing how to monitor variables), invoking a specific service for registration of the relevant traces, and recovering useful material for human users (videos, manuals, etc).

### Tracking Web

This provides similar functionalities to those offered by the tracking application programming interface using just the support of a Web browser.

### Traceability Manager

This provides a Web interface designed to support 1) functionalities related to traceability, such as checking historical traces according to user preferences, date, location, and related services, 2) an advanced search engine supporting advanced queries, 3) facilitating the definition of logical inference patterns and automatic analysis of procedures, problems, alerts, etc, 4) statistical analysis of existing traces to enable high-value services, and 5) automatic verification of adherence to protocols according to existing traces.

**Figure 3.** General architecture including server modules.

## Evaluation of the Platform

We developed simulation testbeds to test the validity of the prototype we developed. A test-retest control detected possible errors or conflicts in different contexts and control processes throughout the entire cycle of the PN mixture. From these data, we calculated the absolute and relative frequencies (percentages). We controlled information quality by double entering data; we corrected inconsistencies by consulting the original data.

## Results

### Prototype

We generated a mobile app for the Android operating system according to our presented models. This app reads different types of labels and tags, and interacts with the local server under the proposed schema. Also, the above-mentioned app ensures operability of the system, even in case of network disconnection, by means of an internal caching mechanism.

During the prototype implementation process, the following elements were provided: the central server, to redirect requests to the proper local server responsible; the local servers, to provide the necessary functionality for control and traceability; and the client app that supports efficient mechanisms for the discovery of CP and CCP.

Within the frame of the proposed model (see Figure 4), on reading the QR tag associated with a nutrition bag, the client software retrieves the list of invokeable services (offered by the system) and displays them to the user. To select the desired service, the user accesses a form on the device screen to submit the variables to be monitored. Finally, the information is sent to the server, which processes the new information and records it as a trace.

In this way, after reading a label attached to a PN bag using a mobile device with Internet access, the user can discover the control operations related to the identified element, at run time. That is, the platform dynamically retrieves control operations that can be invoked by the user according to the role assigned in the system (nurse, pharmacist, doctor, etc), the element under consideration, and other context variables such as time and location. All collected data are stored on a server that acts as a repository of information. And, using data mining techniques, the server can reuse these data and generate new knowledge by applying inference and discovery processes.

Use of the software is very intuitive and user centric, as the user interfaces are generated dynamically and ad hoc according to the descriptions provided by the server. Figure 5, for example, shows the list of services that the user can access after reading a label as the software agent generates it. In the same way, Figure 6 illustrates how the dynamically generated form is displayed to invoke service control.

Summing up, the developed prototype server covers the functionality required for the proper functioning of the overall process control and traceability support. Consequently, we have implemented mechanisms for logical reasoning that allow for the application of advanced processing methods on traces generated in this framework. Figure 7 is a screenshot showing the list of historical traces available in the system. In addition, this log of traces can be customized through various search filters (eg, prescription, type of nutrition, responsible for delivery, composition).

During the evaluation process, we collected 1040 test traces in different testbed scenarios. Table 1 lists the issues we identified, along with their proposed solutions.

To achieve the desired results and functionalities from the point of view of the final users, we identified several functional and nonfunctional requirements.

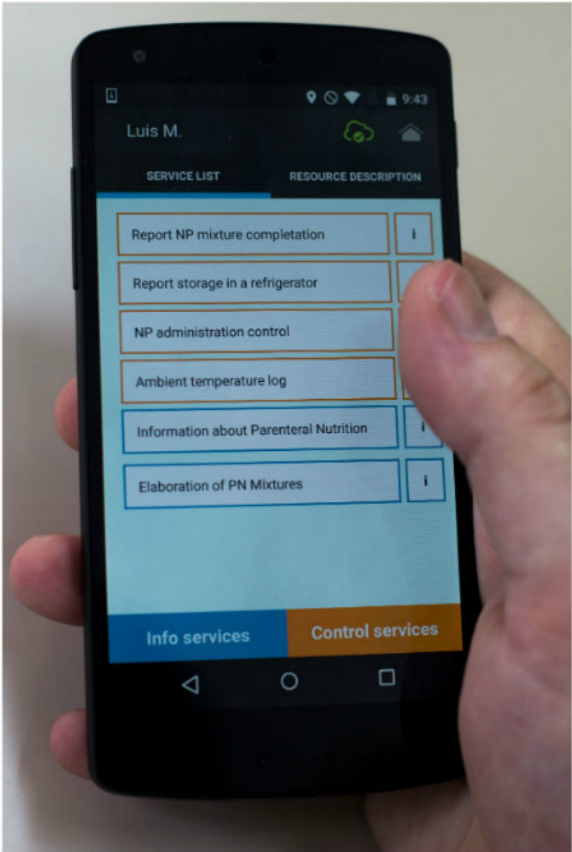

**Table 1.** Frequency (f) and percentage of errors (undesired situations) identified in the assessment of the management and traceability platform and their suggested corrections.

Undesired situation	f <sub>0</sub>	%	Solution
The QR <sup>a</sup> tag was stained and not readable.	9	0.87	Laminate labels.
QR tag was attached to a surface with a large curvature and was not readable (the camera was not able to capture a defined image of the whole QR code).	11	1.06	Reduce the size of the label to minimize the curvature radius or change its location to a nearby flat surface.
In poorly lit places, the camera was not able to read the QR tag.	5	0.48	While reading, the app triggers a flash to illuminate the corresponding surface.
The NFC <sup>b</sup> tag could not be read because it was attached to a metallic surface.	9	0.87	Replace basic NFC tags with special NFC tags designed to be used on metallic surfaces or place them on another spot.
The NFC tag was located behind a plastic sign on the door and could not be read.	14	1.35	Remove any surface between the mobile and NFC tag.
User was unable to log on to the app when offline the first time the app was used on that mobile device (no preexisting cache contents).	6	0.58	The system requests the user to log in, at least the first time, in an online context.
The user, trying to read the tag, noted that the battery was drained	2	0.19	User training (no solution in the app).
The user typed a decimal value by entering a comma instead of a period. As a result, data were misinterpreted.	21	2.02	Unblock use of the comma button in the app.
The system noted that it was impossible to invoke the service when the form was including incorrect values. No hints on the wrong values were provided.	6	0.58	Update the app to display a warning message when wrong data are detected. Also, present information about accurate expected values.
In the input form, when trying to send multiple documents (eg photographs) with the same name, the server could only recover the last one.	4	0.38	Implement a mechanism in the app to avoid file name conflicts.
Leaving the input form by mistake was possible, resulting in losing all data entered so far.	1	0.10	Modify the app so that trying to leave the input form prompts a message that the entered data would be lost and that requests explicit confirmation to leave the form.
The implementation required activating the GPS <sup>c</sup> service to inform the server of the location of the operator in each of the traces generated. This circumstance caused high battery consumption.	14	1.35	Replace the initial mechanism to recover coordinates based on continuous queries with an intelligent mechanism that checks the GPS service according to the user's mobility over time.
Total	102	9.81	

<sup>a</sup>QR: quick response.<sup>b</sup>NFC: near field communication.<sup>c</sup>GPS: global positioning system.**Figure 4.** Outlining the interaction with the platform through the QR code attached to a bag of PN mixture.

2015 - ToCP (Tracking of Control Points)

## Requirements

### Simple and Unobtrusive Use

Use of the platform should fit into the existing standard operating procedures, which should not intrude on or misuse the platform.

### Availability Throughout the Entire Life Cycle

The platform must include a highly adaptable and configurable framework. Thus, it would be possible to support a large range of organizations and to enable them to establish and manage their own procedures and services for the whole life cycle of the products.

### Support for Different Types of Labels

The labels we used allowed for unique identification of the elements in the domain. Due to their popularity and low cost, we used 2-dimensional labels (QR and data matrix code) and NFC.

### Mobile Devices

Smart mobile devices (mobile phones and tablets) offer the capacity and portability required for client use. Moreover, they are simple and intuitive to use and are highly available among potential users.

### ***Different Types of Services***

Services that could be generated and supported within the platform were of two types: control and information. Control services allow monitoring of one or more variables, while information services provide access to suitable pieces of information relevant to the context.

### ***Support for Different Roles***

The platform provides customization mechanisms. Thus, it was possible to filter the services available according to the role of the current user.

### ***Security***

Given the sensitive nature of the information exchanged, it is essential that the platform offer mechanisms to ensure the confidentiality of the exchanged information.

### ***Offline Operability***

Due to the nature of the problem, it is of the utmost relevance that no trace be lost at any point of the processes being monitored. Therefore, we developed software capabilities to make use of the platform possible even without a network connection.

## ***Discussion***

### **Principal Findings**

We outlined the provision of a holistic computerized control and verification system, for the entire process of production and distribution of a PN mixture. Our solution meets the recommendation of the consensus on the preparation of parenteral nutrient mixtures of the Spanish Society of Hospital Pharmacy [1] and is in line with clinical guidelines on guarantees and rational use of PN [16].

Nevertheless, the key point to using labels as described to uniquely identify the items under consideration in any stage is related to the platform's application in the analysis and monitoring of hazards (by means of CCP) within a system of hazard analysis and critical control points (HACCP) implemented in the whole process of preparation and administration of PN mixtures. Intravenous therapy management is a critical process in clinical patient safety involving traceability, accountability, and security. Thus, the use of HACCP-based systems ensures excellence in its control [17]. This tag, attached to the PN bag, can be very useful in ensuring links with the prescription, reporting about its proper use according to established standards, and providing data such as elaboration, issue or expiration date, dosage, and possible side effects [18]. Regarding home care, these labels integrated into PN containers facilitate the exchange of information between caregivers and the medical team, and in emergency care this platform contributes to immediate patient identification and comprehensive knowledge of medical history. This model provides, at the same time, security features in clinical data transmission [19,20].

In addition, the software developed for the Android operating system supports an internal cache mechanism that makes regular operation of the system possible even if the network connection is not available [21]. Among its capabilities, the central server acts as a repository of publicly accessible information that enables the reuse of existing knowledge in an open and free manner. To make this feature possible, the central server periodically retrieves the public records of each of the deployed servers. Then, this information is automatically enriched with external information gathered over the Web using semantic enrichment mechanisms that we have already deployed successfully in previous work [22].

Besides features related to control management and traceability, the prototype system we developed has the following advantages: improved management of patient care and quality of care, empowerment of the actors involved, and ensured continuity of the action planned. The association of these characteristics with reducing the rate of patients with missing data and better monitoring of adherence to treatments and of iatrogenic risks has been previously proven [23]. Regarding adherence to PN treatments, it has been found that only intensive care units met established goals, with adherence being especially problematic in monitoring patients admitted to home care units [24]. This problem can be addressed by using the platform we have developed.

The evaluation tests showed a low rate for the unfavorable situations we observed. Also, we were able to solve most of them fully except for those related to lack of user training. Nevertheless, this was an expected issue. We were well aware that training and user feedback should always be present in the deployment of mobile technologies [25,26].

In addition to the good evaluation results, an advantage that must be considered is the positive adoption of mobile apps due to their low cost and simplicity of use. Previous studies have shown that these apps are feasible for real life, and are productive for clinical application [27].

### **Limitations**

Among possible limitations of this study, it must be mentioned that, although we conducted the evaluation in a testbed designed in a realistic way from the point of view of prescription logistics, preparation, and delivery, the overall evaluation would benefit from an actual usage scenario in a heavy load condition to ensure optimal application [28].

### **Conclusions**

The prototype platform is fully operational and ready to be tested in a real context. Consequently, we have generated and tested a system based on mobile technology that allows better monitoring and management of the quality of PN mixtures and that is easy to incorporate into the daily praxis of health care processes.

## Abstract

**Background:** According to established ethical principles and guidelines, patients in clinical trials should be fully informed about the interventions they might receive. However, information about placebo-controlled clinical trials typically focuses on the new intervention being tested and provides limited and at times misleading information about placebos.

**Objective:** We aimed to create an informative, scientifically accurate, and engaging website that could be used to improve understanding of placebo effects among patients who might be considering taking part in a placebo-controlled clinical trial.

**Methods:** Our approach drew on evidence-, theory-, and person-based intervention development. We used existing evidence and theory about placebo effects to develop content that was scientifically accurate. We used existing evidence and theory of health behavior to ensure our content would be communicated persuasively, to an audience who might currently be ignorant or misinformed about placebo effects. A qualitative 'think aloud' study was conducted in which 10 participants viewed prototypes of the website and spoke their thoughts out loud in the presence of a researcher.

**Results:** The website provides information about 10 key topics and uses text, evidence summaries, quizzes, audio clips of patients' stories, and a short film to convey key messages. Comments from participants in the think aloud study highlighted occasional misunderstandings and off-putting/confusing features. These were addressed by modifying elements of content, style, and navigation to improve participants' experiences of using the website.

**Conclusions:** We have developed an evidence-based website that incorporates theory-based techniques to inform members of the public about placebos and placebo effects. Qualitative research ensured our website was engaging and convincing for our target audience who might not perceive a need to learn about placebo effects. Before using the website in clinical trials, it is necessary to test its effects on key outcomes including patients' knowledge and capacity for making informed choices about placebos.

**Introduction**

Clinical trials must be conducted in accordance with Good Clinical Practice guidelines [1] and ethical principles espoused in the Declaration of Helsinki [2]. In particular, patients should be fully informed about the interventions they might receive and must give written informed consent. In a placebo-controlled randomized clinical trial this means that all participants should be fully informed about both the new intervention being tested and the placebo control. However, a content analysis of participant information leaflets from United Kingdom-based placebo-controlled trials found that written information about placebos is typically incomplete and at times misleading [3]. For example, despite strong evidence of placebo effects and mechanisms in the scientific literature, [4-7] only 1 of 45 leaflets explicitly stated that patients might experience beneficial effects from the placebo [3]. Using placebos in clinical trials appears to be generally acceptable to patients, but crucially this depends not only on the severity of the condition being treated and available alternative controls, but also the adequacy of informed consent [8]. Furthermore, evidence from surveys and qualitative studies shows that clinical trial participants often have false beliefs about, and partial understanding of, placebos and their possible effects [9-11]. Examples of such false beliefs include the belief that placebo effects are fake, or illusory, and that people who respond to placebos are gullible or foolish [11-13]. This might explain why the inclusion of placebo controls can deter people from volunteering to participate in trials [14]. Overall, it seems that a significant proportion of clinical trial participants might have inadequate understandings of the potential clinical effects of placebo interventions [9-13], thus jeopardizing the ethical validity of informed consent [3] and potentially hampering recruitment [14]. More accurate and complete information about placebos could usefully address this ethical shortcoming, could combat patient anxiety about placebo effects [12], and reduce distress at being debriefed in placebo condition participants [15,16].

This paper describes the development of an educational website about placebo effects. We aimed to create an informative, scientifically accurate, and engaging website that could be used to improve understanding of placebo effects among patients

who might be considering taking part in a placebo-controlled clinical trial. We chose to develop a website rather than a traditional printed information leaflet because websites (1) are increasingly popular sources of consumer health [17-20], suggesting that this format reflects consumer preferences, (2) easily incorporate interactive features [21], which can enhance engagement and effective education [22], (3) are easily and cheaply disseminated for widespread access [21] (86% of UK households had Internet access and 78% of adults accessed the Internet daily or almost daily in 2015 [23]), and (4) can be readily adapted and/or tailored to different subgroups [21]. Our intention was to develop a resource that could potentially be used across a large number of clinical trials and/or adapted for use in specific trials. However, because the effects and mechanisms of placebos differ across symptoms and diseases [24], we chose one clinical target to focus on for this version of the website. We chose placebo analgesia as pain is relevant to a large number of clinical conditions and placebo analgesia is a well-documented placebo effect [4,25-27]. The target audience for this website was thus adults experiencing pain symptoms (from any clinical condition).

**Methods****An Evidence-, Theory-, and Person-Based Approach**

We drew on existing evidence and theory, and conducted qualitative research to develop our website using an approach derived from evidence-based, theory-based [28,29], and incorporating elements of person-based [30] intervention development. In the context of a website about placebos, we felt this combined approach was more valuable than any single approach. It was important to use existing evidence and theory about placebo effects to ensure our content was scientifically accurate. Drawing on existing evidence and theory about health behavior was essential to ensure our content would be communicated persuasively to an audience who might currently be ignorant or misinformed about placebo effects. Conducting our own qualitative research was necessary to ensure our website was engaging and convincing for our target audience who might not have a perceived need to learn about placebo effects. Figure 1 provides an overview of the process of developing the website.

**Figure 1.** Overview of methods used to develop the website.

### Planning the Intervention

To plan the content and structure of the website we considered four key questions:

What psychological targets are relevant to providing information about placebos? In other words, what would we expect to change as a result of viewing our website?

What do patients typically believe about placebos and placebo effects?

What is the current scientific understanding of placebos and placebo effects?

How should information about placebos and placebo effects be provided to be most effective?

### Psychological Targets

Given current partial understandings, misunderstandings, and poor quality information about placebos [3,9-11], we decided our website should focus on promoting informed choices about

placebos. Making an informed choice can be understood as choosing to act in a way that is based on one's knowledge and one's values [31-33]. According to this definition, it is incorrect to specify that a particular option is the correct choice for everyone: what counts as the informed choice will differ across equally knowledgeable individuals according to their values. To make an informed choice, a person needs to have an accurate understanding of the options available, have formed an opinion about the options based on their values, and make a decision (or otherwise act in a way) that is consistent with their knowledge and values. We chose to focus on informed choice, rather than informed consent, because the process of informed consent to take part in a placebo-controlled clinical trial would typically involve a face-to-face interaction between trial personnel and potential participants and would involve the provision of trial-specific information (eg, about the trial intervention). Our website is intended to provide a generic resource to educate and inform members of the public who may be considering receiving placebos as part of a clinical trial.

In the context of placebos, an informed choice to receive a placebo (eg, by taking part in a trial) requires knowledge about the possible effects of placebos, a positive attitude to taking placebos, and a decision to take placebos. An informed choice not to receive a placebo requires knowledge about the possible effects of placebos, a negative attitude to taking placebos, and a decision not to take placebos. To promote informed choice our website thus needed to improve people's knowledge of placebos. Therefore, knowledge about placebos and their effects was our primary target for change.

Making an informed choice to receive placebos can be understood as a volitional behavior, and thus can be modelled using the Theory of Planned Behavior [34]. According to the Theory of Planned Behavior, patients' intentions to take placebos are driven by attitudes, subjective norms, and perceived behavioral control. These, in turn, are determined by beliefs [34]. Thus, patients will be more likely to make an informed choice to receive placebos if they (1) believe that placebos are effective/good for them and value these effects (attitudes), (2) believe that people whose opinion they value would approve of placebos (subjective norms), and (3) believe that they control whether or not they receive placebos (perceived behavioral control). While we did not want to encourage people to decide to receive placebos (except in the context of an informed choice), we did want to provide information that was consistent with people's existing cognitive structures. Therefore, we designed the website to address the following: consequences of receiving placebos for the individual (attitudes), other people's views on placebos (subjective norms), and practicalities around receiving placebos (perceived behavioral control).

### Typical Beliefs About Placebos

To understand typical beliefs about placebos we reviewed qualitative studies of patients' experiences of placebos in clinical trials. This literature showed that people are interested in but often anxious about or confused by placebos [35,36]. For example, in qualitative studies embedded in acupuncture trials patients described interest or anxiety as to whether they receive placebo or real treatment [37], and the knowledge that they may receive placebo made them doubt any perceived improvements in symptoms [12,13]. Patients conceptualize placebos and their effects in various ways, dominant among which are understandings of placebos: as fake treatments that fool people into thinking they are better; as tools that are necessary for scientific research; and as interventions that have real effects mediated by psychological mechanisms [11]. Patients' reactions to being told they had been in the placebo arm of one clinical trial included surprise and disbelief. Some worried that they would 'throw the trial off' and interpreted their experiences in a way that affirmed their understanding of their illness or emphasized the positive effect of social support from trial staff [15].

Based on these findings, we devised website content to describe the possible (positive and negative) effects and experiences of placebo ('can it help?', 'what is it like?'). The website also addresses common concerns about placebos ('what concerns me'), debunks myths that placebo responders are malingerers

or gullible ('who does it help?'), and explains the mechanisms underpinning placebo effects ('how could it work?').

### Scientific Understanding of Placebo Effects

To ensure scientific accuracy we consulted systematic and narrative reviews and seminal studies concerning the effects and mechanisms of action of placebos [4,6,7,24]. We selected key evidence-based facts about placebo effects to convey in the website including: placebos can relieve pain and stiffness in osteoarthritis [27]; placebos can improve reported pain across a number of painful conditions [25]; and placebos can elicit side effects in what is called a 'nocebo' effect [38] (ie, the negative aspect of the placebo effect that occurs when an adverse event, such as experiencing side effects, is triggered by negative expectations [39]). The website also conveyed that it is difficult to know how many people placebos will work for, but they seem to improve pain for between 26% and 51% of people in placebo studies [6].

The mechanisms of action of placebos have been described in neurobiological, psychological, and anthropological terms. Patients also appear to develop understandings of placebo effects at different levels, with some focusing on psychological processes and others emphasizing social processes [11,15]. To accurately represent the scientific literature and appeal to different patients, we therefore chose to convey a number of different theories of placebo effects, specifically neurobiological pathways [40], expectancy [41], conditioning [42], meaning response [43], and the therapeutic relationship [44].

We also drew on scientific literature when developing material on other aspects of placebos outlined in the previous section. For example, in addressing concerns that doctors have to lie to patients to give them placebos, we drew on evidence about open-label placebo prescribing, suggesting that doctors do not have to lie to patients to elicit placebo effects [5].

### Effective Information Provision

To plan how to provide information effectively to educate people about placebos and thus improve their knowledge, we considered a selection of relevant theories. In particular, we drew on theories of motivation, learning, and attitude formation.

We drew on Self-Determination Theory [45] to plan how to design our website so that it would be maximally engaging for people. Self-Determination Theory distinguishes between intrinsic motivation (eg, curiosity) and extrinsic motivation (eg, payment) as drivers for action; our website relies on intrinsic motivation as we do not anticipate eventual users to receive external rewards for using it. Cognitive Evaluation Theory (1 of 6 'mini-theories' within Self-Determination Theory) elaborates on how social contexts can impact on intrinsic motivation, and suggests that intrinsic motivation can be enhanced by satisfying basic human needs of competence and autonomy [45]. Thus, if the website supports people's perceptions of themselves as competent and autonomous it should enhance intrinsic motivation and be more engaging. To promote perceptions of competence, we designed easy quizzes (using the word 'surprise' rather than 'wrong' to give feedback on incorrect answers) and used simple and consistent navigation. To promote perceptions of autonomy, we allowed users as much

freedom of choice as possible, for example in terms of the order in which to view different pages.

Educational theory suggests that people have different learning styles [46]; therefore, we decided to provide information in different formats: written text, photographs and images, audio clips, and film. We used quizzes to engage readers in active learning [47] and to test readers' knowledge (tests are an effective means of improving learning [48]). We also considered to whom to attribute different sources of information. According to Social Learning Theory, when we identify with another person (a 'model') and perceive them to be competent and similar to us, we may learn from observing them [49-51]. Therefore, we decided to use actors to narrate first-person accounts of patients' experiences of taking placebos, and to choose actors of various ages, genders, and ethnicities. We drew on qualitative studies of real patients' experiences in clinical trials to develop the first-person accounts [11-13,15].

While our focus was on educating people by providing accurate information about placebos, attitude formation and change processes might also occur in response to information provision. According to leading theories of attitude change, there are both central and peripheral routes to attitude formation and change [52]. Central routes are well-described by the Elaboration Likelihood Model and entail highly-motivated individuals engaging in an effortful way with substantive messages, assessing new information in relation to previously held beliefs, and coming to a reasoned conclusion [53]. Peripheral routes, as described by the Heuristic Systematic Model of persuasion, entail the use of simple heuristics or 'rules of thumb' based on superficial cues such as source credibility and number of arguments presented [54,55]. To encourage the development of more informed attitudes toward placebo effects, we described scientific evidence to support our substantive message that placebos can have effects, presented multiple scientific theories about how placebos produce effects, and bolstered the credibility of the message source by describing the website and study authors' academic credentials.

We followed guidance for developing patient-focused health information by considering five key issues: information needs, accessibility, quality, readability and comprehensibility, and usefulness [56]. To ensure we addressed different needs for information, we allowed readers a choice about whether to access basic or more complex information. In other words, we used simple text to convey basic information about a topic (based on the literature), then offered a click-through to a more detailed evidence summary describing a specific study or review, and then offered another click-through to access the actual scientific paper. To provide access to scientific evidence we wrote accurate text, evidence summaries, and in some cases, provided full papers. We considered color blindness and dyslexia in our choice of colors and formatting; for example, using clear, plain text and consistent formatting throughout. We also ordered the items on the pages to make them more accessible for people using text-reader software. To ensure we provided high-quality information we used peer-reviewed publications and reviews. To enhance readability we wrote in short sentences with simple sentence construction and used readability indices to guide our writing. To enhance usefulness, we provided information on

relevant topics (according to the literature on patients' views of placebos), included patient representatives in the research team, and conducted a think aloud study to elicit users' feedback.

## Designing and Building the Intervention

We used the insights gained during the planning phase to write the content and map out the initial structure of our website using PowerPoint slides. Content was based on published evidence, as described above. To ensure content was relevant to our primary targets for change (knowledge, informed choice) and mapped onto existing cognitive structures (attitudes, subjective norms, perceived behavioral control), we reviewed each draft page for relevance to these targets and structures. We then built the website using LifeGuide open source software to facilitate the design and scientific testing of Web-based behavior change interventions [57].

Audio clips were produced for first-person narratives about the phenomenology of placebo effects. A film was scripted and produced to illustrate a placebo effect in an experimental context (using a cold pressor task) and to describe the effects and mechanisms of action of placebos. As a visual medium that lends itself well to linear narrative, film provides an unrivalled, vivid view of the world and may capture events, people, and performances with detail and richness. Koumi [58] suggested a number of considerations for writing instructional film scripts including: the 'hook' (an element which captures viewers' attention), asking questions, synergy between image and narration, clarity of argument, audio/visual cues to denote changes, and argument consolidation. The film we produced integrated these steps through the use of animated infographic, live action, interview, and narration to reinforce key messages. While there is no hard-and-fast rule as to how many messages a video can contain, studies show that people can store approximately four discrete 'chunks' of information in short-term memory [59], and some writers advise that a 30-minute video can comfortably elucidate three essential points in some detail. As the placebo video has a running time of 4 minutes 20 seconds, the script was written to focus on two key points: that placebos have significant, measurable, positive effects on health, and that these effects are present in conventional treatments.

Korakidou and Charitos [60] asserted that film involves viewers on an emotional as well perceptual level, employing empathy to facilitate engagement and retention. In addition, in productions that include the spoken word it is believed that viewers prefer and empathize more readily with conversational language that is easily understood [61]. To facilitate this, the video used live action sequences to encourage viewers to imagine themselves in similar situations, and simple, jargon free narration to ease comprehension and reduce cognitive load.

## Think Aloud Study

A small qualitative study during this phase informed the final content and structure of the website. Ethical approval was obtained from the host institution (reference: ergo id 10933) and all participants gave written informed consent. Posters and Web-based advertisements were used to recruit 10 participants

from the host institution (9 female, a mix of staff and students, aged 19-35 years, 4 with musculoskeletal pain). They worked through the website in the presence of the researcher, speaking aloud their thoughts and answering specific, probing questions (eg, “what do you think this page is about?”, “What did you think about navigating through the site?”). The mean interview duration was 32 minutes (range, 22-40) and interviews were audio-recorded. Interviewees’ comments were reviewed and coded according to the topic to which they referred using deductively derived codes based on aspects of the website (eg, “placebos in clinical practice”, “patients’ stories”) and inductively derived codes for comments that did not relate directly to specific contents (eg, “technical terms”). Comments were further categorized as primarily related to content, style, or navigation. Two researchers were involved in interpreting interviewees’ comments, which avoided an idiosyncratic focus on particular issues and enabled discussion of which comments to prioritize when deciding on modifications to the website (eg, in cases where interviewees provided divergent and/or conflicting perspectives). Interviews proceeded iteratively, with early interviews being analyzed first and used to inform changes to the website that were then presented in later interviews.

## Results

Comments from participants in the think aloud study highlighted aspects of the website that participants felt were engaging as well as occasional misunderstandings and stylistic and structural

features that were off-putting and/or confusing, and thus needed improving. Elements of content, style, and navigation were therefore modified to improve participants’ experiences of using the website. [Table 1](#) presents selected quotes from participants, illustrating how their perspectives were used to inform website modifications. Content changes included: elaborating on ‘mind-body healing processes’ as participants found this vague and wanted more information about how placebo effects might work; adding reassurance that pain is still real even if it reduces with placebo; adding specific details and evidence from scientific papers about how many doctors use placebos; and adding an example to address participants’ concerns about how doctors can justify using placebos clinically: “For example, sometimes doctors may listen to a patient’s chest, even when it is not essential for making a medical diagnosis, because it can be reassuring for the patient.” Stylistic changes included: choosing photos (for patient’s stories) that look more realistic as participants felt some looked like stock photos, and thus lacked authenticity; ensuring alignment and consistent logo placement throughout as participants noticed minor misalignments and saw them as unprofessional, reducing the credibility of the website; and modifying patients’ stories to always use convincing lay language, and thus avoid the off-putting impression of advertising. Navigation changes included: adding a menu bar to all pages to make each page accessible from any other page, and page buttons changing color once viewed.

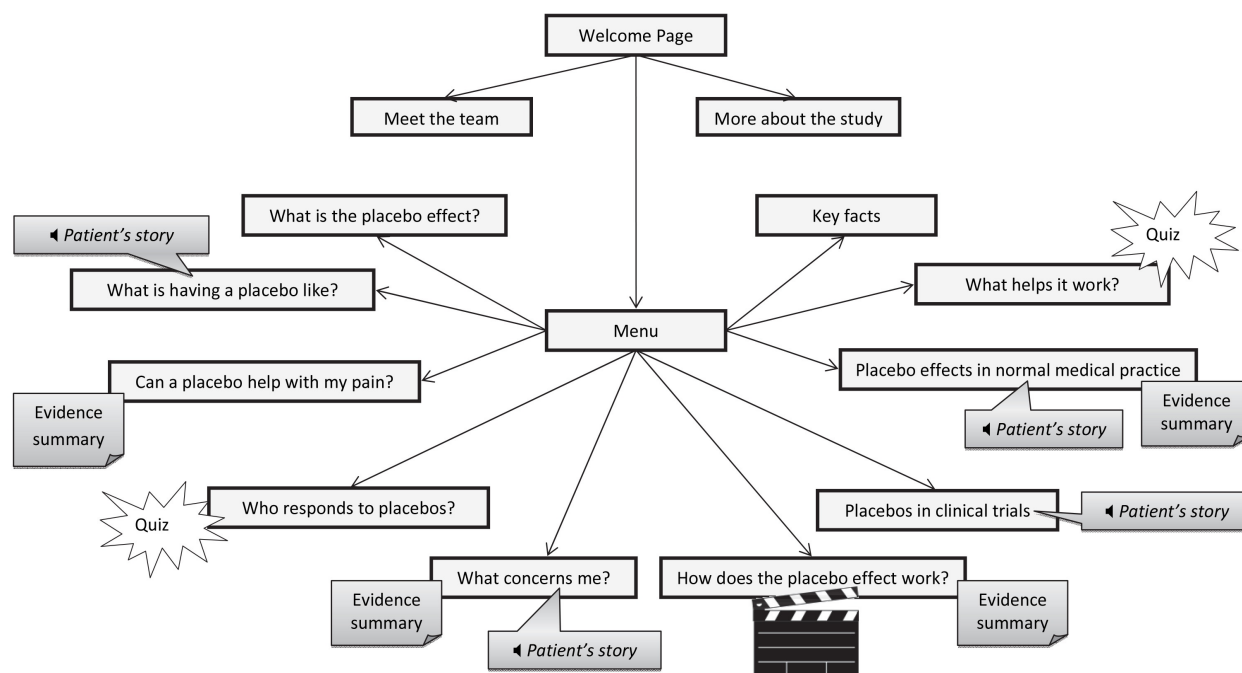

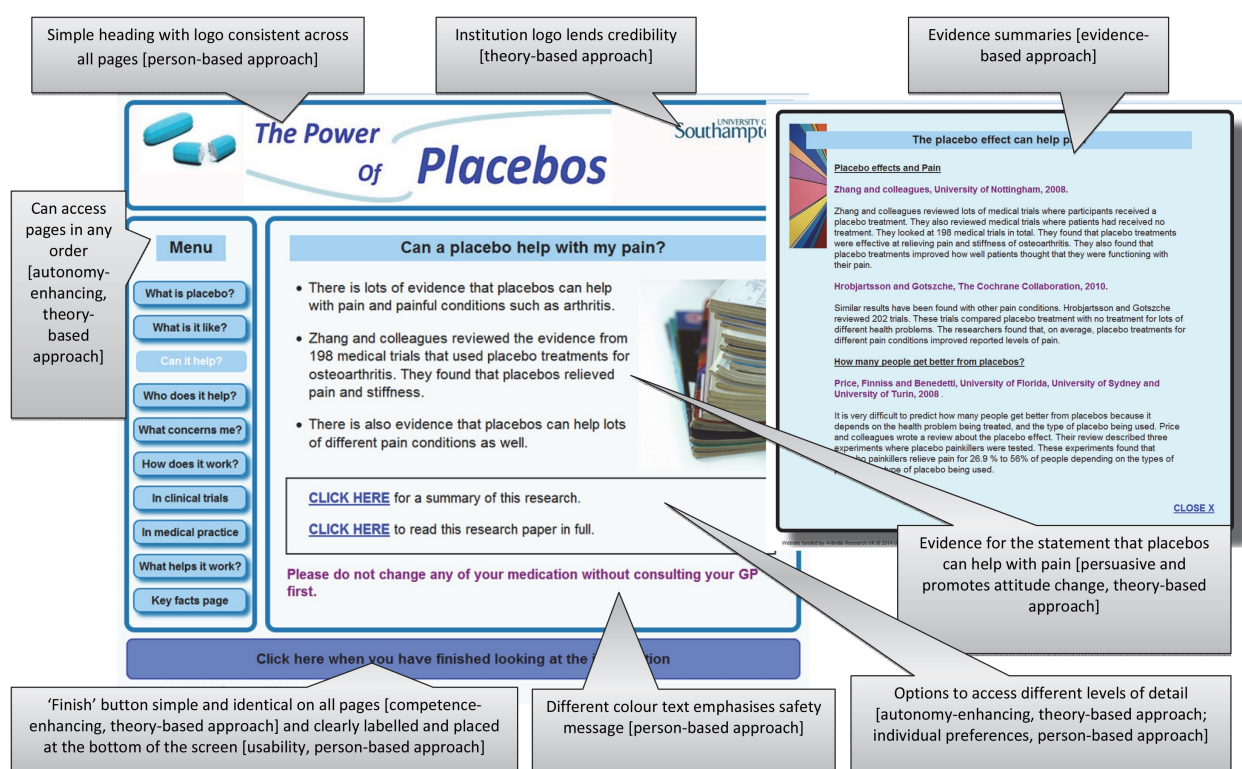

**Table 1.** Illustrative Quotes from Participants Used to Refine the Website

Topic	Quote	Modification
Content: information on placebo effects	So it’s basically asking a question that yes it can help with your pain. And obviously there’s been quite a big study that shows that it can definitely relieve pain and stiffness. There’s obviously useful information. (Participant 2)	None needed
Content: patients’ stories	I think it’s good to have a case study. I didn’t realize you could do placebo surgeries so that’s quite interesting. (...) It’s nice to have a picture of the person as well. It’s good to have the option to read what he says as well, so if you don’t want to read it, you can listen to it. (Participant 3)	None needed
Content: technical terms	Maybe explain what ‘mind-body self-healing processes’ are. Um otherwise I think like I understand what it says, yeah. (Participant 1)	Expand on ‘mind-body self-healing’
Content: placebos in clinical practice	What is going through my mind maybe a little bit is maybe kind of if I was to receive the placebo and not actually know. So maybe something that addresses that, how common it is to be given a placebo in the health care sector. (Participant 8)	Add specific details about how many doctors use placebos
Style: patients’ stories	Are these the pictures of the actual people who are talking or are they stock pictures? (Participant 6)	Change photos
Navigation: menu	Like usual websites have everything on the same page, so it’d have a menu at the side that you always see. So is a bit confusing because I’m going back, but I cannot remember what I’ve clicked on necessarily. It’s all like a flow, you have to go through it, and back again. I think it might be more useful to have a menu at the edge or something. (Participant 5)	Add a side menu bar that is always available

The final structure and main content of the website is shown in [Figure 2](#). Nine topics are covered across 10 main pages (the last page offering a summary of key facts), which can be accessed in any order. Text and images are supplemented by scientific evidence summaries (on 4 pages), audio clips with photos and

transcripts of patients’ experiences (on 4 pages), a film, and 2 quizzes (with immediate feedback). [Figure 3](#) shows one page (“Can a placebo help with my pain”), annotated with key features that illustrate the contribution of evidence-, theory-, and person-based approaches.

**Figure 2.** Overview of structure and contents of website.**Figure 3.** Example page annotated to highlight key features and their development from evidence-, theory-, and person-based approaches.

## Discussion

### Summary

We have developed a new website about placebos that conveys scientifically accurate information in a way that should engage members of the public and enable them to make informed choices about placebos. The development process drew on evidence about placebo effects, theory about education, attitudes

and motivation, and qualitative research to maximize the website's likely effects.

### Strengths and Limitations

Strengths of this project include the multidisciplinary team and the combination of evidence-, theory-, and person-based approaches [28-30]. Team members shared expertise in topics, including placebo effects, digital interventions, film, and chronic pain, and contributed diverse professional perspectives (eg,

psychology, general practice, physiotherapy, acupuncture). Two team members were patient representatives whose input helped ensure our website addressed important issues in an accessible and nonpatronizing manner. By drawing on a combination of approaches we were able to incorporate evidence, theory, and users' perspectives in a flexible manner throughout the intervention development process.

The main limitation of the study was the homogeneous sample of participants. Involving a more diverse sample of patients in our think aloud study would have allowed us to better gauge the comprehensibility of the website among members of our target audience, adults with experience of pain symptoms. The same issues were raised repeatedly across the 10 interviews, suggesting additional interviews would have produced diminishing returns for additional cost. However, additional interviews with people with other characteristics (eg, more severe chronic pain conditions) might have elicited novel comments. While participants' views on the format and structure of the website were vital for improving its usability, these issues may have been particularly pertinent for our sample because, from their comments, they appeared to be experienced Internet users with a good baseline understanding of placebo effects. A more diverse sample might have uncovered additional issues and/or misunderstandings about placebos and placebo effects. Future think aloud studies for website development would benefit from sampling diverse participants from the population of likely end-users and finding ways to encourage them to focus on the substance of the website as well as its style and structure. The full person-based approach includes guidance on how to

achieve this to ensure qualitative research goes beyond user-testing to focus on participants' perspectives on substantive issues [30].

## Applications

Using our website to inform potential clinical trial participants about placebos could have both beneficial and detrimental consequences. For example, it might improve the validity of informed consent [3], alleviate anxiety about placebos, ease the process of unblinding to placebo allocation at the end of trials [15,16], reduce adverse effects [62], and/or enhance recruitment [14]. However, increasing patients' expectations of benefit during trials by encouraging positive beliefs about placebos might increase the size of the placebo effect [63,64]. This could introduce bias [65] particularly if placebo and intervention effects are not additive [66] and/or could reduce estimated treatment effects [11]. It is therefore vital to test the effects of providing comprehensive information about placebos before changing research practice. To contribute to this much-needed evidence base, we will report separately a randomized experiment testing the effects of our new website on knowledge and informed choice about placebos.

## Conclusions

In conclusion, we have developed an evidence-based website that incorporates theory-based techniques to inform members of the public about placebos and placebo effects. Before using the website in clinical trials it is necessary to test its effects on key outcomes, including patients' knowledge and capacity for making informed choices about placebos.

## Acknowledgments

This project was funded by a grant from Arthritis Research UK (grant reference 20113). The funder had no role in the design of the study and collection, analysis, and interpretation of data and in writing the manuscript.

The authors would like to thank the participants who took part in the think aloud study, Christine Bagg (patient representative) who contributed to study design and helped review the website, the student volunteers who helped to test the website, and Dr Jin Zhang and the core LifeGuide team who provided technical support for programming the webpage.

## Abstract

**Background:** Web-based interventions may have the potential to support self-care in patients with chronic disease, yet little is known about the feasibility of Web-based interventions in patients with heart failure (HF).

**Objective:** The objective of our study was to develop and pilot a Web-based self-care intervention for patients with HF.

**Methods:** Following development and pretesting, we pilot tested a Web-based self-care intervention using a randomized controlled design. A total of 28 participants completed validated measures of HF knowledge, self-care, and self-efficacy at baseline and 1-month follow-up.

**Results:** Change scores and effect size estimates showed that the mean differences in HF knowledge ( $d=0.06$ ), self-care ( $d=0.32$ ), and self-efficacy ( $d=0.37$ ) were small. Despite email reminders, 7 of 14 participants (50%) of the sample accessed the site daily and 4 of 14 (28%) had no record of access.

**Conclusions:** Larger randomized controlled trials are needed that attend to all sources of self-efficacy and include more comprehensive educational tools to improve patient outcomes.

## KEYWORDS

heart failure; knowledge; patient education; self-care; self-efficacy; self-management; web-based intervention

## Introduction

Despite improvements in treatment and prevention, chronic heart failure (HF) remains a serious health burden and carries a poor prognosis [1]. Given the complex and progressive nature of HF, interventions are needed that slow disease progression and prevent hospital admissions [2]. One strategy to improve health outcomes in patients with HF is to enhance self-care behavior related to physical activity, nutrition, fluid management, and treatment adherence [3]. Self-care is defined as “a process of maintaining physiological stability by monitoring symptoms, adhering to the treatment regimen (self-care maintenance), and promptly identifying and responding to symptoms (self-care management)” [4]. Self-care

education is a critical strategy in empowering HF patients to be informed and actively engaged in monitoring their condition and adjusting treatment accordingly [5].

Although findings are mixed, previous research suggests that Web-based interventions may have the potential to improve clinical outcomes and reduce hospitalizations in patients with chronic diseases including HF [6,7]. Using a Web-based app as a cost-effective intervention might facilitate access to education and improve self-care skills [8]. Yet there are very few clearly conceptualized studies that have evaluated Web-based interventions for HF patients. Two descriptive studies reported high levels of patient satisfaction with educational websites providing information [9] and a daily communication method between HF patients and health care

providers [10]. Findings indicated that older HF patients with limited computer skills were willing to engage with Web-based education if provided adequate resources and instruction [9].

Only two controlled studies could be identified that examined the effectiveness of a Web-based HF self-care program. Westlake et al [11] tested a Web-based HF and symptom management education program specifically designed for older HF patients ( $\geq 60$  years). In addition to educational modules, patients were encouraged to use the website at home to email a clinical nurse specialist for support, link to video-based Web content, and monitor personal clinical data. A total of 40 patients attending an outpatient HF clinic were recruited to the 12-week Web-based intervention and were compared with 40 age- and sex-matched historical controls who received HF care as usual. Groups were similar at baseline, and results showed a modest benefit for perceived control over health status and mental health quality of life, but not for physical health quality of life.

Another study [12] also tested a Web-based HF self-care program. In addition to usual care, 16 HF patients randomly assigned to the treatment group received a computer with Internet access, as well as basic computer training. The website provided self-care information and videos, access to record and monitor vital signs, health behavior, and HF symptoms daily, and emails from health professionals for feedback on progress and emotional support as needed. It was found that at both 6- and 12-month follow-ups, only the treatment group showed significantly improved HF knowledge, amount of exercise, and quality of life, as well as reduced HF symptoms, blood pressure, and health care utilization [12].

The preliminary findings of the HF studies above, combined with systematic reviews [13,14], suggest that Web-based educational interventions may have a role in supporting HF patients in the community. In this study, we pilot tested a Web-based self-care intervention that provided education and self-monitoring tools for ambulatory HF patients. Our primary aim was to evaluate the feasibility of a Web-based intervention in improving HF patients' knowledge, self-care, and self-efficacy.

## Methods

### Design

The website development phase involved seeking expert feedback and pretesting the user friendliness and appropriateness of the intervention and outcome measures with HF patients. We recruited an expert panel comprising two cardiologists, four cardiac nurse researchers, and one HF nurse practitioner to advise on the development and content of the website. The software was developed by an information technology team that also provided feedback on the design. We recruited a group of 10 patients with chronic HF visiting a community outpatient HF service to pretest the intervention. During face-to-face meetings, patients provided their feedback and recommendations on the Web-based app content, ease of navigation, and user friendliness. To examine the feasibility of the Web-based HF self-care intervention, we then piloted the intervention using a randomized controlled design over a 1-month period.

### Participants

The pilot sample comprised 29 patients consecutively recruited from a tertiary hospital HF service and a university health clinic located in Brisbane, Australia, between December 2013 and May 2014. Patients were eligible if they were English-speaking adults, had cardiologist-diagnosed class I–III HF according to the New York Heart Association (NYHA) classification and had a left ventricle ejection fraction  $< 40\%$ . Participants were required to have home or mobile Internet access. Exclusion criteria included nursing home residents, severe cognitive impairment, and critical illness.

### Procedure

After providing informed consent at an introductory face-to-face session, participants completed a baseline questionnaire and were randomly assigned to the intervention or control group. Participants in the intervention group were assigned a username and password and were provided basic training on how to use each component of the website. They could then access the website educational modules each day, and record and monitor personal data such as HF-specific symptoms. The intervention group also received a weekly personalized email to improve engagement with the intervention. Both intervention and control groups received usual care from the HF service or clinic, which included comprehensive educational information consisting of topics such as medication, nutrition, exercise, and psychosocial issues. Individual patients were referred to the programs for a duration of 12 weeks and were followed up by HF nurses, and physical and occupational therapists. At 1-month follow-up, all participants completed the same questionnaire as at baseline. Due to the scope of the study, the primary researcher collected all data, as blinding was not possible. All study procedures were approved by the relevant hospital and university human research ethics committees. The intervention was also made available to the control group after completion of the research.

### Intervention

The pedagogical principals underpinning the Web-based app were based on two key elements of self-efficacy theory [15,16]: role modelling and mastery experience. Helping adults to improve their self-efficacy is a powerful and central factor in increasing chronic disease self-care [5,17]. Patients with greater self-efficacy have been found to be more willing to learn and commit to achieving goals, whereas low self-efficacy has been associated with task avoidance [18]. We anticipated that the use of informational sources such as role modelling and mastery experience would help patients to increase their self-efficacy. Role modelling can take the form of observing the actions of others [18]. As such, we created female and male avatars to resemble role models and to help users engage with educational materials on the website. We encouraged mastery experience by asking participants to monitor and record their signs and symptoms related to HF fluid overload. The daily weight measurements and HF symptoms were able to be recorded to show trends over time. We used a further source of self-efficacy, verbal persuasion, through weekly emails to each participant.

We developed the Web-based app based on feedback from three groups: HF experts, an information technology team, and HF

patients. The role of the HF expert panel was to ensure integrity of the content according to evidence-based guidelines, applicability of study instruments, appropriate language and images, and appropriate user interfaces. HF patients provided their feedback and recommendations on the content, ease of navigation, and user friendliness. We developed the Web-based educational materials based on the National Heart Foundation of Australia and the Cardiac Society of Australia and New Zealand chronic HF guidelines [3]. The website was password protected, and both HF patients and their health care professionals had access to content including interactive HF teaching tools, self-care tools, a chart for recording daily measures, and self-care questionnaires.

### **Teaching Tools**

This section consisted of educational topics including an explanation of HF (with animations), HF signs and symptoms, daily weighings (related to fat and fluid differentiation), suggestions for healthy eating and being active, methods to avoid salty foods and tips for reading food labels, and taking appropriate action when symptoms were exacerbated.

### **Self-Care Tools**

To reinforce self-monitoring, patients could enter daily clinical data including daily weight and any signs of fluid retention such as tight shoes or socks.

### **My Chart**

This tool allowed patients to visually monitor their daily weight and severity of HF symptoms through simple graphs. In addition, health care professionals were able to monitor their patients' self-reported data by accessing their charts.

### **Self-Care Questionnaires**

The final section was designed to help patients assess their knowledge and self-care skills over time. It included questionnaires such as the Self-Care of Heart Failure Index (SCHFI) and the Dutch Heart Failure Knowledge Scale (DHFK).

### **Outcome Measures**

In addition to baseline demographics, questionnaires assessed the primary outcomes including HF knowledge, self-care, and self-efficacy. The DHFK [19] consists of 15 multiple-choice items concerning HF in general (4 items), HF treatment (6 items on diet, fluid restriction, and activity), and HF symptoms and symptom recognition (5 items). The scale has a minimum score of 0 (no knowledge) and a maximum score of 15 points (optimal knowledge). It is a frequently used measure of HF knowledge and has been validated in previous research evaluating educational intervention [1].

We measured self-care skills using the SCHFI version 6.2 [20,21]. This tool has 21 items, which are scored as three subscales: maintenance (symptom monitoring and adherence behaviors performed to prevent HF exacerbation), management (patients' abilities to recognize symptoms when they occur, treatment implementation in response to symptoms, and treatment evaluation), and confidence (measures task-specific self-efficacy behaviors to manage the process of self-care) [5]. The management subscale was answered only if the patient reported having trouble breathing or ankle swelling in the past 4 weeks. Each standardized subscale score ranged from 0–100, with a score of  $\geq 70$  or more indicating adequate self-care [21].

We also used the 6-item Self-Efficacy for Managing Chronic Disease Scale (SEMCD) [22] as a general measure of chronic disease self-efficacy. It covers several domains relevant to chronic disease self-care, including symptom control, role-function, emotional functioning, and communicating with physicians. Each item is rated on a 10-point scale ranging from “not at all confident” (1) to “totally confident” (10). A mean score is calculated, with higher scores indicating higher perceived self-efficacy.

### **Data Analysis**

We analyzed data using IBM SPSS Statistics version 21 (IBM). We compared baseline characteristics using Fisher exact and *t* tests. Descriptive statistics were examined for all variables, and pre-post change scores were calculated for outcome measures. Given the small sample size and nonnormal distribution of outcome variables and to analyze between-group differences over time, we compared change scores using Mann-Whitney *U* tests. We considered  $P < .05$  to be significant and report effect sizes where possible.

## **Results**

### **Study Recruitment and Baseline Characteristics**

Of 75 HF patients who were assessed for eligibility, 29 agreed to participate and were enrolled into the study (see Figure 1). Table 1 shows the baseline demographic and clinical characteristics of the 28 patients who participated in the pilot study. One participant dropped out. Of the total sample, the majority were men ( $n=22$ , 79%) and the mean age was 60.8 (SD 11.9) years. The mean self-reported disease duration was 4.0 (SD 6.9) years. Most participants were asymptomatic (class I,  $n=14$ , 50%) or had mild HF (class II,  $n=12$ , 43%) according to the NYHA functional classification. Comparisons showed no significant differences between the intervention and control groups at baseline.

**Table 1.** Baseline characteristics of participants in a pilot study of a Web-based self-management intervention for chronic heart failure.

Characteristic	Control (n=14)	Intervention (n=14)
Age in years, mean (SD)	60.0 (14.0)	61.7 (9.9)
<b>Sex, n (%)</b>		
Male	11 (79)	11 (79)
Female	3 (21)	3 (21)
<b>Marital status, n (%)</b>		
Married	8 (57)	9 (64)
Widowed, divorced, or never married	6 (43)	5 (36)
<b>Living arrangement, n (%)</b>		
Live alone	6 (46)	5 (36)
Live with others	7 (54)	9 (64)
<b>Level of education, n (%)</b>		
<12 years or high school diploma	7 (50)	8 (57)
Some college/associate degree, bachelor's degree, or postgraduate degree	7 (50)	6 (43)
<b>Total household income, n (%)</b>		
≤A\$40,000/year	4 (29)	9 (64)
≥A\$70,000/year, or do not know, or refused	10 (71)	5 (36)
<b>Overall perceived health, n (%)</b>		
Excellent, very good, or good	7 (50)	7 (50)
Fair or poor	7 (50)	7 (50)
<b>Medication treatment</b>		
Angiotensin-converting enzyme inhibitor	10 (71)	10 (71)
Angiotensin II receptor blocker	4 (29)	2 (14)

Duration of heart failure in years, mean (SD)	3.0 (4.8)	4.9 (8.5)

**Figure 1.** Consort study flow chart.

### Heart Failure Knowledge

Table 2 compares the change in knowledge scores for the intervention and control groups. As the maximum possible knowledge score is 15, the baseline mean scores of 12.5 (SD 1.1) for the intervention group and 12.2 (SD 2.4) for the control

group indicated that participants had relatively high levels of HF knowledge at the outset. While change scores at 1 month showed slight improvement in HF knowledge, there was no significant difference between the intervention and control groups ( $U=91.5$ ,  $P=.75$ ), with a negligible effect size ( $d=0.06$ ).

**Table 2.** Change score analysis: change in scores from baseline preintervention (pre) to post intervention (post).

Scale	Intervention group (n=14)		Pre-post difference, mean (95% CI)	Control group (n=14)		Pre-post difference, mean (95% CI)	Mann-Whitney <i>U</i> test	<i>P</i> value	Effect size ( <i>d</i> )
	Pre, mean (SD)	Post, mean (SD)		Pre, mean (SD)	Post, mean (SD)				
DHFK <sup>a</sup>	12.5 (1.1)	12.9 (1.3)	0.35 (–0.67 to 1.3)	12.2 (2.4)	12.8 (1.7)	0.57 (–0.05 to 1.2)	91.5	.75	0.06
SCHFI <sup>b</sup> (maintenance)	61.9 (20.9)	71.9 (15.1)	9.9 (–3.6 to –23.6)	70.2 (17.4)	66.6 (17.7)	–3.5 (–10.3 to 1.3)	59.5	.07	0.32
SCHFI (confidence)	67.1 (20.3)	73.0 (18.0)	3.8 (–4.3 to 12.0)	65.5 (21.4)	69.9 (19.2)	3.8 (–4.3 to 12.0)	89.5	.94	0.16
SEMCD <sup>c</sup>	7.3 (1.6)	8.0 (1.7)	0.70 (–0.54 to 1.9)	7.1 (1.4)	7.4 (1.5)	0.35 (–0.21 to 0.92)	87.0	.61	0.37

<sup>a</sup>DHFK: Dutch Heart Failure Knowledge Scale.

<sup>b</sup>SCHFI: Self-Care of Heart Failure Index.

<sup>c</sup>SEMCD: Self-Efficacy for Managing Chronic Disease Scale.

## Self-Care

As presented in Table 2, change scores showed an improvement in the SCHFI maintenance subscale in the intervention group to above the minimum level of self-care adequacy (mean difference 9.9, 95% CI –3.6 to –23.6), whereas the control group scores decreased over time (mean difference –3.5, 95% CI –10.3 to 1.3). While the effect size suggests an important trend ( $d=0.32$ ), given the small sample size it did not reach statistical significance ( $U=59.9$ ,  $P=.07$ ). In addition, while we observed small improvements in the SCHFI confidence subscale, we found no significant between-group differences ( $U=89.5$ ,  $P=.94$ ). As answers to the management subscale were indicated by only 5 patients, we did not compare this subscale.

## Self-Efficacy

Table 2 shows that both groups also reported high levels of self-efficacy at baseline. Change scores indicated an improvement among the intervention group (mean difference 0.70, 95% CI –0.54 to 1.9,  $d=0.37$ ), although this was not statistically significant ( $U=87.0$ ,  $P=.61$ ).

## Use of the Intervention

The intervention group accessed the website on average 16.8 times during the 1-month intervention period. Of the 14 participants, 7 (50%) accessed the intervention site every day, 4 (28%) had no record of access, 11 (78%) accessed the website from home and 3 (22%) through a mobile phone. The most reviewed section of the website was “How do I learn to read food labels?” followed by “How do I reduce salt in my daily meal?,” “What is the difference between fat and fluid weight gain?,” and “How do I become more physically active?” Based on personal data recorded, 7 participants entered their data every day, 1 participant on 25 days, 1 on 12 days, and 1 on 4 days; 4 participants did not enter any data.

To explore a possible dose-response relationship, we ran correlations between participants’ change scores and frequency of usage of the website. Within the intervention group, Spearman correlations between frequency of usage of the intervention and outcome change scores suggested greater use was associated

with higher knowledge ( $p=.34$ ), SCHFI subscales ( $p$  range .40–.43), and self-efficacy scores ( $p=.45$ ).

## Discussion

### Principal Findings

In this pilot study, we developed and investigated the feasibility of a Web-based self-care intervention for HF outpatients. Overall, results showed that the intervention did not improve patients’ outcomes at 4 weeks’ follow-up. While there was a trend toward improved self-care and self-efficacy in the intervention group for behaviors such as symptom monitoring and strategies to prevent HF exacerbation, given the small sample size, the results were not statistically significant. In contrast to previous studies [10,11] we also found that a Web-based educational intervention was challenging for older HF patients, and usage was low. Despite face-to-face training and email reminders, only 50% of the sample accessed the site daily and 28% had no record of access.

### Comparison With Prior Work

This study differed in important ways from previous intervention studies of Web-based HF self-care [11,12], which may account for the negative findings. Our cohort had shorter disease duration and less severe HF according to the NYHA classification than in previous studies [11,12]. The follow-up period was relatively short to examine changes in patient outcomes, and we acknowledge that a minimum of 6 months’ follow-up is recommended in the literature [12,23]. There were also differences in the scope of the intervention. The educational content of the website was at a basic level and focused on self-care skills. The standard face-to-face patient education received by both groups in the HF clinic, therefore, may not have been comprehensive enough to diminish the effect of the Web-based intervention. Our primary outcome measures of self-care skills and self-efficacy differed from previous studies, which focused on HF knowledge, symptoms, and quality of life [11,12]. Nonetheless, using validated measures was a strength of this study. Yet, because most of the participants in the sample were asymptomatic, we did not compare the management

subscale of the SCHFI. In addition, as the maximum score for the DHFK questionnaire was 15 and a score >10 indicated adequate knowledge [19], the high knowledge scores of participants at baseline (mean 12.5, SD 1.1) likely created a ceiling effect.

Notwithstanding the above limitations, our study findings are consistent with a body of literature that points to mixed evidence of the effectiveness of Web-based self-care interventions for chronic disease [13,24]. Despite the development of a plethora of Internet-based interventions over recent decades, systematic reviews have not shown any benefit of Web-based self-care interventions for chronic disease [25,26]. Moreover, meta-analyses have not demonstrated a significant benefit in the use of Web-based interventions when combining samples [27,28]. This is attributed, in the first instance, to issues of methodology and variability in research design [13,29-31]. There are significant differences in configuration (eg, educational materials, asynchronous discussion, live conferencing), instructional methods (eg, practice exercise, cognitive interactivity), and presentation [13]. These also extend to types of assessments, study populations, the etiology of symptoms, and times of intervention [27,32]. A further and related issue is a lack of appropriate theoretical frameworks [33,34]. Many studies are missing the theoretical rationale for multiple assessments and how these informed the development of the Web-based interventions. The authors of a previous study [33] reported that a limited number of interventions applied evidence-based theory and, more recently, a meta-analysis of research on reducing blood pressure with Internet-based interventions [34] emphasized that a priority for future research is to design and evaluate interventions according to theoretically grounded hypotheses.

In contrast to other kinds of educational intervention studies in HF patients [1], the role of theory in developing Internet-based interventions has been largely disregarded. While precise measures of key constructs and outcomes and well-defined associations improve research precision, theory is needed to inform the choice of study design and to enhance an understanding of causal relationships [35]. Robust theory is also critical in identifying the effectiveness of the specific components of the interventions and optimizing their intensity [35-37]. Key theoretical constructs and associations should therefore be applied in efficacy trials, tests of effectiveness, and adoption and sustainability studies. There is some evidence for the use of Bandura's self-efficacy theory as the most important element in developing self-care interventions [7].

### Implications for Future Research

This pilot study presented a fundamental phase of the development of a Web-based self-care intervention for patients with HF that can be used to inform future research. To examine the effectiveness of the proposed Web-based intervention, a larger, adequately powered randomized controlled trial is needed. Longer follow-up periods at 3, 6, and 12 months are required to examine clinically meaningful change over time. In addition, we recommend that researchers actively support older HF patients to engage with Web-based interventions through face-to-face education sessions for basic computer and Internet

skills. Greater resources may improve adherence and resolve possible barriers or difficulties in using Web-based self-care tools.

Well-designed educational strategies grounded in theory and contemporary evidence are crucial in improving HF self-care and patient outcomes [38]. More comprehensive educational content is needed, including nutrition and diet, physical activity, effects of alcohol and smoking, medications and their side effects [5], as well as psychosocial and emotional issues [1,39]. Moreover, as Tomita et al [12] argued, interventions should target improved physical activity and provide practical advice about appropriate types and levels of exercise. This would include walking, breathing, stretching, range of motion, and upper and lower extremity strength training. For better outcomes and in order to encourage HF patients to maintain healthy lifestyles, interventions would also incorporate more information on recommended diet and nutrition [12].

To strengthen the efficacy of the Web-based intervention, we recommend drawing on the sources and mediators of self-efficacy theory. Feedback, goal setting, videos of peer storytelling, monitoring tools such as for blood pressure, daily weight, and physical activities, and diaries are some examples of self-efficacy information sources [40]. We strongly recommend using a combination of the four primary information sources in Bandura's work to promote a stronger sense of self-efficacy and a greater willingness to undergo behavioral change and thus produce optimal results [41]. There are examples [6,7] of previous studies that have used the four primary dimensions of self-efficacy to enhance self-care in adults with chronic diseases. The primary focus of these interventions was the provision of efficacy-based information sources, including the mastery of performance accomplishments, role modelling (vicarious learning), social persuasion (verbal encouragement), and the interpretation of physiological and emotional responses [7].

### Limitations

Recruitment was slow in part due to HF patients' lack of interest in the intervention, Internet access, or computer skills. Among the HF patients who were invited to participate in the study, 26 were not eligible based on the study inclusion and exclusion criteria. This exploratory pilot study was confined to an HF management program provided at a single-hospital HF service and university health clinic. To participate, it was essential that HF patients had access to the Internet at home or workplace or via a mobile phone. Although a large proportion of the HF population did have access to the Internet, a significant minority (22 participants) did not. As a result, our study was based on a small sample size, which limited statistical power. Finally, the study follow-up was relatively short for the examination of the Web-based intervention on patient knowledge, self-care, and self-efficacy.

### Conclusion

This study examined the feasibility of a Web-based self-care intervention in improving HF knowledge, self-care, and self-efficacy. Although preliminary, our findings are consistent with current literature that demonstrates negative to small effects

of Web-based self-care interventions in chronic disease. Larger, theoretically informed, and more comprehensive studies are needed to support or refute this proposition. Nonetheless, the challenges of this study and lessons learned give some support

to the argument that Web-based programs, as discrete interventions, will not be the remedy for the cost and social burden of chronic illness.

## Acknowledgments

Thanks to Associate Professor John Atherton, Mrs Linda Prentice, Mr Carlos Fernandez, and HF clinic staff and participating patients at the Royal Brisbane and Women's Hospital. Special thanks to Professor Robyn Clark from Flinders University and Mrs Chris Horton and Dr Johannes Moolman from Ipswich Community Health and Ipswich Hospital for their generous support during phase one of the study.

## Conflicts of Interest

None declared.

## Abstract

**Background:** Tablet-based health care interventions have the potential to encourage patient care in a timelier manner, allow physicians convenient access to patient records, and provide an improved method for patient education. However, along with the continued adoption of tablet technologies, there is a concomitant need to develop protocols focusing on the configuration, management, and maintenance of these devices within the health care setting to support the conduct of clinical research.

**Objective:** Develop three protocols to support tablet configuration, tablet management, and tablet maintenance.

**Methods:** The Configurator software, Tile technology, and current infection control recommendations were employed to develop three distinct protocols for tablet-based digital health interventions. Configurator is a mobile device management software specifically for iPhone operating system (iOS) devices. The capabilities and current applications of Configurator were reviewed and used to develop the protocol to support device configuration. Tile is a tracking tag associated with a free mobile app available for iOS and Android devices. The features associated with Tile were evaluated and used to develop the Tile protocol to support tablet management. Furthermore, current recommendations on preventing health care-related infections were reviewed to develop the infection control protocol to support tablet maintenance.

**Results:** This article provides three protocols: the Configurator protocol, the Tile protocol, and the infection control protocol.

**Conclusions:** These protocols can help to ensure consistent implementation of tablet-based interventions, enhance fidelity when employing tablets for research purposes, and serve as a guide for tablet deployments within clinical settings.

## KEYWORDS

tablet computers; mHealth; infection control; clinical research protocol; mobile device management

## Introduction

The proliferation of tablet technologies has ushered in a new realm of connected health care and research-based interventions in the clinical setting. According to the Pew Research Center, 64% of American adults own a smartphone, and of those, 53% also own a tablet [1]. Advancements in policy, health information technology adoption by providers, mobile/social technology adoption by consumers, and development of health-focused mobile apps have created ideal conditions to enable the expansion of tablet-based interventions. According

to the 2015 *Healthcare Information and Management Systems Society Mobile Technology Survey*, 47% of responding organizations labeled mobile service implementation to access information as a top priority, and 57% indicated already having a mobile technology policy [2]. Further, as noted by the IMS Institute for Healthcare Informatics, more than 165,000 mobile health (mHealth) apps are currently available for consumer download through Google Play and the Mac App Store [3].

The use of electronic tools and services has created new opportunities for individuals to actively participate in monitoring and directing their health care through digital health

interventions. The body of evidence that supports the use of such strategies to improve health outcomes continues to expand [4]. However, insufficient guidance exists on deployment methods that could be used to support replication or subsequent scaling. To address this gap, we describe protocols relevant to three major phases of digital health intervention activities using tablets: initial device configuration, remote management of deployed technologies, and the ongoing maintenance of tablets deployed within clinical environments. The protocols are intended for use by three major audiences: (1) public health investigators responsible for the design of a digital health intervention, (2) research technologists seeking guidance on deployment methods, and (3) clinical staff responsible for monitoring tablets and carrying out infection control procedures in a health care setting.

There is scant literature describing the implementation of tablet-based public health interventions and the management of tablets. Tablet use takes place across multiple populations and settings including urban ambulatory care practices, grocery stores, pediatric practices, and primary care practices [5-8]. Several interventions describe the use of Web-based material optimized for delivery via tablets, whereas others used operating system-specific tablet-based interventions [7-13]. Irrespective of the mode of content delivery (eg, native app, hybrid app, or responsive Web application), proper configuration, management, and maintenance of the tablet computer is essential to ensure technical fidelity and control of participant exposure to intervention materials. To the best of our knowledge, no studies describe these procedures, and there are no predeveloped protocols surrounding the use of tablets in digital health interventions. We describe protocols to address the gap within the literature that can serve as a basic guide for configuration, management, and maintenance of tablet-based interventions.

## Methods

### Tablet Configuration

#### *Characteristics of Configurator*

The mobile device management software, known as Configurator, is a resource that may improve the reliability and enhance the reproducibility of digital health interventions. Configurator is a free utility available from the Mac App Store. It is designed to configure and deploy multiple iPhones, iPod Touches, iPads, or Apple TV devices [14]. Configurator users have the ability to push images, settings, apps, and security profiles across groups of iPhone operating system (iOS) devices [15]. These devices can be configured using an XML

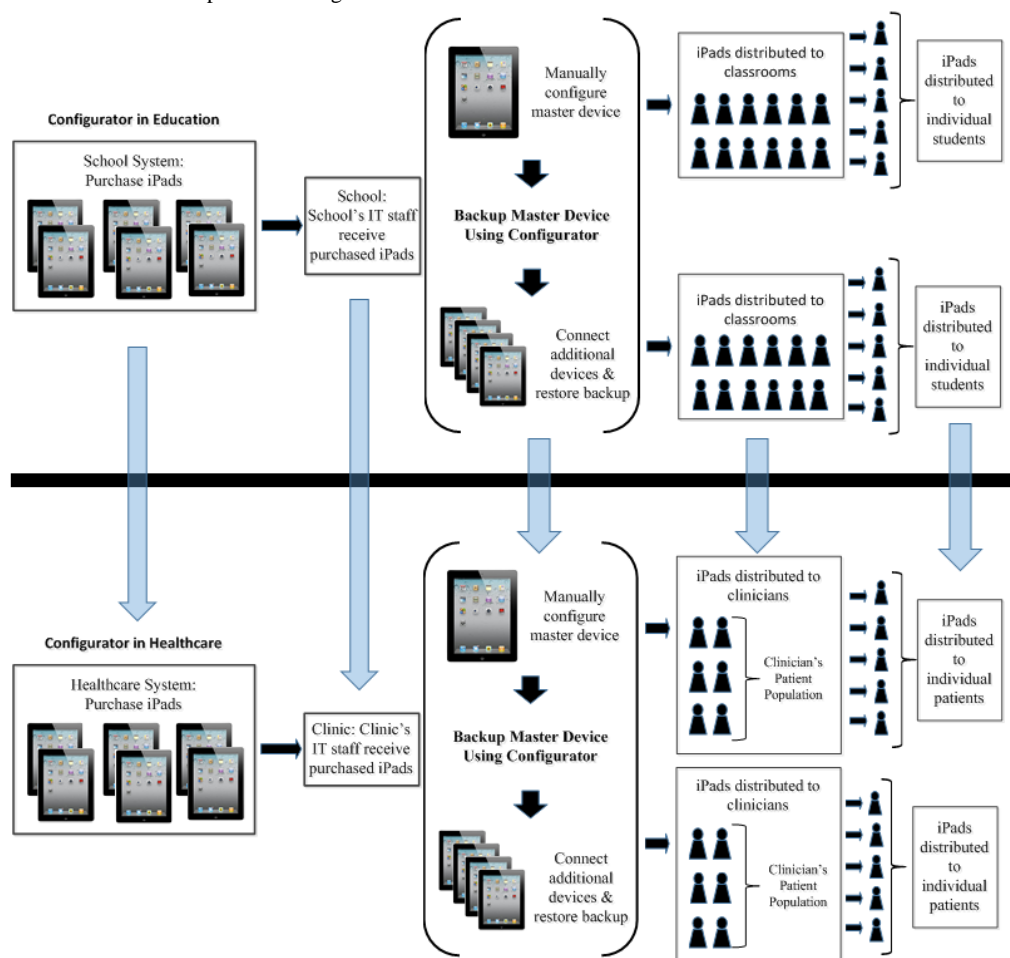

configuration file or by using the backup of a master iPad [16,17], which is configured by hand. The configuration can include all network and security settings as well as installs for the selected free or in-house apps. Once set, the master iPad is imaged using Configurator's backup function [16]. Remaining iPads are connected to the Mac OS device via universal serial bus (USB), and the image of the master iPad is restored to the remaining iPads. This can be done with up to 30 iPads [15]. Using Configurator to set up and maintain iOS devices gives administrative control over every aspect of the device, including wallpaper and lock screen settings, virtual private network and Wi-Fi (wireless local area network) settings, mail and calendar accounts, iOS version and upgrades, documents, and application access [16]. The end result is a number of identical, incrementally identified iOS devices. Subsequent alterations, including software updates, can only be made using Configurator by connecting the devices via USB to a Mac OS computer.

#### *Applying Configurator to Tablet Deployment*

Presently there is limited guidance available regarding tablet configuration for digital health interventions. However, with reported sales of more than 4.5 million iPads to educational institutions within the United States and almost twice that worldwide, Configurator is extensively used within the field of education [18,19]. Recommendations from Configurator's application in education can be applied to digital health interventions deployed for research or clinical purposes.

The Configurator application is widely used in education for configuring multiple iOS-based devices at scale, whether it be for a single classroom, school, or district. Consequently, a considerable amount of guidance is available about Configurator's setup and use in schools. Additionally, the Configurator education deployment model provides institutions with flexibility to manage multiple deployment scenarios, such as one-to-one, shared-use, and student-owned devices. Schools may choose to deploy iPads in one specific scenario or all three scenarios. However, Configurator is ideally used to set up one-to-one or shared-use devices, which gives educational IT staff the ability to customize and be flexible in addressing the school's specific needs.

The iOS education Configurator deployment model can easily be transposed to other domains, such as deployment within clinical settings or health research studies. The example provided in Figure 1 outlines how the educational infrastructure is similar to the health care infrastructure, as can be seen by changing the nomenclature from schools to clinics, teachers to clinicians, and students to patients.

**Figure 1.** Education and healthcare comparative configurator infrastructure.

## Configurator Protocol

As the use of tablets continues to expand within clinical settings and tablets become more commonplace components in digital health interventions, a consistent method for configuring devices will become increasingly necessary. The protocol, as shown in [Multimedia Appendix 1](#), provides a generic outline for iPad deployment using Configurator within research or clinical settings. The protocol reviews the requirements associated with Configurator's use and provides the steps for setting up an iPad using Configurator.

## Tablet Management

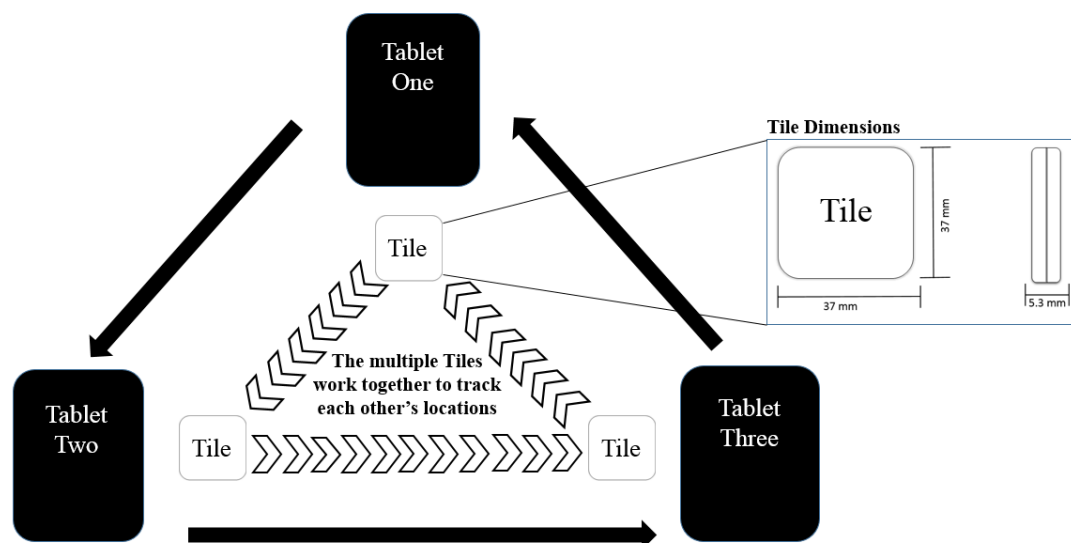

### Characteristics of Tile

The ability to track tablets (or other mobile devices) is an investment in the retention of the digital health intervention. Tile is a small tracking tag (see [Figure 2](#) for dimensions) associated with a free app compatible with iOS and the Android operating system [20-23]. The primary purpose of Tile is to assist users in locating lost items. While Tile was not designed for mobile device management, its capabilities and small size offer a unique method of tracking mobile devices in clinical settings to augment native management features, such as Find

My iPhone, where a Global Positioning System (GPS) signal may not be available.

The Tile app is free and the cost of Tile's hardware is relatively low—usually less than \$25 per device [24]. Tile locates items by using Bluetooth low energy (BLE) 4.0 [22,23]. BLE works optimally at a range of 30 feet but can extend to a maximum range of 100 feet [22,23]. If an item is lost but is in the range of the BLE, Tile can be triggered to play a short tune by selecting the *Find* option within the app to assist the user in locating the lost device [23,25]. If Tile is unable to track an item via BLE, the user can select the app's *Mark as Lost* option to report a missing Tile [23]. The app can also inform users about the last place their lost device was seen. As noted in the Tile informational material [23], "Tile maps the last place you had it."

Additionally, multiple Tiles can work together. While an individual Tile is only visible to its registered user, each Tile can be used in a *Community Find*, which allows any Tile to assist in communicating the location of a lost item to its registered owner [22,25,26]. Separate from the *Community Find* feature, the Tile app can share a Tile's location with another Tile app user [27]. The *Share* feature allows two different app users access to the same Tile [23,28].

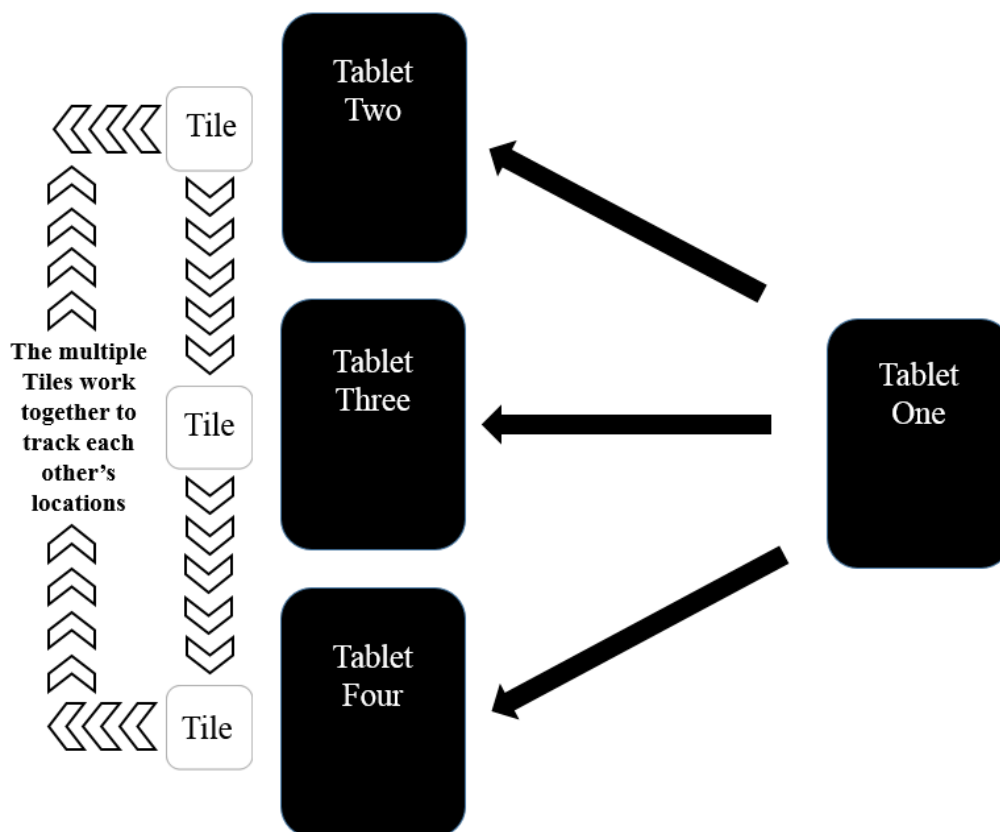

**Figure 2.** Entity relationship diagram: option 1 and tile dimensions.

### Applying Tile to Tablet Deployment

There are two approaches to applying Tile technology to tablet deployments. The first option, as outlined in Figure 2, displays three devices that each track one other device within the diagram. Since each Tile's BLE can only connect to one device at a time [27], each tablet is limited to tracking only one other tablet. That is, tablet 1 is used to track the location of tile 2 (attached to tablet 2); tablet 2 is used to track the location of

tile 3 (attached to tablet 3); tablet 3 is used to track the location of tile 1 (attached to tablet 1).

The second option for applying Tile technology to tablet deployments is outlined in Figure 3, which displays four devices, three with Tiles attached and one device that is solely used for tracking the deployed Tiles. Because one Tile app can simultaneously track multiple individual Tiles, a single tablet can track the three deployed Tiles via BLE; that is, tablet 1 can track tablets 2, 3, and 4.

**Figure 3.** Entity relationship diagram: option 2.

## Tile Protocol

Considering the compact nature of many tablets, the risk of theft, misplaced devices, or loss is a concern. Consequently, enhanced use of tablet technology in digital health interventions must be accompanied by innovative methods of device management. [Multimedia Appendix 2](#) provides a protocol outlining the requirements for deployment as well as how to set up and use the various features offered by the Tile tracking device.

## Tablet Maintenance

### Characteristics of Infection Control

As tablets continue to proliferate the health care setting, the risk of device-based pathogen transmission increases [29]. In a 2009 study, the mobile phones of 200 intensive care and operating room health care workers were tested, and 94.5% showed some form of bacterial contamination [30]. Although the study does not discuss tablets, the same concerns of bacterial contamination and infection surrounding mobile phones are applicable to tablets.

Presently, Apple recommends using a soft, lint-free cloth for cleaning mobile devices, avoiding liquids, solvents, or spraying cleaners directly onto the device [31]. However, a plain cloth will not remove contagious pathogens such as methicillin-resistant *Staphylococcus aureus* (MRSA) or vancomycin-resistant enterococcus (VRE) from a mobile device [29]. A study by Howell and colleagues [29] compared six different wipes (Sani-Cloth CHG 2%, Trigene, Clorox, Tristel, soap and water, and a plain cloth) and found that the Sani-Cloth CHG (chlorhexidine gluconate 2%/alcohol 70%) wipes were the most effective cleaning agent for tablets, with very low risk to the tablet's functional capabilities or accessories.

### Infection Control Protocol

Proper disinfection is an important component to consider as tablets are increasingly integrated into both research studies and

patient care. The infection control protocol is reviewed in [Multimedia Appendix 3](#) and provides a list of the required supplies as well as an outline of the steps needed to disinfect tablet devices using CHG 2% wipes.

## Results

This article provides three protocols within the multimedia appendices that can be applied to support the configuration, the management, and the maintenance of mobile devices employed in digital health interventions: the Configurator protocol, the Tile protocol, and the infection control protocol.

## Discussion

This article addresses the literature gap on tablet protocols used in digital health interventions and describes three protocols supporting tablet configuration, management, and maintenance. The protocols discussed are furnished as generalized instructions or as a foundation for further enhancements, allowing for customization to further optimize tablet adoption. While these protocols can be used to support a single intervention, the resources may be used individually or bundled, at the discretion of investigators or clinicians, depending on the methodological requirements and deployment environment.

The availability and utilization of tablets is advancing the way researchers work, clinicians provide health care, and patients receive health care. However, along with the proliferation of tablets comes the need to advance tablet-focused protocols. The goal of this paper was not to test the effectiveness of Configurator, Tile, or the proposed infection protocol. Rather, we sought to review various options available to augment consistent tablet configuration, management, and maintenance. Further research is necessary to evaluate the feasibility and efficacy of the developed tablet-focused protocols.

## Acknowledgments

## Abstract

**Background:** The annual number of new human immunodeficiency virus (HIV) infections in the United Kingdom among men who have sex with men (MSM) has risen, and remains high among heterosexuals. Increasing HIV transmission among MSM is consistent with evidence of ongoing sexual risk behavior in this group, and targeted prevention strategies are needed for those at risk of acquiring HIV.

**Objective:** The Attitudes to and Understanding of Risk of Acquisition of HIV (AURAH) study was designed to collect information on HIV negative adults at risk of HIV infection in the United Kingdom, based on the following parameters: physical and mental health, lifestyle, patterns of sexual behaviour, and attitudes to sexual risk.

**Methods:** Cross-sectional questionnaire study of HIV negative or undiagnosed sexual health clinic attendees in the United Kingdom from 2013-2014.

**Results:** Of 2630 participants in the AURAH study, 2064 (78%) were in the key subgroups of interest; 580 were black Africans (325 females and 255 males) and 1484 were MSM, with 27 participants belonging to both categories.

**Conclusions:** The results from AURAH will be a significant resource to understand the attitudes and sexual behaviour of those at risk of acquiring HIV within the United Kingdom. AURAH will inform future prevention efforts and targeted health promotion initiatives in the HIV negative population.

## KEYWORDS

HIV infection; HIV negative; HIV undiagnosed; HIV transmission; HIV testing; men who have sex with men; black Africans; sexual risk behaviour; health and wellbeing.

## Introduction

### Background

During 2013, 6000 people were newly diagnosed with human immunodeficiency virus (HIV) in the United Kingdom (UK), and the estimated number of people living with HIV in the United Kingdom was 107,800 by the end of that year [1]. Despite no reported rise in the annual number of new diagnoses since 2005 in the overall UK population, there is evidence that HIV incidence is increasing among men who have sex with men (MSM) [2], and in 2013 the number of new HIV diagnoses remained high in black African men and women, who constitute two thirds of all heterosexuals living with HIV in the United Kingdom [1].

An estimated 38,700 black Africans were living with HIV in the United Kingdom in 2013. Despite a decline in new diagnoses among people born in sub-Saharan Africa, black Africans form the second largest social group affected by HIV in the United Kingdom [1]. The combination of high prevalence of HIV in the black African community [1] and the high proportion of undiagnosed infection as a consequence of late presentation [3] means that the potential for onward transmission of HIV is high within this community. Although the proportion of late HIV diagnoses has declined overall in the last decade, late diagnosis was highest among black African men (69%) and women (57%) in 2013 [1]. Research into factors that affect attitudes towards HIV and access to HIV testing and services is important. The African Health and Sex survey in 2013-2014 demonstrated a low level of awareness on HIV prevalence within black African people living in the United Kingdom, and poor knowledge of HIV treatment and care availability [4], which may impact on access to HIV testing services and sexual risk behavior. Furthermore, previous research into late presentation among black Africans demonstrated that HIV awareness did not translate into individual perception of risk or use of services, and that major structural barriers such as stigma, confidentiality and migration issues inhibit the uptake of HIV testing and services [5].

Evidence of ongoing, and likely increasing, HIV transmission among MSM [1,2,6-8] is consistent with evidence of ongoing

sexual risk behavior in this group and there is evidence that the prevalence of condomless sex among MSM in the United Kingdom may have changed over the last few decades. In the United Kingdom the extensive research carried out in community-venue and clinic based studies [6,8-15] has indicated an increase in the prevalence of condomless anal intercourse among MSM during the late 1990s and early 2000s, coincident with the widespread introduction and use of successful combination antiretroviral treatment (ART) for HIV in developed countries. Research from the United States [16,17] and Europe [18-21] also describes an increase in diagnoses of other sexually transmitted infections (STI) over this time. It has been suggested that the increase in condomless sex that occurred in the late 1990s in the Western world may now have plateaued [9], and recent data from NATSAL-3 (a large representative survey of sexual behavior in the UK general population from September 2010 to August 2012) described no change in prevalence of condomless sex or risk perception in MSM over the last decade [22]. However, the incidence of HIV in MSM in the United Kingdom appears to have increased [2]. This increase cannot be explained by changes in HIV testing alone [23], but would be compatible with a modest ongoing increase in condomless sex among MSM [2].

Sexual transmission risk arises as a result of perceptions and behaviors which may differ depending on the HIV serostatus of individuals. Strategies aimed at reduction of HIV transmission need to address differences in both HIV positive and negative individuals' perceptions, choices, and behaviors [24]. As increasing evidence shows that a suppressed HIV viral load (VL) greatly reduces the risk of onward transmission of HIV to sexual partners [25,26], it is important to consider how this research might have reached and influenced HIV negative persons in different ways to those who are HIV positive. The PARTNER study recently presented transmission estimates of zero in heterosexuals and MSM for condomless sex where the positive partner was on suppressive ART, albeit with a high upper confidence limit in MSM [27]. These data may also influence HIV negative persons in understanding and perception of HIV transmission risks. Research from the United States suggests that HIV negative MSM perceive a number of sexual practices with HIV positive MSM on ART as less risky than

with HIV positive MSM who are not on ART [24]. Furthermore, evidence from Australia has demonstrated that a behavioral response by MSM to the risk of HIV transmission has evolved considerably over time [28]. Risk reduction strategies such as using HIV VL to negotiate condom use [28], serosorting (using HIV status as a decision-making point in choosing a sexual partner [29,30]), strategic positioning (choosing a different sexual position or practice depending on the serostatus of a partner [31]), negotiated safety (choosing not to use condoms with a primary partner and establishing specific rules for sex outside of the primary relationship [32]), and withdrawal are now commonly used to reduce the risk of transmitting or acquiring HIV during condomless anal intercourse.

Current data from the United Kingdom that inform on these themes from the perspective of HIV negative MSM and black Africans are limited. In particular, information is needed on HIV testing behavior and preferences, patterns of sexual behavior, prevalence of specific types of condomless sex (to capture potential risk reduction strategies), attitudes to condomless sex with individuals of known and unknown HIV status, and associations with factors such as mental/general health, STI history, and alcohol and drug use. Data from the Attitudes to and Understanding of Risk of Acquisition of HIV (AURAH) study will contribute to an understanding of how knowledge of ART and detectable/undetectable VLs among HIV negative individuals may affect attitudes and perceptions which lead to condomless sex with partners of unknown and/or known HIV status in the United Kingdom.

Uptake and frequency of HIV testing among MSM in the United Kingdom remains inadequate (an estimated 25% never tested [2]), as it does in black Africans (an estimated 40% never tested [33]). Therefore, improving efforts to expand testing outside sexual health clinics is a priority, and it is a key recommendation from Public Health England to reduce the burden of undiagnosed HIV in these two groups [1]. The first self-testing HIV kit featuring a Kitemark (a UK product and service quality certification) was released in the United Kingdom in April 2015 [34]. Although the majority of HIV tests are currently conducted in sexual health clinics, emerging evidence suggests that HIV self-testing is highly acceptable to both MSM and black Africans in low and high income settings [35,36]. HIV self-testing may remove some of the barriers around accessing sexual health services that are experienced by black Africans and MSM, and may help to improve access to HIV testing. However, there is a need to assess HIV testing preferences in HIV negative individuals, given the recent expansion of testing options to include HIV self-testing [34], and the need to increase HIV testing in the most at-risk populations in the United Kingdom. Results from the AURAH study will seek to inform on HIV testing preferences and acceptability of HIV testing outside of the traditional sexual health clinic setting.

The AURAH study will allow comparison of HIV negative or undiagnosed MSM and black Africans with HIV positive participants from the Antiretrovirals, Sexual Transmission Risk and Attitudes (ASTRA) study [37], a previous questionnaire study undertaken in 2011-2012 by the same group. The ASTRA study focused on patients with HIV under care within the United Kingdom, and asked many of the same questions as the AURAH

about sexual behavior, attitudes, and health and lifestyle factors. The ASTRA study aimed to assess sexual risk behaviors, beliefs about HIV transmission risk, and attitudes towards the use of early ART in this population [37]. Previous studies have illustrated high prevalence rates of depression, anxiety, and drug and alcohol use in MSM [38], whilst black and minority ethnic groups in the UK's general population are also more likely to be diagnosed with mental health problems and experience poor outcomes from treatment than other ethnic groups [39,40]. There is some evidence that depression in MSM is associated with higher levels of condomless sex and higher risk behaviors [41] but there is limited data on mental health and wellbeing, and sexual behavior, among MSM or black Africans in the United Kingdom. Data from the AURAH study will allow insight into these issues. Furthermore, comparison between HIV positive and negative individuals in both MSM and black Africans will help to elucidate the specific effect of HIV and HIV treatments on health, wellbeing, and lifestyle among MSM and black Africans.

This paper describes key aspects underlying the AURAH study, including its rationale, design, methods and response rates. A description of the participant characteristics is also outlined. Details of both response rates and participant characteristics may be of use in the comparison to other studies set in sexual health clinics or outpatient settings, and inform future design and planning of subsequent studies. Further publications will address detailed research questions based on the data collected from the participants in the AURAH study.

## Aims and Objectives

The primary aim of the AURAH study was to assess patterns of sexual behavior, and attitudes to sexual risk, among HIV negative adults at risk of HIV infection, and to investigate associations with demographic, socio-economic, health, and lifestyle factors.

## Study Objectives

The detailed objectives of the AURAH study were to assess the following in HIV negative (not known to be HIV positive) sexual health clinic attendees:

1. Levels of recent condomless vaginal or anal sex according to demographic groups (sexuality, ethnicity).
2. Among those who have had condomless sex, the distribution of: number of sexual partners, type of partners, knowledge of HIV status of partners, number of times had condomless sex, type of condomless sex, and reasons for not using condom.
3. Among those having condomless sex with partners of positive or unknown HIV serostatus, the prevalence of risk-reduction measures such as seropositioning.
4. The prevalence of psychological and physical symptoms (ie, depression, anxiety) and lifestyle factors (ie, drug and alcohol use), and whether demographic/social factors, psychological and physical symptoms, quality of life, and lifestyle factors are associated with condomless sex.
5. Beliefs regarding the effect of ART in HIV positive individuals, and undetectable VL, on HIV transmission risk

(transmission risk beliefs) and the association of such beliefs with sexual behavior.

6. History of any HIV testing and attitudes to HIV and HIV medications, including awareness of, and any history of, taking post-exposure prophylaxis (PEP) and pre-exposure prophylaxis (PrEP).
7. Attitudes towards testing for HIV in different settings (ie, sexual health clinic, general practitioner, community based testing), type of testing (ie, self-sampling, self-testing) and preferred sample type for HIV self-testing (ie, saliva based or finger-prick sample of blood).

## Methods

### Study Design

AURAH was a cross-sectional self-administered questionnaire study in individuals attending 20 sexual health (Genito-Urinary Medicine) clinics, in 15 clinical centers (National Health Service trusts), across the United Kingdom. The recruitment period was 17 months, commencing June 2013.

### Population and Setting

AURAH was conducted among individuals attending sexual health clinics for routine STI and/or HIV testing. The inclusion criteria were as follows: HIV negative (or undiagnosed) subjects aged 18 years or over, attending for routine STI or HIV testing in sexual health clinics. Individuals not known to be HIV positive at the time of recruitment to AURAH, but testing positive on that (or a subsequent) clinic visit were retained in the AURAH sample.

The 20 clinical centers were situated across England, and details of the locations and clinics are listed in the Acknowledgements section. The sites were selected on the understanding that they could provide access to large numbers of HIV negative patients attending clinics for STI screening and HIV testing, including the key demographic *at risk* subgroups in the United Kingdom (MSM and black Africans). Most clinics were able to provide a mixed demographic of study participants but a few clinics recruited large numbers of one type only. For example, the 56 Dean Street clinic and the Mortimer Market Center recruited a large number of MSM to the study. Similarly, there were other centers that provided a larger number of black African male and female participants for the study, including the Greenway Center, City of Coventry Healthcare Center, and the Sydenham Center, Barking, London.

### Sample Size

The AURAH study adopted a recruitment target of 2000 total sample size, of which 1000 would be MSM, and 1000 heterosexuals, of whom 600 would be black African. After calculations the study would have sufficient power to:

1. Ascertain the proportion of individuals who report that they have had condomless sex in the past 3 months with a partner of unknown or positive HIV status and that one of the

reasons for this was *"I knew there was a risk of acquiring HIV but I am not so concerned about having the disease that it made me want to have sex using a condom."* This would be calculated as a proportion of all study participants and as a proportion of all participants reporting condomless sex.

2. Ascertain the proportion of individuals who report that they have had condomless sex in the past 3 months with a positive partner who gave a reason as *"I thought the risks of catching HIV were low because my partner was taking anti-retroviral therapy."*
3. Compare the prevalence of depression on the Patient Health Questionnaire (PHQ-9) scale [42] between HIV positive and HIV negative individuals, separately for HIV negative MSM, heterosexual men and women, and black African men and women.

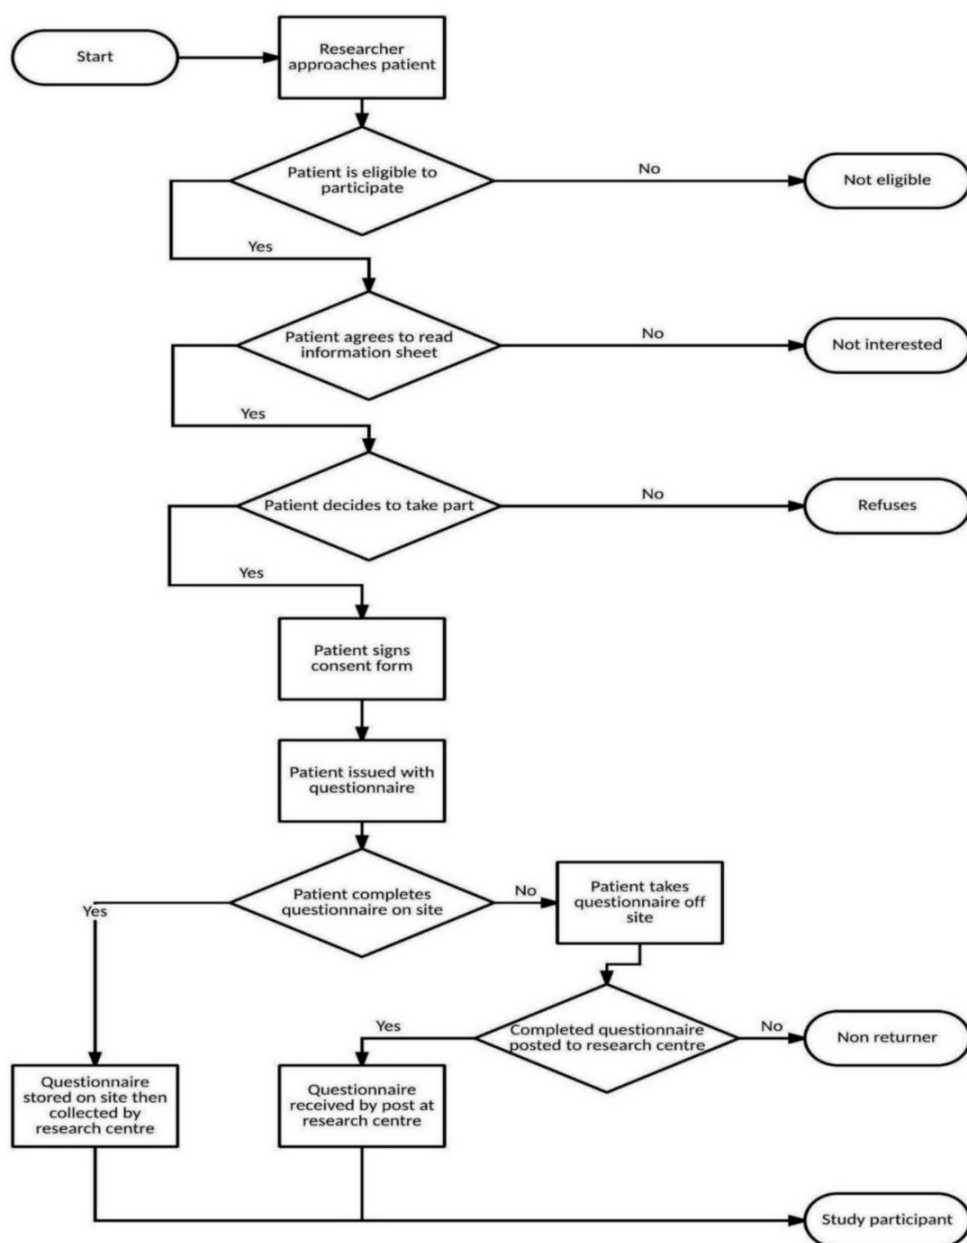

For objectives (1) and (2), the planned sample size of 1000 MSM would allow estimation of a 5% prevalence (95% CI 3.65-6.35), a 10% prevalence (95% CI 8.65-11.35), and a 20% prevalence (95% CI 17.52-22.48). For the planned sample size of approximately 300 black African men (or women), prevalences of 5% (95% CI 2.55-7.45), 10% (95% CI 6.60-13.4) and 20% (95% CI 15.47-24.53) would be estimated.

For objective (3), given approximately 2250 MSM, 200 black African men and 450 black African women in the ASTRA sample [37], and assuming a prevalence of depressive symptoms of 25% among each of these groups, the study would have 80% power (with 5% 2-sided significance level) and absolute difference in prevalence of 4.5% for MSM, 10.0% for black African men, and 8.5% for black African women.

### Recruitment

Recruitment to the study took place between June 2013 and November 2014 during different periods at the 20 clinics. A flowchart of recruitment procedures for the study is included (see Figure 1).

Initial recruitment in the clinics was not restricted. Each site identified specific clinics each week, at which subjects were recruited, aiming to ensure a reasonably representative study population. Consecutive subjects attending each clinic were identified, approached, and invited to take part. It was more feasible to initially recruit in this unrestricted way, and the intent was to modify recruitment strategy as necessary to recruit a sufficient number of MSM and black Africans. After 6 months of unrestricted recruiting, targeted recruitment was implemented across all study sites, and clinic staff were asked to identify and recruit only MSM or those of black ethnicity. Once the recruitment target of 1000 MSM had been met (11 months into the study), 15 clinics were asked to concentrate on recruiting only those known to have specifically black African ethnicity before finishing recruitment, and the 5 sites that had recruited the largest number of MSM continued with sole recruitment of MSM to increase the power for some research questions.

**Figure 1.** Flowchart of AURAH clinic recruitment.

## Consent

All subjects who were invited to participate were given an information sheet about the study. Those who agreed to complete the questionnaire were asked to sign a consent form. The form included an optional section for participants to provide details to allow contact regarding study reminders and, in the future, to invite participants to join future research studies. Participants were informed that consent to be contacted was optional but that those who provided contact details would be entered into a monthly draw offering a prize of £100 of shopping vouchers. Participants who agreed to be contacted were asked for their preferred contact details (email address and mobile phone number for short message service contact). The consent form noted that participants' contact details would only be used for these purposes and would be held securely at the study management center as part of the study records, but would be

deleted after a period of two years. During the consent process, it was reiterated that the study was for HIV negative or undiagnosed individuals only. Participants were told that the questionnaire would take between 15 and 30 minutes to complete and were given an envelope to seal it in, so that their answers were not available to clinic staff. There was an option for participants to take the questionnaire off-site for completion, and postage paid envelopes were provided to return the questionnaire directly to the study management center if required. The option of taking the questionnaire off-site was aimed at including participants who did not have time to complete the questionnaire before they were called for their clinic appointment. Participants were encouraged to complete the questionnaire on-site if possible, to minimize non-return of questionnaires by consented participants.

## Clinical Data

Participants were made aware that their participation included supplying information on the results of any STI or HIV tests that took place in the clinic on the day they were enrolled in to the study. The study log was used to record whether any HIV or STI tests were undertaken and to record the result of any HIV test (negative/positive) performed on the day of enrolment.

## Data Processing

Completed questionnaires were collected in the clinic and transferred regularly to the study management center. Questionnaires were identified only by a unique study number. Participants were instructed not to write their name or clinic number on the questionnaire to maintain their anonymity.

Details of all clinic attendees approached for the study were collected in a study log maintained securely and updated daily at each clinical site. The study log contained study numbers, clinic identifiers and details of consent status for all patients invited to participate in the study, whether or not HIV and other STI tests had been done, and the result of any HIV test. Contact details of participants were also entered in the log if participants consented to being contacted about future research. Selected information from the study log at each clinical center was securely transferred on a regular basis to the study management center. At the study management center, contact details for future research were kept securely and separately from the questionnaire data.

Regular reports were sent from the study management center to each site during the recruitment period, detailing trends and overall progress in recruitment for each of the study sites. In addition, regular checks were made on the completeness and quality of the study log and its concordance with received questionnaires.

Questionnaires received at the management center were digitized by an external data processing contractor. Each paper questionnaire was checked for legibility, digitally scanned, and the resulting images were used as the source for two manual data entry rounds with subsequent quality checking. The completed data entry batches delivered by the contractor were checked for accuracy at the study management center by fully examining a 5% sample.

The original pseudonymized study datasets, including scanned images of the questionnaires, were stored at the study management center in encrypted digital form. They were preserved by being duplicated and stored on managed servers with regular backup and professional administration. The original paper questionnaires were stored securely in locked cabinets. The study datasets will be made freely and readily available to the research community after a suitable interval in a form that ensures that participant anonymity and confidentiality is maintained.

## Study Questionnaire

The questionnaire was based on the design of the ASTRA study questionnaire, a cross sectional study that took place among HIV positive participants attending outpatient HIV clinics across the United Kingdom in 2011-2012 [37] that aimed to include a

representative sample of outpatients attending for care at each center. The AURAH study questionnaire was adapted to capture relevant information from HIV negative participants. An initial questionnaire design was printed in A5 booklet format and piloted at one study site in June 2013, using the recruitment procedures described above. Following feedback from participants and research staff, minor revisions were made to the final questionnaire, the patient information sheet, the consent form, and an insert was designed to attain further information on preferences for HIV testing. These changes were submitted as amendments for ethical approval and were incorporated into the final version employed during the main recruitment period, which commenced in July 2013.

The final questionnaire consisted of a printed A5 booklet, with versions for men (24-page questionnaire) and women (20-page questionnaire). The pilot study indicated that the questionnaire took roughly 20-25 minutes to complete. The questionnaire sought detailed information on the following factors:

1. *Demographic and social factors*: including gender, age or year of birth, ethnicity, education, employment, housing, financial status, sexuality, relationship status (whether in long-term partnership and HIV-status of partner), country of birth, and number of children.
2. *Health and well-being*: including psychological and physical symptoms (modified version of Memorial Symptom Assessment Scale Short-Form [43,44]), depression (PHQ-9 [42]), anxiety (Generalized Anxiety Disorder 7 [45]), health-related quality of life (EuroQoL-3L [46]), and social support (modified version of the Duke-UNC Functional Social Support Questionnaire [47]).
3. *Health and relevant medical history*: including any major medical conditions, recently diagnosed STIs, symptoms of STIs, diagnosed hepatitis B and C, treatment for depression, treatment for other mental health problems, pregnancy status for women, and whether circumcised for men.
4. *HIV-related information*: including HIV status (participants reporting HIV positive status on the questionnaire were excluded from the study), history of any HIV tests, beliefs about transmission risk in relation to ART and undetectable VL, knowledge and history of use of PEP and PrEP, and attitudes towards HIV self-testing and clinic based tests.
5. *Lifestyle factors*: including cigarette smoking status, usual alcohol intake, evidence of alcohol dependency (the CAGE questionnaire [48]), recent use of recreational drugs (with details), and recent use of injecting drugs.
6. *Sexual lifestyle*: MSM participants were asked about disclosure of their sexuality to others and involvement in the gay social scene.
7. *Sexual activity*: sexual activity (vaginal or anal sex) during the previous 3 months was ascertained separately for (i) men having sex with women, (ii) men having sex with men, and (iii) women having sex with men. For those participants who reported condomless sex in the past 3 months, there were questions on number of partners, type of partners (long-term or other), attitudes to the risk of HIV infection, and knowledge of the HIV status of partners. There were additional questions on the number and type of partners if the participant reported condomless sex with people known

to be HIV positive. All participants were also asked about the use of the Internet to find sexual partners, different sex practices and group sex, attitudes towards disclosure of HIV status to sexual partners and negotiation of condom use, their total number of new sexual partners in the past year, and preferred information sources (if any) about safer sex.

8. *HIV testing preferences*: participants were asked to rank different ways of testing for HIV. Ranking from least liked to most appealing on a scale of 1-4, the options were (i) in a sexual health clinic, (ii) general practitioner, (iii) self-sampling, and (iv) self-testing. Participants were also asked to indicate a preference for saliva or blood based self-testing options.

## Ethics Statement

The research protocol and all versions of the study documents for the AURAH study (information sheet, consent form, questionnaires and insert) were approved by the designated Research Ethics Committees (REC) (National Research Ethics Service committee London-Hampstead, ref: 13/LO/0246). Based on these documents, the study subsequently received permission for clinical research at all participating National Health Service (NHS) sites from local Research & Development (R&D). The REC (NRES committee London-Hampstead) further approved the protocol and study documents for the AURAH2 study in December 2014 (REC ref: 14/LO/1881) and subsequent permission by local R&D for clinical research at the three NHS clinic sites in March 2015.

## Study Management

The study was managed on a day-to-day basis by a core group of five staff at the study management center: the HIV Epidemiology and Biostatistics Group, Research Department of Infection and Population Health, Royal Free Campus, University College London.

An advisory group was also established at the start of the study to provide guidance and support. The advisory group consisted of representatives from University College London, HIV i-Base, the London School of Hygiene and Tropical Medicine and City University London.

## Results

Over the 17-month study period a total of 4393 eligible patients were approached and asked to participate in this study. Of those approached, 3340 (76.03%) gave consent to take part in the study. The number of completed questionnaires finally collected was 2630 and thus the response rate was 59.87% (2630/4393) of eligible patients approached, and 78.74% (2630/3340) of those who gave consent. The majority of respondents

(1432/2630, 54.44%) agreed to provide their contact details for participation in future research.

Eighteen of the 20 participating clinics were able to provide estimates of the number of outpatients seen in all clinical sessions over the same period, and the numbers of these in the key groups (MSM and black Africans). More than 288,090 patients were found to have attended these 18 clinics at some point during the respective recruitment periods. Of the combined total attending the clinics, it was estimated that approximately 7.6% were black African and 13.6% were MSM. Table 1 shows the patient population (recruited to AURAH) and response rates for the 20 clinical centers.

## Characteristics of Those Recruited

The mean age (of the 2630 participants who supplied details) at the time of questionnaire completion was 32 years (SD 10, range 18-80 years). Overall, 1954 (74.30%) participants were men and 676 (25.70%) were women. Of the 1939 male participants whose sexuality was known, 1484 (76.53%) self-classified as MSM and 455 (23.47%) as heterosexual. Of the 1484 MSM participants, 965 (65.03%) agreed to provide their contact details for participation in future research, whereas only 36.92% (168/455) of heterosexual males and 43.20% (292/676) of females agreed to provide these details.

In terms of ethnic origin, 1505 of the 2630 (57.22%) participants self-classified as white, 580 participants (22.05%) as black African ethnicity, 249 (9.47%) as other black ethnicity, 264 (10.04%) as other ethnicity, and ethnic status was missing for 32 (1.22%). Of 548 people of black African ethnicity, 323 (58.9%) were female and 225 (41.1%) were male. Of 250 men of black African ethnicity whose sexuality was known, 30 (12.0%) self-classified as MSM and 220 (88.0%) as heterosexual. Of the 580 participants of black African ethnicity, 213 (36.7%) agreed to provide contact details for participation in future research.

Overall, 2535 of the 3340 consenting participants (75.90%) took an HIV test on the day they were approached in clinic. Of those tested, 18 of 2535 (0.71%) received a positive result that they were unaware of at the time. Of these 18 participants, nine returned completed questionnaires (these are retained in the AURAH sample). All nine of these cases were male, of which five were MSM and four were black heterosexuals. Clinics reported that 2624 of the 3340 consenting (78.56%) also tested for STIs on the day, although information on the nature of each test and the results were not collected for this study.

The characteristics of those recruited at the 20 clinical centers in terms of gender, sexual orientation, relevant ethnic status and testing are detailed in Table 2.

## Discussion

The AURAH study recruited 2630 participants from 20 UK sexual health clinics during 2013-2014. The initial rate for consent (2630/3340, 78.74%) was relatively high in this study, and the overall response rate (questionnaires received) was 59.87% (2630/4393) of eligible patients approached. However, there was considerable variation between the clinics in the response rate achieved (ranging from 35% to 93%). The difference in response rates between the clinics could be due to a number of reasons. When researchers at the sites with low response rates were asked about potential barriers to participation they noted education and literacy levels, level of English fluency, and the perceived amount of time that the study questionnaire would take to complete, among clinic attendees at their sites. It was felt that the monthly prize draw had not had a significant effect as an incentive to participate but potentially a smaller cash sum might have, however the study did not seek ethical approval for this due to time restraints.

The intention of this study was also to recruit large numbers within the key demographic sub-groups most affected by HIV in the United Kingdom, namely MSM and black African men

and women. The study succeeded in this aim, and there were 2034 individuals in these groups of interest: 1484 MSM participants and 580 black African participants, with 30 individuals (1.47%) falling into both of these categories.

It is difficult to compare the overall study response rate with other studies of HIV negative MSM, as many Internet or venue-based studies have no records of numbers not agreeing to participate, and therefore response rate cannot be calculated. Our response rate is comparable with other surveys taking place outside the clinical context that have investigated sexual behavior (70% [49]; 65% [50]), and with the previous ASTRA study on HIV positive patients whose response rate was 64% [37]. Many of the 1746 non-responding eligible patients were those who directly refused to participate (1036/1746, 59.34%). However, the remaining 710 were consenting participants who took a questionnaire away but did not return it (710/1746, 40.66% of non-responders). Although the option of taking a questionnaire off-site for completion was intended to maximize participation, some of the non-response in this study can be attributed to factors impacting upon questionnaire completion and postage after the questionnaires had been taken away from the study site. For example, lack of time or continued motivation

to complete and post the questionnaire. However, overall the consent rate was slightly lower than in the comparable ASTRA study and this may reflect the differences between the respective clinic populations in terms of potential ongoing engagement with care, and familiarity with the clinic research staff among those attending HIV and general sexual health clinics.

The average age of AURAH study participants was 32 years and, as expected, this was much younger than the average (45 years) of the ASTRA (HIV diagnosed) study participants [37]. The lower mean age for AURAH is consistent with the study's intention to sample from large numbers of currently HIV negative but *at risk* individuals, who could be expected to be younger than the HIV positive population.

The study population was not a random sample of those attending the clinics, as targeted recruitment was implemented after 6 months of recruitment. It should be noted that the target number for MSM recruitment (1000) was exceeded and that the target was reached early in the study. Recruitment was continued because it was desirable to increase power for some research questions. The number of black Africans recruited was 548, however this took a long time to achieve and required selective recruitment in 15 centers. A similar pattern of relative difficulty of recruitment in these two respective populations was observed in the ASTRA study (on HIV diagnosed individuals) [37] where it was found that MSM were over-represented in its sample in relation to the national HIV positive population, and conversely black Africans were under-represented. However, the relative difficulty of recruitment in AURAH may also be a reflection of the different proportions within the populations attending the sexual health clinics, with the overall proportion of MSM (13.6%) being almost double the proportion of black Africans (7.6%).

The number of study participants diagnosed as HIV positive in-clinic during this study was 18 (0.71%, 95% CI 0.38-1.04, of 2535 consenting and tested). The selective nature of our sampling means this is not a meaningful prevalence estimate but, as might be expected in those attending sexual health clinics, this is very much higher than the general UK population HIV estimate for undiagnosed HIV of 0.07% [1]. However, it should be noted that in those identifying as MSM, there were 5 HIV positive cases out of 1484 (0.34%, 95% CI 0.04-0.63) in this study, which is a relatively low value when compared with the estimated 0.94% for the prevalence of undiagnosed HIV in the UK MSM population as a whole [1]. This could reflect the fact that MSM who regularly attend STI clinics are likely to test more frequently for HIV than MSM in the United Kingdom overall.

## Conclusions

In summary, the AURAH study includes a substantive but selective sample of those considered to be at risk of being infected with HIV in the United Kingdom. AURAH will give insights into the relationships between socio-demographic factors, physical and psychological symptoms, lifestyle factors, health-related quality of life, and sexual behavior in this population.

The results of the AURAH study will be relevant for understanding the process of HIV transmission within the United Kingdom, and for targeting of national prevention efforts. The data from AURAH will contribute to understanding the social, psychological and health-related factors that are linked to high risk sexual and HIV-testing behaviors, and therefore to ongoing transmission of HIV in the two most *at risk* groups of people in the United Kingdom.

## Acknowledgments

We would like to thank all the study participants for their time and effort. We gratefully acknowledge the 20 participating sites and the contributions and efforts of the following at each site: *Barking* - Sydenham Center, Barking, Havering and Redbridge University Hospitals NHS Trust, London (Dr Sharmin Obeyesekera); *Barts* - Barts Sexual Health Center, Barts Health NHS Trust, London (John Saunders); *Birmingham* - Birmingham Heartlands Hospital, Heart of England NHS Foundation Trust (Gerry Gilleran, Cathy Stretton); *Brighton* - Claude Nicol Center, Brighton and Sussex University Hospitals NHS Trust (Nicky Perry, Elaney Youssef, Celia Richardson, Louise Kerr, Mark Roche, David Stacey, Sarah Kirk); *Bristol* - Brecon Unit, North Bristol NHS Trust (Louise Jennings, Caroline Holder, Katie-Anne Baker); *Calderdale & Huddersfield* - Princess Royal Community Health Center, Calderdale and Huddersfield NHS Foundation Trust (Matthew Robinson, Dr Emma Street); *Coventry* - City of Coventry Healthcare Center, Coventry and Warwickshire Partnership NHS Trust (Abayomi Shomoye); *Dean Street* - 56 Dean Street, Chelsea and Westminster Hospital NHS Foundation Trust, London (Ali Ogilvy); *Homerton* - Clifden Center, Homerton University Hospital NHS Foundation Trust, London (Sfiso Mguni, Rebecca Clark, Cynthia Sajani, Veronica Espa); *John Hunter* - John Hunter Clinic, Chelsea and Westminster Hospital NHS Foundation Trust, London (Ali Ogilvy, Sarah Ladd); *Kings* - King's College Hospital NHS Foundation Trust, London (Jonathan Syred, Lisa Hamza, Lucy Campbell, Emily Wandolo, Janagan Alagarajah); *Leicester* - Leicester Royal Infirmary, University Hospitals of Leicester NHS Trust (Linda Mashonganyika, Sally Batham); *Mortimer Market* - The Mortimer Market Center, Central and North West London NHS Foundation Trust, London (Rita Trombin, Ana Milinkovic, Clare Oakland); *Newham* - Greenway Center, Newham Hospital, Barts Health NHS Trust, London (Nyasha Makoka); *Reading* - Florey Unit, Royal Berkshire NHS Foundation Trust, Reading (Ruth Wilson, Elizabeth Green, Sheila O'Connor, Sarah Kempster, Katie Keating-Fedders); *Royal Free* - Marlborough Clinic, Royal Free Hospital NHS Foundation Trust, London (Nicola Tyrrell, Jemima Rogers, Silvia Belmondo, Manjit Sohal); *St George's* - Courtyard Clinic, St George's Healthcare NHS Trust, London (Wendy Majewska, Anne Patterson, Olanike Okolo, David Cox, Mariam Tarik, Charlotte Jackson, Jeanette Honigsbaum, Clare Boggon, Simone Ghosh, Bernard Kelly, Renee Aroney); *The London* - Ambrose King Center, The London Hospital, Barts Health NHS Trust, London (James Hand, Nyasha Makoka); *WLCSSH* - West London Center

for Sexual Health, Chelsea and Westminster Hospital NHS Foundation Trust, London (Ali Ogilvy); *Whipps Cross* - Whipps Cross Hospital, Barts Health NHS Trust, London (Monica Lascar, Nyasha Makoka, Elias Phiri, Zandile Maseko); the CAPRA grant Advisory Board: Nick Partridge; Kay Orton; Anthony Nardone; Ann Sullivan.

## Authors' Contributions

## Abstract

**Background:** While the online environment may promote important developmental and social benefits, it also enables the serious and rapidly growing issue of cyberbullying. Cyberbullying constitutes an increasing public health problem – victimized children and youth experience a range of health and mental health concerns, including emotional and psychosomatic problems, maladaptive behaviors, and increased suicidality. Perpetrators demonstrate a lack of empathy, and may also struggle with health and mental health issues.

**Objective:** This paper describes the protocols applied in a longitudinal and multi-perspective mixed-methods study with five objectives: (1) to explore children/youth's experiences, and children/youth's, parents', and teachers' conceptions, definitions, and understanding of cyberbullying; (2) to explore how children/youth view the underlying motivations for cyberbullying; (3) to document the shifting prevalence rates of cyberbullying victimization, witnessing, and perpetration; (4) to identify risk and protective factors for cyberbullying involvement; and (5) to explore social, mental health, and health consequences of cyberbullying.

**Methods:** Quantitative survey data were collected over three years (2012-2014) from a stratified random baseline sample of fourth (n=160), seventh (n=243), and tenth (n=267) grade children/youth, their parents (n=246), and their teachers (n=103). Quantitative data were collected from students and teachers during in-person school visits, and from parents via mail-in surveys. Student, parent, and teacher surveys included questions regarding: student experiences with bullying/cyberbullying; student health, mental health, and social and behavioral issues; socio-demographics; and information and communication technology use. In-depth semi-structured qualitative interviews were conducted twice with a sub-sample of students (n=57), purposively selected based on socio-demographics and cyberbullying experience, twice with their parents (n=50), and once with their teachers (n=30).

**Results:** Data collection for this study is complete. Planned analyses include transition probabilities and repeated measures analyses to determine involvement in cyberbullying. Repeated measures analyses, including between-subject factors (eg, socio-demographics), will be utilized to determine factors that protect or increase risk of involvement in cyberbullying. Qualitative analysis utilizing grounded theory is planned, to permit rich understanding of participant experiences and perspectives. Results will be reported in 2016 and 2017.

**Conclusions:** This study will offer insight into the contemporary phenomenon of cyberbullying while also informing interventions to curb cyberbullying and address its pervasive social, mental health, and health consequences. Knowledge mobilization strategies and implications for research and practice are discussed.

## Introduction

### Information and Communication Technology Use Among North American Youth

Information and communication technologies (ICTs) are pervasive among socio-demographically diverse populations of young people in North America. Use of these technologies is increasingly mobile (eg, cell phones, smartphones, tablets). In the United States in 2014, 92% of adolescents (13-17 years) were online daily (56% several times per day), while 91% of youth went online occasionally, at minimum, through a mobile device [1,2]. The recent advances in ICTs offer immense benefits for children and youth, including innumerable and unprecedented opportunities for education, growth, and development [3-7], as well as facilitating their health and mental health [8]. The ever-growing ubiquity of ICTs has, however, inevitably brought new challenges [9,10]. Despite their technical proficiency, children and youth do not typically possess the critical thinking and decision-making abilities required to use technology safely [11], and may be exposed to significant risks in ICT environments, including cyberbullying.

### Cyberbullying: A Growing Public Health Problem

In the past few years, there has been an explosion in research on cyberbullying, documenting it as a serious, prevalent, and growing problem. Prevalence rates for cyberbullying vary due to definitional inconsistencies, the population studied, and the time frames and methodologies used [12,13,14]. It has been established, however, that between 10-40% of youth report being cyberbullied, while 50% know someone who has experienced cyberbullying [15]. Bullying is generally defined as a form of aggression that can be direct or indirect, and includes hostile physical, verbal, psychological, or relational behaviors. Bullying is characteristically intentional, commonly occurring in the context of a relationship, and comprising a power imbalance among those involved. The aggressive behavior is typically repeated over time, resulting in harm or negative consequences for the victimized child or youth [2]. Although consensus on the definition of cyberbullying has been difficult to establish, it may be generally defined as the use of ICTs to bully another person [15-21]. Young people may be involved in cyberbullying as victim, perpetrator, and/or witness. These roles appear to be more fluid and difficult to distinguish in the case of cyberbullying compared to traditional offline

bullying [22]. Occurrence of bullying and cyberbullying are also highly correlated [14]. Research suggests that regardless of the role played in cyberbullying incidents, all children and youth can experience serious negative social, mental health, and health consequences as a result of involvement [19-25].

Cyberbullying constitutes a mounting public health problem, as both victimized youth and perpetrators may experience significant and prolonged distress [14,17], as well as an array of mental health concerns and problem behaviors. Victimized children and youth are at risk of developing depression, anxiety, poor self-esteem, eating disorders, sleep difficulties, emotional problems (eg, fear, sadness, loneliness), psychosomatic problems (eg, abdominal pains, headaches), and suicidal ideation and behavior [26-28]. Victimized youth may also be at increased risk of using substances, experiencing difficulties in school, participating in delinquent behavior, and engaging in unsafe sexual practices [29-31]. Youth who are perpetrators similarly experience increased risk of problems including depressive symptoms, substance use, aggression, and suicidal ideation, and may demonstrate less empathy and more conduct problems [23,32,33]. Students who are marginalized due to particular social markers (such as race/ethnicity, gender, religion, appearance, sexual orientation, socioeconomic status, or disability) may be disproportionately vulnerable to experiencing cyberbullying and associated negative social, mental health, and health consequences [34,35].

While research to date has illuminated a great deal about the nature and consequences of cyberbullying, several areas require further examination. Additionally, few studies have employed a longitudinal study design to assess trends in cyberbullying over time. The purpose of this paper is to describe the protocols implemented in a longitudinal and multi-perspective mixed-methods cohort study that contributes to the existing research by investigating several of these underdeveloped areas.

### Study Objectives

This study had five objectives: (1) to explore children/youth's experiences, and children/youth's, their parents', and their teachers' conceptions, definitions, and understanding of cyberbullying; (2) to explore how children/youth view the underlying motivations for cyberbullying; (3) to document the shifting prevalence rates of cyberbullying victimization, witnessing, and perpetration; (4) to identify risk and protective factors for cyberbullying involvement; and (5) to explore social,

mental health, and health consequences of cyberbullying among children/youth. In this paper, the methods of the study are clearly outlined, and future quantitative and qualitative data analysis plans are discussed.

## Methods

### Sample

Three participant groups were included in the baseline study sample: (1) students in 4<sup>th</sup> (n=160), 7<sup>th</sup> (n=243), and 10<sup>th</sup> (n=267) grades; (2) their teachers (n=103); and (3) their parents (n=246). A stratified random sampling strategy was utilized to select participants. First, a random sample of 19 schools was drawn from one of the largest school boards in North America [36], situated in Toronto, Canada, which is a large metropolitan city. Schools were stratified into three categories of need (low, medium, and high) based on an index developed by the school board that ranked schools on external challenges to student achievement. The school board developed this index using census data associated with the postal code of students attending each school. Neighborhood-level census data used to develop the index included income and education levels, ratio of households receiving social assistance, and ratio of single parent families [37]. The stratification of the sample based on this index ensured representation of ethno-cultural and

socioeconomic diversity - factors that potentially impact access to ICTs, experiences of cyberbullying, and the manifestation of negative outcomes [1,38,39]. In year three of the study, 10 additional schools were recruited for participation in order to follow those students transitioning from elementary/middle school to middle/secondary school. A total of 29 schools participated in the study. All students in the selected grades at the original participating schools were offered the opportunity to participate, as were their parents and teachers.

Participating students and their parents provided data in all three years of the study, while matching teachers provided data in year one only (as student participants' teachers changed each year). All three participant groups completed quantitative questionnaire packages, and a sub-sample of each group participated in qualitative interviews. Quantitative data were collected from students and parents in each year of the study, while qualitative data were collected only during years one and three, in order to allow for enough time to elapse for any changes in beliefs, perceptions, attitudes, and understanding of cyberbullying to emerge (Figure 1). Sub-samples of students, parents, and teachers were purposefully selected to participate in interviews based on level of school need, and were representative of gender, grade, and bullying/cyberbullying involvement.

### Study Team and Training of Research Assistants

The research team consisted of a principal investigator and five co-investigators (responsible for general study oversight), one research manager responsible for data management (including entry and cleaning), and four research coordinators. The research coordinators worked in collaboration, but were responsible for separate aspects of the project: (1) survey administration and overall coordination, (2) consent and maintenance of administrative databases, (3) qualitative interview coordination, and (4) coordination of supports for students identified as experiencing distress. Coordinators managed a team of approximately 10-15 research assistants (RAs) who held diverse and often multiple roles, including: collecting survey data in

the school setting, collecting interview data in the school setting or by phone, following up with students in distress, and assisting with administrative tasks. Most RAs were in progress towards (or held) a Master of Social Work degree, while several were from other related professional faculties, such as public health and education.

Prior to working on the project, all RAs participated in a two-hour general training on study methods and procedures. RAs were then trained for specific roles and duties depending on their educational background, clinical experience, and interests. Training was provided for administering quantitative surveys in the school setting, conducting qualitative interviews in person or on the phone, completing assessments to evaluate

whether a student was in distress, and accomplishing various administrative study tasks.

### Ethics and Consent Process

Ethics approval was sought and received from the University of Toronto Research Ethics Board (Protocol #26753). The External Research Review Committee at the partnering school board also provided ethics approval for this project.

Consent to participate in the study was obtained actively in year one and, with approval of the school board, passively in years two and three. In year one, RAs visited each 4<sup>th</sup>, 7<sup>th</sup>, and 10<sup>th</sup> grade classroom from the 19 selected schools to explain the study and distribute consent forms. Parents/guardians were asked to sign the form if they agreed to allow their child to participate, if they were interested in participating themselves, and/or if they permitted the research team to ask their child's teacher to participate. After collection of the parent/student consent forms, teachers were asked if they would like to participate, and completed a consent form. In years two and three (passive consent), parents/guardians were mailed a letter reminding them that they had consented for their child and/or themselves to participate in the study, and that the next year of the study was ready to commence. The letter also provided detailed instructions on how to withdraw from the study if desired.

A \$5 gift card was offered to all students, teachers, and parents who participated in the quantitative survey portion of the research in each of the three years. A \$10 gift card was offered to all participants who took part in an interview (in person or by telephone) in years one and three.

In anticipation that some questions could lead to distress or disclosure of information of a potentially sensitive or distressing nature, a Research Ethics Board-approved protocol (agreed upon by both the University and school board) was established to identify and assist students categorized as being *in distress* through their questionnaire and/or qualitative interview responses. Student participants were classified as *in distress* if they met one (or more) of the following five criteria: (1) indicated on the Bullying & Cyberbullying: Perpetrators, Victims & Witnesses Survey (B&C:PVWS) that they needed

help and would like to speak to a researcher; (2) endorsed item related to fire-setting on the Youth Self Report (YSR); (3) endorsed items related to self-harm/suicide on the YSR; (4) scored above the 85th percentile on the YSR, which is indicative of experiencing numerous behavioral problems; and/or (5) indicated during qualitative interviews that they were highly stressed and in need of support. All children and youth identified as *in distress* were individually interviewed in a private and confidential school setting by a clinically trained researcher, who was a Master of Social Work student or who possessed equivalent education and experience [40]. Children and youth were interviewed regardless of whether the nature of their distress was bullying related. Participants were then connected to appropriate services established within the school board. This attention to the distress of participants was particularly salient in the research context, as access to mental health services in Canada remains problematic [41].

### Data Collection

#### Quantitative Data Collection Methods

In year one, students in 4<sup>th</sup> grade (n=160), 7<sup>th</sup> grade (n=243), and 10<sup>th</sup> grade (n=267) completed a 45-60 minute survey in the school setting, while parents (n=246) completed a 30-45 minute survey by mail. This procedure changed somewhat for years two and three of the study, with some students completing questionnaire packages by mail due to changing schools. Questionnaires for teachers (n=103), which took approximately 45-60 minutes to complete, were administered in the participating schools. Teachers were given approximately two weeks to complete the questionnaires about their students participating in the study, which were then collected by the research team.

#### Quantitative Data Collection Measures

This study utilized a variety of quantitative measures, including both standardized measures as well as measures developed specifically for the study (Table 1). Student, parent, and teacher surveys collected information regarding experiences with bullying/cyberbullying, socio-demographics, ICT use, and student mental health, health, social, and behavioral issues.

**Table 1.** Measures completed by students, parents, and teachers.

			Students			Parents	Teachers
			Grade Level				
Area	Measure	Captures	4	7	10		
Experiences with Bullying/Cyberbullying	<i>Bullying &amp; Cyberbullying: Perpetrators, Victims &amp; Witnesses Survey</i> (B&C:PVWS)	Experiences as victims, perpetrators, and/or witnesses of both bullying/cyberbullying; Experiences with bullying/cyberbullying types (eg, physical, verbal, social, sexual); Experiences with (and content of) bullying/cyberbullying specific to a variety of socio-demographic factors (eg, race, sexual orientation, gender, disability, appearance, religion); Responses to bullying/cyberbullying; Thoughts about potential interventions to address bullying/cyberbullying. <i>Measure used to identify distress.</i>	✓	✓	✓		
Mental Health, Health, Social, & Behavioral Issues	<i>Youth Self-report</i> (YSR) [ 42]	Youth’s self-reported anxiety/depression, suicidal ideation, self-harm, somatic complaints, social, thought and attention problems, delinquent (eg setting fires) and aggressive (eg hurting others) behaviors; <i>Measure used to identify distress.</i>		✓	✓		
	<i>Child Behavior Checklist</i> (CBCL) [ 43]	Parent counterpart to YSR.				✓	
	<i>Teacher Report Form</i> (TRF) [ 44]	Educator counterpart to YSR.					✓
	<i>Self-Perception Profile for Children</i> (SPPC) [45]	Self-esteem.	✓	✓			
	<i>Self-Perception Profile for Adolescents</i> (SPPA) [ 46]	Self-concept.			✓		
	<i>Social Support Scale for Children</i> [ 47]	Children’s perceived support and regard from parents, teachers, close friends, and classmates.	✓	✓			
	<i>Social Support Behaviors Scale</i> [ 48]	Youth’s perceived support from family members and peers with subscales: emotional, socializing, practical assistance, financial, advice/guidance.			✓		
Socio-Demographics	Developed for the purpose of this study (Multiple Versions)	Gender, age, country of birth, country of parents’ birth, main language spoken at home, race/ethnicity, sexual orientation, disability, family composition, grades, and other socio-demographic characteristics. Four versions: (1) 4 <sup>th</sup> Grade; (2) 7 <sup>th</sup> and 10 <sup>th</sup> Grade; (3) Parents; (4) Teachers.	✓	✓	✓	✓	✓
Information & Communication Technology Use	Developed for the purpose of this study (Multiple Versions)	Access to ICTs at home, activities while using ICTs, frequency of activities, online friends and connections. Four versions: (1) 4 <sup>th</sup> Grade; (2) 7 <sup>th</sup> and 10 <sup>th</sup> Grade; (3) Parents; (4) Teachers.	✓	✓	✓	✓	✓

Children/youth's experiences with bullying and cyberbullying were measured using the B&C:PVWS, which is a compilation of survey questions developed from the research team's previous studies. The bullying and cyberbullying literature was reviewed and feedback was sought from the participating school board in order to ensure age-appropriate language. Specific questions were adapted or removed based on the feedback from the school board (eg, questions regarding online sex). For the questions measuring experiences of being bullied and bullying others, the Cronbach alphas were .77 and .71, respectively, indicating good internal consistency.

Children/youth's mental health, health, social, and behavioral issues were captured for 4<sup>th</sup>, 7<sup>th</sup> and 10<sup>th</sup> grade cohorts. We captured mental health, health, and behavioral issues using the YSR, intended for children aged eleven and older [42]. Parents completed the Child Behavior Checklist (CBCL), which is the parental counterpart to the students' YSR [43], while teachers completed the Teacher Report Form (TRF), which is the educator counterpart to the YSR and CBCL [44]. These surveys are widely used measures with excellent reported test-retest reliability [42-44]. We captured children/youth's social issues, including self-esteem, using subscales from the Self-Perception Profile for Children (SPPC) [45] and the Self-Perception Profile for Adolescents (SPPA) [46]. These scales have adequate

internal consistency, and both measures have a stable factor structure [45,46]. We measured social support for students in the 4<sup>th</sup> and 7<sup>th</sup> grade cohorts using the Social Support Scale for Children, a 24-item instrument which assesses children's perceived support and regard from parents, teachers, close friends, and classmates [47]. The internal consistencies of the four subscales range from .72 to .88 using Cronbach alphas [47]. Adolescents in the 10<sup>th</sup> grade cohort completed the Social Support Behaviors Scale to assess perceived support from family members and peers (emotional, social, practical assistance, financial, and advice/guidance) [48]. Strong internal consistency (Cronbach alpha exceeding .85) has been reported for this scale, which includes several college samples [48,49].

Socio-demographics were collected using two versions of the student demographic questionnaire, capturing characteristics such as age, gender, and country of birth, which were developed by the research team with feedback from the school board (one for the 4<sup>th</sup> grade cohort and one for 7<sup>th</sup> and 10<sup>th</sup> grade cohorts). The questionnaires included similar items for both age groups and were based on previous instruments administered by the school board, instruments developed by co-investigators for similar studies, and a review of the literature. The questionnaire for the older cohorts included items regarding sexuality, which were not included in the version for 4<sup>th</sup> grade students. Similar questionnaires (two versions) were developed for parents and teachers.

Lastly, we collected data on ICT use, using two versions of the student ICT usage questionnaire (one for the 4<sup>th</sup> grade cohort and one for 7<sup>th</sup> and 10<sup>th</sup> grade cohorts), developed by the research team. Again, both included similar questions, soliciting information on access to ICTs at home, activities while using ICTs, frequency of activities (6-point scale, ranging from *never to more than once a day*), and online friends and connections. The questionnaire for older cohorts included items related to taking and distributing intimate and/or sexual photos, which were not included in the 4<sup>th</sup> grade version. These questionnaires were adapted from two previous studies. Parents and teachers also completed ICT usage questionnaires (two versions) similar to those filled out by students.

### Qualitative Data Collection Methods

Student participants from 4<sup>th</sup> grade (n=20), 7<sup>th</sup> grade (n=21), and 10<sup>th</sup> grade (n=16) in the qualitative sub-sample were purposefully selected from the larger quantitative sample for qualitative interviews based on diversity of gender, grade, school need level, and whether they reported bullying/cyberbullying victimization, perpetration, and/or witnessing. Subsequent to selecting student participants, their teachers (n=30), and their parents (n=50) were also invited to participate in in-depth interviews. Interviews lasted approximately one hour, ranging in length from thirty to ninety minutes. All year one interviews (with students, parents, and teachers) took place in the school setting, and utilized a semi-structured interview guide. Following preliminary analysis, this interview guide was expanded and refined for use in the year three follow-up phone interviews with the students and parents (Multimedia Appendix 1).

Interviews provided nuance and context to the information obtained through the quantitative measures. Areas explored included views and understanding of cyberbullying and how it compares with traditional offline bullying, experiences of online aggression, and others' attitudes and responses to the issue. Questions were guided by existing literature and the research team's considerable experience. Parent and teacher interviews included questions about their awareness and understanding of cyberbullying, their child or student's involvement in cyberbullying, links between cyber and traditional bullying, supports, and their responses to cyberbullying.

### Data Management

All participants were assigned a unique code to maintain anonymity. Participants' names do not appear anywhere in the quantitative survey packages or qualitative transcripts. Paper surveys were scanned using Cardiff Teleform software, and entered into a project-specific IBM SPSS Statistics 22 database. Entry and cleaning of quantitative data took place throughout the study, and all cases were cross-referenced by hand twice (during entry and after preliminary data sets were compiled) to ensure accuracy of entries. Qualitative data were transcribed verbatim, anonymized, and prepared for analysis. The same unique identifiers were used to identify the qualitative interviews and quantitative surveys, in order to facilitate matching these two data sources for individual participants.

## Results

Data collection for this study is complete. Results of the proposed analyses, outlined below, will be reported in 2016 and 2017.

### Proposed Quantitative Data Analyses

Descriptive analyses will be conducted to calculate frequencies for categorical variables, and means and standard deviations for continuous variables. We will summarize socio-demographic variables among participants in each grade level (4, 7, 10) and differences between grades will be assessed using Student t-tests for continuous variables, and  $\chi^2$  analyses or Fisher's exact tests for categorical variables. Items for each outcome scale (eg, Social Support Scale for Children) will be summed to calculate total or subscale scores for each measure. Reliability of scaled measures will be described using Cronbach alphas. Advanced statistical analyses are also planned. An example of a more advanced analysis that will be conducted is transition probabilities, which will determine involvement in cyberbullying, consistent with our objective of documenting the shifting prevalence rates of cyberbullying victimization, witnessing, and perpetration. To meet our objective of identifying factors that protect against (or increase risk of) involvement in cyberbullying, between-subject factors will be included in a repeated measures analysis. These factors include demographic variables, CBCL scales, self-esteem, and social support to determine their individual and combined contribution to cyberbullying experiences. Considering participants are clustered in classrooms, independence of the data cannot be assumed, and the data are dependent to some degree. Thus, classroom will be included as a dummy variable in the regressions. Multilevel analysis will be used to assess the

contribution of school need level (low, high, and medium) on individual cyberbullying experience.

### Proposed Qualitative Data Analyses

Using the systematic procedures of a rigorous grounded theory inquiry, a theory about children/youth's, parents', and teachers' conceptions of cyberbullying and underlying motivations will be generated. Using this approach, researchers concurrently collect, analyze, and theorize about data in a reciprocal process of constant comparison to inductively construct empirically corroborated, explanatory theories [50-53]. The iterative process permits the analytical and theoretical categories developed by previously collected data to inform, as well as refine and focus, subsequent collection of data [52,54,55]. This refining and focusing commenced during data collection for this study, particularly between the qualitative interview phases (years 1 and 3), and is ongoing. With future analyses, emergent themes among youth, parents, and teachers over time will continue to be identified, and children's and adults' views compared.

While the intent is to develop a theoretical model, grounded theory methods will simultaneously allow for further exploration of interpersonal processes and experiences in a process of reciprocal analysis. Line-by-line and open coding of transcripts were, and will continue to be, conducted to establish preliminary analytic focuses, and subsequently emerging categories will be built and expanded. Axial coding will promote connections both within and between categories and sub-categories, and facilitate synthesis and explanation [50,51,56]. Several measures have been employed to ensure trustworthiness and authenticity. The researchers' prolonged engagement through many years of research and practice in this area will guide development of the grounded theory. Theory development will continue until saturation occurs. Reflexive journaling, bracketing, an audit trail, and dense descriptions will further ensure trustworthiness and transferability [50,51,54].

## Discussion

The study described in this paper provides one of the first assessments of the understanding and experiences of children and youth involved in cyberbullying as victims, perpetrators, and/or witnesses, and involved the investigation of their perceptions, as well as those of their parents and teachers. We followed a baseline sample of 4<sup>th</sup> (n=160), 7<sup>th</sup> (n=243), and 10<sup>th</sup> (n=267) grade children/youth and their parents (n=246), for three years (2012-2014), along with collecting baseline data from their teachers (n=103). This study's multi-perspective approach allows for triangulated analysis of cyberbullying issues, and the design was strengthened by tracking participants longitudinally, during a period in which ICT use has continued to expand rapidly [57]. Recruiting students across grades/ages/socio-economic status permits the comparison of experiences across diverse socio-demographic groups and allows for an examination of trends in primary, middle, and secondary schools. Data collection for this study is complete, with results of proposed analyses anticipated in 2016 and 2017.

This research will elucidate the complex dynamics of cyberbullying incidents and contributes to the growing body of

literature on the rates of cyberbullying, as well as risk and protective factors of involvement. In addition, this study will explicate how children/youth understand cyberbullying and how they experience and judge the underlying motivations for involvement. This inquiry addresses the lack of research capturing children and youth's experiences, feelings, and conceptions of cyberbullying, and uniquely examines the congruence or incongruence of children and youth's views with those of significant adults in their lives. Identifying how children, youth, and adults conceptualize cyberbullying is critical to ensuring the understanding of its extent and impact, and developing effective prevention and intervention strategies [15]. Developing informed strategies relevant to contemporary young people's lives and contexts is especially salient, as increasing recognition of the negative consequences of cyberbullying "has lead parents, educators, and policymakers to embrace intervention efforts, and there is now substantial educational and clinical interest in programs that help to mitigate... harmful outcomes" [58]. For emerging findings based upon study objectives, please refer to [Multimedia Appendix 2](#).

Knowledge translation and exchange activities will be a priority in order to translate study findings for study participants, educators, helping/healthcare professionals, and the broader community. Presentations will be made to the partner school board and a report will be provided to schools, participants, and community members. Any requests by individual schools for presentations will be accommodated by a member of the research team. Findings will be disseminated within the academic community through refereed journals and presentations at juried Canadian and international conferences. We will publish in relevant academic journals, and results will be disseminated to policy makers and practitioners, and presentations will be made to professional organizations and to the community.

Most importantly, these findings can inform interventions to curb cyberbullying among young people in an effort to prevent the negative social, mental health, and health consequences. In keeping with the preliminary findings of this study, previous research has indicated that most children and youth do not disclose their experience with cyberbullying to parents, and are even less likely to disclose cyberbullying experiences to school-based adults (eg, teachers, administrators) [12]. Such lack of disclosure indicates a critical need to provide prevention and intervention efforts in school settings as a way to promote disclosure [12]. Further, little evidence for best practices in intervention efforts exists [13]. The study described in this paper can inform intervention efforts by offering insight into student perceptions of what is helpful or not helpful when experiencing, perpetrating, and/or witnessing cyberbullying, as well as the contexts in which prevention and intervention efforts may be most effective (including via ICTs) [12]. Results of our quantitative data analysis exploring the social, mental health, and health consequences of cyberbullying can inform the development of resources at the school-level. Moreover, future papers focusing on the research process of this study may glean important insights into the challenges of conducting longitudinal studies with children and youth in a school-based setting (ie, participant retention), and potential strategies to mitigate these

challenges (ie, the use of passive consent). Future research may also focus on mechanisms, beyond built-in research study protocols, to support students in distress.

The burgeoning body of literature on the phenomenon of cyberbullying is a relatively recent scholarly development, highlighting the crucial need to engage in discourse regarding this emerging field of research. This unique study offers insight

into cyberbullying and provides a foundation for future research in this important and flourishing field. Importantly, as the frequency of ICT use is constantly growing, and with younger and younger children increasingly using ICTs, understanding the social, mental health, and health consequences of cyberbullying across grade levels may point to differing developmental impacts and inform targeted interventions.

---

## Acknowledgments

This study was funded by a Social Sciences and Humanities Research Council Grant (Grant #410-2011-1001). We would like to acknowledge first and foremost the Toronto District School Board for their utmost commitment to participating in the study, as well as each school for their dedication to both data collection and ensuring the mental health needs of students identified through the study were addressed. Thank you to the students, parents, and teachers for sharing your experiences with us. Thank you to the research assistants, without whom we could not have completed this large study.

---

## Authors' Contributions

FM, WC, TB, DJP, JW, and DJ, KS, JD conceived of the study and developed the initial study protocol. FM, ALD, LBM, KS, PB, and AB and MVW contributed to writing the protocol for publication and provided ongoing data collection oversight during the duration of the study. JD managed the data throughout the duration of the study and contributed to writing the protocol for publication. All authors read and approved the final protocol for publication.

## Abstract

**Background:** Anastomotic leakage (AL) remains the most important complication following colorectal surgery, and is associated with high morbidity and mortality rates. Previous research has focused on identifying risk factors and potential biomarkers for AL, but the sensitivity of these tests remains poor.

**Objective:** This prospective multicenter observational study aims at combining multiple parameters to establish a diagnostic algorithm for colorectal AL.

**Methods:** This study aims to include 588 patients undergoing surgery for colorectal carcinoma. Patients will be eligible for inclusion when surgery includes the construction of a colorectal anastomosis. Patient characteristics will be collected upon consented inclusion, and buccal swabs, breath, stool, and blood samples will be obtained prior to surgery. These samples will allow for the collection of information regarding patients' inflammatory status, genetic predisposition, and intestinal microbiota. Additionally, breath and blood samples will be taken postoperatively and patients will be strictly observed during their in-hospital stay, and the period shortly thereafter.

**Results:** This study has been open for inclusion since August 2015.

**Conclusions:** An estimated 8-10% of patients will develop AL following surgery, and they will be compared to non-leakage patients. The objectives of this study are twofold. The primary aim is to establish and validate a diagnostic algorithm for the pre-operative prediction of the risk of AL development using a combination of inflammatory, immune-related, and genetic parameters. Previously established risk factors and novel parameters will be incorporated into this algorithm, which will aid in the recognition of patients who are at risk for AL. Based on these results, recommendations can be made regarding the construction of an anastomosis or deviating stoma, and possible preventive strategies. Furthermore, we aim to develop a new algorithm for the post-operative diagnosis of AL at an earlier stage, which will positively reflect on short-term survival rates.

**Trial Registration:** Clinicaltrials.gov: NCT02347735; <https://clinicaltrials.gov/ct2/show/NCT02347735> (archived by WebCite at <http://www.webcitation.org/6hm6rxCsA>)

## KEYWORDS

Anastomotic leakage; Colorectal surgery; Postoperative complications; Biomarkers; Personalized medicine

## Introduction

Surgery remains the predominant curative treatment for patients with colorectal cancer (CRC), but can lead to severe post-operative complications, of which anastomotic leakage (AL) is the most feared. AL occurs in 8-15% of patients undergoing colorectal surgery and is associated with high morbidity and short-term mortality rates of up to 39% [1-4]. AL often requires one or more re-interventions, leading to a significant increase in length of hospital stay and subsequently to high health care costs [3]. Some authors even suggest that AL is associated with an impaired oncological prognosis [5-8]. Both decreased disease-specific survival (odds ratio [OR] 1.75) [9,10] and an increased local recurrence rate of CRC (OR 2.9) [10] have been reported.

In the past decades, important risk factors for AL such as male gender [4], neo-adjuvant chemotherapy [11], tumor size [12], malnutrition [13], smoking [14], steroid treatment [1,15], and the use of non-steroidal anti-inflammatory drugs (NSAIDs) [16] have been identified. Despite the determination of these risk factors for AL, surgeons' prediction of the risk to develop AL for the individual patient remains inaccurate [17]. Despite decades of extensive research on preventive methods, the introduction of innovative surgical techniques, and fast-track protocols, incidence rates of AL have remained stable [18].

A recently conducted study in one of the participating centers, that can be considered a pilot study, suggests that pre-operative levels of a certain plasma marker (intestinal fatty acid binding protein, I-FABP) can predict the development of AL in patients undergoing CRC surgery. I-FABP is present in mature enterocytes of the small and large intestine, and is released upon intestinal damage [19]. It is hypothesized that increased plasma levels of I-FABP are the result of an underlying clinical condition of the gastrointestinal tract, predisposing the patient to AL [20].

Cumulative evidence in the literature suggests that perioperative pain treatment with NSAIDs, commonly prescribed analgesics that inhibit cyclo-oxygenase 2 (COX-2) expression, increase the risk of AL [16,21,22]. COX-2 knockout mice have an increased risk of developing AL, and this risk can be reduced by the administration of prostaglandin E2, a product of COX-2 [23]. Another study conducted by our research group has demonstrated that decreased COX-2 expression, due to a polymorphism in the COX-2 gene, leads to an increased risk of the development of AL [23]. Furthermore, it has been shown that patients with different genotypes of mannose-binding lectin (MBL), an important complement factor of the immune system, respond differently to intestinal damage [24].

In the pilot study mentioned previously, it was shown that a combination of C-reactive protein (CRP) and calprotectin levels in plasma provides high diagnostic accuracy for AL during the post-operative period. Finally, we have shown that functional compromise (characterized by malnutrition, frailty, and sarcopenia) is associated with post-operative morbidity and mortality [25]. Malnutrition, as indicated by high Short Nutritional Assessment Questionnaire (SNAQ) scores, and sarcopenia were predictive for, or showed a trend towards, prediction of AL.

Based on previous literature and both our experimental and clinical data, we hypothesize that the occurrence of AL is partly due to patient-derived factors such as a compromised immune response, sarcopenia, genetic predisposition, and an aberrant intestinal microbiome composition, and that the post-operative course can be further influenced by surgical stress, ischemia, and a derailed systemic response. Our hypothesis is that, based on these parameters, individual risks for the development of AL can be assessed pre-operatively.

Besides the obvious improvements that can be made regarding pre-operative risk assessment, the post-operative recognition and management of AL has also proven to be challenging. The timing of AL diagnoses varies greatly, from post-operative day 3 to beyond 30 days, with a mean of 12.7 days post-operatively [26]. Abnormal vital signs and biochemical tests are quite common following the construction of a colorectal anastomosis, and can therefore not be used adequately in the diagnosis of AL. The presentation of AL can vary from abdominal pain and low-grade fever to peritonitis and severe sepsis. This nonspecific course of AL often delays radiologic imaging, and even if this test is undertaken, the diagnoses frequently remain uncertain. Previous research has presented false-negative rates varying from 17-52% for both contrast enemas and computerized tomography (CT) scans [27], resulting in a significant delay of re-intervention [28].

Since a delayed diagnosis of AL is associated with poor outcome [29] and premature re-intervention could lead to a high number of negative re-explorations, one should outweigh the risks of a delayed intervention and the morbidity of re-intervention. Physicians are armed with a restricted number of parameters contributing to risk analysis for the development of AL, with only limited specificity and sensitivity.

## Study Objectives

The objectives of the Predictive Factors of Anastomotic Leakage after Colorectal Surgery (REVEAL) study are twofold. The primary aim of this study is to establish a risk assessment tool for the pre-operative prediction of the development of AL based on a combination of inflammatory, immune-related, and genetic parameters. This algorithm should enable surgeons to make an

adequate estimation for every individual patient's risk of AL, and will eventually aid in the decision-making process regarding the construction of anastomoses and deviating ostomies. In addition, this study aims to provide additional post-operative biomarkers for AL diagnosis at earlier stages, thereby reducing the clinical impact of this feared complication.

## Methods

This is a study protocol for a multicenter, prospective observational study. This study is approved by the Medical Ethical Committee of the Maastricht University Medical Centre. A written informed consent is required from all participating patients and the trial will be conducted in compliance with the rules of *Good Clinical Practice*.

### Study Population

All patients aged >18 years undergoing elective colorectal surgery for colorectal carcinoma, with the construction of an anastomosis, in one of the three participating centers are eligible for inclusion. Patients with large adenomas (large tubular, tubulovillous, or sessile) that cannot be resected radically by means of endoscopy will be included as well, provided that the adenoma is removed surgically with the construction of a colorectal anastomosis. Sample size analysis revealed that 588 consecutive patients have to be included at the outpatient department, prior to surgery. Patients undergoing colorectal surgery for benign conditions, those with permanent stomata without anastomosis, or patients that are unable to give informed consent will be excluded from participation in this study, as well as pregnant patients. If no anastomosis is constructed during surgery, the patient will be withdrawn from the study. Eligibility for inclusion will be determined during a visit at the outpatient department. Upon approval, the patient will receive oral and written information regarding the study, after which he/she will have ample time to reconsider participation. Informed consent will be signed in the presence of the surgeon or researcher.

### Participating Centers

This study will be conducted at Maastricht University Medical Centre (MUMC+, Maastricht, The Netherlands), Zuyderland Medical Centre (Sittard-Geleen and Heerlen, The Netherlands), and Máxima Medical Centre (MMC, Veldhoven, The Netherlands).

### Study Outline

Patients will be admitted to the ward one day prior to surgery, and perioperative care will be performed according to *Enhanced Recovery After Surgery* guidelines for elective colonic surgery [30]. Due to the compelling evidence regarding the detrimental effects of NSAIDs on intestinal wound healing, these drugs will not be administered in this patient population during the perioperative phase. Instead, adequate pain treatment will be provided by means of acetaminophen and opioids if necessary. A *Data Safety Monitoring Board* has been commissioned to evaluate the quality of data collection and monitor patient safety. A web-based system was constructed in order to facilitate the collection of standardized and coded patient data.

The primary end point of this study is post-operative AL, occurring during the first 30 days after surgery, either during hospital admission or following discharge. AL is defined as a communication between the intra- and extra-luminal compartments, resulting from a defect in the integrity of the intestinal wall. Leakage from the suture or staple line from a neorectal reservoir, as well as an abscess near the anastomosis, are also considered leaks [31]. The impact of AL on clinical management is recorded, together with the presence of subclinical (radiological) leaks.

Upon hospital admission, a buccal swab will be performed in order to collect DNA to screen for MBL and COX-2 polymorphisms. In addition, composition of volatile organic compounds (VOCs) in exhaled air will be measured both pre- and post-operatively. Various metabolic processes produce markers that are released into the circulation and, upon passage through the pulmonary system, can be identified as volatile products in exhaled air. The occurrence of (chronic) inflammation and/or oxidative stress can result in the excretion of volatile compounds that generate unique VOC patterns [32]. Furthermore, several baseline characteristics will be acquired prior to surgery, and stool will be collected on three occasions (pre-operatively, post-operatively and at the outpatient department during a control visit) in which the intestinal microbiome can be identified. It has been suggested that the microbiota play an important role in the pathogenesis of AL [33] and that the composition of the intestinal flora can be altered by surgical stress [34]. Plasma will be collected prior to surgery and on post-operative days 1, 3, and 5, in order to determine the concentration of markers for enterocyte damage (eg, I-FABP, citrullin, and calprotectin), transmural ischemia (eg, smooth muscle protein 22), and general inflammation markers (eg, CRP and leukocyte count).

In addition, SNAQ and Malnutrition Universal Screening Tool scores are obtained to assess the nutritional status of the patient, and CT-images are analyzed for total skeletal muscle cross-sectional area in order to distinguish sarcopenic patients from those in good nutritional health [25]. Generalized atherosclerosis will be assessed using abdominal CT-scans, as this is a proposed risk factor for AL [35,36]. Finally, a tissue sample will be obtained from the resected specimen, on which conventional and immunohistochemical staining will be performed.

### Statistical Analyses

The sample size is calculated with a power analysis and is aimed at our main study outcome, AL. From literature, we know that approximately 10% of all colorectal patients receiving an anastomosis will develop AL [14,37]. The aim of the study is to detect significant and clinically relevant differences between the AL group and the non-AL group. Therefore, we used data from a previous study undertaken by our group to determine sample size [20]. We chose our least significant finding, to avoid the study being underpowered. Based on an effect size of 0.41 (calculated with mean calprotectin levels and SD on day 1), with a power of 0.80 and a 95% confidence interval, the total sample size will be 560, of whom an estimated 51 patients will

develop AL. Assuming a 5% dropout rate, the total number of patients that needs to be included in this study is 588.

After data collection, normality will be tested by the D'Agostino-Pearson test. Student's t-tests will be used for between-group comparisons for continuous data. Dichotomous variables will be compared using Pearson's chi-squared test. All data will be presented as mean and standard error of the mean. The area under the curve of receiver operating characteristic (ROC) curves will be used to calculate the diagnostic ability of the studied markers predicting AL. The area under the ROC curve is a summary measure of accuracy, lying in the range from 0.5 to 1, with 1 indicating perfect discrimination and 0.5 indicating no discrimination capacity. To determine the most ideal combination of markers, logistic regression analyses will be performed.

## Results

This study has been open for inclusion since August 2015.

## Discussion

Despite important improvements in peri-operative care for CRC surgeries and increased awareness of AL, incidence rates of this dreaded complication have remained stable for several decades. Most strikingly, leakage continues to occur in patients treated under the most expert care, without the presence of any known risk factors [38]. The lack of knowledge regarding the pathophysiological process of AL and the process of normal intestinal healing hampers the development of novel predictive and preventive methods. AL has significant impacts on morbidity and mortality, quality of life, and health care costs, and is suggested to negatively interfere with oncological prognoses [5,6,7,8]. Although large numbers of clinical trials have identified important patient-related and technical factors that aid in the prediction of AL [38,39], the search for a predictive biomarker for AL has hitherto remained unsuccessful. Almost all previously conducted studies reported a single risk factor for the development of AL in CRC patients undergoing surgery. The multi-modal design of the current study enables us to bypass the limitations encountered by previous studies.

In order to minimize the potentially life threatening clinical consequences of a leak, some surgeons opt to perform a deviating ostomy directly following the initial operation [41]. Although it is generally accepted that the presence of a colostoma or ileostoma reduces the sequelae of AL and the need for reoperation in case of a leak [42,43], a decrease in incidence of post-operative mortality has not yet been proven [42-46]. The presence of selection bias, in which an ostomy is performed in high-risk patients, should be considered when interpreting these results. Surgeons perform elective deviating ostomy in approximately 70% of cases of low rectal carcinoma, of which a significant percentage (19-40%) will never have their temporary ostomy reversed [47,48]. Possible benefits of a deviating stoma should be weighed against stoma-related morbidity, the impact on quality of life, and the mortality rates after stoma closure [49,50]. An adequate pre-operative risk analysis could aid surgeons and their patients in the decision-making process regarding the construction of temporary ostomies. The successful implementation of risk assessment tools would have a positive influence on morbidity and mortality rates, duration of hospital stays, and number of readmissions, re-interventions, and admissions to the ICU, leading to a significant increase in quality of life for the general patient population [38]. Anastomoses are also constructed in gastrointestinal surgery for other purposes than malignancies, such as inflammatory bowel disease or diverticulitis [51,52]. We have chosen to exclude these patients since their inflammatory status can be a confounding factor in the early detection and/or risk assessment of AL [53-55].

This study outline is based on the hypothesis that AL is partly due to patient-derived factors such as a derailed immune response, genetic predisposition, and a deficient microbiome composition, and that the clinical course can be further influenced by surgical stress, ischemia, and a compromised systemic response. This study aims at broadening our understanding of the pathophysiological process of AL by introducing novel biomarkers of intestinal damage and function, and to decrease the clinical burden of AL by both individual pre-operative risk assessment and early post-operative detection in the future.

## Authors' Contributions

JD originated the study. AJ, JB, JD, TL and ND were involved in the study design. AJ and JB drafted the manuscript. AJ, SK, JB, TL, MS, GS and JS are local investigators at the participating centers. FS is head of the toxicology department and coordinates the VOC analyses. The study is supervised and coordinated by JD and NB. All authors provided essential feedback to the successive versions of the manuscript and approved the final version.

## Conflicts of Interest

None declared.

## Abstract

**Background:** Recent progress in the pathophysiology of heart failure (HF) has led to the development of new therapeutic options such as gene therapy and the use of adeno-associated viral (AAV) vectors. Despite the promising results in early clinical trials of gene therapy for HF, various obstacles have been faced, such as the presence of neutralizing antibodies (NAbs) against the capsid vectors. NAb activity limits vector transduction levels and therefore diminishes the final therapeutic response. Recent studies evaluating the prevalence of NAbs in various populations found considerable geographic variability for each AAV serotype. However, the levels of NAbs in Latin American populations are unknown, becoming a limiting factor to conducting AAV vector therapeutic trials in this population.

**Objective:** The goal of this study is to determine for the first time, the prevalence of anti-AAV NAbs for the serotypes 1, 2, and 9 in HF patients from the city of Bucaramanga, Colombia, using the *in vitro* transduction inhibition assay.

**Methods:** We will conduct a cross-sectional study with patients who periodically attend the HF clinic of the Cardiovascular Foundation of Colombia and healthy volunteers matched for age and sex. For all participants, we will evaluate the NAb levels against serotypes AAV1, AAV2, and AAV9. We will determine NAb levels using the *in vitro* transduction inhibition assay. In addition, participants will answer a survey to evaluate their epidemiological and socioeconomic variables. Participation in the study will be voluntary and all participants will sign an informed consent document before any intervention.

**Results:** The project is in the first phase: elaboration of case report forms and the informed consent form, and design of the recruitment strategy. Patient recruitment is expected to begin in the spring of 2016. We expect to have preliminary results, including the titer of the viral vectors, multiplicity of infections that we will use for each serotype, and the general validation of the assay, at the end of 2016. The final results are expected mid-2017.

**Conclusions:** This project is the first effort to evaluate NAb levels against AAV1, AAV2, and AAV9 serotypes in patients with HF in Latin America. Our results will allow us to check the cross-reactivity response between the serotypes assessed, to describe the epidemiological characteristics of the participant population, and to set up a link with earlier reports of NAb prevalence in the literature.

**Introduction**

Heart failure (HF) is the cardiovascular disease (CVD) with the highest mortality and morbidity globally. Recent reports indicate that up to 1% to 2% of adult populations in developed countries have HF, with an increasing prevalence of  $\geq 10\%$  among people  $\geq 70$  years old [1]. Despite the significant improvement in management of disease symptoms and the decreased disease progression achieved with newly developed pharmacological therapies and invasive procedures, alternative therapeutic approaches are still urgently needed to provide a definitive cure [2]. Recent advances in structural and molecular cardiology have shown that abnormalities in the calcium cycling proteins play a significant role in the induction and progression of HF. Decreased sarcoplasmic reticulum  $\text{Ca}^{2+}$ -ATPase (SERCA2a) activity has been described to be a critical pathway responsible for pathologic modification of the cardiomyocytes during HF [3]. These findings, together with advances in gene transfer technologies, have led to gene therapy being considered as a new therapeutic option for CVDs, and specially for HF. Encouraging results from early clinical trials involving the use of adeno-associated viral (AAV) vectors delivering the *SERCA2* gene have generated high expectations [4]. Additionally, other proteins have shown promising results in preclinical models of HF, such as S100A1 and adenylyl cyclase 6 [5,6].

**Emergence of Gene Therapy as a Therapeutic Option for HF and CVD**

Three elements must be considered in the design of a gene therapy strategy: the therapeutic gene that will be cloned into the transgene expression cassette; the target cells or tissues in which the vector will deliver the genetic material; and the viral vector used to facilitate entry of the gene into the target tissue [7]. Viral vectors consist of genetic material surrounded by a protein capsid, which facilitates the transcellular transport and internalization of the therapeutic gene into the target cell [7]. Additionally, the capsid protects the transgene expression cassette from lysosomal degradation during its trafficking to the nucleus [8]. The discovery of viral vectors with cardiomyocyte and endothelial tropism accelerated the progression of gene therapy as a therapeutic option for HF [9]. Novel transductional modifications of the first-generation vectors and translational strategies in the transgene expression cassettes have been developed to achieve higher and longer-term expression of the transfected gene while trying to decrease the amount of adverse effects [10]. As Mingozzi and High state, "The gene is the active agent of therapeutic, but the vector, in most cases derived from a virus, is also a critical determinant of therapeutic success and of the toxicity profile" [11]. Importantly, depending on the viral vector selected, the immune response to the vector or to the cells expressing the modified gene varies and can become a limiting factor for successful therapy [12]. Specific immune responses can prevent vector gene transfer after readministration of the vector, limit the

duration of gene expression, or produce an immune response against the genetically modified cells [13].

Viral vectors derived from adenovirus, retrovirus, lentivirus, or AAV have been used as therapeutic tools for a broad spectrum of genetic and nongenetic diseases, including CVD and HF. Lentivirus vectors originate from human immunodeficiency virus 1 and have been used successfully to treat hematopoietic monogenic diseases thanks to their therapeutic long-term effects [14,15]. However, their use in gene therapy applications for CVD or specifically for HF is more limited, given their relatively poor transduction after systemic administration and the risk of insertional mutagenesis [16]. Adenoviral vectors are non-enveloped double-stranded DNA vectors, which are not able to insert the genome into the host cell DNA. Adenovirus serotype 5 has been used predominantly in preclinical and clinical trials of gene therapy for myocardial infarction and ischemic diseases, in which short-term transgenic expression is required [17].

The most commonly used viral vectors for HF and the focus of our project are the AAV vectors. AAV vectors are single-stranded DNA vectors with a favorable safety profile and the ability to achieve long-term transgene expression in a wide range of tissues, including heart [18]. The storage capacity of the AAV vector (up to 4.7 kB) restricts the size of the transgene expression cassette that can be used and needs to be considered beforehand [19]. More than 100 AAV serotypes existing in nature have been reported, many of them with variable tissue tropism, which is determined by the structure of the proteins in the capsid [18]. AAV1, AAV6, AAV8, and AAV9 have been reported as the serotypes with favorable tropism for cardiomyocytes after systemic administration. However, tropism for other cell types, such as hepatocytes, is still present and needs to be carefully considered before any clinical trial [9,20,21]. Satisfactory preclinical results in large experimental animal models with a heart anatomy similar to that of humans led to the clinical translation of AAV-based technology for transgene expression of key proteins involved in the progression of HF, such as SERCA2a [22]. The first clinical trial for HF was conducted using an AAV1 vector, the Calcium Upregulation by Percutaneous Administration of Gene Therapy in Cardiac Disease (CUPID) trial [23]. Simultaneously, two other clinical trials are in the late phases of recruitment, the phase 2 study Investigation of Safety and Feasibility of AAV1/SERCA2a Gene Transfer in Patients With Chronic Heart Failure (SERCA-LVAD; NCT00534703) and the AAV1-CMV-SERCA2a Gene Therapy Trial in Heart Failure (AGENT-HF; NCT01966887), with results expected in 2016.

**Immune Response Against AAV Vectors**

Immune responses of T cells against antigens of the AAV capsid presented in association with major histocompatibility complex class I on the surface of transduced target cells can reduce long-term gene expression, after an immune rejection of the genetically modified target cells [11]. Transient immunosuppressive therapies or AAV capsid variants that

reduced the presentation of peptides derived from the AAV capsid can decrease this risk of immune responses [24,25]. The vector capsid is, in most cases, an exact replica of the viral capsid, and thus the immune response against the vector may be influenced by previous exposure of the immune system to environmental viruses from which the vector is designed [26]. Humans, early in life, are naturally exposed to wild-type AAV, and consequently the frequency of seropositivity of anti-AAV steadily increases after 2 years of age [26]. Humoral immunity to AAV can also be found in infants, as a result of vertical transmission of anti-AAV antibodies from the mother. In adults, anti-AAV2 antibodies are the most prevalent (up to 70% of healthy humans), followed by serotypes such as AAV5, AAV9, and AAV8, which are much less frequent [27]. Although the risk of inflammatory immune responses after AAV vector transduction is significantly lower than with adenoviral vectors, there are still significant immunological complications that must be evaluated. In particular, the high prevalence of preexisting anti-AAV neutralizing antibodies (NAbs) in the population may result in rapid neutralization of vectors derived from AAV, preventing adequate gene transfer [12]. Similarly, the induction of NAbs after AAV-based gene therapy impedes adequate therapeutic response following readministration of AAV vectors [7,28].

### Anti-AAV NAbs

There is a high degree of amino acid sequence conservation between AAV capsids, leading to anti-AAV antibody cross-reactivity in a wide range of serotypes [29]. Although antibodies to AAV2 are clearly the most prevalent in humans (up to 70%), the natural host for this serotype, antibodies that recognize virtually all serotypes of AAV may be found in a high proportion of humans [26]. Studies have shown that, after AAV vectors were introduced into the systemic circulation in humans, the preexisting humoral immunity to AAV vectors profoundly reduced transduction efficiency in the target tissue. Results of the first clinical trial for hemophilia B showed that relatively low titers of NAbs, as low as 1:17, can completely neutralize large vector doses, without detection of transgene expression [12]. The existence of anti-AAV NAbs is one of the main limitations faced in gene therapy clinical trials after intravascular delivery of AAV vectors. In the CUPID 2 trial, patients with high levels of NAbs were excluded. Of the 509 patients initially evaluated, >50% were excluded for presenting levels of NAbs outside of the safety range established in the study [30], suggesting the importance of prior determination of anti-AAV NAb circulating levels in different populations.

The prevalence of NAbs against AAV in humans was initially reported in the 1960s and 1970s, mainly anti-AAV1 and -AAV2 serotypes, the only known serotypes at that time. NAb variation is estimated at between 30% and 80% based on previously published studies in other populations [31,32]. More recent studies have evaluated the prevalence of NAbs in the most commonly used serotypes for preclinical studies (AAV5, AAV7, AAV8, and AAV9) and compared them with previously described serotypes. One study that collected samples from 10 countries on 4 continents (United States, Europe, Africa, and Australia) showed a prevalence of NAbs to AAV2 of between 30% and 60% of the total population [27]. This was significantly

higher than the prevalences of NAbs to AAV7, AAV8, and AAV9 serotypes, which were reported to be between 15% and 30%. Notably, higher frequencies of NAbs were observed for all AAV serotypes in Africa than in the other regions [27]. However, none of the existing reported studies have included a Latin American population.

An interesting finding is the significant variability in the prevalence of anti-AAV NAbs, influenced by the geographic origin of the population. While the prevalence of NAbs against AAV1 in Africa and China is around 50% to 70%, in other countries such as Belgium, Greece, Italy, and the United States, it is only 20% to 30% [27]. Overall, the prevalence of anti-AAV NAbs appears to be greater in developing countries. Factors such as living conditions, population density, hygienic conditions, different levels of health care, and the AAV detection method for NAbs can influence these results; in particular, the prevalence of anti-AAV1 NAbs was higher in women than in men [27]. The health status of the target population can also affect the prevalence NAbs against AAV, especially in those patients with a compromised immune system. These people had a lower prevalence of anti-AAV NAbs than that in the healthy population [26,27,33,34]; furthermore, the prevalence of NAbs was higher in elderly than in younger populations [35].

### AAV Antibody Determination

Diverse methods have been developed to detect antibodies against different serotypes of AAV. Some of them are based on total binding antibodies to the AAV capsid, and others on the functional determination of antibodies that neutralize AAV vector transduction *in vitro* or *in vivo* [29]. The first reports, in the 1970s, were based on binding of antibodies to AAV capsid vector evaluated by enzyme-linked immunosorbent assay (ELISA) and Western blot [32]. These studies focused on AAV1 and AAV2. The discovery in the last decade of new AAV vectors required more accurate assays to evaluate not only the level of binding but also the effect of the specific NAb for each AAV serotype on vector activity. Given the profound effect of anti-AAV antibody on transduction efficiency, the development of sensitive and reliable methods for measuring patients' titers of NAbs is critical before starting a clinical trial with gene therapy. Furthermore, the method of choice must ensure correlation of titers with the clinical outcome reported for gene therapy.

#### Elisa

ELISA is based on a capture assay in which the entire AAV capsid or peptides coated on a plate and AAV immunoglobulin antibodies present in serum are detected with a secondary antibody. ELISAs are easier to configure and are relatively sensitive at determining antibody levels. However, the total amount of anti-AAV antibodies is not always proportional to its neutralizing activity, especially in people with low titers, making this assay unreliable for determining the eligibility of people for their participation in clinical trials with AAV vectors.

#### In Vitro Cell-Based Assays

These are among the most widely used methods to determine anti-AAV NAbs [27,36,37]. Specifically, the *in vitro* transduction inhibition assay has become the standard test to

evaluate the presence of anti-AAV NAb [37]. Typically, an AAV vector expressing a reporter gene is mixed with serially diluted amounts of the test sample, and this vector serum mixture is incubated with the cell line of choice, which is then analyzed for reporter gene expression. The starting dilution of the test sample, which defines assay sensitivity, varies across studies, ranging from 1:2 to 1:20. The NAb50 titer is reported as the highest serum dilution that inhibits the transduction of the reporter gene by 50% [37]. While NAb *in vitro* assays are relatively easy to set up and give consistent results, they have some limitations: the most important derives from the fact that most of the AAV serotypes are highly inefficient for *in vitro* cell transduction. This limitation can be at least partially overcome with the use of reporter genes with high detection sensitivity (eg, luciferase) and cell lines more permissive for AAV transduction [37]. In addition, several related parameters of the cell culture conditions can contribute to variability of the assay, such as the cell line used, cell density, and the number of passages of cells during cultivation.

In summary, recent reports highlight the importance of identifying the prevalence of NAb for each AAV serotype in various human populations, due to the serotypes' geographic variability and their major role in selection of participants for AAV vector clinical trials. This increases the importance of conducting NAb prevalence studies in the Latin American population. Considering the major impact of CVD on the health care systems of developing countries, we intend to determine the prevalence of anti-AAV vector NAb for the serotypes AAV1, AAV2, and AAV9 in patients with HF in the Cardiovascular Foundation of Colombia (FCV) by the *in vitro* transduction inhibition assay.

## Methods

We will conduct a cross-sectional study to evaluate NAb against AAV1, AAV2, and AAV9 serotypes in patients with

HF at the FCV-HF clinic. Patients who fulfill the inclusion criteria will be invited to participate in the study. Those who accept will be asked to read and ask the questions they deem relevant to informed consent before signing the form (see [Multimedia Appendix 1](#)). Once the patients consent to participate, a standardized and approved survey to evaluate epidemiologic and socioeconomic variables and major CVD risk factors will be applied and complemented with relevant clinical information obtained from the electronic medical record system (SAHI 2.0 software, integrated hospital management system) developed by the FCV. A physical examination will be performed, including evaluation of blood pressure levels, anthropometric measurements, and a record of the last echocardiographic parameters available. Finally, a sample of peripheral blood will be collected from each participant to determine the presence of anti-AAV NAb.

### Study Population

We will evaluate 60 patients with a diagnosis of HF (American Heart Association stage B or higher criteria) followed in the FCV-HF clinic (see [Textbox 1](#) for inclusion criteria for the patient group). All adult patients ( $\geq 18$  years old) followed in the HF clinic at FCV will be eligible for the study. We will use various methods to recruit patients, including electronic clinical data from the SAHI 2.0 records. Additionally, we will invite 60 healthy volunteers, matched by age and sex, to participate. Participants will be considered as healthy volunteers if they are  $\geq 18$  years old, nationals from a Latin America country with a residence address in Colombia, and not meeting any of the exclusion criteria detailed in [Textbox 2](#). We selected the number of participants as convenience size due to the internal financial and technical limitations of the project.

**Textbox 1.** Inclusion criteria for patients in the ANVIAS study.

- Age  $\geq 18$  years
- Diagnosis of heart failure stage B or higher according to the American Heart Association criteria
- National of a Latin America country with residence address in Colombia
- Followed in the Cardiovascular Foundation of Colombia heart failure clinic

**Textbox 2.** Exclusion criteria for patients simultaneously presenting with heart failure and for volunteer participants the ANVIAS study.

- Multiple blood transfusions
- Recent plasmapheresis
- Infection with human immunodeficiency virus
- Immunosuppression or recent treatment with corticosteroids
- Solid organ or bone marrow transplantation
- Diagnosis of Chagas disease
- Pregnancy
- Preexisting condition of asthma, obstructive sleep apnea, or chronic obstructive pulmonary disease
- Prior hormone replacement therapy
- Heavy drinking, defined as the consumption of  $\geq 5$  alcoholic drinks on the same occasion on each of  $\geq 5$  days in the past 30 days (US Substance Abuse and Mental Health Services Administration definition)

## Storage of Biological Material

Participants will be asked to consent to donate biological material to be stored according to all quality and ethical requirements in the biobank of the FCV. The FCV biobank is a biomedical platform for future research, which is of great relevance in contributing to establishing bridges between basic, translational, and clinical research, and health care practice. Importantly, participants in this proposed study will be required to grant additional consent for taking and storing samples in the biobank (see [Multimedia Appendix 1](#)).

## Blood Sample Collection and Separation of Components

Samples of peripheral blood will be collected by antecubital venipuncture with a Vacutainer system (Becton, Dickinson and Company, Franklin Lakes, NJ, USA) into 2 tubes containing 4 mL of EDTA anticoagulant and labelled to identify the participant. Then, the sample will be centrifuged to separate the components and stored according to established protocols by the FCV biobank. A physical and digital date and time record of sampling separation and storage components will be kept, as well as the name of the person responsible for the procedures.

Samples will be handled from the first to the final phase by the following FCV biobank storage steps: 1) obtaining informed consent for storage of samples in the biobank: Protocol PR-BIO-01, 2) blood sampling: Protocol PR-BIO-03, 3) transporting biological samples: Protocol PR-BIO-02, 4) receiving and storing samples: Protocol PR-BIO-05, 5) quality control of human biological material, storage, and registration: Protocol PR-BIO-08.

## Data Processing and Quality Control

The data will be recorded on case report forms previously designed for that purpose. After completing the case report form, the monitor of the study will review the data to confirm completeness, readability, accuracy, and consistency. All detected errors will be reported, evaluated, and properly corrected by the originator of the forms. All corrections will be noted with dates and initials of the person issuing the correction in accordance with the World Health Organization's Guidelines

for Good Clinical Practice [38]. Immediately after the form is correct, the information will be recorded in a database.

## Production and Purification of Viral Vectors

We will produce the AAV1, AAV2, and AAV9 vectors using the cotransfection strategy of human embryonic kidney 293 cells specially modified to facilitate transfection of AAV (AAV-293; Agilent Technologies, Santa Clara, CA, USA; catalog #240073) via calcium phosphate (ThermoFisher Scientific, Waltham, MA, USA) [39]. We will use a pAAV with the plasmid of interest, a helper adenoviral plasmid, and a chimeric construct having the AAV2 *rep* gene, along with the corresponding AAV1, AAV2, or AAV9 *cap* gene [9].

We will evaluate the AAV-293 cells for microbial contamination using the polymerase chain reaction protocol for detecting mycoplasma. Following the previously described protocol, 2 days after transfection, we will collect cells and purify the vector particles using precipitation gradient centrifugation methods. The harvested cells will be lysed by successive cycles of freezing, thawing, and sonication, then treated with Benzonase nuclease (Novagen, Madison, WI, USA) and deoxycholic acid (Sigma-Aldrich, St. Louis, MO, USA), and then subjected to 3 successive rounds of cesium chloride density-gradient ultracentrifugation (ThermoFisher Scientific). We will collect the fractions containing AAV vector, concentrate it using 1-mmol/L  $\text{MgCl}_2$  (phosphate buffered saline) (Gibco, BRL), and store it at  $-80^\circ\text{C}$  until use. Quantification of AAV1, AAV2, or AAV9-cytomegalovirus-luciferase (in viral genomes/mL) vectors will be determined by quantitative real-time polymerase chain reaction probes using SYBR Green Supermix (Bio-Rad, Hercules, CA, USA) and primers specific for luciferase complementary DNA. The forward and reverse primers that we will use are CCCACCGTCGTATTCGTGAG5'-3' and 5'TCAGGGCGATGGTTTTGTCCC-3', respectively.

Typically, we have managed to standardize the protocol and achieve titers in the range of  $2 \times 10^{12}$  to  $5 \times 10^{12}$  viral genomes/mL. To generate standard curves, we will use a plasmid of known copy numbers corresponding to the vectors used to generate AAV vectors carrying the appropriate complementary DNA. Viral vectors will be produced in collaboration with the laboratory of the Department of Gene Therapy and Regenerative

Medicine, Free University of Brussels, by the principal investigator, Dr Melvin Rincon.

### Determination of Neutralizing Antibodies

We will determine NAb titers against serotypes AAV1, AAV2, and AAV9 following the recently published protocol in *Human Gene Therapy Methods* by Dr F Mingozi's group [37]. This protocol is used due to high reproducibility of the results, in addition to the efficiency and safety it offers. Determination of NAb titers is based on an AAV vector expressing a reporter gene, which is incubated with the sample to be evaluated before *in vitro* transduction of a specific cell line. We describe the main features of the protocol below; for a more detailed protocol please review the publication by Meliani et al [37].

### Multiplicity of Infection Selection

Importantly, as Meliani et al [37] mention, an optimal multiplicity of infection (MOI) should be determined for each serotype. We will select the MOI for each serotype NAb assay by determining the viral vector needed to give a luciferase signal above background signal and below saturation levels, measured in relative light units, considering that the number of AAV genome copy particles to be used is equal to the desired MOI multiplied by the number of cells to be infected.

For our project, we will transduce human embryonic kidney 293-derived 2V6.11 cells with an increasing MOI of the corresponding serotype (AAV1, AAV2, or AAV9); 24 hours later we will measure luciferase expression and select the most appropriate MOI for each serotype.

### Assay Validation

Validation of any assay is fundamental before translation to clinical practice. Simultaneously with execution of the project and, based on initial results from the patients' samples, we will

perform a process similar to the following (to be reported in the final paper): 1) determine the optimal cut point (threshold), 2) determine sensitivity, 3) select quality controls, 4) set specificity and assay precision, and 5) determine selectivity. We refer the reader to previously published papers for more detailed information [40,41].

After selecting the desired MOI and establishing the conditions of the assay, we will conduct a 4-day NAb assay protocol, as follows.

#### Day 1: Cell Culture 2V6.11

We will suspend  $2 \times 10^4$  2V6.11 cells in 100  $\mu$ L of Dulbecco's modified Eagle's medium (DMEM)/Ham's nutrient mixture F-12 culture medium (Sigma-Aldrich) supplemented with 10% fetal bovine serum. The cells will be cultured for 24 hours in an incubator (37°C, 5% CO<sub>2</sub>) in 96-well culture plates. To induce expression of the *E4* gene, Ponasterone A will be added to the culture medium (Sigma-Aldrich) (10 mL).

#### Day 2: Sample Controls and AAV Vector Preparation

For transduction, we will prepare serial dilutions of 10 mL of patient serum and a control sample using fetal bovine serum as the diluent (Table 1). One control sample will correspond to 100% transduction of the vector and another to 0% transduction of the vector to allow for determining the background luminescence signal. The viral vector will be diluted to the concentration selected (according to the desired working MOI) in DMEM without the use of fetal bovine serum. Subsequently, we will add 20  $\mu$ L of the vector to each of the sample dilutions and controls. These samples will be grown for 1 hour at 37°C and, subsequently, 7.5  $\mu$ L of each neutralized sample will be added to the cell culture medium. Cells will remain in overnight incubation at 37°C and 5% CO<sub>2</sub>.

**Table 1.** Example<sup>a</sup> of half-log dilution preparation for the test sample and control using fetal bovine serum as the diluent before being mixed with the viral vector (20  $\mu$ L) and added to 96-well plated cultured cells.

Dilution no.	Relation	Volume ( $\mu$ L) of sample/control	Volume ( $\mu$ L) of diluent
1	1:1	40	0
2	1:3.16	12 of dilution 1	26
3	1:10	12 of dilution 2	26
4	1:31.6	12 of dilution 3	26
5	1:100	12 of dilution 4	26
6	1:316	12 of dilution 5	26
7	1:1000	12 of dilution 6	26
8	1:3160	12 of dilution 7	26

<sup>a</sup>Modified from Meliani et al [37].

#### Day 3: Cell Lysis and Measurement of Luciferase Activity

On this day, we will use the protocol for the Bright-Glo Luciferase Assay System (Promega Corporation, Madison, WI, USA). After incubating the assay for 15 minutes at room temperature, we will add 100  $\mu$ L of cell lysis medium and the luminescence substrate, then wait for 3 minutes until lysis is

complete. Luminescence will be measured using the EnSpire reader (PerkinElmer, Inc, Waltham, MA, USA).

#### Day 4: Determination of Anti-AAV NAb titers

To calculate the luciferase expression percentage (LEP) and luciferase inhibition percentage (LIP), we will use the formulas  $LEP = [(test\ sample\ luciferase\ reading - no\ virus\ luciferase$

signal)/(maximum luciferase signal–no virus luciferase signal)] $\times 100$  and  $LIP = 100 - LEP$ .

The neutralizing titer of the sample is reported as the first dilution at which  $\geq 50\%$  inhibition of luciferase expression is measured. For example, if  $\geq 50\%$  inhibition is observed at a sample dilution of 1:10, then the neutralizing titer is reported as 1:10. NAb titers will be determined for the selected serotypes in collaboration with the laboratory of the Department of Gene Therapy and Regenerative Medicine at the Free University of Brussels by the principal investigator, Dr Melvin Rincon.

### Statistical Analysis

We will describe data from all measurements of continuous variables using measures of central tendency such as means and standard deviations, considering the coefficients of variation between replicates (3) of the experiments. We will report counts and proportions of categorical variables with their respective 95% confidence intervals. For tests between study groups, we will use analysis of variance to assess differences between means and the chi-square test for differences between proportions. Differences with a value of  $P < .05$  will be considered significant. We will use Stata 8.0 statistical software (StataCorp LP).

### Results

We have completed the first phase of the project. During this stage, all the documents necessary for recording and storing information have been elaborated and submitted to the ethical committee of the FCV for approval. We expect to begin recruiting patients in the spring of 2016. We expect to complete the second phase, in which we will validate all the protocols for the project—including determining the titer of the viral vectors, selecting the MOI that we will use for each serotype, and validating the assay—by the end of 2016. Finally, we will conduct the third phase, in which we will analyze serum samples

from patients and healthy volunteers, during 2017. We expect to have the first results in mid-2017.

### Discussion

For this project, we will evaluate anti-AAV1, -AAV2, and -AAV9 NABs by using the *in vitro* transduction inhibition assay, to determine the presence, activity, and titers of NABs in patient sera. Several critical steps and validation of the protocol should precede analysis of the patient samples (eg, selection of MOI, selection of the cells to be used during the assay). We expect that the final results may indicate the seroprevalence of NABs for the selected serotypes and allow for comparison with previously reported results from other populations. The causes of the demonstrated high variability between the evaluated populations continue to be debated, and more studies including different healthy populations and under specific pathologic circumstances need to be conducted worldwide. Importantly, the method of determination should be standardized to obtain more reliable and comparable data. Recent reports support the higher sensitivity of intramuscular *in vivo* assays to determine NAB response [42], suggesting that *in vivo* NAB assays are more sensitive than *in vitro* assays for determining inclusion and exclusion criteria in clinical trials; however, the technical difficulties and higher cost associated with using *in vivo* assays in population studies mean that *in vitro* assays still have an important function.

### Conclusion

We expect to have preliminary results, including the titer of the viral vectors, the MOI that we will use, and test assay validations, at the end of 2016. The results of this study will become the initial step for bigger population studies to characterize our population and provide the necessary epidemiological information for clinical trials using AAV in Latin America.

### Acknowledgments

Ethics approval and consent to participate: This research is classified as “Research with minimal risk,” and all biosecurity measures will be strictly followed by the researchers for taking a blood sample (not more than 10 mL) from participants. All patients who choose to participate in the study and whose whole blood sample (see [Multimedia Appendix 1](#)) will be used will sign an informed consent form. The realization of this project does not obstruct the performance of other related work or present a conflict of interest within the work of the scientific community. According to the study design and procedures to be performed, we do not anticipate any disturbance to the environment or human health in the short, medium, or long term. All methods and procedures implemented during this study have the scientific and ethical support of the Cardiovascular Foundation of Colombia, an organization known for the quality of services provided (certification ISO 9001: 2000, ICONTEC), and of its research department, which has been certified for the design, preparation, and development of projects in basic, clinical, epidemiological, and administrative research. The ethics committee of the Cardiovascular Foundation of Colombia, act 376/2015, approved the study.

MYR received funding from the Patrimonio Autonomo Fondo Nacional de Financiamiento para la Ciencia, la Tecnologia y la Innovacion Francisco José de Caldas, Fundación Cardiovascular de Colombia/Colciencias Postdoctoral Fellowship. The project was selected for funding by the Department of Science and Technology of Colombia, COLCIENCIAS, after a peer reviewed evaluation.

### Conflicts of Interest

None declared.

## Abstract

**Background:** The objective of focal brachytherapy (BT) is to provide effective prostate cancer control for low-risk disease but with reduced genitourinary, gastrointestinal and sexual side effects in a cost-effective way.

**Objective:** The aim of this study is to describe a phase II study examining technical and dosimetric feasibility and toxicity, quality of life changes, and local control with post-treatment biopsy outcomes in men with early stage low volume prostate cancer treated with focal iodine-125 seed BT.

**Methods:** The study design is a prospective, multicenter trial with a planned sample size of 20 patients including men with a minimum age of 60 years, a life expectancy estimated to be greater than 10 years, with low or low-tier intermediate risk prostate cancer, unilateral disease on the biopsy, and a Gleason score of  $\leq 3+4$  and  $<25\%$  cores involved. The investigations specific for the study are multi-parametric magnetic resonance imaging (Mp-MRI) baseline, at 20 and 36 months to rule out high grade disease and a transperineal mapping biopsy (baseline and at 36 months) for more accurate patient selection. The hemigland region will receive 144 Gy. Standard normal tissue constraints will be considered as for a whole gland (WG) implant. Dosimetric parameters will be evaluated at day 30 after the implant. Toxicity and quality of life will be evaluated with international validated questionnaires focusing on urinary, rectal, sexual domain, and general health-related quality of life. The patients will complete this assessment at baseline and then approximately every 6 months after the implant up to 10 years.

**Results:** To date, one patient is involved in the trial. He underwent the pre-implant investigations which found bilateral disease. Therefore, a standard seed implant was performed. If the results from this trial provide evidence that the treatment is safe, feasible, and improves toxicity, funding will be sought to conduct a large, multicenter, randomized controlled trial (RCT).

**Conclusions:** This protocol is designed to show feasibility in delivering hemigland focal therapy with seed BT. It may answer crucial questions and obtain data which will enable downstream decisions on focal low dose rate (LDR) prostate BT.

**ClinicalTrial:** Clinicaltrial.gov NCT02643511; <https://www.clinicaltrials.gov/ct2/show/NCT02643511> (Archived by Webcite at <http://www.webcitation.org/6ghLCzIhY>)

## Introduction

Prostate cancer is the most commonly diagnosed non-cutaneous neoplasm in males in the United States and the second leading cause of cancer mortality. Estimated new cases and deaths from prostate cancer in 2014 were 233,000 and 29,480, respectively. [1].

Widespread screening with the prostate-specific antigen (PSA) test, which can identify patients with asymptomatic tumors that have little or no lethal potential, has decreased the age of diagnosis [2]. With an enormous reservoir of cancers in ageing men, there is a major risk of detection of many cancers that will often never cause symptoms or death [3,4]. Surgery and radiotherapy are widely-employed definitive treatment options; however, their corresponding side-effects include urinary, sexual (ie, erectile dysfunction), and gastrointestinal complications [5]. There are reports showing similar or better outcomes for brachytherapy (BT) versus surgery regarding quality of life in the urinary, bowel or sexual domain [6,7].

It is increasingly apparent that some older men with low volume favorable cancers and significant medical co-morbidities may be appropriately managed with observation [8]. Recently, active surveillance (AS) has been advocated for selected low-risk cancers with the recognition that Gleason 6 disease is rarely a cause of cancer mortality. A recent cohort study published in 2010 showed, at a median follow-up of 6.8 years, the 10-year prostate cancer actuarial survival was 97.2% in patients undergoing AS [9,10]. After 2 to 3 years of follow-up, approximately one third of patients ceased AS and switched to active therapy [11]. The most common reason for this change was a change in risk classification as a result of repeated biopsies, leading to definitive therapy [12]. Despite the fact that AS was associated with the greatest quality-adjusted life expectancy when compared with definitive treatment of low-risk prostate cancer [13], a considerable majority of men in the United States and Europe who are diagnosed with screen-detected localized tumors still receive aggressive treatment [14,15].

### What is Focal Therapy?

There is increasing evidence that the largest tumor focus within the prostate (called the index lesion) drives the natural history of prostate cancer [16]. Liu and colleagues have shown that metastases in prostate cancer have a common origin (ie, these metastatic cells originate from the same clone) [17]. If the single lesion harboring this metastatic clone could be accurately identified and then conformally targeted, it seems likely that the side effects of treatment for prostate cancer could be reduced due to a smaller treatment volume. Other lesions could then potentially undergo a surveillance approach. The pathological characteristics of the index lesion, namely, the grade and the presence or absence of extracapsular extension, generally indicate the prognosis. Both the index lesion hypothesis and the monoclonal origin of metastatic prostate cancer open the way to a consideration of focal therapy in the majority of men who have multifocal, bilateral disease in which only the clinically important lesion might be ablated [18].

There is no standard definition for focal therapy, but in general it refers to a tissue preservation technique that does not treat the entire prostate gland but instead focuses the treatment to either an index lesion or some defined part of the prostate [19]. This approach is based on the premise that, in appropriately selected men, treating only part of the prostate can be as clinically effective as treating the whole prostate with far less morbidity. This, therefore, is an attractive option for patients where quality of life issues are important. Prostate focal treatment is a potential compromise between definitive treatment and AS. Advances in ultrasound and magnetic resonance imaging (MRI) techniques, as well as tissue sampling, have enhanced the ability to select these patients [20-23].

### Why Low Dose Rate Brachytherapy for Focal Therapy?

A variety of treatment modalities have been used to deliver prostate cancer focal therapy. The literature mainly includes reports on high intensity focused ultrasound (HIFU) [24,25] and cryotherapy [26-28], but neither modality is first line for whole gland (WG) treatment because of toxicity and lack of comparable efficacy.

Low dose rate (LDR) monotherapy has established long-term track record in terms of biochemical control for low and low tier intermediate risk prostate cancer. For favorable risk prostate cancer, LDR BT as monotherapy provides a highly effective treatment option, commonly achieving an undetectable PSA within 4 to 7 years [29,30]. A 15-year biochemical relapse-free survival has been reported at 85.9% for low risk patients [31], and a 10-year disease-specific survival at 96% [32].

The hallmark of LDR prostate BT toxicity is urinary side effects. About 50% will have moderate irritative and obstructive urinary symptoms after the procedure lasting several months. By 12 months, the urinary symptoms of most patients (90%) will return to baseline, although full recovery can be prolonged in 10% to 20% of individuals in 2 to 3 years [33-35]. Mild self-limiting rectal irritation affects 20% to 30% of patients in the first 1 to 2 years after the implant, and rectal bleeding is reported in 2% to 7% of patients [36,37]. The risk of rectal complications has consistently been linked to greater rectal wall doses [38-40]. In a series by Tran et al in which 503 patients were treated with permanent interstitial prostate BT using iodine-125 or palladium-103, 44 patients developed persistent rectal bleeding, including 2 patients with fistula formation. In both of these cases, the volume of rectum receiving greater than or equal to the prescription dose (RV100) exceeded 1 cc [41]. Merrick et al [42] reported on the incidence of BT-related bulbomembranous urethral strictures in a series of 1186 men. The authors described 29 cases (3.6%) noting an association with urethral radiation dose and external beam radiation therapy (EBRT). Kamrava et al [43] compared hemigland BT treatment plans to WG. Hemigland plans revealed a statistically significant decreased radiation dose to organs at risk. The degree of reduction in the dose of 2 cc to these organs was from 64% to 53% for the rectum, 67.5% to 56% to the bladder, and from 95% to 69% to the urethra. One Swiss group used high dynamic range imaging (HDRI) as a partial boost after 64 to 64.4 Gy of EBRT to the prostate, followed by either bilateral or unilateral

HDR BT boost. They found no differences in late rectal toxicity and in severe grade  $\geq 3$  late urinary toxicity at five years [44]. However, with a background of a significant dose to the WG it is hard to detect a significant decrease in toxicity that this trial aims to achieve.

All curative treatments for prostate cancer have a major potential impact on sexual function. Erectile dysfunction (ED) rates are low at 1 year after the implant with 70% to 80% of men retaining erectile function; this rate declines to around 50% at 5 years post-implant [45]. Although Princess Margaret Hospital published a report on 1111 men with follow-up ranging to over 9 years, with 82% retaining satisfactory erectile function beyond 5 years [29]. Many patients will have improvement in their function with oral phosphodiesterase5 (PDE-5) inhibitors such as sildenafil, vardenafil, and tadalafil [46]. Merrick et al strongly suggested that BT-induced ED is related to the radiation dose delivered to the penile bulb and the proximal crura [47]. As the proximal penis is the most significant treatment-related predictor of BT-related ED, techniques to minimize the radiation dose to the proximal penis such as hemigland may result in improved rates of potency preservation [47].

Apart from the potential of a more favorable toxicity profile due to a dose reduction to the organs at risk with LDR hemigland BT, there are also some technical advantages of delivering LDR BT. LDR is a less invasive procedure that can be done in two stages with a pre-plan before the implant [48] or in a 1-step procedure planned intra-operatively with real-time dosimetry [49]. Although excellent dose distributions can be achieved with pre-planning techniques, intra-operative planning takes into account the intra-operative geometry of the prostate and the surrounding normal tissues. There are methods to dynamically modify the treatment plan as the implant procedure is ongoing based on the coordinates of the deposited seeds such as minimizing the possibility of tumor under dosage and enhancing the conformality of LDR prostate BT [50].

The proposal described here is based on the long-term evidence in the literature that we have for LDR monotherapy for low and low tier intermediate risk prostate cancer over HDR or other techniques. Other treatments available for focal therapy have lack of comparable efficacy and long-term follow-up. It might be more logical to consider whether a therapy might be suitable for focal application after it has been demonstrated to be effective as a WG treatment.

The radiation source used for LDR, iodine-125, has a lower energy of 0.028 MeV giving us more flexibility for planning purposes than the HDR radiation source iridium-192 with 0.38 MeV. Most importantly, prostate seed BT has a post-implant quality verification process where seeds are identified giving us a permanent record of the prostate region treated enabling salvage approaches easier. Focal therapy utilizing LDR BT has been chosen as the above mentioned data provides the most comprehensive treatment modality that addresses the issues of

local efficacy, quality assurance verification, excellent toxicity profile, and the ability to localize previous therapy in the setting of potential salvage therapy.

### Summary of the Evidence on Brachytherapy on Focal Therapy

While the use of LDR BT for WG treatment is very well established, there is little data with its use in focal-only treatment. LDR has been delivered to the peripheral zone alone identified by intra-operative magnetic resonance imaging (MRI) [51] with a biochemical free survival (BFS) for low risk patients at 5 and 8 years that was acceptable at 95.6% and 90.0%, respectively, using the Phoenix definition plus PSA velocity greater than 0.75 ng/ml/year. However, the results were poor for intermediate risk patients with a 5 and 8 year progression-free survival (PFS) at 73% and 66%, respectively. Cosset et al [52] have reported their preliminary results on the first 21 patients treated with focal BT with iodine-125 loose seeds targeting the positive region in the biopsy within the prostate and the suspicious sites on MRI, an approach called ultra-focal (UF) BT. After 12 months of follow-up only, a borderline advantage was seen in the International Prostate Symptom Score (IPSS) recovery at 6 months after the implant when compared with a previous cohort treated by WG treatment ( $P = .04$ ). The pre-implant dosimetric parameters for the UF volume with a minimum dose received by the 90% of the prostate volume (D90) of 183.2 Gy and the volume of the prostate receiving 100% prescription dose of 99% (V100) were successfully achieved [52]. Currently, there are three active phase II trials using LDR BT as focal therapy (Table 1). Morris et al are recruiting patients with low or low tier intermediate risk after MRI elastography transrectal ultrasound biopsy targeting high grade areas [53]. In France, Bachaud is recruiting patients with low risk prostate cancer for a focal target seed implantation [54], and Langley et al in the United Kingdom are evaluating side effects, quality of life, and cancer control in patients with prostate cancer diagnosed on only one side of the prostate gland [55]. Zelefsky opened a phase II study for men with early-stage low-risk prostate cancer treated with hemigland and focal LDR BT examining the tolerance profile. Unfortunately, this trial was terminated due to lack of accrual [56].

The aim of this study is to address the toxicity, feasibility, and utility of hemiablativ focal LDR BT as treatment for localized prostate cancer. We hypothesize that this form of LDR BT is safe and will give similar disease control outcomes when compared to established WB treatment techniques, but with decreased toxicity leading to an improved quality of life. As this is a feasibility study, we are looking at toxicity and safety (adequate implant) in highly selected candidates.

### Trial Objectives

The trial objectives for this study are described in Textbox 1.

**Table 1.** Phase II studies using low dose rate focal brachytherapy.

Study details	Phase II study			
	Morris et al [53]	Bachaud [54]	Langley et al [55]	Zelevsky [56]
Location	British Columbia Cancer Agency (BCCA), Canada	Institut Claudius Regaud, France	Royal Surrey county Hospital NHS, United Kingdom	Memorial Sloan Kettering Cancer Center, United States
Current progress	Recruiting	Recruiting	N/A	Terminated in February 2016 due to lack of accrual
Treatment	LDR focal BT	LDR focal BT; prescription dose (PD) 160 Gy +/- 5%	LDR BT hemigland 145 Gy	Hemigland LDR BT; PD 144 Gy
Patients <sup>a</sup> , n	10	17	34	80
Stage	≤T2a	≤T2a	≤T2b	≤T2a
Gleason	≤3 4≤2 cores	≤3+3	≤4+3	Up to Gleason 7 in just 2 cores
PSA	<10	<10	<15	<10
Inclusion tests	Transrectal ultrasound (TRUS)	3D prostate mapping biopsy, MRI	Transperineal template-guided mapping (TTGM) multi-parametric magnetic resonance imaging (Mp-MRI)	TRUS
Primary outcome	To fit for focal disease and adequate treatment plans	Successful post-implant dosimetry	Urinary, sexual and bowel toxicity, and quality of life	Late toxicity
Secondary outcome	Quality of life, treatment evaluation	Progression-free survival (PFS; (Phoenix definition), quality of life, biopsy, toxicity	Tumor control	Efficacy, quality of life, post-treatment MRI vs post-biopsy
Timeframe, years	4	3	5	2

Objectives
<ul style="list-style-type: none"> <li>Primary objective <p>To demonstrate the feasibility of delivering hemigland focal therapy (the delivery of the prescription dose to the half of the prostate) with a seed BT implant in a multi-center Australian study.</p> </li> <li>Secondary objectives <ul style="list-style-type: none"> <li>To determine acute and late rectal, urinary, and sexual toxicity following hemiablative iodine-125 brachytherapy (BT) treatment.</li> <li>To assess the change from baseline in quality of life indicators at specific time intervals using the following validated international questionnaires after hemiablative iodine-125 (BT) treatment: <ul style="list-style-type: none"> <li>International Prostate Symptom Score (IPSS)</li> <li>International Index of Erectile Function (IIEF)</li> <li>Expanded Prostate Cancer Index (EPIC)</li> </ul> </li> <li>To evaluate the local tumor control in terms of biopsy outcomes after focal BT 36 months after the treatments.</li> <li>To compare target coverage and relative doses to the rectum and the urethra for the same patient performing a hemigland treatment planning versus WG treatment planning, and compare rates of toxicity and quality of life after hemigland implant with historical WG cohorts.</li> </ul> </li> </ul>

## Methods

### Study Design

This multi-institution, prospective phase II trial aims to determine whether hemiablative treatment with LDR for prostate cancer is dosimetrically safe and feasible. This study will record

data for patient quality of life parameters, in particular in terms of urinary, rectal, and sexual function side effects.

### Study Group

Patients with ipsilateral low grade disease (N=20) will be evaluated prospectively after hemiablative focal therapy. Because of the historically small size of trials in this area, probably reflecting the difficulty of recruitment of patients in

this scenario, a pilot will be conducted to establish the feasibility of a full scale trial prior to committing to a large study.

### Eligibility Criteria

To be eligible for the study, participants must meet each of the eligibility requirements (Textbox 2). If a participant has one of the following, they will be ineligible for the study: (1) does not

meet staging criteria for low risk or low tier intermediate risk prostate cancer, (2) bilateral prostatic disease, (3) prior hormonal therapy, (4) recent IPSS more than 17, (5) unfit for general anesthetic, (6) MRI contraindicated, (7) unable to cease anticoagulant therapy, and (8) life expectancy less than 10 years. The trial schema is shown in Figure 1.

**Textbox 2.** Eligibility requirements.

#### Requirements

Patients must have histologically proven adenocarcinoma of the prostate.

Patients must have low or low tier intermediate prostate cancer.

Low risk prostate cancer patients must have:

- Clinical stage  $\leq$  T2a
- Gleason score of 6 and iPSA  $\leq$ 10 ng/ml
- Less than 25% cores positive

Low tier intermediate risk patients may have:

- Clinical stage T2a
- Gleason score  $\leq$ 3+4=7
- PSA  $\leq$ 10 ng/ml
- Less than 25% cores positive

Patients must be fit for general anesthetic.

Patients must have unilateral disease on biopsy.

Patients must have an Eastern Cooperative Oncology Group (ECOG) performance status of 0-2.

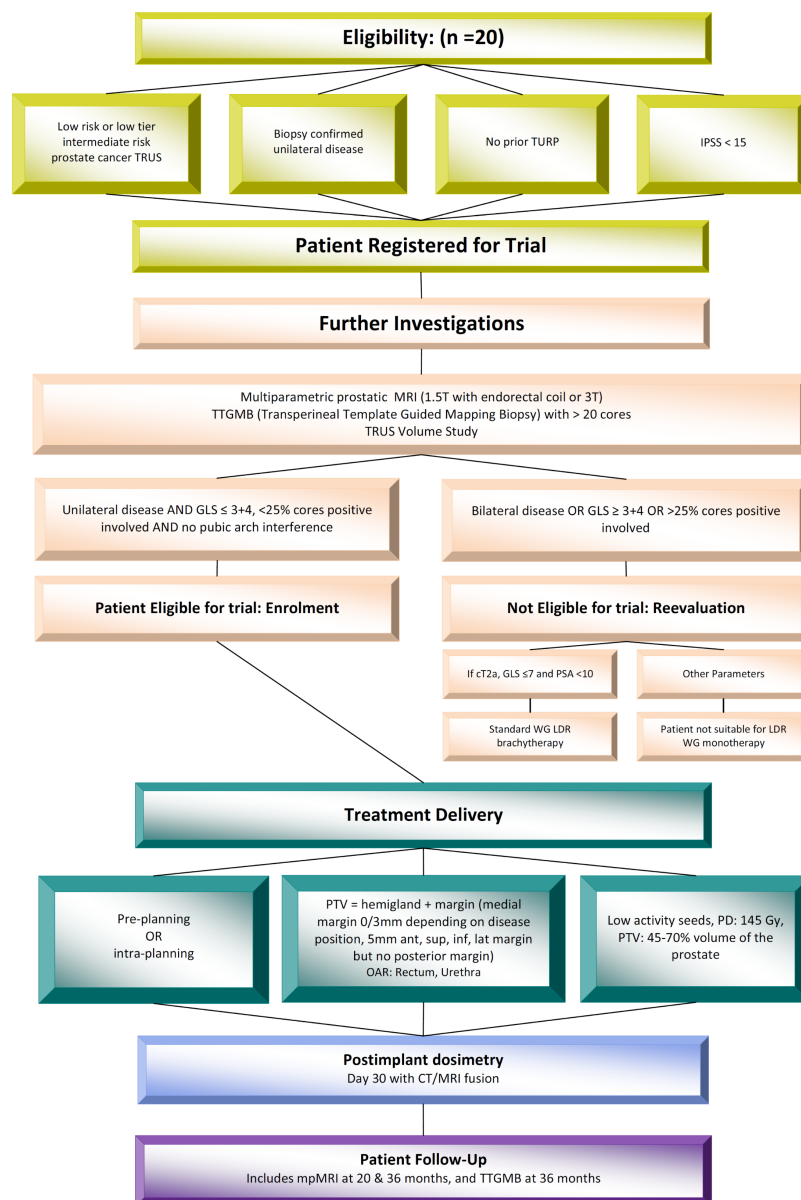

Men  $\geq$ 60 years of age with a life expectancy estimated to be  $>$ 10 years.

Patients must have no contraindications to interstitial prostate BT.

International Prostate Symptom Score (IPSS)  $\leq$ 16

Patients on anticoagulant therapy must be able to stop therapy safely for at least 7 days.

Patients must not have any contraindications to MRI.

**Figure 1.** Trial schema.

### Pre-Treatment Evaluation

The components of the pre-treatment evaluation are shown in [Textbox 3](#). The transperineal template is diagramed in [Figure 2](#).

The protocol includes a screening phase with multi-parametric magnetic resonance imaging (Mp-MRI) and mapping biopsy

for patient selection. Improved imaging techniques coupled with better sampling of the prostate [57,58] allows to identify men with low volume focal disease selection who may be suitable for tissue preservation strategies. It has been estimated that between one half and two thirds of men with prostate cancer may be amenable to some form of focal therapy [59,60].

**Textbox 3.** Pre-treatment evaluation.

## Pre-treatment

Patient demographics and histological information from transrectal ultrasound (TRUS) prostate biopsy will be collected.

For preplanning technique, ultrasound volume study to assess prostatic volume and pubic arch interference will be performed.

A multi-parametric prostatic MRI (Mp-MRI) (1.5 T with endorectal coil or 3T). The data set should include T1-weighted, T2-weighted, diffusion-weighted, and contrast-enhanced MRI. Imaging could be adequately performed at 1.5 T with endorectal coil or 3T without endorectal coil [57]. Suspicion of bilateral disease or high grade unilateral disease will exclude the patient from the study. Biopsy of any suspicious target lesions as identified on Mp-MRI is recommended.

If a TRUS biopsy has only been performed then the patient will also undergo a transperineal template guided mapping (TTGM) biopsy, with a minimum of 20 cores obtained, at the time of the volume study (for preplanning technique) (Figure 2). A single anatomical pathologist will review the biopsy. In addition the following parameters will be recorded to allow for stratification according to:

- T stage: T1c vs T2a
- Gleason: 3+3=6 vs 3+4=7
- Presence of lymphovascular invasion
- Presence of perineural invasion

Baseline quality of life assessments:

- International Prostate Symptoms Score (IPSS) questionnaire
- International Index Erectile Function (IIEF) questionnaire
- Expanded Prostate Cancer Index Composite (EPIC) questionnaire

**Figure 2.** Transperineal template. Diagram prepared by Warick Delprado at Douglass Hanly Moir Pathology and used by permission.

**Informed Consent, Registration, and Enrolment**

All patients must sign an informed consent form to be registered in this study. Completed consent forms will be sent to the Radiation Oncology Clinical Trials Office at the St George Cancer Care Centre (STGCCC) and eligibility will be confirmed by the study coordinator. A patient identification number (PIN) will be assigned to the patient. The registration process will include the consent and the prostate Mp-MRI and a transperineal

template-guided mapping (TTGM) biopsy of the prostate to rule out high grade disease and ensure eligibility for focal therapy. Only patients still suitable for focal therapy after these studies will be enrolled in the trial and will go ahead with the treatment. They will be followed up to 10 years. Patients not suitable for the trial will go ahead with standard WG BT if they still wish to have active radiation treatment. This is a feasibility study to assess the feasibility of this technique with a permanent seed implant to half of the prostate in terms of acute side effects

and post-implant dosimetry parameters. Normal tissue tolerance will have the priority in the planning algorithm. There is no randomization process.

## Investigations

All investigations required before study entry are standard for this grade and presentation of prostate cancer and include a TRUS-guided prostate biopsy for diagnosis and a PSA test within the last 3 months. Investigations specific for the study include a Mp-MRI of prostate using either a 3 Tesla magnet alone or a 1.5 Tesla magnet and an endorectal coil. A baseline Mp-MRI should be performed at least 6 to 8 weeks after the initial biopsy and the Mp-MRI should be repeated at 20 and 36 months after treatment or earlier if PSA is detected to be rising during follow-up. Patients should be scanned on the same scanner for all three examinations, especially when tracking changes in apparent diffusion coefficient (ADC) values over time. A central radiology review of the images will take place in Southern Radiology by Dr Jonathan Seef. In addition, a TTGM prostate biopsy with a minimum of 20 cores and at 36 months post treatment will be included. Central pathology review of the specimens will take place in a center assigned in each participating Australian state.

## Interventions

A preplanned technique or intra-operative planning technique will be used depending on the individual institutional preference. Patients participating in this study will undergo hemigland LDR prostate BT performed by experienced BT teams that perform a minimum of 40 cases per year (Figure 3).

The prostate volume study will be performed under sedation or general anesthesia, and patients will be set up in the dorso-lithotomy position. The urethra will be identified by insertion of aerated gel allowing visualization on ultrasound. A TRUS volume of the prostate will be performed. A set of 5 mm slice images are acquired using the transverse mode for 3D reconstruction of the prostate. Pubic arch interference will be identified in case modification of probe angle or leg position if necessary.

For the hemigland preplanning, the pre-implant clinical target volume (CTV) will be defined as half of the prostate excluding the urethra, as visualized and contoured on the reconstructed ultrasound images. The planning target volume (PTV) will be created by adding a 3 to 5 mm margin around the CTV except for the posterior margin that will be 0 mm. The PTV will encompass 45% to 70% of the total prostate volume maximum. A hemiablation approach over two different focal therapy scenarios has been chosen, as shown in Figure 1, with hemiablation or zonal ablation (hockey stick 5 mm beyond midline). An experienced medical physicist will plan the iodine-125 seed and needle positions achieving dosimetric parameter goals. All plans will be approved by both the

responsible radiation oncologist and a medical physicist, both of whom are experienced in prostate BT; the STGCC team of investigators has performed more than 1000 prostate BT procedures.

The treatment planning dosimetric parameters used for optimization aim for prostate PTV V100 is greater than 98%, with a V150 of 55% to 65% and V200 of less than 20%. (V100, V150, and V200 are the percentage of the prostate volume covered by the prescription isodose, the 150%, and the 200% isodose, respectively). Urethral dose (UD) is usually described as the UD5 or UD30, which are the dose to 5% and 30% of the urethra, respectively. UD5 is representative of a urethral maximum dose and should be less than 150% of the prescription dose, while UD30 should be less than 125%. For the rectum, the rectal volume in cubic centimeters receiving 100% of the prescribed dose (RV100) is commonly used and should be less than 1.3 cm<sup>3</sup> for day 30 dosimetry.

In addition, a whole prostate LDR planning will be performed for a potential matched historical control toxicity comparison with patients from the existing large LDR database based on standard whole prostate dosimetric features as well as other clinical features like prostate volume, IPSS and potency, and medical conditions (eg, diabetes). This will enable us to report the difference in dose for the two plan sets for the targets hypothesized to be responsible for toxicities like urethritis or proctitis. This will require a pre-implant CTV defined as the prostate excluding the urethra, as visualized and contoured on the reconstructed ultrasound images. The PTV will be created adding a 5 mm margin around the CTV except for the posterior margin that will be 0 mm. The same planning dosimetric parameters will be recorded as for the hemigland treatment planning.

For the implant procedure, the patient will be under general anesthesia and set up in the dorsal lithotomy position on the operating table in the BT theatre as per the local institutional seed implant protocol. A TRUS volume of the prostate will be matched to the images of the preplanned study. An intra-operative approach is also acceptable. Iodine-125 seeds will be inserted under US template and fluoroscopy guidance according to the plan.

At the completion of the needle and seed insertion, the Foley catheter will be kept in place and the patient will be taken to the post-anesthesia recovery (PAR) area. Patients will be discharged from PAR when they have made an appropriate recovery from anesthesia and have successfully voided urine after the Foley catheter is removed.

Patients participating in this study will be followed in the usual fashion and only require the following additional tests beyond those of standard practice: Mp-MRI at 18 and 36 months and TTGMB at 36 months.

Figure 3. Hemiablation.

Patient Follow-Up

Postimplant Dosimetry

Post-plan quality assurance using magnetic resonance computed tomography (CT) fusion (MR-CT fusion) is required because it reduces inter-observer variation by improving prostate edge

detection, and allows appreciation of treatment margins [61,62]. Fusion can be accurately performed to sub-millimeter accuracy using the seeds as fiducial markers. It is essential to use the appropriate MR sequences in order to facilitate both prostate contouring and seed localization. A Fast Spin Echo T2-weighted MR sequence is used, with the technical parameters described in Textbox 4.

Textbox 4. Technical parameters used with the Fast Spin Echo T2-weighted MR sequence.

Parameters
<ul style="list-style-type: none"><li>• Repetition time (TR) = 4500 msec</li><li>• Echo time (TE) = 90 msec</li><li>• Echo train length (ETL) =10,</li><li>• Pixel bandwidth (BW) = 580 Hz/pixel</li><li>• Field of view = 20 x 20 cm</li><li>• 3 mm slice thickness, 0 mm gap</li><li>• Acquired matrix size = 320 x 224 with phase encoding direction along rows</li><li>• Flip angle = 90°</li></ul>

CT images are likewise obtained in the supine position, imaging the prostate and all seeds visible on the scout image in 2 mm slices. Aerated gel with Ultravist contrast is inserted for the pelvic CT for urethral localization by the oncologist. No specific bowel preparation is used before either scan but they should be performed sequentially, with the CT following the MRI

generally within half an hour. Patients will also undergo a pelvic and chest x-ray to assess for any seed migration.

In order to improve this pilot trial consistency and check the hemi-implant quality, MR-CT fusion for all the participants will be reviewed by one of the two primary investigators with experience in MRI contouring and MRI-CT fusion; Dr A Fernandez has performed more than 100 MRI-CT fusions.

### **Follow-Up Schedule**

Routine assessment following completion of treatment includes PSA and clinical evaluation 4 to 6 weeks after the implant to manage and document any acute toxicity. The assessment will continue every 3 to 6 months depending on symptoms up to 3 years, and then every 6 to 12 months, with a PSA and digital rectal exam at each visit beyond 6 months up to 10 years. The IPSS, the International Index of Erectile Function (IIEF), and the Expanded Prostate Cancer Index Composite (EPIC) questionnaire are recorded at baseline and at each visit as is standard for all men receiving any type of prostate BT in the STGCCC. Specific follow-up for the study will involve a repeat Mp-MRI by 20 and 36 months and a TTGMB at 36 months. Patients will be followed up to 10 years after the implant, although the study finishes after 36 months of enrollment. Once we reach a median of 3-year follow-up (ie, sufficient time to determine rate of local control with the biopsies in 50% patients), then it would be adequate to commence the randomized controlled trial (RCT).

### **Exit Strategy and Rescue Therapy**

Biochemical failure will follow a PSA velocity greater than 0.75 ng/ml years in addition to nadir +2. Both parameters appear to better predict clinical failure after therapies that target less than the WG. Failure may also be proven on the TTGM control biopsies at 36 months or earlier in case of biochemical failure defined by Nguyen et al [51].

Definition of treatment failure will involve relapse in PTV or outside our PTV confirmed by biopsy. Relapse outside the PTV is not essentially a local treatment failure, and may be due to suboptimal patient selection. Due to the additional resources required to continue on this trial, these cases will be recorded as a treatment failure for further validation of the hemifocal BT as a treatment alternative to WG therapy. Interval from treatment to failure will be recorded.

After biochemical or local failure, the patient will exit the study. After appropriate investigations different salvage therapies can be offered to the patients who have failed. For local failure radical prostatectomy, HDR salvage BT or salvage cryotherapy in case of ipsilateral or contralateral relapse, or hemigland focal seed BT in case of contralateral relapse alone will be initiated. A choice of the treatment will be made after appropriate discussion in a multidisciplinary meeting and will be individualized.

### **Study Endpoints**

#### **Primary**

Feasibility of the hemigland focal therapy (the delivery of the prescription dose to half of the prostate) using a BT seed

implant, while respecting standard tolerance doses of adjacent normal organs is the primary study endpoint.

#### **Secondary**

Secondary study endpoints are (1) assessment of rectal, urinary, and sexual toxicity following hemiablativ prostate seed BT; (2) change from baseline in quality of life indicators at specific time intervals using validated international questionnaires (IPSS, IIEF, EPIC) following hemiablativ iodine-125 BT treatment; (3) evaluation of local tumor control in terms of biopsy outcomes after focal BT 36 months after completion of therapy; and (4) comparison of target coverage and relative doses to the rectum and the urethra for the same patient performing an hemigland treatment planning versus WG treatment planning and toxicity and quality of life after hemigland implant comparison with historical whole gland cohorts.

### **Measurement of Endpoints**

#### **Feasibility**

Dose parameters for prostate (V100, V150, V200), rectum (V100), and urethra (D5, D30) will be recorded for the hemigland and the WG treatment planning. Dosimetric parameters in the post-implant dosimetry at day 30 for WG BT are well defined in the literature and they are correlated to efficacy and toxicity. The post-implant dosimetric study for hemigland BT patients will aim for the same dosimetric parameters at day 30 after the implant for tumor coverage and organs at risk dose.

#### **Toxicity Evaluation Assessment**

Patients will be assessed on the day of enrollment, at 4 to 6 weeks, and every time they come back for follow-up (every 6 months) to determine acute, sub-acute, and late toxicity after the implant in the urinary, rectal, and sexual domain. An adverse event is any deleterious effect which may occur as a result of the intervention. Treatment-related toxicities will be graded using the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) Version 4.0 as follows: (1) grade 0 is no adverse events, (2) grade 1 is mild events not requiring intervention, (3) grade 2 is moderate events interfering with normal activities, (4) grade 3 is severe events causing inability to carry out normal activities, (5) grade 4 is life threatening or disabling events, and (6) grade 5 is death (Figure 4). A follow-up assessment will be undertaken within seven days in patients reporting greater than grade 1 toxicities, and will continue in this manner until toxicity has resolved, with documentation of action taken at each time point. Failure of an adverse event to resolve and its translation to chronicity at a given time point will be documented by the clinician. Serious adverse events (grade 3 or greater) will require assessment by the clinician and documentation of action taken.

**Figure 4.** The necessary data to be collected at various time points of the study.

### Quality of Life

Quality of life will be assessed using the IPSS, IIEF, and EPIC questionnaires. The change from baseline will be measured at specific time points ([Multimedia Appendix 1](#)).

### Local Tumor Control

Local tumor control will include negative or indeterminate TTMB 36 months after the treatment within the whole prostate. Definition of treatment failure will involve relapse in PTV or outside our PTV and confirmed by biopsy. In addition, dosimetric parameters and toxicity rates will be compared with historical WG treatment cohorts.

### Data Collection

The necessary data to be collected at various time points of the study is outlined in [Figure 4](#).

### Statistical Considerations

It is anticipated that a sample size of 20 patients will be accrued to enable the investigator to deliver hemiablativ seed BT with a reasonable amount of confidence. This feasibility study will proceed in 5 participating centers. Failure to accrue 15 patients in 24 months will initiate early closure of this study. The time-frame for completion of recruitment will be approximately 12 months, with a further 24 months required for collection of acute and late toxicity data, maturation of quality of life data, and correlation with the biopsy by 36 months.

We do not consider it necessary to use early stopping rules for poor quality implants (not adequate dosimetric parameters on day 30), or acute treatment-related toxicities because of the low number of patients we are aiming for. An analysis will be performed after 20 patients have participated in the study. Therefore, if greater than 20% of patients have poor quality implants, this procedure will be unacceptable.

Descriptive statistics will be used to describe the frequency at which prostatic cancer low grade disease can be seen on

Mp-MRI, and the frequency of unilateral prostatic disease is found after a mapping of the prostate. In addition to standard PSA follow-up, response will be assessed by imaging at 20 and 36 months as well as by TRUS-guided biopsy at 36 months.

Data analysis will be undertaken by Dr Ana Fernandez with the assistance of a qualified statistician.

### Resources and Implementation

#### Ethics

The application for the South Eastern Sydney Local Health District (SESLHD) Human Research Ethics Committee has been recently approved.

#### Skills and Resources

Three of the investigators are experienced BT proceduralists with extensive experience in the use of TRUS and transperineal needle implantation. The fourth investigator is a BT fellow in training and will be assisting with the procedure.

Planning systems will be institution-dependant but must allow appropriate collection of the above mentioned data. Acceptable planning systems will include Variseed, Nucletron First, PSID, and MIM Symphony. TGA-approved iodine-125 seeds may be purchased from any of the vendors within Australia.

#### Data Collection

The necessary data to be collected at various time-points of the study is outlined in [Figure 4](#). The principal and co-investigators will be responsible for collection of this data. This data will be manually entered onto paper forms and transferred to a secure database which is password protected and accessible only to the investigators.

#### Budget and Funding

The investigations beyond normal practice that are required for this protocol are (1) two TTGM biopsies of the prostate, one pretreatment and another one at 36 months following treatment;

and (2) Mp-MRI of the prostate, required at baseline and again 20 and 36 months following completion of treatment to assess response.

The post-implant quality assessment will require a non-Mp prostatic MRI at day 30. This is not our standard practice but we arrange it sometimes for specific patients that require more accurate post-implant quality evaluation. Apart from the 20 month and 36 month assessments, follow-up after completion of treatment is standard. The costs entailed by the MRI examinations and the TTGM prostate biopsy will be billed to the Internal Hospital Research Budget. Internal funding prior to commencement will be undertaken by each institution. SGCCC has already coordinated local funding using trust fund cost centre number and hence can proceed immediately after ethics approval. A grant application will cover part of the expenses. There will be no out-of-pocket cost for the patients enrolled in the study.

## Results

The study opened for recruitment in September 2015. One patient has been involved so far in the study that initially met the eligibility criteria and signed the consent. During the pre-treatment evaluation process he underwent a Mp-MRI which showed Prostate Imaging Recording and Data System Score 5 (PI-RADS 5) on the left lobe and PI-RADS 4 on the right lobe. A PI-RADS 5 represents clinically significant, highly likely to be present and PI-RADS 4 is clinically significant and cancer likely to be present [63]. Subsequently, as per protocol, a

TTGMB was performed finding a Gleason score of 3+4= 7 in 3 cores on the right side and in 8 cores of the left side. The histopathology report was reviewed. The patient underwent a standard seed implant prescribing 144 Gy to the whole prostate.

## Discussion

This protocol is designed to show feasibility in delivering hemigland focal therapy with seed BT. Our whole-prostate seed BT program has been running for more than 10 years with excellent results (data not published). We believe that our well-established experience with seed BT will ease the performance of the hemigland technique. The reduction in toxicity can be of significant importance, particularly in a well-selected population, therefore we consider the pre-implant investigations crucial.

If the trial is successful, showing feasibility meeting the dosimetric parameters in the post-implant setting, toxicity parameters, quality of life, and tumor local control will be evaluated. Once evaluated we will be able to move towards a RCT scenario comparing standard WG seed implant versus hemigland to confirm the benefit in toxicity and quality of life with the highest level of evidence. Cost effective analysis should be performed in the future given the cost of the pre-implant investigations before establishing the focal therapy technique.

Furthermore, this protocol will give us opportunities to study more data, such as the correlation between Mp-MRI findings with TTGMB which is still in early stages [64,65].

## Conflicts of Interest

None declared.

## Abstract

**Background:** The Patient-Centered Outcomes Research Institute (PCORI) created a new national network infrastructure to enable large-scale observational comparative effectiveness research across diverse clinical care settings. As part of testing the feasibility of this effort, each clinical data research network (CDRN) was required to construct cohorts of patients, including one of patients with overweight and obesity.

**Objective:** The aim of this paper is to report on the development of the Patient Outcomes Research to Advance Learning (PORTAL) overweight and obese cohort, which includes patients from 10 health plans located across the United States.

**Methods:** Information was gathered from each plan's electronic health records (EHR). Eligibility included 18 years of age or older, a valid height and weight in 2012 or 2013, and body mass index (BMI) greater than 22.9 kg/m<sup>2</sup>. Pre-diabetes and diabetes status was defined using the American Diabetes Association (ADA) criteria, using lab values of glycated hemoglobin (HbA1c) or fasting glucose available in the EHR. Hypertension was identified from the International Classification of Diseases (ICD) diagnosis codes. Individuals were classified into BMI categories: healthy weight (23.0-24.9 kg/m<sup>2</sup>), overweight (25.0-29.9 kg/m<sup>2</sup>), obese class 1 (30.0-34.9 kg/m<sup>2</sup>), obese class 2 (35.0-39.9 kg/m<sup>2</sup>), obese class 3 (40.0-49.0 kg/m<sup>2</sup>), and obese class 4 (>50.0 kg/m<sup>2</sup>).

**Results:** A cohort of 5,293,458 non-pregnant adults was created. Weight status was 20.39% (1,079,289/5,293,458) healthy weight, 40.40% (2,138,520/5,293,458) overweight, 22.78% (1,205,866/5,293,458) obese class 1, 9.86% (521,872/5,293,458)

obese class 2, 5.59% (295,786/5,293,458) obese class 3, and 0.98% (52,125/5,293,458) obese class 4. Race/ethnicity was 49.02% (2,594,776/5,293,458) non-Hispanic white, 22.89% (1,211,677/5,293,458) Hispanic, 10.40% (550,608/5,293,458) Asian, 10.83% (573,506/5,293,458) black, and 6.59% (348,830/5,293,458) other. About 34.33% (1,817,438/5,293,458) met the definition of hypertension, 20.49% (1,660,940/5,293,458) of individuals met the criteria for pre-diabetes, and 14.98% (793,069/5,293,458) met criteria for diabetes. Prevalence of pre-diabetes and diabetes varied across health plans to a greater extent than expected based on hypertension prevalence and BMI status variability.

**Conclusions:** This large, race, ethnic, and geographically diverse cohort will be useful for future studies of rare exposures or outcomes and differences in health care practices.

## KEYWORDS

overweight; obesity; race and ethnic diversity; pre-diabetes; diabetes

## Introduction

In 2014, the Patient-Centered Outcomes Research Institute (PCORI) funded 11 Clinical Data Research Networks (CDRN) and 18 Patient-Powered Research Networks to develop a National Patient-Centered Clinical Research Network (PCORnet), with the purpose of building a common infrastructure across the CDRNs to enable highly representative future clinical outcomes research. The goal of PCORnet is to "transform clinical research by engaging patients, care providers, and health systems in collaborative partnerships to improve healthcare and advance medical knowledge." One of the CDRNs is the Patient Outcomes Research to Advance Learning (PORTAL) network. PORTAL combines four health care delivery systems that have about 11 million members enrolled across nine states (CA, CO, GA, HI, MD, MN, OR, VA, WA) and the District of Columbia, reaching into most regions in the United States and offering a diverse patient population.

The PORTAL health care systems are previously described [1]. In brief, PORTAL includes all Kaiser Permanente regions (Hawaii, Northwest [Northern Oregon and Southwest Washington], Northern California, Southern California, Colorado, Mid-Atlantic States [Maryland, Virginia, and District of Columbia], and Georgia [through 2015]), Group Health Cooperative (Washington), HealthPartners (Minnesota and Wisconsin), and Denver Health. Individuals of all the health care systems except for Denver Health are insured (public or private); Denver Health is a safety net institution that provides medical services regardless of ability to pay.

All CDRNs were required to develop three cohorts to demonstrate each network's ability to identify individuals with a condition of interest and to test the commonality of data elements across sites. They also were required to field a survey of the cohorts to test the ability to reach out to patients. One of the pre-specified cohorts common to all of the PCORnet CDRNs was a cohort of individuals with obesity. The PORTAL overweight and obesity cohort was defined as adult members of our health care systems during 2012 or 2013 that were overweight or obese, defined as having a body mass index (BMI) greater than or equal to  $23.0 \text{ kg/m}^2$ . Although overweight is defined as BMI greater than  $25 \text{ kg/m}^2$  we recognize that the World Health Organization (WHO) recommends lower overweight and obesity cut points for Asians:  $23.0\text{-}27.4 \text{ kg/m}^2$  for

overweight and greater or equal to  $27.5 \text{ kg/m}^2$  for obesity [2]. Given that our health plans have a significant number of Asian individuals, we chose this lower cut point so future studies can examine health risks for Asians deemed overweight by WHO recommendations.

We constructed a cross-sectional cohort of adults enrolled in any of the PORTAL health plans; all of those meeting eligibility criteria are considered cohort members. For all sites except Denver Health, we first identified health plan members with at least 12 months of continuous membership between January 1, 2012 and December 31, 2013, and who were at least 18 years of age on December 31, 2013. Members were further restricted to those who had a weight recorded during 2012 or 2013, had a height recorded in the electronic health record (EHR), and who were not pregnant during 2012-2013. For Denver Health, the initial eligibility criteria included all adults who had a primary care encounter during 2012 or 2013 because Denver Health, as a safety-net organization, does not enroll members.

## Methods

### Data Harmonization

Each health care system has its unique methods of capturing its electronic health care data, resulting in information that widely varies in terms of content, format, and structure, thus requiring consistent data standards and terminology. We used the Health Care Systems Research Network (formerly HMO Research Network) Virtual Data Warehouse (VDW) for data extraction. The VDW is a federated database in which all data reside at each health system behind each site's secure system, or firewall [3]. The data model consists of taking the clinical and claims datasets from the individual health care systems and converting them into a series of identical dataset standards, automated processes, and common data dictionaries. This allows for a single Statistical Analysis System (SAS) program to be written and distributed to other sites with a minimum of site-specific customization. Sites typically return the datasets to the lead site within 2 weeks. Future studies using data from the PORTAL cohort will use the PCORnet common data model (CDM), which is the data structure built for all PCORnet networks. The CDM and VDW have similar data structures; sites run a program that extract data from the VDW into the CDM. The PCORnet CDM was being developed concurrently with the PORTAL cohort; thus, we used the VDW for data extraction.

Kaiser Permanente Southern California (KPSC) is the lead site for the cohort and obtained its institutional review board's (IRB) approval for human subjects protections for the research. The IRBs at the other sites reviewed the protocol and subsequently ceded review to the KPSC IRB.

### Weight and Height

Weight is routinely measured as part of obtaining vital signs during outpatient clinic visits. Height is typically assessed less often, as it is considered to be more static. If BMI was not available in the EHR, it was calculated. If more than one weight, height, or BMI was in the EHR in 2012-2013, the most recent value was used. EHR records of heights less than 4 ft or equal to or greater than 8 ft, and weights less than 50 lbs or equal or greater than 1000 lbs were considered implausible and were removed from the data set. Similarly, calculated BMI less than 5 kg/m<sup>2</sup> or equal to or greater than 90 kg/m<sup>2</sup> were excluded. A total of 6954 (0.11%, 6954/6,255,688) individuals were excluded from the cohort because they had no biologically plausible weight, height, or BMI values.

We categorized individuals as healthy weight (BMI 23.0-24.9 kg/m<sup>2</sup>), overweight (25.0-29.9 kg/m<sup>2</sup>), obese class 1 (30.0-34.9 kg/m<sup>2</sup>), obese class 2 (35.0-39.9 kg/m<sup>2</sup>), obese class 3 (40.0-49.9 kg/m<sup>2</sup>), or obese class 4 (>50 kg/m<sup>2</sup>) [4]. We classified Asian/Pacific Islanders in the same manner for this initial analysis.

### Race and Ethnicity

Race and ethnicity was obtained from self-report during enrollment into the health plan, during a health care encounter, or from birth certificates (if applicable). Individuals had the option to identify themselves as Asian, Black or African American, Hispanic, Native Hawaiian or other Pacific Islander, American Indian or Alaskan Native, White, or other. If the information was not available in the VDW or individuals identified themselves as belonging to another race or ethnic group, the individual was categorized as "other/unknown."

### Education and Income

Our health plans do not routinely collect individual-level data on educational attainment or income levels, so investigators rely on neighborhood-level information to estimate socioeconomic status. Neighborhood education and income were estimated using geospatial entity object codes (geocodes) that linked addresses to 2010 US census data at the block group level. The probability of different education levels within a block group was used to calculate individual averages. The probability of different family and household income levels within a block group was used to calculate individual averages.

### Pre-Diabetes and Diabetes

Pre-diabetes was defined by the American Diabetes Association (ADA) and from the work of Schmittiel et al as follows: if during the study period the EHR had (1) at least one HbA1C between 5.7% and 6.4%, or (2) at least one fasting plasma glucose measurement between 100 and 125 mg/dL, or (3) at least one oral glucose tolerance test between 140 and 199 mg/dL,

or (4) at least one outpatient International Classification of Diseases, Ninth Revision (ICD-9) code of 790.2, 790.29, 790.21, or 790.22 [5,6]. These laboratory and diagnoses criteria qualified for pre-diabetes only if they were not superseded by the criteria used to meet the definition of diabetes (see below).

Diabetes was defined using the methodology developed for Surveillance, Prevention, and Management of Diabetes Mellitus (SUPREME DM), a large multi-site observational diabetes study [7]. The definition was adapted from the ADA definition of diabetes [5]. Briefly, the definition included one inpatient diagnosis of diabetes or any combination of two other events (outpatient diagnosis, dispense of an anti-hyperglycemic medication, HbA1C equal or greater than 6.5%, fasting plasma glucose equal or greater than 126 mg/dL or random plasma glucose equal or greater than 200mg/dL).

### Hypertension

Hypertension was considered present if an individual had at least two outpatient or one inpatient ICD-9 codes of 401-405xxx.

### Bariatric Surgery

Individuals who had undergone bariatric surgery were identified by an algorithm developed by Arterburn et al in 2009, which used the Current Procedural Terminology 4 (CPT-4) codes (43842, 43843, 43846, 43847), and ICD-9 codes (CPT-4 codes 43659, 43621, 43633) [8]. Verification of this strategy resulted in sensitivity of 99.2% and specificity of 99.9% [8]. Since additional bariatric procedure codes have been created since 2009, the above algorithm was adapted by adding the following codes: 43.82, 43.89, 44.31, 44.38, 44.39, 44.68, 44.69, 44.95, 43633, 43644, 43645, 43770, 43775, 43844, 43845, S2082, S2085. The algorithm was used to search EHR records from the years 2009 to 2013 to identify possible cases of bariatric surgery.

### Charlson Index

Presence of comorbid conditions was assessed with a modified Charlson Comorbidity Index [9-11], which used diagnosis codes for 22 health conditions during the two-year period of January 1, 2012 to December 31, 2013 to create a summary score.

### PORTAL Health Survey

A random sample of 675 overweight and obese English or Spanish reading or speaking individuals were selected from each of the seven KP health plans and Denver Health to complete a brief health survey, for a total of 5400 individuals. An equal number of participants were selected from the categories of overweight, obese class 1, and obese class 2 (n=1080 per category). We randomly selected 2160 for those with obese class 3 and greater, as we were concerned that the extremely obese may not choose to complete the survey. The survey took about 10 minutes to complete and included items on general health and well-being, physical activity, eating patterns, sleep patterns, and perceived health care sensitivities surrounding weight status. The survey was mailed to individuals with telephone follow-up for those who did not return the survey. A US \$20 incentive was offered to complete the survey.

**Figure 1.** PORTAL overweight and obesity flow chart to construct the cohort.

**Figure 2.** The number of individuals in each BMI category, all PORTAL sites combined.

## Results

### Cohort

The cohort includes over 5 million adults with a BMI  $>23.0$  kg/m<sup>2</sup>. The cohort flow chart with all sites combined is displayed in [Figure 1](#). We identified over 10 million individuals who had continuous membership in 2012 to 2013. After excluding those who were less than 18 years old ( $n=2,309,558$ ), those who did not have a height and weight recorded ( $n=1,715,657$ ), who were pregnant during 2012-2013 ( $n=181,129$ ), and those with implausible height, weight, or BMI measurements ( $n=6954$ ), a total of 6,218,734 adults remained. We then excluded individuals with a BMI less than 23.0 kg/m<sup>2</sup> ( $n=925,276$ ), leaving a cohort of 5,293,458 individuals. A subgroup of the cohort includes a nested cohort of 3,166,919 members who were also enrolled in one of the health plans in 2009 that can be used for future analyses. Although these individuals were members in 2009 and 2013, they may have had different health plan coverage from 2010 to 2012.

Cohort demographics are displayed in [Multimedia Appendix 1](#). Across all network sites 51.95% (2,750,077/5,293,458) are women and 49.02% (2,594,776/5,293,458) are white, 22.89% (1,211,677/5,293,458) are Hispanic, 10.40% (550,608/5,293,458) are Asian, and 10.83% (573,506/5,293,458) are Black. Even though only 1% (75,489/5,293,458) of the cohort is Native Hawaiian/other Pacific Islanders and less than 1% (28,964/5,293,458) is American Indian/Alaskan Natives, they total 75,489 and 28,964 individuals, respectively. The race and ethnicity distribution and neighborhood education and income at each of the ten sites is consistent with the underlying demographics of each region's population [3-6]. About 2.58%

(136,374/5,293,458) of the cohort is insured through a state-subsidized medical insurance plan (eg, Medicaid); another 22.47% (1,189,209/5,293,458) are Medicare recipients. Most individuals (74.81%, 3,959,913/5,293,458) have private insurance, with employer or self-pay options the most prevalent.

Overall, about 85.03% (5,293,458/6,225,688) of non-pregnant individuals over the age of 18 with valid BMI measures obtained in 2012 to 2013 are members of the cohort ([Figure 1](#)). The cohort by BMI category, both by the numbers of individuals and prevalence of individuals in each category are shown in [Figure 2](#) and [Multimedia Appendix 1](#). The most common category is overweight, which includes 40.40% (2,138,520/5,293,458) of the individuals in the cohort. The cohort has 52,125 (0.98%, 52,125/5,293,458) persons categorized as obese class 4 (BMI  $>50$  kg/m<sup>2</sup>). The distribution of BMI category is remarkably similar across sites; for example, the prevalence of those in the healthy weight category varied from 17.23% (23,935/138,900) to 21.96% (397,683/1,810,899) and in the obese class 2 category ranged from 8.95% (23,837/266,470) to 11.66% (16,195/138,900) across the 8 sites.

Pre-diabetes varied across sites, with an overall cohort prevalence of 29.49% (1,560,940/5,293,458) and a range from 15.30% (21,248/138,900) to 34.45% (39,171/113,699) across the health plans ([Multimedia Appendix 1](#)). Diabetes is prevalent among 14.98% (793,069/5,293,458) of individuals with a range of 12.03% (32,051/266,470) to 20.56% (10,232/49,776), and hypertension is prevalent among 34.33% (1,817,436/5,293,458) of individuals with a range of 31.86% (84,886/266,470) to 39.26% (110,560/281,641) in the cohort. Over 25,000 individuals (0.97%, 25,187/5,293,458) were identified as previously having had bariatric surgery.

**Table 1.** Sociodemographic and BMI categories for those who returned the PORTAL health survey (N=2809) compared with those who did not (N=2591).

	Returned survey, n (%)	Did not return survey, n (%)
Sex		
Female, n=3290	1737 (52.80)	1553 (47.20)
Male, n=2110	1072 (50.81)	1038 (49.19)
Age category		
<20 years, n=80	24 (30.00)	56 (70.00)
20-29 years, n=546	215 (39.38)	331 (60.62)
30-39 years, n=866	347 (40.07)	519 (59.93)
40-49 years, n=1115	539 (48.34)	576 (51.66)
50-59 years, n=1220	680 (55.74)	540 (44.26)
60-69 years, n=1019	638 (62.61)	381 (37.39)
70-79 years, n=442	296 (66.97)	146 (33.03)
>80 years, n=112	70 (62.50)	42 (37.50)
Race/ethnicity		
White, n=2535	1435 (56.61)	1100 (43.39)

Asian, n=304	165 (54.28)	139 (45.72)
Black, n=1144	596 (52.10)	548 (47.90)
Native Hawaiian/other Pacific Islander, n=301	168 (55.81)	133 (44.19)
American Indian/Alaskan Native, n=34	20 (58.82)	14 (41.18)
Other/unknown, n=95	5 (5.26)	90 (94.74)
BMI category		
Overweight (25.0-29.9 kg/m <sup>2</sup> ), n=1080	577 (53.43)	503 (46.57)
Obese class 1 (30.0-34.9 kg/m <sup>2</sup> ), n=1080	566 (52.41)	514 (47.59)
Obese class 2 (35.0-39.9 kg/m <sup>2</sup> ), n=1080	550 (50.93)	530 (49.07)
Obese class 3 (40.0-49.9 kg/m <sup>2</sup> ), n=1811	936 (51.68)	875 (48.32)
Obese class 4 (>50.0 kg/m <sup>2</sup> ), n=349	179 (51.29)	170 (48.71)

## Health Survey

From the sample of 5400 individuals, 2809 surveys were completed, 114 were deemed ineligible (ie, no valid address, deceased), 924 persons refused, and 1553 did not respond to mail or telephone attempts, resulting in a 53.14% response of those eligible. Among those who were selected for the survey, women (52.80%, 1737/2809) were slightly more likely to complete the survey than men (50.81%, 1072/2809), and more older individuals returned the survey, for example 62.61% (638/1019) of those age 60 to 69 years completed the survey compared with 39.38% (215/546) of those age 20 to 29 years (Table 1). Completion by race/ethnicity was 59% (20/34) American Indian/Alaskan, 56.61% (1435/2535) White, 55.81% (168/301) Native Hawaiian/Pacific Islanders, 54.28% (165/304) Asians, 52.10% (596/1144) Black, and 42.55% (420/987) Hispanics. There was virtually no difference in response by BMI category, with responses ranging from 50.93% (550/1080)

to 53.43% (577/1080) across the five categories, or by self-reported education level.

## Discussion

### Principal Findings

The PORTAL overweight and obesity cohort is large and extends across all regions in the United States. Racial and ethnic diversity, as well as socioeconomic diversity, is large and generally representative of the underlying populations of the health plans' service regions [12]. The large sample size is particularly useful to support the study of rare exposures or outcomes. Available clinical information is robust and reflects "real world" information that clinicians and health plans use to document health care rather than research quality data collected at pre-specified study intervals. However, prior studies have shown that BMI information collected in the medical record is valid [13]. The cohort can be examined retrospectively and

prospectively. For example, exposures identified in 2009 in the sub-cohort can be linked to outcomes identified in 2012 to 2013. The variation across regions, across medical practices, and across different types of health plans with variations in coverage can be examined. A large majority of individuals have access to health insurance (public or private); thus, confounding by health care access is reduced for research focused on health disparities.

The prevalence of individuals across BMI categories and hypertension prevalence was fairly similar across health plans. In contrast, pre-diabetes and diabetes prevalence varied to a greater extent than expected based on hypertension prevalence and BMI status variability. This variability may be due to local differences in testing for pre-diabetes and diabetes, which requires blood work while weight and blood pressure are routinely measured at each visit. The ADA recommends testing for pre-diabetes and diabetes for all adults starting at age 45 years or for those who are overweight and who have additional risk factors, including physical inactivity, hypertension, and being from minority race and ethnicities [5]. However, according to National Health and Nutrition Examination Survey (NHANES) data, only about one-half of those eligible have been tested [14]. Additional research is needed to understand the processes that may explain differences in testing for pre-diabetes and diabetes across sites.

Follow-up of the cohort will be through the clinical information available in EHR. The five year retention is expected to be about 60%, but will vary by health care system. For the 3.1 million individuals who were health plan members in 2009 and 2013, clinical data are available with 5 year follow-up. This information includes repeated measures of height, weight, BMI, prevalent and incident diagnoses from inpatient and outpatient encounters, procedures performed, laboratory test results, pharmaceuticals dispensed, and pathology and radiology results.

PCORnet is created to foster collaborative partnerships across networks and institutions and PORTAL investigators adhere to

this principle. The PCORnet CDM (similar to the VDW) has a query function to allow non-PORTAL investigators to inquire about data availability. In general, the information available in the EHR is protected and confidential and remains behind each health plan's firewall. We welcome external collaborations, particularly collaborations that include establishment of research questions, study design decisions, and analysis and interpretation of the data. Current analyses underway include descriptions of cardiometabolic health among cohort members, incidence of outcomes across BMI categories, and survey results.

### Limitations

In some regions, individuals with low socioeconomic status may be underrepresented, although all health plans except one include individuals covered under state-subsidized insurance, and Denver Health's mission is to serve those with limited ability to pay for medical services. There is also marginal underrepresentation of those with high incomes. While a large population, the cohort does not include individuals from all 50 states and, therefore, cannot be considered as fully representative of the United States. Because data are collected as part of clinical care, some data elements may not be research quality and are likely to have errors or misclassifications imbedded in them. The classifications of disease status (eg, hypertension, diabetes status) are based on data available in the VDW and have not been chart-reviewed for their validity. However, the quality of diagnosis codes is relatively high in managed care systems and has been validated for many health conditions [15-17]. The cohort does not include individuals with BMI values less than 23.0 kg/m<sup>2</sup>; therefore we cannot directly compare the cohort to national data sets, such as NHANES.

### Conclusion

The PORTAL overweight and obesity cohort is a rich resource of considerable diversity. It represents the ability of clinical data to be combined across health plans to be available for future epidemiological and comparative effectiveness research.

## Abstract

**Background:** One of the greatest challenges facing health promotion and disease prevention is translating research findings into evidence-based practices (EBP). There is currently a limited research base to inform the design of dissemination action plans, especially within medically underserved communities.

**Objective:** The objective of this paper is to describe an innovative study protocol to disseminate colorectal cancer (CRC) screening guidelines in seven Asian subgroups.

**Methods:** This study integrated a market-oriented Push-Pull-Infrastructure Model, Diffusion of Innovation Theory, and community-based participatory research approach to create a community-centered dissemination framework. Consumer research, through focus groups and community-wide surveys, was centered on the adopters to ensure a multilevel intervention was well designed and effective.

**Results:** Collaboration took place between an academic institution and eight community-based organizations. These groups worked together to conduct thorough consumer research. A sample of 72 Asian Americans participated in 8 focus groups, and differences were noted across ethnic groups. Furthermore, 464 community members participated in an Individual Client Survey. Most participants agreed that early detection of cancer was important (434/464, 93.5%), cancer could happen to anyone (403/464, 86.9%), CRC could be prevented (344/464, 74.1%), and everyone should screen for CRC (389/464, 83.8%). However, 35.8% (166/464) of participants also felt that people were better off not knowing it they had cancer, and 45.5% (211/464) would screen only when they had symptoms. Most participants indicated that they would screen upon their doctor's recommendation, but half reported that they only saw a doctor when they were sick. Data collection currently is underway for a multilevel intervention (community health advisor and social marketing campaign) and will conclude March 2016. We expect that analysis and results will be available by June 2016.

**Conclusions:** This study outlines a complementary role for researchers and community organizations in disseminating EBP, and incorporates social interactions and influences to move individuals from simple awareness to decisions towards positive action.

## Introduction

One of the greatest challenges facing health promotion and disease prevention is translating research findings into evidence-based practices (EBP). Despite significant accomplishments in basic, clinical, and population health research, a wide gap persists between what we know and what we do. Failing to translate knowledge into practice is costly and harmful; it leads to overuse of ineffectual care, underuse of effective care, and errors in execution [1]. In recent years, there has been a growing effort to bridge the knowledge and practice gap, yet there is a limited research base to inform the design of dissemination action plans, resulting in slow and uneven adoption of EBP [2-6]. EBP is essential in health care, since it provides direction and rationale for guiding health behaviors, decision-making, and treatments [7]. Based on marketing and diffusion theories, many researchers agree that a fundamental obstacle to successfully disseminating EBP to a wider audience is the lack of systems and infrastructure to carry out marketing and distribution [8-12]. Marketing and distribution systems bring products and services from development to use through a system of intermediaries [13]. These intermediaries identify potential users, promote the product to them, provide them with easy access to the product through multiple channels, and support the product after purchase [14,15]. Building a successful marketing and distribution system to bring EBP to medically underserved communities has great potential to reduce unnecessary disease burden.

Asian Americans (AAs) are the fastest growing minority group in the United States, and there are approximately 17.3 million AAs nationwide [16]. More than 65% of AAs are foreign-born with greater than 30% having limited English proficiency [17]. AAs are the first and only racial/ethnic group to experience cancer as the leading cause of death [18]. Although colorectal cancer (CRC) is the third most common cancer in the United States, it is the second most common cancer among AAs [19,20]. Disturbingly, 50% of new cases diagnosed yearly in the United States could have been avoided with routine CRC screening [21,22]. Although there was a significant increase in CRC screening in the overall US population between 2008 and 2010, AAs remained the only racial/ethnic subgroup without any improvement [23]. In addition, important differences exist in knowledge, attitudes, and beliefs among Asian subgroups [24]. In this project, we aim to develop a community-centered dissemination system for EBP in Asian communities.

## Methods

### Conceptual Framework

We integrated a market-oriented Push-Pull-Infrastructure Model [25] with Diffusion of Innovations Theory [26], and Community-Based Participatory Research (CBPR) approach to create a community-centered EBP dissemination framework (Figure 1). The Push-Pull-Infrastructure Model implies that a sole emphasis on pushing (supplying) knowledge from science is ineffective. The supply of knowledge must be accompanied by both an increase pull (demand) for innovations and an increase in capacity of the infrastructure to deliver the innovations [11]. To date, most efforts in dissemination research have focused mainly on disseminating innovations, with little emphasis on increasing demand among potential users [27]. Consumers' preexisting dispositions, preferences, perceptions, capacities, and behaviors determine their response to the innovation and shape their decision-making processes [9]. Partnering with the community is a critical component to translate research into a wider population practice [28-30], and community involvement may enhance the translation and dissemination process [31-34]. In this new model, we use a CBPR approach to bridge the gap between research and practice, as well as academia and community. A successful market depends on the availability of information about the available products and the ability of individuals to access that information, and it can be achieved by using multiple formal and informal media, including newspapers and websites [26]. However, this one-way communication, even if it is repeated through multiple channels, is typically insufficient to move an individual toward a positive action. Persuasion through a two-way communication of social influence has proven more effective [35]. In this project, we used community health advisors (CHAs) who were familiar with the culture, language, and local community, to spread information and generate demand from community members. A social norm marketing campaign in the form of small media, which was found to be effective in promoting CRC screening [36], was conducted to build public awareness and generate demand. This project was approved by the University of Chicago Institutional Review Board (IRB: 052689-0). All procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation, and with the Helsinki Declaration of 1975.

**Figure 1.** A community-centered dissemination framework for evidence-based practice.

### Creating a Research-Community Dissemination Infrastructure

We invited six Asian-American community-based organizations (CBOs) to join our EBP dissemination community task force during year one. These six CBOs provide direct services to five Asian subgroups (Cambodian, Chinese, Korean, Laotian, and Vietnamese). In Year two, we invited two additional CBOs that serve Filipinos and Southern Asians. Recognizing that the complexity in translating lessons learned from science into practice required a multilevel approach, we also assembled an academic EBP steering committee to accelerate the integration. The academic EBP steering committee consisted of seven different internal departments from the academic institution. Our EBP dissemination community task force and academic EBP steering committee met periodically, separately and jointly, to communicate project progress and disseminate study findings.

### Assessing Community Partners' Capacity and Readiness for Evidence-Based Practice Dissemination

The adoption of EBP depends on the capacity of CBOs to implement and sustain particular activities. An initial assessment of each CBO's capacity, based on the strength of its leadership, existing programs and outreach, strategic plan, financial stability, and support staff, was important for the implementation

of dissemination-related activities. Assessments were completed via a paper-and-pencil survey. Not all items contributed equally to the implementation process, so the research team used a Delphi method to develop a score system to consider the significance of each item. The Delphi expert panel included three academic experts and two community experts. The research team also developed an EBP readiness survey based on literature review and expert inputs. The EBP readiness survey assessed the stage of our CBO partners along a continuum of readiness. The 7-item EBP readiness survey measured four domains related to the readiness to adopt EBP. These four domains were (1) a defined need for EBP, (2) readiness for change in organizational culture, (3) time, resources, and personnel for EBP, and (4) ability to sustain the change. Under each item, CBO partners chose the stage statement that described their current state of readiness for EBP. Findings from the organizational capacity assessment and EBP readiness survey were used to inform the dissemination process and capacity building.

### Conducting Consumer Research

Although evidence-based CRC screening guidelines have been widely communicated through mainstream media channels, these messages likely have limited reach among AAs because dissemination methods and content are not culturally sensitive

or language-specific. Consumer research is one of the significant components of the Market-Orientated Push and Pull Model. Consumer research allows researchers to listen to their consumers to ensure that marketing strategies are well designed, well implemented, and effective by centering the product on their consumers, keeping the product relevant, and understanding which of the product's *constellation of benefits* to prioritize. In this project, we used a two-step approach to conduct consumer research in our partner communities.

First, we conducted 8 focus groups with a total of 72 participants from 7 Asian subgroups (Cambodian, Chinese, Filipino, Korean, Laotian, South Asian, and Vietnamese) to elicit beliefs and attitudes related to CRC screening. These focus groups were facilitated by bilingual, bicultural CBO staff members, who participated in a 4-hour training session to enhance their facilitation skills. A focus group guide was developed to ensure consistency across groups. Eligibility criteria for the focus group required that participants were (1) between age 40 and 65, (2) lived in different households, and (3) were capable of giving consent. The focus groups were conducted in participants' native language and tape recorded. The tape recordings were then translated into English by the facilitator. A team of five people

worked together to perform content analysis, using template analysis method based on the Theory of Planned Behavior Model.

Secondly, findings from the focus groups were used to develop an Individual Client Survey. The goal of the Individual Client Survey was to determine behavioral beliefs, normative beliefs, and perceived control beliefs regarding CRC screening within the target population. The development of the Individual Client Survey included (1) developing a pool of survey statements ( $n=91$ ) from the focus group findings, (2) soliciting feedback from CBO partners ( $n=11$ ) regarding relevance and cultural appropriateness, and (3) weighting the statements for their relevance and significance. The final survey instrument contained 20 statements and was approved by all community partners. Besides the English version, the final survey instrument was translated into six different languages. The survey used a cross-sectional design with a purposeful (based on age group and sex) and convenient sample. A total of 470 surveys were collected from 7 different Asian communities (Table 1). Findings from the Individual Client Survey were then used to design a dissemination plan, train community health advisors, and develop a social marketing campaign.

<sup>a</sup>Two Korean community based organizations participated in the Individual Client Survey.

## Generating Public Awareness Through Social Marketing and Social Influence.

In this project, we used consumer-centered social marketing. Consumer-centered social marketing goes beyond pushing the product to the consumer by building demand for the product. The marketing campaign aimed to address sociocultural norms as well as linguistic barriers regarding CRC screening. Although social marketing campaigns can create public awareness, which is the first step toward taking action, information alone is not enough to prompt interest, shape attitudes, and bring about behavior change. Ultimately, the goal of dissemination is not to simply get the word out, but to take the user from awareness to understanding, to commitment, and then to action. We used CHAs as an influencer, each of whom was a bilingual, bicultural community health professional who understood the social norms of the community. To build on these strengths, and to equip them to carry out this work, all CHAs attended a 6-hour training on CRC screening, motivational interviewing techniques, and the application of Stage of Change Theory.

## Investigating the Effectiveness of Community Health Advisor Intervention in Conjunction with Social Marketing

We will use a multiple baseline design to evaluate the effectiveness of our CHA intervention. If every group shows a similar change after crossing to the intervention condition and does not change at other times, the findings will provide compelling evidence that the changes resulted from the intervention [37]. In addition, multiple baseline design guards the internal validity of the study by ruling out the possibility that a single external event (eg, a celebrity cancer diagnosis) could explain the results. In this project, each community will experience a transition from the baseline condition to the intervention condition, but these transitions will be observed over different time periods. The study procedure is outlined as follows:

A baseline CRC screening education session will be conducted in each community prior to the rollout of the CHA intervention and social marketing campaign.

Partner CBOs will be asked to post event flyers as usual, but to refrain from active recruitment.

Participants at each educational session will be asked to fill out a survey, which includes demographic items and beliefs statements selected from the Individual Client Survey.

Partner CBOs will be divided into two cohorts: cohort 1 (Chinese, Filipino, and Laotian) and cohort 2 (Cambodian, Korean, South Asian, and Vietnamese).

Depending on the cohort assignment, partner CBOs will be asked to implement the CHA intervention and social marketing campaign, or do nothing.

The CHA intervention will be a 12-week long intervention and will be carried out concurrently with the social marketing campaign.

At the end of each intervention period, an educational session will be conducted in each community, and no-cost Fecal Immunochemical Test (FIT) kits will be offered to participants.

Participants who took home a FIT kit will have two weeks to return the kit for testing.

The primary outcomes will be the number of participants in each education session, the number of no-cost FIT kits distributed after the education session, and the number of FIT kits returned. Other secondary outcomes will include beliefs and attitudes in CRC screening and intention to screen within the next 12 months. Beliefs and attitudes regarding CRC screening will be measured using items selected from the Individual Client Survey. Participants will also be asked whether they spoke with the CHA prior to the session. The unit of analysis will be cohort ( $n=2$ ). Statistical tests will be carried out to assess post-intervention differences within and between cohorts, as well as over time.

### **Evaluating the Implementation Process and Translatability Using the RE-AIM Framework.**

Glasgow and associates (1999) designed an evaluation framework to assess the impact of interventions based on five factors: *Reach*, *Efficacy*, *Adoption*, *Implementation*, and *Maintenance* (RE-AIM [38]). This framework expands the assessment of interventions beyond efficacy to multiple criteria that are better able to identify the translatability and public health impact of interventions. In this project, the evaluation will focus on organization level measurements and include both qualitative and quantitative data. Quantitative data will be collected through weekly CHA reports. Each CHA will be required to maintain a daily activity log and to submit weekly reports including number of individuals educated, number of group education sessions ( $>5$  participants) conducted, number of printed materials distributed, and number of follow-up encounters. Qualitative data will also be collected during site visits at week 3, week 7, and week 10. This data will include, but are not limited to, compliance to the intervention protocol, barriers, facilitators, and concerns. Post-intervention focus groups with implementation CHAs will be conducted to obtain feedback regarding the implementation process and experience. In-depth interviews with partner CBO leadership will also be

conducted to assess the CBPR process, satisfaction with the project, and sustainability of the dissemination infrastructure.

## **Results**

### **Assessing Community Partners' Capacity and Readiness for EBP Dissemination**

Of the seven partner CBOs, only one CBO had an organization capacity weighted score above the 70<sup>th</sup> percentile, and two CBOs had a weighted score below the 50<sup>th</sup> percentile. Of the four stages of readiness for EBP dissemination (stage 1 = there is no agenda or promotion for EBP in the organization; stage 4 = totally ready for EBP dissemination), two CBOs were at stage 3, two were between stage 2 and 3, and three were at stage 2. In general, there was some understanding of the needs for EBP, but there was a lack of mechanism in the organization to move EBP forward. Although three of the CBOs included EBPs in their organizational agenda and were specially discussed, they had not yet been promoted by leadership.

### **Consumer Research**

A convenience sample of 72 AAs participated in 8 focus groups. Most of the participants were female (47/72, 65%), and average age was 55 years. All participants were born outside of the United States, and 20 of 72 (28%) had been in the United States 10 years or less. Although differences were noted across ethnic groups, many respondents were unaware of CRC risk, screening benefits, or screening access. Many respondents attributed CRC to pollution in their home countries, stress of immigrant life, or diet. Respondents from countries with more advanced healthcare systems, such as Korea, were more knowledgeable of screening options.

A total of 470 participants completed the Individual Client Survey from 7 Asian subgroups, with 464 surveys entered for final statistical analysis. Most participants (457/464, 98.5%) were foreign-born, and 222 of 464 (47.8%) had lived in the United States more than 20 years. The average age was 56 years, and 146 of 464 respondents had completed less than 9 years of education. Most participants agreed that early detection of cancer was important (434/464, 93.5%), cancer could happen to anyone (403/464, 86.9%), CRC could be prevented (344/464, 74.1%), and everyone should screen for CRC (389/464, 83.8%). However, 35.8% (166/464) of participants also felt that people were better off not knowing if they had cancer, and 45.5% (211/464) would screen only when they had symptoms. Most participants (402/464, 86.6%) said that they would screen upon their doctor's recommendation, but approximately half of the participants (231/464, 49.8%) reported that they only saw a doctor when they were sick.

Currently, we are conducting our social marketing campaign and implementing the CHA intervention. Data collection is underway and will conclude March 2016. We expect that analysis and results will be available by June 2016.

## **Discussion**

There is a limited research base to inform the design of successful action plans for dissemination and implementation

EBP, especially in underserved and marginalized populations. Little attention has been paid to contextual factors, as well as what the users really need and want during the dissemination process. Users' preexisting dispositions, preferences, perceptions, and capacities impact individual decision-making processes. Although several conceptual frameworks have been developed, and are useful for generating hypotheses for future research [11,39,40], we urgently need practical frameworks for developing and testing dissemination approaches. A multi-level approach is needed to accelerate integration of lessons learned from science into community health care. The combination effect of a multilevel intervention may have a synergistic effect greater than the sum of the individual parts of the intervention. Such synergy can occur when a set of necessary conditions must be jointly present for change to take place, or when an intervention at one level facilitates or reinforces an intervention at another [41]. This project targeted three different levels

(community, interpersonal, and individual) to accelerate the adoption of CRC screening guidelines. Our community-centered Dissemination and Implementation Model provides a systematic approach that is feasible to implement in real-life settings, even within resource-restricted communities. The model also outlines a complementary role for researchers and community organizations in disseminating EBP. Our focus on partnerships and understanding potential adopters has the potential to produce wanted and sustainable innovations. Finally, our model incorporates social interactions and influences to move individuals from simple awareness, to decisions, and then to positive action. By triggering a demand for evidence-based innovations, we can increase the success of our dissemination efforts and the adoption of EBP among the underserved and vulnerable populations most in need of effective, evidence-based practice.

## Acknowledgments

This material is the result of work supported by the Agency for Healthcare Research and Quality (AHRQ: 1R24HS022063-01) and the Chicago Community Trust and Retirement Research Foundation. We thank our community partners (Alliance of Filipinos for Immigrant Rights and Empowerment, Cambodian Association of Illinois, Chinese American Service League, Hanul Family Alliance, Korean American Community Services, Lao American Organization of Elgin, Muslim Women Resource Center and Chinese Mutual Aid Association) for their cooperation and feedback in developing survey instruments, their recruitment of participants, and their assistance with the CHA intervention. We thank all project participants for their time and sharing personal information about their health and well-being.

## Authors' Contributions

KK acted as the principal investigator, conceptualized and secured funding for the study, and materially edited the manuscript. She was also responsible for overseeing all aspects of the study. MQ acted as co-investigator, had the principal responsibility for survey development and data analysis, conceptualized, materially edited the manuscript, and had the principal responsibility for the project evaluation. EC acted as the community co-investigator, conceptualized, secured private funding for the study, and assisted data collection. RP coordinated project activities, and was responsible for data collection and communication with partner organizations. HL had the principal responsibility for the preparation and editing of the manuscript, conceptualized, had the principal responsibility for the study coordination and data management, and was responsible for survey development and data analysis.

## Abstract

**Background:** Experience and development of pain may be influenced by a number of physiological, psychological, and psychosocial factors. In a previous study we found differences in neuronal activation to noxious stimulation, and microstructural neuroanatomical differences, when comparing healthy volunteers with differences in size of the area of secondary hyperalgesia following a standardized burn injury.

**Objective:** We aim to investigate the degree of association between the volume of pain-relevant structures in the brain and the size of the area of secondary hyperalgesia following brief thermal sensitization.

**Methods:** The study consists of one experimental day, in which whole-brain magnetic resonance imaging (MRI) scans will be conducted including T1-weighted three-dimensional anatomy scan, diffusion tensor imaging, and resting state functional MRI. Before the experimental day, all included participants will undergo experimental pain testing in a parallel study (Clinicaltrials.gov Identifier: NCT02527395). Results from this experimental pain testing, as well as the size of the area of secondary hyperalgesia from the included participants, will be extracted from this parallel study.

**Results:** The association between the volume of pain-relevant structures in the brain and the area of secondary hyperalgesia will be investigated by linear regression of the estimated best linear unbiased predictors on the individual volumes of the pain relevant brain structures.

**Conclusions:** We plan to investigate the association between experimental pain testing parameters and the volume, connectivity, and resting state activity of pain-relevant structures in the brain. These results may improve our knowledge of the mechanisms responsible for the development of acute and chronic pain.

## Introduction

The experience and development of pain may be influenced by a number of physiological, psychological, and psychosocial factors. However, our knowledge of the mechanisms responsible for acute and chronic pain is still not complete. A standardized burn injury in the skin provokes reversible primary and secondary hyperalgesia in healthy volunteers. Injury-induced primary hyperalgesia is located in the traumatized area and is characterized by reduced thresholds for thermal and mechanical stimulation. Secondary hyperalgesia is located around the traumatized area, and is characterized by reduced thresholds for mechanical stimulation [1,2].

Previous studies have demonstrated that secondary hyperalgesia to punctate mechanical stimuli is a result of changes in the central nervous system, in part due to sensitization in response to nerve signals by A-fiber nociceptors [1,3-5]. Secondary hyperalgesia can be provoked by a number of different conditioning stimuli, and according to previous studies this is a robust phenomenon that can be applied to investigate basic pain physiology [2,6,7]. Central neuronal sensitization is presumed to play an important role in a number of different pain conditions, such as osteoarthritis, fibromyalgia, and postoperative pain [3].

To investigate the basic physiological mechanisms of pain, our research group has worked extensively with experimental physiological pain models [8-10]. In previous studies, we found indications of large inter-individual variations in the size of the area of secondary hyperalgesia following identical experimental pain stimulation. Moreover, we observed that the area of secondary hyperalgesia may be an identifiable phenotypic indicator and predictor of individual pain responses [10,11].

To further explore the pathophysiology of central sensitization, we first investigated functional changes in the brain by magnetic resonance imaging (MRI) after induction of secondary hyperalgesia by a first degree burn injury. The first degree burn injury was induced 100 minutes before initiation of MRI, and interestingly we found differences in neuronal activation to noxious stimulation in healthy volunteers that developed either large or small areas of secondary hyperalgesia. These findings suggest differences in central pain processing related to phenotypical expression of secondary hyperalgesia. Furthermore, we found indications of differences in the volumes of the caudate nuclei, as well as other microstructural neuroanatomical differences between the two groups [11], encouraging further studies with larger sample sizes to elucidate the importance of each finding in the pathophysiology of pain and central sensitization.

The basal ganglia have proved to be essential in the pain processing in humans [12-14]. Moreover, the role of the caudate nuclei in the processing and modulation of pain have been investigated in human [12-27] as well as animal [28-39] studies.

The caudate nuclei are believed to play a role in integration and control of sensory, motor, and motivational information, and thus essential in coordinating behavioral responses [14]. The caudate nuclei have also been demonstrated to be involved in the sensory processing and spatial location of noxious stimuli [24], in the suppression and modulation of pain [26], and are activated during pain expectancy [40].

Reduced grey matter volume of the caudate nuclei has been demonstrated in patients with trigeminal neuralgia [20], knee osteoarthritis [22], lumbar disc herniation [21], and migraines [15,27]. Moreover, reduced regional cerebral blood flow in the caudate nuclei has been seen in patients with fibromyalgia [23], familial restless legs syndrome [25], and chronic fatigue syndrome [16]. Thus, the caudate nuclei are essential sites of pain processing, and may play a role in the development of secondary hyperalgesia, and consequently in the processes involved with central sensitization.

A recent study confirmed that areas of secondary hyperalgesia have a low intra-individual variation compared to the inter-individual variation [41]. This finding enables us to phenotype healthy volunteers based on the size of the area of secondary hyperalgesia. It remains uncertain whether these phenotypes are related to other pain syndromes or entities, are involved in the risk of developing chronic pain, or influence factors in the individual's pain sensitivity. Likewise, it is unclear if important structures such as the caudate nuclei (or other CNS differences) are closely related to secondary hyperalgesia phenotyping, warranting more research in this area.

With this study we aim to investigate the association between the volume of pre-defined pain-relevant structures in the brain and the size of the areas of secondary hyperalgesia.

## Methods

### Study Design

This study is a confirmatory study designed to investigate the association between the size of the area of secondary hyperalgesia following brief thermal sensitization (BTS; see *Clinical Evaluations*) and the volume of the caudate nuclei in healthy volunteers. On the experimental day, a whole brain MRI scan will be conducted including T1-weighted three-dimensional (3D) anatomy scan, diffusion tensor imaging, and resting-state functional MRI (rs-fMRI), in consecutive sequence (see *Clinical Evaluations*). No other tests or assessments will be performed on the experimental day. The total duration of the experimental day is approximately 50 minutes.

Before the experimental day, all included participants will undergo pain testing in a parallel study (Clinicaltrials.gov Identifier: NCT02527395). Results from the pain testing, as well as the size of the area of secondary hyperalgesia from the included participants, will be extracted from this parallel study. The experimental day will be conducted at a maximum of 2

months and a minimum of 2 weeks after the completion of the BTS and additional pain testing.

## Setting

The MRI scans will be conducted at the Department of Radiology, Bispebjerg and Frederiksberg Hospitals, Copenhagen, Denmark. The data analysis will be conducted at the Department of Anesthesiology, Centre of Head and Orthopedics, Rigshospitalet, Copenhagen, Denmark.

**Table 1.** Inclusion, and exclusion criteria.

Inclusion criteria	Exclusion criteria
Age $\geq 18$ years and $\leq 35$ years	Study participants who cannot cooperate to the test
Male sex	Study participants with a substance abuse, assessed by the investigator
Study participants who have a weekly intake of $>21$ units of alcohol, or a have consumed $>3$ units of alcohol within 24 hours before experimental day	Study participants who have consumed analgesics within 3 days before experimental day
Speak and understand the Danish language	Study participants who have consumed antihistamines within 48 hours before experimental day
Signed informed consent	Study participants who have consumed antidepressant medication within 30 days before the study
Have participated and completed the study: “To determine the degree of association between Heat Pain Detection Threshold and area of secondary hyperalgesia following Brief Thermal Sensitization in healthy male volunteers” (Clinicaltrials.gov Identifier: NCT02527395)	Study participants who have consumed prescription medicine within 30 days before the study
	Study participants with neurological illnesses
	Study participants with chronic pain
	Study participants with psychiatric diagnoses
	Study participants with eczema, wounds, or sunburns on the sites of stimulation
	Study participants with a Body Mass Index of $>30$ kg/m <sup>2</sup> or $<18$ kg/m <sup>2</sup>
	Study participants with contraindications to MRI <sup>a</sup>
	Study participants that decline information regarding potential pathological findings in relation to the MRI
	Study participants that have any kind of trauma resulting in pain and administration of analgesics in the period between experimental pain testing and MRI scan
	Study participants that experience a head trauma in the period between the experimental pain testing and the MRI scan

<sup>a</sup>Contraindications to MRI includes: claustrophobia, pacemaker implant, artificial heart valve, cochlear/stapes prosthetics, irremovable insulin pump, neurostimulator, metal clips from previous surgical procedures, other metallic foreign objects, shrapnel or shell splinter, catheters (eg, Swan Ganz), shunts and drainage tubes, and surgical procedures within 6 weeks before the study (subjected to individual evaluation).

Before the experimental day, each participant will be tested with the experimental pain models: BTS, heat pain detection threshold (HPDT), and pain during 1 minute of thermal stimulation of the skin (p-TS), as well as two psychological tests: Pain Catastrophizing Scale (PCS) and Hospital Anxiety and Depression Score (HADS; see [Multimedia Appendix 1](#) and Clinicaltrials.gov identifier: NCT02527395). The results will be blinded to the investigator evaluating the MRI scans. Prior to, as well as on the experimental day, the investigator will interview all participants, and those that have one or more psychiatric or neurological diagnoses or illnesses will be excluded. All participants with prior history of psychiatric or neurological illness will also be excluded.

## Study Participants

Healthy male volunteers will be included in the study. The study participants will receive information regarding possible risks and side effects, and will be provided with written and oral information concerning the study. The participants will receive €67 (US \$74) for their participation in the study. Inclusion and exclusion criteria are presented in [Table 1](#).

## Clinical Evaluations

### Pain Testing

BTS, HPDT and p-TS are not performed as a part of this study per se, but all participants in the present study have been tested using these methods in a parallel non-imaging study (Clinicaltrials.gov Identifier: NCT02527395). Data concerning secondary hyperalgesia from this concurrent study will be extrapolated and included in the present study. The BTS method is briefly explained below. For further details, please refer to [Multimedia Appendix 1](#).

### Brief Thermal Sensitization

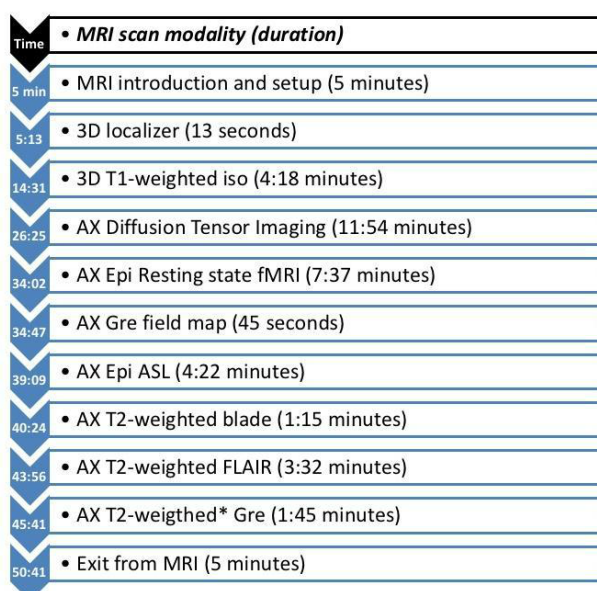

A computer-controlled thermode (Somedic MSA Thermotester; size 2.5 x 5 cm) is placed on the participant's skin, centrally on the anterior part of the right thigh. The initial temperature of

the thermode is 32°C, and the temperature is increased 1°C/second until it reaches 45°C. The temperature of the thermode remains a constant 45°C for 3 minutes, and while the thermode still has contact with the skin, the assessment of secondary hyperalgesia is conducted. The assessment of secondary hyperalgesia takes approximately 1-2 minutes, with a maximum duration of heat stimulation of 5 minutes.

### Assessment of Secondary Hyperalgesia

The area of secondary hyperalgesia is quantified after stimulation with a 19G monofilament (von Frey hair) in 4 linear paths arranged in 90° around the center of stimulation. Stimulation will begin 15 cm from the center of stimulation and advance in steps of 5 mm with 1 second intervals towards the center of stimulation. When the participant states a clear change in sensation (ie, intense pricking, burning, tenderness) the place will be marked with a felt pen and the transverse and longitudinal axes will be measured for later area calculation.

**Figure 1.** Schematic presentation of experimental day. Abbreviations: MRI, Magnetic Resonance Imaging; fMRI, Functional Magnetic Resonance Imaging.

### Diffusion Tensor Imaging

Diffusion tensor imaging (DTI) is sensitive to the diffusion of water molecules. The net-diffusion of water molecules roughly occurs along the direction of the axons; hence, DTI can be utilized to perform white matter tractography (neuronal connections of the brain), or to detect changes in the white matter by using Tract-Based Spatial Statistics.

### Resting State Imaging

In rs-fMRI the intrinsic connectivity networks of the brain are mapped by indirectly measuring so-called *spontaneous brain activity*. Rs-fMRI measures spontaneous changes in blood-oxygenation-level-dependent signal by detecting concomitant changes in magnetization that accompanies regional changes in brain blood flow.

### MRI Scans

The MRI scans will be performed with a Siemens MAGNETOM Verio 3-tesla, with b17 software, and a 32-channel head coil. The specific MRI sequence and settings are detailed in [Multimedia Appendix 2](#).

### Anatomical MRI Scans

T1-weighted images are recorded in order to construct detailed anatomical images of the brain. These images will be used to perform morphometry/volumetric analysis of cortical and subcortical structures in order to determine possible differences in the study population. To look for potentially confounding structural lesions and perfusion asymmetry, T2-weighted, T2-FLAIR, diffusion weighted imaging, gradient echo, and arterial spin labeling will also be performed as part of the imaging protocol ([Figure 1](#)).

### Other Scans

As a supplement to the previously mentioned MRI scans, it is necessary to perform a number of technical MRI scans as well (ie, B0 field maps). These supplementary scans are necessary and important for later data analyses, and will not result in any further discomfort for the participants. For schematic presentation of the general procedure and the MRI scan sequence on the experimental day, please refer to [Figure 1](#).

Participants will be informed that they must stay awake during the MRI scan period, and if they fall asleep they are obliged to inform the investigator. Participants that fall asleep during the MRI scan period will be excluded from the study.

### Outcomes

#### Primary Outcome

We aim to investigate the association between the volume of the left and right caudate nuclei and the size of the area of secondary hyperalgesia induced by brief thermal sensitization.

The association will be expressed in adjusted and non-adjusted  $R^2$  and prediction intervals for the area of secondary hyperalgesia, given fixed values of the caudate nucleus' volume.

### Secondary Outcomes

We aim to investigate the association between cortical and subcortical brain areas relevant for pain processing and the area of secondary hyperalgesia (primary somatosensory cortex, anterior- and mid-cingulate cortex, basal ganglia [putamen, accumbens nucleus, and globus pallidus], insula, and the cerebellum [12,42]). We will also use diffusion tensor imaging to investigate the association between the area of secondary hyperalgesia and white matter microstructure using tract based spatial statistics (TBSS) [43], and determine the connections between the pain-related areas, as specified previously using white-matter tractography.

### Exploratory Outcomes

We will investigate the association between the volume of the left and right caudate nuclei and the following six parameters: (1) HPDT score, (2) p-TS max, (3) p-TS visual analog scale-area under the curve (VAS-AUC), and (4) the score of PCS-total, PCS-subscores, HADS-total, and HADS-subscores. When comparing healthy volunteers with a large (upper quartile) versus small (lower quartile) area of secondary hyperalgesia following BTS, we plan to investigate (5a) structural differences (volume) and the association with the size of the area of secondary hyperalgesia, (5b) differences in the association between area of secondary hyperalgesia and regions of interest extracted from TBSS, and (5c) differences in white matter microstructure in connections between pre specified pain related areas by white-matter tractography. In addition, we will examine (6) differences in resting state networks measured by rs-fMRI using independent component analysis (ICA; dual regression method).

### Hypothesis

The area of secondary hyperalgesia and the volume of the caudate nuclei are associated, with an inverse correlation (ie, a large area of secondary hyperalgesia is associated with a small volume of the caudate nuclei).

### Sample Size Estimation

Based on results from a previous study [11], sample size calculations are based on a Z-test of the Fisher transformed Pearson correlation. With a true correlation of  $r=-0.4$  between the area of secondary hyperalgesia and the caudate nuclei, and a significance level of 2.5% to 5% according to the single step method (refer to *Statistical Significance*), a sample size of 52 is needed to obtain a power of 0.80 ( $\beta=0.20$ ).

### Data Analysis Plan

#### T1-Weighted 3D Anatomical Images

Anatomical images will be pre-processed using the FreeSurfer imaging analysis suite version 5.3. FreeSurfer is a semi-automatic software package that performs volumetric segmentation of cortical and subcortical structures [44-46]. All volumes will be adjusted for total intracranial volume, and will result in volume estimates ( $\text{mm}^3$ ). This analysis is performed

to avoid possible confounding results due to differential head-size between participants. The size of the area of secondary hyperalgesia will be blinded until completion of the T1-weighted 3D anatomical image analyses.

#### Diffusion Tensor Imaging

Diffusion-weighted images will be pre-processed using the Functional Magnetic Resonance Imaging Brain Software Library (FSL) software package version 5.0. This analysis includes corrections of potential head movement and inspection of image quality. The resulting data will then be processed via dtifit and tract-based spatial statistic. The re-aligned images will then be fed into bedpostx for local modelling of diffusion parameters. Using bedpostx in conjunction with TBSS allows for the modelling of crossing fibers. The re-aligned images will be fed into probtrackx2 for tractography between the anatomical areas mentioned above.

#### Resting-State Functional Magnetic Resonance Imaging

Rs-fMRI scans will be analyzed using FSL MELODIC. Pre-processing steps will include spatial smoothing, motion correction, high pass filtering, and brain extraction. In the pre-processing steps we will apply ICA using predefined (no less than 60) ICA's without automatic dimension detection. Rs-fMRI scans will be co-registered initially to the individual T1-weighted 3D anatomical scans (after neutral flipping and brain extraction), and subsequently to the Montreal Neurological Institute (MNI)-152 brain atlas using non-linear registration. A full quality assurance will be performed consisting of inspection of head movement ( $<3$  mm and  $<3$  degrees), acceptable co-registration, and inspection of image quality.

Rs-fMRI data will be analysed using a model-free ICA and the dual regression method, as described by Abou-Elseoud et al [47], to determine differences in network connectivities with the whole brain. Standard, published brain networks in healthy participants will be used to identify the different networks using publicly available datasets from the Oxford FSL Group publication [48]. Once we have run an ICA analysis, the resulting components will be spatially cross-correlated with Oxford's templates to identify those that better match the canonical networks described in the Oxford FSL Group publication [48].

Noise reduction will be performed manually. Randomized command with 10.000 random computations will be performed with a design matrix consisting of the unpaired t-tests (predefined high responders vs. low responders, and repeated with area of secondary hyperalgesia as co-variate). Results will be displayed upon the MNI-152 normal brain atlas after dimension change as  $P<0.05$  after correction for multiple comparisons. Activated areas will be identified semi-automatically.

### Statistical Analyses

#### Statistical Analysis of Primary Outcome

The estimates of the volumes, from the T1-weighted 3D anatomical scans of the caudate nuclei ( $\text{mm}^3$ ), will be exported to a spreadsheet for regression analysis to assess the association between volume of caudate nuclei and secondary hyperalgesia

areas. The association of the volume of the left and right caudate nuclei and the area of secondary hyperalgesia will be investigated by linear regression of the estimated best linear unbiased predictors (EBLUPS) on the individual volumes of the left and right caudate nuclei. The ability of the volume of caudate nuclei to predict individual variation in the area of secondary hyperalgesia will be investigated by linear regression on the EBLUPS as a function of the individual volumes of the caudate nuclei.

Significance of the caudate nuclei as a predictor will be assessed by analysis of variance (ANOVA) methods and the predictive ability will be quantified by summary of prediction error, including 95% prediction interval for the prediction of the size of the area of secondary hyperalgesia. Relevant examples will be presented illustrating how accurately the volume of the caudate nuclei predicts the area of secondary hyperalgesia in the individual participants or vice versa. The association will be expressed in  $R^2$  and prediction intervals for the area of secondary hyperalgesia given fixed values of the caudate nucleus' volume. All analyses of structural MRI data (both in the primary, secondary, and exploratory outcomes) will be adjusted for age.

### ***Statistical Analysis of Secondary Outcome #1***

From the T1-weighted 3D anatomical scans, volume estimates of the cortical and subcortical brain areas relevant for pain processing ( $\text{mm}^2$ ,  $\text{mm}^3$ ) will be exported to a spreadsheet for regression analysis to assess the association between volume of the relevant areas for pain processing and areas of secondary hyperalgesia. The association of the volume of areas relevant for pain processing and the area of secondary hyperalgesia will be investigated by linear regression of the EBLUPS in relation to the volumes of individual areas relevant for pain processing. The association will be expressed in  $R^2$  and prediction intervals for the area of secondary hyperalgesia given fixed values of the volume of the relevant brain areas for pain processing.

Significance of the predictor will be assessed by ANOVA methods and in cases of significance the predictive ability will be quantified by summary of prediction error, including 95% prediction interval. Relevant examples will be presented illustrating how accurately the volume of the individual areas relevant for pain processing predicts the area of secondary hyperalgesia in individual participants, or vice versa. The association will be expressed in  $R^2$  and prediction intervals for the area of secondary hyperalgesia given fixed values of the caudate nucleus' volume.

### ***Statistical Analysis of Secondary Outcome #2***

The exact values of white matter structure expressed as the diffusion coefficient (Fractional Anisotropy value) of the relevant pain related areas will be extracted, and separate statistical analyses will be performed. To test the association between the white matter microstructure extracted following analysis using TBSS/DTI and the area of secondary hyperalgesia, individual measures computed from the TBSS and DTI will be investigated by linear regression.

### ***Statistical Analysis of Exploratory Associations #1-4***

From the T1-weighted 3D anatomical scans, volume estimates of the caudate nuclei ( $\text{mm}^3$ ) will be exported to a spreadsheet for regression analysis to assess the association between volume of caudate nucleus and the score of HPDT, p-TS-max, p-TS VAS-AUC, PCS, and HADS respectively. The association of the volume of the right and left caudate nucleus and HPDT, p-TS-max, p-TS VAS-AUC, PCS and HADS will be investigated by linear regression of the EBLUPS in relation to the volume of caudate nucleus.

Significance of the ability of the caudate nucleus' volume as a predictor will be assessed by ANOVA methods. The ability of the caudate nucleus' volume to predict individual variations in HPDT, p-TS-max, p-TS VAS-AUC, PCS, and HADS will be investigated by linear regression on the EBLUPS of the individual volumes of the caudate nucleus. Significance of the caudate nucleus as a predictor will be assessed by ANOVA methods and in case of significance, the predictive ability will be quantified by summary of prediction error, including 95% prediction interval. Relevant examples will be presented illustrating how accurately the volume of the caudate nucleus predicts HPDT, p-TS-max, p-TS VAS-AUC, PCS, and HADS in individual participants, or vice versa.

### ***Statistical Analysis of Exploratory Associations #5-6:***

Quantile-quantile plots and Shapiro Wilk's test will be applied in assessment of normal distribution. If data are not normally distributed, Mann-Whitney U-test will be applied. If data are normally distributed, unpaired t-tests will be applied to investigate structural differences in brain volume, differences in white matter, and differences in rs-fMRI between the groups. To investigate potential differences in rs-fMRI, correction for multiple comparisons will be conducted by the MRI software using False-Discovery-Rate. Values of secondary hyperalgesia areas will be entered into the FSL-software, and a t-test will be performed.

### ***Missing Data***

For all analyses, an intention-to-test analysis will be performed including all subjects that participated in the experimental day. Analyses will be based on all observed data. In case of missing data exceeding 5%, and indication of violation of *missing completely at random* by a statistically significant Little's test, a sensitivity analysis based on an appropriate model for *missing data at random* or *missing data not at random* will be performed.

### ***Statistical Significance***

Earlier studies have demonstrated that the volumes of the right and left hemispheric caudate nuclei are associated with one another [11]. To preserve a family-wise error rate of 5% for the two co-primary outcomes of associations between the right and left caudate nuclei and the area of secondary hyperalgesia, we will adjust for multiple comparisons of the co-primary outcomes. The two  $P$ -values will be evaluated at a significance level between 2.5% and 5% according to the single step method. For this method the significance level is determined by the correlation between the two resulting test statistics. If they are

perfectly correlated the result will be 0.05, whereas if they are independent it will be 0.025.

*P*-values in the secondary and exploratory outcomes are evaluated at a 5% significance level, and to adjust for multiple comparisons, *P*-values are adjusted by means of single-step correction [49]. In the analysis of rs-fMRI data, the software's standard methods and False-Discovery-Rate will be applied for correction for multiple comparisons.

## Software

All statistical analyses not computed by the standard MRI software will be generated using the open source statistical programming environment R (R Foundation for Statistical Computing, Vienna, Austria).

## Discussion

We plan to investigate the association between experimental pain testing parameters and the volume, connectivity, and resting state activity of pain-relevant structures in the brain. We have designed this study to investigate basic pain physiology in healthy pain-free individuals, and we aim to investigate if any basic characteristics in the pain-free individual predict experimental pain responses. Current knowledge of basic pain physiology in humans is still sparse, and in order to compensate for the many factors that can affect pain responses, we have chosen to include a very homogenous population, consisting of healthy male volunteers between the ages of 18 and 35. The strict inclusion criteria diminish the influence of factors related to differences in the brain's structure and function (eg, sex, age). Thus, this study aims to investigate aspects of basic pain physiology in healthy male individuals, and relevant caution should be taken when applying the results in a more heterogeneous population.

Our hypothesis, as well as our sample size estimation, are based upon previous results from Asghar et al [11]. Moreover, we wish to investigate if the volume of the caudate nuclei is associated with the size of the secondary hyperalgesia areas, indicating that this structure may be involved in the processes of central sensitization. Decreased volumes of the caudate nuclei have been demonstrated in a wide array of chronic pain patients, suggesting that these patients have a decreased ability to suppress and modulate pain stimuli [15,16,20-23,25]. With this study we plan to investigate if healthy participants with low volumes of caudate nuclei have a higher degree of central sensitization, and thus may be at a higher risk of developing chronic pain conditions.

The results of this study may also be informative for future studies and trials in the clinical setting, where pain remains a

serious problem for postoperative patients. Knowledge of predictive factors and baseline pain dispositions in patients awaiting surgery may improve the design of trials on postoperative pain interventions, and improve our knowledge of the mechanisms responsible for the development of acute and chronic pain.

## Ethics

MRI uses a strong magnetic field and, unlike other imaging modalities, does not use radiation. MRI is non-invasive and has no known side effects. Due to the strong magnetic field, persons in the MRI room are not allowed to wear any metallic objects, and study participants will be informed of this prior to the MRI scans. Special MRI-compatible equipment will be used to monitor the participants inside the MRI scanner. Study participants will wear ear plugs and/or ear protection to avoid noise disturbances from the MRI scans, and will be equipped with an alarm call button in case of emergency.

A consultant radiologist will review all MRI scans. In the rare case of pathological findings, the radiology department at Bispebjerg and Frederiksberg Hospital has instructions for further treatment procedures. Briefly, the participant will be informed of the possible pathological findings and the participant will be scheduled for further radiological testing and referred to a specialist in neurology. Prior to inclusion in the study, participants will be informed of this procedure. If the participants do not wish to be informed of potential pathological findings, we reserve the right to exclude them before commencement of the MRI scan.

Likewise, the experimental pain testing conducted in the parallel study (Clinicaltrials.gov identifier: NCT02527395) do not cause damage to the skin or have any other long-term adverse effects. In rare cases, changes comparable with a first degree sunburn may appear. This study will be conducted in accordance with the principles of the Declaration of Helsinki. The protocol is approved by the local Danish Research Ethics Committees (identifier: H-15010473), and the Danish Data Protection Agency (identifier: RH-2015-149). This study is also reported on the international database (clinicaltrials.gov identifier: NCT02567318).

Informed written consent will be received from all volunteers before inclusion in the trial. Relevant provisions of the Research Ethics Committee regarding informed consent will be followed. Negative, positive, conclusive, and inconclusive test results will be published. We aim to publish the results in two separate publications, the first of which will report the primary and secondary outcomes, and the exploratory outcomes 1-4, and the second publication will report the exploratory outcomes 5 and 6.

## Acknowledgments

This work was supported by grants from the Augustinus foundation, Toyota Fonden – Denmark, DASAIM pain research award, and the Aase and Ejnar Danielsen's foundation. The funders had no role in the conception or design of the study, or on the decision to publish the results.

## Authors' Contributions

MSH contributed to the conception and design of the study, and manuscript writing. JBD, MSA, and JW contributed to the conception and the design of the study, and critical revision of the manuscript. CBP contributed to the design of the study, with emphasis on the statistical and sample size analyses, and critical revision of the manuscript. JM contributed to the conception and the design of the study, with emphasis on the MRI data processing, and critical revision of the manuscript. AC, JDN, MB and IH contributed to the conception and the design of the study with emphasis on the MRI theory and sequence, and critical revision of the manuscript. LB contributed to the conception and the design of the study with emphasis on the MRI theory, and critical revision of the manuscript. All authors have read and approved the final manuscript. We wish to thank the staff of the department of Radiology, Bispebjerg and Frederiksberg Hospital, for support in obtaining the MRI scans.

## Abstract

**Background:** Increasing physical activity (PA) brings many health benefits, but engaging people in higher levels of PA after their 60s is not straightforward. The Functional Fitness MOT (FFMOT) is a new approach which aims to raise awareness about the importance of components of fitness (strength, balance, flexibility), highlight benefits of PA, engages older people in health behavior change discussions, and directs them to local activity resources. This battery of tests combined with a brief motivational interview has not been tested in terms of feasibility or effectiveness.

**Objective:** To assess whether the FFMOT, provided in a health care setting, is appealing to older patients of a community physiotherapy service and to understand the views and perceptions of the older people undergoing the FFMOT regarding the intervention, as well as the views of the physiotherapy staff delivering the intervention. Secondary aims are to assess the feasibility of carrying out a phase 2 pilot randomized controlled trial of the FFMOT, in the context of a community physiotherapy service, by establishing whether enough patients can be recruited and retained in the study, and enough outcome data can be generated.

**Methods:** A mixed-methods feasibility study will be conducted in two physiotherapy outpatient clinics in the United Kingdom. A total of 30 physically inactive, medically stable older adults over the age of 60 will be provided with an individual FFMOT, comprising a set of six standardized, validated, age-appropriate tests aimed at raising awareness of the different components of fitness. The results of these tests will be used to provide the participants with feedback on performance in comparison to sex and age-referenced norms. This will be followed by tailored advice on how to become more active and improve fitness, including advice on local opportunities to be more active. Subsequently, participants will be invited to attend a focus group to discuss barriers and motivators to being more active, health behavior change, and the scope for individuals to improve their PA levels. To inform the design of a future trial, descriptive (eg, recruitment and retention rates), quantitative (Community Healthy Activities Model Program for Seniors; CHAMPS physical activity questionnaire), and qualitative data (focus group discussions, semi-structured staff interviews) will be collected.

**Results:** Recruitment and enrolment for the trial started in September 2015. Follow-up will be completed in June 2016. Results are expected to be available at the end of 2016.

**Discussion:** Allied health professionals play a key role in encouraging older adults to increase their PA, but with little evidence on how best to do this within their clinical practice. The purpose of this feasibility study is to examine the introduction of a new

service: The FFMOT. The views and perceptions of the older people undergoing the FFMOT and relating to its delivery in clinical practice will be explored. Data, which will inform the feasibility of a randomized controlled trial of effectiveness of the FFMOT in promoting improved PA, will be reported.

**Trial Registration:** International Standard Randomized Controlled Trial Number (ISRCTN): ISRCTN38950042; <http://www.isrctn.com/ISRCTN38950042>

## KEYWORDS

physical activity; physical fitness; physical therapists; aged; health behavior; health services for the aged; feasibility studies

## Introduction

Increasing physical activity (PA) brings many health benefits, improved health care outcomes, and reduced health care costs [1]. PA recommendations for the health of older adults include being active daily and doing activities that improve strength and balance at least twice a week. Over a week, activity should add up to at least 150 minutes of moderate intensity activity in bouts of 10 minutes or more [1]. However, only one in five people aged 65-74 years and one in ten over-75 years achieve recommended activity levels [2].

The Scottish Government has recommended that allied health professionals play a central role in encouraging people to be more active [3]. Physiotherapists are expected to raise the question of activity levels at each initial consultation, and promote PA at any given opportunity to improve the overall health and well-being of people using their services. However, engaging older people in higher levels of PA is not straightforward. In fact, evidence for the effectiveness of interventions to promote healthier levels of PA among adults [4-6] and older adults [7] is not compelling. Recently, one study showed that older people recruited through general practice and undergoing a 6-month group exercise intervention, increased their moderate intensity activity by about 15 minutes a day a year after the intervention finished [8]. However, this approach is costly and many older people do not find group exercise appealing. Therefore, not only effective but cost-effective approaches to increase PA are needed.

Rikli and Jones [9] previously developed and validated a battery of performance tests to provide a means of assessing key physiological parameters that are associated with functional mobility in independent older adults between 60-90 years. This test battery was recently adapted and further developed into the Functional Fitness MOT (FFMOT) [10]. The FFMOT is a new approach that aims to raise awareness of the importance of components of fitness such as strength, balance, and flexibility among the over-60s, highlight the benefits of PA, engage older people in health behavior change discussions, and direct them to appropriate local activity resources. It involves one face-to-face session to measure participants' fitness using seven age-appropriate functional fitness tests. Immediate feedback is given on the person's abilities in each test in relation to normal values for their age and sex, followed by tailored advice on how to become more active and improve fitness. This brief motivational set of tests and discussion is based on the principles of health behavior change, incorporating awareness raising, breaking down barriers, improving self-efficacy, building on

history of activity, incorporating needs and preferences, and goal setting [11]. To date the FFMOT has been piloted in non-clinical settings only [10].

Due to the lack of in-depth research and existing data about the FFMOT in a clinical setting, a feasibility study is indicated [12]. Therefore, in line with Medical Research Council guidance [13], the first phase of this work program is a feasibility study to evaluate the approach in clinical settings. According to the guidelines for the design of feasibility studies proposed by Bowen et al [12], the key areas of focus for this study are (1) *acceptability, demand, implementation, and practicality* for the participants, that is, to assess whether the FFMOT, provided in a health care setting, is appealing to older patients of a community physiotherapy service, and to understand their views and perceptions undergoing the FFMOT regarding the intervention, and (2) *acceptability, demand, implementation, practicality, and integration* for the staff delivering the FFMOT, that is, to assess their views on delivering the intervention to the target participants and within the setting of a community physiotherapy clinic. Secondary aims are to assess *limited efficacy*, that is, the feasibility of carrying out a phase 2 pilot randomized controlled trial of the FFMOT, in the context of a community physiotherapy service, by establishing whether enough patients can be recruited and retained in the study, and relevant outcome data can be generated.

## Methods

### Design

This is a mixed-method phase I feasibility study with a pre-post design.

### Participants

A convenience sample will be identified and recruited from one UK health board area, from among the current caseloads of community physiotherapists working in two physiotherapy clinics for musculoskeletal (MSK) conditions. Participants are eligible for participation if they are (1) aged 60 years or above, (2) not physically active for at least 30 minutes in 5 days or more, or for at least 150 minutes (2½ h) in total in the past week, as indicated by the questions on the Scottish Physical Activity Screening Question [14], and (3) interested in increasing their level of PA (where this is seen as an appropriate goal by the screening physiotherapist). Participants are excluded if the screening physiotherapist identifies health risks (contraindications to exercise; eg, cardiovascular disease) which prevents participation, and if they have been diagnosed with

moderate/severe cognitive impairment, a learning disability, severe mental illness, or the screening physiotherapist believes that any of these impairments/disorders are present.

Where patients are deemed eligible, the screening physiotherapist will introduce the nature of the study verbally to them. The screening physiotherapist will then ask potential participants if they wish to receive a study information pack and, if so, they will be given the pack during the appointment. Participants who are interested will then complete a contact details form and post it to the main researcher, who will subsequently telephone them in order to explain the consent procedures, and make an appointment for them to attend an FFMOT session. All participants will continue to receive standard physiotherapy assessment and intervention as deemed appropriate by the screening physiotherapist, irrespective of their involvement in the study.

### Sample Size

This study is a feasibility study so no formal power calculation has been carried out. However, rates of participant retention at 3-month follow-up in feasibility studies of exercise interventions for adults range between 71-100% [15-18]. Adopting a conservative estimate of 70% retention, 30 participants will be recruited with the aim of retaining 21 at the 3-month follow-up. Six blocks of FFMOT sessions will be provided over 12 weeks, with provision to run two to three additional blocks beyond this if required to achieve the recruitment target.

### Physiotherapy Staff

All physiotherapists working at the two participating physiotherapy clinics, who assess and treat MSK outpatients, will be eligible to screen patients as potential participants. There are 3 physiotherapists involved in coordinating the study within the service. They will also supervise the 2 trained technical instructors (TIs) who will deliver the FFMOT. The TIs will receive training in both the delivery of the FFMOT [19] and in motivation and support strategies for engaging older adults in PA [20].

### Functional Fitness MOT

Each recruited participant will be provided with an individual FFMOT session, which lasts for 45-60 minutes. The FFMOT in this study comprises 6 of the 7 standardized, validated, age-appropriate tests aimed at raising awareness of the different components of fitness:

- 1) 30 Second Chair Stand [21,22], as an indicator of lower limb strength and endurance;
- 2) Chair Sit and Reach [21,23,24], as an indicator of lower limb flexibility;
- 3) Back Scratch [21], as an indicator of upper body shoulder flexibility;
- 4) 8 Foot Up and Go [21,25], as an indicator of dynamic balance;
- 5) Handgrip Strength [26], as an indicator of strength;
- 6) Single Leg Stance [27,28], as an indicator of static balance.

The 6-minute walk test, for endurance, will not be used within this FFMOT battery due to space constraints within the clinic.

The results of these tests will be used to discuss the different components of fitness, to highlight the individual's strengths and weaknesses in these components, and to provide the participants with personal feedback on performance in comparison to sex and age-referenced norms. This then allows discussion around the person's activity history, needs, and preferences so that information about local opportunities to engage in PA can be introduced and encouraged. Specific goal setting (short and longer term) is discussed and each participant is provided with information about appropriate local activity opportunities and home exercises, based on their FFMOT results. This information will be provided in the form of written booklets/leaflets and links to websites of some of the opportunities available. For those who wish to exercise at home, home exercise booklets will be provided [29].

### Data Collection

#### *Descriptive Data*

The following information from every patient screened during the recruitment phase will be collected: (1) the clinic at which the patient was assessed/treated, (2) sex, (3) age, (4) postcode, (5) patient responses to the 3 questions in the Scottish Physical Activity Screening Question, (6) eligibility criteria, (7) whether the study was introduced verbally to the patient, and (8) whether the patient accepted the study information pack. Recruitment and retention rates at the key stages of the study (eg, attendance for the FFMOT and focus group, return of completed follow-up questionnaires) will also be monitored and recorded.

The Community Healthy Activities Model Program for Seniors (CHAMPS) Activities Questionnaire for Older Adults [30] will be administered before the FFMOT. This questionnaire is a valid and reliable instrument to measure recent levels and types of PA in detail in this age group. Twelve weeks after the FFMOT session a follow-up CHAMPS, and a bespoke post-intervention questionnaire will be sent by post. The latter questionnaire aims to measure the participants' contact with community organizations and facilities with a PA focus since attending the FFMOT session.

#### *Qualitative Data*

Between 2-4 weeks after participants have attended the FFMOT session, they will be invited to attend a 60-90 minute focus group. Each group will consist of a maximum of 12 participants. The focus groups will be moderated by the first author (LDdJ) according to a bespoke, predesigned discussion guide. The discussion guide contains a set of semi-structured, open-ended questions. The interview process during the focus group comprises a 4-step approach to ask the participants the following:

1. Their reason(s) for taking part in the study.
2. Their PA awareness (eg, reasons for not adhering to PA guidelines, perception changes after the FFMOT, views on and awareness about the importance and benefits of PA, perceived importance of and changes in PA behavior since the FFMOT,

and changes in awareness of local opportunities to become more physically active).

3. The FFMOT and its appeal (eg, how it felt to undergo it, what was liked and disliked, clarity of the feedback by the TIs, impact of the test results when compared with other people of the same age group, reasons for (not) recommending it to others, suggestions for improvement to make it more appealing, and views on timing and location of provision of the service).

4. Their experiences of the study procedures (eg, concerns about taking part, clarity of the participant information sheet, experiences with completing the consent procedure and CHAMPS questionnaires).

Four semi-structured individual interviews, of up to 60 minutes, with the supervising physiotherapists and the 2 TIs will be held no more than 2 weeks after all FFMOT sessions have been provided. The interview process for these interviews comprise a 3-step approach to ask the staff about the following:

1. Previous experiences in working with older people, therapy, fitness testing, exercise, research, and background knowledge of fitness tests/testing.

2. Perceptions of the FFMOT (eg, views on the pretrial training, appropriateness and constraints of the screening criteria and fitness tests, experiences with administering the tests, representativeness of the participants' results, issues during administration of the tests, views on the appeal, benefits, disadvantages, and value of the FFMOT, suggestions for improvement).

3. The FFMOT in the context of a community physiotherapy service (eg, appropriateness of the physiotherapy service to deliver the FFMOT, views on feasibility, barriers and motivators to deliver it in a physiotherapy service, views on improvements in the delivery of the FFMOT).

All focus group discussions and staff interviews will be audio recorded onto an encrypted digital recorder.

## Analysis

As this is a feasibility study, the analyses will be primarily descriptive. Reasons for exclusion, participant recruitment and retention rates, number of completed questionnaires returned, and incidence of missing questionnaire item responses will be explored. Additional analyses will be conducted of any demographic differences (including sex, age, the clinic where screening occurred, the Scottish Index of Multiple Deprivation [31] rank of participant's home postcode, and travelling distance from home to clinic between (a) eligible and non-eligible patients, (b) eligible patients who accepted an information pack and those who did not, (c) eligible patients who were recruited and those who were not, and (d) completers and non-completers. CHAMPS data will be compared between baseline and 12-week follow-up to provide an initial estimate of effect size to inform the design of a future trial. A previous study [8] using CHAMPS has shown positively skewed distributions, so it is likely that similar logarithmic transformations (CHAMPS score +1) will have to be carried out. Qualitative data (focus group and staff interview audio recordings) will be fully transcribed and coded using thematic analysis. Thematic analysis will be carried out

by two of the authors (LDdJ, DAS), with all authors agreeing the final themes.

## Informed Consent

Written informed consent will be obtained from all participants. The decision regarding participation in the study is entirely voluntary. The researcher will emphasize to potential participants that consent regarding study participation can be withdrawn at any time without giving any reason, and without affecting their physiotherapy/medical care. It will also be emphasized to potential participants that all of the information that is collected about them during this project (personal, medical, and audio recordings) will be anonymized, will not affect their confidentiality in any way, and that it will not be possible to identify information about them when the results of the study are published.

## Ethical and Organizational Review

A favorable ethical opinion of this study was granted by the NHS South East Scotland Research Ethics Committee 01, Scotland UK (Reference 15/SS/0118). Approval was also granted by the NHS Lothian Research & Development Office (Reference 2015/0283). The study is sponsored by Glasgow Caledonian University (Reference RIE13-127).

## Results

Recruitment and enrolment for the trial started in September 2015. Follow-up will be completed in June 2016. Results are expected to be available at the end of 2016.

## Discussion

Allied health professionals are tasked with playing a key role in encouraging older adults to increase their PA. Older adults need unique consideration in how they are recommended to become more physically active, in particular doing activities that improve strength and balance, but there is little evidence for allied health professionals on how best to do this within their clinical practice. The FFMOT is a new approach that aims to raise awareness among the over-60s of the importance of components of fitness such as strength, balance and flexibility, highlight the benefits of PA, engage older people in health behavior change discussions, and direct them to appropriate local activity resources. However, there is no existing data about whether the FFMOT could work in this setting, and therefore performing a feasibility study is indicated. The purpose of this mixed-method phase I feasibility study with a pre-post design is to examine the introduction of the FFMOT for older adults, within two community physiotherapy MSK clinics in the United Kingdom. Specifically, the views and perceptions of a convenience sample of older people undergoing the FFMOT relating to the delivery of the FFMOT in clinical practice will be explored. Patient recruitment/retention rates, and the extent to which outcome data can be collected, will be evaluated with a view of planning a future randomized controlled trial of the FFMOT compared with the usual treatment provided (recommendations for increased activity). Participants included in this study will be provided with single, 45-60 minute consultation, including age-appropriate functional tests, which

could potentially increase their motivation to become more physically active. Increased PA could help them improve their gait, balance, mobility, and general health in the longer term. If this feasibility study suggests the FFMOT can work in the

clinical setting, then a definitive RCT will be proposed in order to look at whether the FFMOT is efficacious and effective at increasing PA in older adults.

## Acknowledgments

This study was funded by a grant from the Edinburgh and Lothians Health Foundation (reference number 10-338). Andy Peters is supported by Edinburgh Clinical Trials Unit.

## Conflicts of Interest

DAS and RMEL are Directors of Later Life Training Ltd, a not for profit organization that delivers training on motivation to exercise, and exercise delivery for older people. RMEL is a Consultant for the BHF National Centre for Physical Activity and Health, and delivers FFMOT training across the UK. The other authors declare that they have no competing interests.

## Authors' Contributions

AP, JH, NC, CH, RMEL, and DAS conceived the study and participated in its design, and together with LDdJ wrote and refined the trial protocol. LDdJ has had the responsibility of preparing this manuscript. All authors have been involved in revising it critically for important intellectual content, and read and approved the final manuscript.

## Abstract

**Background:** It has long been suspected that a worker's risk of developing an ischemic heart disease (IHD) may be influenced by his or her working time arrangements. A multitude of studies have been performed, and special attention has been given to long working hours and nighttime work. The statistical powers of the individual studies have, however, generally been too low to either dismiss or confirm an actual relationship, and meta-analyses of underpowered studies are generally associated with publication bias. Hence, uncertainty remains and whether these factors indeed are related to IHD has yet to be settled.

**Objective:** This project will test whether the incidences of IHD and usage of antihypertensive drugs among employees in Denmark are independent of weekly working hours and nighttime work. The objective of this paper is to present the intended analyses.

**Methods:** We will link individual participant data from the Danish labor force survey, 1999–2013, to data on socioeconomic status, industry, emigrations, redeemed prescriptions, hospitalizations, and deaths from registers covering the entire population of Denmark. The study will include approximately 160,000 participants, who will be followed through the registers, from the time of the interview until the end of 2014, for first occurrence of IHD and for antihypertensive drug treatment. We will use Poisson regression to analyze incidence rates as a function of nighttime work and of weekly working hours.

**Results:** We expect results to be ready in mid-2017.

**Conclusions:** To our knowledge, this will be the largest study ever of its kind. It will, moreover, be free from hindsight bias, since the hypotheses, inclusion criteria, significance levels, and statistical models will be completely defined and published before we are allowed to link the exposure data to the outcome data.

## KEYWORDS

occupational health; prescription drugs; hospital treatment; night worker; long working hours

## Introduction

### Background

Our project will look at rates of ischemic heart disease (IHD) among Danish employees as a function of weekly working hours and nighttime work.

From the viewpoint of cardiovascular risk factors, there appear to be both advantages and disadvantages of long working hours and nighttime work.

One of the advantages of nighttime work is that it usually eliminates exposure to rush hour commuting stress, both to and from work; such stress has been associated with psychological strain [1,2], increased blood pressure [3], and increased rates of acute myocardial infarction [4,5]. Moreover, a survey of more than 400 people in United Kingdom indicated that 44% of people believed that rush hour traffic was the single most stressful part of their life [6]. Daytime workers may reduce their exposure to rush hour traffic, at least in one direction, by choosing to work long hours.

Another potential advantage of nighttime work and long working hours is that they can generate extra income, compared with ordinary daytime work, and thereby reduce the risk or intensity of financial strain. An increased income has been associated with a decreased risk of IHD [7], while financial strain has been associated with an increased risk of hypertension [8] and acute myocardial infarction [9].

The disadvantage of long working hours and nighttime or shift work is that they usually are associated with short sleep duration, mismatch of circadian rhythm, social disruption, and behavioral changes [10,11], which in turn are associated with an increased risk of IHD [12]. The mechanism may be related to disturbed regulation of inflammatory, metabolic, and cardiovascular processes. Thus, short-term sleep restriction increases heart rate [13] and blood pressure [14], changes immune function [13], increases C-reactive protein concentration [13], and decreases glucose tolerance and sympathetic nervous system activity [15].

The evidence of an association between night or shift work and IHD has been reviewed by Frost et al [16], Ha et al [17], and Vyas et al [18]. Frost et al [16] reviewed 14 research papers and concluded that "the available evidence concerning the influence of the type and duration of shift work, as well as sex, on the risk of IHD is too limited to permit any conclusions on these issues." In a meta-analysis that combined the results from 8 studies, Ha et al estimated the effect of night or shift work versus ordinary daytime work, first at a rate ratio (RR) equal to 1.17 (95% CI 1.00–1.37) and then, after adjustment for publication bias, at RR=1.12 (95% CI 0.94–1.33) [17].

Vyas et al [18] reviewed 35 research papers and used the results of the papers in meta-analyses, which estimated the RR of night or shift work versus ordinary daytime work at 1.24 (95% CI 1.10–1.39) for coronary events, 1.23 (95% CI 1.15–1.31) for acute myocardial infarction, and 1.05 (95% CI 1.01–1.09) for ischemic stroke. However, 87% (1,750,565/2,011,935) of the participants in the meta-analyses came from ecologic studies, which of course makes the estimates less certain than their confidence intervals imply.

Virtanen et al [19] investigated the relationship between long working hours and coronary heart disease in a systematic review and meta-analysis, which included results from 12 research papers. The RR for coronary heart disease among workers with "long" versus "normal" working hours was estimated at 1.80 (95% CI 1.42–2.29) when all studies were included and 1.39 (95% CI 1.12–1.72) when restricted to prospective studies. The cut points for long weekly working hours ranged from >40 to >65 hours.

The reviews by Vyas et al [18] and by Virtanen et al [19] suggested that the disadvantages of nighttime work and long

working hours tend to outweigh the advantages of such work time arrangements. However, since the meta-analyses only included published studies, we cannot rule out publication bias. The risk of publication bias is especially high if the included studies are too small to be of interest unless the results are statistically significant [20], and this is definitely the case with the studies that Virtanen et al [19] included in their meta-analysis.

Kivimäki et al [21] conducted a more reliable meta-analysis of the relationship between long working hours and IHD, in which they mitigated the risk of publication bias by conducting and inserting a series of new and hitherto unpublished studies. By combining the results from the unpublished studies with corresponding results from published studies, they obtained the following RRs for long versus normal (35–40) working hours a week: 1.02 (95% CI 0.91–1.15) for 41–48 hours, 1.07 (95% CI 0.92–1.24) for 49–54 hours, and 1.08 (95% CI 0.92–1.24) for >54 working hours. These RRs are most probably the best estimates ever of the strength of association between long working hours and coronary heart disease. We should, however, keep in mind that meta-analyses that include published results never can be done blinded. The researchers often know the literature before they formulate inclusion criteria and, however systematic and objective they attempt to be, it can never be ruled out that the selection of papers as well as the selection of estimates within the papers might be influenced by their a priori expectations. From this viewpoint, it would be good to know whether the null finding by Kivimäki et al would be reproduced if it were tested in an equally sized blinded study, that is, a study in which the inclusion criteria, hypotheses, and statistical models were completely specified and published before any results were available.

Kivimäki et al [21] based their RRs on a total of 2481 new cases among 129,301 participants. Our project has access to person-based data on work time arrangements for approximately 160,000 employees with long or normal working hours, which, upon follow-up, we expect to yield approximately 3200 new cases of IHD. The exposure data of the project have not been linked to health data before, and this provides an opportunity to study the relationship between work time arrangements and subsequent IHD, with a remarkably high statistical power, completely blinded.

## Aims and Hypotheses

We want to know whether the incidence of antihypertensive drug usage and the incidence of hospital treatment or death due to IHD are independent of weekly working hours and nighttime work among full-time employees in Denmark, and will address these research questions in a series of nested hypothesis tests (Textbox 1).

**Textbox 1.** Hypotheses to be tested.

1. The incidence of antihypertensive drug usage and the incidence of hospital treatment or death due to ischemic heart disease (IHD) among full-time employees in Denmark are prospectively independent of weekly working hours, as well as interaction between weekly working hours and each of the following variables: socioeconomic status, sex, and nighttime work.
  - 1.1. The incidence of hospital treatment or death due to IHD is prospectively independent of weekly working hours, as well as interaction between weekly working hours and each of the following variables: socioeconomic status, sex, and nighttime work.
    - 1.1.1. The prospective association between weekly working hours and incidence of hospital treatment or death due to IHD is independent of socioeconomic status.
    - 1.1.2. The prospective association between weekly working hours and incidence of hospital treatment or death due to IHD is independent of sex.
    - 1.1.3. The prospective association between weekly working hours and incidence of hospital treatment or death due to IHD is independent of nighttime work.
    - 1.1.4. The incidence of hospital treatment or death due to IHD is prospectively independent of weekly working hours when we disregard interaction effects.
  - 1.2. The incidence of antihypertensive drug usage is prospectively independent of weekly working hours, as well as interaction between weekly working hours and each of the following variables: socioeconomic status, sex, and nighttime work.
    - 1.2.1. The prospective association between weekly working hours and incidence of antihypertensive drug usage is independent of socioeconomic status.
    - 1.2.2. The prospective association between weekly working hours and incidence of antihypertensive drug usage is independent of sex.
    - 1.2.3. The prospective association between weekly working hours and incidence of antihypertensive drug usage is independent of nighttime work.
    - 1.2.4. The incidence of antihypertensive drug usage is prospectively independent of weekly working hours when we disregard interaction effects.
2. The incidence of antihypertensive drug usage and the incidence of hospital treatment or death due to IHD among full-time employees in Denmark is prospectively independent of nighttime work, as well as interaction between nighttime work and each of the variables socioeconomic status and sex.
  - 2.1. The incidence of hospital treatment or death due to IHD is prospectively independent of nighttime work, as well as interaction between nighttime work and each of the variables socioeconomic status and sex.
    - 2.1.1. The prospective association between nighttime work and incidence of hospital treatment or death due to IHD is independent of socioeconomic status.
    - 2.1.2. The prospective association between nighttime work and incidence of hospital treatment or death due to IHD is independent of sex.
    - 2.1.3. The incidence of hospital treatment or death due to IHD is prospectively independent of nighttime work when we disregard interaction effects.
  - 2.2. The incidence of antihypertensive drug usage is prospectively independent of nighttime work, as well as interaction between nighttime work and each of the variables socioeconomic status and sex.
    - 2.2.1. The prospective association between nighttime work and incidence of antihypertensive drug usage is independent of socioeconomic status.
    - 2.2.2. The prospective association between nighttime work and incidence of antihypertensive drug usage is independent of sex.
    - 2.2.3. The incidence of antihypertensive drug usage is prospectively independent of nighttime work when we disregard interaction effects.

We will set the overall significance level for the effect of weekly working hours at .05 and we will set the overall significance level for the effect of nighttime work at .05. We will solve the multiple testing problems by the following strategy:

- A null hypothesis at the first level will be rejected if either of its two second-level null hypotheses is rejected.
- A null hypothesis at the second level will be rejected if the *P* value of its statistical test is  $\leq .025$ .
- A null hypothesis at the third level will be rejected if (1) its associated second-level null hypothesis is rejected and (2) the *P* value of its statistical test is  $\leq .025$ .

Hospital treatment or death due to IHD is the primary outcome of the study, and a statically significant association with this outcome would afford direct statistical evidence of an association with IHD.

Hypertension plays an important role in the etiology of IHD [22], and relative rates of antihypertensive drug usage have been

shown to be highly correlated with relative rates of IHD among occupational groups in Denmark [23,24]. We will therefore regard results obtained for antihypertensive drug usage as indirect statistical evidence of an association with IHD if they are statistically significant and show a similar pattern to the results obtained for hospital treatment or death due to IHD.

## Methods

### Ethics Approval

The study will comply with The Act on Processing of Personal Data, Denmark (Act No. 429 of May 31, 2000), which implements the European Union (EU) Directive 95/46/EC on the protection of individuals. The data usage is approved by the Danish Data Protection Agency, file number 2001-54-0180. The ethical aspect of the project was examined and approved by Statistics Denmark, account number 704291.

## Data Material

The data base of the project will consist of interview data from the Danish Labour Force Survey 1999–2013, which are linked to data from the central person register [25], the employment classification module [26], the national patient register [27], the cause of death register [28], and the national prescription register [29]. The linkage will be based on the participants' personal identification numbers.

The Danish Labour Force Survey has been conducted since 1994, in accordance with EU directives, which apply to all member states of the EU. It is based on random samples of 15- to 74-year-old people in the Danish population. The samples are drawn quarterly and the participants are invited to be interviewed 4 times over a period of one and a half years. The structured interviews, which are done by telephone, cover various aspects of labor market participation, including specifications on working hours and work schedules [30]. The response rate is currently 65% [30].

The central person register contains information on sex, addresses, and dates of birth, death, and migrations for every person who is or has been an inhabitant of Denmark sometime between 1968 and the present. A person's socioeconomic status (SES), occupation, and industry have been registered annually in the employment classification module since 1975. The national hospital register has existed since 1977 and contains data from all public hospitals in Denmark (>99% of all admissions). From 1977 to 1994, the register only included inpatients, but from 1995 it has also covered outpatients and emergency ward visits. Since 1994, the diagnoses have been coded according to *International Classification of Diseases, Tenth Revision* (ICD-10) [31]. The national prescription register covers all redeemed prescriptions at pharmacies in Denmark since 1995, and the products are coded in accordance with the Anatomical Therapeutic Chemical Classification System (ATC).

## Exposure Variables

The labor force surveys gather person-based information on weekly working hours, calculated by adding the hours worked in secondary jobs to the ones worked in a primary job. The participants are asked first how many hours they usually work and then how many hours they worked during the reference week (a predetermined work week, which occurred 1–4 weeks prior to the interview). They are also asked whether and to what extent they work at night. The questions used to gather this information have changed slightly with time. Before 2001, there was no mention of whether meal breaks should be counted as working hours. During 2001–2006, all participants were instructed to exclude meal breaks when they counted their work hours. As of 2007, the time used for meal breaks is to be counted if the person was paid while eating and is to be excluded otherwise. Another peculiarity that was introduced in 2007 is that the participants are asked whether the weekly working hours vary a lot or there are other reasons that make it difficult to provide a meaningful estimate of usual weekly working hours. If they answer "yes" to any of these questions, then "average working hours" is to be used as a proxy for "usual working hours."

Before 2001, the participants were simply asked whether they worked at night, but from 2001 onward the question has been whether they worked at night during the last 4 weeks. Until 2006 the response categories were "yes, regularly," "yes, occasionally," and "no, never". From 2007 onward the response categories were expanded to "yes, regularly" (ie, more than half of the working days in the last 4 weeks), "yes occasionally" (ie, at least once within the last 4 weeks, but less than half of the working days), and "no, not within the last 4 weeks."

We will disregard the changes in the data collection routines in the primary analyses of this project. We will define the exposure variables as follows.

## Weekly Working Hours

In keeping with Kleppa et al [32] and Hannerz and Albertsen [33], we will treat working hours as a categorical variable, with 32–40 hours representing normal weekly working hours, 41–48 hours representing overtime work that lies within the limits of the European working time directive, and 49–100 hours representing overtime work beyond the threshold of the directive. We will base the categorization on the person's usual working hours.

## Nighttime Work

Participants who responded with either "yes, regularly" or "yes, occasionally" to the question about nighttime work will be defined as being exposed and those who responded with "no..." will be defined as being unexposed to nighttime work.

## Clinical End Points

The primary end point is hospital treatment or death, with IHD as the principal diagnosis or cause of death, respectively. The case definition includes the following ICD-10 codes: I20 angina pectoris, I21 acute myocardial infarction, I22 subsequent myocardial infarction, I23 certain current complications following acute myocardial infarction, I24 other acute IHDs, I25 chronic IHD. The secondary end point is redemption of a prescription for antihypertensive drugs. The following ATC codes are included: C02 antihypertensives, C03 diuretics, C07 alpha- and beta-blockers, C08 calcium channel blockers, and C09 angiotensin-converting enzyme inhibitors and angiotensin-II antagonists.

## Follow-Up and Inclusion Criteria

The participants will be followed from the beginning of the calendar year that succeeds that of their baseline interview. The follow-up will end at the time the participant is diagnosed with IHD, emigrates, or dies, or the end of the study period (December 31, 2014), whichever comes first. To be eligible for inclusion, they should be between 21 and 59 years old at the start of the follow-up period and employed with  $\geq 32$  weekly working hours at the time of the interview. People who received hospital treatment for IHD during the calendar year of the interview will be excluded from the IHD analysis. People who redeemed a prescription for antihypertensive drugs during the calendar year of the interview will be excluded from the antihypertensive drug analysis.

## Primary Analysis

We will use Poisson regression to analyze incidence rates of hospital treatment or death due to IHD as a function of weekly working hours (32–40, 41–48, or >48 hours/week), nighttime work (yes vs no), sex, age (10-year classes), calendar time (2000–2004, 2005–2009, or 2010–2014), time passed since start of follow-up (0–4, 5–9, or ≥10 years), employment in the health care industry (yes vs no), and SES (low, medium, high, or unknown). Age, calendar time, and time passed since start of follow-up will be treated as dynamic (time-varying) variables. The remaining variables will be fixed at baseline (the calendar year of the interview). The logarithm of person-years at risk will be used as offset. People who participated in more than one interview will be classified in accordance with the responses given in their first interview. Later interviews will be disregarded.

We will retrieve information on occupation and industry from the employment classification module, and refer it to the status

during the calendar year of the baseline interview. Industries were coded in accordance with the Statistics Denmark classification DB93 [34] in 1999–2002, DB03 [35] in 2002–2007, and DB07 [36] in the calendar years 2008–2013. Occupations were coded in accordance with DISCO-88 (the Danish version of the International Standard Classification of Occupations, ISCO-88) [37] in the calendar years 1999–2009 and DISCO-08 (the Danish version of ISCO-08) [38] in the calendar years 2010–2013.

We will code the variable “employment in the health care industry” as “yes” if the 3-digit industrial code of DB93 or DB03 equals 851 or the 2-digit code of DB07 equals 86.

We will base SES on the participant’s occupation and will code it as “high,” “medium,” or “low” in accordance with the 3-class version of the European Socio-economic Classification (ESeC). The coding will be performed in accordance with the SAS (SAS Institute) programming statements shown in [Textbox 2](#).

**Textbox 2.** SAS programming statements for occupations coded according to the Danish version of the International Standard Classification of Occupations (DISCO-88) and socioeconomic class (SES) coded according to the European Socio-economic Classification (ESeC).

```
/* SES classification (ESeC three class version) of employees by use of DISCO-88 */
if '1' le substr(DISCO_88, 1, 1) le '2' then SES = "High";
if '3' le substr(DISCO_88, 1, 1) le '4' then SES = "Medium";
if '5' le substr(DISCO_88, 1, 1) le '9' then SES = "Low";
if '31' le substr(DISCO_88, 1, 2) le '32' or substr(DISCO_88, 1, 3) in ('334', '342', '344', '345', '348', '521') then SES = "High";
if substr(DISCO_88, 1, 3) = '731' then SES = "Medium";
if substr(DISCO_88, 1, 3) in ('413', '414', '421', '422') then SES = "Low";
/* SES classification (ESeC three class version) of employees by use of DISCO-08 */
if '1' le substr(DISCO_08, 1, 1) le '2' then SES = "High";
if '3' le substr(DISCO_08, 1, 1) le '4' then SES = "Medium";
if '5' le substr(DISCO_08, 1, 1) le '9' then SES = "Low";
if substr(DISCO_08, 1, 3) in ('311', '312', '314', '315', '321', '322', '323') then SES = "High";
if substr(DISCO_08, 1, 3) in ('224', '742') then SES = "Medium";
if substr(DISCO_08, 1, 2) = '42' or substr(DISCO_08, 1, 3) = '432' then SES = "Low";
```

## Statistical Models and Tests to Analyze Effects of Weekly Working Hours

The full model will include the following covariates: calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, nighttime work, working hours, working hours × sex, working hours × SES, and working hours × nighttime work. We will use the parameter estimates

obtained with the full model to calculate RRs for incident use of antihypertensive drugs and for hospitalization or death due to IHD as a function of weekly working hours, by sex, SES, and nighttime work. We will consider the following contrasts: 41–48 versus 32–40 working hours/week, and >48 versus 32–40 working hours/week. The results will be presented as outlined in [Table 1](#).

**Table 1.** Dummy table for reporting the RR<sup>a</sup> with 95% CI for incident use of antihypertensive drugs and hospitalization or death due to IHD<sup>b</sup> as a function of weekly working hours among Danish employees during 2000–2014, stratified by sex, socioeconomic status, and night shift status.

Worker subgroups	Weekly working hours	Antihypertensive drugs			Hospitalization or death due to IHD		
		Cases	RR	95% CI	Cases	RR	95% CI
Sex

<sup>a</sup>RR: rate ratio.<sup>b</sup>IHD: ischemic heart disease.

We will test hypotheses 1.1 and 1.2 by use of likelihood ratios comparing the full model with a model containing only the following covariates: calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, and nighttime work.

We will test hypotheses 1.1.1 and 1.2.1 by use of likelihood ratios comparing the full model with a model containing only the following covariates: calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, nighttime work, working hours, working hours  $\times$  sex, and working hours  $\times$  nighttime work.

We will test hypotheses 1.1.2 and 1.2.2 by use of likelihood ratios comparing the full model with a model containing only the following covariates: calendar time, time passed since start

of follow-up, employment in the health care industry, age, sex, SES, nighttime work, working hours, working hours  $\times$  SES, and working hours  $\times$  nighttime work.

We will test hypotheses 1.1.3 and 1.2.3 by use of likelihood ratios comparing the full model with a model containing only the following covariates: calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, nighttime work, working hours, working hours  $\times$  sex, and working hours  $\times$  SES.

We will test hypotheses 1.1.4 and 1.2.4 by use of likelihood ratios comparing a model containing only the covariates calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, nighttime work, and working hours with a model containing only the covariates calendar time,

time passed since start of follow-up, employment in the health care industry, age, sex, SES, and nighttime work.

### **Statistical Models and Tests to Analyze Effects of Nighttime Work**

The full model will include the following covariates: calendar time, time passed since start of follow-up, employment in the

health care industry, age, sex, SES, working hours, nighttime work, nighttime work  $\times$  sex, and nighttime work  $\times$  SES. We will use the parameter estimates obtained with the full model to calculate RRs for incident use of antihypertensive drugs and hospitalization or death due to IHD as a function of nighttime work, by sex and SES. The results will be presented as outlined in [Table 2](#).

**Table 2.** Dummy table for reporting the RR<sup>a</sup> with 95% CI for incident use of antihypertensive drugs and hospitalization or death due to IHD<sup>b</sup> as a function of nighttime work among Danish employees during 2000–2014, stratified by sex and socioeconomic status.

<sup>a</sup>RR: rate ratio.

<sup>b</sup>IHD: ischemic heart disease.

We will test hypotheses 2.1 and 2.2 by use of likelihood ratios comparing the full model with a model containing only the following covariates: calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, and working hours.

We will test hypotheses 2.1.1 and 2.2.1 by use of likelihood ratios comparing the full model with a model containing only the following covariates: calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, nighttime work, working hours, and working hours  $\times$  sex.

We will test hypotheses 2.1.2 and 2.2.2 by use of likelihood ratios comparing the full model with a model containing only the following covariates: calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, nighttime work, working hours, and working hours  $\times$  SES.

We will test hypotheses 2.1.3 and 2.2.3 by use of likelihood ratios comparing a model containing the covariates calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, nighttime work, and working

hours with a model containing only the covariates calendar time, time passed since start of follow-up, employment in the health care industry, age, sex, SES, and working hours.

### **Power Calculations**

To estimate the statistical power of the hypothesis tests, we first needed to estimate the expected number of cases in the various exposure categories.

To obtain such estimates, we followed the entire population of 21- to 59-year-old employees in Denmark from January 1, 2000 and onward in the same registers that we will use to follow up the samples of this project. While discounting prevalent cases (those who had experienced the clinical end point of the study during the calendar year 1999), we noted all new cases that occurred and tabulated those against the time that had passed since the start of the follow-up. [Table 3](#) gives the results, where the values for the first 13 years of IHD cases and the first 12 years of antihypertensive drug cases are based on actual data, whereas we extrapolated the values for the remaining years by use of a second-degree Taylor polynomial.

**Table 3.** Cumulative percentage of new cases among employees in Denmark aged 21–59 years at baseline, as a function of time passed since start of follow-up (January 1, 2000).

Years of follow-up	Hospitalization or death due to IHD <sup>a</sup>		Antihypertensive drugs	
	Men	Women	Men	Women
1	0.34	0.14	1.41	2.38
2	0.65	0.26	2.89	4.63
3	0.98	0.41	4.44	6.76
4	1.32	0.55	6.15	8.98

<sup>a</sup>IHD: ischemic heart disease.

Since the sample of participants who were interviewed in calendar year  $n$  will be followed for 2014– $n$  years, the expected percentages of new cases in that sample can be found in the row headed by 2014– $n$  years of follow-up, and so forth.

By relating the frequency distribution of the participants stratified by calendar year of interview, sex, and exposure category to the percentages given in Table 3, we finally obtained the expected numbers of cases that were needed to calculate the power (see Table 4).

**Table 4.** Expected number of new cases under the null hypothesis.

Type of exposure	Level	No. of participants	Expected no. of IHD <sup>a</sup> cases	Expected no. of antihypertensive drug cases
Night shifts	Yes	20,337	439	2924
	No	137,521	2786	21,068
Weekly working hours	>48	9734	210	1304
	41–48	15,872	297	2082
	32–40	132,252	2718	20,606

<sup>a</sup>IHD: ischemic heart disease.

Since our hypotheses will be evaluated by use of chi-square distributed likelihood ratio tests, we have chosen to depict the statistical power as a function of Cohen  $w$ , which is an effect size defined by equation (1) (Figure 1). Cohen classified  $w=0.1$  as a small effect,  $w=0.3$  as a medium effect and  $w=0.5$  as a large effect [39].

Figure 2 shows the statistical power of hypotheses 1.1 and 1.2. Figure 3 shows the power of hypotheses 2.1 and 2.2. The calculations are based on the total number of expected cases and the noncentral chi-square distribution with 12 degrees of freedom for the effects of long working hours (hypotheses 1.1 and 1.2) and 5 degrees for the effects of nighttime work (hypotheses 2.1 and 2.2).

**Figure 1.** Equation (1): calculation of Cohen effect size  $w$ , where  $p_{0i}$  and  $p_{1i}$  are the expected proportions of cases that fall into exposure category  $i$  under the null hypothesis and the alternative hypotheses. Equation (2): calculation of expected rate ratio,  $E[RR]$ , where  $RR_1$  is the rate ratio for ischemic heart disease (IHD) among employees in the body mass index (BMI) category  $25 \leq \text{BMI} < 30$  versus  $\text{BMI} < 25 \text{ kg/m}^2$ ,  $RR_2$  is the rate ratio for IHD among employees in the category  $\text{BMI} \geq 30$  versus  $\text{BMI} < 25 \text{ kg/m}^2$ , and  $RR_3$  is the rate ratio for IHD among smoking versus nonsmoking employees. The parameters  $p_1$  and  $q_1$  are the proportions of employees who belong to the category  $25 \leq \text{BMI} < 30 \text{ kg/m}^2$ ,  $p_2$  and  $q_2$  are the proportions of employees who belong to the category  $\text{BMI} \geq 30 \text{ kg/m}^2$ , and  $p_3$  and  $q_3$  are the proportions of smokers among employees with and without nighttime work.

$$w = \sqrt{\sum_i \frac{(p_{1i} - p_{0i})^2}{p_{0i}}} \quad (1)$$

$$E[RR] = \frac{1 + p_1(RR_1 - 1) + p_2(RR_2 - 1)}{1 + q_1(RR_1 - 1) + q_2(RR_2 - 1)} \times \frac{1 + p_3(RR_3 - 1)}{1 + q_3(RR_3 - 1)} \quad (2)$$

**Figure 2.** Power to detect that the examined incidences depend on weekly working hours either as a general effect or as an effect of interaction with sex, socioeconomic status, or nighttime work, as a function of Cohen  $w$ . IHD: ischemic heart disease.

**Figure 3.** Power to detect that the examined incidences depend on nighttime work either as a general effect or as an effect of interaction with sex or socioeconomic status, as a function of Cohen  $w$ . IHD: ischemic heart disease.

### Sensitivity Analysis 1

Since the questions used to obtain information about nighttime work and weekly working hours were revised in 2001 and then again in 2007, we will perform a sensitivity analysis with the results stratified by calendar period of interview (1999–2000, 2001–2006, and 2007–2013). The end point, covariates, and statistical model of the sensitivity analysis will be the same as the ones used to test hypotheses 1.1.4 and 2.1.3.

### Sensitivity Analysis 2

To ascertain that an observed instance of hospital treatment during the follow-up is a new episode rather than a revisit in a course of treatment that was initiated before baseline, the primary analysis will exclude all workers who were treated for IHD sometime during the calendar year preceding baseline. It will, however, not exclude all former cases of IHD, and it is possible that the estimates of the primary analysis will be affected by nonexcluded workers who were treated for IHD more than 1 year earlier than baseline. We will address this issue with a sensitivity analysis, which will exclude all workers who received hospital treatment for IHD one or more times during a 5-year period prior to baseline. The analysis will include only those who were at least 20 years old and lived in

Denmark throughout the 5-year period of interest. In all other respects, the design will be the same as the one used to test hypotheses 1.1.4 and 2.1.3.

### Sensitivity Analysis 3

The actual working hours, that is, the hours worked during the reference week, constitute a well-defined quantity with minimal recall bias. The usual working hours are less well defined, and the way they are understood and remembered might vary between individuals. In spite of this drawback, we chose to base our analysis on the workers' usual rather than their actual working hours. We did so because some of the participants, by chance, would have worked less than usual during the reference week due to, for example, holidays, vacation, or sickness absence, while others would have worked more than usual due to, for example, a deadline or a temporary staff shortage. Since the usual working hours might be associated with recall bias, we will perform a sensitivity analysis in which we include only participants who belong to the same category according to their actual working hours as they do according to their usual working hours. In all other respects, the design will be the same as the one used to test hypotheses 1.1.4 and 2.1.3. Table 5 gives a -tabulation of the actual and usual working hours.

**Table 5.** Number of economically active 21- to 59-year-old participants, stratified by combinations of actual and usual weekly working hours.

Actual weekly working hours	Usual weekly working hours				Total
	0–31	32–40	41–48	>48	
Missing	187	56	16	19	278

41–48	462	10,981	8250	869	20,562
>48	413	5686	1956	6513	14,568
Total	34,759	132,252	15,872	9734	192,617

## Statistics on Smoking, Overweight, and Obesity

It is recognized that the risk of IHD depends on a person's body mass index (BMI) and smoking habits. Among Danish employees, the RR for IHD has been estimated at 1.54 for current versus never smokers [40], at 1.41 for  $25 \leq \text{BMI} < 30$  versus  $\text{BMI} < 25$ , and at 2.69 for  $\text{BMI} \geq 30$  versus  $\text{BMI} < 25$   $\text{kg/m}^2$  [41].

Unfortunately, the Danish Labour Force Survey does not contain any information about the worker's weight and smoking habits,

which makes us unable to control for these factors in our analyses. We therefore wanted to know in what direction and to what extent we can expect the estimates of the project to be influenced by differences in smoking habits and BMI. To shed some light on this issue, we compiled some descriptive statistics on the prevalence of smoking and high BMI in relation to long working hours and nighttime work among a random sample of employees in Denmark (Table 6, Table 7). The sample was drawn in 2010 and the data were collected by use of a mailed questionnaire. The response rate was 48% [42].

**Table 6.** Crude percentages of current smokers, persons with moderate overweight ( $25 \leq \text{BMI} < 30$   $\text{kg/m}^2$ ), and persons with obesity ( $\text{BMI} \geq 30$   $\text{kg/m}^2$ ), by working time arrangement, in a random sample of 20- to 59-year-old employees in Denmark, 2010.

Working time arrangements	Current smoker % (n/N)	$25 \leq \text{BMI} < 30$ % (n/N)	$\text{BMI} \geq 30$ % (n/N)
32–40 working hours/week	22.4 (1205/5383)	33.8 (1821/5383)	12.9 (695/5383)
41–48 working hours/week	20.7 (255/1231)	36.1 (445/1231)	12.8 (157/1231)
>48 working hours/week	21.0 (141/671)	39.6 (266/671)	12.1 (81/671)
Without nighttime work	21.7 (1465/6766)	34.5 (2335/6766)	12.7 (858/6766)
With nighttime work	26.2 (136/519)	38.0 (197/519)	14.5 (75/519)

<sup>a</sup>BMI: body mass index.

**Table 7.** Age (10-year classes) and sex standardized percentages of current smokers, persons with moderate overweight ( $25 \leq \text{BMI} < 30$   $\text{kg/m}^2$ ), and persons with obesity ( $\text{BMI} \geq 30$   $\text{kg/m}^2$ ), by working time arrangement, in a random sample of 20- to 59-year-old employees in Denmark, 2010.

Working time arrangement	Current smoker		$25 \leq \text{BMI} < 30$		$\text{BMI} \geq 30$	
	%	95% CI	%	95% CI	%	95% CI
32–40 working hours/week	22.6	21.5–23.7	34.7	33.4–35.9	12.9	12.1–13.9
41–48 working hours/week	21.0	18.8–23.5	34.8	32.2–37.5	12.5	10.7–14.5
>48 working hours/week	21.3	18.0–25.2	35.3	31.6–39.5	10.8	8.5–13.7
Without nighttime work	21.6	20.7–22.6	34.5	33.4–35.6	12.7	11.9–13.5
With nighttime work	25.8	22.3–30.0	38.4	34.5–42.8	15.4	12.5–19.0

<sup>a</sup>BMI: body mass index.

Table 7 suggests that the prevalence of smoking, overweight, and obesity tend to be higher among employees who work at night than among those who don't. To get an idea of the extent to which such differences may influence the RR of IHD between employees with and without nighttime work, we calculated an expected rate ratio, E[RR], under the assumption that the groups are equal in all respects other than the smoking and BMI distributions, using equation (2) (Figure 1).

Our calculations imply that a failure to control for smoking, overweight, and obesity (in a study population in which the prevalences are equal to those given in Table 7) would increase E[RR] of IHD between employees with and without nighttime work by a factor of 1.07.

## Results

We expect results to be ready in mid-2017.

## Discussion

This study protocol provides a detailed description of the hypotheses, inclusion criteria, significance levels, and statistical models of a project designed to estimate prospective associations between different types of work time arrangements and IHD in the general working population of Denmark.

Statistics Denmark randomly sampled the participants in the study from the target population and we have strengthened the prospective design by the strategy to exclude prevalent cases.

For nighttime work and long working hours, the statistical power is sufficient (compare [43]), and the nested hypothesis testing ensures that the probability that statistically significant findings will arise by chance alone is <5%.

Since the design of the project is being peer reviewed and published before the exposure data are linked to health data, we have eliminated hindsight and within-study selection bias. We have also eliminated bias from missing follow-up data, since

the clinical end points are ascertained through registers that cover the entire target population.

It has previously been shown that the incidence of IHD is highly dependent on age [44], sex [44], and SES [23,45,46]. It has, moreover, been suggested that employment in the health care sector is associated with referral and prescription bias [23,47,48]. Our statistical models will mitigate the bias from these factors, by incorporating them as control variables. We can, however, not rule out the possibility of bias due to factors that we cannot control for. For example, the EU Working Time Directive stipulates that night workers are entitled to a free health assessment, prior to their assignment and at regular intervals thereafter, and such a stipulation might be associated with detection bias [49].

Another drawback is that the definition of “night worker” that we use in this project differs from the legal definition that is used in the EU Working Time Directive. According to the Danish implementation of the directive, “nighttime” means any period of at least 7 hours, which includes the period between

midnight and 5:00 AM, while “night worker” means “any worker, who, during nighttime, work at least three hours of his daily working time as a normal course” or “any worker who is likely to work at nighttime at least 300 hours during a period of twelve months” [50]. In contrast, our project classifies a participant as a night worker if she or he worked at night either regularly or occasionally during the 4-week period preceding the interview. Prior to 2007, the questionnaire did not specify how to interpret the response categories, but from 2007, “regularly” meant “more than half of the working days in the last 4 weeks,” while “occasionally” meant “at least once within the last 4 weeks, but less than half of the working days.” Hence, some of the night workers in this project would probably not qualify as night workers in a strictly legal sense.

In conclusion, this is an observational study, which cannot be used to confirm etiological hypotheses. It may, however, confirm that long working hours or nighttime work, or both, are predictors for IHD and thereby lend support to the hypothesis of a causal relationship.

## Acknowledgments

The project was initiated by Otto Melchior Poulsen, former research director at the National Research Centre for the Working Environment (NRCWE). It is funded by the Danish taxpayers, through the Danish Work Environment Research Foundation, grant number 20130069288. The data of the project were and will be supplied by Statistics Denmark. Jesper Møller Pedersen and Simone Visbjerg Møller, NRCWE, helped us with project administration and data management.

We would like to thank the members of our advisory committee: Hermann Burr, Bundesanstalt für Arbeitsschutz und Arbeitsmedizin (BAuA); Karen Albertsen, Team Working Life, Denmark; Martin Lindhart Nielsen, Bispebjerg Hospital, Denmark; Jan Hyld Pejtersen, Danish National Centre for Social Research; and Hans Bay, NRCWE.

We would also like to thank Mette Andersen Nexø, Elsa Bach, Elizabeth Bengtsen, Rikke Nilsson, Pia Gøtterup, Tina Norlén Thomsen, and Bodil Holst, NRCWE, for valuable advice and discussions.

## Abstract

**Background:** The treatment of ulcerative colitis (UC) patients with moderate to severe inflammatory activity with anti-tumor necrosis factor alpha (TNF $\alpha$ ) antibodies leads to a clinical remission rate of 10% after 8 weeks of therapy. However, it must be taken into account that patient selection in clinical trials clearly influences both response and remission rates. An unsatisfactory response to anti-TNF $\alpha$  medication after week 12 often leads to a discontinuation of treatment. The early prediction of clinical response could therefore help optimize therapy and potentially avoid ineffective treatments.

**Objective:** The aim of this study is to develop an algorithm for optimizing golimumab administration in patients with moderate to severe UC by calculating the probability of clinical response in Week 26 based on data from Week 6.

**Methods:** The study is designed as a prospective, single-arm, multicenter, non-interventional observational study with no interim analyses and a sample size of 58 evaluable patients. The primary outcome is the prediction of clinical response in Week 26 based on a 50% reduction in fecal calprotectin and a positive golimumab trough level in Week 6.

**Results:** Enrollment started in October 2014 and was still open at the date of submission. The study is expected to finish in December 2016.

**Conclusions:** The early identification of patients who are responding to an anti-TNF $\alpha$  antibody is therapeutically beneficial. At the same time, patients who are not responding can be identified earlier. The development of a therapeutic algorithm for identifying patients as responders or non-responders can thus help prescribing physicians to both avoid ineffective treatments and adjust dosages when necessary. This in turn promotes a higher degree of treatment tolerance and patient safety in the case of anti-TNF $\alpha$  antibody administration.

**Clinical Trial:** German Clinical Trials Register, Deutsches Register Klinischer Studien DRKS00005940; [https://drks-neu.uniklinik-freiburg.de/drks\\_web/navigate.do?navigationId=trial.HTML&TRIAL\\_ID=DRKS00005940](https://drks-neu.uniklinik-freiburg.de/drks_web/navigate.do?navigationId=trial.HTML&TRIAL_ID=DRKS00005940) (Archived by WebCite at <http://www.webcitation.org/6i4Xoo1sH>)

**KEYWORDS**

ulcerative colitis; golimumab; fecal calprotectin; tumor necrosis factor alpha

## Introduction

### Background

The treatment of ulcerative colitis (UC) patients with moderate to severe inflammatory activity with anti-tumor necrosis factor alpha (TNF $\alpha$ ) antibodies leads to a clinical remission rate of 10% (ULTRA1 study, 80/40 mg adalimumab) [1] to 39% (ACT1 study, infliximab 5 mg/kg body weight [2] and SUCCESS study [3]) after 8 weeks of therapy. However, it must be taken into account that patient selection in clinical trials clearly influences both response and remission rates. In addition, the results of these studies are not consistent with those of observational trials with a high degree of target population representativeness. International guidelines therefore recommend that the success of an anti-TNF $\alpha$  therapy beyond the 12-week mark must be predicted as soon as possible in order to adjust or discontinue treatment depending on the clinical situation [1,4-6]. An unsatisfactory response to anti-TNF $\alpha$  medication after Week 12 often leads to a discontinuation of treatment. The early prediction of clinical response could therefore help to optimize therapy and potentially avoid ineffective treatments [7].

In this regard, the PURSUIT study showed that the administration of the new human anti-TNF $\alpha$  immunoglobulin G1 monoclonal antibody golimumab to subjects with moderately to severely active UC induced clinical response in Week 6 after two injections (Weeks 0 and 2) in 51.0-54.9% of patients in a randomized clinical trial, whereas placebo response was 30.3% ( $P<.001$ ) [8].

After 6 weeks, responders in the golimumab group were randomized again to receive either placebo or 50 or 100 mg golimumab doses every 4 weeks for a further 54 weeks. The analysis of clinical response in this trial showed a statistically significant response for golimumab 50 mg versus placebo ( $P<.001$ ) after 54 weeks (47.0% and 31.2% respectively) [9].

### Study Objective

This early Monitoring of Response (MORE) study (DRKS00005940) seeks to achieve a more thorough understanding of therapeutic development in patients with moderate to severe ulcerative colitis receiving regular doses of golimumab. The aim is to develop an algorithm for optimizing golimumab administration in patients with moderate to severe ulcerative colitis by calculating the probability of clinical response in Week 26 based on data from Week 6.

## Methods

### Trial Design

The study is carried out in conformity with the German Medicinal Products Act (Arzneimittelgesetz, AMG) and is a non-interventional study in accordance with the Medicinal Products Act (§ 4 section 23 p. 3 AMG). The study is designed as a prospective, single-arm, multicenter, non-interventional observational study with no interim analyses and a sample size of 58 evaluable patients, for which 61 patients must be recruited.

### Outcomes

#### Primary

The primary outcome is the prediction of clinical response in Week 26 based on a 50% reduction in fecal calprotectin and a positive golimumab trough level of  $>2.5$   $\mu\text{g/ml}$  in Week 6.

Our definition of a clinical response is a reduction in the partial Mayo score by 2 points between baseline and Week 6, or a partial Mayo score of  $\leq 1$  in Week 6.

#### Secondary

In addition to the primary study goal, the following secondary outcomes are analyzed:

1. At which point in time is a 50% reduction in fecal calprotectin a reliable predictor of response?
2. How strong is the correlation between antibody towards golimumab (ATG) level and fecal calprotectin level?
3. How strong is the correlation between ATG and the partial Mayo score?
4. How strong is the correlation between golimumab trough level and fecal calprotectin?
5. How strong is the correlation between golimumab trough level and the partial Mayo score?
6. Do the following parameters exert any influence on clinical response?
  - a) C-reactive protein (CRP)
  - b) white blood cells (WBC) count
  - c) hemoglobin
  - d) platelet count
  - e) ferritin
7. Frequency of adverse reactions

### Statistics

#### Analysis

Our aim is to study the detection of a positive trough level of golimumab of  $>2.5$   $\mu\text{g/ml}$  and a significant reduction in fecal calprotectin of 50% from baseline in Week 6 as a reliable predictor for clinical response in Week 26 during long-term treatment with golimumab. In this connection, a level between 2.5  $\mu\text{g/ml}$  and 4.3  $\mu\text{g/ml}$  is regarded as being associated with a therapeutic effect of golimumab [8,9].

Statistical analysis is mainly carried out with descriptive methods such as frequency tables, and statistical parameters such as mean, standard deviation, and quantiles. Bar graphs are used for qualitative data and box-and-whisker plots for quantitative data. In addition, inferential statistical analysis is carried out with relevant significance tests and confidence intervals. Missing data are not imputed.

In order to evaluate the primary outcome, the test problem presented in the section on statistical hypotheses is formulated and solved. The test is carried out with a power of 80% and a

two-tailed significance level of  $\alpha=0.05$ . Analysis is carried out with a logistic regression model based on the percentage change of fecal calprotectin and golimumab trough levels. In addition, secondary parameters (eg, ATGs, CRP, WBC) are also analyzed to identify further correlations between the data of Week 6 and therapy outcome in Week 26. The aim is to identify further constraints to the statistical model in order to take into account all relevant parameters in the final version of the algorithm. Secondary outcomes are assessed in an explorative way, that is, no pre-formulated hypotheses are tested. The *P* values obtained are thus interpreted according to Fisher's method: a *P* value is considered a metric value, and the smaller the *P* value, the larger the significance of the corresponding effect. No interim analyses are planned. Data analysis is carried out only once, at the end of the study.

### Hypotheses

The following two-tailed test problem is used for the primary outcome:

Hypothesis 0:  $\beta_1=0$  versus Hypothesis 1:  $\beta_1 \neq 0$ , where  $\beta_1$  is the coefficient of the logistic regression model, and

null hypothesis:  $H_0$ . There is no correlation between a significant reduction in fecal calprotectin of 50% from baseline in Week 6 and clinical response to therapy with golimumab in Week 26.

Therefore, our research hypothesis,  $H_1$ , is that there is a correlation between a significant reduction in fecal calprotectin of 50% from baseline in Week 6 and clinical response to therapy with golimumab in Week 26.

### Sample Size

#### Rationale

Sample size is planned based on data from studies researching a correlation between fecal calprotectin and response to an anti-TNF $\alpha$  therapy.

De Vos et al [10] describe response rates as: "After 10 weeks anti-TNF $\alpha$  therapy induced endoscopic remission in 63% (confidence interval: 47–78%) of patients". Molander et al [11] describe the correlation between the predictive quality of fecal calprotectin and the remission rate. The results are displayed in Table 1.

**Table 1.** Cross classification of fecal calprotectin predictive quality and remission.

	Fecal calprotectin decline		Total
	Yes	No	
Remission			
Yes	30	3	33
No	6	21	27
Total	36	24	60

Based on these results, the odds ratio (OR) is calculated as  $OR = (30 \times 21) / (6 \times 3) = 35$ . It should be noted that for the above study the cut-off point for fecal calprotectin decline was a reduction of >75% from baseline. Lower cut-off points, for example, a 50% reduction, would lead to smaller OR, as the number of patients with neither decline nor response is described as being almost constant in the above-mentioned literature: "Absence of decrease in calprotectin levels at week 6 identified patients resistant to the treatment" [11]. It is therefore assumed for sample size calculation that 80% of the patients will have a "fecal calprotectin decline." Table 2 summarizes the scenarios that have been taken into consideration.

**Table 2.** Sample size rationale: Response rates and their effect on resulting OR for 9 different scenarios.

Scenario	Response rate (%)	OR
1	40	10
2	40	20
3	40	30
4	50	10
5	50	20
6	50	30
7	60	10
8	60	20
9	60	30

### Calculation

Sample size calculation is carried out with the statistical analysis software SAS. Table 3 shows the required number of evaluable

patients for each scenario. It is expected that 5% of the intention-to-treat principle population will be excluded. Sample size is inversely proportional to the OR and the response rate.

**Table 3.** Sample size calculation: Number of evaluable subject and total number of subjects considering dropouts for 9 different scenarios.

Scenario	Response rate, %	OR	Evaluable subjects, n	Subjects including potential dropouts, total n
1	40	10	58	61
2	40	20	40	42
3	40	30	34	36
4	50	10	50	53
5	50	20	34	36
6	50	30	29	31
7	60	10	45	48
8	60	20	31	33
9	60	30	26	28

To prevent study failure due to an underpowered study, a worst case scenario with a response rate of 40% and an OR of 10 is used as a basis for sample size. A total of 58 evaluable subjects are therefore necessary for the trial, thus 61 patients must be recruited.

### Study Population

The evaluation of primary and secondary outcomes is carried out according to the intention-to-treat principle. The corresponding population comprises all patients included in the study regardless of possible protocol violations (eg, dropouts). In addition to intention-to-treat analysis, sensitivity analysis according to the per-protocol principle is carried out. Relevant protocol violations leading to exclusion from the per-protocol group are defined in the statistical analysis plan.

### Selection of Study Centers

All study centers are part of the German Inflammatory Bowel Disease (IBD) Study Group and are chosen according to their main area of focus and their experience in the treatment of UC. By signing the investigator agreement, each study center selected confirms its fulfilment of all formal requirements for inclusion in the study and guarantees its compliance with data privacy laws and any other regulations pertaining to the execution of this observational study.

### Participant Criteria

The inclusion criteria for the study include (1) clinically and endoscopically confirmed diagnosis of UC, (2) study-independent treatment with golimumab according to current medical practices, (3) age  $\geq 18$  years, (4) sufficient German language communication skills, (5) ability of the patient to understand the nature, significance, and scope of the clinical trial and make an independent decision based on this knowledge, and (6) elevated calprotectin levels ( $\geq 100$  mg/L or  $\geq 100$  mg/kg) within 3 weeks prior to inclusion.

Our exclusion criteria include (1) infectious colitis, (2) off-label treatment with golimumab, or (3) treatment with golimumab within the previous 3 months.

### Study-Specific Interventions

No medical interventions are carried out in the course of the study other than those required by standard medical procedure. When taking routine blood samples, golimumab serum levels and ATG levels should also be monitored if possible. Only the natural progress of the disease in UC patients is monitored and evaluated.

### Schedule of Visits

There are no defined study visits. In the course of the study, the only clinical and laboratory data recorded are those corresponding to standard medical procedure. Data are recorded in the following observational weeks: baseline, 2, 6, 14, 22, and 26. Deviations of  $\pm 3$  days from this documentation schedule fall within the scope of the study protocol. The period until the next examination is subsequently shortened or lengthened accordingly in order to compensate for deviations and maintain the examination rhythm.

The following data are recorded at the initial screening/baseline examination: date of consent, screening date, inclusion and exclusion criteria, personal information (date of birth, sex, height, weight), date of initial diagnosis, information regarding prior anti-TNF $\alpha$  medication, partial Mayo score, laboratory tests (hemoglobin, WBC, platelet, ferritin, CRP, fecal calprotectin, and ATG), and medication (dose of golimumab, cortisone, and azathioprine).

The following data are recorded during each subsequent examination (week 2, 6, 14, 22, and 26) in the course of the study: partial Mayo score, laboratory tests (hemoglobin, WBC, platelet, ferritin, CRP, and fecal calprotectin), and medication (dose of golimumab, cortisone, and azathioprine). In addition, in Weeks 2 and 6, golimumab trough serum levels and ATG are measured.

### Documentation

Data are recorded using case report forms (CRF). The investigator is responsible for the timely, correct, complete, and legible recording of study data in the CRF and confirms recording by signature. CRF are completed with a black ballpoint pen. Corrections are documented as follows. The wrong entry is crossed out with a single line, and corrections

are entered next to the crossed-out text and verified by date and initials, stating the reason for the change if necessary. Instructions for use (entry and corrections) are included in each CRF. Source data according to the ICH E6 guideline on good clinical practice (GCP) are original documents in patient files, as well as doctors' letters, certified copies of original records, and laboratory printouts. In addition, all patient questionnaires (self-reporting) are also considered source data. Study data are to be recorded from patient files.

### **Patient Identification**

All patient data are pseudonymized. Each patient will be clearly identified by a patient identification number assigned at each study center. The investigator will keep a patient identification list documenting the patient identification number with the patient's full name, date of birth, sex, and date of informed consent.

The patient identification list is part of the investigator file and will remain at the clinic. The patient identification number consists of a 2-digit clinic number, a hyphen, and a running 3-digit number of recruited patients per study center.

### **Trial**

#### ***Start of Patient Participation***

Any patient with a clinically and endoscopically confirmed diagnosis of UC and qualified for golimumab treatment according to routine medical practice is a potential study candidate. All potential candidates who come to the attention of the investigator will be informed regarding the possibility of participating in the study. Potential candidates interested in participating in the study will be promptly informed about the study in order to obtain their informed consent in accordance with the section "Patient Information and Informed Consent".

#### ***End of Patient Participation***

The observation of each patient ends according to the schedule with the last study visit. A patient's participation in the study will be terminated prematurely if at least one of the following criteria is met: (1) withdrawal of informed consent, (2) termination of golimumab treatment, (3) lack of medical justification for further participation in the study, (4) premature termination of the complete trial, or (5) subsequent discovery that not all inclusion criteria are met and/or that any exclusion criteria are met.

#### ***Trial Duration/End of Trial***

The recruiting phase has a planned duration of 18 months. The observational phase has a planned duration of 26 weeks. The complete trial is considered to have ended after all queries from the study coordination center have been answered by each individual study center, but at the latest 4 months after the last visit of the last patient.

Study centers that grossly violate the AMG, data protection regulations, or the GCP guidelines can be excluded from the further recruitment and observation of study patients. Premature termination of the study as a whole will be taken into consideration if ethical or scientific justification for the trial is compromised or no longer valid, errors or violations

significantly compromise the scientific integrity of the data collected for the study with regard to the study aims, or the requirements for a successful execution of the study are no longer fulfilled for other reasons.

The principal investigator will consult the corresponding biometrician regarding any possible premature termination of the trial. The minutes of the aforementioned consultation meeting will be recorded and subjected to the approval of both parties. Any decision regarding the premature termination of the trial will be taken jointly by the principal investigator and the corresponding biometrician.

### **Data Quality Assurance**

Upon receipt at the study coordination center, CRF will be checked for completeness and consistency (in-house review). Queries will be generated for missing or implausible entries and sent to the corresponding study centers. After the clarification of implausible entries and completion of missing data, CRF will be handed over to the corresponding data management department for data entry.

### **Quality Control and Assurance**

Quality control in the study is ensured by the possibility of monitoring the study centers involved. For each monitoring visit, a monitoring report is generated documenting the progress of the observational study and describing any problems that may have arisen. The exact nature and extent of the monitoring activities are described in a separate monitoring manual. All investigators declare their consent to regular visits of study monitors to the study centers. In addition, they must provide direct access to all necessary study documents, including original patient documents relevant to the study. The principal investigator and/or auditors designated by the principal investigator are entitled to conduct audits at the study centers and any other facilities participating in the study. They are entitled to inspect and review all study-relevant documents. This right also applies to regulatory inspectors.

### **Ethical and Regulatory Aspects**

The study is conducted in compliance with the current version of the Declaration of Helsinki (10/2013, Fortaleza, Brazil). This study cannot begin before approval has been obtained from the corresponding ethics committee. Prior to inclusion in the study, the investigator will inform each patient about the nature, significance, risks, and scope of the study, as well as the patient's right to withdraw from the study at any time without prejudice. An informed consent form is handed to the patient describing the study in non-scientific and generally understandable language. Each patient must consent to study participation in writing. The patient must be provided with ample time to make a decision and given the opportunity to ask any questions before the consent form is signed. In accordance with AMG, § 40 Abs. 2a, patients are informed that the data related to their disease will be stored with a pseudonym and analyzed for scientific purposes. Patients must consent to the use of their pseudonymized data in writing. Informed consent forms are to be signed and dated by the patient and the treating physician.

This clinical study is carried out in conformity with the requirements of the current German Medicinal Products Act, as well as all applicable legal provisions regarding data protection and the GCP guidelines. The general notification requirement as per § 67 AMG will be complied with.

## Results

Enrollment started in October 2014 and was still open at the date of submission. The study is expected to finish in December 2016.

## Discussion

### Rationale for the Trial

The early identification of patients who are responding well to an anti-TNF $\alpha$ -antibody is therapeutically beneficial. At the same time, patients who are not responding can be identified earlier. The development of a therapeutic algorithm for identifying patients as responders or non-responders can help prescribing physicians both to avoid ineffective treatments and to adjust dosages when necessary. This in turn would promote a higher degree of treatment tolerance and patient safety in the case of anti-TNF $\alpha$  antibody administration.

There is a clear association between detectable trough levels of anti-TNF $\alpha$  inhibitors and clinical therapeutic response. On the other hand, the detection of anti-drug antibodies is associated with a poor response.

Fecal calprotectin levels reflect mucosal inflammation status. The strong correlation between high fecal calprotectin and mucosal inflammation has been widely described. Furthermore,

it is also clear that fecal calprotectin levels decrease if there is therapeutic response.

A regular question among IBD patients is how long they will have to take their medication in total. Yet there is currently insufficient data regarding optimal treatment length with TNF $\alpha$  inhibitors. In view of the elevated costs and possible side effects associated with this type of treatment, it is desirable to clearly define a patient population for which continued therapy is justifiable.

### Justifications for Trial Design

This study is prospective, as the aim is to use the data from trial Week 6 to calculate the probability of clinical response in Week 26. Only one study cohort is required to answer this question, and no comparison group is necessary.

In order to achieve a higher degree of representativeness of the results for the intended population, the trial is carried out throughout Germany and at multiple centers specifically chosen for this purpose. Treatment, including diagnosis and monitoring, does not follow a predefined study protocol and is carried out exclusively in accordance with current medical practices. The aim of this non-interventional approach is to ensure a high degree of representativeness of the study results for daily medical practice.

### Conclusion

This early Monitoring of Response (MORE) study aims to achieve a more thorough understanding of therapeutic development in patients with moderate to severe ulcerative colitis receiving regular doses of golimumab by developing an algorithm for optimizing golimumab administration in patients with moderate to severe ulcerative colitis.

## Acknowledgments

This study is supported by MSD Sharp & Dohme GmbH (Haar, Germany) and the German IBD Study Group (Kiel, Germany).

The authors are grateful to all parties involved in the study, the study coordinating center German IBD Study Group, the sites, and the participants.

## Authors' Contributions

All authors contributed to design of the study protocol, revision of draft article, and final approval of version to be published.

## Conflicts of Interest

## Abstract

**Background:** Because vital details of potential pharmacokinetic drug-drug interactions are often described in free-text structured product labels, manual curation is a necessary but expensive step in the development of electronic drug-drug interaction information resources. The use of nonexperts to annotate potential drug-drug interaction (PDDI) mentions in drug product label annotation may be a means of lessening the burden of manual curation.

**Objective:** Our goal was to explore the practicality of using nonexpert participants to annotate drug-drug interaction descriptions from structured product labels. By presenting annotation tasks to both pharmacy experts and relatively naïve participants, we hoped to demonstrate the feasibility of using nonexpert annotators for drug-drug information annotation. We were also interested in exploring whether and to what extent natural language processing (NLP) preannotation helped improve task completion time, accuracy, and subjective satisfaction.

**Methods:** Two experts and 4 nonexperts were asked to annotate 208 structured product label sections under 4 conditions completed sequentially: (1) no NLP assistance, (2) preannotation of drug mentions, (3) preannotation of drug mentions and PDDIs, and (4) a repeat of the no-annotation condition. Results were evaluated within the 2 groups and relative to an existing gold standard. Participants were asked to provide reports on the time required to complete tasks and their perceptions of task difficulty.

**Results:** One of the experts and 3 of the nonexperts completed all tasks. Annotation results from the nonexpert group were relatively strong in every scenario and better than the performance of the NLP pipeline. The expert and 2 of the nonexperts were able to complete most tasks in less than 3 hours. Usability perceptions were generally positive (3.67 for expert, mean of 3.33 for nonexperts).

**Conclusions:** The results suggest that nonexpert annotation might be a feasible option for comprehensive labeling of annotated PDDIs across a broader range of drug product labels. Preannotation of drug mentions may ease the annotation task. However, preannotation of PDDIs, as operationalized in this study, presented the participants with difficulties. Future work should test if these issues can be addressed by the use of better performing NLP and a different approach to presenting the PDDI preannotations to users during the annotation workflow.

## Introduction

Exposure to interacting drug combinations can lead to patient harm. Recent estimates indicate that between 5.3% and 14.3% of hospital patients in the United States experience a clinically meaningful alteration in the exposure or response of one drug occurring as a result of coadministration of another drug [1]. Fortunately, such harm can often be avoided by employing appropriate management strategies [2]. Toward that goal, US federal regulations require the mention of known, clinically relevant potential drug-drug interactions (PDDIs) in prescription drug labeling [3,4].

Structured product labels (SPLs) are mandated by the US Food and Drug Administration. The labels, produced by pharmaceutical manufacturers, are presented in a standardized format [5] and approved by regulators. As detailed descriptions subject to regulatory approval, SPLs play a vital role in disseminating drug information. However, the structure in these documents is only in the form of high-level sections such as *Description*, *Indications and Usage*, *Contraindications*, and *Warnings*. Specific PDDI details are given in plain text, tables, and figures within the *Drug Interactions* section or other locations throughout the label. Although future efforts may lead to more structured and therefore more computable labels, the regulatory importance of the SPLs and the legacy labels of more than 16,000 drugs make the labels key resources for drug-drug interaction information.

Unfortunately, product labeling is incomplete. A study of drugs that interact with the narrow therapeutic range drug warfarin found PDDI information deficiencies in 15% of relevant product labels [6]. A broader study of drugs sold in the United States, United Kingdom, and Germany found that a warning about a critical drug interaction was missing from the label of one of the interacting drugs at least 40% of the time [7]. Although publicly available PDDI information sources can serve as useful adjuncts to product label information, these collections are often far from complete. Our recent analysis of 14 collections of PDDI information found significant divergence, with overlap between pairs of sources usually less than 50% [8]. Addressing the issue of missing product label PDDI information is important to better meet the information needs of drug experts, clinicians, and patients.

We hypothesize that a computable representation of PDDIs present in product labels and other high-quality sources will enable novel methods for drug information retrieval that will in turn provide researchers and clinicians with improved capabilities for finding complete and current DDI information. Testing this hypothesis requires an efficient means of generating computable representations of PDDI mentions.

In prior work, we developed a prototype system that used simple named entity recognition (NER) and Semantic Web Linked Data [9] to link claims about PDDIs from publicly available external resources to the *Drug Interactions* section of the product label [10]. Experiments found that our system linked at least

one potentially novel interaction (ie, not mentioned in the label) to the *Drug Interactions* section of product labeling for 20 antidepressants. Moreover, there were several cases where all of the PDDI mentions linked to the *Drug Interactions* section for an antidepressant were potentially novel and would complement product label information. For example, an interaction between escitalopram and tapentadol mentioned in the National Drug File-Reference Terminology [11,12] was potentially novel to all 20 escitalopram product labels.

While promising, the simple NER approach often missed potentially important links between the label and other sources. Sophisticated natural language processing (NLP) methods might prove to be more complete, accurate, and scalable than simple NER. However, there is reason to believe that even the best NLP methods would not perform well enough to guarantee automatic identification of all PDDI mentions across all drug product labels. The PDDI NLP algorithm that performed best against the 2013 SemEval Challenge text corpus had a sentence-level recall of 0.81 and a precision of 0.86 ( $F_1=0.84$ ) [13]. An algorithm we developed in prior work focusing specifically on NLP identification of pharmacokinetic PDDI mentions within product label sections had a document level recall of 0.84 and a precision of 0.88 ( $F_1=0.86$ ) [14] (sentence-level performance was not evaluated).

Based on these findings, we have concluded that the involvement of human curators is necessary for the task of generating computable representations of PDDIs present in product labels and other high-quality sources. The use of semiautomatic curation is relatively common in biomedicine [15]. Unfortunately, the high cost of expert annotation is a major potential barrier to further progress. New approaches are needed to increase the scale and quality of data curation.

Replacing experts with nonexpert crowds (crowdsourcing) can increase the feasibility of large-scale annotation tasks for biomedical data [16-18]. Initial efforts at crowdsourcing for the annotation of medical text have found the method to be effective when the workflow is properly managed [16]. Results can be comparable in quality to those obtained via more traditional and expensive expert annotation methods [17]. Crowdsourcing is particularly attractive for obtaining results faster and at a lower cost than other participant recruitment schemes [17]. The Informatics for Integrating Biology and the Bedside (i2b2) 2010 workshop assessment found that a well-selected group of nonexperts could perform extraction of drug information from clinical reports [19]. Other biomedical efforts have applied crowdsourcing to gene-mutation mentions in the biomedical literature [20] and for clinical trial announcements [21]. A study of the feasibility of using people recruited through Amazon's Mechanical Turk to annotate medication indications found that nonexperts could achieve accuracy of greater than 95% on the binary question of whether a medication is an indication for a disease mentioned in the medication's drug label [22]. Similar approaches have been used to engage communities of experts in tackling challenges such as linking medications and problems

in clinical texts from electronic medical records [23,24] and developing mappings between institutional procedure descriptions and Logical Observation Identifiers Names and Codes (LOINC) [25,26].

Our experience with NLP methods for extracting PDDI annotations suggests the possibility of using NLP annotation to provide suggestions to human annotators. Previous efforts have explored the possibility of using such preannotation. Hanauer et al [27] found that iterative alternation between human annotation and model building facilitated rapid creation of NLP models. Some comparative studies have shown that preannotation can improve annotator performance relative to unassisted annotation [28-30], but other studies have seen no difference [31].

The goal of this study was to assess the potential feasibility of using persons who are not drug experts in the task of annotating PDDIs mentioned in drug product labels. A secondary goal was to test the influence of NLP assistance on the annotation quality of both experts and nonexperts.

## Methods

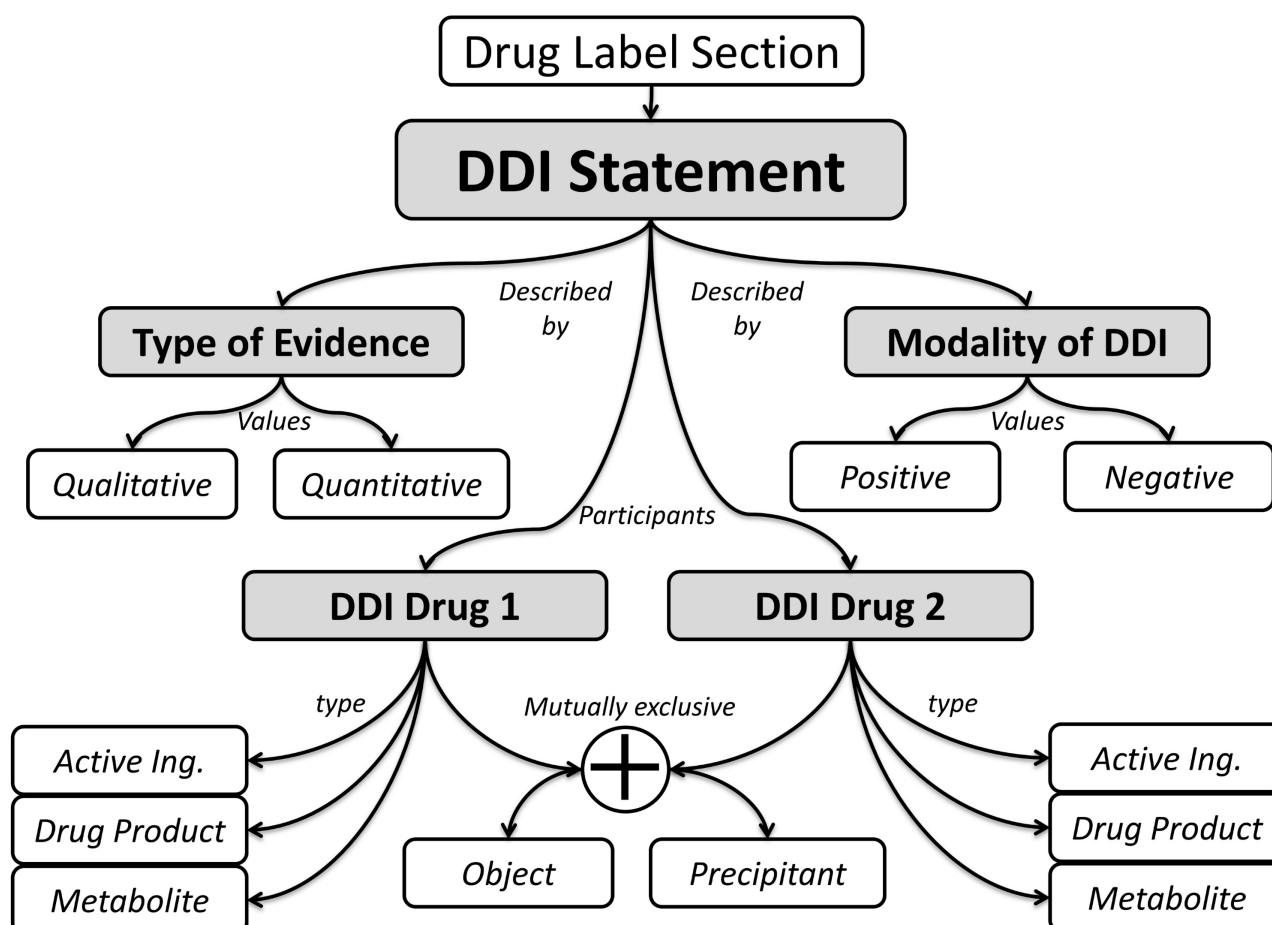

### The Annotation Model

PDDI annotation requires a data model that describes the types of information that must be collected. The PDDI data model

used in this study is given in Figure 1. Each PDDI mention is extracted from a span of sentences present within a product label and can include four features:

- Type of evidence (active ingredient, metabolite, or drug product): an active ingredient is a pharmacologically active chemical component used in a drug product. A metabolite is a biochemical entity produced as a result of drug metabolism. A drug product is a packaging of an active ingredient for sale or distribution, often identified by a brand name. Throughout this paper, we use the generic term “drug” to mean any of these three types.
- Role (object or precipitant): the role that each drug plays within the interaction. In pharmacokinetic PDDIs the precipitant drug affects an enzyme that regulates the absorption, distribution metabolism, or excretion of the object drug.
- Statement (quantitative or qualitative): an indication of whether the PDDI mention describes the pharmacokinetic effect of a DDI in quantitative terms (50% increase) or qualitative terms (increase or decrease) with no indication of magnitude.
- Modality (positive or negative): whether the PDDI mention is making a positive or negative claim. A positive claim is one that supports the existence of the interaction. A negative claim is one that explicitly states that no interaction exists between the drugs in question.

**Figure 1.** Data model used in this study for PDDIs mentioned within drug product labels.

## Natural Language Processing Pipeline and Postprocessing Module

In prior work, we developed algorithms for extracting drug named entities and pharmacokinetic PDDI mentions from drug product labels [14]. We integrated our NLP algorithms into a preannotation pipeline (Figure 2). The pipeline used the following steps:

1. The NLP process applies NER to each product label section [32]. The NER algorithm uses the National Center for Biomedical Ontology BioPortal Annotator to extract drug mentions and synonyms from the RxNorm and MeSH terminologies [33]. The results are postprocessed to improve recall and precision by filtering out entities that are not active ingredients, drug products, or metabolites based on entity relationships provided by RxNorm and WordNet [34].
2. Output from the NER process is then processed by an NLP algorithm for identifying pharmacokinetic PDDI mentions [14]. For each product label section, the PDDI extraction algorithm outputs a table of sentence spans labeled as to whether they include a pharmacokinetic PDDI (true or false). Spans including PDDI mentions are also labeled to indicate the modality of the mention (positive or negative). Output of the NLP algorithm is passed to a postprocessing module designed to increase the process's precision and recall (Figure 2). This module uses RxNorm relationships and exact case-insensitive matching to map drug product mentions to unique identifiers of the sole active ingredients.
3. The PDDI mentions present in the corpus are transformed into a machine-readable annotation schema using the Open Annotation data model [35], necessary for subsequent loading into the study annotation tool.
4. Finally, the resulting preannotated named entities and PDDI mentions are loaded into the study annotation tool.

**Figure 2.** Pipeline for extraction of pharmacokinetic PDDIs from drug labels sections.

## Reference Standard

In an earlier study, we developed a corpus of 208 annotated PDDI statements from SPLs. Two experts in drug information used the data model described above to annotate these sections, with subsequent discussions used to develop a consensus model. The resulting corpus contains 607 pharmacokinetic PDDI mentions along with 3351 active ingredients, 234 drug products, and 201 metabolite mentions [14]. These sections were used in the current study, with the consensus annotations acting as a gold standard.

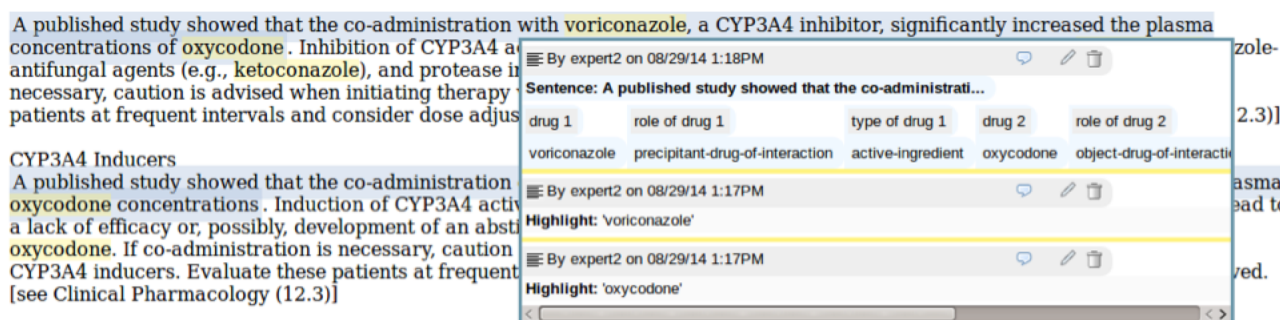

## Drug-Drug Interaction Annotation Tool

Participants used a custom-designed user interface (Figure 3) based on the DOMEO Web-based system [36] to annotate PDDI

mentions. DOMEO is an extensible Web application that supports scalable Web-based annotation necessary for crowdsourcing efforts [37]. We extended DOMEO with a plugin that can be used to link text in drug label sections with details of the PDDI data model (Figure 1) [38]. To complete a PDDI annotation task, users would view a product label section and select one or more sentences from the section that discusses the PDDI. They would then use our PDDI annotation plugin to provide values in a Web form indicating the two drugs involved in the interaction, the type and role for each drug, the type of PDDI mention (quantitative or qualitative), and the modality of the mention (positive or negative).

**Figure 3.** Screenshots of the DOME0 PDDI annotation plugin: (a) product label excerpt with text selected by an annotator as being relevant to a PDDI and (b) form with the fields that the annotator must complete in order to describe the PDDI using the data model described in Figure 1.

(a)

(b)

## Annotation Scenarios

We explored four annotation scenarios aimed at assessing the impact of different approaches to NLP preannotation. The 208 product label sections from our reference standard [14] were distributed across four scenarios so that each scenario had roughly the same number of long and short sections:

- Scenario 1 (no assistance) consisted of 52 label sections with no NLP assistance for annotation. Annotators had to read and highlight all drugs and PDDI mentions within the assigned drug label sections.
- Scenario 2 (drug mentions) consisted of 52 drug label sections with preannotations for drug mentions but not PDDI mentions. Annotators had to correct preannotated drug mentions, identify any drug mentions that the NLP missed, and highlight all PDDIs mentioned in the label sentences.
- Scenario 3 (drug mention plus PDDIs) consisted of 53 label sections preannotated with both drug and PDDI mentions. The annotator had to edit and correct NLP preannotations and add any mentions missed by the NLP.

- Scenario 4 (no assistance, second time), a second completely unassisted scenario, was included with the intent of measuring any learning effects associated with the completion of the NLP-assisted tasks. This scenario consisted of 48 drug label sections.

Each participant completed all four scenarios in order. Three of the 208 sections were reserved for training purposes to familiarize participants with the annotation tool and process, leaving 205 sections to be annotated by each participant.

## Participants

A drug expert was defined as a professional in pharmacy or related field with a Doctor of Pharmacy degree or equivalent and more than five years' experience in drug-drug interaction research. A drug nonexpert was defined as an undergraduate or graduate student with some basic training in chemistry. Both expert and nonexpert participants were recruited from personal contacts of the investigative team. All participants were compensated for participating in this study. The University of Pittsburgh Institutional Review Board approved the study protocol as exempt.

## Annotator Guidelines and Training

Annotators were provided with guidelines describing the annotation task. Guidelines were written based on assumption of college-level formal training in chemistry (eg, general chemistry) for both groups. The complete guidelines are provided in [Multimedia Appendix 1](#). Participants attended a half-day training session that introduced the goal of the annotation task and provided the annotation guidelines.

## Annotation Tasks

Each participant completed all of the four scenarios in the order given above. For each task, the annotators were asked to read the entire content of the relevant drug label sections, identify all drug and PDDI mentions, and record information about the PDDI corresponding to the PDDI annotation model. They were also asked to self-report the amount of time it took to completely annotate each section. The results of each training task were verified to ensure that each annotator completed each scenario according to the study requirements. A short questionnaire completed at the end of each scenario included closed- and open-ended questions about the participant's perception of the usability and effectiveness of the annotation tool and NLP preannotation.

## Annotation Performance Metrics

Performance metrics were calculated by comparing the PDDIs in each participant's results with the reference standard described above [14]. User's annotations were considered true positives if they (a) matched the precipitant, object, and modality of the reference standard and (b) used sentences that either partially or exactly overlapped the sentences used in the reference standard. Metrics were computed by label and then averaged by scenario.

We supplemented the standard metrics of precision, recall, and  $F_1$  with additional metrics to gain more insight into the effect of NLP preannotation on the PDDI annotation task. Specifically, for Scenario 3 (ie, the full NER plus NLP preannotation), we evaluated how often participants decided to change NLP annotations and whether those NLP annotations agreed or disagreed with the reference standard.

## Results

Two experts and 4 nonexperts were recruited into the study. One expert left the study after experiencing too many difficulties with the PDDI annotation user interface. One nonexpert left the

study because of not having time to complete annotations due to work and school commitments. The remaining participants completed the annotation task for all scenarios.

Annotation performances measured in  $F_1$  score relative to the reference standard [14] indicate relatively strong performance ( $F_1 > 0.7$ ) for all participants for the first two scenarios, with a drop in performance for the last two scenarios. ([Figure 4](#) and [Table 1](#); full recall and precision results in [Multimedia Appendix 2](#)). The performance of the entire NLP pipeline is included for each scenario for comparison even though participants were only provided PDDI preannotations in Scenario 3.

[Tables 2](#) and [3](#) summarize self-reported task completion times and subjective feedback across the first three scenarios. As Scenario 4 was conducted solely to assess learning effects, task completion time and subjective responses were not collected. Participants differed in their reports of time required, ranging from Nonexpert 1 reporting times comparable to those of the expert to Nonexpert 3 reporting more than 5 hours spent completing Scenario 3 ([Table 2](#)).

Results from the subjective question assessing ease of use are given in [Table 3](#). Users agreed that the PDDI annotation interface was moderately difficult when full preannotation assistance was enabled and also agreed that the PDDI annotation plugin without NLP assistance or using a lower level of assistance is relatively easy to use. Full questionnaires and results are given in [multimedia appendices 3-7](#).

[Tables 4](#) and [5](#) illustrate the agreement between the participants, NLP, and reference standard in the scenario with NLP and preannotation assistance (Scenario 3). [Table 4](#) addresses performance on the 151 PDDI annotations found in the reference standard, while [Table 5](#) summarizes false positives—mentions extracted in the NLP or by users that were not found in the reference standard.

Though exploratory because of the very small sample size, success in detecting true-positive PDDI mentions missed by the NLP was similar between the expert and nonexperts ([Table 4](#), column 2). The expert also had slightly more false negatives than the nonexpert participants irrespective of whether spans were found by NLP ([Table 4](#), columns 1 and 3). False-positive rates for the expert were comparable to those of the nonexperts ([Table 5](#), column 1). Nonexperts also seemed to be slightly more likely to agree with false-positive mentions extracted by the NLP ([Table 5](#), columns 2 and 3).

## Discussion

### Overview

Our long-term goal is to develop tools that will deliver computable representations of reliable, accurate PDDI information to clinicians, facilitating decision support and hopefully reducing adverse events. The number of drugs that might need to be addressed (more than 16,000) and the complexity of the content in the SPLs make this a daunting task. Our experience in building NLP tools for the extraction of PDDI information [10,14] illustrated some of the difficulty and led us to the conclusion that some amount of manual involvement in the process was required.

Our goal in this study was to address two key questions in the development of human-assisted processes for curating PDDI information. Specifically, who should conduct the annotation and what sort of assistance should they receive? Although pharmacists and other domain experts familiar with drug information presumably have the background and training necessary to interpret SPLs, annotation by experts is often prohibitively difficult. Thus, we set out to gain some preliminary insight into the practicality of asking participants not specifically trained in drug information to annotate this data. Second, we were interested in understanding what level of assistance might be helpful for users. If our NLP tools were found to speed completion of annotation tasks without reducing accuracy, this would decrease the cost of PDDI annotation even for nonexperts.

### Is It Possible for Nonexperts to Produce Reliable PDDI Annotations From Drug Labels?

Annotation results from the nonexpert group were relatively strong in every scenario and better than the performance of the NLP pipeline (Figure 4). These findings suggest that nonexperts might be able to produce reliable PDDI annotations from drug

labels with accuracy levels similar to those of experts and that crowdsourcing might be a feasible option for annotating PDDIs across a broader range of drug product labels. Our results are consistent with earlier demonstrations of the feasibility of applying crowdsourcing to related problems in annotation of biomedical texts [19-22].

Ensuring the success of nonexpert annotations of PDDI mentions will likely require greater attention to two key issues: the usability of the annotation tools and the selection of the annotators.

Although self-reported task completion times (Table 2) indicated that two of the nonexperts were able to complete all tasks in times comparable to those of the expert, one nonexpert (Nonexpert 3) needed substantially more time. Differences in F<sub>1</sub> scores (Table 1) suggest that annotations provide by Nonexpert 3 were of slightly lower quality than those of the other two nonexperts. The combination of increased task-completion time and lower F<sub>1</sub> scores suggest that Nonexpert 3 may have struggled more than the other participants with the annotation task. In addition, difficulties with the annotation interface prevented one expert user from completing the annotation tasks.

Despite these difficulties, responses to the usability questions (Table 3) were generally positive, suggesting that usability concerns should not be insurmountable. The small sample size and self-reported time results limit our ability to develop a nuanced understanding of specific issues that might have led to increased task completion times or dissatisfaction with the user interface. Observational user studies, including think-aloud feedback from participants, would likely provide insight into usability problems, potential opportunities for redesign [39], and any difficulties associated with the longer task completion times and lower performance of Nonexpert 3.

Results from the repeated no assistance scenario (Scenario 4) do not appear to show any learning effect based on the previous three scenarios. Exposure to the preannotations in scenarios 2 and 3 may have confused participants, pointing out complexities in interpretation of the labels that might have negatively impacted performance.

Identification of individuals who are likely to produce high-quality results will be a key challenge for successful nonexpert annotation results. Although our nonexpert participants all had relevant educational backgrounds and computer experience, variations in the task completion times and  $F_1$  scores suggest that some participants might find PDDI annotations more approachable than others. Future nonexpert PDDI annotation recruitment might draw on experience from prior efforts in crowdsourcing which have found that appropriate screening and training of participants can help improve outcomes [40,41].

### What Is the Influence of NLP Assistance on Annotation Quality?

Most participants perceived PDDI annotation to be easier when NER preannotation was provided. However, the full NLP assistance (Scenario 3: drug mention plus PDDI preannotations) was associated with lower levels of perceived usability for both expert and nonexpert participants (Table 2). Complaints about deleting false positives were commonly expressed in the questionnaire data. These results suggest that the performance of the NLP algorithm and the presentation of NLP preannotated PDDIs might have adversely impacted participant performance. Participants suggested several possible improvements, including preannotating with NER and then presenting NLP preannotations only after a section is annotated. The purpose then would be to highlight possibly missed interactions. We think this approach would depend on an NLP algorithm with much better sentence-level performance than the algorithm used in this study.

Although exploratory, the comparison of the agreement between users, NLP preannotations, and the reference standard (tables 4 and 5) suggests several questions for future study. The expert was slightly less likely than the nonexperts to correct NLP false negatives (Table 4, column 1), possibly because the expert might have inappropriately used knowledge of the domain or applied an overly strict interpretation of the PDDI identification guidelines. The expert user was also more likely to reject a correct NLP interpretation (Table 4, column 3) and more likely to reject an incorrect NLP assertion (Table 5, column 2)

suggesting that the expert user's thought processes were somehow different than those of the nonexperts. It is also possible that the nonexpert agreement with NLP false positives might be associated with greater trust in NLP on the part of the nonexpert participants. Of course, given the small size of this study, it is entirely possible that these participant-level observations are not statistically significant. Subsequent studies involving more participants and including investigation of user thought processes—perhaps via think-aloud protocols or retrospective interviews—would be needed to understand these phenomena.

### Limitations

The generalizability of this study is limited by the small sample size; a larger study would be needed to more accurately characterize the differences between nonexperts, experts, and the NLP annotation. Another potential limitation of our study is that we could not evaluate the characteristics of label sections that might be more difficult to read and annotate by nonexperts. The experimental design attempted to address this concern by balancing the number of sections across each scenario to minimize the effect of differences in difficulty level. The study results might have been influenced by the accuracy of the NLP algorithm and the reliability and usability of the annotation user interface. Interface revisions based on usability might lead to improved performance for experts and nonexperts. Finally, as we did not conduct any debriefing interviews or otherwise assess participant mental states, we are only able to speculate as to factors that might contribute to differences in task performance.

### Conclusions

Our goal was to explore use of nonexperts to annotate PDDI mentions in drug product labels. Our results suggest that nonexperts could produce reliable PDDI annotations from drug labels with efficiency comparable to that of an expert annotator with training in pharmacy or pharmaceuticals, indicating that the task of extracting PDDIs from drug product labeling might be suitable for crowdsourcing. Although NER preannotation was found useful to both experts and nonexperts, NLP preannotation as implemented in this study seemed to present an obstacle to all participants. A high performance NLP algorithm might still be helpful if NLP preannotations are shown to annotators after a section is annotated, if only to highlight possibly missed interactions. Improvements in the usability of the annotation tool and screening of potential annotators might further increase performance.

### Acknowledgments

Research reported in this paper was partially supported by the Fogarty International Center of Global Health of the National Institutes of Health under grant number 1D43TW008443-01, National Institute on Aging grant K01AG044433, and National Library of Medicine grant 1R01LM011838-01. ## Abstract

**Background:** There's scarce evidence about cardiovascular events (CV) in patients with hospitalization for acute heart failure (HF) and no indication for immediate device implant.

**Objective:** The CARDiac RhYthm monitorING after acute decompensation for Heart Failure study was designed to assess the incidence of prespecified clinical and arrhythmic events in this patient population.

**Methods:** In this pilot study, 18 patients (12 (67%) male; age 72±10; 16 (89%) NYHA II-III), who were hospitalized for HF with low left ventricular ejection fraction (LVEF) (<40%) and no immediate indication for device implant received an implantable loop recorder (ILR) before hospital discharge. Follow-up visits were scheduled at 3 and 6 months, and at every 6 months until study closure; device data were remotely reviewed monthly. CV mortality, unplanned CV hospitalization, and major arrhythmic events during follow-up were analyzed.

**Results:** During a median follow-up of 593 days, major CV occurred in 13 patients (72%); of those, 7 patients had at least 1 cardiac arrhythmic event, 2 had at least a clinical event (CV hospitalization or CV death), and 4 had both an arrhythmic and a CV event. Six (33%) patients experienced 10 major clinical events, 5 of them (50%) were HF related. During follow-up, 2 (11%) patients died due to a CV cause and 3 (16%) patients received a permanent cardiac device.

**Conclusions:** After an acute HF hospitalization, patients with LVEF<40% and who are not readily eligible for permanent cardiac device implant have a known high incidence of major CV event. In these patients, ILR allows early detection of major cardiac arrhythmias and the ability to react appropriately in a timely manner.

**KEYWORDS**

continuous cardiac monitoring; implantable loop recorder; acute heart failure; arrhythmias

## Introduction

Acute heart failure (AHF) episodes that induce hospitalizations represent one of the largest causes of health status deterioration [1]. About 45% of patients hospitalized with AHF will be rehospitalized at least once (and 15% at least twice) within 12 months [2]. Estimates of the risk of death or rehospitalization within 60 days of admission vary from 30% to 60%, depending on the population studied [2-8]. A significant proportion of heart failure (HF) patients do not undertake any device implant strategy since they do not meet the guidelines criteria [2]. Very little, if any, monitored information exists in those patients experiencing AHF with modest left ventricle impairment or with HF with preserved left ventricular ejection fraction (LVEF). Timely information might allow interventions that then avoid major cardiovascular (CV) events and possible progressive worsening of the disease leading to hospitalization. The availability of implantable devices to continuously monitor cardiac trends may provide early warning of changes in cardiac status, which would then allow early clinical management and possibly reduce the number of HF hospitalizations. The CARdiac RhYthm monitoriNG after acute decompensation for Heart Failure (CARRYING ON for HF) trial was designed to assess the efficacy of implantable loop recorders (ILRs) in the early detection of prespecified clinical and arrhythmic events in this patient population.

## Methods

### Study Design and Patient Population

In this prospective pilot study, patients who were hospitalized for AHF, had an LVEF <40% but no immediate indication for device implant, and received an ILR before hospital discharge were enrolled.

Clinical follow-up visits were scheduled at 3 and 6 months and every 6 months thereafter. Device data were reviewed monthly

through the Care-Link remote monitoring system or at any time the patients had symptoms (ClinicalTrials.gov; Identifier: NCT01216670). CARRYING-ON for HF Study design is reported in Figure 1.

Informed consent was obtained from each enrolled patient and the study protocol conforms to the ethical guidelines of the 1975 Declaration of Helsinki as reflected in a priori approval by the local ethics committee.

The aim of the study was to assess the capability of loop recording to recognize early signs of prespecified clinical and arrhythmic events in this cohort of patients. Prespecified events were: (1) CV mortality or unplanned CV hospitalization and (2) any cardiac arrhythmic event detected by the implanted device (Sinus bradycardia:  $\leq 30$  beats per minutes (bpm),  $\geq 8$ s; Sinus arrest:  $\geq 5$ s; atrioventricular (AV) block (2°, 3°):  $\leq 30$  bpm,  $\geq 8$ s; atrial fibrillation (AF):  $> 6$  min; non-sustained ventricular tachycardia (VT):  $\geq 125$  bpm,  $\geq 16$  beats; sustained VT:  $> 30$  sec). The main inclusion criteria were: (1) a history of at least 1 HF hospitalization, emergency department visit, or urgent office visit necessitating intravenous (IV) diuretic or augmentation of oral diuretic, IV inotropic, or IV vasodilator or other HF parenteral therapy within 15 days prior to device implant; (2) an implanted Medtronic Reveal XT ILR device ( $< 15$  days post-implant); and (3) LVEF  $< 40\%$ . Main exclusion criteria were: (1) New York Heart Association (NYHA) Class IV (chronic or ambulatory); (2) planned or previous implant of an implantable cardioverter defibrillator (ICD) or pacemaker device; (3) severe chronic obstructive pulmonary disease; (4) permanent AF at time of enrolment; and (5) ST segment elevation at electrocardiogram (ECG). A Reveal XT ILR was used for continuous cardiac monitoring. The ILR was implanted within 15 days the AHF event. All the patients enrolled received a remote monitoring system and were requested to transmit Reveal XT data on a monthly base or in case any symptoms occurred.

**Figure 1.** Study design.

### Statistical Analysis

Continuous data were summarized as mean and standard deviation or median and 25th-75th percentiles in case of skewed distributions. Absolute and relative frequencies were reported for categorical variables. Kaplan-Meier method was used to display the time to first event. The mean cumulative function (MCF) plot for the number of recurrent events was used to display the overtime trend of the events rate. Statistical analyses were performed using SAS 9.3 for Windows (SAS Institute Inc, Cary, NC).

### Results

#### Baseline Characteristics

The patients on average were  $73 \pm 10$  years old, 12 (67%) were male, and 7 (39%) had ischemic cardiomyopathy. According to guidelines, all the patients at the time of enrollment had no immediate indication to receive a permanent implantable cardiac device: 8 (44%) patients had LVEF > 35%, 2 patients were in NYHA functional class I, and 9 (50%) patients were not under optimized pharmacological treatment for HF at the time of the AHF event. Most patients (15/18, 83%) were on beta-blocker therapy (11 were on bisoprolol 2.5 mg twice a day and 4 were on carvedilol 12.5 mg twice a day). Further baseline characteristics are reported in Table 1.

**Table 1.** Baseline characteristics of study population.

Baseline Patients Characteristics <sup>a</sup>		N=18 (%)
Age, y		73±10
Gender	Male	12 (67%)
Ischemic etiology		7 (39%)
History of AF		8 (44%)
CHADS <sub>2</sub> score (for AF patients)		3.0±0.7
History of NS-VT		2 (18%)
QRS complex, ms		106±23
LBBB		4 (22%)
NYHA	Functional class I	2 (11%)
	Functional class II	13 (72%)
	Functional class III	3 (17%)
Cardiovascular-Related Diseases	MI + CAD	6 (35%)
	Hypertension	11 (65%)
	Valvular heart disease	6 (35%)
	Previous cardiovascular surgeries	9 (50%)
	Type 2 diabetes	4 (22%)

	LVESV ≥ 100 mL	7 (47%)
Drug Therapy at Discharge	Diuretic	17 (94%)
	ACE inhibitor and/or ARB	16 (89%)
	Beta blocker	15 (83%)
	Amiodarone	10 (56%)
	Anticoagulant	14 (78%)

Abbreviations: ACE, angiotensin-converting enzyme; AF, atrial fibrillation; ARB, angiotensin receptor blocker; CAD, coronary artery disease; LBBB, left bundle branch block; LVEF, left ventricular ejection fraction; LVESV, left ventricular end-systolic volume; MI, myocardial infarction; NS-VT, non-sustained ventricular tachycardia; NYHA, New York Heart Association.

<sup>a</sup>Data are expressed as mean ± standard deviation or absolute (relative) frequencies.

### Clinical Outcomes

During a median follow-up of 593 days (mean 509±260), major CV events occurred in 13 patients (72%, median time to first

combined event 162 days (39-606)); 11 patients had at least 1 cardiac arrhythmic event, 2 had at least 1 clinical event (CV hospitalization or CV death), and 4 had both arrhythmic and clinical events. [Figure 2](#) shows clinical and arrhythmic events incidence and distribution.

Six (33%) patients experienced 10 major clinical events; 5 (50%) of which were HF-related with 1 patient dying due to HF (terminal rhythm: asystole) and 1 patient dying due to an acute CV event (ruptured cerebral aneurysm). Distribution of detected major clinical and arrhythmic events is reported in [Table 2](#).

**Table 2.** Type and frequency of clinical and arrhythmic events that occurred<sup>a</sup>.

Clinical Events	Events (n=10)	Patients with Events (n=6)
CV death <sup>b</sup> , n (%)	2 (20%)	2 (33%)
of which HF-related death, n (%)	1 (10%)	1 (1.7%)
CV hospitalizations, n (%)	10 (100%)	6 (100%)
of which HF-related hospitalizations, n (%)	5 (50%)	3 (50%)
Arrhythmic Events	Events (n=1326)	Patients with Events (n=11)
Synus bradycardia, n (%) ( $\leq 30$ bpm, $\geq 8$ s)	8 (0.6%)	3 (27%)
Sinus arrest, n (%) ( $\geq 5$ s)	2 (0.2%)	2 (18%)
AV block, n (%) ( $\leq 30$ bpm, $\geq 8$ s)	--	--
AF-AT, n (%) ( $> 6$ min)	1297 (97.7%)	8 (73%)
Non-Sustained VT, n (%) ( $\geq 125$ bpm, $\geq 16$ beats)	13 (1%)	2 (18%)
Sustained VT, n (%) ( $> 30$ sec)	6 (0.5%)	2 (18%)

Abbreviations: AF, atrial fibrillation; AT, atrial tachycardia; AV, atrioventricular; CV, cardiovascular; HF, heart failure; VT, ventricular tachycardia.

<sup>a</sup>Data are expressed as absolute (relative) frequencies.

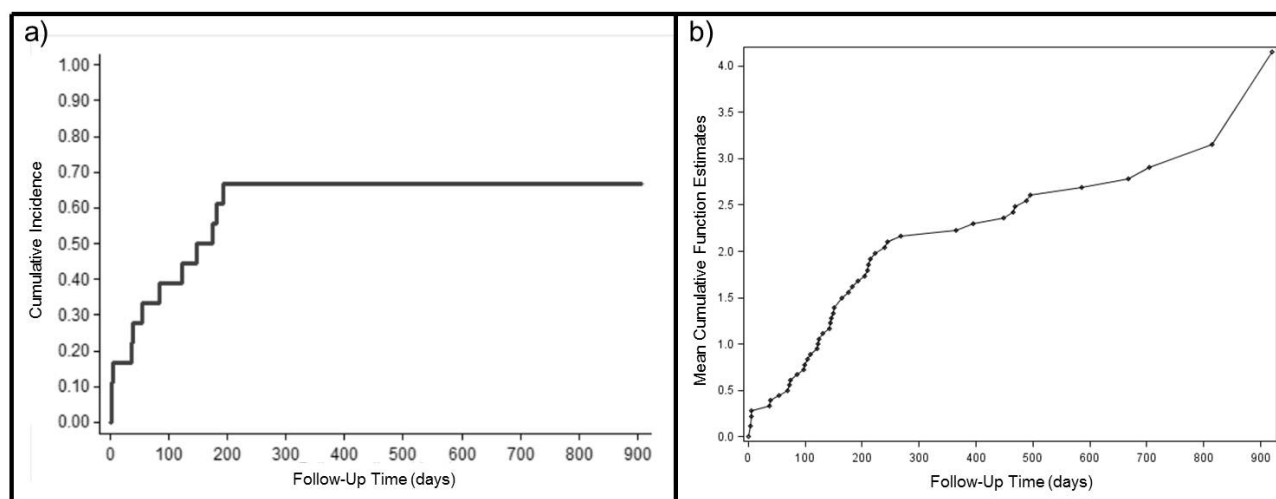

<sup>b</sup>The 2 events of death also had previous hospitalizations.

During follow-up, 3 (16%) patients were implanted with a permanent cardiac device according to current guidelines (in 2 patients who developed sustained-VT, a cardiac resynchronization therapy with defibrillator backup device (CRT-D) was implanted; in the 1 patient with sinus arrest and

LVEF  $< 35\%$ , a single chamber ICD was implanted). Eight patients suffered paroxysmal AF that was often asymptomatic (62%); the mean CHADS<sub>2</sub> score in these 8 patients was  $3.0 \pm 0.7$ , as all had a CHADS<sub>2</sub> score  $\geq 2$ .

As per heart rate (HR), we computed its circadian behavior: the 2 patients who had a nocturnal HR  $> 70$  bpm for  $> 85\%$  of the night had major clinical events, while this occurred in only 3/16 (19%) of the patients with nocturnal HR  $< 70$  bpm.

Figure 3 shows Kaplan-Meier analysis for clinical and arrhythmic events, both for time to first combined event (Figure 3a) and for cumulative combined events incidence (Figure 3b).

**Figure 2.** Clinical and arrhythmic events incidence and distribution.**Figure 3.** Kaplan-meier analysis for clinical and arrhythmic events.

## Discussion

The main finding from this study, which might carry significant clinical implications, is that continuous ECG and HR monitoring by loop recorders might contribute to the early recognition of cardiac rhythm abnormalities contributing to an observed very high incidence of major CV (72%) events. Such high event risk is known to occur in patients with LVEF < 40% who are not eligible for ICD implant within 6 months after an HF hospitalization. The study population, despite its small size, was representative of the clinical reality: elderly patients, prevalently NYHA class II, with a mean CHADS<sub>2</sub> score of 3.

The high morbidity detected in the study was not unexpected, but the clinical information provided by the CARRYING ON for HF study deserves specific attention. We can conjecture that the appropriate use of remote monitoring as part of a more comprehensive approach to such patients may decrease the observed high re-hospitalization rate after an AHF. The CARRYING-ON HF study was designed to record events but did not prescribe any specific intervention. It is, however, reasonable to believe that the early detection of rhythm and conduction disturbances by ILR will allow clinicians to react appropriately in a more timely manner, avoiding quick progression of the disease and worst outcomes.

In fact, half of the study population had an AHF during the study period. These patients were being treated with a suboptimal HF medical strategy and the continuous monitoring led to subsequent optimal medical titration for HF, arrhythmia management, and stroke prevention. This should be understood in view of the CRYSTAL AF study [9] indicating that stroke may be the first clinical manifestation of AF. The analysis of the time to first combined event (Figure 3) and of the cumulative combined events provides further important information. The first is that a 6-month-long monitoring period is not sufficient to detect a first significant event in all the patients who are bound to have them. Secondly, beyond 6 months a small proportion of combined events occurred possibly because of the fatal event on one side and the optimization of patient management induced by the monitoring device on the other. In this context it is noteworthy that 16/18 (89%) patients had an optimal nocturnal HR (less < 70 bpm). Thus, it may not be incidental that the only 2 patients with an overnight inappropriate HR had clinical events while this occurred in only 3/16 (19%) patients with controlled nocturnal HR. This observation is indeed coherent with the predictive value of HR and its circadian variation [10-11]. Furthermore the ILR detected episodes of sustained VT that met the criteria for 2 CRT-D implants. In a third case, a detection of a life-threatening event occurred: nocturnal long pauses (> 8 sec) were discovered. In

this patient, the concomitant presence of LVEF < 35% and the AV conduction disturbance led to a single chamber ICD implant. These 3 cases were diagnosed by the ILR and allowed the timely intervention that prevented a potential life-threatening event.

### Limitations

The main limitation of this pilot study is the small number of patients enrolled. Our study, planned as a feasibility and methodology study, was not powered to determine the overall prevalence of CV events after an AHF episode nor to test the effectiveness of ILR in reducing CV events in this population. The primary aim was descriptive as a preliminary fundamental information to design a larger comparative study.

### Conclusions

The CARRYING ON for HF study provided meaningful information on the many (72%) patients hospitalized for an acute HF episode who are not eligible, according to current guidelines, to receive an implantable cardiac device and who later develop CV and arrhythmic events during the follow-up.

The present finding provides some background for future prospective studies aimed at the assessment of the risk stratification of continuous cardiac monitoring in HF patients who are not deemed eligible for immediate implantation of a permanent cardiac device.

### Acknowledgments

We would like to thank Sabrina De Cicco and Melissa Gioia for their support in data collection. We also thank Alessio Marseglia and Marco Vimercati for the management of data. This work was supported by Medtronic Italia.

## Abstract

**Background:** Clinical research often lacks participants of young age. Adding to the small amount of scientific studies that focus on the population entering adulthood, there are also difficulties to recruit them. To overcome this, there is a need to develop and scientifically evaluate modes for data collection that are suitable for adolescents and young adults. With this in mind we performed 39 online focus group discussions among young survivors of childhood cancer to explore thoughts and experiences around dating, being intimate with someone, and having children.

**Objective:** The aim of the study was to evaluate online focus group discussions as a mode for data collection on sensitive issues among young persons with a cancer experience.

**Methods:** One hundred thirty-three young persons (16-25 years) previously diagnosed with cancer, participated in 39 synchronous online focus group discussions (response rate 134/369, 36%). The mode of administration was evaluated by analyzing participant characteristics and interactions during discussions, as well as group members' evaluations of the discussions.

**Results:** Persons diagnosed with central nervous tumors (n=30, 27%) participated to a lower extent than those with other cancer types (n=103, 39%;  $\chi^2 = 4.89$ ,  $P=.03$ ). The participants described various health impairments that correspond to what would be expected among cancer survivors including neuropsychiatric conditions and writing disabilities. Even though participants were interested in others' experiences, sexual issues needed more probing by the moderators than did fertility-related issues. Group evaluations revealed that participants appreciated communicating on the suggested topics and thought that it was easier to discuss sex when it was possible to be anonymous toward other group members.

**Conclusions:** Online focus group discussions, with anonymous participation, are suggested to be a feasible and valid mode for collecting sensitive data among young persons with a cancer experience.

**KEYWORDS**

adolescent; data collection; focus groups; Internet; neoplasms; young adult

## Introduction

Focus group discussions is an established mode for collecting data that have the possibility to, in some ways, move beyond individual interviews by simultaneously taking different perspectives and opinions into account when letting participants interact during a moderated discussion [1,2]. Such discussions may also be performed online [3], which can increase response rates in groups comfortable using computers (eg, young populations) [4].

Based on the abovementioned, we performed online focus group discussions with young childhood cancer survivors to explore their thoughts about fertility and sexuality. The aims were to investigate what adolescent and young adult survivors of childhood cancer think about the risk of being infertile and how they reason about having biological children [5]. Additionally, we aimed to explore this group's views about sex and sexual experiences and their possible needs for care and support from health care professionals regarding sexual life [6]. The transcripts from the group discussions were analysed inductively with content analysis [7]. The risk of infertility was viewed to negatively impact on well-being and intimate relationships [5]. The findings regarding sexuality showed that many participants had not reflected over the possibility that their cancer experience could impact on sexual life [6]. Still, thoughts and worries were expressed, such as feeling insecure and not keeping up with your peers. Physical complaints included vaginal dryness, difficulties getting and keeping erections, and reaching orgasm.

While online focus group discussions may facilitate discussion of sensitive issues [4], advantages and disadvantages of this mode of data collection in vulnerable populations (eg, patients) are largely unknown [8]. The aim of the present study was therefore to evaluate online focus group discussions as a mode for data collection on sensitive issues among young persons with a cancer experience.

## Methods

The main study's procedure and aims have briefly been presented in the introduction. This paper will evaluate the mode of administration (ie, online focus group discussions).

### Participants

Four hundred young persons, 16-24 years old, and 5 years or more beyond a childhood cancer diagnosis, were identified through the Swedish Childhood Cancer Registry. Diagnoses were selected based on their potential negative impact on fertility: Hodgkin's lymphoma, Ewing/Ewing-like sarcoma, osteosarcoma, rhabdomyosarcoma, neuroblastoma, and tumors of the central nervous system (CNS). The register's total population of persons with solid tumors in the age range of focus, except tumors of the CNS, was approached (N=280). As the number of persons treated for tumors of the CNS was large, a random sample was selected (n=120 from the total sample). Thirty-one persons were excluded due to self or parent-reported

cognitive disabilities (n=7), other disabilities (n=1), not being possible to reach at a Swedish address (n=19), deceased (n=1), or other reasons, such as undergoing cancer treatment (n=3). Among the remaining 369 eligible participants, 36% (134/369) accepted participation. One discussion included only one participant and was not included in the analysis why the results are based on 133 participants.

### Procedure

Ethical approval was obtained from the Regional Ethical Review Board in Stockholm. Potential participants received a letter with information about the study; voluntariness and confidentiality were stressed. Written informed consent was obtained from all participants.

### Data Collection

Focus group discussions were performed through an existing chat platform developed together with an Internet consultancy company [9]. Thirty-nine discussions were conducted with two to five participants in each group. Group discussions were performed synchronously and lasted for approximately 90 minutes (range, 65-130). Each group was typically led by two moderators with backgrounds in cancer care, pediatric care, midwifery, and/or psychology. Those who had signed up for a focus group discussion received login details by text message or phone before start of the discussion. The platform allowed the informants access from a computer at any location, using an alias. In this way, participants could be anonymous toward each other while not in relation to the moderators. It was, however, not uncommon that participants chose her/his real name as alias. An effort was made to mix sexes and to have similar ages in the groups. Directly after participation, each participant was invited to anonymously report their experiences from participating in the study in a separate chat forum by answering five items with fixed-response alternatives and four questions with an open response format.

### Analysis

The advantages and disadvantages with the mode of data collection was studied in three ways. We analyzed characteristics of those who participated, interactions during discussions, and the participants' evaluation of the focus group discussions.

## Results

### Who Participated?

The median age of participants was 21 ranging from 16 to 25 (interquartile range 4); self-reported relationship status and sexual experience as disclosed during group discussions are presented in Table 1. All but 4 of 39 conducted groups had mixed sexes. The response rate was higher among those diagnosed with solid tumors than among those diagnosed with CNS-tumors (n=103, 39% vs. n=30, 27%;  $\chi^2=4.89$ ,  $P=.03$ ). Apart from sexual problems and fertility-related concerns, participants mentioned various health impairments such as being amputated, fatigued, depressed, and having cognitive difficulties.

However, as health was not the focus of this study, we do not know if the mentioned health problems were related to sexuality or fertility.

**Table 1.** Characteristics of participants.

Self-reported situation	Total n=133 (%)	Females n=67 (%)	Males n=66 (%)
<b>Relationship status</b>			
Partner relationship	48 (36)	28 (42)	20 (30)
Dating/flirting	5 (5)	3 (5)	3 (5)
Single	62 (47)	28 (42)	34 (52)
Not reported	17 (13)	8 (12)	9 (14)
<b>Sexual experience</b>			
Have sexual experience	103 (77)	58 (87)	45 (68)
No sexual experience	16 (12)	3 (5)	13 (20)
Not reported	14 (11)	6 (9)	8 (12)

All of those who signed up to participate in a group also showed up and almost all of them who started in a group discussion stayed through the whole discussion. Some participants spontaneously declared that they had writing disabilities, which also was obvious in their spelling and grammar. A few, on their own initiative, disclosed that they had a neuropsychiatric disorder such as Asperger's and still, they reported the chat format as feasible. Participants who used an alias, possible to identify as a gendered name, never explicitly expressed having a relationship with someone of the same sex but the opposite was common (ie, heterosexual relationships). Moderators used gender-neutral expressions (eg, partner) when discussing partner relationships.

### Were Sensitive Issues Discussed and How Did Participants Interact With Each Other?

Sexual issues needed more probing by the moderators than did fertility-related issues. However, when sex was brought up on the agenda, the issue was discussed. Communication between participants in the group discussions was overall respectful and supportive. Participants encouraged each other to take steps in their lives if they considered something problematic (eg, to meet

someone or try a different approach). Different views were often expressed but there were seldom clear disagreements [6]. Participants were curious and asked each other about age, diagnosis, and sometimes where in the country they had received their treatment. Some of them identified themselves and agreed to continue chatting afterward on Facebook.

### Participants' Evaluation of the Online Discussions

Directly after participation, group members were invited to anonymously report their experiences in a Web-based survey which 50% (67/134) chose to do. Almost all participants who answered the evaluation experienced their participation as overall positive, and a majority reported that it was easier to discuss when you were anonymous, and that the moderators stimulated the chat (Table 2). Participants' responses to the open questions revealed positive experiences of chatting with others with similar experiences and expressed that the online format made it possible to be anonymous which facilitated sharing of sensitive information. Suggestions for improvement included more developed discussion topics, a higher speed in the discussions, not having discussions with too few participants (ie, 2), and having longer or repeated discussions (Textbox 1).

**Table 2.** Participants' evaluation of the chat discussions (n=67).

	Highly agree n (%)	Somewhat agree n (%)	Do not agree n (%)
Overall positive experience	60 (91)	6 (9)	0
Possibility to express yourself <sup>a</sup>	58 (87)	7 (10)	0
The web hindered the discussion <sup>a</sup>	5 (8)	7 (10)	54 (81)
Anonymity made it easy to discuss <sup>a</sup>	38 (57)	10 (15)	17 (26)
Did moderators stimulate the chat? <sup>a</sup>	48 (72)	16 (24)	1 (<1)

<sup>a</sup>Due to missing answers percentages do not reach 100% for all questions

**Textbox 1.** Examples of participants' answers on the free text items in the evaluation form.

What information would have been difficult to communicate face-to-face?

- *Issues around sex and things like that maybe*
- *Maybe you do not dare to say what you want in a group if you aren't anonymous*
- *To talk about sex and relations is easier behind a screen*

What was good?

- *To hear what others feel and think. The anonymity made it possible to be honest and you could be at home without spending too much time*
- *The anonymity and the internet chat idea was very good, it made it possible to write things you wouldn't dare to share otherwise*

What was bad?

- *I thought the discussion leaders were a little unclear with some questions. I also thought the issues were a bit 'fluffy' and that only 2 persons really discussed*
- *A little slow at times*
- *The time was a bit short*

Do you have any suggestions for improvement?

- *A little more tempo*
- *Have longer time or repeated chat forums*
- *More participants in the chat*

## Discussion

### Advantages with the Mode

Online focus group discussions, performed with the possibility for participants to be anonymous toward each other, was shown to be a feasible mode for collecting sensitive data among young persons treated for cancer during childhood. Both persons with and without health problems participated in the group discussions. The lower response rate seen for participants diagnosed with CNS tumors may indicate that this mode of data collection is less suitable for certain groups. Still, persons with self-reported cognitive impairments signed up and participated in group discussions and this did not generate problems.

The study partly used a random sampling procedure not typical for these kinds of studies. Without a purposeful sampling technique you risk including persons that may have difficulties to communicate that can result in a less interactive dialogue. However, we did not experience this, which may reflect the fact that we had experienced moderators, preferably two per group, who carefully followed all group members through every discussion. Nevertheless, we recommend the number of participants in online focus group discussions, if conducted synchronously, to be at least three but not to exceed five.

### Relation to Previous Findings

The present study confirms previous findings showing that an online format meets the need of convenience commonly addressed by young cancer survivors [4] and may be advantageous for sensitive topics [10] in contexts with high access to computers and Internet [11]. Furthermore, in the present study, the possibility to use an alias to be able to be anonymous while chatting about sensitive issues was highlighted as positive by many participants.

Discussing sexual experiences in groups with mixed sexes was found to be feasible and appreciated in a Swedish context and, to our knowledge, not previously performed among cancer survivors. The approximate numbers of female and male participants who, during a group discussion, reported that they had sexual experiences with a partner are in line with figures for the general population of similar ages [12].

### Conclusion

Based on our findings, online focus group discussions are recommended for collecting data on sensitive topics among young people with various health deficiencies. This may be of great value when reaching out to populations who might be difficult to engage in face-to-face focus groups.

## Acknowledgments

The study was supported by the Swedish Childhood Cancer Foundation, the Cancer Research Foundations of Radiumhemmet and the Doctoral School in Health Care Sciences at the Karolinska Institutet in Sweden.

## Abstract

**Background:** The prevalence of major depression is particularly high in medical students, affecting around one-third of this population. Moreover, online social media, in particular Facebook, is becoming an intrinsic part in the life of a growing proportion of individuals worldwide.

**Objective:** Our primary objective is to identify the prevalence of depression in medical students at the Lebanese University Faculty of Medicine, a unique state university in Lebanon, its correlation with the utilization of the interactive features of Facebook, and the way students may resort to these features.

**Methods:** Students of the Lebanese University Faculty of Medicine were assessed for (1) depression and (2) Facebook activity. To screen for major depression, we used the Patient Health Questionnaire-9 (PHQ-9) scale. To test for Facebook activity, we developed the Facebook Resorting Questionnaire (FbRQ), which measures the degree to which students resort to Facebook.

**Results:** A total of 365 out of 480 students (76.0%) participated in the survey. A total of 25 students were excluded, hence 340 students were included in the final analysis. Current depression was reported in 117 students out of 340 (34.4%) and *t* tests showed female predominance. Moreover, PHQ-9 score multiple regression analysis showed that feeling depressed is explained 63.5% of the time by specific independent variables studied from the PHQ-9 and the FbRQ. Depression varied significantly among the different academic years ( $P < .001$ ) and it peaked in the third-year students. One-way analysis of variance (ANOVA) showed that depression and resorting to Facebook had a positive and significant relationship ( $P = .003$ ) and the different FbRQ categories had significant differences in resorting-to-Facebook power. The like, add friend, and check-in features students used when resorting to Facebook were significantly associated with depression.

**Conclusions:** This study showed that depression was highly prevalent among students of the Faculty of Medicine at the Lebanese University. Moreover, Facebook may be a promising, helpful, psychological tool for optimizing the management of depression. Our study brought to bear further questions that now prompt further observation and scrutiny to know more about the high rates of depression in this student population, more so in the part of the world studied, and to the growing role of social media.

## Introduction

### On Depression

Depression was shown to have high prevalence rates among university students [1,2]. These rates were even higher when it came to medical students, where depression affected one-third [3] to one-half of this population [4]. Coping strategies, such as social support, were recommended for medical students to improve their quality of life [5]. Moreover, it was shown that social support per se may even be a potent protective factor for depression [6].

### On Facebook

On average, there are about 864 million daily active users on Facebook, the most visited online social network (OSN) in the world [7]. Kross et al showed that Facebook negatively affected a person's well-being in two ways: affective well-being (ie, how he/she feels moment to moment) and cognitive well-being [8]. In addition, individuals who have used Facebook accounts longer and users who have a greater number of nonpersonal Facebook friends believe that others' lives are better and are even more pleasant than their own [9]; this and other Facebook-mediated comparisons were associated with greater depression [10]. Furthermore, Forest et al reported that people with low self-esteem will not take advantage of the easy means of disclosure on Facebook, despite their beliefs in such a possibility [11]. In addition, it was reported that the increased usage of Facebook photo applications is correlated with body image disturbance and weight dissatisfaction [12].

As a part of *infodemiology* [13], which is a new method to study health determinants and information on the Internet, Facebook is one possible screening method to study health-related issues. For instance, a previous study based on verbatim text analysis showed that displayers of depressive symptoms are more likely than nondisplayers to have a positive Patient Health Questionnaire-9 (PHQ-9) measure [14].

Furthermore, announcing suicide on Facebook could provide enough time for an intervention [15]. Also, Facebook may be a good means for individuals to disclose their depression, hence enabling others to constantly be updated [16]. Seemingly depressed participants in Social Network Service (SNS) had the opportunity to communicate with peers that they selected. Such behavior may have been promoted by anonymity, hence avoiding face-to-face contact [17].

Finally, depressed people had a declined usage of Facebook features such as *location tagging*, *add friend*, and the *like* feature [18]. However, we were concerned more with the increased usage of Facebook as a possible tool that students could resort to in fighting depression. From this perspective, a subjective report of how each feature is resorted to might be more significant than counting the usage of each. Hence, when it comes to depressed Facebook users, we questioned whether resorting to Facebook may be a means to relieve depressive symptoms.

### Objectives

Our primary objective was to study the prevalence of major depression in medical students attending the only state university in Lebanon and its correlation with these students resorting to Facebook.

## Methods

### Participants

Participants were medical students from the second up to the fifth year who attended the Faculty of Medicine at the Lebanese University. Sixth- and seventh-year students could not be included since they were in clinical rotations in several hospitals. Taking into consideration that all students at the Faculty of Medicine had taken an advanced English course and since lectures are delivered in English, we distributed the questionnaires in English. The survey extended from February 6-25, 2014. We visited each class twice on two consecutive days in order to guarantee maximum attendance.

### Questionnaires

#### *Patient Health Questionnaire-9*

The PHQ-9 is a reliable and valid criteria-based diagnostic tool for depressive disorders and is used to measure the severity of depression [19]. Indeed, this scale has a high specificity (94%) and a relatively low sensitivity (73%) [19]. Up to the date of our field work, the PHQ-9 was not validated in the Lebanese population.

#### *Facebook Resorting Questionnaire*

Previous reports focused on one of two things in screening Facebook features related to depression: (1) declined Facebook activity [18] or (2) disclosures on Facebook that showed depression [14-16]. We assembled a new questionnaire—the Facebook Resorting Questionnaire (FbRQ)—that aimed to study the tendency of users to resort to Facebook features and the objectives of their usage. The FbRQ assesses the reasons users eventually resort to Facebook features during a current depressive state. Our questionnaire was not designed to measure time spent on Facebook or how many times each feature is used.

The FbRQ was comprised of seven questions targeting the different features of Facebook and the purpose underlying their utilization:

1. Question about the *like* feature: “Do you like topics on Facebook that you couldn’t own, meet, visit...in your real life?” What mattered was whether this feature allowed the user to stay up to date with the subject of interest.
2. Question about the *location-tagging* feature: “Do you have the habit of tagging your current location wherever you go?” This tag feature used by Facebook friends could provide the user with the possibility to navigate new locations and to check them.
3. Question about the *disclosure* feature: “Do you feel that Facebook is a way to express your feelings or whatever you want to declare in your real life and you do better in expressing on Facebook than on a real scale?” The disclosure feature might

provide the user with a basis for social support and electronic feedback that could become a source for generating new ideas.

4. Question about the *add friend* feature: “When you want to meet someone, do you feel that Facebook, by the feature *add friend* and further chatting, makes you more comfortable than a verbal meeting?” This question and answer provided an understanding about the clinical importance of depression and whether the user found it easier to add and meet friends on Facebook compared to real life.

5. Question about the *photo* feature: “Do you think that Facebook, by posting photos, saves your best life moments and helps you evoke your positive memories?” Posting photos is another feature that users tend to use. Sticking to our objectives, we aimed to detect whether this feature helped the user recall positive memories that the user would then ruminate about.

6. Question about the aim behind using Facebook: “Is Facebook a way to show the best out of your life?”

7. Question about the aim behind using Facebook: “Does Facebook render your voice audible and your existence noticeable?” Questions 6 and 7 aimed to help us understand the motives behind the use of Facebook.

The FbRQ was chiefly designed to cover all the above-mentioned points of every Facebook feature and aim of usage. [Multimedia Appendix 1](#) is a snapshot that shows the FbRQ. Each question was given 1 point if answered positively, for a total of 7 points. We decided to divide users resorting to Facebook into three categories: low (0-1 points), moderate (2-3 points), or high (4-7 points). We also collected some sociodemographic data concerning the following: gender, academic year, psychiatric history, and whether users were smokers or nonsmokers, among other criteria.

## Survey Leaflet

The survey was totally anonymous. The ethics committee at our university required that we provide clear information to the participants prior to their written consent (see [Multimedia Appendices 2](#) and ).

## Statistical Analysis

Statistical analysis was conducted using IBM SPSS Statistics for Windows version 16.0 (IBM Corp). Correlation analysis between depression and resorting to Facebook, along with sociodemographics, was performed using the chi-square test for which we calculated the *P* value and Cramer's *V* value, which is the appropriate measure of association. We performed *t* tests to show the predisposition to depression concerning gender. Furthermore, one-way analysis of variance (ANOVA) was conducted to determine the significance of the relationship between resorting to Facebook and depression, the variability of depression among the different academic years, as well as determining a significant difference between each FbRQ category. Moreover, multiple regression analysis was conducted to examine the relationship between different variables in the study for which we calculated the  $R^2$  value, which reflects the degree of correlation, and the *F* statistic, which tells us if the model is a good fit. Statistical significance for hypothesis testing was set at 5% ( $P < .05$ ).

## Results

### Overview

A total of 365 of 480 students (76.0%) took the survey; the remaining students were absent on the days of our survey. A total of 25 students out of 365 (6.8%) were excluded from the study because some did not complete the three questionnaires; 9 of these students refused to participate. Hence, we included a total of 340 students in the study. The sociodemographic characteristics of the sample are summarized in [Table 1](#).

**Table 1.** Sociodemographic characteristics of the sample (n=340).

Characteristics	n (%)
Participants who took the survey (n=480)	365 (76.0)
Participants with depression	117 (34.4)
Males	145 (42.6)
Females	195 (57.4)
Participants with functional impairment	256 (75.3)
Participants living in dorms	196 (57.6)
Married	3 (0.9)
Smokers	35 (10.3)
Participants with psychiatric history	62 (18.2)

On the PHQ-9 scale, for a cut-off of 10, the prevalence rate of depression was 34.4% (117/340). Severity was distributed as follows: out of 117 students, 5 (4.3%) had severe depression, 32 (27.4%) had moderate depression, and 80 (68.4%) had mild depression. Suicidal thoughts in depressed students—represented by Question 9 on the PHQ-9 scale—were attributed to 27.4%

(32/117) of students. [Table 2](#) shows the multiple regression analysis conducted between Question 2 of the PHQ-9 as a dependent variable and Questions 1, 3, 4, 6, 8, 9, and 10 of the PHQ-9 and Question 2 of the FbRQ as independent variables. The  $R^2$  value reached 63.5%, the *F* statistic showed that the model was a good fit, and this regression was a good model

( $P < .001$ ). As plotted in Figure 1 and as seen in Table 3, after a one-way ANOVA, depression scores averaged 8.7, 9.0, 7.5, and 6.2, and depression reached 41.5%, 46.9%, 31.6%, and 21.4% in the second through the fifth year, respectively. The

calculated value of  $F$  was 6.1 ( $P < .001$ ). Comparing the different academic year classes, the statistical significance was owed only to the relationship between year 5 with respect to second- and third-year students ( $P < .05$ ).

### Patient Health Questionnaire-9 and Sociodemographic Parameters

Among sociodemographics, the chi-square test showed a significant relationship between depression and gender only ( $P=.007$ ), as shown in Table 4. In addition, Cramer's V value

was significant ( $P=.007$ ) and equaled .189. To determine which gender was more predisposed to depression, a  $t$  test was performed and showed that females had higher rates of depression than males with a factor of 1.8, as shown in Table 5.

**Table 4.** Depression categories distributed by gender (n=340).

Participants	Depression category <sup>a</sup> , n (%)				Total, n (%)	Pearson chi-square
	<10	10-14	15-19	≥20		<i>P</i> value
<b>Gender</b>

Female	195 (57.4)	8.7538	4.6541	0.3333

### Patient Health Questionnaire-9 and Facebook Resorting Questionnaire

Table 6 is a result of the one-way ANOVA showing that, out of 340 students, resorting to Facebook was high in 61 students (17.9%), moderate in 149 students (43.8%), and low in 130 students (38.2%). It was shown that there is a positive and significant relationship between the depression mean and the

categories related to resorting to Facebook, whereby the depression mean was 6.9 in the low FbRQ group, 8.4 in the moderate group, and 9.0 in the high group. The  $F$  value was 5.843 ( $P=.003$ ). Comparing the different FbRQ groups, the relationship was significant between the low and moderate groups ( $P=.03$ ), and between the low and high groups ( $P=.01$ ); however, it was not significant between the moderate and high groups.

**Table 6.** Variation of resorting to Facebook with respect to depression mean (n=340).

<sup>a</sup>FbRQ: Facebook Resorting Questionnaire.

<sup>b</sup>N/A: not applicable.

There was no statistically significant relationship between the sociodemographic parameters studied and the FbRQ results as determined by the chi-square test. However, a regression analysis was performed locking the PHQ-9 score as a dependent variable and all the Facebook features as the independent ones.

The  $R^2$  equaled 25.3%, the model was a good fit, and the regression was a good model ( $P < .001$ ). Table 7 shows the different ratios and the significance of each independent variable.

**Table 7.** Different ratios and significance of each independent variable.

## Discussion

### On Depression

The current prevalence of depression in our sample (34.4%) is slightly higher than what is reported in the literature, which is around 30% [1,2]. Studies on Question 9 of the PHQ-9 showed the suicidal ideation in the studied sample to be lower than in previous reports (23%) [20]. Nevertheless, it is always considered high since a significant proportion of people reporting suicidal ideation accounted for half of fatal or nonfatal suicide attempts [20]. Multiple regression analyses showed the question of depressive mood (Question 2), locked as the dependent variable, to correlate highly with other PHQ-9 items; hence, reports of feeling down or depressed by the students was explained 63.5% of the time by all the independent variables

studied. Among these variables, the problems of interest in doing things, fatigue, regarding one's self as a failure, and functionality were positively and significantly correlated and, thus, each 1% increase in these problems will increase feelings of depression by a factor of 0.19%, 0.15%, 0.1%, and 0.28%, respectively. On the other hand, a 1% increase in resorting to the *check-in* Facebook feature was associated with a 0.31% increase in feeling depressed, as shown in Table 2. Moreover, depression varied significantly among the different academic year classes and it peaked in the third year, which can be explained by the female predominance, then decreased gradually to a minimum PHQ-9 average of 6.2 in the fifth year. Female predominance was observed with a factor of 1.8, which is consistent with other reports [6,14,21]. From Cramer's V value of .189, we can conclude that this significant relationship was

low to moderate. Finally, our results regarding family history as a predisposing factor is not consistent with the literature [6].

## On Resorting to Facebook

### Overview

About one-third of students with Facebook accounts are active on Facebook [14,16]. Moreover, depressed users are expected to exhibit a decreased usage of Facebook [18]; however, in our sample a depressed user had an increased need to resort to Facebook. The one-way ANOVA came to show that as the mean of depression increases, resorting to Facebook increases as well ( $P=.003$ ). Hence, depressed medical students at the Faculty of Medicine are more likely than the nondepressed students to resort to Facebook, which leads to the hypothesis that Facebook may be a coping mechanism for depression. Moreover, this analysis provides credibility for the FbRQ by showing that the difference in resorting to Facebook is significant between each and every FbRQ category, except when it comes to comparing the moderate and high categories. Unlike prior studies [14] where resorting to Facebook was higher among females, there was no predilection to resorting to Facebook among genders.

What is common to the features surveyed by the FbRQ scale is that resorting to Facebook provides some pattern of social life without necessarily improving deficient communication skills. Users' subjective reports on the FbRQ show that Facebook may provide users who have a tendency to experience depression a chance to stay in contact with topics of interest, new places, and horizons; to ruminate on positive memories; express ideas; meet friends; and show the best out of their lives. According to the multiple regression analysis, resorting to the *like*, *add friend*, and *check-in* features was associated with depression; for each 1% increase in their usage, the PHQ-9 scores increased by 0.1, 0.6, and 0.1%, respectively. Hence, Facebook could have a positive psychosocial impact by allowing users to resort to these features.

### Facebook in Relation to Psychotherapy

Interpersonal therapy aims to (1) improve communication skills and (2) increase self-esteem [22]. Facebook improved depression in university students [23] by expressing the opinions of a depressed person that are usually suppressed on a daily basis; this was demonstrated by Questions 6 and 7 on the FbRQ, in addition to the *add friend* feature, chatting, and the *like* feature.

On the other hand, Facebook was shown to clearly improve self-esteem [24]. Indeed, Internet use improved self-esteem as

well as social support, while decreasing the percentage of depression and loneliness [25]. This seems to be linked to the *add friend* feature and the aim of the usage of Facebook as per the responses to the FbRQ.

Facebook, as a humanistic therapy, provides a social environment where individuals may compare old and new habits or attitudes with friends. At the same time, individuals may find out that similar problems may also be encountered by others, hence providing some kind of relief [26]. In conclusion, psychotherapies are providing hope, empathy, and care; hence, individuals who are supported by close friends and caring people are less likely to need or seek therapy [26].

### Facebook Social Support

Notably, social support is a key protective factor against depression [6]. Computer-mediated interaction has been shown to improve a user's confidence over the course of a conversation and strengthens judgments while negotiating. Most importantly, it helps a person get rid of uncertain behaviors [27]. On the other hand, lonely people find it hard to introduce themselves to, or take the first step in meeting, new people [4]. Facebook may be an option to overcome those difficulties by allowing an individual to choose the contact of his/her preference.

### Study Limitations

As a cross-sectional study, our results were confined to comparing, and not eliciting, a cause-and-effect relationship between depression improvement and resorting to Facebook. The standardized PHQ-9 questionnaire had not been validated in the Lebanese population during our survey. On the other hand, the FbRQ is a novel tool that we developed due to the lack of an equivalent standardized questionnaire; its point of weakness lies in not using a continuous variable scale.

### Conclusions

Depression was shown to be highly prevalent among medical students of the Lebanese University. Moreover, depressed Facebook users were more likely than nondepressed users to resort to Facebook; the subjective report by the FbRQ allows us to hypothesize that Facebook may be a means to alleviate depressive symptoms. Specifically, among all the Facebook features, *like*, *check-in*, and *add friend* may be of therapeutic significance. These results should stimulate health care providers to question the high depression rate in this student population and to acknowledge the possible role of Facebook in a multidisciplinary treatment strategy to relieve depression.

## Acknowledgments

This study was funded by the authors and had no other sponsors. Our acknowledgements go to Mr Raed Bou Chebel for his generous assistance in statistical analysis. We also acknowledge the Dean of the Faculty of Medicine, Pr Boutros Yared, who made the survey feasible. We are very grateful to Dr Nadine Yared for her assistance in planning the survey. Finally, we thank Dr Nevine Matar for proofreading our paper.

## Abstract

**Background:** Virtual worlds allow users to communicate and interact across various environments, scenarios, and platforms. Virtual worlds present opportunities in health care to reduce the burden of illness and disability by supporting education, rehabilitation, self-management, and social networking. The application of virtual worlds to older adults who bear the burden and cost of health conditions associated with age has not been evaluated.

**Objective:** The aim of this study is to explore the usability, ease of use, and enjoyment of a virtual world by older adults, the types of virtual world activities that older adults may engage in, and the perceptions of older adults regarding the application of virtual worlds in health care.

**Methods:** This quasi-experimental pre-post design research was guided by the Technology Acceptance Model (TAM). Participants were recruited from a Lifelong Learning Institute (LLI) program at Nova Southeastern University. Participants attended four training sessions over a 5-week period in the Second Life (SL) virtual world. Subjects were surveyed before and after the training on perceived ease of use, attitudes towards technology, behavioral intention to use the system, facilitating conditions, effort expectancy, and self-efficacy.

**Results:** Older adults (N=19) completed the informed consent and attended the first training session, and 11 participants (58%, 11/19) completed the full training and the post survey. Completers (82%, 9/11) were more likely than non-completers (37%, 3/8) to consider themselves technologically savvy ( $P=.048$ ), and to express confidence in being able to use the virtual world (100%, 11/11 vs 37%, 3/8;  $P=.002$ ). All completers (100%, 11/11) perceived that SL has application in health behaviors and disease and reducing social isolation among people who are homebound. Of the completers, 10 (91%, 10/11) responded that they enjoyed learning how to use SL. Completers suggested that future trainings include more assistants and smaller groups.

**Conclusions:** This pilot study suggests that virtual worlds can be both a feasible and an applicable method to promote health among some seniors. Future research on virtual worlds with older populations should consider using state-of-the art technology including large monitors, providing a minimum of one trainer for every two to three participants, and distributing a comprehensive training manual at the start of the training to support organization and recall.

## KEYWORDS

Second Life; virtual worlds; older adults; seniors; health care; training

## Introduction

As the population ages, the burden and cost of health conditions associated with age, including chronic disease and dementing illnesses is growing [1]. Strategies that promote self-management of chronic disease, cognitive function, and social connectedness contribute to improved health outcomes and quality of life [2-4]. Among other methods, computer-based interventions including computer-based gaming, interactive multimedia systems, exergaming, and virtual worlds are emerging as innovative methods to promote health among older adults [5-8].

Virtual worlds are three-dimensional computer-simulated environments that users navigate via Avatars to communicate and interact across various environments, scenarios, and platforms. In the past decade, virtual worlds have emerged as important tools for socialization, engagement, networking, and entertainment, virtually changing how people interact, communicate, and collaborate [9]. Internet-based virtual worlds offer opportunities in health care to reduce the burden of illnesses and disability through promoting rehabilitation [10-12], self-management of disease [13-18], healthy lifestyle behaviors [19-21], and social networking [11,22]. However, most research and evaluations on the application of virtual worlds in health are conducted among younger, computer literate populations, though the application to older adults has been identified [23].

Older adults comprise an important population for virtual computer and Web-based health interventions, including virtual worlds [24]. Today, 59% of adults 65 years of age use the Internet [24]. Usage increases with higher education, higher income, and lower age. Among seniors who reported using the Internet, more than two thirds of them go online every day. Similarly, among seniors who use social networking sites, 81% reported using them daily or near-daily.

Use of virtual worlds among seniors is low, but is expected to increase [25,26]. Currently there is a lack of evidence regarding the acceptance, adoption, and health applications of virtual

worlds among older adults. Here, a pilot study was conducted to inform on the feasibility and potential health care applications of using a virtual world environment with older adults. The specific research aims of this study are as follows: (1) to understand the usability, ease of use, and enjoyment of a virtual world environment by older adults, (2) probe engagement and types of virtual world activities by older adults, and (3) identify older adults' perceptions regarding the application of virtual worlds in health care.

## Methods

### Study Design

A quasi-experimental pre-post design was used. After providing written consent subjects completed a pre-test, which included questions regarding demographics, computer and digital device usage, and potential advantages of virtual worlds ([Multimedia Appendix 1](#)). Subjects then attended four training sessions over a 5-week period using the Second Life (SL) virtual world in the computer lab at Nova Southeastern University. SL is the largest virtual world. Conceptualized by Philip Rosedale who founded Linden Lab, SL offers a persistent, open, unlimited, and highly customizable space. The content of SL is created by its users who rent virtual land (islands). The training was conducted by a faculty member. Another faculty member and one student were available to provide direct support to participants at each training session. The training topics covered were (1) introduction to SL, "friending" and messaging (week 1); (2) navigating and teleporting in SL (week 2); (3) changing the appearance of your Avatars (week 3); and (4) health and sports activities (week 4). Screen shots demonstrating examples of activities performed in SL during training are shown in [Figure 1](#). Subjects completed a 19 question post-test assessing their experience with the virtual world, the potential advantages of virtual worlds, and the specific health applications of virtual worlds. The post-test is provided in [Multimedia Appendix 2](#). Subjects who completed all four training sessions received a US \$60 gift card to a local supermarket chain.

#### Training Session 1: Introduction to Second Life

#### Training Session 3: Changing the appearance of your Avatar

#### Training Session 2: Navigating and Teleporting

#### Training Session 4: Health and Sports Activities

## Participants and Setting

Participants were recruited from the Lifelong Learning Institute (LLI) at Nova Southeastern University's College of Osteopathic Medicine. As an educational extension program the LLI attracts many active and educated older adults from the nearby community.

Study investigators made recruiting announcements during LLI events and were available during LLI educational program breaks to discuss the training program with interested members. Though recruitment was slow at first, an interested LLI board member agreed to make several announcements to his peers, appealing to those interested in technology resulting in higher interest. Inclusion criteria for the study included having an email address and availability to attend the training programs. There were no exclusion criteria.

## Conceptual Framework

The research was guided by the Technology Acceptance Model (TAM) [27]. The TAM is an extension of the Theory of Reasoned Action (TRA) which predicts a person's behavioral intention based on attitudes and subjective norms [28]. TAM extends TRA by predicting acceptance of information technologies and assumes that two major variables of interest drive an individual's acceptance of technology: perceived usefulness and perceived ease of use [29]. TAM has been used successfully to test a variety of computer technologies in dividers settings and user groups, including in health care [30-35]. TAM evolved over several iterations into the Unified Theory of Acceptance and Use of Technology (UTAUT) [36]. To our knowledge, this is the first application of TAM and the extended UTAUT towards understanding acceptance and adoption of virtual worlds among older adults.

## Outcome Measures

The pre- and post-survey instruments were developed by the investigators based on validated items used in the development and testing of the TAM and UTAUT [27,36]. The tool measured perceived ease of use, attitudes towards technology, behavioral intention to use the system, facilitating conditions, effort expectancy, and self-efficacy. The pre-survey included questions on demographic characteristics, current computer and device usage, technological savviness, confidence in using the virtual world, and perceived usefulness of virtual worlds. The post-survey tool included the same set of questions regarding perceived usefulness as in the baseline survey and assessed activities performed in SL as a result of the training. The post-survey tool also included five open-ended questions to inform on specific lessons that could be learned through this pilot and applied to future research on virtual worlds and seniors.

## Data Collection

Study data were collected and managed using Research Electronic Data Capture (REDCap) electronic data capture tools hosted at Nova Southeastern University [37]. REDCap is a secure, Web-based application designed to support data capture for research studies providing (1) an intuitive interface for validated data entry; (2) audit trails for tracking data manipulation and export procedures; (3) automated export procedures for seamless data downloads to common statistical packages; and (4) procedures for importing data from external sources.

## Statistical Analyses

We performed bivariate analysis of baseline completer and non-completer demographic characteristics using *t* test for independent samples for age and the Pearson chi-square statistic for categorical data. Paired-sample *t* tests were used to compare

changes in self-reported usefulness on a scale from 1 (strongly agree) to 5 (strongly disagree) among completers and to estimate power for future studies. An alpha of .05 was used for each test without correction for multiple comparisons. Descriptive statistics were used to describe activities completed and perceptions regarding the application of virtual worlds to health. All analyses were conducted in SPSS (V23).

## Results

### Study Participants

There were 19 older adults who completed the informed consent and baseline survey and 10 older adults who completed the 4-week training program. One participant missed the last class, however, the material was reviewed with the participant at the end of the prior training. This participant's post-test was included with the completers, for an overall number of 11 completers, and a completer to non-completer rate of 58% (11/19).

The demographic and baseline characteristics of completers and non-completers are summarized in [Table 1](#). The mean age of

participants was 71.2 among both completers and non-completers. Completers (82%, 8/11) were statistically more likely than non-completers (37%, 3/8) to consider themselves technologically savvy ( $P=.048$ ) and to express confidence in being able to use the virtual world (100%, 11/11 vs 37%, 3/8,  $P=.002$ ). There was an absolute difference in mean hours on the computer of 3.65, but this difference was not significant. Though not significant, completers were more likely to agree or strongly agree with the perceived benefits of a virtual world in terms of usefulness in managing health (36%, 4/11 vs 25%, 2/8), usefulness for social interaction (45%, 5/11 vs 37%, 3/8), usefulness to themselves (36%, 4/11 vs 25%, 2/8), and usefulness in terms of improving quality of life (27%, 3/11 vs 25%, 2/8).

### Activities Performed in Second Life

Activities performed in SL by completers are listed in [Table 2](#). While faculty and graduate students verified that all completers performed all of the activities assessed at each class, several participants in the post-survey said that they were not able to "friend each other", find new places to visit, go shopping in SL or change their Avatar's appearance in SL.

**Table 1.** Baseline demographic and characteristics of non-completers and completers of a virtual world training program (N=19).

Characteristic	Non-completers (n=8)	Completers (n=11)	P value
Age <sup>a</sup> , mean	71.2	71.2	.99
Hours on computer per week <sup>a</sup> , mean	8.75	12.4	.31
Male, %	50	36	.55
College graduate, %	75	91	.55
"I consider myself to be technologically savvy", agree/strongly agree (%)	37	82	.048
"I am confident I will be able to use the virtual world", yes (%)	37	100	.002
"A virtual world could be useful in managing my health", agree/strongly agree (%)	25	36	.60
"A virtual world could be useful for social interaction", agree/strongly agree, %	37	45	.73
"A virtual world could be useful to me", agree/strongly agree (%)	25	36	.60
"Using a virtual world could improve the quality of my life", agree/strongly agree (%)	25	27	.91

<sup>a</sup>One completer did not provide age or mean hours on computer per week.

**Table 2.** Activities in Second Life performed by completers during the training program (N=11).

Activity	n, (%)
"Friending each other"	6 (54)
Finding new places to visit	9 (82)
Teleporting	11 (100)
Shopping	8 (73)
Changing your Avatar's appearance	9 (82)
Sports activities (eg, jet skiing, parasailing, fishing, etc)	11 (100)

### Usefulness of Second Life

The change in perceived usefulness of SL was analyzed in terms of managing health, social interaction, overall usefulness, and improvement in quality of life among completers ([Table 3](#)).

Though only the usefulness of SL for social interaction approached significance ( $P=.046$ ) there was improvement across three of the four questions from baseline to follow-up.

### Application of Second Life to Health and Ease of Use

The application of SL to health and the ease of use of SL among completers was assessed (Table 4). All subjects (100%, 11/11) responded that SL is applicable to health behaviors and disease and that SL can be applied to reduce social isolation among

people who are homebound. Of the participants, 10 (91%, 10/11) responded that they enjoyed learning how to use SL. In addition, 8 (73%, 8/11) and 9 (82%, 9/11) responded that it was easy for them to learn to create their Avatar and that it was easy for them to navigate their Avatar in SL, respectively.

**Table 3.** Changes in mean score of usefulness of Second Life among completers improved from baseline to follow-up (N=11).

Usefulness	Baseline completers score <sup>a</sup> , mean	Follow-up completers score <sup>a</sup> , mean	P value
"A virtual world could be useful in managing my health"	2.82	2.27	.051
"A virtual world could be useful for social interaction"	2.55	1.91	.046
"A virtual world could be useful to me"	2.60	2.40	.55
"Using a virtual world could improve the quality of my life"	2.80	3.10	.47

<sup>a</sup>Mean score based on a 1 (strongly agree) to 5 (strongly disagree) scale.

**Table 4.** Participants' perception regarding ease of use and applications of Second Life to health (N=11).

Application	n (%)
Application of Second Life to health behaviors and disease	11 (100)
Application of Second Life to self-management and chronic conditions	6 (54)
Application of Second Life to support brain health among people with dementing illnesses	7 (64)
Application of Second Life to support behavior and lifestyle change (eg, physical activity)	6 (54)
Application of Second Life to reduce social isolation among people who are homebound	11 (100)
I enjoyed learning how to use Second Life?	10 (91)
It was easy for me to learn to create an Avatar in Second Life?	8 (73)
It was easy for me to learn to navigate my Avatar in Second Life?	9 (82)

### Qualitative Feedback on Second Life

Participants also responded to open-ended questions regarding what they liked about SL, what they least liked about SL, their motivation to participate in the training, and potential improvements both in terms of the SL application and the training program. In summary, respondents liked the graphics, the variety of virtual experiences (eg, virtual travel) and engaging in fantasies and other sports activities that they would not normally engage in real life (eg, flying, power sailing). Several respondents also said they enjoyed designing their own Avatars and creating environments that are "outside the norm". In terms of what they liked least, several respondents said they

found SL frustrating (difficulty maneuvering the Avatar and/or not knowing where to go when they arrive at a site), that the on-screen help is limited and hard to understand, and that there is a long learning curve. One respondent also noted that the computer lab environment where the training took place was overloaded and crashed. With regards to motivation to participate, all participants responded that they wanted to help with interesting research and/or to learn something new. Feedback with regards to improving the usability of SL for the senior population and improving the training are provided in Table 5. The responses to both questions are combined as there was significant overlap.

**Table 5.** Respondent feedback on improving the usability of Second Life for the senior population and improving the training program for seniors in SL (N=11).

Feedback	n (%)
Provide more assistants during training; provide individualized or small-group training	5 (45)
Teach exercises slower in a step-by-step manner	4 (36)
Provide a comprehensive, more organized training program and manual; simplify directions	3 (27)
Enlarge the print on the screen	2 (18)
Make it less challenging to navigate in Second Life	1 (9)
Provide the training on an Apple platform	1 (9)

## Discussion

### Principal Findings

Findings from this pilot study to investigate the feasibility and potential health care applications of using a virtual world environment with older adults suggest that perceived usefulness of virtual worlds in terms of health, managing health, overall usefulness, and improving quality of life increased following the training program. Seniors who considered themselves technologically savvy and are confident in their ability to learn the virtual world technology were more likely to complete the training compared to those who had less confidence and self-reported themselves as not technologically savvy. Seniors who completed the training were successful at creating Avatars, learning to "friend each other", instant messaging, teleporting, and engaging in activities in SL. All completers reported that SL has application in health and managing disease, as well as to reduce social isolation among people who are homebound.

### Limitations

A limitation of the study was the high number of drop-outs. During the first class participants (N=19) were instructed to set up their SL account. However, the trainers did not know that there was a limit on the number of new accounts that could be set up per Internet Protocol (IP) address. As a result, many participants had difficulty creating accounts. Trainers resolved this issue by connecting to personal hotspots on cell phones, but the interruption contributed to frustration that may have resulted in drop-outs. Participants were also frustrated that they had to wait, often for several minutes, for assistance. In retrospect, because subjects learned how to use an Avatar at different rates and had varying levels of attention, several smaller groups should have been formed with at least one trainer to two to three participants. Persons providing assistance to participants needed to have mastered basic Avatar and SL skills, which was not always the case in this study. While most completers reported they enjoyed learning SL (100%, 11/11), that they found it easy to create an Avatar (73%, 8/11), and navigate in SL (82%, 9/11), there were other important lessons learned through this pilot. Participants experienced frustration with using and navigating in SL. Some of the frustration can be attributed to the computer lab conditions. The computer lab was equipped with laptops, which met the recommended requirements for screen resolution and graphics, but only had 14 inch screens. In addition, some activities in SL were slow at certain points in the training, likely due to Internet congestion caused by a large number of computers working simultaneously with intense graphic displays. A few of the computers even crashed.

In addition to increasing the number of trainers available to support setting up accounts and using high-end technology with large monitors, suggested improvements for future trainings include providing more support during each of the trainings and providing a comprehensive training manual. There were several challenges to maintaining a tempo acceptable for all participants. First, some participants failed to remember their username and password in subsequent trainings and then not having access to their email accounts to access the email from SL to reset their credentials. Second, subjects were at different stages of readiness to use an Avatar in a virtual world, making it difficult to learn new skills as a group. More SL technologically savvy students wanted to press ahead with learning new skills while others in the class were still learning previously-taught tasks. Future projects may want to consider grouping participants by tempo. In addition, while handouts were provided to students at the beginning of each training, there was no overall comprehensive training manual. In retrospect, such a manual would have helped with organizing the material and facilitating recall of previously taught activities. Plus, many participants wanted to practice on their home computers for which the manual would have been conducive.

### Effect Size

One of the purposes of a pilot study is to calculate an effect size for more robust, larger-scale studies. To this end, in a post-hoc analysis, we calculated the magnitude of the effect of the change in participant reported usefulness (composite of four questions) of SL pre- and post-training. Using a power of 80% and an alpha of .05, we calculated that 90 participants should be enrolled in future studies to achieve a medium effect size (30%). Precaution should be taken when applying our effect size to future studies as we modified TAM questions to fit our population and virtual world technology. It is also important to note that older adults who participated in this pilot had a college degree and that estimated results may vary if the study is replicated with a less-educated population.

### Conclusions

The purpose of this pilot study was to test the feasibility and applicability of virtual worlds to older adults. This pilot suggests that virtual worlds can be both a feasible and applicable method to promote health among some seniors. Future research on virtual worlds with older populations should consider using state-of-the art technology including large monitors, providing a minimum of one trainer for every two to three participants, and distributing a comprehensive training manual at the start of the training to support organization and recall.

## Abstract

**Background:** Aging of the European population and interest in a healthy population in western countries have contributed to an increase in the number of health surveys, where the role of survey design, data collection, and data analysis methodology is clear and recognized by the whole scientific community. Survey methodology has had to couple with the challenges deriving from data collection through information and communications technology (ICT). Telemedicine systems have not used patients as a source of information, often limiting them to collecting only biometric data. A more effective telemonitoring system would be able to collect objective and subjective data (biometric parameters and symptoms reported by the patients themselves), and to control the quality of subjective data collected: this goal be achieved only by using and merging competencies from both survey methodology and health research.

**Objective:** The objective of our study was to propose new metrics to control the quality of data, along with the well-known indicators of survey methodology. Web questionnaires administered daily to a group of patients for an extended length of time are a Web health monitoring survey (WHMS) in a telemedicine system.

**Methods:** We calculated indicators based on paradata collected during a WHMS study involving 12 patients, who signed in to the website daily for 2 months.

**Results:** The patients' involvement was very high: the patients' response rate ranged between 1.00 and 0.82, with an outlier of 0.65. Item nonresponse rate was very low, ranging between 0.0% and 7.4%. We propose adherence to the chosen time to connect to the website as a measure of involvement and cooperation by the patients: the difference from the median time ranged between 11 and 24 minutes, demonstrating very good cooperation and involvement from all patients. To measure habituation to the questionnaire, we also compared nonresponse rates to the items between the first and the second month of the study, and found no significant difference. We computed the time to complete the questionnaire both as a measure of possible burden for patient, and to detect the risk of automatic responses. Neither of these hypothesis was confirmed, and differences in time to completion seemed to depend on health conditions. Focus groups with patients confirmed their appreciation for this "new" active role in a telemonitoring system.

**Conclusions:** The main and innovative aspect of our proposal is the use of a Web questionnaire to virtually recreate a checkup visit, integrating subjective (patient's information) with objective data (biometric information). Our results, although preliminary and if need of further study, appear promising in proposing more effective telemedicine systems. Survey methodology could have an effective role in this growing field of research and applications.

## Introduction

Survey methodology and medical research are becoming more connected: statisticians have always cooperated with clinicians in the analysis of collected data, and in recent years new research questions have arisen, along with new research fields (eg, health technology assessment and health economics). The aging European population and the interest in a healthy population in western countries have contributed to the increase in the number of health surveys, such as the English Longitudinal Study of Ageing (ELSA, since 2002) [1], the Survey of Health, Ageing and Retirement in Europe (SHARE, individuals from 20 European countries aged  $\geq 50$  years) [2], and the Health and Retirement Study (HRS) since 1992 in United States [3], to cite only the most well-known and relevant for the number of countries involved or for the systematic nature of the survey.

In all these surveys, as well as in more traditional clinical trials, the role of methodology in survey design, data collection, and data analysis is clear and recognized by the whole scientific community. The role of statisticians in clinical trials is now complemented by survey methodology: patients are often surveyed at the beginning and at the end of the trial to assess their well-being or other characteristics connected to the topic under investigation. Furthermore, patients are often requested to give feedback on their satisfaction with health structures, and, last but not least, health data management and analysis are now mandatory in health services assessment. Therefore, the contact points between medical and statistical research are numerous. Due to the complexity of research topics, the requested skills and knowledge are multidisciplinary and interdisciplinary: the role of researchers has been changing, and researchers now need to interconnect with each other, in order to achieve their research goals.

In the same years, survey methodology has had to couple with the challenges deriving from data collection through information and communications technology, the movement from landline telephones to mobiles and smartphones, and the increasing spread of Wi-Fi connections: modes and techniques to collect responses from people is always changing [4-8]. Guidelines and standards to follow are constantly being updated in order to be able to cover ever-changing and dynamic situations and data gathering modes [9,10], and new metrics derived from macro- and microparadata are being proposed and tested [11-16]. At the same time, the evolution of information and communications technology is giving a strong push to telemonitoring, telemedicine, and home rehabilitation systems [17-21]: new systems are being tested, and are quickly evolving from static to wireless devices, and from obtrusive to less-obtrusive equipment, also making it possible to follow patients and collect their information on their activities and reactions potentially everywhere and continuously.

In our opinion, there are new and common challenges for medicine and survey methodology. Which data are useful to be collected and analyzed? How? And when? What is the data's value for the well-being of the patient, which is the ultimate aim of a telemonitoring system? What about the quality and usefulness of the data collected?

In the vast scientific literature on telemedicine systems, we have found only a few reports of systems that use data and information coming directly from patients [22-27], although several systems, as for example Philips' eCareCompanion and eCareCoordinator [28], are now moving on to collecting this information through tablets or smartphones [29,30]. Surely researchers are exploring the implications of how and when these subjective data are collected, their utility for effective monitoring, and, more relevant from our point of view, whether there is a quality control process for this subjective information and how it works, but results have not reached the publication stage.

Our vision is that an effective telemonitoring system would be able to 1) collect objective and subjective data at the same time (biometric parameters and symptoms reported by the patients themselves), 2) control the quality of data collected, and 3) analyze data both at the individual and at an aggregated level.

This ambitious goal can be achieved only by using (and merging) all the technologies and skills available from both survey methodology and health research. In this paper we focus on the contribution of subjective data, that is, data reported by the patients themselves, about themselves, in way that simulates a standard medical examination: this, in our opinion, constitutes the real innovation in the scheme above.

## From Acquisition of Vital Signs to an Integrated Telemedicine System

It is quite obvious that remote monitoring and telemedicine systems apply only to patients with chronic conditions. For them, a remote monitoring system is extremely useful, as it is designed to store data collected directly at the patient's home, with the goal of detecting as soon as possible any worsening of the patient's health status.

Patient-doctor communication seems to be neglected in home monitoring, and yet it is always present in medical checkups (and in their telephone communications). Data and information are always the objects of the patient-doctor communication in each (first or follow-up) medical visit, and yet it seems that telemedicine systems do not include this relevant source of information. Generally, patient-doctor communication is face-to-face. In the first contact with the patient, the physician starts with a clinical interview: this allows the physician to know how the patient feels and the symptoms that he or she reports, and it precedes the objective physical examination. Thereafter, the patient undergoes further examinations (electrocardiography, echocardiography, chest x-ray, etc, and laboratory tests according to the physician's request). Only after all the data and information have been collected and read is the physician able to confirm the diagnosis and prescribe suitable therapy.

We underline that—as physicians themselves state—listening to the patient's account of his or her symptoms and feelings is key to acquiring all of the information about the patient's health status. To have only biometric or laboratory data is not sufficient for making a correct diagnosis and consequent decisions, for taking actions, and for giving prescriptions. For patients with a chronic disease, there are recognized guidelines (standardized by each disease) that have to be followed in a medical checkup:

guidelines recommend not only which laboratory and other tests to take, but also that the symptoms reported by the patients themselves be recorded. Last but not least, patients with chronic diseases are increasingly able to recognize and communicate correct and useful information about their conditions. From these considerations, it follows that a remote monitoring system must have the aim of daily collecting vital signs and biometric data, as well as subjective data, from the patient.

Information and communications technology tools and survey methodology allow for collection of these types of data according to the ideal standards: the questions (asked by a physician) and the responses (given by the patient) can be easily recognized as simulating a questionnaire, whose content and frequency of administration are determined by physicians.

### **The Role of Survey Methodology in Health Monitoring**

The medical checkup can be transformed into a computer-assisted Web interview, and the Web-collected data can be used to generate a longitudinal survey. Subjective data can be analyzed together with objective data in order to have an assessment of the patient's health status or to detect potential risks.

In chronic diseases, the checkup visit can be more easily transformed into a structured questionnaire, because the clinical interview focuses mainly on presenting symptoms and their variations since the last visit. It is possible to acquire and store on a daily basis (or with a different periodicity; in any case, more frequently than the face-to-face checkup visits) all responses and information given by the patient. More important, it is possible to analyze both clinical and patient variables

(measured at the same time) along appropriate longitudinal statistical models.

The aging of the population in western countries calls for the unavoidable and necessary use of a system to automatically assess the health status of patients with chronic conditions, supporting and complementing face-to-face clinic activities, with the aim of focusing the efforts of medical staff on the most serious cases. In order to reliably automate prediction of the state of health of a chronically ill patient, it is also necessary to ensure that data collection is at the highest possible level of reliability and that the data are validated according to metrics established and accepted by the scientific community.

To sum up, in a telemedicine system, questionnaires can be administered (almost) daily for a group of patients for an extended length of time. Are the questionnaires collected in a telemedicine system similar to a longitudinal survey? If we consider that a survey "is a systematic method for gathering information from (a sample of) entities for the purposes of constructing quantitative descriptors of the attributes of the larger population of which the entities are members" [5], then the answer is indeed positive, and we name it a Web health monitoring survey (WHMS).

### **Quality Measures of a WHMS**

If "the quality of a survey is best judged not by its size, scope, or prominence, but by how much attention is given to [preventing, measuring, and] dealing with the many important problems that can arise" [31], then it is relevant to compare the American Association of Public Opinion Research's (AAPOR) criteria to "produce a quality survey" with the particular situation of a WHMS (Table 1) [31].

**Table 1.** Comparison between the American Association of Public Opinion Research's (AAPOR) criteria [31] for a general survey and the features of a Web health monitoring survey (WHMS).

	AAPOR survey criteria	Features of a WHMS
Points better addressed by a WHMS	Have specific goals.	Have specific goals.
	Consider alternatives.	Consider alternatives.
	Take great care in matching question wording to the concepts being measured and the population studied.	Easier than in other fields of research. More attention to question wording in different languages or contexts.
	Maximize cooperation or response rates within the limits of ethical treatment of human subjects.	Patients are strictly involved and their active role in the monitoring system can stimulate a high participation rate, a high response rate, and a low item nonresponse rate. The patient AND the patient's relatives or caregivers can have more positive feelings in participating in the survey.
Points easily respected by a WHMS	Select samples that well represent the population to be studied	The sample is not probabilistic, rather it resembles an opt-in one.
	Use designs that balance costs with errors.	Use designs that balance costs with errors.
	Pretest questionnaires and procedures.	Pretest questionnaires and procedures.
	Train interviewers carefully on interviewing techniques and the subject matter of the survey.	Train and supervise patients (and doctors).
	Use appropriate statistical analytic and reporting techniques.	Use appropriate statistical analytic and reporting techniques.
	Develop and fulfill pledges of confidentiality given to respondents.	Develop and fulfill pledges of confidentiality given to respondents.
Point to be studied for a WHMS	Disclose all methods of the survey to allow for evaluation and replication.	Disclose all methods of the survey to allow for evaluation and replication.
	Check quality at each stage.	New indicators and metrics are required.

## Methods

The main contribution that survey methodologists can make to WHMS is related to the quality of the survey at each stage.

As a first contribution, we offer some indicators, calculated on data collected during the trial of an integrated telemedicine system (*Assistenza domiciliare allo SCOMPENSO cardiaco attraverso Le Tecniche Avanzate di comunicazione digitale*, or ASCOLTA, the Italian word for listen) [32] conducted in 2011 in Pisa, Italy, involving 12 patients with a diagnosis of heart failure. We collected both biometric and subjective data for a period of 2 months for 11 patients and for <1 month for 1 patient, who was the only one hospitalized for noncardiac problems and was thus not included in the study. Patients had to connect daily to a website, at the time most convenient for the patients themselves. A Web questionnaire—dynamically constructed with a different number of questions (and answers) according to the patient's clinical condition—collected the patients' health data, including additional physical data (weight and arterial pressures) measured and reported by the patients themselves. At the end of the questionnaire, the system asked the patient to wear wireless electrocardiograph, pulse oximetry oxygen saturation, and respiratory rate recorders for 5 minutes. The patients were free to ask for a new connection at their discretion.

We have previously described and discussed the positive contribution of subjective data to detecting potential risks [32]: variables obtained during a virtual visit substantially contributed

to assessment of clinical status (69% of correct classifications), similar to the traditional biometric variables (70%), as assessed by a random forest classification algorithm. The combined use of both variables led to a more correct classification of the patient's health status (84%).

The questionnaire (see [Multimedia Appendix 1](#) for the English translation) was designed under cardiologists' supervision, tested, and transformed into a Web questionnaire. The wording of questions and answers and their sequence were in accordance with European Society of Cardiology guidelines [33] for heart failure patients and with the cardiologists' clinical experience.

We also collected paradata during the study period, along with instrumental and subjective data.

During the 2-month trial, we collected a total of 478 records from 11 patients, 243 for the first month and 235 for the second month.

As described before, a WHMS is a longitudinal survey that is quite different from a panel survey in terms of duration and contents; therefore, we needed more specific indicators than the well-known and consolidated indicators available in the literature [12,34,35].

We therefore propose the use of indicators that measure the response and attrition rates at the patient level. The item nonresponse rate is calculated as a proxy of the patient's cooperation. To measure whether there was any habituation to a daily questionnaire, we compared the time span to complete the questionnaire between the two halves of the entire study

period. Finally, we measured the consistency of the time chosen to complete the questionnaire as a proxy of the patient's compliance and satisfaction. Focus groups with patients were organized and conducted both at the beginning and at the end of the trial.

## Results

### Patient Adherence and Response Rate

As expected, patients were very cooperative due to an effective strategy to encourage patient involvement. The number of missing questionnaires was very low. Figure 1 illustrates the response rate by each patient.

**Figure 1.** Response rate, by patient, during the 2-month ASCOLTA study.

### Item Nonresponse

We measured the rate of nonresponse to each item, obtaining good results (Table 2). The 3 biometric variables that the patients

were asked to report in the questionnaire all had a nonresponse rate of 0%, which we interpret as denoting a cooperative attitude among all of the patients: during the final focus group the patients expressed positive reactions for their active role.

**Table 2.** Rate of nonresponse to questionnaire items (N=514).

Items	Nonresponses	
	n	%
Overall feeling	2	0.39
Weight relative to previous day	31	6.03
Swollen legs	5	0.97
Shortness of breath yesterday	4	0.78
Shortness of breath when combing	28	5.45
Shortness of breath when washing	34	6.61
Shortness of breath when getting dressed	38	7.39
Shortness of breath when tying shoes	31	6.03
Shortness of breath when climbing steps	33	6.42
Palpitations	2	0.39
Chest tightness	2	0.39
Tiredness	2	0.39
Maximum blood pressure	0	0
Minimum blood pressure	0	0
Weight	0	0

To measure habituation to the questionnaire, we compared the item nonresponses between the first and the second month. We found no significant differences (Figure 2).

**Figure 2.** Comparison of nonresponses to questionnaire items by period of the study (period 1: first month; period 2: second month) and by question.

**Time to Complete the Questionnaire**

From paradata collected, we calculated the time spent to complete the questionnaires both for the daily and the discretionary questionnaires (Table 3). The time required seemed to depend on the patients' health conditions; in general, time required was very short and acceptable, and at our advice was not perceived as a burden by the patient.

**Table 3.** Time spent to complete the daily and discretionary questionnaires, by patient.

Patient	Daily		Discretionary		Total	
	n	Mean time (min.s)	n	Mean time (min.s)	n	Mean time (min.s)
CLMG	73	1.07	1	8.00	74	1.12
CLTS	55	1.08	0	0	55	1.08
CNCV	20	1.36	1	4.00	21	1.43
CNID	85	1.46	1	1.00	86	1.45
CNNV	24	1.03	1	1.00	25	1.02
DNTC	22	3.49	3	2.20	25	3.38
FRSG	27	1.27	1	1.00	28	1.26
LCUL	46	1.46	0	0	46	1.46
MCLN	57	1.09	1	1.00	58	1.09
PCCL	50	1.34	5	1.24	55	1.33
PSQN	19	1.16	2	1.30	21	1.17
Total	478	1.31	16	2.04	494	1.32

We also tested for difference in completion time between the first and second period (Figure 3 and Table 4). Although the difference was statistically significant for 3 patients, the overall difference was not.

**Table 4.** Time (min.s) spent to complete the daily questionnaires: comparison between first and second period of the study, by patient.

Patient	Period		<i>t</i> test	<i>P</i> value	<i>df</i>
	First half	Second half			
CLMG	1.09	1.05	0.71	.48	71
CLTS	1.16	1.02	2.10	.04 <sup>a</sup>	53
CNCV	1.00	2.20	-2.47	.02 <sup>a</sup>	18
CNID	1.37	1.56	-0.51	.61	83
CNNV	1.05	1.00	0.92	.37	22
DNTC	2.04	6.53	-1.71	.10	20
FRSG	1.47	1.05	1.18	.25	25
LCUL	1.37	2.10	-1.10	.28	44
MCLN	1.08	1.14	-0.49	.63	55
PCCL	1.30	1.41	-0.49	.63	48
PSQN	1.30	1.05	2.13	.05 <sup>a</sup>	17
Total	1.25	1.37	-1.06	.29	476

<sup>a</sup>Significant difference ( $P \leq .05$ ).

**Figure 3.** Time spent to complete the questionnaires, by patient and by period of the study (period 1: first month; period 2: second month).

### Patients' Chosen Time of Day to Complete the Questionnaire

To accommodate the patient's lifestyle, each one could choose the hour of the day when they would complete the questionnaire, with an interval of  $\pm 1$  hour (Table 5).

During the final focus group, the patients expressed their appreciation for this support, and therefore their behavior is a proxy of a cooperative attitude.

**Table 5.** Time of day chosen to complete the questionnaire, by patient.

Patient	Total no. of daily questionnaires completed	Median time at start of questionnaire (h.min.s)	Mean time at start of questionnaire (h.min.s)	Mean difference from median	Mean difference from mean
CLMG	73	8.05.00	8.13.39	18.27	17.54
CLTS	55	14.42.00	14.42.11	16.13	15.46
CNCV	20	15.23.00	15.33.14	13.53	15.51
CNID	85	17.48.30	17.45.53	14.28	14.42
CNNV	24	19.24.30	19.14.28	24.33	26.3
DNTC	22	9.45.00	9.55.55	22.55	25.3
FRSG	27	9.29.30	9.25.56	18.13	18.11
LCUL	46	8.20.00	8.26.29	22.26	22.12
MCLN	57	9.20.00	9.30.47	17.02	19.25
PCCL	50	7.56.30	8.36.28	11.51	31.42
PSQN	19	20.07.00	19.58.11	20.09	19.32

The mean difference was about 20 minutes, both from the median and from the mean.

## Discussion

It is worth noting that our WHMS is part of a telemedicine system, making its goal different from that of other health surveys such as a Web-based daily questionnaire for health [26]. Telemedicine data are collected and must be analyzed at the patient level, because the main goal is to assess the health status of the single patient. On the contrary, in epidemiological studies the focus is on measuring health parameters for the entire population.

Moreover, a WHMS is designed for patients with chronic conditions, and therefore they may already be greatly involved in the survey or their cooperative attitude can be reinforced: no incentive is needed, because the implicit incentive for each patient is to get better attention from the medical staff and to contribute actively to the management of their chronic disease. As a consequence, all indicators based on response rate (although—or perhaps because—they have values never obtained in a general survey) seem less relevant to measure the quality of the WHMS. Nonetheless, their trend over time for longer study is worth computing and controlling.

WHMS is a longitudinal survey with very strict periodicity, even daily, which could be a burden for the respondent [36], resulting in a possible high attrition rate. The attrition rate at the patient level is therefore relevant in monitoring the quality of data collection. Our results demonstrate that this risk is very low, taking into account that only a few minutes are required to complete the questionnaire.

Even with a diligent patient, there is the risk that patients' responses will become automatic. The results we obtained led us to reject the hypothesis of the presence of automatic responses; therefore, the patient's responses are deemed to be reliable.

Signing in to the daily questionnaire and the patients' choice of when during the day to sign in seem a good measure of their cooperation.

Focus groups with patients confirmed the efficacy of the questionnaire and the positive reactions of patients to the new mode of collecting this information. Patients appreciated their new active role in the ASCOLTA system.

## Study Limitations

We acknowledge that our study has some critical limitations, such as the small number of patients studied and the short duration of the longitudinal survey. Furthermore, the study involved only patients with heart failure. Other paradata can be collected, such as those needed to measure response latency or time-to-click [16,37].

In more general terms, the digital skills of potential respondents to a WHMS is a challenge: a sample of patients with chronic conditions would be older, and the greater digital divide in this group could be a barrier to their participation in such a survey [38–40].

Many aspects of a WHMS deserve to be developed, by applying the same approach to other kinds of chronic pathologies (eg, chronic obstructive pulmonary disease, diabetes, and hypertension) [41,42]. Moreover, the expansion of wireless technologies on platforms such as smartphones and tablets will enable the collection of biometric data to extend even to people who are not yet ill (eg, people at risk) or to healthy people who participate in amateur sports. In addition, although this is an open field, the reactions of medical staff to the virtual visit are worth investigating, as patient satisfaction is further explored [43–47].

Information and communications technology solutions can be applied to facilitate and enable patient-doctor communication [48–53]. Many virtual medical visit applications are being developed [54–56] and the increasing number of websites testifies to patients' willingness to play a more active role in their own health management [57,58].

The main and innovative aspect of our proposal is the use of a Web questionnaire to virtually recreate a checkup visit, integrating subjective (patient information) with objective data (biometric information) in a unique database that can be analyzed with appropriate statistical methods. We suggest here some indicators to control the process of data collection, along with criteria already established by survey methodology, but we are conscious that other specific metrics need to be studied.

Our results, although preliminary, appear promising and, in our opinion, could be of significance to the ongoing debate about the most appropriate type of telemonitoring and remote care of patients. Further studies, in a larger population, could be useful to ultimately confirm our preliminary results and to provide a

more efficient cost-benefit ratio, according to health technology assessment.

Survey methodology could have an effective role in this growing field of research and applications.

In agreement with the Couper's statement that "We constantly need to hone our skills, update our knowledge, and expose ourselves to new developments in other disciplines and fields of research and application." [59], we think that monitoring of health data is a challenge for survey methodologists. Skills and competencies of survey methodologists and statisticians must guide data collection and data analysis in health monitoring surveys.

## Acknowledgments

ASCOLTA Project was funded by the Regione Toscana (BANDO UNICO R&S, anno 2008 POR CREO Attività 1.6 Linea A) to a pool of firms (CAEN SpA - leader, Evidence Srl, EMAC Srl, Develer Srl, Sinergest Srl, Laboratori ARCHA Srl). Sant'Anna School of Advanced Studies (Institute of Economics, Institute of Life Sciences, and Institute of Communication, Information, and Perception Technologies) and the Department Cardiac Thoracic and Vascular Department (University of Pisa) gave scientific support. The project was presented in April 2009, approved in April 2010, and concluded in March 2012.

The study protocol was approved by the Ethical Committee of the Hospital of Pisa (Study No. 3461/2011, presented November 29, 2011, approved February 9, 2012).

## Abstract

**Background:** eHealth apps have the potential to meet the information needs of patient populations and improve health literacy rates. However, little work has been done to document perceived usability of portals and health literacy of specific topics.

**Objective:** Our aim was to establish a baseline of lung cancer health literacy and perceived portal usability.

**Methods:** A survey based on previously validated instruments was used to assess a baseline of patient portal usability and health literacy within the domain of lung cancer. The survey was distributed via Amazon's Mechanical Turk to 500 participants.

**Results:** Our results show differences in preferences and literacy by demographic cohorts, with a trend of chronically ill patients having a more positive reception of patient portals and a higher health literacy rate of lung cancer knowledge ( $P < .05$ ).

**Conclusions:** This article provides a baseline of usability needs and health literacy that suggests that chronically ill patients have a greater preference for patient portals and higher level of health literacy within the domain of lung cancer.

**KEYWORDS**

consumer health information; health literacy; eHealth; patient portal

## Introduction

Life expectancy has nearly doubled in the last century [1], due in part to preventive care, screening protocols, and the conversion of previously lethal diseases into manageable, chronic conditions through medical advances. Recently, lung cancer screening with computed tomography (CT) has been shown to significantly reduce lung cancer mortality and has resulted in paradigm shifts such that screening is now a covered medical procedure by both third party payers and Medicare [2], providing the opportunity for more patients to be screened. However, lung cancer is still the single greatest cause of cancer-related death. Accurate and timely patient education is

considered to be one of the critical elements underlying improvements in public health, to better inform patients of the underlying causes of their conditions, the measures they can take to mitigate risk, and the basis, and balance of benefits to risks, of certain interventions.

However, low levels of health literacy are seen as a hurdle to accessing health information [3]. The US Department of Health and Human Services defines health literacy as patients' ability to acquire, read, and understand health information in order to make health decisions appropriate to their situation [4]. The National Center for Education Statistics maintains that health literacy is crucial for all adults to understand and improve their health, as they encounter health information in a variety of

digital and hardcopy formats (eg, websites, blogs, federated search engines, magazine articles, pamphlets, prescription directions) [5].

Further study of patients' health literacy in the subject of lung cancer is necessary to inform the design of patient education tools. Lung cancer screening protocols have recently been revised due to the findings in [2], demonstrating the efficacy of annual CT scans for high-risk individuals. Given the major policy change in lung cancer screening, it is expected that moderate patient education will be required to better understand the etiologies of lung cancer and basis for screening. eHealth apps are a potentially potent medium for the task of providing educational materials.

The term eHealth can be broadly described as the use of information technology in health care, examples of which include patient portals, personal fitness apps that run on mobile phones or personal computers, and digital consumer health educational guidelines. eHealth tools are increasingly available; however, availability does not ensure greater health literacy or increased use of these tools. The term usability refers to the ease of use and learnability of a tool, the measure of which can serve as one gauge of the effectiveness of a tool in helping the user reach their objectives [6]. Usability is necessary to ensure use of and application of the information within eHealth technologies [7,8]. Contributing to perceived usability is perceived feasibility. Feasibility, which can be defined as the effectiveness of an intervention, can be further divided into eight areas of focus, including acceptability, for example, how users react to an intervention, and demand, for example, an estimated need of a tool [8].

While no design will be able to anticipate all information needs, the content of a patient portal has the potential to influence perceived usability and satisfaction, as well as improve health literacy and outcomes [9,10]. Generally, a patient portal is a secure website that provides individuals with access to their personal medical information [11]. Although there has not been lengthy discussion on the content of portals in particular, the content of personal health records (PHRs) has received more attention. Basic consensus has been reached on certain data points that should be included: problem lists, procedures, lab tests, diagnoses, and notes [7,12-15]. These data points would likely prove beneficial in a portal as well. Portals also have a range of functions not available in PHRs, such as the ability to email a physician, renew a prescription, view clinical reports, and make appointments. However, patient information needs may differ by diagnosis, and in order to improve health literacy and outcomes, some diagnoses may require more specific additional information, educational content, and functions [7,16]. For instance, cancer patients have been shown to want access to targeted information about their particular diagnosis (benign vs cancerous), treatments (chemotherapy, radiation, surgery), and prognosis (quality of life, 5-year survival) [17]. However, the specific needs of cancer patients by diagnosis are not well known. Identifying these needs, as well as their literacy levels on specific subjects, would prove helpful in the design of tools meant to serve specific populations, such as lung cancer. Before this can be done, it is necessary to establish a baseline of a general population's information needs.

Additionally, as lung cancer is the leading cause of cancer death and the majority of lung cancer cases are due to tobacco smoke, it is important that the general population be informed regarding lung cancer and the means through which risk can be mitigated (smoking cessation) [18]. While campaigns to inform the general population of this health issue have been wide spread, it is important to document how effective these campaigns have been in providing health consumers with knowledge, especially when considering recent reforms to screening protocol. Assessment of lung cancer literacy can help to inform portal module design aimed at improving literacy rates.

As an initial starting point, we were interested in two areas of study: (1) understanding the perceived usability and, in turn, feasibility of information content of patient portals of a convenience cohort taken from the general public, and (2) the demand for lung cancer specific health literacy of a convenience cohort taken from the general public. Our goal was to establish a baseline to understand how perspectives and literacy vary by basic patient (consumer) demographics.

## Methods

To assess baseline health information needs and preferences, as well as lung cancer knowledge, a survey was developed based on previously validated surveys [19,20], which were designed for the purposes of documenting patients' health portal preferences and lung cancer knowledge. While the questions in our survey are taken from these validated tools, not all questions from the original surveys were used. Instead, in an effort to keep our survey concise and focused, we chose those questions that most closely focused on our concerned topics, perceived usability and feasibility of patient portals, and lung cancer knowledge. We chose to rely on prior validated surveys, as developing and validating a survey would require considerable additional research beyond our current scope. Our instrument consisted of three modules (see [Multimedia Appendix 1](#)). The first module captured information needs and preferences regarding patient portals posed as statements that were rated by participants on a 7-point Likert scale ranging from 1 (completely disagree) to 7 (completely agree). The second module consisted of factual statements about lung cancer and computed tomography with multiple choice answers, of which only one answer was correct. The third module contained demographic questions, based primarily on the US census [21]. Two free-text questions allowed participants to describe concerns and the effects of using a portal. This study was certified exempt by an internal review board committee at University of California, Los Angeles (UCLA).

## Recruitment

The survey was distributed via the website MTurk, a crowdsourcing Internet site devoted to human intelligence tasks [22] that has been used in prior medical informatics studies [23-26] and in the evaluation of consumer health tools [27,28]. The MTurk site was used as it has been demonstrated by those studies as a reliable method to survey a convenience sample and because it provided access to individuals across the country, as opposed to one geographical area. The survey was made available only to those MTurk participants within the United

States. The survey was posted on the MTurk website for 3 weeks in May 2015. Participants were invited to complete the survey with the guarantee of compensation of US \$1 per completed survey; each participant completed only one survey. The first 500 individuals to fully complete the survey were chosen as a convenience sample for purposes of analysis. We sought 250 participants age 41 and older, and 250 participants age 40 and younger. To do this, the survey was distributed twice, once as a survey available to those who were age 40 and younger, and once as a survey to those who were age 41 and older. Participants were asked to affirm their age cohort.

## Statistical Analysis

### Power and Statistical Tests

A power analysis indicated that in order to demonstrate a 0.95 power with  $\alpha=.025$ , we would require 324 participants. Survey results were analyzed using SPSS version 20 software. Statistically significant results are those with a  $P$  value  $\leq .05$ . Independent  $t$ -tests and one-way analyses of variance (ANOVAs) were used in univariate analyses to determine differences in information needs and preferences based on mean values of demographic variables. Chi-square was used in univariate analysis to identify differences in health literacy based on mean demographic variables. To determine if combinations of demographic variables can predict dependent variables, stepwise logistic regression was done using all significant variables from univariate analysis, with each model using the independent variable(s) that had significant univariate results for a particular question ( $P \leq .05$ ). Logistic regression was used in order to make the data as parsimonious as possible, as the number of cases per group were limited. Alongside  $P$  values, log-odds, and prediction probabilities, Nagelkerke  $R^2$  values were also reported. The Nagelkerke  $R^2$  statistic is used to demonstrate how useful the independent variables are in predicting the dependent variable [29].

### Variables

All variables can be seen in [Multimedia Appendix 2](#). Due to sparse data, the demographic variables sex and race were

collapsed into dichotomous variables (seen [Multimedia Appendix 1](#)). The variable sex included one response listed as “other.” This single response was eliminated from univariate analysis of portal preferences based on sex. For logistic regression, the 7-point Likert scales used to record patient portal responses were also dichotomized as follows: Agree (Scores 5-7) and Disagree (Score 1-4). For regression analysis, a score of 4 on Likert scale responses was included within the Disagree category, as the purpose of our analysis was to compare those who agreed to others. For lung cancer knowledge variables, binary values were coded as “0” for incorrect and “1” for correct.

## Results

Only surveys with no missing data elements were analyzed. Participants who returned surveys with missing data points were contacted via email and invited to supply the missing data points. There was no consistent pattern to the types of data elements not completed. The surveys of participants who supplied the missing data were included in analysis. In total, out of the 500 surveys issued, 473 complete surveys were collected.

### User Demographics

The majority of participants were white (389/473, 82.2%) (see [Table 1](#)). Although accounting for fewer respondents, Asian (26/474, 5.4%) and black (25/473, 5.2%) participants were the second largest group and were roughly equivalent. The majority of participants had some college education, with very few (27/473, 5.7%) participants listing high school as their highest level of educational attainment. Roughly half of respondents reported an annual income of US \$35,000 or less. Participants tended to spend over 11 hours a week online (349/473, 73.7%), but most had used a portal 10 times or less (216/473, 45.6%) or had never used a patient portal (174/473, 36.7%). This rate of portal use suggests that responses to the survey are both a measure of needs for those with experience using a portal, and expectations for those who have not used a portal before.

**Table 1.** Demographic results.

Demographics	n	%
<b>Age in years</b>		
18-20	14	3
21-30	131	27.7
31-40	95	20.1

Male	244	51.5
Female	228	48.2
Other	1	0.2

## Evaluation Outcomes

### *Influence of Participant Characteristics on Patient Portal Questions*

Patient response frequencies to all survey questions can be seen in [Multimedia Appendix 3](#), and results to all univariate analyses can be seen in [Multimedia Appendix 4](#). Demographic variables that significantly influenced participant perceptions of patient portal usability and feasibility are shown in [Table 2](#). For all significant results, females rated statements about portal perceptions with higher positive responses. For example, the average Likert response to the question “Portals are not difficult to use” was 4.97 for males and 5.32 for females ( $P=.009$ ).

Females tended to have higher, more positive average Likert scores across all questions relating to portal use.

Respondents reporting a chronic illness also tended to have more positive views of portals, with higher average ratings than those without chronic illness. The average response was significantly higher for chronically ill participants for all four questions relating to portals (see [Table 2](#)). This trend was also seen across all questions relating to portal preferences.

Differences in responses significantly varied based on the number of times participants had used a patient portal. However, there was no consistent trend seen across answers. Additionally, while not statistically significant, 33% of participants reported concern about “unauthorized access” to their patient portal.

**Table 2.** Statistically significant results of univariate analysis of patient portal preferences.

Independent variable	Survey question	Eta <sup>2</sup>	P
<b>Sex<sup>a</sup></b>	Portals are not difficult to use.	0.014	.009
	Using a portal can make me accomplish tasks (eg, review my diagnoses and tests) quickly in managing my personal health information.	0.009	.044
<b>Chronic illness</b>	A portal can be useful to manage my personal health information.	0.025	.003
	Using a portal can make me accomplish tasks (eg, review my diagnoses and tests) quickly in managing my personal health information.	0.29	.001
	A personalized portal can suit my needs of managing my personal health information.	0.014	.034
	It should be easy to become skillful at using a portal.	0.027	.001
<b>Portal use</b>	A personalized portal can suit my needs of managing my personal health information.	0.036	.002

<sup>a</sup>Independent variable that utilized an independent  $t$  test; all others used ANOVAs.

### *Influence of Patient Characteristics on Lung Cancer Screening Knowledge*

Questions pertaining to lung cancer and chest CT had multiple choice answers, of which one answer was correct. The chronic illness predictor was most frequently associated with correct

responses (see [Table 3](#)). Those reporting a chronic illness had a higher rate of correct answers for three of the four significant results. However, those not reporting chronic illness performed better on the two questions with the outcome variable “Someone who has quit smoking...” and “Lung cancer is one of the most common cancers.”

**Table 3.** Statistically significant results of univariate analysis of demographic variables on lung cancer knowledge.

Independent variable	Survey question	P
<b>Education</b>		
	In the past, before the CT scan was introduced, the chance of dying due to lung cancer after diagnosis was high.	.005
<b>Income</b>		
	A change of cough pattern is a frequent sign of lung cancer.	.034
	Coughing up blood is a frequent sign of lung cancer.	.030
<b>Smoking habit</b>		
	Lung cancer is one of the most common cancers.	.036
<b>Hours online</b>		
	CT images are made with X-rays.	.016
	To complete a CT scan, subjects must undress their upper body.	.006
	Lung cancer is infectious.	.030
<b>Sex</b>		
	Coughing up blood is a frequent sign of lung cancer.	<.001
<b>Chronic illness</b>		
	CT images are made with X-rays.	.012
	To complete a CT scan, subjects must undress their upper body.	.017
	A change of cough pattern is a frequent sign of lung cancer.	.014
	Lung cancer is infectious.	<.001
<b>Portal use</b>		
	Lung cancer is infectious.	<.001

Other predictors with significant test results included time spent online, income, education, smoking habit, sex, and portal use. Time spent online had the second highest number of significant tests with three results. However, there was no consistent pattern observed within the rates of answers, with those who spent more time sometimes outperforming and sometimes underperforming those who spent less time. For the income predictor, correct answers to the question “Coughing up blood is a frequent sign of lung cancer” increased as income increased, until the level of US \$76,000 or more. Those who made US \$76,000 or more a year had a lower rate of correct answers than those who made less. For the smoking habit predictor, those who smoked had a slight but significantly lower rate of correct answers (78.4% versus 78.7%) for the question “Lung cancer is one of the most common cancers.” Men had a significantly higher rate of correct answers for the question “Coughing up blood is a frequent sign of lung cancer” than women (75.4% vs 73.7%). As portal use increased, correct answers to the question “Lung cancer is infectious” decreased. There was no pattern observed in response rates for the question “In the past, before the CT scan was

introduced...” when stratified by the education predictor, nor for the question “A change of cough pattern is a frequent sign of lung cancer” response rates when stratified by the income predictor.

### Logistic Regression

Stepwise logistic regression was performed for demographic variables that had statistically significant relationships as seen in Tables 2 and 3. Statistically significant results for logistic regression are seen in Table 4. Increased portal use was positively associated with agreeing with the statement “It should be easy to become skillful at using a portal,” meaning participants who used a portal more than 10 times were more likely to agree with the statement. However, prediction success was weak with 32.6% of outcomes correctly predicted. The chronic illness predictor was positively associated with having the correct answer for “A change of cough pattern is a frequent sign of lung cancer,” indicating that those with a chronic illness were more likely to choose the correct answer for the question. However, prediction was not improved in comparison to the constant model, remaining at 52.4%.

**Table 4.** Statistically significant results for logistic regression analysis.

Independent variable	Survey question	Log-odds	<i>P</i>	Nagelkerke $R^2$	Prediction percentage correct, %
<b>Portal use</b>					
	It should be easy to become skillful at using a portal.	0.996	.016	0.024	32.6
<b>Chronic illness</b>					
	A change of cough pattern is a frequent sign of lung cancer.	0.611	.008	0.020	52.4

## Discussion

### Principal Results and Comparisons With Prior Work

In this study, a convenience cohort of the general public was asked to rate their perceptions of usability and feasibility of patient portals and knowledge of lung cancer, in order to demonstrate the demand for lung cancer knowledge and status of patient portal usability. Overall, we observed that respondents reporting chronic illness tended to have more positive opinions of patient portals and to perform better on lung cancer knowledge questions than those without a chronic condition. Chronically ill patients having a more positive opinion of eHealth is a finding that has also been observed [30,31]. Similarly, a review of literature on portals found that participant interest in patient portals varied by health status [32].

Interestingly, some studies have found that chronically ill patients may have lower health literacy [33,34]. In contrast, a study found that those with a chronic illness reported higher rates of literacy regarding test results [35]. In our work, it may be that the higher performance we observed relates to higher levels of educational attainment, as those respondents reporting chronic illness in our survey more frequently had Associate, Bachelor's, and Master's degrees than those reporting no chronic illness (14.6% vs 12.9%, 39.8% vs 36.8%, and 9.7% vs 8.8% respectively).

Having used a portal was associated with significant difference in opinions of patient portals. However, there was no consistent trend observed, with some statements being rated in higher agreement by those who had used portals more and other statements being rated higher by those who had used them less. It is also worth noting that for those who had never used a portal, these statements are measuring expectations of portals, while with those who have used portals, these statements are measuring experience. These results suggest that opinions about the usability of portals do not demonstrate a clear trend whether being drawn based on expectations or experience.

We also found that women reported more positive ratings of portals. While use does not equal preference, positive ratings may be influenced by the higher use of portals we observed in this survey (19.7% of women had used a portal over ten times, compared to 14.3% of men), which is consistent with higher eHealth resource use observed in women [36-38]. We also documented a statistically significant difference in correct responses for lung cancer knowledge stratified by the amount

of time spent online. Others have found similar relationships between Internet use and health literacy [34], but our results showed no consistent trend and are inconclusive.

Although two logistic regression models had significant *P* value results, neither model had strong prediction success. While the low *P* values (<.05) indicate that the findings are unlikely due to chance, the prediction values, as well as the Nagelkerke  $R^2$  values, indicate that these models will not perform prediction well. Further research is required to determine predictors that would predict answer cohorts to these questions successfully.

Finally, 33% of participants noted that they were "concerned about unauthorized access," which was the most commonly chosen option (see [Multimedia Appendix 4](#), Question 26). In other work, security was a concern for two thirds of health information consumers, although users of PHRs had less observed concern [39]. The overall percentage of participants concerned with security in this study was less than in [39]. However, a similar trend was observed with 32.5% of those who had used a portal more than 10 times were concerned with unauthorized access while 33.1% of those who had used a portal 10 times or less were concerned. Similarly, security has also been a concern [40]. This common theme suggests that eHealth users may associate eHealth tools with a lack of security. This concern has the potential to impact portal use, as it would likely limit satisfaction and perceived usability and, thus, feasibility.

### Limitations

There are several limitations to this study that may have influenced our results. Most importantly, we used a convenience sample of the first 500 respondents to a survey posted on MTurk. As such, the results derive from Internet users; those with less Internet experience may well have different views regarding patient portals and lung cancer health literacy than those documented here. Our respondents also had higher levels of education than seen in the US population [41], which may have influenced health literacy. Moreover, although we specifically asked respondents not to look up answers to lung cancer questions, we have no guarantee that responses were not informed by additional online queries.

An additional limitation is the potential bias that may be introduced by the use of a digital survey format. Others have found that patients who have used eHealth technology have more positive opinions of it than those who do not [42], suggesting that experience with technology can cause one to

regard it more favorably. Here, completing a digital survey on eHealth may bias respondents to rate statements about patient portals more highly.

## Conclusion

This work documents a baseline for consumer information needs and health literacy within the domain of lung cancer. Our results suggest that women and those with chronic illness had more positive views of patient portals and that chronically ill patients had higher health literacy in lung cancer. Although chronically ill patients are a likely user group for patient portals, non chronically ill patients can also benefit from opportunities to manage and learn about their health as well as mitigate risk via portals. Given this, the results suggest a need for further

lung cancer education with opportunities to use patient portals to better educate individuals who do not have a chronic illness about lung cancer. Further study is also needed in order for portals to better address the information needs of patients who are not chronically ill in order to improve perceived usability and feasibility.

This baseline can be used in future comparison studies as well as to inform portal design to improve usability and raise lung cancer health literacy with educational modules. Our future work includes designing a patient portal influenced by these results and then surveying a patient population at UCLA who will have access to the portal, to compare those survey results to this baseline, in order to identify any difference between them.

## Abstract

**Background:** A key challenge for longitudinal cohort studies is follow-up and retention of study participants. Participant follow-up in longitudinal cohort studies is costly and time-consuming for research staff and participants.

**Objective:** This study determined the feasibility and costs of using Web-based technologies for follow-up and collection of patient-reported outcomes in the Mediators of Atherosclerosis in South Asians Living in America (MASALA) study.

**Methods:** The MASALA study is a community-based cohort of 906 South Asians in the United States. Since the baseline in-person visits (2010-2013), a yearly telephone follow-up survey was used to assess participants' health status and incidence of cardiovascular disease. A Web-based version of the follow-up survey was developed using the REDCap (Research Electronic Data Capture) Web app. Participants from the Chicago field center who were due for their annual follow-up and who had a valid email address were sent an email link to a secure online portal where they could complete the survey. Telephone follow-up was used with nonresponders.

**Results:** A link to the Web survey was emailed to 285 participants (February to October 2014) and the overall completion rate was 47.7% (136/285). One-third of participants who were unresponsive (n=36) to annual telephone follow-up completed the Web survey. Web responders were younger, more likely to be married, and to have higher education and income compared ( $P<.05$ ) to telephone-only responders. Web survey development involved 240 hours of research staff time. Since launching, the Web-based survey has required 3 hours per week of staff time.

**Conclusions:** Although electronic follow-up will not be a panacea for cohort operations, it will serve as an adjunctive strategy to telephonic follow-up for maximizing cohort retention with lower costs.

cardiovascular diseases; cohort studies; Internet; South Asian

## Introduction

Population-based cardiovascular cohort studies contribute important scientific information about risk factors and pathophysiology of cardiovascular disease by collecting high-quality detailed data linked to longitudinal outcomes. However, longitudinal follow-up of cohorts can be costly, time-consuming, and burdensome to research staff and study participants. The balance of cost, data validity, and feasibility is increasingly important for determining the value of traditional population-based cohorts [1]. To remain relevant in a technologically evolving world, cohort studies should be able to capture data using newer methods, such as Web-based follow-up, without sacrificing participant retention rates [2,3]. This study determined the feasibility and costs of using Web-based technologies to longitudinally follow participants in a cardiovascular cohort study, the Mediators of Atherosclerosis in South Asians Living in the United States (MASALA) study.

## Methods

The MASALA study is a community-based longitudinal cohort study designed to understand the risk factors and etiology of cardiovascular disease (CVD) among South Asians living in the United States aged 40 to 84 years who were free of CVD at baseline [4]. Baseline clinical visits were conducted from 2010 to 2013. Once per year, follow-up was conducted using a brief telephone survey to assess changes in participants' health status, hospitalizations, procedures, and self-reported CVD events. In 2013, the Chicago site received pilot funding to implement and test the feasibility of using Web-based technology for participant follow-up and patient-reported outcomes (PRO) measurement and data collection. Starting in 2014, participants from the Chicago site who had provided a valid email address were given the option of completing the annual follow-up using a Web-based survey. This study was approved by the Institutional Review Board at Northwestern University, Chicago, IL, and informed consent was administered to all participants at the study baseline visit.

### Choice of Web-Based Platform

Initially, the study team evaluated three Web-based platforms: SurveyGizmo, Assessment Center [5], and REDCap (Research Electronic Data Capture) [6]. SurveyGizmo is a proprietary electronic survey tool that was used for follow-up of cohort participants from the Coronary Artery Risk Development in Young Adults (CARDIA) study and is compliant with the Health Insurance Portability and Accountability Act (HIPAA). However, concern about a third-party website hosting study

data was an important barrier for using SurveyGizmo. Assessment Center is a platform funded by the National Institutes of Health that was specifically created to collect PROs [7] and to reduce respondent burden. It is widely used by biomedical and behavioral research programs. REDCap is a consortium developed among various institutions for research data capture, including electronic surveys. Both Assessment Center and REDCap platforms are secure, are HIPAA compliant, and allow easy data export. Both Assessment Center and REDCap utilize email as a means of sending the survey link to participants.

REDCap was chosen as the Web-based platform for the MASALA study because it had several necessary features and capabilities that were not available through Assessment Center, such as branching capacity and dynamic templates. Assessment Center can be customized, but the cost of customization was prohibitive for the MASALA study.

### Development of Web-Based Survey

The MASALA annual follow-up survey used paper surveys and the TeleForm version 9.1 software system (Verity Inc, San Francisco, CA, USA) for automated data entry; the survey was converted by study staff into a Web-based survey in REDCap. If a participant reported a hospitalization, CVD event, or other cardiac testing, they were asked to provide further details on the event date, hospital or clinic, and physician's name so that MASALA staff could obtain the records for event adjudication. In addition to the 21 annual follow-up questions, we added three PRO measures (15 new questions on physical function, applied cognition, and satisfaction with social roles) from the static PRO short forms developed by the Patient-Reported Outcomes Measurement Information System (PROMIS) to the end of the Web-based follow-up survey. These questions were added to collect pilot data for future studies related to aging and cognition among MASALA participants (Figure 1).

We conducted beta testing of the Web-based electronic MASALA (e-MASALA) follow-up survey and PRO using REDCap with 10 South Asian men and women aged 27 to 77 years. Participants varied in their computer literacy and familiarity with the Internet. All participants were able to follow the on-screen instructions, complete the survey, and reported that they understood the questions and response options. When asked about preferences related to how the survey would be viewed in the browser, seven of 10 preferred a one-page survey. Participants also preferred using a matrix to answer questions that had the same stem rather than repeating the stem for each question. The first version of the Web questionnaire required approximately 240 hours of a research assistant's (RA) time to design, test, and implement.

Figure 1. Matrix included in the Web-based questionnaire.

## Web Survey and Security

Participants received a link to the survey through their email. The survey linked to an online portal from which patients could gain access to a study-specific REDCap page. REDCap allows for secure Web authentication, data logging, and Secure Sockets Layer (SSL) encryption. REDCap is built around HIPAA guidelines, but is not suitable for clinical trials governed by the Federal Drug Administration because it is not compliant with 21 CFR Part 11 [8]. The participant's study ID and an acrostic were the only identifiers for completed surveys.

## Protocol for Web-Based Survey Follow-Up

Before implementing the Web-based survey, annual follow-up of MASALA participants was completed by telephone using teleforms. If a participant was not reachable after six telephone calls, project staff would mail the teleforms, instructions, and a stamped envelope addressed to the site principal investigator so teleforms could be returned.

The Web-based follow-up survey was sent out to participants who were due for their annual follow-up on the first Friday morning of each month. Four weekly reminders were sent out every Friday if the participant did not complete the survey in the prior week. The participant's baseline clinical visit date determined when the annual follow-up survey was sent. During the initial 2 months of this pilot study, the Web-based survey

was also sent to participants who had been unresponsive to telephone follow-up since their baseline visit. Participants who did not complete the Web-based survey after four reminders were contacted at the end of the month by telephone to complete their annual follow-up. If time allowed, the RA asked participants about reasons for not completing the Web-based survey.

Initially the participants received three emails over a 4-week period to complete the survey. After observing the first month's completion rate, a fourth and final reminder email was added. This fourth email resulted additional survey completions without any obvious increase in participant burden. We continued to send four emails and the final email for the month was sent with the subject heading: "Final reminder: Last chance to complete your annual MASALA follow-up survey via Internet." This subject heading used a deadline and time-sensitive language to create a sense of urgency in participants [9].

The participants were emailed on Friday each week. The decision to send the email link to the survey on a Friday was based on study staffs' prior experience contacting MASALA study participants. Previously, we found that participants were more likely to read study recruitment letters or respond to study phone calls on Fridays and over the weekend because they had more time. Thus, we used the same protocol for the Web survey.

RedCAP is equipped with a scheduling feature that can be used to schedule and automate scheduled email reminders on a particular day and time. This feature was important for reducing staff burden during holiday season and during long weekends while ensuring that participants received their emails reminders weekly.

Descriptive statistics were used to calculate the completion rate for the Web survey to compare Web responders to telephone responders and to calculate estimated costs of using a Web-based survey for follow-up data collection. Differences between Web responders and telephone responders were compared using unadjusted chi-square test and *t* test for age with a *P* value of .05 or less to determine statistical significance. Analyses were conducted using SAS version 9.4 software (SAS Institute, Inc, Cary, NC, USA).

## Results

To date, we have completed 9 months of data collection using the Web-based platform at the Chicago field center of the MASALA study. A link to the follow-up survey has been emailed to 285 participants and the overall rate of completion was 47.7% (136/285) (Table 1). The majority of surveys were completed on the same day that the first email was sent. There were demographic differences in participants who completed the follow-up survey by Web or telephone. For example, Web responders were significantly younger and more likely to have higher education and incomes than telephone-only responders (Table 2). Two participants reported a CVD event using the Web-based survey.

**Table 1.** Completion rates of a Web-based follow-up survey in the Mediators of Atherosclerosis in South Asians Living in America (MASALA) study, Chicago field center, 2014 (N=285).

Month (2014)	Total surveys emailed, n	Weekly survey completion, n				Completed Web-based survey, n (%)
		Week 1	Week 2	Week 3	Week 4	
February	66	5	9	3	— <sup>a</sup>	20 <sup>b</sup> (33)
March	58	10	6	9	13	39 (67)
April	20	5	6	2	0	11 (55)
May	22	3	2	1	0	6 (27)
June	28	7	3	6	1	17 (60)
July	18	5	2	2	0	9 (50)

100,000-200,000	36 (30.2)	35 (29.6)	15 (29)	
>200,000	41 (34.4)	13 (11.0)	14 (27)	

<sup>a</sup>Marital status of 21 nonrespondents is not known.

One-third (12/36) of participants who were unresponsive to telephone follow-up since their baseline exam (n=36) completed the Web-based survey. Some surveys were partially completed (n=8), where participants opened the link but did not complete the survey. A personal reminder from the site principal investigator was sent to participants who opened, but did not complete, the survey. After receiving the reminder email, six of eight participants revisited and completed the Web-based survey.

Among participants who were contacted by telephone to complete the follow-up survey and who were asked about reasons for not completing the Web survey (n=32), most (78%, 25/28) said it was because they were too busy, did not check

their email regularly, or did not pay attention to the email. These participants said that they would try to complete the Web-based survey in the future because they were subsequently aware of it.

An RA developed and implemented the Web survey. During the initial development stages, the RA spent 20 hours per week for 8 weeks exploring different platforms and their capabilities (Table 3). This time was primarily spent on exploring different Web platforms and designing and implementing the Web-based survey. During survey development in REDCap, the RA spent 10 hours per week meeting with REDCap staff, designing the branching and skip patterns, and pretesting and modifying the Web survey.

**Table 3.** Comparison of approximate costs for telephone, Web-based, and mixed mode (50% Web-based and 50% telephone) follow-up.

Activity	Survey type (US\$)		
	Telephone	Web-based	Mixed method
Development (exploration, instrument building, usability testing)	\$8500 (5 teleform pages at \$1700/page)	\$3600 (at \$15/hr)=\$2400 (20 hr/wk for 2 months) + \$1200 (10 hr/wk for 1 month)	\$12,100/year
Operation and maintenance	\$3120/year (4 hr/wk at \$15/hr)	\$2340/year (3 hr/wk at \$15/hr)	\$3120/year
Data management	\$2340/year (at \$45/wk)	Included in maintenance	\$1170/year
Total annual cost	Year 1: \$13,960; Year 2 onward: \$5460	Year 1: \$5940; Year 2 onward: \$2340	Year 1: \$16,480; Year 2 onward: \$4290

Since its launch, the Web survey and platform required 3 hours per week of the research staff's time to build new batches of participants who are due for follow-up, send out the surveys, track survey completion, and send follow-up emails to participants who did not complete the survey in the prior week. The process of collecting annual follow-up information via telephone required research staff to make multiple attempts to contact participants, spend 5 to 10 minutes interviewing participants, and then fax the teleforms to the study's data management center. The annual cost of the telephone follow-up and data management of teleforms was US \$13,960 annually (Table 3). During its first year of design and implementation, the annual cost of the Web survey was US \$6660 and the projected cost of operating and maintaining the Web-based survey is expected to be US \$2340 per year. REDCap provides automated export procedures for data, whereas the telephone survey required manual entry of data onto a teleform and data verification after the teleform was faxed to the data-coordinating center.

## Discussion

This study found that a Web-based platform was feasible and at a lower cost than telephone follow-up for the collection of longitudinal follow-up data in the MASALA study cohort. Of participants who received a link to the Web survey, we found that 48% completed it. Differences between Web responders and telephone-only responders included age, sex, income, and education. Telephone follow-up of participants who did not respond to Web surveys was still required; however, the Web survey allowed research staff to spend far less time on follow-up. Web-based follow-up also lowered the number of telephone contacts between participants and study staff, which may in turn help to reduce participant burden. One important finding was that one-third of respondents who had not previously responded to the follow-up survey completed the Web survey, which suggests that a Web platform can help engage participants who may be difficult to reach by telephone. The majority of costs that were associated with development of a Web survey were for development, beta testing, and initial implementation. Since the initial implementation, the cost of maintaining the Web survey and follow-up data have been minimal compared to the costs of telephone follow-up and management of teleform data.

We had a higher completion rate of the Web survey compared to what was reported in the Black Women's Health Study; in 2007-2008, the investigators reported that approximately 25% of participants completed the Web survey [10]. However, they noted that completion of Web surveys among participants was increasing over time, suggesting that temporal trends in Internet use would lead to more individuals having access to the Internet and feeling more comfortable with Web surveys. The finding that age and socioeconomic status influenced mode of response has been reported by others [10-14].

In October 2014, the National Heart, Lung, and Blood Council (NHLBI) Board of External Experts Working Group's Recommendations to the NHLBI Advisory Council stated that, "NHLBI should actively engage in studies to establish the

validity, reliability, and scalability of electronic tools for primary data collection" [3]. The board also recommended active support by NHLBI for the development, validation, and sharing of digital tools. Along with the Health eHeart [15] and the CARDIA cohort's recent experiences, these data represent some of the first describing the methods and findings from "e-epidemiology" in the United States. The primary difference between e-MASALA and studies such as Health eHeart is the lack of an in-person examination among the latter's participants. Other cohort studies, such as the Nurses' Health Studies [16] and others, have not included in-person examinations and have relied solely on telephone and postal mail to capture data. Such cohort studies can be efficient, but can also lack in-depth phenotyping with in-person examinations or advanced imaging.

It also remains uncertain how participant retention rates may differ, if at all, among participants who are recruited and followed in an Internet-based cohort compared to a traditional cohort study. A study of the association between communication strategies used for recruitment (offline, online, face-to-face) and follow-up participation in nine Internet-based cohorts found that follow-up participation ranged from 43% to 89% depending on the cohort. The study also found that participants who became aware of the study through an online communication campaign, compared with those through traditional offline media, seemed to have a lower follow-up participation in eight of nine cohorts [17].

Studies have also found associations between sociodemographics and participation in follow-up reporting. In the Influenzanet study, participants from seven European countries were asked to report weekly symptoms during influenza season using a Web-based reporting system [18]. Sociodemographic factors associated with lower participation in follow-up reporting included younger age, lower education, living in a household with children, and not being vaccinated for influenza. However, another Web-based cohort study found that individuals with lower self-reported computer skills and literacy were more positive toward the study and less concerned about the burden of study follow-up than those with higher education [14]. Given this information, it appears that any well-designed cohort study, regardless of how data are collected, should use a combination of Internet and non-Internet engagement and retention activities to enhance follow-up of all participants and to potentially reduce selection bias.

Strengths of this study include novel development, implementation, and evaluation of a Web-based survey instrument within a traditional cohort and inclusion of start-up and maintenance time and cost estimates to help researchers leading other longitudinal cohort studies. However, our study also has limitations. First, we piloted the Web-based follow-up study only among MASALA participants from the Chicago field center. However, we might expect even higher response to Web-based follow-up among the San Francisco-based participants because those participants tend to have higher education and income levels, which were associated with higher use of the Web-based follow-up instrument. This program was expanded to the San Francisco field center in January 2015. Second, our results are limited to South Asians in the United States and results from other race/ethnic groups and nationalities

may be different, particularly when differences in sex, education, and income are present. Our ability to demonstrate feasibility and lower costs with Web-based follow-up serve as an initial step toward more advanced methods of data capture.

We successfully implemented a Web-based survey for follow-up and collection of PRO measures among MASALA cohort participants. These results demonstrate the benefits of using Web-based methods for longitudinal follow-up in epidemiologic

cohort studies and that a combination of modalities may be most effective. Although electronic follow-up will not be a panacea for cohort operations as hypothesized by some, it will serve as an adjunctive strategy to telephone follow-up for maximizing cohort retention, lower costs, and possibly lower participant and research staff burden. Other traditional cohort studies can adapt these methods for Web-based follow-up of research participants.

## Abstract

**Background:** It is important to enhance the return to work of cancer survivors with an appropriate intervention, as cancer survivors experience problems upon their return to work but consider it an essential part of their recovery.

**Objective:** The objective of our study was to develop an eHealth intervention to enhance the return to work of cancer survivors and to test the feasibility of the eHealth intervention with end users.

**Methods:** To develop the intervention we 1) searched the literature, 2) interviewed 7 eHealth experts, 3) interviewed 7 cancer survivors, 2 employers, and 7 occupational physicians, and 4) consulted experts. To test feasibility, we enrolled 39 cancer survivors, 9 supervisors, 7 occupational physicians, 9 general physicians and 2 social workers and gave them access to the eHealth intervention. We also interviewed participants, asked them to fill in a questionnaire, or both, to test which functionalities of the eHealth intervention were appropriate and which aspects needed improvement.

**Results:** Cancer survivors particularly want information and support regarding the possibility of returning to work, and on financial and legal aspects of their situation. Furthermore, the use of blended care and the personalization of the eHealth intervention were preferred features for increasing compliance. The first version of the eHealth intervention consisted of access to a personal and secure website containing various functionalities for cancer survivors blended with support from their specialized nurse, and a public website for employers, occupational physicians, and general physicians. The eHealth intervention appeared feasible. We adapted it slightly by adding more information on different cancer types and their possible effects on return to work.

**Conclusions:** A multistakeholder and mixed-method design appeared useful in the development of the eHealth intervention. It was challenging to meet all end user requirements due to legal and privacy constraints. The eHealth intervention appeared feasible, although implementation in daily practice needs to be subject of further research.

## KEYWORDS

cancer; return to work; eHealth; survivorship; feasibility studies; self-management

## Introduction

Due to the improved survival rates for cancer in recent decades [1], remaining in or returning to work has become a relevant

topic to address for people with a job when being treated for cancer. The number of people who have a job when diagnosed with cancer is expected to increase considerably in the coming years. This is mainly due to an increase in the retirement age, with the incidence of cancer within the working age group

predicted to increase by 45% with the inclusion of people aged 65–70 years [1].

Research done over the past 10 years has indicated that cancer survivors are more likely than cancer-free controls to be unemployed [2,3] and they also experience problems upon their return to work [4]. These adverse work outcomes need to be improved through an appropriate intervention, as returning to work is considered a key survivorship issue by cancer survivors [5]. It also contributes to their quality of life and reduces financial problems [6]. A few interventions with the potential to enhance the return to work of cancer survivors have been studied in randomized controlled trials, with some interventions showing positive results on sustainable return to work, while others did not [7]. Of these interventions, multidisciplinary interventions showed the most promising results [7].

An overview of the outcomes of these above-mentioned intervention studies, as well as studies of factors predicting the return to work of cancer survivors, led to the following main insights. First, it is both feasible and appreciated by cancer survivors to address the issue of return to work in an early stage of psycho-oncological cancer care [8,9], although the amount of time available to spend on this topic is limited [9]. Second, self-assessed work ability is an important prognostic factor, irrespective of clinical characteristics [10]. Third, cancer survivors differ considerably in the time needed before their return to work [11] and the amount and timing of support required, suggesting that support needs to be tailored to the individual [12]. Fourth, employers are important stakeholders who can facilitate or hamper the return to work [13], while at the same time it appears difficult to establish cooperation between primary care, occupational care, and the workplace [9]. These main findings led to 2 hypotheses: 1) that an intervention aimed at enhancing the return to work of cancer survivors could be based on the theory of self-management, which can address misconceptions about self-assessed work ability through the technique of cognitive restructuring; and 2) that cooperation between specialist cancer care, the general practitioner, and occupational health care might be improved with integrative care management [14,15].

Based on the assumption that information and support need to be tailored to the individual, a stepped-care eHealth intervention

may be a suitable solution. Other advantages of eHealth interventions include that they are easy to access and to tailor to the individual, both of which are important, as information on the Internet can be overwhelming [16]. Furthermore, eHealth interventions can be delivered interactively and also be integrated with traditional health care visits, which is much needed, given the limited availability of time in the health care system. Such eHealth approaches have also demonstrated that they are suitable for delivering self-management interventions for cancer survivors [17] and self-management interventions to enhance the return to work [18]. Finally, eHealth has also been used to facilitate involvement of the employer [14]. Nevertheless, a few drawbacks of eHealth interventions have been reported, such as difficulties with patients' noncompliance, high dropout rates, and security and privacy issues [19,20].

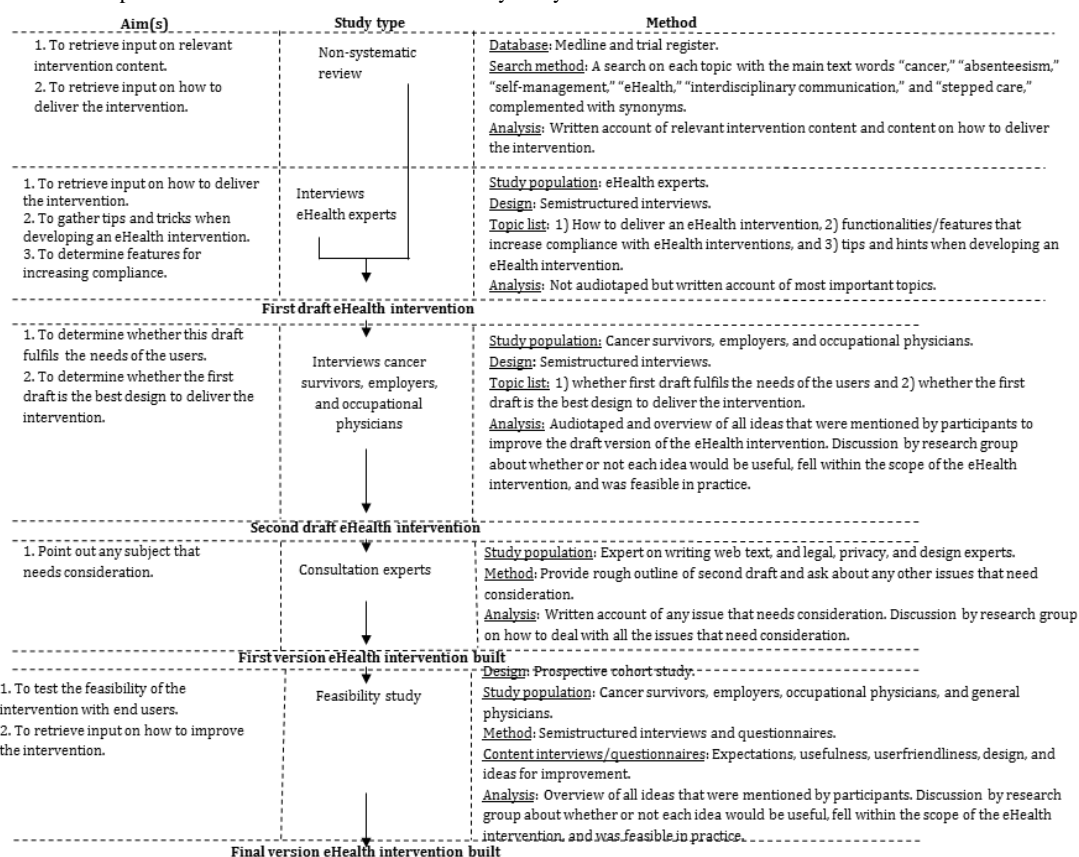

Based on all of the above-mentioned findings, we decided to develop an intervention that would be part of psycho-oncological care and be based on the theory of self-management and integrative care management. We decided to deliver the intervention as stepped care through eHealth. In this paper, we report on this process, specifically addressing the above-mentioned challenges to eHealth interventions, including noncompliance.

The objectives of this study were to develop an eHealth intervention to enhance the return to work of cancer survivors and to test the feasibility of the eHealth intervention with end users.

## Methods

We sought ethical approval to interview cancer survivors, employers, and occupational physicians, as well as approval for the feasibility study, from the Medical Ethics Committee of the Academic Medical Center, Amsterdam, the Netherlands, which judged that ethical approval was not required for either of the 2 studies (METC number W13\_028 and W13\_122). Participants (with the exception of experts) gave either their oral or written informed consent before the interview took place, or their written informed consent before participating in the feasibility study. We executed the following steps for objective 1 (Figure 1).

**Figure 1.** Flowchart of the development of Cancer@Work and the feasibility study.

## Objective 1: Development of the Intervention Cancer@Work

We conducted a stepwise development of the intervention (Figure 1). We developed a first draft based on 1) a nonsystematic literature review and 2) interviews with experts in an iterative manner. Thereafter, we undertook 3) semistructured interviews with end users (cancer survivors, employers, occupational physicians) to test whether this first draft fit the needs of the users and whether it was the best design to deliver the intervention. Subsequently, we adapted the first draft on the basis of the results of these interviews. Using this second draft, we built a first version of the website after 4) consultation with experts, including a legal expert.

### Nonsystematic Literature Review

#### Methods

Our literature search was focused on self-management, integrative care management, stepped care, and eHealth in a nonsystematic manner. The aim of this search was to retrieve input on relevant intervention content and input on how to deliver the intervention. We restricted our search to MEDLINE, searching the trial register for relevant interventions. The search was carried out between March and May 2012. We completed a search for each topic using the main text words: "cancer," "absenteeism," "self-management," "eHealth," "interdisciplinary communication," and "stepped care," complemented with synonyms. We also searched references from relevant studies. The results of our search were analyzed on the basis of a written

account of the relevant intervention content and relevant information on how to deliver the intervention.

### Results

Several studies described self-management interventions that aimed to improve individuals' skills and confidence, helping them deal with their disease more effectively in daily life [21]. Research on self-management has shown that it has positive effects in cancer survivors dealing with survivorship issues [22], as well as in chronically ill patients dealing with work-related issues [23]. The key elements of self-management interventions are information and assignments. Self-management interventions can be based on problem-solving techniques or cognitive behavioral techniques, and have proven to be equally effective in treating patients with depression [24]. When addressing misconceptions about cancer and work, a cognitive behavioral component seems most appropriate, since the core focus of this technique is on cognitive reframing. In addition, to resolve a patient's work-related problems, a problem-solving component seems most appropriate, since this technique attempts to resolve patients' problems by teaching them structured problem-solving skills and how to generate achievable and simple action plans [26]. Moreover, one self-management intervention based on a problem-solving technique aimed at increasing the work functioning of employees with rheumatoid arthritis demonstrated its feasibility and was appreciated by both patients and care providers [27]. We therefore decided to include both components, offering problem-solving and cognitive behavioral techniques.

A few studies have tried to enhance collaboration between primary and occupational health care, but the level of effectiveness is still inconclusive. Some studies have shown positive results with respect to feasibility [28] and effectiveness [15], but others did not demonstrate any positive results [9,29]. One strategy that did prove feasible is integrative care management [15]. The goal of integrative care management is to establish the much-needed collaboration between all stakeholders (eg, the sick-listed employee, the occupational physician, the employer, the general physician, and the treating physician) to achieve a successful return to work of the sick-listed employee. A coordinator is ideally situated to establish this collaboration. However, collaboration can also be established using a secure website, where stakeholders can work together toward a common goal and share the necessary information to achieve this. In the eHealth intervention developed by Vonk Noordegraaf et al [14], almost half of the participants invited their supervisor to be involved in the eHealth intervention and that approximately 60% of the supervisors took this opportunity [30].

In a stepped-care intervention, all patients start with a low-intensity intervention, with the intensity increasing only if an intervention goal is not achieved at a certain point in time (eg, [31]). The advantages of a stepped-care intervention include the ability to deliver the right intensity of an intervention to each patient, lower intervention costs, and less time wasted by patients who participate [32]. The challenge for stepped-care intervention, however, is determining the cutoff value that indicates whether the intervention goal has been met and when a judgment can be made about whether the intervention goal has been met. When using a self-management intervention based on problem-solving techniques, it has been proposed that patients should be carefully selected to reduce noncompliance and dropout [27]. For this reason, a self-management intervention based on problem-solving techniques seems relevant only in cases where a patient experiences problems with his or her return to work, and it should therefore be offered only as a second step in an intervention.

Several eHealth intervention features are related to enhanced patient compliance: peer and counsellor support, email and phone contact, updates, record keeping, and individualized feedback [33,34]. Furthermore, eHealth interventions that are combined with face-to-face contact with a health care professional also showed enhanced patient compliance [35].

### ***Interviews With Experts on eHealth Interventions***

#### **Methods**

We approached approximately 10 experts based on the fact that they had recently developed an eHealth intervention for cancer survivors or an eHealth intervention aimed at increasing return to work of sick-listed employees. The first author (ST) undertook semistructured interviews based on a topic list. This list consisted of questions on 1) how to deliver an eHealth intervention, 2) features required to increase compliance with eHealth interventions, and 3) tips and tricks for developing an eHealth intervention. The interviews were held in August 2012. They were not audiotaped but the first author (ST) provided a

written summary of the most important issues mentioned during the interview.

#### **Results**

In total, 7 eHealth experts were interviewed with the aim of 1) gaining input on how to deliver the intervention, 2) gathering tips and tricks for developing an eHealth intervention, and 3) determining features that increase compliance. These eHealth experts reported that the following elements were required to deliver an eHealth intervention: choose a modular or a structured form; and use a combination of text, film, and pictures. The following additional features that increase compliance with eHealth interventions were also suggested: sending reminders, and using blended care with a health care professional. Finally, the experts also noted that what was most important when developing an eHealth intervention was 1) to consider, before starting, what type of “track and trace data” would be required to study use and compliance, and 2) to consult an information technology expert at the beginning of the development of the intervention because they can give advice at an early phase about the functionalities that are possible given financial and practical constraints. As return-to-work trajectories vary across patients in terms of length [36] and needs, we decided to deliver the eHealth intervention in a modular form. As we considered the remainder of the above-mentioned suggestions to be valuable for our eHealth intervention, we decided to use them all. Based on the literature search and interviews with these experts, we created a first draft of the intervention ([Multimedia Appendix 1](#), [Multimedia Appendix 2](#), [Multimedia Appendix 3](#)).

#### ***First Draft***

This first draft of the eHealth intervention consisted of access to a personal, tailored, and secure website containing various functionalities for cancer survivors, blended with support from their nurse, occupational physician, and employer ([Multimedia Appendix 1](#), [Multimedia Appendix 2](#), [Multimedia Appendix 3](#)). We presented this first draft as an online working environment. Blended care delivered by specialized nurse encompassed 1) answering questions, 2) monitoring and supervising use of the eHealth intervention, 3) providing personal feedback on assignments on the eHealth intervention, and 4) encouraging patients to comply with the intervention. Functionalities included providing insight into laws and regulations, a library, and a self-test to gain insight into opportunities to return to work (based on the problem-solving technique component), and redressing negative ideas concerning the possibilities to work after cancer, including the idea that one can return to work only after complete recovery (based on cognitive behavioral technique components). The occupational physician and employer had access to a specific part of the secure website that contained certain information, allowed them to access the cancer survivor's return-to-work plan, and allowed them to add their suggestions to facilitate their employee's return to work.

### ***Interviews With Cancer Survivors, Employers, and Occupational Physicians***

#### **Methods**

Cancer survivors were eligible to participate if they had been working at the time of diagnosis, were fluent in Dutch, and were

aged between 18 and 65 years. Occupational physicians and employers were eligible to participate if they had recently encountered an employee with cancer and were fluent in Dutch. We intended to interview 10 cancer survivors, 5 employers, and 5 occupational physicians. The first author (ST) undertook semistructured interviews after the interviewees had been given a rough outline of the first draft of the intervention. They were asked whether this first draft accorded with their needs and whether they thought the design was the most appropriate to deliver the intervention. The interviews were held in March 2013; they were audiotaped but not transcribed verbatim. We analyzed the interviews using a direct content analysis [37] in order to obtain an overview of all ideas mentioned by the participants that could improve the draft version of the intervention. Subsequently, 3 of the authors (ST, AdB, MF) discussed whether each idea would be useful, whether it fell within the scope of the intervention, and whether it was feasible in practice (eg, financial constraints).

## Results

In total, we interviewed 7 cancer survivors, 2 employers, and 7 occupational physicians with the aim of determining whether this draft fulfilled the needs of the users and whether it was the best design for delivering the intervention. We added the following functionalities to the first draft for cancer survivors: assignments providing insight into possible financial consequences, a documentary called *Irrevocable*, and assignments providing insight into the individual importance of work (Multimedia Appendix 1). We added the assignments providing insight into possible financial consequences and the individual importance of work because cancer survivors mentioned that they would have benefited from such insight and that this information is not readily available. In addition, to meet the needs of cancer survivors for peer support, and given our financial constraints, we added the documentary, which follows the return-to-work trajectories of 3 cancer survivors. For employers, we added a functionality that addressed the need to involve colleagues. Finally, in relation to occupational physicians, we added advice for cancer survivors on how to remain in contact with their workplace and references to relevant guidelines. We altered or removed some functionalities of the first draft of the eHealth intervention (eg, the occupational physician's and employer's access to a specific part of the secure website containing certain information, and the possibility to see the cancer survivor's return-to-work plan and add their suggestions to facilitate their return to work). In addition, we excluded some suggested functionalities from the eHealth intervention due to legal, privacy, financial, or practical constraints (eg, the ability to obtain peer support from former cancer survivors) or because we did not consider them to be of added value (eg, teaching the user how to deal with the expectations of others) or within the scope of the intervention (eg, information on benefits from municipalities and on the long-term disability pension) (Multimedia Appendix 1). Based on these interviews, we developed a second draft (Multimedia Appendix 1, Multimedia Appendix 2, Multimedia Appendix 3).

## Second Draft

The second draft consisted of access to a personal and secure website containing various functionalities for cancer survivors blended with support from their nurse, and a public website for occupational physicians, general physicians, and employers (Multimedia Appendix 1, Multimedia Appendix 2, Multimedia Appendix 3). Blended care delivered by specialized nurse encompassed 1) answering questions, 2) monitoring and supervising use of the eHealth intervention, 3) providing personal feedback on assignments on the eHealth intervention, and 4) encouraging patients to comply with the intervention. Functionalities for patients included support to draw up a strategy to manage specific personal problems that might inhibit their return to work, assignments providing insight into possible financial consequences of being on sick leave, support to draw up a return-to-work plan, and how to redress negative ideas concerning the possibilities of working after cancer, including the idea that one can return to work only after complete recovery (based on cognitive behavioral technique components).

## Consultation With Experts on Writing Web Text and Website Design, Privacy, and Legal Aspects of Building an eHealth Intervention

### Methods

We consulted an expert on writing text for websites and an expert on design, privacy, and legal aspects of building an eHealth intervention. They were given the rough outline of the second draft of the intervention and were asked to point out any issues that required further consideration.

### Results

Consultation with an expert on writing Web text taught us that it is important to 1) draft a "tone of voice document," which reflects the key values of the intervention, and on the basis of which the text is written, 2) to write clear and concise sentences without ambiguity, and 3) to develop the website in such a way that it is personal, for example, by using quotes from former cancer survivors that include their name, age, and occupation. The key values for this intervention were reliability, activating, personal, confrontational, serious, and directed to work and income. The design expert showed us that it is essential to match the design of the website with the tone of voice and Web text. Based on the tone of voice we wanted, the design expert created style sheets (Multimedia Appendix 4, Multimedia Appendix 5). After consultation with privacy and legal experts, it appeared that some functionalities would not be possible due to privacy legislation and that we needed to add a disclaimer pointing out the risk of using two functionalities and provide more secure alternatives (Multimedia Appendix 1, Multimedia Appendix 2, Multimedia Appendix 3).

## First Version

Based on consultations with these experts, we built a first version of the eHealth intervention, consisting of access to a personal and secure website containing various functionalities for cancer survivors blended with support from their nurse, and a public website for occupational physicians, general physicians, and employers (Multimedia Appendix 1, Multimedia Appendix 2, Multimedia Appendix 3). Functionalities for patients included

support in gaining insight into the individual importance of work, the ability to invite their employer, occupational physician, or general practitioner to use the public website (as a first step), and guidance in drawing up a strategy to manage specific personal problems that might inhibit their return to work (as a second step). Cancer survivors and specialized nurses were given a unique username and password to log in to the secure webpage, while verification would take place by text message.

## **Objective 2: Feasibility of the Intervention Cancer@Work**

After developing the first version of the intervention, we tested its feasibility by interviewing 1) cancer survivors, 2) employers, occupational physicians, and general physicians, and 3) social workers. All of the interviews discussed below were audiotaped but not transcribed verbatim. We intended to interview 40 cancer survivors, 10 employers, 10 occupational physicians, and 10 general physicians. We analyzed the interviews using a direct content analysis [37] in order to obtain an overview of all of the ideas that were mentioned by participants that might improve the first version of the eHealth intervention. Subsequently, we discussed whether each idea would be useful, whether it fell within the scope of the eHealth intervention, and whether it was feasible in practice. The cancer survivors also filled in 2 questionnaires.

### ***Feasibility of the Intervention for Cancer Survivors***

#### **Methods**

To test the feasibility of the intervention for cancer survivors, 1) we invited cancer survivors who had taken part in previous research by our department and who had given their consent to be approached in future research on cancer and work, and 3) the treating physician also invited cancer survivors who were treated between 2012 and 2014 in the department of gynecological oncology of an academic medical center. Cancer survivors were eligible to participate if they had been working at the time of diagnosis, were fluent in Dutch, and were aged between 18 and 65 years. The patients were sent an informative letter about the study. If interested, they could return a consent form agreeing to telephone contact, whereupon 1 of the researchers contacted the patient by phone. During this

conversation they could ask questions and decide whether they wanted to participate.

We used the following criteria to assess feasibility: 1) appropriateness of each functionality, 2) which functionalities needed improvement, 3) usefulness of the eHealth intervention, 4) user friendliness of the eHealth intervention, and 5) whether the eHealth intervention met their expectations. We considered the eHealth intervention feasible when at least 50% of the patients responded positively to each criterion.

After patients gave their informed consent, they filled in a questionnaire on their expectations of the intervention (eg, “What are your expectations regarding the Internet program Cancer@Work?”) and their need for support regarding their return to work (eg, “Do you need support on questions or problems regarding your work?”). After completing the questionnaire, they were given access to the eHealth intervention for 6 weeks, after which they filled in another questionnaire about the usefulness and user friendliness of the intervention (eg, “Which functionalities from Cancer@Work did you find useful?”) and whether the intervention met their expectations (eg, “Did Cancer@Work meet your expectations?”; “Cancer@Work did (not) meet my expectations because...”). All of the participants who filled in both questionnaires were invited to participate in a telephone interview by 1 of the researchers (SvH) to potentially gain greater insight into the answers to the questionnaire and to ask whether they had any further suggestions to improve the eHealth intervention and its functionalities. These interviews were held in June 2015. Based on these interviews, we developed a final version of the eHealth intervention for cancer survivors.

#### **Results**

Of the 177 cancer survivors invited to participate, 39 (22.0%) filled in the first questionnaire, while 20 filled in the second questionnaire (each participant was contacted by phone to remind them to fill in the questionnaire). We used the data of the 20 participants who filled in both questionnaires for our analysis. Table 1 details the participants' characteristics. The main reason that 19 participants did not fill in the second questionnaire was that they did not feel the need to use the intervention because it was, on average, 3 years since they had received their cancer diagnosis and they had already returned to work.

**Table 1.** Characteristics of cancer survivors who participated in the feasibility study (n=20).

<sup>a</sup>Numbers do not add up because of possibility of giving multiple answers.

In total, 11 participants (55%) used the eHealth intervention. The other participants did not use the intervention either because they forgot to log in or they did not have any problems at work and thus did not feel the need to use the intervention. [Table 2](#) details the results of the questionnaires. One of the participants' expectations regarding Cancer@Work were not met because she had already fully returned to work and did not have any work-related problems. Furthermore, 1 participant did not find the eHealth intervention user friendly because there was too much theoretical information and not enough opportunities to interact with other cancer survivors.

All of the 20 participants were invited for a telephone interview and 11 participated. The other 9 participants did not participate because of time constraints, practical issues, or lack of interest. During the interviews, the participants were positive about the intervention and its functionalities. They proposed several ideas to improve the intervention, such as making it easier to log in by using less-complicated passwords or not using text message authentication, or to make the intervention accessible for vision-impaired people by making it possible to enlarge the size of the text or to have the text read aloud. For an overview of all of the ideas that were proposed to improve the intervention, see [Multimedia Appendix 1](#), [Multimedia Appendix 2](#), and [Multimedia Appendix 3](#). We did not use any of these ideas to improve the intervention in the final version, either because they did not meet the security or privacy regulations or because of practical constraints. Therefore, we made no changes and the first version became the final version of the intervention for cancer survivors.

### *Feasibility of the Intervention for Employers, Occupational Physicians, and General Physicians*

#### **Methods**

Employers were eligible to participate if they had recently encountered an employee with cancer, while occupational physicians and general physicians did not need to have recent experience with a cancer patient or the associated work-related problems. All of the participants had to be fluent in Dutch. After giving informed consent, participants visited the eHealth intervention website designed for their respective profession and then participated in a semistructured interview to gather information on participants' experience with the intervention, its usefulness, and its user friendliness. The interviews were conducted in January and February 2015 by 1 of the authors (SvH) and they were audiotaped but not transcribed verbatim. Based on these interviews, we developed a final version of the intervention for employers, occupational physicians, and general practitioners.

#### **Results**

In total, 9 employers, 7 occupational physicians, and 6 general physicians participated in the interviews. For a full overview of the ideas that were mentioned, see [Multimedia Appendix 1](#), [Multimedia Appendix 2](#), and [Multimedia Appendix 3](#). The main issue that arose from the interviews was that participants needed more detailed information, mainly on the different cancer diagnoses and treatments, and their possible effects on the employee's ability to return to work. The occupational physicians were least enthusiastic about the intervention, since they felt that they already had a lot of knowledge on this topic. Thus, the occupational physicians in particular indicated that more detailed information was required to make the intervention useful. As a result, in the final version of the intervention, we

added more detailed information on different cancer diagnoses and treatments and their possible effects on the employee's ability to return to work. In addition, we added many institutions to the list of support agencies they could consult.

When asked about the user friendliness, design, and practical usefulness of the intervention, almost all of the participants indicated that the intervention was easy to use ( $n=21$ , 96%), that the design matched the content and purpose of the website ( $n=20$ , 91%), and that they would recommend this intervention, for example, to their friends or colleagues if they had to deal with an employee, client, or patient with cancer ( $n=19$ , 86%). Thus, we made no changes regarding these aspects in the final version of the intervention (see [Multimedia Appendix 1](#), [Multimedia Appendix 2](#), [Multimedia Appendix 3](#)).

### ***Feasibility of Blended Support From the Cancer Survivor's Specialized Nurse***

#### **Methods**

We asked 2 social workers from a gynecology department of a Dutch hospital who had experience supporting cancer survivors in their return to work to visit the section of the eHealth intervention for specialized nurses and to participate in a semistructured interview with 1 of the authors (SvH). Based on this interview, we developed a final version of the section of the eHealth intervention for specialized nurses.

#### **Results**

A total of 2 social workers participated in 1 interview, on the basis of which we added information on financial and legal issues to the final version of the intervention in order to provide specialized nurses and social workers with access to the same information as that provided to the patients they are supporting ([Multimedia Appendix 1](#), [Multimedia Appendix 2](#), [Multimedia Appendix 3](#)). In this way, it would be easier for them to advise patients on financial and legal issues by referring to the intervention. Furthermore, the social workers indicated that the intervention was easy to use, and that they anticipated no problems in using the intervention in practice.

### ***Discussion***

The objectives of this study were to develop an eHealth intervention to enhance the return to work of cancer survivors and to test the feasibility of the eHealth intervention with end users. The results of our development study show that cancer survivors particularly want to receive information and support on opportunities to return to work, and on the financial and legal aspects of their position. Furthermore, we found that the use of blended care and the personalization of the eHealth intervention are preferred features for increasing compliance. The results of the feasibility study showed that the eHealth intervention was feasible; however, we adapted it slightly by adding more information on different types of cancer and its treatment and on the possible effects of these on the return to work.

#### **Strengths and Limitations**

The strengths of our study include the use of a multistakeholder and mixed-method design to develop our eHealth intervention. In this way, the content, design, and delivery of the eHealth

intervention could best fulfill the needs of the end users and be the most suitable option to achieve the intervention goal, given Dutch law and our framework of psycho-oncological care. This also ensured that the risk of a type III error (ie, theory failure) was minimized [38].

We did not test the feasibility of the eHealth intervention in precisely the same conditions under which the intervention is intended to be used, as the feasibility study among cancer survivors was a prospective cohort study, with a short follow-up period of 6 weeks, that started on average 3 years after diagnosis, while the eHealth intervention is intended to be used from the initial cancer diagnosis until sustainable return to work. As a result, we are unable to draw firm conclusions about the usefulness of the content of the eHealth intervention, the features that enhance compliance, and the features that enhance integrative care management. We have partly overcome this drawback by consulting the literature, and interviewing experts and end users under our first objective. However, implementation of the eHealth intervention in daily practice should be the subject of further research. We were able to test the appropriateness of all the functionalities and the user friendliness, the usefulness, and the design of the eHealth intervention, for which we found positive results, so that the criteria for feasibility were met.

The employers, occupational physicians, and general practitioners who participated in the interviews and feasibility study were generally very interested in this subject for personal reasons, for example, as a cancer survivor. This was very useful for generating ideas about the content of the eHealth intervention, but it might have led to an overestimation of its future use by other members of their profession in daily practice. Implementation in daily practice should, for this reason, also be the subject of further research.

#### **Interpretation of Findings**

Cancer survivors, employers, occupational physicians, general practitioners, and specialized nurses were generally positive about the eHealth intervention. Not surprisingly, occupational physicians saw the least added value of the eHealth intervention for their own profession, as they thought that they were already applying the content in their daily practice. However, in their experience, they believed that employers would particularly benefit from the content, as they rarely have to deal with an employee with cancer, and cancer remains a difficult topic to address in the workplace [13,39]. We also added specific content to the eHealth intervention for general practitioners, for two reasons. First, patients themselves wanted more return-to-work guidance from their general practitioner, in addition to guidance from their occupational physician or in the absence of an occupational physician [25]. Second, general practitioners play a more prominent role in psycho-oncological care after primary treatment, including dealing with the possible effects on social outcomes such as being able to return to work [40]. We hope that we have equipped general practitioners with sufficient information and referral options. Apart from these issues, it seems important that future research examine what general practitioners specifically require to support cancer survivors in their return to work.

Although 97% of Dutch society has Internet access [41], Internet illiteracy is associated with a lower educational level [41]. At the same time, research indicates that self-management interventions are more effective in patients with a lower educational level [23]. Moreover, cancer survivors with a lower educational level are less likely to return to work [42], indicating that the intervention might be especially needed among this group. For these reasons, we spent additional time and effort to ensure that the eHealth intervention was very easy to use so that people with limited Internet literacy would be able to use the eHealth intervention as well. As appeared from both our quantitative study and our qualitative study, where we found that participants had very few problems using the eHealth intervention, we might have succeeded in this goal.

Due to legal regulations, we were obliged to add a disclaimer to two functionalities explaining the risk of using each of them and suggesting a more secure alternative, for example, in relation to inviting their employer, occupational physician, or general practitioner to view personal information via an email. The use of email is generally not considered a secure way to exchange information if you wish to keep the information completely confidential. Although we fully agree that it is our responsibility to inform patients about any possible harm, such warnings might cause unnecessary concern and discourage them from using the eHealth intervention at all, which might lead to otherwise preventable dropout. We therefore recommend that researchers engage the services of a legal adviser from the start when developing an eHealth intervention.

The process evaluation of the study by Bouwsma et al [30], which investigated an interactive eHealth intervention on the return to work of gynecological patients with benign tumors, showed that only half of the participants invited their employer

to visit an anonymous section of the website. Most participants reported that the reason for not using this tool was “finding it unnecessary because of fast recovery and good relationship with employer” [30], while most employers reported being satisfied or very satisfied with the information provided [30]. As the return-to-work trajectories of patients with malignant tumors are significantly longer than for patients with benign tumors (median sick-leave days 102 vs 44) [43,44], we expect that there will be more substantial need to use this functionality among our population. We therefore decided to include a comparable functionality without alteration.

### Implications for Further Research

One subject of further study should be the feasibility of the eHealth intervention in daily practice, and such a study should especially focus on the functionalities aimed at increasing compliance and integrative care, as we were unable to study them in this feasibility study. In addition, the effectiveness of the eHealth intervention on a sustainable return to work should also be further studied, and the intermediate effect of the eHealth intervention on self-management skills and work-related self-efficacy should be analyzed (ie, a measure to study a change of ideas regarding possibilities to return to work). We are studying both of these in a multicenter randomized controlled trial.

### Conclusion

A multistakeholder and mixed-method design appeared useful in the development of the eHealth intervention. However, it is challenging to meet all end users' requirements due to legal and privacy constraints. The eHealth intervention appeared feasible, although implementation in daily practice requires further research.

## Abstract

**Background:** Drug repurposing (defined as discovering new indications for existing drugs) could play a significant role in drug development, especially considering the declining success rates of developing novel drugs. Typically, new indications for existing medications are identified by accident. However, new technologies and a large number of available resources enable the development of systematic approaches to identify and validate drug-repurposing candidates. Patients today report their experiences with medications on social media and reveal side effects as well as beneficial effects of those medications.

**Objective:** Our aim was to assess the feasibility of using patient reviews from social media to identify potential candidates for drug repurposing.

**Methods:** We retrieved patient reviews of 180 medications from an online forum, WebMD. Using dictionary-based and machine learning approaches, we identified disease names in the reviews. Several publicly available resources were used to exclude comments containing known indications and adverse drug effects. After manually reviewing some of the remaining comments, we implemented a rule-based system to identify beneficial effects.

**Results:** The dictionary-based system and machine learning system identified 2178 and 6171 disease names respectively in 64,616 patient comments. We provided a list of 10 common patterns that patients used to report any beneficial effects or uses of medication. After manually reviewing the comments tagged by our rule-based system, we identified five potential drug repurposing candidates.

**Conclusions:** To our knowledge, this is the first study to consider using social media data to identify drug-repurposing candidates. We found that even a rule-based system, with a limited number of rules, could identify beneficial effect mentions in patient comments. Our preliminary study shows that social media has the potential to be used in drug repurposing.

## KEYWORDS

social media; drug repurposing; natural language processing; patient comments

## Introduction

New drug development costs US \$500 million to \$2 billion and takes 10-15 years [1]. A well-known approach to reduce risk and cost of new drug development is drug repurposing (or drug repositioning) [2]. Drug repurposing (defined as discovering new indications for existing drugs) could play a significant role

in drug development, considering the declining success rates of developing novel drugs. From 2007-2009, 30-40% of newly approved drugs were repurposed medications [3]. Considering the high cost of launching a new drug, this emphasis on repurposing could markedly affect drug development. Typically, a new indication for an available drug is identified by chance. However, new technologies and a large number of available

resources enable the development of systematic approaches to identify and validate drug repurposing candidates with considerably lower costs. Drug repurposing has been exhaustively studied, and various approaches have been used [3-5] to identify novel drug repurposing candidates, using clinical data [6], genetic information [7-9], and scientific literature [10-13].

Grau and Serbedzija [4] named two types of drug repurposing: (1) identification of off-target drug actions and (2) identification of relevance of a known drug target to a new disease. From an informatics perspective, freely available and relevant resources such as scientific literature, clinical trials, and biological resources can be used to conduct drug-repurposing studies. The compound database PubChem [14] has been used in several drug-repurposing studies [15]. Hoehndorf et al [16] implemented a system that inferred novel associations between drugs and diseases by linking drug-gene associations in the PharmGKB database to phenotype studies and animal models of disease. Moriaud et al [17] presented a computational method that mined the Protein Data Bank [18] to identify drug repositioning candidates. Several studies [10,11,16,17,19,20] considered literature mining for drug repurposing; this approach has been comprehensively reviewed elsewhere [21,22].

Social media provides a platform for patients to share their experiences with illnesses, medications, and also medical centers [23]. Patient posts, usually written in an informal language, contain hidden and valuable information. Owing to the massive amount of data derived from social media, computerized systems are needed to analyze and extract useful information from patient experience. Unlike scientific literature, these comments are usually written by non-experts users who do not have any obligation to follow proper grammar in their comments or report accurate observation. These differences make mining social media more complicated and challenging compared to scientific literature. Nevertheless, there have been several attempts to extract knowledge from social media. Leaman et al [24] examined comments posted in a medical forum to identify reported adverse drug events. After manually annotating a corpus of patient posts, they used natural language processing methods to develop a system that extracted adverse drug reactions from the text. Chee et al [25] studied patient posts on Health and Wellness Yahoo! groups and applied common natural language processing methods to predict adverse drug events and identify medications that might require further scrutiny by the Food and Drug Administration. Freifeld et al [26] evaluated the correlation between adverse drug events reported in Twitter (where statements are limited to 140 characters) and spontaneous reports received by a regulatory agency. Rastegar et al [27] implemented a binary classifier to identify adverse drug reactions in tweets. Sharif et al [28] proposed a sentiment classification framework to detect adverse drug reactions in medical blogs and forums. Recently, Karimi et al [29] provided a corpus of 1321 medical forum posts on patient-reported adverse drug events, which allows researchers to develop and evaluate pharmacovigilance systems.

Although patients mostly use medically oriented social media to describe adverse events associated with drugs [30,31], their experiences may help others to conceive of new indications for

existing medications if their descriptions also include beneficial effects. A well-known example is Zolpidem, an insomnia medication that, through social media and patient reviews, was subsequently used for brain injury [32]. Leaman et al [24] identified 157 beneficial effects, in 3600 patient posts that could lead to drug repurposing. The accuracy of these reported beneficial effects in social media may be questionable, but considering the value of drug repurposing and huge amount of available social media data, it is worthwhile to study this type of information and investigate the possibility of identifying potential drug-repurposing candidates. In this study, we assessed the feasibility of using social media data in identifying potential drug repurposing candidates. Our hypothesis is that this imperfect resource could lead to drug repurposing.

## Methods

### Data Sources

In this study, we used data from four public resources: WebMD [33], DrugBank [34], SDe Effect Resource (SIDER) [35], and Unified Medical Language System (UMLS) [36]. Below are brief descriptions of the resources and their uses in this research.

WebMD is an US corporation that provides Web-based health-related services, including a forum for patients to share their experiences with medications. The comments are entered as free text, and the length of comments is not subject to a character or word count limit. WebMD [33] allows users to score three different aspects of the medication in their reviews: (1) effectiveness, (2) ease of use, and (3) satisfaction. WebMD provides some basic information about the users such as age, sex, and duration of treatment. The patient comments from WebMD were the main material used in this study.

DrugBank is a bioinformatics and cheminformatics resource that provides drug information, such as indication, synonyms, gene target, drug interactions, and structure. This database was used to identify known indications of drugs.

SIDER, developed by Kuhn et al [35], contains information about 1430 marketed medications and 5880 side effects (140,064 drug-side effect pairs) extracted from public documents and package inserts. SIDER retrieved adverse drug reaction and disease names from UMLS to generate a dictionary of side effects. We used SIDER to detect known side effects of drugs mentioned in the comments.

UMLS [36] integrates medical terminology and coding standards to help researchers and developers create interoperable biomedical information systems. We used UMLS resources to create a dictionary of disease names. The dictionary contains all spelling variants of diseases provided in UMLS. The dictionary includes 239,227 entries for 86,839 unique diseases.

### Method

In the first step, we generated a list of the top 180 most frequently searched medications on WebMD. All patient comments pertaining to these drugs were retrieved. Through DrugBank, we collected known and approved indications related to those medications. To locate the drugs in DrugBank, we searched synonyms and brand name entries in addition to drug

name entry. In the next step, a list of known side effects for each drug is retrieved from SIDER.

We next developed a natural language processing system to identify beneficial or adverse effects. Any mention of disorders in the reviews was tagged by using two disease named entity recognition (NER) approaches: (1) dictionary-based and (2) machine learning. In the dictionary-based approach, a list of disease names from UMLS was retrieved and a string-matching technique was applied to identify diseases mentioned in the comments. The dictionary-based approach did not consider any grammatical or semantic reasoning or spelling errors. For the machine-learning NER approach, we used MetaMap [37], a tool to recognize UMLS concepts (eg, diseases) in the text. Unlike the dictionary-based method, MetaMap uses natural language processing and computational linguistic techniques to incorporate semantic and grammatical reasoning in the identification task.

We discarded comments that contained only known indications or adverse effects for related medication. We then manually reviewed some of the remaining comments to develop a list of textual patterns commonly used to report beneficial effects or indications. We developed a rule-based system to tag the comments containing at least one of those patterns. In the final

step, the tagged comments were manually reviewed to identify potential drug repurposing candidates.

## Results

We retrieved 64,616 patient posts from the top 180 most commonly searched drugs in WebMD (mean number of posts per drug was 358). Lisinopril (an angiotensin-converting enzyme inhibitor used to treat high blood pressure and heart failure) had the most comments (n=2931), whereas metoclopramide (used to treat gastric esophageal reflux disease) had the fewest comments (n=8). Table 1 shows the top 10 reviewed medications and includes the three most frequently named diseases in the respective comments.

The dictionary-based NER approach identified 2178 disease names in the comments, whereas MetaMap identified 6171 disease mentions. Table 2 shows the 10 most commonly named diseases in the comments (after disambiguated terms were removed manually). Of the 180 drugs, 164 (91.1%) were listed in DrugBank but only 74 (41.1%) were listed in SIDER. We filtered comments to remove text describing known indications and adverse drug events from the list of recognized disease names; frequently named diseases from the text that remained are shown in Table 3 (note the overlap with Table 1).

**Table 1.** Most-reviewed medications in WebMD and most frequently named diseases in the reviews.

Drug name	Reviews, n	Disease names, n		Most frequent disease names	
		Dictionary-based	MetaMap	Dictionary-based	MetaMap
Lisinopril	2931	288	1135	Itch	Blood pressure
				High blood pressure	Cough
				Rash	Dry cough

			Arthritis	Back pain

## Textual Patterns

The frequency of ten common textual patterns, used to report beneficial effects, were counted in the comments and shown in Table 4. Table 5 shows the frequency of the patterns after

removing the comments, which mentioned only known side effects or indication. A manual review of the remaining comments identified five drugs with potential for repurposing (see Table 6).

**Table 4.** Textual patterns to identify drug-repurposing candidates.

Pattern	Count	Example drugs and comments <sup>a</sup>
I use * for	307	Methadone: I use this for diabetic neuropathy. works well with very little side effects. Percocet: I use this for M.S. pain Percocet: I use this med for peripheral neuropathy pain.
I use it for	42	Cymbalta: My use of Cymbalta is two fold. I use it for depression and fibromyalgia pain. Spironolactone: I use it for acne. Go figure it works Promethazine: I use it for gastroparesis. I also use it for sleep 4 or 5 times a month
It helps with	131	Nucynta: It helps with my pain from surgery Percocet: it helps with my back pain, better then any drug Klonopin: I like this medication it helps with my anxiety.
It help with	11	OxyContin: it help with muscle spasms Neurontin: i had drop foot and much pain. it help with the pain along with the 3 epidurals i receiveed in my spine. Cymbalta: i started this medication years ago. not only did it help my depression, it help with my auto immune, muscle and nerve pain.
I take it	1,161	Nucynta: I take it for severe headache and neck pain from arthritis, bulging disks, and bone spur in my neck (cervical spine) Methadone: I take it for chronic pain it helps a lot Flexeril: I take it for muscle spasms related to fibromyalgia.
I take it for	91	Methadone: I take it for chronic pain it helps a lot Methadone: I take it for degenerative disk deterioration in my neck. Hydrocodone-acetaminophen: i take it for my scoliosis of my back
It works for	258	Methocarbamol: It works for my muscle tension, but gives me a headache. Diazepam: it works for my pain weal good Tramadol: It works for my Arthritis Pain.
It is useful for	0	...
Useful for	18	Methadone: very useful for chronic and severe pain associated with fibromyalgia/rheumatoid arthritis. Effexor: I have been reading the reviews of this med. I have been using it for 1.5 yrs and has been very useful for my depression. Ultram: this med has been very useful for my hip and back pain.
Prescribed for	319	Percocet: I was prescribed for kidney stones. definately took the pain away and very high. Zoloft: I feel like the antidepressant is used in conjunction with my cymbalta which I am prescribed for both depression and fibromyalgia. Celebrex: I was prescribed for knee pain following surgery for torn muniscus.

<sup>a</sup>Consumer comments are shown exactly as they appeared on the WebMD site.

**Table 5.** Frequency of common textual patterns after removing known indications and adverse drug effects.

Pattern	Count	Example drugs and comments <sup>a</sup>
I use * for	171	Flector: it's not so bad. I use them for stress headaches only if I have a mild headache Hydroxyzine: I use this drug for itching attacks and it works fast and effective for me. Elavil: I use this medication for restless leg syndrom
I use it for	23	Promethazine: I use it for gastroparesis.i also use it for sleep 4 or 5 times a month Amitriptyline: I use it for ic Seroquel: I m in love with seroquel its amazing! I use it for sleep and I wake up refreshed
It helps with	72	Neurontin: it helps with numbness in my legs and arms Neurontin: I was diagnosed with rsd in from a fall on the ice. It helps with controlling the pain; Seroquel: although it helps with my depression I have gained over 50lbs
It help with	6	Oxycontin: it help with muscle spasms Hydrocodone-acetaminophen: it is ok I think and it help with my back pian. Neurontin: I had drop foot and much pain. It help with the pain along with the 3 epidurals I receiveed in my spine.
I take it	729	Methadone: I take it for chronic pain it helps alot Pristiq: I take it for depression and ptsd as well as for chronic pain from failed cervical fusion. Zoloft: I have taken it for three years almost and when I take it my depression worsens rather in the summer when I wouldnt take it I was the happiest
I take it for	48	Percocet: I take it for pain after a shoulder surgery and it works Buspar: I take it for stress. Effexor: I take it for depression.
It works for	155	Pristiq: I do not think it works for me makes me very consipated and I think it makes the back of my legs hurt in the muscle part. Metformin: I take it before bed no sideeffect so for taking one month hope it works for me yes I am scared Flexeril: back problems healed up then came right back. overall it works for a little while.
Useful for	13	Effexor: I have been reading the reviews of this med. I have been using it for 1.5 yrs and has been very useful for my depression. Hydrocodone-acetaminophen: this med. is useful for short term relief of pain. Ultram: this med has been very useful for my hip and back pain.
Prescribed for	0	...

<sup>a</sup>Consumer comments are shown exactly as they appeared on the WebMD site.

**Table 6.** Example comments suggesting the possibility of drug repurposing.

Medication	Indication	Adverse effect	Patient comments <sup>a</sup>
Methadone	Dry cough, drug withdrawal syndrome, opioid type drug dependence, and pain	Amenorrhea, phlebitis, sneezing, suffering, withdrawn, hypomagnesemia, urticaria, rhinorrhea, fever, spasm, ...	I use this for diabetic neuropathy. Works well with very little side effects.
Elavil	Depression, chronic pain, irritable bowel syndrome, sleep disorders, diabetic neuropathy, agitation and insomnia, and migraine prophylaxis	None in SIDER	elavil is an old school antidepressant that is now considered a dirty drug because of its undesired side effects. one of the unintended side effects is to relax the skeletal muscle tissue. I use elavil off label to treat my tmj
Spironolactone	Low-renin hypertension, hypokalemia, and Conn syndrome	Hyperkalemia, amenorrhea, urticaria, epidermal necrolysis, anaphylaxis, fever, toxic epidermal necrolysis, lethargy, nausea, ...	I use it for acne. go figure it works
Strattera	Attention-deficit/hyperactivity disorder, alone or in combination with behavioral treatment	None in SIDER	I was prescribed this medication for slight adhd with off label anxiety help.
Viibryd	Acute episodes of major depression	None in SIDER	It even helps my migraines somewhat (maybe it will be off label in the future for migraine prophylaxis)

<sup>a</sup>Consumer comments are shown exactly as they appeared on the WebMD site.

## Discussion

### Comparison of MetaMap Versus Dictionary-Based Approach

MetaMap is a sophisticated tool that uses natural language processing and machine learning methods; thus, it is more accurate than the dictionary-based approach. MetaMap, to some extent, tackled some general concerns such as disambiguation, misspelling, and word normalization, but none of these is addressed in the dictionary-based approach. For example, in the phrase “My stomach and back hurts to sit, lay down, or stand,” the dictionary-based approach would tag “down” as a disease because of overlap with the “genetic disorder down syndrome.” As Table 2 shows, MetaMap recognized about three times the number of disease names than the dictionary-based approach. The main reason for this difference is word normalization in MetaMap. The dictionary-based approach is limited by its requirement for exact matches—for example, a dictionary that contains only “dizzy” would not detect “dizziness” as a relevant word. In contrast, MetaMap uses stemming and lemmatization to normalize words. The main advantage of dictionary-based mapping over MetaMap is speed (the dictionary-based approach is considerably faster).

### Using Patient Comments for Drug Repurposing

The reviews commonly described general disorders such as pain, itching, and headache. This is expected because comments usually are not authored by medical experts. We observed that patients tend to report adverse drug events instead of beneficial effects, as some of the previous studies reported a similar trend [24]. For example, in the corpus provided by Leaman et al [24], they annotated 157 beneficial effects in 3600 posts, while they found 1260 adverse drug events. Nevertheless, some patient comments contain beneficial effects of medication, which makes

social media a useful resource for drug repurposing. This imbalance distribution makes identifying beneficial effects more difficult, especially for training a classifier. Our results (see Tables 4, 5, and 6) suggest that an effective approach for this task is to recognize the textual patterns that people used to report beneficial effects (eg, “I use [drug] for [disease]”). For example, in a review of Viibryd, a user mentioned, “It even helps my migraines somewhat,” clearly noting a beneficial effect of the drug, which could be captured by our rule-based system. Similar to other computational drug repurposing approaches, these findings need to be reviewed manually by experts and then confirmed or rejected by laboratory tests or clinical trials. But as these reviews provided by non-expert users, compared to other drug repurposing studies, which use resources provided or generated by experts such as clinical data or biomedical literature, our findings need more validation before going through clinical trials or laboratory tests.

### Limitations

We acknowledge some limitations to this study. Analysis of the patient comments, which are written in an informal manner, obviously needs a system that can handle spelling and grammatical errors. Our current implementation does not address these issues.

Our system covered only simple textual patterns, although examples in Tables 4 and 5 highlight the need to decode complex patterns. A simple pattern-matching system obviously is insufficient for a statement such as “I use it for nose allergies and it does not clear up my nostrils.” A system should be able to handle negation and coreference.

Another limitation of this study was that comments originated from only one forum. Other social media sites such as Yahoo! Answers, PatientsLikeMe [38], and even Twitter have similar information, which can be studied and added to our corpus. In

addition, using only one resource for known side effects and one for indication was another limitation. In Table 3, there are several known indications and adverse drug events, which highlight this limitation.

In this study, we were not able to evaluate our system precisely and provide common performance metrics because of the lack of an annotated corpus. As future work, we plan to annotate a corpus of comments from various forums, to allow us to explore this valuable resource extensively and implement and evaluate different approaches.

## Conclusion

We assessed the feasibility of using social media to identify drug-repurposing candidates. After collecting patient reviews

of medications from WebMD, we used dictionary-based and MetaMap approaches to identify disorders mentioned in the reviews. Reviews describing known indications or known adverse drug events were excluded, and the remaining reviews were searched for textual patterns commonly used to report beneficial effects. Although the most commonly reported disorders were nonspecific (eg, pain, itching, headache), we nevertheless showed that consumer comments contain beneficial effects of medication and have the potential to be used for drug repurposing. Our textual patterns were able to capture some beneficial effects, but there is a need for a more complex and sophisticated system to identify beneficial effects in social media.

## Abstract

**Background:** Inner-city, minority children with asthma have the highest rates of morbidity and death from asthma and the lowest rates of asthma controller medication adherence. Some recent electronic medication monitoring interventions demonstrated dramatic improvements in adherence in lower-risk populations. The feasibility and acceptability of such an intervention in the highest-risk children with asthma has not been studied.

**Objective:** Our objective was to assess the feasibility and acceptability of a community health worker-delivered electronic adherence monitoring intervention among the highest utilizers of acute asthma care in an inner-city practice.

**Methods:** This was a prospective cohort pilot study targeting children with the highest frequency of asthma-related emergency department and hospital care within a local managed care Medicaid plan. The 3-month intervention included motivational interviewing, electronic monitoring of controller and rescue inhaler use, and outreach by a community health worker for predefined medication alerts. We measured acceptability by using a modified technology acceptability model and changes in asthma control using the Asthma Control Test (ACT). Given prominent feasibility issues, we describe qualitative patterns of medication use at baseline only.

**Results:** We enrolled 14 non-Hispanic black children with a median age of 3.5 years. Participants averaged 7.8 emergency or hospital visits in the year preceding enrollment. We observed three distinct patterns of baseline controller use: 4 patients demonstrated sustained use, 5 patients had periodic use, and 5 patients lapsed within 2 weeks. All participants initiated use of the electronic devices; however, no modem signal was transmitted for 5 or the 14 participants after a mean of 45 days. Of the 9 (64% of total) caregivers who completed the final study visit, all viewed the electronic monitoring device favorably and would recommend it to friends, and 5 (56%) believed that the device helped to improve asthma control. ACT scores improved by a mean of 2.7 points ( $P=.05$ ) over the 3-month intervention.

**Conclusions:** High-utilizer, minority families who completed a community health worker-delivered electronic adherence intervention found it generally acceptable. Prominent feasibility concerns, however, such as recruitment, data transmission failure, and lost devices, should be carefully considered when designing interventions in this setting.

**KEYWORDS**

electronic medication monitoring; adherence; beta-agonists; inhaled steroids; motivational interviewing; community health workers

**Introduction**

Inner-city children with asthma experience high morbidity and mortality from persistent asthma [1-3]. Compared with their white counterparts, non-Hispanic black children have four times the rate of asthma-related emergency department visits, three times the rate of hospitalization, and five times the mortality. These disparities in adverse asthma outcomes have persisted over time despite advances in treatment [4].

Inhaled corticosteroids (ICS) remain the mainstay of therapy for persistent asthma [5]. However, suboptimal adherence to ICS regimens is a major barrier to achieving asthma control [6]. Self-reported adherence is unreliable and consistently overestimates medication use [7,8]. Actual ICS adherence rates measured using electronic monitoring in clinical studies are low for both adults and children [9-11]. Poor adherence to controller regimens is associated with poor asthma control [12], increased utilization of emergency and hospital care [13,14], and higher mortality from asthma [15,16]. Urban minority youth in particular demonstrate some of the lowest rates of adherence, ranging from 11% to 45% of prescribed doses [11,17-19]. Better strategies to improve adherence are needed to engage this patient population, especially for those experiencing high levels of asthma morbidity. In this setting, interventions involving community health workers have demonstrated great promise [20-22].

Electronic monitoring is a strategy used in a variety of settings to measure and increase medication adherence among patients with chronic conditions [23-26]. Studies in adults with asthma have shown that electronic monitoring interventions can increase adherence to ICS regimens [27-29]. In the few pilot studies of electronic monitoring interventions done in children, behavior modification strategies that included direct feedback about electronically monitored adherence were thought to be critical components of the strategies' success [30-34]. Motivational interviewing is a behavior modification strategy that has also been shown to improve medication adherence [35,36], and it helps address barriers to adherence such as parental beliefs about medications [37]. Thus far, electronic monitoring studies have not focused on the highest utilizers of emergency and hospital care among inner-city, minority children with asthma. By targeting this highest-risk group, an electronic adherence intervention could have a greater impact on health care utilization, cost of care, health disparities, and quality of life [38].

In this study, we sought to assess the acceptability and feasibility of an intervention that combined the community health worker strength of family engagement and the technologic benefits of electronic medication monitoring in a high morbidity patient cohort. Prior to developing large-scale trials, we posited that first exploring acceptability and feasibility issues in this high-risk population would be critical, especially given the complex social, economic, and cultural factors. In this study,

we sought to assess caregiver attitudes toward monitoring and ease of use of the devices, as well as acceptable modes and frequency of feedback, in the families of children with the highest health care utilization for asthma.

**Methods**

We conducted a single-center, prospective cohort study of children with moderate to severe persistent asthma to assess the feasibility of a larger-scale intervention to improve adherence to asthma medications. The protocol for the conduct of this study was approved by The Children's Hospital of Philadelphia Institutional Review Board.

**Study Participants**

Eligible participants were children aged 3 through 16 years who received their primary care at an academic primary care clinic in West Philadelphia affiliated with The Children's Hospital of Philadelphia, Philadelphia, PA, USA. Additional inclusion criteria were 1) enrollment in a local Medicaid managed care plan (Keystone First, Philadelphia, PA, USA), and 2) identification as a "high utilizer" of hospital and emergency services for asthma. For the purposes of this study, we defined a high utilizer as a patient whose frequency of emergency department and hospital use for asthma-related reasons was in the top 50 in the year preceding the study. Our target enrollment was 15 to 20 patients for this feasibility study. Patients were excluded from the study if they were  $\geq 17$  years of age, or had congenital heart disease, neurologic disorders, cystic fibrosis, or other chronic respiratory conditions and structural abnormalities of the upper or lower airway. Children younger than 3 years were excluded, as other wheezing illnesses may confound the diagnosis of asthma in this age group.

**Recruitment**

We identified 50 potentially eligible participants using health insurance claims for the preceding year provided by the Medicaid managed care organization. An asthma navigator (a community health worker with background expertise and training in the care of children and families with asthma) contacted eligible families sequentially until 20 patients were scheduled for an initial visit. A total of 15 patients had an initial visit and 14 were enrolled in the study.

**Intervention**

The study intervention included 1) motivational interviewing, 2) electronic monitoring of adherence to prescribed inhaler regimens (controller and rescue medications), and 3) outreach by the asthma navigator based on specific, predefined inhaler use criteria.

Prior to study participant enrollment, study staff members (including the asthma navigator and the study physicians) received two training sessions in motivational interviewing by experts experienced in this technique. These sessions included lectures, videos, role play of modeled behaviors, and feedback.

Participant families were asked to list their three primary barriers to medication adherence at the initial study visit; these barriers were addressed using motivational interviewing techniques by the asthma navigator and, if necessary, a study physician (CK, JC, SW, or JF). Examples of such barriers were not remembering to take medications, concerns about ICS side effects, and perceptions about the severity of the child's asthma that differed from the perceptions of the child's clinical team. Counseling techniques for the initial visit and follow-up calls were based on strategies outlined in a review of brief motivational interviewing for asthma medication adherence by Borrelli et al [39]. To ensure fidelity of delivery, the research team developed prompts to standardize the initial portion of the telephone encounters and participated in intermittent direct observation of counseling by the asthma navigator.

Each family received SmartTouch (Adherium, Auckland, New Zealand) electronic monitoring devices for both the controller and rescue medication. SmartTouch monitors are electronic adherence monitors that can be affixed to the exterior of patients' inhalers. Previous versions of these devices have shown both good reliability and validity in monitoring daily inhaler use [38]. Study staff affixed these devices to participants' rescue and controller inhalers. In the case that participants did not bring their inhalers to the first study visit or had less than a month's supply remaining, we provided participants with new rescue (albuterol) and controller inhalers (fluticasone or fluticasone-salmeterol) to ensure availability. The electronic devices transmitted inhaler usage information to a cellular modem in the home, which we also provided. Medication usage data were then uploaded to a US Food and Drug Administration-approved, Health Insurance Portability and

Accountability Act-compliant website [50]. Medication usage alerts were registered for overuse of rescue medications and underuse or overuse of controller medications at predetermined frequencies (Figure 1). Families were encouraged at enrollment to take their controller medications as directed by their primary care doctor and to continue with daily and rescue asthma care as they usually would. We provided them with chargers for the devices, and instructed them on how to monitor battery life and to charge the devices when battery life was low (indicated by a red light).

The asthma navigator and a study physician (CK) actively monitored the electronic monitoring website for medication alerts. The asthma navigator contacted families after the initial study visit to ensure the study modem was connected and that the system was transmitting inhaler usage data to the monitoring website. Study staff made no subsequent contact with families for the first month to allow participants' medication use patterns to return to their baseline. After this observation period and for the subsequent 2 months, when alerts were triggered for controller medication underuse, the asthma navigator contacted families and used motivational interviewing techniques to address suboptimal adherence. The asthma navigator monitored the site daily, except on weekends. For those with persistent daily alerts beyond 2 consecutive days, calls were attempted twice weekly. In the case of rescue medication overuse, the family was instructed to call the clinic triage nurse to determine whether a clinic appointment was needed for an asthma exacerbation. We provided basic cell phones with unlimited minutes and text messaging to families to facilitate communication with study staff during the study period.

**Figure 1.** Thresholds for asthma medication alerts (based on controller schedule of 2 puffs twice a day).

Controller Underuse	Less than	3	puffs per day for	3	days out of	5
	Less than	2	puffs per day for	3	consecutive days	
or						
Rescue Overuse	More than	4	puffs per day for	3	days out of	5
	More than	8	puffs per day for	1	consecutive day	
or						

## Outcomes

The primary outcomes for this study were acceptability and feasibility. To measure acceptance of the electronic monitoring technology, we assessed the perceived ease of use, result demonstrability, and perceived usefulness of the new technology using these subscales from the previously validated technology acceptance model instrument [40,41]. For our evaluation of feasibility, we assessed the functionality of the technology, initiation and duration of use of the electronic monitors by the caregivers of study participants, and the ability to contact study participants in response to adherence alerts.

Secondary outcomes were asthma control and daily adherence. We assessed parental perception of asthma control with the Asthma Control Test (ACT) [42]. An ACT score of  $\leq 19$  is consistent with uncontrolled asthma. ACT questionnaires were completed by participants with the asthma navigator at the initial visit and follow-up visit, and scores were recorded for comparison at the end of the study. Daily adherence was captured using the electronic monitoring devices.

## Analysis

We used descriptive statistics to characterize study participants' demographic composition, prior health care utilization, and responses to the modified technology acceptance model

questionnaire. We identified qualitative patterns of daily controller use in the month preceding asthma navigator contact with the family based on two criteria: the percentage of days in the observation window with controller actuations; and runs of consecutive days with controller actuations (see Patterns subsection of Results section). We used both paired *t* tests and Wilcoxon signed rank sum test to compare ACT scores at the start of the study with scores at the completion of the study based on the assumption of the data with and without normality. The American Thoracic Society suggests that the minimally clinically significant ACT score change is 3 points [43].

Results

Of the 50 highest utilizers of emergency asthma care, we enrolled 14 patients for this study, of whom 6 (43%) were female. Their median age was 3.5 years (range 3–9), and all families identified their race as non-Hispanic black. Enrolled participants had a mean of 7.8 (range 5–15) combined emergency visits and hospitalizations in the preceding year, and the mean ACT score at the first visit was 15.9 (range 9–24) (Table 1).

Table 1. Participant characteristics (n=14).

Characteristics	Median (range) or n (%)
Age in years, median (range)	3.5 (3–9)
Female, n (%)	6 (43)
Race/ethnicity non-Hispanic black, n (%)	14 (100)
Prior emergency visits and hospitalizations, mean (range)	7.8 (5–15)
Asthma Control Test score, mean (range)	15.9 (9–24)
<b>Baseline adherence pattern, n (%)</b>	
Sustained	4 (29)
Periodic	5 (36)
Lapsed	5 (36)

Baseline Patterns

We identified distinct patterns of controller use over the first 30 days of the study interval (Figure 2): 4 patients had sustained

use (>50% of days with use and <7 consecutive days of missed doses), 5 patients had periodic use (<50% of days with use with >7 consecutive days with no use), and 5 patients had lapsed use (<50% of days with use and no return of use after 14 days).

Figure 2. Patterns of asthma controller and rescue medication use in the first 30 days of the study. ID#: participant identification number.

Acceptability

Of the 14 caregivers, 9 (64%) completed the modified technology acceptance model questionnaire at the final study visit. All 9 found the electronic monitoring devices to be easy to use, saw clear benefit in the devices, and would recommend the devices to others, and 5 (56%) of these caregivers felt that the device itself actually helped to improve asthma control. A total of 8 families (89%) felt that the devices were small enough to carry easily.

Feasibility

All 14 participants initiated use of the electronic monitors; however, no modem signal was transmitted for 5 of them after a mean of 45 days. Of the 9 caregivers who completed the final study visit, 2 had lost one of the monitoring devices; we were not able to retrieve the 10 devices from the 5 caregivers who did not complete the final study visit. Thus, in total, 16 of the 28 electronic monitoring devices were returned, and 10 of them (63%) were either uncharged or no longer responding to a charge. Families who disconnected their cellular modems noted competition for use of the electrical outlets and concerns about

the additional use of electricity contributing to their electricity bills. Because of these issues with data capture during the intervention window, we report adherence data for only the first 30 days of the intervention, when all participants had a transmitting modem signal.

Telephone contact was achieved with all participants (up to 2 calls per week for those with frequent adherence alerts) and ranged from short messages on their answering services to 10-minute calls to troubleshoot device issues or adherence lapses. Of the 9 caregivers who completed the final study visit, all were happy with the relationship they had with the asthma navigator, none felt that she contacted them too frequently, and 8 of them (89%) believed calls from the asthma navigator helped to avoid missing doses.

### Limited Efficacy

Though the study was not powered to detect a change in asthma control, mean ACT score improved by 2.7 points (95% CI 0–5.5,  $P=.05$ ) over the duration of the study, just below the minimally significant ACT change threshold of 3 points.

### Loss to Follow-Up

The 5 caregivers who did not complete the final study visit were either unable to be contacted or unable to schedule and complete the final study visit following at least five attempts by the study team. Of these 5 participants, 3 were female, their median age was 3, and mean baseline ACT was 17.8 points, none of which were statistically significantly different from the characteristics of those who completed the final study visit.

## Discussion

In this study, we partnered with a local managed care Medicaid plan to assess the feasibility of an electronic monitoring intervention for high-risk inner-city minority children with asthma. To our knowledge, this is the first study to assess the acceptability and feasibility of an electronic monitoring intervention delivered by a community health worker in the highest-risk children with asthma. With respect to feasibility, our findings demonstrate several prominent challenges in the delivery and sustainability of this intervention. While all 9 of the caregivers who completed the final study visit found the technology and monitoring devices acceptable, we were not able to complete the survey for 5 families (36%). And while all of the families initiated use of the monitoring technology, half of the caregivers either unplugged the cellular modem or lost the monitoring devices, leading to difficulty in interpretation of adherence data beyond the initial observation month. Despite these challenges, we noted a trend toward improved asthma control over the study interval, and we noted some qualitatively distinct patterns of ICS use from the observation period of this study that may inform future inquiry and interventions in high-risk asthma populations.

Studies have demonstrated that electronic monitoring of ICS adherence with some form of feedback can improve medication adherence in selected populations. In a recent randomized trial of patients ages 14–65 years with poorly controlled asthma in Australia, patients who received inhaler reminders and feedback demonstrated adherence rates of 73% compared with 46% in

the groups that had usual care or personalized adherence discussions [29]. A randomized trial of electronic monitoring with an audiovisual reminder in children 6–15 years old conducted in New Zealand demonstrated rates of adherence of 84% in the intervention group compared with 30% in the control [34]. An earlier review of electronic monitoring of inhaler use described the accuracy and reliability of newer electronic monitoring devices and efficacy of monitoring and feedback interventions, but highlighted feasibility concerns in vulnerable populations, including “the patient’s ability and willingness to use electronic monitoring devices” [38]. Our study offers a first glimpse of feasibility issues in a high-utilizer, inner-city minority cohort of children in the United States.

One of our primary concerns prior to launching this study was that inner-city minority families might feel that electronic monitoring interventions are overly intrusive and, thus, unacceptable. In this small study, we found no evidence to suggest this, though only 9 families (64%) completed the acceptability survey. A total of 5 (36%) families did not complete the final study visit and, though we cannot be sure of the reasons why they did not follow-up, this relatively high rate of loss to follow-up could be interpreted as their revealed lack of acceptability.

Another prominent feasibility question was whether families would initiate and maintain use of the devices. Our findings show that, while all the enrolled families effectively set up and began to use the electronic monitoring systems, there were challenges in maintaining the devices and data transmission. Several families unplugged the modem devices either temporarily or permanently, noting competition for available electrical outlets and concerns about electricity bills. Also, many of the monitoring devices that were returned had no remaining charge. These issues might have been mitigated at the onset of the study by including a power strip and communicating the negligible daily use of electricity of the cellular modem and charging devices.

With respect to outcomes, while the study was not designed to detect an improvement in asthma control, we found a statistically, but just short of clinically, significant improvement in ACT score over the course of the study for those who completed both study visits. It is important to note, however, that the study was uncontrolled; improvements in parental perception of asthma control may reflect regression to the mean or a placebo effect. We also noted distinct patterns of medication use over the first month of the study, prior to the initiating outreach for adherence alerts. Different patterns of daily medication use have been noted in one prior study of asthma in adults [44], as well as in pediatric conditions such as epilepsy [45], inflammatory bowel disease [46], and cancer [47]. While these categories have different labels in each prior study, further research should be directed at learning which potentially modifiable factors drive more sustained use patterns; this may assist families with lapsed or periodic use patterns in improving the consistency and duration of their controller medication use.

Based on the findings of this feasibility study, we offer a few considerations for future studies seeking to use electronic medication monitoring to improve the care of high-risk

populations. Investigators should 1) establish regular communication with the electronic device company and gain assurance that there is robust technological support to troubleshoot technological issues that arise during the intervention, 2) consider practical issues such as competition for electrical outlets within the house and cellular or wireless coverage in the community of interest that might affect data transmission, and 3) include team members with knowledge and credibility in the community (such as community health workers) who can assist in recruitment and outreach and help elicit subtle reasons for changes in medication use or data transmission.

Our study has a few limitations. First, since this was a feasibility study, the sample size was small and restricted to one clinic population. Thus, the feasibility concerns we present may not be representative of high-risk populations in other settings. Second, the families who agreed to participate in the study (and completed the final study visit) may have been more open to and accepting of any type of intervention, inclusive of electronic monitoring, than other high utilizers or the general population. Participants' ratings of acceptability may have been further enhanced by the receipt of a cellular phone with unlimited minutes and by social desirability bias, as this outcome was collected by a member of the study team (the asthma navigator). The feasibility of wide-scale provision of cellular phones for high-risk families would depend on the cost effectiveness of similar interventions, an outcome beyond the scope of this study. With respect to our assessment of asthma control, we assessed parental perception of asthma control using the ACT, since the median age of patients in our cohort was 3.5 years and there are no validated measures of asthma control in children younger than 4 years. More broadly, the children in our cohort were

young, with the oldest child enrolled being 9 years old. Because of this, our results may not be generalizable to older children, who tend to have greater responsibility for administering their medication [48].

With respect to adherence outcomes, we used different adherence categories than an earlier adult asthma study [44] for two reasons: 1) we were not able to capture multiple inhaler actuations occurring in the same minute in the first month of the study, and 2) even with our most conservative estimate, none of our participating patients met their criteria for "compliance" (75% of prescribed doses). Lastly, our assessment of adherence beyond 1 month was substantially limited by incomplete data resulting from causes such as unplugged cellular modems and uncharged monitoring devices. Therefore, we have presented medication use data for only the first month of the study prior to the onset of these issues, but also prior to the onset of the outreach intervention.

As payers, health systems, and providers seek new approaches to improving the care of high-risk populations, new or adapted technologies for "automated hovering" offer the potential to influence the 5000 hours that patients spend outside of the reach of the health care system [49]. While some electronic ICS monitoring interventions have shown promise in other populations, our findings demonstrate some of the prominent feasibility challenges of implementation in adapting such an intervention to a vulnerable patient cohort, even despite the strength of having a community-based peer as our effector arm. The findings of this study can be used to both anticipate challenges when planning future interventions and specify areas of future inquiry germane to understanding medication use behaviors of high-risk populations.

## Acknowledgments

This work was supported by funding from and program staff at Keystone First. The authors have no financial disclosures. We thank Andrew Weinstein, MD, Meg Grant, Lily Higgins, MD, Steven Dinsmore, and John Holland, PhD, for their assistance in the conception and development of the study protocol and review of manuscript drafts. We thank Charmaine Braxton for her work in the execution of the study and commitment to improving the health of children with asthma in West Philadelphia.

## Abstract

**Background:** Translating Emergency Knowledge for Kids was established to bridge the research-practice gap in pediatric emergency care by bringing the best evidence to Canadian general emergency departments (EDs). The first step in this process was to conduct a national needs assessment to determine the information needs and preferences of health professionals and parents in this clinical setting.

**Objective:** To describe the development and implementation of two electronic surveys, and determine the feasibility of collecting electronic survey data on iPads with in-person data collectors in a busy clinical environment.

**Methods:** Two descriptive surveys were conducted in 32 general EDs. Specific factors were addressed in four survey development and implementation stages: survey design, survey delivery, survey completion, and survey return. Feasibility of the data collection approach was determined by evaluating participation rates, completion rates, average survey time to completion, and usability of the platform. Usability was assessed with the in-person data collectors on five key variables: interactivity, portability, innovativeness, security, and proficiency.

**Results:** Health professional participation rates (1561/2575, 60.62%) and completion rates (1471/1561, 94.23%) were strong. Parental participation rates (974/1099, 88.63%) and completion rates (897/974, 92.09%) were excellent. Mean time to survey completion was 28.08 minutes for health professionals and 43.23 minutes for parents. Data collectors rated the platform "positively" to "very positively" on all five usability variables.

**Conclusions:** A number of design and implementation considerations were explored and integrated into this mixed-mode survey data collection approach. Feasibility was demonstrated by the robust survey participation and completion rates, reasonable survey completion times, and very positive usability evaluation results.

## Introduction

The Translating Emergency Knowledge for Kids (TREKK) project aims to bridge the research-to-practice gap in pediatric emergency medicine, and reduce variable emergency care, by ensuring that practitioners in general emergency departments (EDs) have access to and apply the latest research evidence in their pediatric practice [1]. The first phase of the TREKK project (the *Needs Assessment*) surveyed health care professionals and parents seeking care for their children in general EDs, to determine information needs and preferences to guide the development of knowledge translation tools on key child health topics. Given the well-documented challenges of survey research [2], particularly in health research [3-9], specific factors were addressed in four survey development and implementation stages, including survey design, survey delivery, survey completion, and survey return. The aim of this research was to increase data quality (ie, increasing participation rates, reducing item nonresponse, and reducing dropouts) [10].

Despite a wealth of research, much debate remains regarding the superiority of electronic and/or mailed paper surveys [4,11]. Recent studies indicate that the future of survey research involves mixed-mode approaches (ie, two or more modes of administration including mail, web, telephone, and/or in-person) [12] and/or additional recruitment techniques to generate higher response rates [13-15]. However, further research is recommended to describe variations in survey content and administration, and effects on participation rates and data quality [12]. In this paper, we describe electronic survey development and implementation using iPads and in-person data collectors. We also detail the feasibility of this novel mixed-mode approach to survey research by providing survey response rate results, average length of time for survey completion, and the results of a usability evaluation with data collectors.

## Methods

### Survey Design

Given the complexity of the ED environment (ie, fast-paced, high volume, high acuity), traditional paper-based surveys were too cumbersome and resource-intensive for this study. An electronic survey was determined to be the most appropriate method to meet study timelines, due to ease of implementation across a large geographic area, and decreased administrative costs [5,12,14,16]. To be included in the survey, each participant was either a health care professional working in a participating general ED, or a parent seeking care for a child in the EDs. Participants were excluded if they were unable to read or write English or French.

Survey questions were developed using relevant research literature [3] and in consultation with content experts in pediatric emergency medicine, nursing, and information science. The surveys underwent several iterations, and face validity was determined through team meetings and pilot testing within the research team. Both surveys were developed in English and translated into French. The *Health Care Professional Needs Assessment* survey collected demographic information, current information-seeking practices, information needs related to

caring for children in the ED, and preferences for receiving new information related to caring for children in the ED ([Multimedia Appendix 1](#)). The *Parent Needs Assessment* survey collected demographic information, information about the current visit to the ED, and health information needs and preferences ([Multimedia Appendix 2](#)).

In addition to survey content, six features affecting response rate of web-based surveys were considered: (1) general format, (2) length, (3) disclosure of survey progress, (4) visual presentation, (5) interactivity, and (6) question/response format [17]. A screen design format was selected to display one question per page, as this design has been shown to have lower item nonresponse than scrolling designs [17]. Much thought was given to survey length, and the surveys were constructed to achieve an average survey completion time of approximately 20 minutes. This target aimed to mitigate busyness as a barrier to health care professional participation [18], and to maximize the opportunity for parents to complete the survey in the waiting room before being brought into an examination room. Disclosure of survey progress has shown limited effect on response rates, so we did not incorporate this feature in our surveys [17]. In terms of visual presentation of the survey, a plain visual presentation approach with selective use of color was used, based on research indicating higher completion rates and later dropouts using this design [17]. *Sans serif* font was selected for ease of readability on a screen [19], questions and responses were numbered, and bolding, shading, italics, and color were used in a consistent fashion, with the aim to enhance understandability. Arrows were used to direct participants to subsequent screens. Interactivity was also incorporated, as it has been linked to lower item nonresponse [17]. This feature included automatic jumps to questions based on previous answers, and a *missing data* message was displayed when an item was left blank; however, responses were not forced due to the association of this option with higher dropout rates [17]. Four question/response formats were used throughout the surveys, and included single and multi-touch responses with radio buttons, sliding scales, and drag and drop boxes in which responses could be dragged to a new column and rank ordered ([Multimedia Appendix 3](#)).

### Survey Delivery

Consistent hardware was used at each site to streamline training and mitigate technological issues in survey delivery [5]. iPads were selected as the most effective survey delivery and data collection device because of their functionality and participant preference. iPads are lightweight devices that are easy to transport and hand to participants. The iPad interface is user-friendly and the touch screen technology, which has been shown to reduce mean time for patients completing questionnaires [20], enabled new and interesting approaches to survey question design [21]. In addition, previous research has demonstrated that both health care professionals and parental respondents preferred participation on a tablet compared to paper-based surveys [22-25], and found these devices easy to use [23,25]. Furthermore, electronic tablets have been shown to be a viable method of collecting patient self-report data in pediatric waiting rooms [26] and in rural settings [24].

## Survey Completion

External validity has been identified as a methodological issue of concern in survey research [3-5,27,28]; we attempted to address this issue by having in-person data collectors accompany the technology while conducting on-site recruitment. Census sampling aimed to recruit all health care professionals, and convenience sampling was used to recruit parents. The protocol for recruitment involved approaching all staff and parents to introduce TREKK and determine study eligibility. iPads were provided to interested parties to review the electronic consent form; once consent was indicated, participants automatically proceeded to the electronic survey. Data collectors were available throughout survey recruitment and completion to answer questions and assist with overcoming any technological barriers, including comfort with web browsers and touch screen technology. This consideration was based on research suggesting that the amount of contact and length of time in the field are important factors in health care professional response rates [4]. Surveys could be kept open for any length of time and were closed when the *Submit* button was indicated at the end of the survey, or the browser window was closed. The survey was designed with this flexibility, as data collection occurred in unpredictable and busy EDs.

## Survey Return & Technical Issues

The electronic survey platform incorporated synchronous and asynchronous data collection capability, meaning that data could be collected online and automatically uploaded to a secure server when a wireless connection was present, and data could also be collected offline, safely stored on the device, and later uploaded to a secure server once a wireless connection was available. This feature was particularly important in the ED setting, as many hospitals do not provide wireless internet and 3G/4G connectivity is limited or non-existent in rural and remote regions. This approach also addressed previously identified security concerns with cloud-based data storage [29,30]. Automatic data upload also eliminated the need for data entry, thus reducing the potential for error, and allowed the research

team to monitor data quality via a secure, password-protected portal to provide feedback or additional training to data collectors. This functionality required enhanced device security; however, iPads are equipped with the appropriate security features to meet this need, including passcodes and restrictions to limit access and usage, encryption to protect information stored on the device, GPS technology to track the device, and remote and automatic data wiping capabilities (in the event that the device is lost or stolen) [31].

## Usability Evaluation of Data Collection Platform

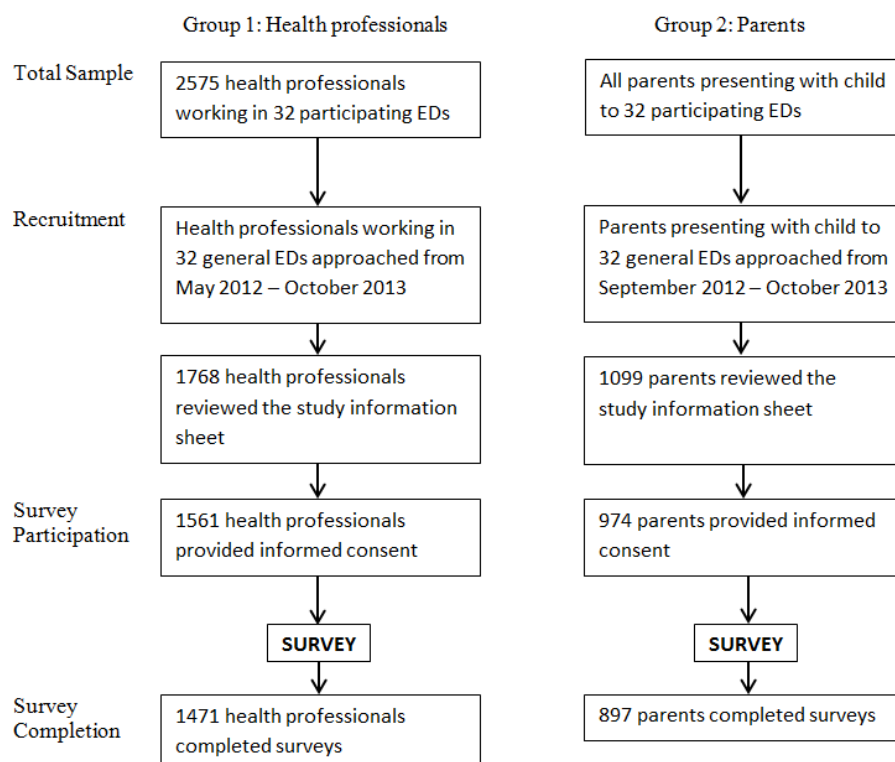

A usability evaluation was conducted with data collectors using an anonymous 20-question electronic survey. The content of the survey was theoretically informed on the basis of a small-scale review of previous studies employing electronic platforms for data collection and the National Institutes of Health's Usability Guidelines [32]. These guidelines outline key features of visual design and user experience, including interactivity, portability, innovativeness, security, and proficiency. The usability survey ranked features of the electronic survey and iPad on a five-point scale according to how positively or negatively these features affected their experience collecting data for the *TREKK Needs Assessment* (Multimedia Appendix 4). Face validity was determined via team meetings and pilot testing within the research team.

## Results

### Survey Participation & Completion Rates

The recruitment rate for health care professionals was 68.66% (1768/2575) and participation rate was 60.62% (1561/2575), and among participants the survey completion rate was 94.23% (1471/1561). Among parents the recruitment rate could not be determined because the eligible population was dependent on people coming into the general EDs; however, the participation rate was 88.63% (974/1099) and among participants the survey completion rate was 92.09% (897/974). See Figure 1 for recruitment and participation details for both populations.

**Figure 1.** Survey recruitment, participation & completion.

### Length of Time for Survey Completion

Of the 1471 health care professional surveys included in the final analysis, 79 surveys did not have a time stamp (ie, participants did not press *Submit* at the end of the survey) and were not included in the calculation of average survey completion time. Of the 1391 surveys with a time stamp, the mean time to survey completion was 28.08 minutes (standard deviation = 118.54 minutes). This estimate includes participants that left the survey open and returned to complete it at a later time (eg, 9 surveys were open for more than 1000 minutes).

Of the 897 parental surveys included in the final analysis, 25 did not have a time stamp and were not included in the calculation for average survey completion time. Of the 872 surveys with a time stamp, the mean time to survey completion was 43.23 minutes (standard deviation = 691.25 minutes). This estimate includes participants that left the survey open and returned to complete it at a later time (eg, 4 surveys were open for more than 1000 minutes).

### Usability Evaluation of Data Collection Platform

Eight data collectors were approached to participate in the usability evaluation, six of whom agreed to participate and complete the survey (75% participation and completion rate). On a five-point scale, responses were largely *positive* (score=4) to *very positive* (score=5) on the five usability measures (see Figure 2). Additionally, respondents could enter free text information to describe, in detail, their perspectives on the strengths and weaknesses of iPads as a data collection tool. Respondents noted that the professional look and feel of the survey created a sense of trustworthiness and legitimacy of the research study, as demonstrated by the following excerpt, “With a unique online survey specific for TREKK, it appears more trustworthy as a legitimate research study, rather than having... paper surveys.” However, respondents illuminated some drawbacks to this approach, such as, “The only real negative of using the iPad relates to the survey participants [sic] level of comfort with technology, but not to such an extent that it affects participation - only initial comfort.”

**Figure 2.** Data collectors' (n=6) ratings on 5 variables to evaluate the data collection platform.

## Discussion

Our findings make an important contribution to the web-based survey literature by addressing calls for research to examine web-based survey response and completion issues [10]. Generally, web-based surveys are correlated with low response rates [10], with estimates suggesting an average 10% decrease in response rates compared to traditional paper-based surveys. Given that 68.66% of health care professionals that were approached in our study reviewed the consent, and 94.23% of those who consented completed the survey, it is apparent that our mixed-mode approach mitigated these commonly accepted disadvantages of web-based surveys.

Utilizing data collectors to approach potential survey participants, and explain the study, eliminated the need for email or web-based invitations and completion reminders, and significantly enhanced survey participation and completion rates. We suggest that the addition of in-person data collectors offered the benefits of personal connection, and caused potential survey participants to make an active decision to participate in the study. In-person data collectors were also able to engage with potential participants and answer any questions the potential participants had about the study or the technology. Deploying a web-based survey without a mixed-mode approach allows potential participants to easily ignore electronic invitations to participate in survey research. With a mixed-mode approach, we were able to capitalize on the many benefits of web-based surveys, including improved data quality and the ability to immediately begin data analysis, while simultaneously

mitigating previously reported downfalls of web-based surveys, including lower response rates and lower completion rates.

Vicente and Reis itemized six areas to consider when designing and implementing web-based surveys [17], and our usability findings support five of these recommendations (general structure, survey length, visual presentation, interactivity, and question/response format). Specifically, the usability findings collected by our in-person data collectors were largely *positive* to *very positive* for interactivity, portability, innovativeness, security, and proficiency. Free text responses further strengthened these findings by highlighting that the general structure, visual presentation, and question/response format of our survey helped to legitimize and enhance the credibility of our study. These findings highlight the importance of the investment of time and resources into survey design and implementation elements. Our participation and completion rates, and survey usability findings, are evidence that attention to survey design and implementation is strategic.

## Conclusions

This study provides strong evidence for the feasibility of a mixed-mode approach to survey data collection using iPads and in-person data collectors, based on strong response rates, reasonable survey completion times, and very positive usability evaluation results. This study also details survey development and implementation considerations that will be useful to survey researchers working with a variety of populations. Great potential exists for utilizing a mixed-mode approach for future survey research in clinical settings.

## Acknowledgments

TREKK is funded by the Networks of Centers of Excellence – Knowledge Mobilization initiative, and supported (either financially or through in-kind contributions) by the following agencies and institutions: Pediatric Emergency Research Canada, Children's Hospital Research Institute of Manitoba, University of Manitoba, Research Manitoba, ManitobaCPD.com, Cochrane Child Health Field, Alberta Children's Hospital Research Institute, Children's Hospital of Eastern Ontario, Ontario ED Local Health Integration Network Leads, Alberta Health Services, and Women and Children's Health Research Institute. SDS is a Canada Research Chair (tier II) for knowledge translation in child health and a Population Health Investigator with Alberta Innovates – Health Solutions (formerly Alberta Heritage Foundation for Medical Research). LA is supported by Alberta Innovates – Health Solutions Graduate Studentship and Women & Children's Health Research Institute Graduate Studentship.

We would like to acknowledge and thank the TREKK Team, including the Board of Directors, Prioritization Committee, Nodal Leaders, and Pediatric Emergency Research Canada Representatives, Coordinators, and Administrative staff for their dedication to this project.

## Authors' Contributions

TPK and SDS obtained research funding. SDS conceptualized and led the research study. SDS, LA and LMG designed the electronic surveys. LA conducted data collection and data analysis for the *Needs Assessment*. SDS and DA conceptualized the small-scale iPad evaluation project. DA conducted data collection and data analysis for this evaluation. SDS and LA wrote the manuscript. All authors provided substantive feedback and approved the manuscript prior to submission.

(*JMIR Res Protoc* 2016;5(2):e92) doi:[10.2196/resprot.5971](https://doi.org/10.2196/resprot.5971)

The title of the paper originally entitled “Content Analysis of Online Focus Group Discussions is a Valid and Feasible Mode When Investigating Sensitive Topics Among Young Persons With a Cancer Experience” (*JMIR ResProtoc* 2016 May 9; 5(2):e86) was corrected to read “Online Focus Group Discussion is a Valid and Feasible Mode When Investigating Sensitive Topics Among Young Persons With a Cancer Experience”. The error was introduced by the editor in the final proofreading process to remove a grammatical issue, but the authors feel that “content analysis” in the title is incorrect because content analysis was not the method used for analyzing data in the present study. The advantages and disadvantages with the mode

of data collection was judged by analyzing characteristics of those who participated, interactions during discussions and the participants’ evaluation of the focus group discussions. Secondly, there was also an incorrect affiliation footnote reading “null” associated with author Lena Wettergren, which has now been removed from the metadata. These errors have been corrected in the online version of the paper on the JMIR website on May 10 and May 12, 2016, respectively, together with publishing this correction notice. There are no changes to the contents of the paper. A correction notice has been sent to PubMed. This was done before submission to Pubmed Central and other full-text repositories.

## Abstract

**Background:** This is a 2-year study to assess the early impacts of a new grocery store intervention in a former food desert.

**Objective:** The purpose of the study is to understand the early health effects of the introduction of a large-scale food and nutrition-focused community-based population health intervention, the Good Food Junction (GFJ) Cooperative Store, in a geographically bounded group of socially disadvantaged neighborhoods (the “core neighborhoods”) in a mid-sized Canadian city. The GFJ grocery store was tasked with improving the access of residents to healthy, affordable food. The 5 research questions are: (1) What is the awareness and perception of the GFJ store among residents of the core neighborhoods? (2) Are there differences in awareness and perception among those who do and do not shop at the GFJ? (3) Will healthy food purchasing at the GFJ by residents of the core neighborhoods change over time, and what purchases are these individuals making at this store? (4) What early impact(s) will the GFJ have on key health-related outcomes (such as household food security status, vegetable and fruit intake, key aspects of self-reported mental health, self-reported health)? and (5) Are the effects of the intervention seen for specific vulnerable population groups, such as Aboriginal people, seniors (65 years old or older) and new immigrants (settled in Saskatoon for less than 5 years)?

**Methods:** The research project examined initial impacts of the GFJ on the health of the residents in surrounding neighborhoods through a door-to-door cross-sectional survey of food access and household demographics; an examination of GFJ sales data by location of shoppers' residences; and a 1-year, 3-time-point longitudinal study of self-reported health of GFJ shoppers.

**Results:** Analyses are on-going, but preliminary results show that shoppers are using the store for its intended purpose, which is to improve access to healthy food in a former food desert.

**Conclusions:** To our knowledge this is the first large-scale study of a full-service grocery store intervention in a former food desert in Canada that has used multiple data sources, as well as longitudinal analyses, to examine its effects. Its findings will contribute significantly to the knowledge base on food environment interventions.

**KEYWORDS**

food environments; intervention; natural experiment

## Introduction

North American lifestyles generally promote food that is packed with calories (ie, energy-dense food) and offer little incentive for being active [1], particularly in low-income neighborhoods [2]. Specifically, food environments are increasingly recognized as a critical determinant of community and population health [3-5]. Townshend and Lake stated that the food environment “can be broadly conceptualized to include any opportunity to obtain food.... This definition of the food environment can include physical, sociocultural, economic, and policy factors at both micro- and macro-levels” [6].

The presence and accessibility of supermarkets and grocery stores has been linked to improved fruit and vegetable consumption [7], general improvement in healthier food intake [8], and lower body weight [9]. Using national-level data, one US study reported that higher prices for vegetables and fruit are significantly associated with greater gains in BMIs in children between kindergarten and the third grade [10]. There is increasing evidence that poor food environments—such as greater access to fast food and convenience stores and limited access to full-service grocery stores—are more likely to be located in neighborhoods with a lower than average socioeconomic status [9,11-14]. Poor food environments may partly explain why individuals of lower socioeconomic status are more likely to be obese.

While early studies focused primarily on characterizing food environments using geographical and other methods [15], more recent research examined food environment interventions, such as healthy corner store studies [16,17] and the health impacts of opening new supermarkets in “food deserts” (ie, neighborhoods where affordable and nutritious foods are unavailable, requiring residents to travel outside of their neighborhood to access nutritious foods) [18-20]. The body of food environment interventions literature is still very limited in Canada, and results from outside of Canada are contradictory [21-23]. As such, there is a need to conduct larger scale, more systematic, and in particular longitudinal intervention research on food environments.

There have been mixed outcomes in previous research examining food store interventions. Wrigley et al [24] offered the first “before and after” study of a new grocery store development in Leeds, England, in a low-income neighborhood with poor retail access to healthy food. The store was a large-scale chain supermarket. Using fruit and vegetable consumption as a proxy for healthy diet, the authors noted that the introduction of a full-service grocery store significantly improved consumption. Cummins et al [19] also studied the impacts of the opening of a for-profit retail grocery store but showed the intervention had little effect on fruit and vegetable consumption. However, they later argued [25] that the community was not a true food desert and had some access to healthy food. They noted that positive consequences of the grocery store opening included community economic regeneration, increased employment, and a “net reduction in poor psychological health for those who directly engaged with the intervention” [26]. Overall there is uncertainty as to whether

grocery store interventions impact healthy eating behavior or other aspects of health.

Drawing on the literature, this study was developed to contribute to the emerging field assessing the impacts of new food access points in low socioeconomic status communities that have previously been characterized as having particularly poor food environments [22,23]. The study is being conducted to assess the early impacts of a new grocery store in a community that had been identified as a food desert [27,28]. The goal of the study is to understand how the introduction of a large-scale food- and nutrition-focused community-based population health intervention (the Good Food Junction Cooperative Store) may impact the health of individuals and families in a geographically bounded group of neighborhoods.

## Intervention and Setting

This study is being conducted in Saskatoon, Saskatchewan, a city of just over 250,000 people. The study is focused on neighborhoods surrounding the Good Food Junction Cooperative grocery store. These are known as the “core neighborhoods,” a set of 7 low socioeconomic status neighborhoods in Saskatoon (Figure 1). The core neighborhoods have several characteristics in common. First, they are located on the west side of the South Saskatchewan River, a river that flows through the center of the city (Figure 1). Second, they are older neighborhoods, built between 1900 and 1930, and finally, they are relatively low-income when compared to the Saskatoon median. These neighborhoods have a relatively high concentration of residents who (1) rent their homes, (2) do not own a vehicle, (3) identify as Aboriginal, (4) are newcomers, or (5) are seniors with fixed incomes [29]. Saskatoon has a large Aboriginal population, compared to other Canadian urban centers, and over half of this population is young (10% of the people living in Saskatoon identify as Aboriginal compared to 3.8% for Canada, and 55% are ≤ 24 y) [30,31]. (The term “Aboriginal” refers to the Indigenous peoples of Canada, descendants of the original inhabitants of this country. It is the legal term used in the Constitution Act of 1982 to refer to First Nations, Métis, and Inuit peoples.)

In September 2012, the Good Food Junction Cooperative Store (GFJ) opened as a result of an 8-year consultation and planning process focused on meeting the food needs of the people living in the area. This grocery store was tasked with improving the access of residents to healthy, affordable food. It is geographically located in the center of a former food desert [27] in the heart of one of the lowest income neighborhoods in the city. The 4900-square-foot store offers a wide range of fresh, frozen, and packaged foods.

The core neighborhoods have had no major chain grocery stores since the mid-1990s, when the last such store closed [28]. The area also saw a loss of small local grocers, going from 12 local grocery stores in 1984 to 5 by 2004 [28]. A 2010 assessment found that residents of the core neighborhoods live much closer to fast food restaurants than to grocery stores, when compared to the citywide average [27].

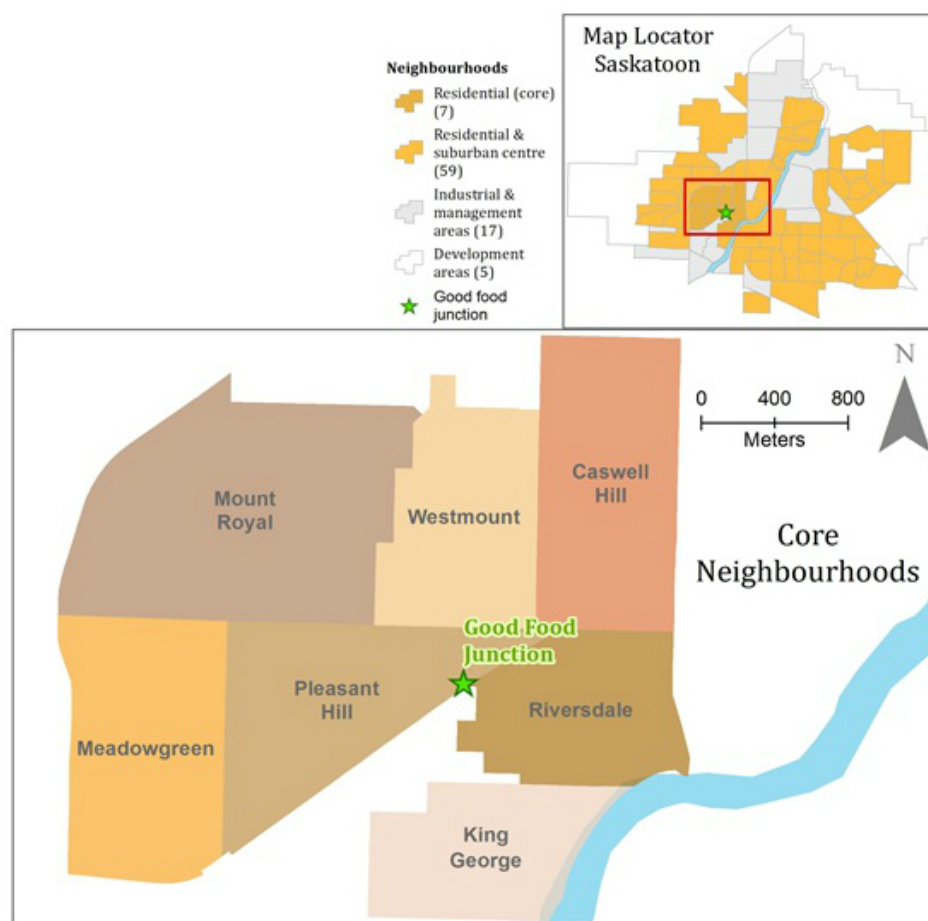

The GFJ grocery store is housed in a building called Station 20 West [27]. Station 20 West includes the GFJ [32], a community

kitchen space, a coffee shop, community meeting space, and several offices for community-based organizations, health services and programming, and community-based research [33].

The goal of this research is to understand and model how the introduction of a large-scale food and nutrition-focused

community-based population health intervention (the GFJ) may impact the health of individuals and families in a geographically bounded group of neighborhoods. The study proposal was peer-reviewed and funded by the Canadian Institutes for Health Research, through the Population Health Intervention Research funding stream (grant #127084).

**Figure 1.** Location of the Good Food Junction Grocery Store.

## Methods

The study employed 3 approaches to data collection that roughly correspond to the 5 research questions stated below. There was (1) a cross-sectional door-to-door survey of household food access and demographics (research questions 1 and 2), (2) an analysis of food purchasing sales data obtained directly from the grocery store linked to unique membership numbers (research question 3), and (3) a year-long longitudinal 3-time-point study of food access and self-reported health of GFJ shoppers (research questions 4 and 5). Data collection was conducted from July 2013 through November 2014.

The following research questions informed the study:

1. What is the awareness and perception of the GFJ among residents of the core neighborhood?
2. Are there differences in awareness and perception among those who do and do not shop at the GFJ?
3. Will healthy food purchasing at the GFJ by residents of the core neighborhood change over time, and what purchases are these individuals making at this store?

4. What early impact(s) will the GFJ have on key health-related outcomes (such as household food security status, vegetable and fruit intake, key aspects of self-reported mental health, self-reported health)?
5. Are the effects of the intervention seen for specific vulnerable population groups, such as Aboriginal people, seniors (65 years or older), and new immigrants (settled in Saskatoon for less than 5 years)?

This complex, community-based study of the early impacts of the opening of a full-service grocery store in a former food desert has required a great deal of careful thought, flexibility, and willingness to adapt to the challenges of this type of research with a marginalized and difficult-to-access population. One of the goals of this paper, in addition to describing the research protocol, is to highlight some of the challenges experienced in conducting it and some of the ways in which the study was adapted due to circumstances outside of our control in studying the natural experiment that is the GFJ grocery store.

The project has received ethical approval from the University of Saskatchewan's Human Behavioural Research Ethics Board (#13-168, approval date: May 30, 2013). Informed consent was

obtained from all study participants. Participants have received detailed information outlining study goals and requirements. We have taken due care to inform participants regarding the purpose and the manner in which the data will be collected, used, and secured.

### Cross-sectional Household Food Procurement Survey

In order to answer the first and second research questions, from July of 2013 to November 2013, a cross-sectional survey was administered. A team composed of 4 trained interviewers conducted the door-to-door survey administration in teams of 2. One of the 4 interviewers was a woman who lived adjacent to Station 20 West and was involved in the local community, and the other 3 were women who worked in or were otherwise involved in the community.

The intent of this quantitative survey was to examine the awareness and use of the GFJ grocery store approximately 1 year after opening and other food sources by individuals who lived within walking distance of the store.

With ArcGIS software, a road network of a 750-meter radius (with the GFJ at the center) formed the geographic boundaries for the study. All residential locations within this radius were considered to be within the sample. The distance of 750 meters from the GFJ was chosen to simulate a reasonable walking distance.

Drawing on information from the City of Saskatoon, a total of 1459 residences were considered to be within the 750-meter radius. Of this number, 271 locations were excluded as they were determined to be nonresidential, inaccessible, unsafe, vacant, or nonexistent. We did not want overlap between those who participated in the cross-sectional household food procurement survey and those participating in the longitudinal study described below. Therefore, given that the recruitment period for the 2 components of the research overlapped somewhat, we asked potential participants if they were already participating the longitudinal research. If they answered to the affirmative they were excluded from this component of the research ( $n=47$  participants). The remaining 1141 households were contacted through door-to-door recruitment over a period of 5 months.

Individuals were eligible to participate in the short interviewer-administered survey if they were over 18 years of age, lived in the residence, and were the person primarily responsible for purchasing food for the household.

Topics covered in the survey included whether the participant was aware of the GFJ; if the participant had shopped at the GFJ; which grocery store was their primary grocer; and what mode/s of transportation the participant used to travel to said primary grocery store. Information regarding whether participants accessed a wide range of food programs provided by local nonprofits was also gathered, as well as sociodemographic and household composition information.

Initially, residences within the geographic boundary were randomly sampled for inclusion in the research, but it soon became clear that in order to cover more ground and efficiently collect data, it would be necessary to contact all households

within the geographic boundaries of the study area. Interviewers worked in pairs and approached households until the successful completion of a survey, a direct refusal by a resident, or the third unsuccessful attempt to connect with a household member. Appointments were arranged with individuals who wanted to participate but were unable at the initial time of contact. Interviewers left printed door hangers on residences if no one was home, informing residents of the study and ways to participate.

For management of the data collection, the targeted geographical area was divided into 4 quadrants. Visits were systematically recorded on a log sheet, and these sheets were updated before each new round of outreach to potential participants. The schedule for conducting on-the-doorstep outreach was designed to ensure that residences were visited on different days, and at different times. For example, if there had been no one home during a weekday, the following visit was conducted on a weekend or in the early evening.

Of the residences approached, there were 180 refusals and 596 nonresponses after 3 visits. A total of 365 households within the 750-meter radius participated in the survey, which was 32% of all “eligible” households. The average length of interview was 10 minutes. Individuals who participated in the cross-sectional household survey were provided with a \$10 gift card to the GFJ as compensation for their time.

All quantitative data for the door-to-door survey was entered and cleaned by study research staff and then analyzed using SPSS version 22 (IBM).

One peer-reviewed paper on this data has been published to date [34] but without description of full methodology as presented here, and full analysis is on-going.

### Multilevel Cross-Sectional Analysis of GFJ Sales Data

In order to answer the third research question, the GFJ shared their sales data to allow the research team to track food sales data by postal code for analysis through a multilevel cross-sectional analytical design.

Since GFJ is a cooperative, members who shop at the store can be tracked to understand their purchasing behavior. For a period of 5 months, from May 1, 2013, to September 30, 2013, the research project paid the membership cost for any shoppers who wished to be a member of the GFJ cooperative. Each GFJ member is assigned a unique membership number, which is recorded at checkout. Food purchasing can be tracked through these membership numbers, as the store records a history of purchases made by each member. Through this database it is possible to analyze the patterns of food purchasing over a period of time.

One limitation with the GFJ sales data is that the membership database contains minimal information (eg, only the members' postal codes and linked purchasing habits). Individual socioeconomic position is not recorded, but each member's neighborhood's socioeconomic position was derived using data from the 2006 Canadian Census, according to Pampalon's deprivation index [35].

To date, the sales data have been used to observe the food purchasing habits of store members over a 1-year period in order to see whether shoppers living near the GFJ (the “targets” of the intervention) have different shopping patterns compared to GFJ members who live farther away from the GFJ (not targets of the intervention) [36]. As only member-purchases for a year-long period at the GFJ have been analyzed to date (plans for future analyses are described below), these results cannot show the full range of food purchases occurring in the store, nor what members purchased at other stores.

The food purchasing sales data was provided directly by the GFJ grocery store and was entered into a research database, then cleaned and categorized to allow for analysis. Sales data from the GFJ contains information on all food purchases made in the store, along with the membership database.

For our initial analyses, this resulted in information on 72,587 food purchases (by all users) during the period of interest of May 15, 2013, to April 30, 2014. During this period, 526 of the 1109 GFJ members in the data set did not make a purchase, leaving 583 members with 38,190 purchases available for analysis. Of the 583 members with purchase data, 361 (62%) lived in the “core” neighborhoods [36].

Food sales data from the store was categorized into 11 different categories using Stock Keeping Unit codes [37]. The categories were developed in reference to 2 Health Canada tools: Canada’s Food Guide and the Canadian Nutrient File (a database containing information about nutrients in food in Canada) [38,39]. Five categories were considered healthy (eg, fruit, vegetables, meat and alternatives, dairy products, grains) and 6 categories were considered less healthy or nonfood (eg, sugar sweetened beverages, nonnutritive beverages, snack foods, prepared foods, flavoring, nonfood items) [39].

### **Longitudinal Food Access and Self-Reported Health Research with Shoppers**

In order to answer the fourth and fifth research questions, a year-long 3-time point longitudinal study was conducted to record potential changes in perceived health status in people who made purchases at GFJ. Designed as a food access and health survey, the questions included perceptions of current health status, vegetable and fruit consumption, household food security, and perceptions of a sense of community in their neighborhood, all of which were taken from the Canadian Community Health Survey [40]. In addition, all participants were asked the questions covered in the cross-sectional food access and demographics survey described above.

The health and food access survey was conducted at 3 time points, with a cohort of 156 shoppers at the first time point. The intention was to have the survey administered 3 times with about 6 months between each administration (creating a year time frame of interviews conducted at months 0, 6, and 12). The first time point occurred between July and August 2013, the second was in February through April 2014, and the third administration occurred during July through November 2014.

Participants for this longitudinal study were recruited on-location at GFJ as they entered the store by the same trained interviewers who administered the cross-sectional door-to-door survey.

Members of the research team were on-location for 2- to 3-hour periods during the initial recruitment phase. Team members alternated shifts between mornings and afternoons, in an effort to recruit as many shoppers as possible. In order to speed recruitment that was initially proceeding slowly, participants were also recruited through advertisement (predominantly poster and word-of-mouth) in the grocery store and nearby service agencies.

To participate, the respondent had to be over the age of 18, the primary shopper for their household, and was required to have shopped at GFJ at least 3 times in the previous 2 months. To prevent any possible overlap of households, participants were asked whether any other member of their household was already participating in the study. There were no stipulations for participants having to live within a certain geographic distance from the GFJ. It should be noted that residents who participated in the door-to-door survey described above were not recruited to participate in this part of the research.

Every effort was made with individual participants to leave a 6-month period between each iteration of survey administration. The surveys took an average 30 minutes to complete with administration always conducted with a trained interviewer. Due to the need for flexibility, a staff member from Station 20 West was trained to deliver the interview midway through the first iteration of data collection. This individual was well respected and known in the community and was available to participants who could not be accessed by the main interview team. This approach enabled the study to stay connected with participants who were highly transient or did not have phone numbers, and were therefore difficult to contact. Because they regularly attended Station 20 West to connect with resources available there, the staff member was able to ask them if they were willing to conduct follow-up interviews then and there. At each of the 3 data collection time points, participants were compensated for their time with a \$25 GFJ gift card.

At the first data collection time point, 156 participants completed the survey. At the second administration of the survey, 129 participants from round 1 participated in the second survey (27 participants were lost to follow-up) but 24 new participants were added (recruitment was done in the same fashion as at the first time point), for a total of 153 participants completing the second round of data collection. In the third administration of the survey, 37 people were lost to follow-up and, therefore, 116 participants completed the survey. A total of 104 participants completed all 3 rounds of data collection and another 37 participants completed 2 rounds for a total of 141 participants with enough data to be included in the analysis.

Participants in this study were also offered a free lifetime membership (usual cost is \$5) at the GFJ cooperative. This was done to provide the research team the possibility of analyzing their sales data in conjunction with their survey responses. It is not possible to determine whether being provided with a free membership influenced shopping habits, or whether this action incentivized usage of the store, but it is unlikely given that members do not receive any benefits beyond eligibility to participate in the annual general meeting.

## Results

Data collection for this study is largely complete, but only a small fraction of it has been analyzed to date. Some data from the cross-sectional household food access survey and from sales at the Good Food Junction have been analyzed, but none of the longitudinal self-reported health and food access data from GFJ shoppers have been analyzed to date. The longitudinal research will likely be the largest contribution of this study to the literature, since very little longitudinal research on grocery store interventions in former food deserts has been published.

Two articles have been published to date: Cross-sectional analysis of a community-based cooperative grocery store intervention in Saskatoon, Canada [34], and Examining food purchasing patterns from sales data at a full-service grocery store intervention in a former food desert [36]. From analysis by Lotoski, Engler-Stringer, and Muhajarine of the door-to-door survey, it appears that residents are highly aware of the store (95% of residents were aware of the GFJ at the time of data collection) and most have shopped at the GFJ at least once [34]. Despite this, only 30 of the 251 (12.0%) households surveyed who had ever visited the GFJ used it as their primary grocery store.

Further analysis indicates that compared to residents who did not shop at the GFJ, residents who did shop at the GFJ had lower annual household incomes and were more likely to use local community-based food programs and services in comparison to non-users. This seems to indicate that the GFJ is serving households that are more likely to be facing food insecurity.

From the analysis by Fuller, Engler-Stringer, and Muhajarine [36], it appears that shoppers living in the core neighborhoods are making more healthy food purchases at the GFJ compared to shoppers who live outside of the core neighborhoods. For example, shoppers living in the core neighborhoods spend more on vegetables, and less on meat and alternatives and prepared foods, than shoppers who do not reside in those neighborhoods. This appears to be an indication that people will make healthy food purchases when healthy foods are accessible.

## Discussion

Data analysis is on-going for this study. We will report on our data in several publications. The 3 time point, longitudinal self-reported health and food access research is currently in the early stages of analysis. There are 2 graduate students analyzing the longitudinal self-reported data on health and food access by GFJ shoppers; one focusing on the self-reported health, mental health, and sense of community of GFJ shoppers over time, and

the other focusing on vegetable and fruit consumption and household food security of GFJ shoppers over time.

In terms of further analyses to be conducted on our door-to-door food access and demographics survey research, we intend to report on the distances traveled to the primary grocery store of choice and detail the use of community-based food programs of study participants. This will contribute to the literature examining food access practices by residents of low-income neighborhoods. In terms of GFJ sales data, we will also report on the temporality and seasonality of vegetable and fruit and other food purchasing in order to better understand (1) how these issues may impact the sustainability of food environment interventions and (2) how these types of interventions can better respond to the needs of users.

Finally, we are working on a publication that will discuss recruitment and retention challenges and lessons learned in conducting our study. We had to recruit and retain study participants from a marginalized population for this research, particularly very low-income and transient participants, and we found that we learned a great deal from this process, much of which we think will be relevant to others conducting similar research.

## Conclusions

The Good Food Junction Grocery Store opened in 2012 due to a long-term concerted effort by Saskatoon core neighborhood residents and their supporters with the intended purpose of improving access to healthy food in a documented former food desert. Analyses in this study are on-going, but results to date show that shoppers are using the store for its intended purpose [34,36]. Our results show that residents of the neighborhoods directly adjacent to the store have very low household incomes and almost three-quarters of them use anywhere from 1 to 4 community-based food programs, including charitable programs (the food bank was the most widely reported) and numerous others, most of which focus on affordable access to vegetables and fruit. We have also found that the people who shop at GFJ have lower incomes and are more likely to be Aboriginal compared to those who do not. What is clear from our analysis to date is (1) the very low socioeconomic status of our study participants and (2) the importance of better understanding the needs of this population in order to support their access to healthy food.

To our knowledge this is the first large-scale study of a full-service grocery store intervention in a former food desert in Canada that has used multiple data sources, as well as longitudinal analyses, to examine its effects. The study's findings will contribute significantly to the knowledge base on food environment interventions.

## Acknowledgments

The authors thank Paula Mowat for her help putting this article together. We also thank the GFJ, the Good Food Healthy Families research team, the Saskatchewan Population Health and Evaluation Research Unit staff, and, especially, Melissa Gan, Jacinda Sigurdson, Elsie Piché-Johnson, and Amanda Guthrie. Funding for this project was provided by the Canadian Institutes for Health Research (#127084).

## Abstract

**Background:** Tobacco smoke exposure (TSE) is unequivocally harmful to children's health, yet up to 48% of children who visit the pediatric emergency department (PED) and urgent care setting are exposed to tobacco smoke. The incorporation of clinical decision support systems (CDSS) into the electronic health records (EHR) of PED patients may improve the rates of screening and brief TSE intervention of caregivers and result in decreased TSE in children.

**Objective:** We propose a study that will be the first to develop and evaluate the integration of a CDSS for Registered Nurses (RNs) into the EHR of pediatric patients to facilitate the identification of caregivers who smoke and the delivery of TSE interventions to caregivers in the urgent care setting.

**Methods:** We will conduct a two-phase project to develop, refine, and integrate an evidence-based CDSS into the pediatric urgent care setting. RNs will provide input on program content, function, and design. In Phase I, we will develop a CDSS with prompts to: (1) ASK about child TSE and caregiver smoking, (2) use a software program, Research Electronic Data Capture (REDCap), to ADVISE caregivers to reduce their child's TSE via total smoking home and car bans and quitting smoking, and (3) ASSESS their interest in quitting and ASSIST caregivers to quit by directly connecting them to their choice of free cessation resources (eg, Quitline, SmokefreeTXT, or SmokefreeGOV) during the urgent care visit. We will create reports to provide feedback to RNs on their TSE counseling behaviors. In Phase II, we will conduct a 3-month feasibility trial to test the results of implementing our CDSS on changes in RNs' TSE-related behaviors, and child and caregiver outcomes.

**Results:** This trial is currently underway with funding support from the National Institutes of Health/National Cancer Institute. We have completed Phase I. The CDSS has been developed with input from our advisory panel and RNs, and pilot tested. We are nearing completion of Phase II, in which we are conducting the feasibility trial, analyzing data, and disseminating results.

**Conclusions:** This project will develop, iteratively refine, integrate, and pilot test the use of an innovative CDSS to prompt RNs to provide TSE reduction and smoking cessation counseling to caregivers who smoke. If successful, this approach will create a sustainable and disseminable model for prompting pediatric practitioners to apply tobacco-related guideline recommendations. This systems-based approach has the potential to reach at least 12 million smokers a year and significantly reduce TSE-related pediatric illnesses and related costs.

## Introduction

### Background

Each year over 480,000 deaths in the United States are attributable to smoking, accounting for one in five deaths, and up to one-half of all smokers die prematurely [1]. In addition to the harmful consequences to the smoker, exposure of nonsmokers to tobacco smoke (TSE) is a serious health hazard. TSE is unequivocally harmful to children's health as evidenced by increased rates of asthma, bronchiolitis, and respiratory infections [2-4]. TSE-related illnesses result in increased Pediatric Emergency Department (PED) visits and hospitalizations [5-8]. In the United States, more than 25.5 million children are treated in PEDs each year [9] and our own research has found rates of smoking in caregivers as high as 48% (865/1809) [10-13]. Therefore, as many as 12 million children who visit the PED are exposed to tobacco smoke.

The American Academy of Pediatrics (AAP) considers tobacco use a "pediatric disease" given the pediatric morbidity caused by adult tobacco use and TSE [14]. The AAP and the *Clinical Practice Guidelines for Treating Tobacco Use and Dependence* (CPGs) [15,16] provide recommendations on the treatment of adult caregivers who smoke for pediatric practitioners, which includes three components: (1) use of electronic health records (EHR) to document or "ASK" about tobacco use and TSE at each clinical encounter, (2) use of clinical decision support systems (CDSS) to "ADVISE" and provide brief cessation counseling in the clinical setting, and (3) "ASSESS" readiness to change and "ASSIST" all smokers in their efforts to make their homes and cars smoke-free and quit smoking. This approach targets the benefits of quitting on reducing the child's TSE, and offers the potential to decrease tobacco-related morbidity in both the caregiver and child. This expanded use of the EHR to prompt nurses to treat tobacco dependence has been used in adult settings [15,17,18], and provides a means to standardize screening and counseling of tobacco users in the PED. However, despite these recommendations and evidence of effectiveness in adult settings, no standardized protocols currently exist in PEDs to guide practitioners in the treatment of adult smokers as recommended by the AAP or the CPGs. Our research has shown that tobacco interventions are feasible and effective in the PED setting [10,13].

This project will develop and test new approaches to increase nurse delivery of TSE and cessation interventions to caregivers who smoke who are not pediatric patients. Because past research has shown that PED nurses do not deliver TSE counseling in a systematic way due to barriers such as lack of training, time, and structured systems in intervening with adults [19-22], we plan to integrate CDSS prompts into the EHR to promote national treatment recommendations for caregivers in the PED in a time-efficient, simple way. We will implement a systems-based strategy that can be widely disseminated, and we will systematically assess tobacco use for all caregivers of PED patients.

For a CDSS to be successful, it must be integrated within the complex environment of the health care setting [23]. This technology must dynamically interact with practitioners, patients/parents, and existing health care systems [23-25]. One of the biggest challenges with implementation is clinical workflow integration because if the CDSS tools are too difficult or cumbersome to incorporate into the workflow, they will not be used [26-28]. Thus, it has been recommended that prior to integrating a CDSS into the health care setting, it is crucial to ensure that it first reflects the needs and preferences of the users (eg, nurses), and the organization systems (eg, PED) within which it is going to be implemented [25]. The CDSS should then only be introduced into clinical practice after an iterative formative evaluation, usability testing, and pilot field testing, designed to facilitate modifications to the CDSS based on user's needs and the clinical environment [25]. We will adopt this developmental approach and pilot testing strategy in the proposed project.

### Framework and Design Objectives for the Clinical Decision Support System

We will adopt the Chronic Care Model as the framework for our proposed CDSS. This model is a widely disseminated paradigm for redesigning health care systems to be more proactive and focused on keeping people healthy rather than reactively treating preventable conditions [29-32]. Because we are addressing caregiver smoking in the PED setting during the child's (and not the caregiver's) acute care visit, this model is particularly appropriate and represents an innovative approach for developing our CDSS. Furthermore, because the elements of the model comprise all of the system approaches recommended for tobacco use, it provides a unifying approach for dealing with multiple behavioral risk factors [29,30]. Using this model as the guide, we will work to ensure positive caregiver-nurse interactions through the use of several systems that start during the PED visit.

The systems that we will use to provide a unifying approach that will facilitate caregiver-nurse interactions during the child's PED visit include: (1) clinical decision support: we will develop and integrate CDSS reminder prompts based on the CPGs [16] that will include "ASK," "ADVISE," "ASSESS," and "ASSIST" ("ARRANGE" and "ASSIST" behaviors will be consolidated under the "ASSIST" prompt) and the AAP recommendations (eg, home and car smoking bans), and provide training using the CPGs as a framework, (2) enhanced delivery: we will clearly define nurse roles and establish accountability for these roles by developing Feedback Reports to inform nurses about their TSE counseling behavior, (3) clinical information: we will create a caregiver registry within the EHR to identify smokers, keep track of who has been provided with TSE counseling, and capture caregiver/patient outcomes (using a convenience sample), (4) personalized cessation resources: we will facilitate a direct, "active" referral to the caregivers' choice of free, evidence-based cessation program/resources (eg, telephone Quitline (QL), SmokefreeTXT, SmokefreeGOV), and (5)

self-management support: we will ensure that caregivers are active participants in their care by providing information on cessation resources and written self-help and motivational materials.

The design objectives will be influenced by a team-oriented workflow of care in the PED and local adaptation of the CPGs and other cessation CDSS that have been integrated with the EHR in adult settings [15-18]. The design will include the following steps: identifying caregivers who smoke using easy-to-use screening prompts, providing an electronic link to the brief counseling advice that nurses should provide to caregivers, and evaluating nurse behavior in the ASK, ADVISE, ASSESS, and ASSIST steps. The CDSS prompts will facilitate screening and counseling reminder systems by integrating four different information systems that are part of the total PED system and clinical research infrastructure considered critical for successful implementation. These four systems are: (1) hospital-wide information systems: an enterprise EHR system, Epic, (2) PED clinical systems: the documentations screens used in the current workflow, (3) clinical research: the Research Electronic Data Capture (REDCap) [33] database, and (4) the CPGs for tobacco use: links will be provided to generate an active referral to cessation resources based on caregiver preference.

The CDSS will be built using a combination of the EHR and REDCap. The Epic EHR has approximately 11.6% of the total EHR market share in the United States [34,35]. It is used by approximately 835 customers in the United States, securely managing over 1.25 million patient health records per month. Approximately 40% of the US population has its medical information stored in an Epic EHR [36]. The emergency department information system allows the addition of modules to existing applications based on customer needs. We will display the child's TSE and the caregiver's smoking status within the child's EHR. However, because the counseling (ie, ADVISE, ASSESS, ASSIST) steps will solely relate to the caregivers, these steps will be completed outside of the child's EHR in REDCap. The use of REDCap is necessary in order to maintain separate records for the parents/caregivers, who are not patients, and for whom information cannot be stored in the child's health record. REDCap is a Web-based application for building and managing Internet surveys and longitudinal databases with a secure Web connection with authentication and data logging. It has the ability to create, share, and modify counseling prompt templates for use in any ED setting, can link to external webpages (eg, smokefreeTXT) and has automated, seamless export procedures for data downloads to statistical packages [33]. Each PED room contains an Internet-connected computer and access to the EHR. The EHR can provide a prompt to link to REDCap after the caregiver is identified as a current smoker so that the nurse will be able to collect data on caregivers, provide caregivers with cessation counseling messages based on the prompts, obtain QL fax referrals and/or TSE reduction tips, or provide "active" referrals by connecting to the SmokefreeTXT or SmokefreeGOV website [33]. REDCap can be accessed at any time so that counseling can be performed and recorded in the patient's room at the nurse's convenience. By using existing nursing workflow and automatic prompts, we

will create a sustainable intervention requiring minimal additional data entry by nurses, and this will facilitate the clinical workflow between the PED nurse and physician.

### **Phase I: Development and Programming of the Decision Support System and Feedback Reports**

We will conduct a two phase project with the following aims: Aim 1: convene an advisory panel of PED and EHR technical experts to develop the prototype CDSS with the ASK, ADVISE, ASSESS, and ASSIST prompts to facilitate caregiver tobacco screening and TSE counseling. The CDSS will use a software program (REDCap) that, due to being Web-based, has the capability to interface with an EHR system to trigger brief TSE counseling tips and direct links for registered nurses (RNs) to provide to caregivers. The CDSS template will contain all the necessary elements of text, graphics, and interactive features to ensure generalizability and disseminability. Aim 2: develop feedback reports from data extracted from the CDSS to show individual and overall RN compliance with the use of the tobacco screening and TSE counseling prompts. Aim 3: to refine CDSS functionality and improve feedback reports by conducting RN focus and user groups.

### **Phase II: Feasibility and Acceptability Trial of the Decision Support System**

Finally, Aim 4: to conduct a feasibility and acceptability trial of the CDSS and feedback reports. We will: (1) obtain a baseline assessment of RNs' attitudes, barriers, and tobacco-related screening, advising, and assisting behaviors, (2) train RNs on the use of the CDSS and evidence-based TSE counseling strategies and resources for on-going tobacco cessation treatment, (3) assess changes in RNs' attitudes, perceived barriers, and behaviors 1- and 3-months after training and obtain RN's satisfaction with the CDSS, (4) assess the smoking behavior and child TSE of a convenience sample of caregivers and children who are current smokers. We will assess changes in TSE-related outcomes of total home/car smoking bans (validated via salivary cotinine) and caregiver smoking behavior (validated by expired CO in those caregivers who report abstinence) in a 10% subset of participants, and (5) conduct exit focused interviews of nurses at 3 months post-training to obtain recommendations for refining and sustaining the CDSS over time.

The following hypothesis will be explored during Phase I and Phase II. Hypothesis 1: at follow-up, there will be an increase in self-reported TSE counseling behaviors and attitudes and decreases in perceived barriers toward TSE counseling by trained RNs. Hypothesis 2: over the 3-month observation period, there will be an increase in CDSS verified TSE counseling behaviors by trained RNs receiving feedback reports. Hypothesis 3: over the 3-month period, there will be lower child TSE and caregivers will report decreases in cigarette use, increased motivation to quit, and increased use of cessation resources compared with baseline.

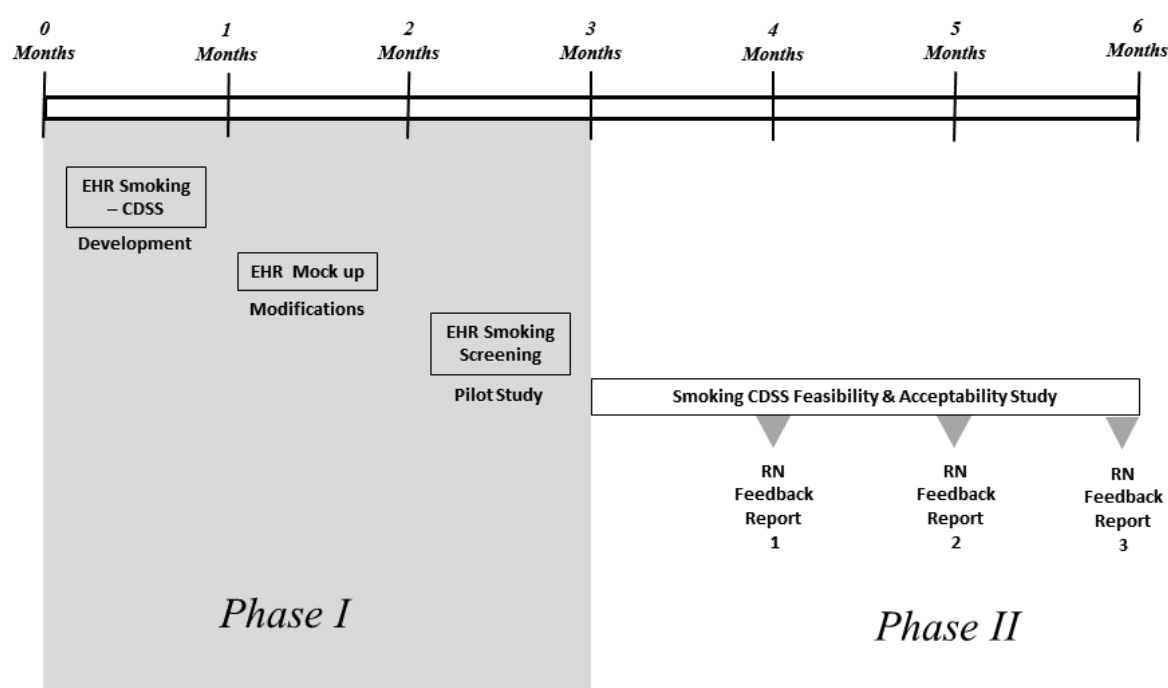

## Methods

### A Two-Phase Study

This study will be conducted in two phases. In Phase I, we will develop an alpha version of the CDSS with an advisory panel; the alpha version will be revised based on feedback from nurses in focused interviews and small focus groups; this refined version will be iteratively evaluated in a test environment. A portion of the alpha CDSS will be tested in the live environment

prior to launching the beta (prototype) full CDSS version. Additionally, we will create nurse feedback reports to encourage the use of the CDSS prompts. The feedback reports will be designed to illustrate how frequently the nurses perform the different tasks within the CDSS compared with other study nurses. In Phase II, we will test the feasibility and acceptability of the CDSS and the feedback reports with RNs working in the Urgent Care portion of the Cincinnati Children's Hospital Medical Center (CCHMC) PED. Please see [Figure 1](#). Descriptions of each phase are listed below.

**Figure 1.** Steps in the development and testing of the smoking Clinical Decision Support System.

### Phase I: Definition Phase and Iterative Usability and Validity Testing

This phase will be devoted to the development, programming, and integration of the CDSS prompts into the EHR and creation of nurse feedback reports. The prompts will facilitate nurse documentation and administration of the screening and TSE counseling components. After developing the CDSS and feedback reports based on input from a multidisciplinary advisory panel, we will conduct nurse-focused interviews, small focus groups, and small user groups to refine the CDSS and feedback report content and interface.

### Setting

CCHMC is the primary provider of inpatient, subspecialty, and emergency care in Greater Cincinnati and the surrounding counties serving over 2 million people. CCHMC is a 628-bed,

freestanding, academic, pediatric medical center with more than 1.2 million patient encounters annually and over 800 faculty members and 15,000 employees. It has over 30,000 admissions, 33,000 surgeries, 900,000 ambulatory encounters, and 125,000 emergency department visits per year. This study will occur in the Urgent Care portion of the PED at CCHMC. The PED is a 24/7 facility with five separate Urgent Care sites. The Urgent Care sites are open 7 days a week with varying hours that range from 3 PM to midnight during weekdays and 9 AM to midnight on the weekends. CCHMC uses an enterprise EHR system from Epic. The EHR has been in use since 2009.

### Participants

The participants will consist of an advisory panel and focused interviews and user groups. The advisory panel will include a multidisciplinary panel consisting of experts in tobacco cessation, biomedical informatics, PED nurse managers, clinical

PED nurses, PED physicians, EHR analysts, and PED flow experts. The focused interviews and user groups will include nurses who work at least once a month in the urgent care will be recruited and verbally consented. These RNs care for 10 to 40 patients during a 12-hour shift. We will obtain institutional review board approval for all study-related activities and consent procedures.

### Procedures for Data Collection and Analysis

The advisory panel will evaluate the current PED workflow and EHR. They will evaluate which providers input information and how data from past records are incorporated into new PED visits. This group will then develop the “ASK, ADVISE, ASSESS, and ASSIST” prompts that will be used to identify and counsel smokers and the group will assess how these prompts will affect patient flow and health care delivery to avoid any interruptions in care of the pediatric patient. The CDSS will use REDCap to trigger brief TSE counseling tips and direct links for RNs to provide to caregivers. The counseling steps will not be part of the child’s EHR.

We will conduct focused interviews and small focus groups with PED nurses. During the focus interviews/groups, nurses will be presented with paper copies of mock-ups of each of the prompts in the CDSS and they will provide input on each of the prompts and on the interface with the CDSS in the EHR and with REDCap. They will provide input to make iterative changes. Nurses will be asked structured questions on the content, appearance, design, and format of the prompts and feedback reports and will provide input on the functionality, use, and adaptation of the prompts into their clinical workflow.

After iterative changes have been made based on the feedback provided by the nurses in the focused interviews/groups, we will user-test the CDSS in a test environment to allow nurses to access the CDSS to assess usability. Staff will perform usability testing of the additions to the EHR using observational and “think-aloud” procedures. Nurses will be observed interacting with the CDSS and will be asked to complete a brief survey upon completion of the suggested tasks; any problems will be noted. Notes will be reviewed and the survey will be completed by nurses to determine which independent thematic aspects will be organized around the CDSS and prompts to assess the following: functionality, content, number of “clicks,” length, appearance, format, and type, ease of use, time to use, linkage from Epic to REDCap, linkage to cessation materials, linkage to the SmokefreeGOV website, SmokefreeTXT, integration with regular PED and Urgent Care workflow, technical support and training required, perception of maintenance of use and sustainability, and acceptability of feedback reports. This data will be used to iteratively refine the CDSS and feedback reports for use in Phase II. We will perform an iterative design process. All data will be analyzed, integrated, and used to refine the prompts with components from the CPGs and prior efficacious TSE and cessation interventions [10,13,16,37-39]. Following these analyses, we will develop a list of design changes that will be incorporated into the revised CDSS by the Epic team and used in the next round of usability testing.

## Programming of the CDSS and Creation of Feedback Reports

### Electronic Health Record Design

The EHR data collection section will fit into the current nursing workflow. The smoking cessation parent and caregiver screening and counseling will be integrated into the existing EHR. This integration will include coding within the EHR and adherence to the existing workflow. This integration will require a link to an external system (REDCap) to complete screening. We will include an external database to collect data because the cessation screening data is directly related to the parents and caregivers (who are not our patients), and therefore is not appropriate to be stored in the child’s EHR. All code is contained and adheres to the CCHMC customization of the Epic EHR.

Adhering to constraints of the EHR, we will integrate cessation screening questions with branching logic to streamline the collection of demographic smoking status data for caregivers. If any caregiver screens positive for smoking, we will launch an alert requesting the nurse provide cessation counseling. The nurse will be able to close the alert and select an appropriate refusal reason if necessary, click a link that goes directly to a REDCap survey, or create a nursing order as a reminder to perform cessation screening at a time that is more convenient. This order will include a link to the REDCap database.

### Research Electronic Data Capture Design

The REDCap database will be developed based on advisory panel recommendations for the ASK, ADVISE, ASSESS, and ASSIST steps. Patient medical record number will be used to link parent responses with the patient chart. We will use branching logic to display a minimum survey if the caregivers answer “No” to cessation information. The survey results will be used to drive the nursing feedback reports.

### Feedback Report Design

The nursing feedback reports will be based on the proportion of patients seen during the prior month’s shifts to account for differences in nursing workloads. Feedback reports will display the number of patient caregivers screened (EHR documentation complete in the “ASK” step) compared with the number of patients that the nurse treated that month. For the caregivers screened as positive, REDCap data will be aligned to calculate the proportion of patients who had the ADVISE, ASSESS, and ASSIST steps completed. These data will be presented graphically to the participating nursing staff monthly through a study email account. Nurses will only have their specific results compared with an aggregate average.

## CDSS Screening and Counseling Prompts and Feedback Reports

### Screening, or ASK Prompt

The caregiver’s current smoking status will be assessed within the EHR, as screening will be integrated into the existing PED workflow during the routine medical intake process by the nurse. The new field will read “Do any of the primary caregivers smoke inside or outside of the home?” If the caregiver answers “Yes,” then a series of question will assess the number of caregivers

who smoke, the relationship of the caregivers to the patient, and then finally, if that caregiver smokes “every day” or “some days”. The appropriate smoking status will be selected and recorded within the EHR. If more than one caregiver is present and verified as primary caregivers, both will be screened. If a caregiver has a repeat visit, the prior screening information will be available from the last visit. Completion of the screening prompt will be optional but strongly encouraged for the nurse to proceed further in the patient’s EHR documentation.

Once these questions are completed and one or more caregivers are identified as current smokers, a Best Practice Advisory, pop-up alert window opens up that recommends that smoking cessation counseling be given and asks if the nurse would like to provide counseling. Nurses may select check boxes to counsel now, counsel later (in which case orders will be generated), or to decline counseling for reasons such as patient acuity, time constraints, non-English speaking caregivers, and so on. The completion of the counseling prompts will not be mandatory so that the nurse can use their clinical judgment to opt out as necessary.

#### *Counseling Prompts – Overview*

When a caregiver(s) is identified as being a current smoker, the coded results from this electronic question will be used to generate counseling prompts and reminders of the stepwise series of the CPGs. To make these prompts and reminders appear less burdensome, we will consolidate the key counseling elements of the CPGs into three steps: ADVISE to quit, ASSESS readiness to quit, and ASSIST in cessation attempt. Our approach is similar to “Ask, Advise, Refer,” which has been used successfully in other settings [40].

#### *ADVISE Prompt*

The ADVISE prompt will assist nurses to provide information on how quitting will benefit their child. Nurses will be given training on additional advice that they can give such as: implementing complete home/car smoking bans and quitting smoking; asking caregivers about the perceived impact of smoking on their child’s health, barriers to implementing smoking bans and/or quitting, and perceived health/lifestyle benefits associated with bans/quitting for their child and themselves; and setting goals for reducing TSE/quitting [41,42].

#### *ASSESS Prompt*

The ASSESS prompt will cue the nurse to ask if the caregiver is ready to quit smoking in the next 30 days. Caregivers who respond that they are not ready will be told “I understand that you’re not ready to quit now” and offered an information packet for when they are ready to quit. Those who respond that they are ready or may be ready to quit will be offered assistance by the nurse.

#### *ASSIST Prompt*

When the ASSIST prompt is selected, a set of options with branched logic will appear. Nurses will be cued to ask “May I tell you about three options?” The nurses will then be prompted to provide information about one or more of the following options: the QL: Nurses will give information about the services that the QL provides and offered a fax referral to the QL [43];

SmokeyfreeGOV website: nurses will give information about the services that SmokefreeGOV provides and they may log directly onto SmokefreeGOV from REDCap using the computer in the patient’s PED room; smokefreeTXT: nurses will give information about the services that SmokefreeTXT provides and they may log directly onto the SmokefreeTXT site from REDCap where they can fill in the caregiver’s information to sign him/her up for text messages. Finally, caregivers will be offered a packet of written materials [40,44], with information about the effects of smoke exposure on children, the benefits of quitting on their child’s health, how to implement smokefree bans, information on quitting, and information on the QL, the SmokefreeGOV website, and SmokefreeTXT.

#### *Feedback Reports*

The use of the CDSS prompts will be further encouraged via feedback reports. Confidential, individualized reports will be provided monthly to each study nurse, similar to the work by Bentz et al [17]. For each nurse, we will compute adherence to each of the intervention behaviors (eg, ADVISE, ASSESS, ASSIST) and present these monthly in a feedback report. Each nurse’s feedback report will include a comparison of individual performance to the overall performance average of all of the study RNs [17,45]. Only the study team will have access to the reports, and each nurse will have access only to their report. The study team will introduce the nurses to their first feedback report. Subsequent reports will be delivered monthly (3 total) to each nurse via their personal email; feedback reports will not be used to judge clinical performance.

#### **Screening Pilot Phase**

We will conduct a pilot phase for a period of 2 months in which the nurses will use only the screening questions in the EHR. These will include some or all of the items that ask if any of the primary caregivers smoke, the number of caregivers that smoke, the relationship of the caregivers who smoke to the patient (eg, mother, father, grandmother), and whether those caregivers smoke every day or some days. We will assess the use of these prompts (eg, how often the prompt is used, how many caregivers who smoke are identified) by nurses, and we will email and ask nurses if they experienced any issues or problems while using the screening prompts and/or have any questions.

#### **Phase II: Feasibility and Acceptability Trial of the Decision Support System**

In Phase II, we will conduct a feasibility trial of the CDSS. They will be assessed at baseline, 1 and 3 months after training. The baseline assessment will consist of self-report assessments of TSE counseling behaviors, attitudes, and perceived barriers. In addition, we will enroll a convenience sample of caregivers and their children and assess caregivers’ smoking behavior and child TSE. We will conduct exit focused interviews with nurses to obtain recommendations on improving the CDSS and perceived barriers to sustainability.

#### **Setting**

##### *Nurses, Caregivers, and Children*

Nurses who work at least once a month in the Urgent Care will be recruited and written informed consent will be obtained for

participation in the feasibility trial. The clinical research coordinator (CRC) will recruit a convenience sample of 150 caregivers who present to the Urgent Care, are screened, and identified as a smoker who smokes “everyday” or “some days.” The CRC will approach them to obtain informed consent to the collection of baseline and follow-up data about their smoking behavior and their child’s TSE. We will validate child TSE on a racial/ethnically representative sample of children under age 6 at baseline and 3 months, as these children are more likely to be exposed to smoke [1-4].

### Procedures for Feasibility Trial

We will conduct a feasibility and acceptability trial of the CDSS and feedback reports. We will (1) obtain a baseline assessment of nurses’ attitudes, barriers, and tobacco-related screening, advising, and assisting behaviors, (2) train nurses on the use of the CDSS and evidence-based TSE counseling strategies and resources for on-going tobacco cessation treatment, (3) assess changes in attitudes, perceived barriers, and behaviors 1 and 3 months after training and obtain nurses’ satisfaction with the CDSS, (4) assess the smoking behavior and child TSE of a convenience sample of caregivers and children who are current smokers. We will assess changes in TSE-related outcomes of total home/car smoking bans (validated via salivary cotinine) and caregiver smoking behavior (validated by expired CO in those caregivers who report abstinence) in a 10% subset of participants, and (5) conduct exit focused interviews of nurses at 3 months post-training to obtain recommendations for refining and sustaining the CDSS over time.

Our hypotheses are that at 3-month follow-up, there will be an increase in self-reported TSE counseling behaviors and attitudes and decreases in perceived barriers toward TSE counseling by trained RNs and that over the 3-month observation period, there will be an increase in CDSS verified TSE counseling behaviors by trained nurses receiving feedback reports. We also hypothesize that over the 3-month period, there will be lower child TSE and caregivers will report decreases in cigarette use, increased motivation to quit, and increased use of cessation resources compared with baseline.

### Training for Participating Nurses

Prior to the launch of the CDSS in Epic and the start of the feasibility trial, nurses must complete a 20-minute Web-based audiovisual training created by the study investigators. The training will provide an introduction on the importance and effectiveness of TSE counseling and tobacco dependence treatment, and instruction in the use of the CDSS, including: completion of the prompts, delivery of brief TSE and smoking cessation counseling, and how to provide connection with the QL, the SmokefreeGOV website, or SmokefreeTXT during the PED visit [46,47]. During and after the training period, study staff will be available to answer any questions and provide help as needed.

### Baseline Assessments

#### *Nurses*

Prior to training, nurses will complete a baseline self-reported assessment to determine their TSE behaviors and attitudes, perception of barriers that inhibit regular intervention with

caregivers, and their self-efficacy in intervening with caregivers who smoke. Using principal components analysis, we have developed scales to measure barriers, confidence, and self-efficacy in providing the ASK, ADVISE, ASSESS, and ASSIST behaviors [48,49]. The CRC will conduct an EHR review on a random sample of patients cared for by the Phase II study nurses over the 1-month period prior to training to assess the TSE-reduction behaviors of nurses.

#### *Caregivers and Their Children*

We will assess and define the smoking status of all caregivers (eg, current every day smoker, current some day smoker) using the CDSS prompts. The data from the nurses’ counseling prompts (eg, ADVISE and ASSIST) will be summarized.

We will collect detailed in-person smoking behavior data (eg, nicotine dependence, number of cigarettes smoked daily, motivation to quit) on a convenience sample of 150 caregivers and detailed TSE data (eg, number of smokers in the home; presence of smoking bans in the home or car) on their children. We will conduct cotinine analyses of child saliva samples collected on a sample of children at baseline to validate child TSE [2-4].

### Follow-up Assessments

#### *Self-Report by Nurses*

Nurses will be reassessed by self-report at 1 and 3 months after training to evaluate change in practice behaviors, attitudes, barriers, and self-efficacy in intervening with caregivers and providing screening and TSE counseling, and maintenance of the intervention components. We will use the same scales as used at baseline to measure their intervention-related barriers, confidence, and self-efficacy.

#### *Exit Focused Interviews*

After the 3-month assessment, the study team will conduct exit focused interviews in which nurses will be asked for suggestions on how to improve the CDSS and they will be asked to identify factors and barriers that they perceive will be associated with the sustainability of the CDSS components into real-world practice. Data will be analyzed and results and recommendations incorporated into the design of a future, large R01 trial.

#### *EHR Review of Patients*

During the entire 3-month period of the pilot trial, the CRC will conduct daily EHR reviews for each patient cared for by the nurses whose caregiver screened positive for current smoking. The review will assess sociodemographics, chief complaint, and discharge diagnosis. The CRC will assess the nurses’ compliance with the TSE components: Ask about smoking, Advise to quit, Assess readiness to quit, Assist in quitting, and delivery of written materials.

#### *Caregiver Cessation and Child TSE*

Smoking behavior and cessation outcomes will be assessed by self-report at 3-months on the convenience sample of 150 caregivers that were assessed at baseline; child TSE will be validated with salivary cotinine on the 10% subsample via in-person visits at 3-months. Outcomes will include nicotine dependence; readiness to change; quit attempts  $\geq 24$  hours;

nicotine replacement therapy or use of cessation resources, abstinence; and child TSE. Abstinence in caregivers will be verified via expired carbon monoxide testing during in-person visits.

## Analytic Plan

### *Preliminary Data Analyses*

Prior to the primary analyses, we will generate descriptive statistics for all variables (eg, means, medians, standard deviations, ranges, skewness) and we will examine potential outliers and patterns of missing data. To assess potential enrollment bias of nurses and/or caregivers, we will compare demographics of those enrolled versus those not enrolled; differences will be assessed according to variable type, chi-square test/Fisher's exact test for categorical variables or *t*-tests/Wilcoxon-Mann Whitney tests for continuous variables. Attrition analyses will be done to assess if those nurses without complete follow-up differ from those retained. If key independent variables significantly predict attrition, we will conduct the analysis with and without drop-outs. Primary outcomes will be compared using complete case analysis and intention to treat, assuming drop-outs are like those who do not comply with the TSE counseling behaviors.

### *Analysis of Focused Interview and User Group Data in Phase I*

We will develop and integrate the CDSS into the EHR using qualitative data from the advisory panel and focused interview and user group data. We will present the prototype CDSS with the ASK, ADVISE, and ASSIST prompts to the advisory panel and ask for their views on use of the CDSS interface with the child's EHR. This CDSS will be iteratively edited based on expert advice. We will create the feedback reports and nurse recommendations, which will be based on user group input. Detailed notes will be obtained, typed, and evaluated to determine which independent thematic aspects will be organized around the CDSS and prompts to assess: functionality, content, number of clicks, length, appearance, format, and type, ease of use, time to use, linkage from the EHR to REDCap, linkage to cessation materials, linkage to the SmokefreeGOV website, linkage to SmokefreeTXT, integration with regular PED and Urgent Care workflows, technical support and training required, perception of maintenance of use and sustainability, and acceptability of feedback reports. This data will be used to iteratively refine the CDSS and reports for use in Phase II. Additionally, exit focused interviews at 3 months will be used to obtain nurses' views on the factors, barriers, suggestions, and recommendations on improving the CDSS. Data will be synthesized and used in future trials.

### *Analysis of Data from Feasibility Trial*

To assess if there are increased self-reported TSE counseling behaviors (primary outcomes), improved attitudes and decreased barriers toward counseling (secondary outcomes) by study nurses, we will use the self-assessment at baseline, 1, and 3 months and examine changes in reported and EHR-verified behaviors, and changes in attitudes and barriers at baseline and each follow-up point. The first approach will be the intention to treat analysis; a generalized linear mixed-model will be used

to allow use of the appropriate link function and examination of change over time. Second, incorporation of generalized estimating equations will allow for missing data, and then addition of any potential covariates.

To assess if there are increased CDSS-based TSE counseling behaviors by nurses receiving feedback reports, we will conduct an EHR review of 100% of the patients cared for by study nurses during the 3 months of the feasibility trial. We will compute descriptive statistics of compliance with the prompts. Options selected under these prompts will include: Ask about smoking, Advise to quit, Assess readiness to quit, and Assist in TSE reduction and quit attempt advice (QL fax, SmokefreeGOV website, SmokefreeTXT, and delivery of written materials). For each nurse, we will compute the percentage of the tobacco cessation intervention behaviors addressed (eg, Advise, Assess, Assist) and obtain descriptive statistics. We will assess if there are trends in the association of nurse protocol to child sociodemographics, chief complaint, or discharge diagnosis. As above, we will employ the generalized linear mixed-modeling to account for the nesting of caregivers within nurses and look at changes over time, adding the potential time-dependent covariates into the model.

Finally, we will assess if there is lower TSE in children and if caregivers will report decreased cigarette use, increased motivation to quit, and increased use of cessation resources at 3 months compared with baseline. Participant characteristics at baseline and 3 months will be summarized using descriptive statistics. Pairwise (within subjects) *t*-tests or McNemar's test or Cochran's Q test, as appropriate, will be conducted to examine differences in child TSE and caregiver smoking behavior and motivation to quit at baseline compared with 3 months.

## Results

This study is ongoing. We are currently in the data collection and analysis stage of Phase II. This study may inform future research among pediatric urgent care or emergency department nurses and other providers working with adult caregivers who use tobacco. The results will provide evidence as to whether brief tobacco screening and tobacco cessation counseling prompts are feasible, acceptable, and easily incorporated into the workflow of urgent care nurses.

## Discussion

This is the first study to develop a CDSS, integrate it with a widely-used EHR (Epic), and test its use to facilitate tobacco screening and TSE counseling of adult smokers in the PED setting. The CDSS will use a system of prompts and templates that can be implemented in all emergency settings regardless of the EHR type. We will ensure that the CDSS is reproducible, generalizable, and disseminable by carefully choosing an EHR platform and research template which allows for the creation, sharing and modification of prompt templates regardless of setting (pediatric or adult). Thus, if effective, this type of CDSS and systems-based strategy can be widely disseminated and incorporated into other emergency settings.

By incorporating tobacco screening and treatment into an existing clinical EHR system and providing prompts and feedback on the delivery of TSE and tobacco treatment, we will maximize the probability of creating a sustainable, disseminable model for use in the PED setting. If successful, this research

has a high likelihood of translation into other emergency settings and sustainability over time. This proposed approach has the potential to reach over 12 million smokers a year and significantly reduce TSE-related pediatric illness and related costs.

## Abstract

**Background:** Previous research has shown that reducing physical workload among workers in the construction industry is complicated. In order to address this issue, we developed a process evaluation in a formative mixed-methods design, drawing on existing knowledge of the potential barriers for implementation.

**Objective:** We present the design of a mixed-methods process evaluation of the organizational, social, and subjective practices that play roles in the intervention study, integrating technical measurements to detect excessive physical exertion measured with electromyography and accelerometers, video documentation of working tasks, and a 3-phased workshop program.

**Methods:** The evaluation is designed in an adapted process evaluation framework, addressing *recruitment*, *reach*, *fidelity*, *satisfaction*, *intervention delivery*, *intervention received*, and *context* of the intervention companies. Observational studies, interviews, and questionnaires among 80 construction workers organized in 20 work gangs, as well as health and safety staff, contribute to the creation of knowledge about these phenomena.

**Results:** At the time of publication, the process of participant recruitment is underway.

**Conclusions:** Intervention studies are challenging to conduct and evaluate in the construction industry, often because of narrow time frames and ever-changing contexts. The mixed-methods design presents opportunities for obtaining detailed knowledge of the practices intra-acting with the intervention, while offering the opportunity to customize parts of the intervention.

## KEYWORDS

musculoskeletal disorders; process evaluation; intervention study; mixed-methods study; social science; physical exposure; masculinity; construction work

## Introduction

Musculoskeletal disorders are a major economic, social, and health challenge in the construction industry, as well as in other occupations characterized by high levels of physical exertion at work [1,2]. Physical exertion and strenuous work tasks such

as heavy lifting, pushing, dragging, and working in awkward positions are known to increase the risk of developing musculoskeletal pain [3]. Considering that most of these risk factors are a natural part of the everyday practices in construction work, it is surprising that only a few interventions are aimed at reducing the physical exposure associated with

construction work. Furthermore, studies of these interventions have reported very low degrees of measurable success [4,5]. In general, interventions targeting the prevention of musculoskeletal disorders have shown very limited effect, or the evidence has been characterized as being of low quality [6-8], except for a few studies focusing on increasing individual workers' physical capacity and thereby their resilience against physical exposure at work [6,9-11].

As a consequence of this limited success in preventing musculoskeletal disorders in the working population in general, and for construction workers in particular, evaluators and researchers have called for more multidisciplinary-anchored interventions [4,6,8]. Furthermore, to achieve a successful intervention and for sustaining organizational change and engagement, several sources point out that the inclusion of relevant parties (ie, health and safety professionals, workers, and management) is pivotal [12-15].

In response to this, we have tailored an intervention that engages workers and management, and integrates the use of technical quantitative measurements of excessive physical workload measured with electromyography and accelerometers, video documentation of working tasks, and a 3-phased workshop program. Whereas Brandt et al [16] described the protocol for the technical physical measurements and quantitative survey on physical exertion and pain, this study protocol describes the mixed-methods process evaluation of social, subjective, and organizational processes that play important roles in the outcome of the intervention project.

Research shows that reducing physical exertion in construction work is a complex issue [15,17]. As Nielsen et al [18] emphasized, evaluations of organizational research must be contextually grounded. To ensure that we obtain the best possible knowledge from our intervention, we must carefully tailor the process evaluation to identify the agential roles of the various agencies intra-acting with rationalities at work—with, in, and between workers, in the physical characteristics of construction workers and work, and in the organizational practices of companies where the interventions are implemented.

Construction work is a broad category that encompasses many different trades composed of different tasks, skillsets, and cultural norms. However, physically exerting work is a common denominator. Across carpentry, bricklaying, concrete work, scaffolding, plumbing, etc, the entangled body and subjectivity of the worker is a main resource of production, a point that takes a line of arguments to unfold. However, it is highly important for understanding the social framing of the intervention context.

The necessity of undertaking tasks in a physically exerting manner is embedded in the organization of work, where planned availability and usage of technical assistive devices play important roles. Technical assistive devices have the potential to substantially decrease physical exertion at work, but numerous political, organizational, and subjective agencies challenge the development, proliferation, and usage of such technical assistive devices [19-21]. Thus, interventions addressing the increased use of assistive devices should carefully consider this context in the process evaluation.

One of these agencies lies in the material and organizational orchestration of work that takes place at geographically delimited sites for a certain amount of time, after which, on project completion, the whole organization breaks up to be reconfigured at new worksites. Here the tasks involve many of the same skills but are usually still markedly different, and pose new and different flows of processes, still containing physically exerting work tasks. For this reason, planning of construction sites is a complicated matter, in which the usage of technical assistive devices is sometimes not thoroughly considered. This means that adequate measures for reducing physical exertion may not always be present in the construction process. Without a rigorous process evaluation, important opportunities and barriers in this regard could easily be missed.

At a political and societal level, the competition among entrepreneurs to secure projects has been described as a barrier for implementing initiatives prioritizing health and safety [20,22]. In previous studies, entrepreneurs described how health and safety measures are often the target of budget cuts. When bids are produced, time pressure as a result of tight planning schedules is also very likely to affect all phases of production, leading to a faster work pace among workers [22]. This may also reduce the incentive for investment in technical assistive devices, particularly in companies where profit margins are relatively narrow. Consequently, process evaluations of interventions should also consider time pressure and budget constraints.

Furthermore, many construction projects are completed on some form of performance-based payment (eg, piece rate), which provides the worker with an economic incentive for working faster with less variation, and not using technical assistive devices unless they directly increase production [22-24]. This can play an important role in relation to the effectiveness of our intervention. Part of the process evaluation should therefore also evaluate incentives for increased bodily strain in the above-mentioned forms. The options for working for performance-based wages are guaranteed in agreements between unions and employers' associations, and are therefore tied to political decision-making processes.

In previous studies, communication between the managerial staff and workers has been suggested as a potential barrier to improving health and safety at the workplace [12,25]. Even though there is a dedicated health and safety organization at every major Danish construction site, the workers' representatives report being ignored by management, and the management report that workers display a lack of interest in both health and safety, and the organizational need for cooperation to obtain smooth production [26]. This may potentially affect experiences of physical exertion and pain among workers, as higher levels of worker influence on health and safety has been linked to lower levels of exertion and pain [27]. This, at times, negative relationship may obstruct implementing and anchoring the intervention within the organization, and is an issue that demands special attention from researchers conducting the intervention to avoid being seen as either employees' or management's allies. Thus, evaluation of communication at the workplace is also an important part of the process evaluation.

In addition, many construction workers embody and socially transmit traditional masculine working-class qualities [28,29], such as endurance, strength, self-reliance, pain habituation, and breadwinning, as positive identity characteristics [20]. Being able to display and participate in discursive-material practices, reconfiguring the worker in accordance with these qualities, in many cases functions as a parameter for maintaining social position in the work gang and a job within the company. Not participating in these traditional masculine working-class practices may be costly to the worker, as sickness absence is frowned upon and employment can be terminated with only 1 day's notice unless the worker has been employed by the company for more than 1 year [22]. As such, the need to participate in these practices can increase physical exertion and may, furthermore, complicate intervention, as taking care of the individual worker's body is likely a low priority for both colleagues and the company. Thus, the process evaluation should also evaluate how worker identity plays into the intervention.

In our evaluation, all these agencies and their entangled roles are points of attention, as we aim to understand the facilitators and barriers to reducing physical exertion. The purpose of the process evaluation is to investigate how the intervention intra-acts with both the worker's body and subjectivity, as well as social and organizational relations acting as facilitators and barriers to reducing physical exertion. An additional aim is to perform analyses using the mixed-methods design to evaluate potential consequences of the intervention in terms of productivity, sickness absence, and time frames.

## Methods

### The Intervention

The intervention is taking place in a design containing several phases as thoroughly described by Brandt et al [16].

In the first phase of the intervention, 20 construction gangs (N=80 workers) will be randomly assigned at a cluster level to a participatory intervention group or a control group. We will record in situ physical workload during a working day using technical measurements (electromyography, accelerometers,

and video recordings) before and after the intervention. Based on these measurements, a physical load matrix for each worker will be developed. This matrix is based on outcomes obtained from the analyses of the simultaneously recorded electromyograms and accelerometer data.

The second phase is designed as a participatory process consisting of 3 workshops: 1) workshop I at baseline, involving presentation of video clips of the work tasks with excessive physical load customized for each gang, followed by a participatory development of solutions on how to reduce excessive workloads, leading to the development of an action plan on how to implement these solutions at the workplace, 2) workshop II, where the implemented solutions will be further developed and qualitatively evaluated during group discussion, 3) workshop III at follow-up to enhance long-term organizational sustainability of the implemented solutions. All workshops will aim to include researchers, workers, occupational health and safety (OHS) staff at the companies, and a management representative as participants. We will facilitate the elaboration of solutions aimed at lowering the physical exertion related to the participants' suggestions. The control groups are not targeted in the evaluation study and are therefore not addressed in this protocol.

### Evaluation Design

The evaluation is designed in a mixed-methods framework to address different aspects of the intervention, which has been recommended by several sources on evaluation research [30,31]. To assure that our evaluation addresses key pieces of information about the interventions, we draw upon an adapted version of the framework presented by Saunders et al for process evaluation in public health interventions [32-34]. More specifically, using this framework means addressing *recruitment, reach, fidelity, satisfaction, intervention delivery, intervention received, and context* [34]. Because previous studies have used these terms differently, we define their specific use in the present study below. [Figure 1](#) shows the timeline for the intervention project and process evaluation. [Textbox 1](#) shows the description of evaluation components.

**Textbox 1.** Process evaluation components and description of their elements.

## Recruitment

- Number of companies asked to participate
- Number of companies agreeing to participate
- Number of gangs participating (intervention and control groups)
- Number of workers participating (intervention and control groups)
- Number of workers responding to questionnaires
- Number of workers asked to participate in interviews
- Number of workers participating in interviews
- Number of occupational health and safety (OHS) staff asked to participate in interviews
- Number of OHS staff participating in interviews

## Reach

- Number of technical measurements completed
- Number of workshops completed

## Fidelity

- The extent to which the workshop program was completed in accordance with intentions

## Satisfaction

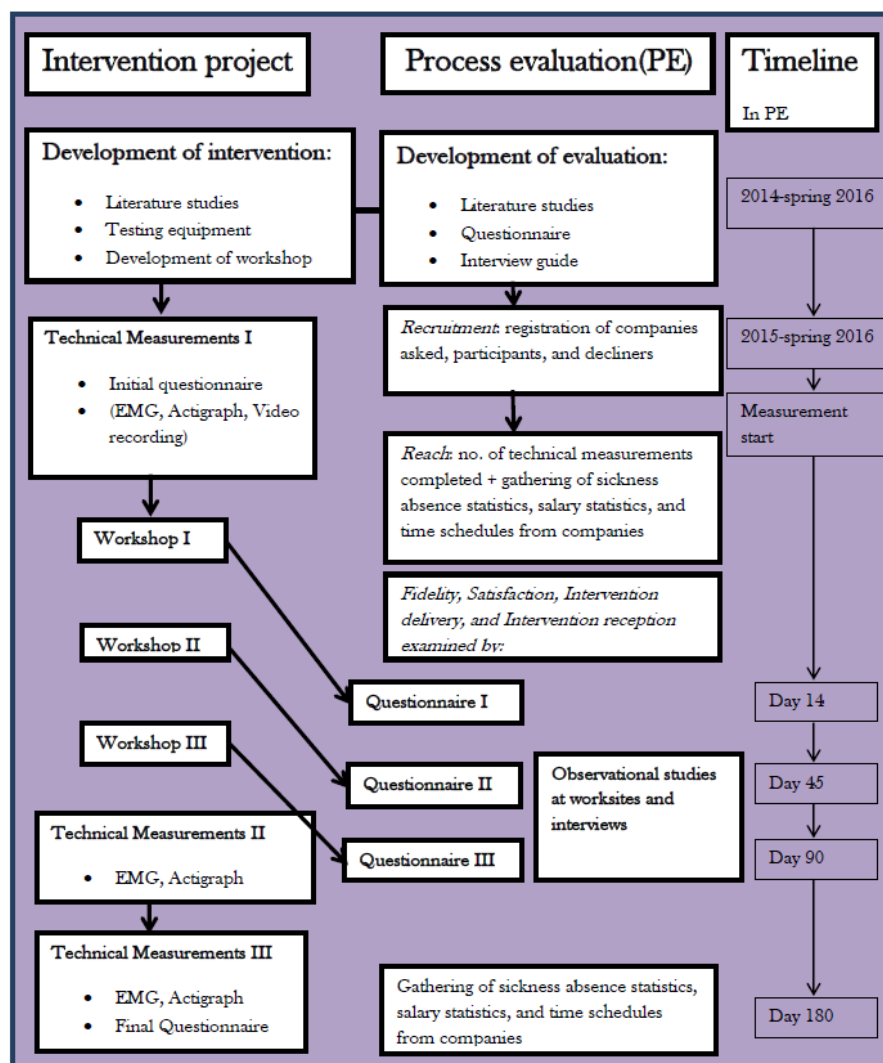

- Workers' and OHS staff's satisfaction with prioritized risk factors, the competencies of workshop facilitators, and the time for workshops
- Workers' and OHS staff's satisfaction with the method of the workshops
- Workers' and OHS staff's satisfaction with the implementation of measures for improving ergonomic work environment

## Intervention delivery

- Perceived intervention implementation according to researchers
- Intervention reception
- Perceived intervention implementation according to workers and OHS staff

**Figure 1.** Process evaluation activities and timeline for a participatory intervention to reduce physical risk factors in construction work. EMG: electromyography.

### Recruitment

In our evaluation, recruitment is defined by several parameters: 1) the number of companies asked to participate, and 2) the number of companies agreeing to participate. We will also record 3) the number of work gangs randomly assigned to the intervention and control groups, as well as how many of these completed the study, 4) the number of workers and OHS staff asked to participate in the intervention at each participating company, to answer questionnaires and to participate in interviews, and 5) the number of workers and OHS staff agreeing to participate in the study, to answer questionnaires and to participate in interviews.

### Reach

Reach can be defined as the proportion of the intended recruited participants who actually received the intervention, as defined by Saunders et al [34]. In our study, the reach of the intervention is defined as the number of technical measurements and workshops completed in each gang of the project in total. We will list the number of workshops that we deliver and will note the reasons for cancellation. We will also list the number of participants volunteering to take part in technical quantitative

measurements and workshops, will note the reasons for individual absence.

### Fidelity and Satisfaction

After each workshop, we will ask all participants to complete a questionnaire addressing workers' and OHS staff's perceptions of the workshop. Fidelity will be addressed in 2 ways. First, we will ask workers to rate each workshop phase on a 5-point scale (very bad, bad, neutral, good, very good). Second, we will record all activities of the workshops to assess whether they were completed in accordance with the planned activities.

Likewise, we will assess satisfaction based on the workers' and OHS staff's satisfaction with 1) prioritized risk factors, 2) the competencies of workshop facilitators, 3) the time frames for the workshops, 4) the structure of the workshops, and 5) the implementation of solutions for lowering physical exertion and improving the work environment. All of these parameters will be rated on 5-point scales (very unsatisfied, unsatisfied, neutral, satisfied, very satisfied). Through qualitative interviews in selected cases, we will gain further knowledge of workers' and OHS staff's satisfaction with and knowledge of particularly well-functioning or dysfunctional elements of the intervention. This will allow us to use the evaluation in a formative manner,

adjusting the intervention for better implementation, as previously suggested [35,36].

### **Intervention Delivery**

What we term *intervention*, *delivery*, and *reception* is based on the definition by Saunders et al [34], originally termed *dose delivered*. Referring to a complex organizational and ergonomic intervention as a dose does, however, in our opinion, risk confusing the intervention with a medical injection, which would be misleading because the intervention is a framework for developing preventive solutions that intra-acts *with* other agencies in work and organizations. The intervention should not be seen as something we inject into the organization with determinate effects.

Immediately after completing each day of technical measurements and each workshop, the facilitating researchers will have an evaluative meeting. Minutes of the meeting will be produced to evaluate the success of the activities. Furthermore, we will conduct observational studies at the worksites during 2–5 workdays between workshops I and III in order to assess whether solutions on how to reduce excessive workloads were actually used during work. We also record the number of visits and observations during these visits.

### **Intervention Received**

After each workshop, we will evaluate the intervention received by using questionnaires. We will ask each of the workers and OHS staff to assess whether the decided measures have been implemented and integrated as part of work. This will be answered on a 5-point scale (very low degree, low degree, moderate degree, high degree, very high degree). More precise descriptions of the measures that were actually implemented will be explored through interviews with participants.

### **Context**

We will investigate the intervention context through interviews with workers and OHS staff to explore their positioning in relation to different agencies intra-acting with the intervention. To address the subjective, social, and organizational practices intra-acting with the implementation of the project, we have designed an in-depth qualitative study consisting of observations, interviews, and document analysis. The qualitative design focused on a limited number of intervention cases offering insights on productivity, sickness absence, and time frames, as well as how the intervention intra-acts with worker identity and meaning in work as initially described.

For the qualitative study we will select 4 work gangs based on a *critical case* argumentation for validity and generalization from case study research. Our aim is to select 2 cases (gangs) in which the implementation seems to be particularly successful, and 2 cases in which the intervention seems to meet resistance or other barriers. By selecting “best” and “worst” cases, we have the opportunity of making generalizations of the type “if the implementation meets X as a barrier/facilitator in this case, it will be likely/unlikely to work better/worse in other cases” [37].

### **Initial and Final Questionnaires**

We will distribute the survey questionnaires to the workers of both the intervention and control groups at the time of the initial technical measurements and again after the intervention period. The questionnaire will contain questions addressing the physical work environment and several risk factors of particular relevance to work in the construction industry drawn from previous research [3,22,38]. Of particular interest are questions related to the worker’s capacity for taking care of the body in work, their physical exertion, managerial support for improving health and safety at work, the worker’s influence on health and safety, and the availability and usage of technical assistive devices.

### **Questionnaires I, II, and III**

These questionnaires will be handed out to participants of the intervention group directly after each workshop and will address fidelity, satisfaction, and the intervention delivered.

### **Interviews**

We will conduct interviews with the intervention group and address the workers’ and OHS staff’s satisfaction and context. As described for *context* above, we will select cases for interviews through a critical case definition, as discussed by Flyvbjerg [37]. Based on this, we will select cases in which the intervention seems to be working particularly well, and cases where the intervention meets particular complications (best and worst cases). From this selection strategy, we will be able to make generalizations of the sort “if this is (not) valid for this case, then it applies to all (no) cases” (p. 230 in [37]). The interviews are aimed at producing knowledge about how the participants make sense of the intervention. To gain in-depth insight into the practices taking place in relation to the implementation, we will interview workers, health and safety professionals, and managers engaged with the project in each of the 4 cases. We will design and conduct the interviews in a semistructured interview format, where most questions will be posed rather openly and important themes will be explored through follow-up questions, asking the participants to discuss and elaborate their answers. To facilitate discussion and positioning statements among workers, we chose to implement a focus group interview structure, because group negotiations of what is going on at the workplace are an important source of information in the analysis of the scope for changing or developing the working environment. This can be challenging with regard to managers and OHS staff, as these groups are often singularly represented on site, but we will carry out focus groups where possible. If this proves impossible, we will conduct interviews with managers and OHS staff individually.

We will conduct the interviews between workshops II and III to ensure that the participants have the intervention fresh in their memories, while also having some experience of the action taking place during the intervention.

All interviews will be transcribed and imported to NVivo (QSR International Pty Ltd) for coding and to facilitate the analysis. The interview analysis will draw on a view of lingual productions as positioning in discursive-material practice in an analytical framework composed on the thoughts of Davies and Harré [39] and Barad [40]. Positioning theory in an agential

realist framework is a theory conceptualizing the ways in which people (re)configure subjectivities through lingual and physical engagement with other people and the materialities of the world, including work. This approach will allow us to analyze how participants draw on elements of work and the body, as well as social and organizational practices, to describe and rationalize their experiences of the intervention.

Observations

Observations will be conducted in 2 forms and particularly address the delivery of the intervention as well as the context. First, we will video record all workshops in the project to permit analysis of the processes taking place during the workshops. This analysis will illustrate the communication concerning lowering physical exertion through the intervention. In particular, we are interested in how participants use the technology and what solutions are reachable in the interplay between workers, health and safety professionals, and management. We will also analyze this observational material through positioning theory [39] in a modified agential realist framework drawing on Barad [40], allowing a focus on positioning of both physical and subjective characteristics of work and the intervention.

Second, a researcher will follow the work at the intervention sites during the intervention period in order to gain insight into the practices in the organization during the time of implementation. These observations will be drawing on observational methodology and analysis by Czarniawska, who suggests observing particular practices, objects, or people [41]. From these suggestions, we intend to follow practices and objects of particular relevance to the solutions on how to reduce

excessive workloads developed in the intervention. During these observations, we will record field notes for analysis. These notes will be taken immediately after each day of observation elaborated by the conducting researcher and used for analysis of practices in the organizations and worksites where the interventions are conducted.

Document Analysis

In the participating companies, we will obtain documentation of sickness absence, time frames, and economic measurements (performance-based salary levels or budget numbers). Through analysis of these documents, we will attempt to gain insight into some of the measures of how the intervention affects productivity, which is very important to estimating the potential costs of this type of intervention.

Mixed-Methods Analysis

We will analyze the different empirical elements of the study in relation to each other. We will focus on combining triangulation and a complementary approach to the mixed-methods design rather than on quantifying qualitative material or other approaches to mixed methods [42]. In practice, our mixed-methods analyses will be focused on discovering consistencies and inconsistencies in the physical measurements, questionnaires, qualitative data, and document. Further, we will use our qualitative data to elaborate on the physical measurements, which are of limited character. By pursuing this approach, we can analyze in a detailed manner how the intervention functioned in the different settings, in line with Bamberger et al [30]. Table 1 summarizes the tools used for each evaluation component.

Table 1. Tools used for each component.

Component	Methodological tool
Recruitment	Checklist, questionnaires, interviews
Reach	Checklist
Fidelity	Summary of researchers' evaluation discussion
Satisfaction	Questionnaires I, II and III, and interviews
Program delivery	Summary of researchers' evaluation discussion, observational studies
Program reception	Questionnaires I, II and III, and interviews

Results

At the time of submitting this paper (February 2016), we have made initial contact with cases for the intervention and evaluation, and 40 workers have agreed to participate so far. We have completed evaluation design and have prepared interview guides and the observational methodology. The intervention and evaluation are designed to run over the course of winter 2015 to winter 2016, after which time we will undertake the analysis.

Discussion

One practical issue when conducting research, interventions in particular, in the construction industry can be that time frames

are often very narrow, which is why workers often do not have the time to participate in interventions. One particular challenge will be to engage workers, OHS staff, and managers to cooperate in developing and implementing solutions for reducing physical exertion in work, as these groups are usually not engaged in such activities. These challenges can complicate our aim to complete the workshops and group interviews. We will, however, attempt to follow through.

A particular strength of the evaluation design is the mixed-methods framework. Through using lingual communications, observed practices, and quantified assessments, we have configured an analytical apparatus capable of describing how the intervention intra-acts with the workplaces in which it is implemented. We get the opportunity to identify mutually supportive configurations of these relationships, as well as the

ability to identify differences occurring through only one or two methodological approaches.

Also, the formative evaluation design allows us to use the insights produced through the evaluation to customize parts of the intervention to better address the context's or participants' requirements for a fruitful implementation.

However, we do expect that completing the mixed-methods analysis of the various sources of data and measurements will pose significant challenges. For instance, weighing the different

approaches in relation to each other will demand attention and carefulness in the research group working with the study. For these reasons, we expect to be able to illustrate how agencies in construction work intra-act in relation with the ergonomic intervention and to reconfigure the boundaries of material work, organization of physically exerting work tasks, and worker subjectivity. These insights will provide pointers for future action and interventions targeting physical exposure in construction work.

---

## Acknowledgments

LLA obtained a grant from the Danish Working Environment Research Fund for this study (grant number 51-2014-03).

In accordance with the Helsinki Declaration, we will collect informed consent to participate in the intervention study from all participants. This will take place only after participants have been informed about the objective and content of the study. This information will be given to a researcher. The intervention study is approved by The Danish National Committee on Biomedical Research Ethics (local ethical committee of Frederiksberg and Copenhagen, H-3-2010-062), and registered at the Danish data Protection agency (215-57-0074) and on ClinicalTrials.gov (NCT02498197).

---

## Authors' Contributions

JZNA, MB, JM, PM, and LLA designed the study; JZNA, MB, LLA, SS, JØV, ES, and MDJ designed the questionnaires. JZNA and JM designed interview guides and observational methodology. JZNA drafted the manuscript, and all authors read, critically reviewed, and approved the final version.

## Abstract

**Background:** Strategies to improve access to health care for people living with human immunodeficiency virus (PLHIV) have demonstrated limited success. Whereas previous approaches have been informed by the views of health providers and decision-makers, it is believed that incorporating patient perspectives into the design and evaluations of health care programs will lead to improved access to health care services.

**Objective:** We aim to map the literature on the perspectives of PLHIV concerning access to health care services, to identify gaps in evidence, and to produce an evidence-informed research action plan to guide the Living with HIV program of research.

**Methods:** This scoping review includes peer-reviewed and grey literature from 1946 to May 2014 using double data extraction. Variations of the search terms “HIV”, “patient satisfaction”, and “health services accessibility” are used to identify relevant literature. The search strategy is being developed in consultation with content experts, review methodologists, and a librarian, and validated using gold standard studies identified by those stakeholders. The inclusion criteria are (1) the study includes the perspectives of PLHIV, (2) study design includes qualitative, quantitative, or mixed methods, and (3) outcome measures are limited to patient satisfaction, their implied needs, beliefs, and desires in relation to access to health care. The papers are extracted by two independent reviewers, including quality assessment. Data is then collated, summarized, and thematically analyzed.

**Results:** A total of 12,857 references were retrieved, of which 326 documents were identified as eligible in pre-screening, and 64 articles met the inclusion criteria (56% qualitative studies, 38% quantitative studies and 6% mixed-method studies). Only four studies were conducted in Canada. Data synthesis is in progress and full results are expected in June, 2016.

**Conclusions:** This scoping review will record and characterize the extensive body of literature on perspectives of PLHIV regarding access to health care. A literature repository will be developed to assist stakeholders, decision-makers, and PLHIV in developing and implementing patient-oriented health care programs.

(*JMIR Res Protoc* 2016;5(2):e71) doi:[10.2196/resprot.5263](https://doi.org/10.2196/resprot.5263)

## KEYWORDS

HIV; HIV Infections; Attitude to Health; Patient Satisfaction; Perspective; Health Services Accessibility; Health Services/Utilization; Access to Health Care

## Introduction

Within the topic of access to health care for people living with human immunodeficiency virus (PLHIV) there are four key ideas which are very important to the conception and planning of research in this area. These ideas are used to guide research in an effective manner to be able to produce the best results and initiate change. These ideas are (1) efforts to improve health care will be wasted unless they reflect what patients want from the service [1], (2) access is a major concern in health care policy and is one of the most frequently used words in discussions of the health care system [2], (3) engagement in care is vital for the prognosis of PLHIV or acquired immune deficiency syndrome (AIDS), and to reduce the transmission of HIV [3], and (4) access and delivery of health care services to PLHIV is challenging and requires a characterization of these people and their perspective of access to health care [4-6].

### Access to Health Care for People Living with HIV

In developed countries, the number of PLHIV is increasing. With advances in HIV treatment and health care services, PLHIV are living longer, necessitating a wider range of preventive, acute, and long-term health care services to meet the needs of PLHIV across their lifetimes [4,5]. The complexity of responses to meet the needs of PLHIV is heightened as HIV continues to disproportionally affect vulnerable populations.

Providing health care for a patient population that experiences complex needs requires societies to develop and sustain appropriate health care, as well as improve access to health care services that ensure engagement and ongoing retention in care [4,7-9]. The positive impact of accessible health care on the health and quality of life of PLHIV has been previously identified [4,7-9]. In a system such as Canada's (that provides universal health care), it is often assumed that there are few barriers to accessing care and treatment, such as antiretroviral therapies. Indeed, Canadian studies show that most people diagnosed with HIV have had encounters with health care providers within one month of their diagnosis [5]. However, there are many people with HIV who have not engaged with care to adequately monitor and treat infection [5]. Access to required services for HIV care also varies across jurisdictions, and many PLHIV report continued difficulty accessing health care services [5]. Previous studies have revealed barriers to access, disparities in health care delivery, and factors contributing to underutilization of services among this

population [4]. In addition, there have been attempts to mitigate these barriers, including strategies such as eHealth or outreach programs to improve access and engagement in health care [7]. However, most of these studies were developed and conducted based on the perspective of health care decision-makers, while patients' views of access to health care may differ from health professionals, managers, and policymakers [10]. Incorporating patients' perspectives into the implementation and evaluation of health care programs is essential [11]. This study represents the first attempt to broadly and systematically identify, classify, and synthesize literature on PLHIV's perspectives on access to health care.

### Concept of End-Users and Patients' Perspectives

It is increasingly recognized that patients' beliefs and desires influence their involvement in their own health, access to health care, and communication with their health care providers. Recent studies also emphasize that patients' perceptions of their access to health care services should be taken into account when implementing health programs [12-14]. However, there is no unique consensus for patients' perspectives that can span all conditions and all populations [10,11].

Most existing literature has documented patients' perspectives by assessing patient satisfaction using questionnaires and surveys; others suggest first identifying a common definition for the end-users of the health care system, including patients, consumers, citizens, and the general public. These studies classify the end-users into two categories. The first group includes individuals *whose role is to provide a societal or lay perspective about health services/technologies* [15]; this category includes groups representing citizens and elected officials. The second category includes *those individuals directly affected by a given health condition or health service/technology* [15]. One study by Cayton suggests that these two categories represent different roles that individuals take on while engaging with health care services, and identifies these categories as two sides of the same coin [16].

Finally, consumer-perspective studies suggest visualizing issues through the eyes of the service users. These investigations include consumers' insights and *experiential* evidence of the totality of features of a product, and consumer-stated satisfaction (or their implied needs) with the products. The challenge in these studies is the implicit assumptions of people's interpretation of quality and their individual values [1,11].

## Concept of Access to Health Care

Access to health care is a complex concept that is usually measured using multiple dimensions, including the characteristics and expectations of health care providers, customers, or patients. A growing body of research has grouped these characteristics into the five A's of access to health care (affordability, availability, accessibility, accommodation, and acceptability) [2]. Many investigators suggest distinguishing between the *potential of having access* and *gaining access*, by identifying whether people who require health care get into the health care system or not.

Individuals' perceptions of their needs for health care, and their decisions to seek health care services, are the first steps in the process of gaining access to health care. Access to health care services suggests that a person distinguishes and accepts his or her needs for health care, consents to be a service user, recognizes resources, and is willing to use the services available [17]. This process is further influenced by demographic, socioeconomic, cultural, and environmental factors. Individuals' anticipation and recognition of a health care service may differ from those of health care professionals [17]. In recent years, efforts to change people's attitudes and behaviors regarding health care services have increasingly shifted to acknowledging the importance of the views of users and their demands in developing services. Some of these advances extend the concept of access (beyond physical access) to the development of remote access via electronic devices and the Internet [18].

## Scope of the Review

We aimed to summarize the perspectives of PLHIV concerning access to health care, as identified in previous studies. In order to provide a more comprehensive overview of the existing knowledge, a scoping review will be conducted instead of a systematic review. Findings from the scoping review will enable us to examine the extent, range, and nature of research activity on this topic, and to evaluate the value and feasibility of performing a full systematic review [19].

## Protocol of the Review

The standard process for this scoping review will include the stages suggested by Arksey and O'Malley, among others [19-23]. The draft protocol is being circulated to knowledge translation experts, systematic review methodologists, a librarian, clinicians, and decision-makers for their review, and the protocol will be modified as required. The quality of individual studies will also be assessed, scored, and synthesized to gauge the overall quality of studies being done [19,21-23].

## Stage 1: Identifying the Research Question

The research question for this review was developed by members of Advancing Primary Healthcare for People Living with HIV (LHIV Innovation Team), a team of researchers, primary and specialist health care providers, policy-makers, and HIV-positive people with experience accessing health care, aiming to improve the community-based care of PLHIV in Canada. Our research question is summarized as: What is the extent of knowledge on the perspectives of PLHIV about access to health care services?

## Goals and Aims

In response to the research question, the main goal of this review is to explore the depth, breadth, and quality of evidence about the perspectives of PLHIV regarding access to health care services internationally, with a particular focus on Canadian studies. The aims of this scoping review are to orient our research team, to provide evidence-based information for the team to conduct the research, and to advance the primary health care for PLHIV in Canada.

## Objectives

We have five main objectives in this study:

1. Map the literature on the perspectives of PLHIV about access to health care services.
2. Describe what is known about the perspectives of PLHIV regarding access to health care services, to identify the gaps in evidence, and to highlight research priorities based on these results.
3. Establish the themes of the perspectives of PLHIV regarding access to health care.
4. Prepare an evidence-based summary of Canadian and international research literature on the perspectives of PLHIV related to health care access.
5. Produce an action plan and a research agenda for the LHIV Innovation Team.

## Methods

### Participants

The participants that will be targeted include anyone living with HIV/AIDS. There will be no exclusion criteria based on age, sex, ethnicity, or geographic location, although sub-populations may be discussed separately depending on our findings.

### Outcomes

Outcomes will be restricted to any measures of PLHIV-stated satisfaction, implied needs, beliefs, and desires concerning access to health care. No restrictions on the type of health care services are to be applied to our search, including traditional and non-traditional services for the diagnosis and treatment of disease or the maintenance of health, in order to include all outcomes in the literature. To distinguish access from other attributes of health care services, including continuity of care and retention, the definitions suggested by Haggerty et al will be used [24,25].

## Stage 2: Identifying Relevant Studies

### Selection of Search Terms

Significant terms from the research question will be selected, and a list of possible synonyms or alternate terms will be compiled. To find the best search terms, Medical Subject Heading (MeSH) terms, MeSH tree, and related words found in key words and references will also be searched.

### Building Search Terms Strategy

To determine the best search strategy, different combinations of words will be tested across databases. The search will include an iterative process to refine the search terms through testing

of different terms, and combining new terms, as new related citations are identified. The search will include a combination of MeSH and keywords searched in the title and abstract (tiab) fields. Search strategies will be modified for other databases as required.

### **Sources of Relevant Studies**

To identify all sources of information, this review will begin with a comprehensive mapping of peer-reviewed publications referenced in electronic databases. The search for studies will be in the following databases, and will be guided by a librarian: EMBASE (1947 to May 5, 2014); MEDLINE via PubMed (1946 to May 5, 2014); CINAHL (1937 to May 5, 2014); Cochrane (1993 to May 5, 2014); and PsycINFO (1880s to May 5, 2014).

Cited references of articles chosen for inclusion in the scoping review will also be searched, as well as additional sources, including the reference lists of included studies, searching ProQuest for PhD theses, contacting experts to request details of any known studies (eg, known Canadian researchers in this subject area), HIV Conferences and Symposia, and all sources identified in [Multimedia Appendix 1](#).

### **Validation of Search Protocol**

To validate the search protocol and calibrate our search strategy, the protocol will be tested on the gold standard studies and journals suggested by content experts. The eligibility criteria will be modified as required.

### **Directory of the Identified Studies**

A directory of publications and grey literature will be created in Refworks [26]. To capture and tag the web-pages' information, other reference manager software will also be used, including Zotero [27] and Mendeley [28]. The tagged webpages will then be imported into Refworks.

### **Stage 3: Study Selection**

Study selection will be an iterative process consisting of searching the literature, refining the search strategy, assessing the eligibility criteria, pre-screening and reviewing the full text of the literature for inclusion, and retaining only articles concerning PLHIV's perspectives on access to health care.

### **Eligibility Criteria**

Decisions about review process methodology will be undertaken by members of our team who will be blinded to the results of the studies in question, and who have expertise in health care services for PLHIV. Inclusion criteria will ensure a wide range of literature from varying resources, but only French and English articles will be used, as reviewers are fluent in these languages. To ensure a good standard of evidence and clinical relevance to the review, the types of articles found under exclusion criteria will not be included.

Inclusion criteria will include (1) literature from peer-reviewed journals, (2) grey literature, such as unpublished theses and reports from relevant websites, and (3) the use of only French and English articles for full-text review. Exclusion criteria will include (1) audits or anecdotal information, (2) research at the planning stage (although this will be included in the research

directory), (3) pilot studies, (4) undergraduate and MSc dissertations, (5) book reviews, and (6) policy analyses.

Qualitative and quantitative studies will be examined. Qualitative studies will include any kind of qualitative study (eg, phenomenology, ethnography, grounded theory, historical and case studies) as identified by the authors. Quantitative studies encompass reviews (systematic reviews, meta-analyses, narrative reviews, scoping reviews), observational studies (cohort, case control, cross-sectional studies, case series, case reports), and interventional studies (field trials, randomized controlled trials, community trials, quasi-experimental).

### **Study Selection Process**

#### **Step 1: Pre-screening**

The titles and abstracts of all articles identified during database searches will be examined by a trained undergraduate student to evaluate eligibility, after duplicates are removed. Studies will be considered unrelated if the articles and abstracts are not related to the search subject, or if the articles are commentaries or editorials. The number of all articles deemed eligible by title and abstract will be recorded for further reference, but only French and English articles are subject to full-text reviews.

#### **Step 2: Verification of Results**

A random sample of 5% of the articles that are excluded by title and abstract will then be re-examined by one of the two reviewers to ensure that all relevant articles are considered. If more than 5% of the sample is found to be relevant, all excluded articles will be re-examined.

#### **Step 3: Full Text Review**

The full texts of retained references will be linked to the PLHIV Perspective Directory in Refworks using the Memorial University Library Services. The number of articles without full texts will also be recorded for further reference. Before commencing the full text review and data extraction, a calibration exercise will be undertaken. Two independent reviewers will be assigned a random selection of 5% of included citations. The eligibility criteria will then be modified if the agreement between the two reviewers is low ( $\kappa < 0.5$ ). The reviewers will also screen the remainder of the citations and discrepancies will be resolved by a third reviewer.

#### **Stage 4: Data Extraction**

A data extraction tool in Excel will be prepared for data abstraction to systematically collect data from identified articles. The tool will be designed to extract information on the citation type (eg, original research), country, date of study, methodological aspects of the study, design, characteristics of the participants, participants' perspectives on access to health care, and the quality of the study. The data extraction tool will be assessed on a random sample of 10 articles. The data extraction tool will also be revised iteratively, as required. Two trained graduate students will independently review and extract the information.

## Stage 5: Collating, Summarizing and Reporting the Results

Collating and summarizing results will include a descriptive summary of the number of identified articles, and an interpretive synthesis using the Arksey and O'Malley framework [19]. It is anticipated that the identified studies will incorporate different methodologies; qualitative and quantitative analyses will then be undertaken. The quality of original studies (both quantitative and qualitative) will be evaluated using a scoring system for Systematic Evaluation of Mixed Studies Review [23]. The quality of the screened articles will be graded, not with the intention of excluding the poorer studies or weighting the studies, but rather to identify the overall quality of studies in the sample. The studies and their characteristics will also be summarized. The frequency of studies will be reported by the study design, including place and date of publication, quality score, identified outcomes (PLHIV's perspectives on access to health care), the positive and negative perspectives, and the PLHIV's reported barriers and facilitators to accessing health care.

Quantitative studies will be reviewed and evaluated using a descriptive summary of key findings (eg, PLHIV's reported facilitators and barriers, PLHIV's views, satisfaction, attitudes, and opinions on access to health care) as well as the measurement tools (see [Multimedia Appendix 2](#)). Qualitative studies will be reviewed and evaluated by identifying the key findings and themes (eg, PLHIV's reported barriers and facilitators, PLHIV's views on access to health care). The findings will then be presented as an initial concept and further broken down into the emerging and final themes within that concept (see [Multimedia Appendix 2](#)).

Analysis will focus on detecting the key concepts among studies. The concepts will then be synthesized and refined to determine core themes; directed content analysis and thematic analysis will be undertaken to classify the data [29-31]. It is also anticipated that this multi-layer synthesis will identify novel concepts not suggested by the individual studies. Using this approach, we will identify research available in this area, the gaps in literature, and whether there is a need for a systematic review of the literature or other future reviews. Need for a systematic review will be determined by the content and methods of the studies and whether they are conducive to performing a systematic review, as the topic is very broad.

The results will then be reported in descriptive tables, frequency tables, and diagrams. The characteristics of the studies, including participants, study setting, study design, and study outcomes will be described. A summary table will also provide the identified themes.

## Knowledge-User Consultation

To ensure applicability, usability, and a clear purpose, the review is being conducted using an integrated knowledge translation approach and knowledge-users will be involved throughout the review's duration. This approach will involve a series of consultations with research experts and the community advisory committee in our team to engage them in the development of the study outcome, action plan and research agenda, and to provide opportunities for knowledge exchange. The team includes researchers, educators, PLHIV, policymakers, clinicians, and trainees.

Preliminary findings of the review will be shared with our team, to validate our findings and guide the review's completion, on a regular basis [20]. We will present the preliminary results and list of findings in the annual meetings of the LHIV Innovation Team. All comments and feedback will be recorded and will be integrated into the study. We will also ask the LHIV Innovation Team whether they can suggest any additional issues related to PLHIV's access to health care from the patients' perspective, which has not yet been identified in our review. Using the final results, a summary of possible implications to practice, including the areas that may require action in the medium and longer term, will be developed. The summary will be presented in the annual meeting of the LHIV Innovation Team for brainstorming, developing the research questions, identifying appropriate strategies, and the production of an action plan and research agenda for the LHIV Innovation Team.

## Results

### Stage 2: Identifying Relevant Studies

The search terms that were selected for the literature search can be found in [Multimedia Appendix 3](#). The literature search strategy for PubMed is outlined in [Table 1](#) (see [Multimedia Appendix 4](#) for search strategies for all other databases). After an extensive literature search, 20,687 articles were found using the appropriate search terms. 7829 of these articles were duplicates which left 12,858 references to be screened.

**Table 1.** The literature search strategy for PubMed and number of identified articles.

#	Searches	
1	"HIV"[Mesh] OR "HIV Infections"[Mesh] OR HIV[tiab] OR AIDS[tiab] OR "Acquired Immunodeficiency Syndrome"[tiab] OR "Human Immunodeficiency Virus"[tiab] OR "Human Immunodeficiency Viruses"[tiab] OR "Acquired Immune Deficiency Syndrome"[tiab]

### Stage 3: Study Selection

After assessing eligibility based on title and abstract, a total of 317 articles were deemed to be relevant (Figure 1). Of the 12,532 articles which were not relevant based on title and abstract, 700 (5%) were randomly selected to verify the results of the exclusion/inclusion process. These articles were re-assessed based on title and abstract. Of the 700, 9 articles were found to be relevant and therefore added to the 317 to be reviewed by full text. This was less than 5% of the sample and therefore verifies the process (Figure 1).

A total of 326 articles were reviewed in full text. Based on the inclusion/exclusion criteria, 260 of these articles were not about patients' perspectives on their access to care, which left 66 articles that met eligibility. A full description of the exclusion process can be found in Figure 1.

### Stage 4: Data Extraction

The final version of the data extraction tool can be viewed in Multimedia Appendix 5. During extraction, two articles were found to not be relevant to this scoping review and therefore were not included in any analysis, which left a total of 64 articles. Of these 64, 36 (56%) were qualitative, 24 (38%) were quantitative and 4 (6%) were mixed methods by design. Throughout the extraction process, a comparison of quality

assessment and extraction were done by two independent reviewers. Quality assessment scores were deemed comparable if they were within 1 point of each other. If differences in extraction results were found, a discussion between the two reviewers was initiated and either a common conclusion was made, or a third party was consulted. Overall, the agreement between the two reviewers was good ( $\kappa=.75$ ). The majority of assessments and extractions were similar between the reviewers, with all differences being discussed and decided upon together.

### Stage 5: Collating, Summarizing and Reporting the Results

Looking at the articles more closely, there were some general initial quantitative results available. The majority of articles were published within the past 10 years, with the most being published in 2009 ( $n=9$ ); a breakdown of all publication years can be found in Figure 2. Of the 20 different countries in which research was performed, a substantial number of the studies were conducted in the United States ( $n=27$ ), with other countries such as Nigeria, Canada, India, and South Africa adding studies to the body of literature. In Figure 3, it is possible to see a visual representation of the proportion of research there has been in each country. The *other* category includes the 11 countries that are only represented in one article of this review. Data synthesis is in progress and full results are expected in June, 2016.

**Figure 1.** Stepwise exclusion of articles.**Figure 2.** Year of publication of research.

**Figure 3.** Country of study.

## Discussion

### Anticipated Challenges

A large number of search results are anticipated, so proactive steps are taken during the review, including (1) working closely with a librarian at Memorial University of Newfoundland to ensure that the review will be manageable, and (2) categorizing the studies in terms of their quality and the proper knowledge synthesis methods. We have a strong team with expertise in research methods, review methods, and content. Our team conducts regular meetings and communications with stakeholders to obtain their comments and iteratively modify the study methodology as required.

Throughout the process there have been some challenges. As there are a large number of articles identified for review, not all are initially accessible electronically through databases, and many have to be found individually. This issue adds to the workload of the research librarian, who has to manually obtain these records. Due to the wide selection of possible outcomes

and the adding of new possibilities (due to an iterative process to include all aspects of patients' perspectives of care), there may be slight variation in how results are classified between graduate students. However, the core results sections (eg, 5 A's) remain the same, so all important results will be accounted for.

### Next Steps

Data extraction has been completed and compared by both graduate student reviewers. The next step in the process is to collate and summarize that data found, in order to answer the objectives within this study.

### Conclusion

A scoping review will record and characterize the extensive body of literature on perspectives of PLHIV regarding access to health care. Without a systematic and well-documented protocol, the scoping reviews are subject to biases. A repeatable and evidence-based protocol is required to broadly and systematically identify, classify, and synthesize literature. A valid protocol will help to identify the issues, resolve some problems, and reduce the risk of bias.

### Acknowledgments

We would like to thank the LHIV Innovation Team for all their work on this project, as well as the Canadian Institutes of Health Research grant for the Advancing Primary Healthcare for PLHIV in Canada project to allow for this research to happen.

## Abstract

**Background:** Migrants form a substantial proportion of the population affected by the human immunodeficiency virus (HIV) epidemic in Europe, yet HIV prevention for this population is hindered by poor understanding of access to care and of postmigration transmission dynamics.

**Objective:** We present the design and methods of the advancing Migrant Access to health Services in Europe (aMASE) study, the first European cross-cultural study focused on multiple migrant populations. It aims to identify the structural, cultural, and financial barriers to HIV prevention, diagnosis, and treatment and to determine the likely country of HIV acquisition in HIV-positive migrant populations.

**Methods:** We delivered 2 cross-sectional electronic surveys across 10 countries (Belgium, France, Germany, Greece, Italy, the Netherlands, Portugal, Spain, Switzerland, and United Kingdom). A clinic survey aimed to recruit up to 2000 HIV-positive patients from 57 HIV clinics in 9 countries. A unique study number linked anonymized questionnaire data to clinical records data (viral loads, CD4 cell counts, viral clades, etc). This questionnaire was developed by expert panel consensus and cognitively tested, and a pilot study was carried out in 2 countries. A Web-based community survey (n=1000) reached those living with HIV

but not currently accessing HIV clinics, as well as HIV-negative migrants. It was developed in close collaboration with a community advisory group (CAG) made up of representatives from community organizations in 9 of the participating countries. The CAG played a key role in data collection by promoting the survey to higher-risk migrant groups (sub-Saharan Africans, Latin Americans, men who have sex with men, and people who inject drugs). The questionnaires have considerable content overlap, allowing for comparison. Questions cover ethnicity, migration, immigration status, HIV testing and treatment, health-seeking behavior, sexual risk, and drug use. The electronic questionnaires, which were available in 15 languages, allowed for complex routing, preventing respondents from answering irrelevant questions.

**Results:** In total, we recruited 2249 participants from 57 HIV clinics as part of the clinic survey and retrieved 1637 complete responses as part of the community survey.

**Conclusions:** The findings will provide much-needed information for improving HIV prevention interventions and access to services for migrant communities.

## KEYWORDS

migrants; HIV; survey; community mobilization

## Introduction

In 2014, with new human immunodeficiency virus (HIV) infections on the decline, the Joint United Nations Programme on HIV/AIDS (UNAIDS) announced the beginning of the end of the AIDS epidemic [1]. Although there are still approximately 35 million people living with HIV worldwide, UNAIDS has set a goal of ending the AIDS epidemic in “every region, every country, in every location, in every population and every community” by 2030 [1]. Reaching this ambitious goal is now possible because of vast improvements in the ability to provide widespread HIV testing and subsequent treatment with antiretroviral therapy. Within Europe, the end of AIDS is dependent on identifying, treating, and preventing onward transmission among an estimated 2.2 million people living with HIV [2], a substantial and disproportionate number of whom are people who were born in another country, that is, migrants. While 9.7% of the European Union (EU)/European Economic Area population were born outside the current borders of their country of residence [3], over a third (35.0 %) of those newly diagnosed with HIV in 2013 were migrants [4]. Approximately 15% of those were people who had migrated from a country with a generalized epidemic, notably sub-Saharan Africa (13%). Smaller proportions of newly diagnosed migrants were from Central and Eastern Europe (5.1%), Latin America and the Caribbean (4.9%), other Western European countries (3.9%), and South and Southeast Asia (2.2%) [4].

Despite the heavy burden of HIV among migrant communities, HIV prevention and treatment for these populations is hindered by a relatively sparse evidence base and the heterogeneity of the populations affected [5]. Migrants are more likely to be exposed to social determinants of ill health (such as poverty, social exclusion, and unemployment), which can result in poor health-seeking behaviors [6]. Other structural factors such as legal and administrative status, together with health care- and community-related barriers, can further prevent migrants from accessing health services, particularly HIV testing [7]. Yet little is known about migrant access to health services, particularly HIV testing, access to treatment, and safer sex practices [8]. Previously it had been assumed that most HIV diagnosed among migrants in Europe was acquired in the country of origin,

particularly those born in sub-Saharan Africa. Yet it is unclear whether infections are acquired pre- or postmigration [5]. Although surveillance data show that people living outside their country of birth form a substantial proportion of the population affected by the HIV epidemic in Europe, limited data are available about migrant populations to inform policy and practice for these communities.

Understanding barriers to accessing HIV care and postmigration transmission dynamics will provide policy makers and program managers much-needed evidence for effectively planning HIV prevention programs for migrant communities. Several cross-sectional sexual health and HIV studies have sampled migrant populations, but these were often limited to migrants from 1 region (black Africans in Burns et al [9] or Central and Eastern Europeans in Evans et al [10]) or migrants in 1 country (Dray-Spira et al [11]), and there has not been a collaborative European study to address these research questions jointly. Within the European Network of HIV/AIDS Cohort Studies to Coordinate at European and International Level Clinical Research on HIV/AIDS (EuroCoord), we set up the advancing Migrant Access to health Services in Europe (aMASE) study whose overall aim is to provide the evidence to prevent HIV infection and improve diagnosis and prognosis of migrant populations living with HIV in Europe in order to support policy development at the European level. Specifically, aMASE aims to identify the structural, cultural, and financial barriers to HIV prevention, diagnosis, and treatment and to determine the likely country of HIV acquisition in HIV-positive migrant populations. In this paper, we present the design and methods of the 2 cross-sectional studies that form aMASE and the unique challenges associated with multisite, multidisciplinary, multinational research.

## Methods

### Study Design

aMASE is formed of 2 cross-sectional, electronic surveys of 2 populations: (1) migrant adults living with HIV and attending HIV services (the clinic survey), and (2) migrant adults living in Europe (the community survey). For the purposes of this study, we define migrants as foreign-born individuals intending

to live in their current country of residence for  $\geq 6$  months. Residency was not dependent on formal documentation, and immigration status, while captured within the survey, was not part of the inclusion or exclusion criteria. The clinic survey was delivered using a computer-assisted self-interview (CASI) or computer-assisted personal interview (CAPI) and augmented with clinical data from patient records. The community study was a Web-based survey designed to reach those living with HIV but not currently accessing HIV clinics, as well as HIV-negative migrants.

## Clinic Survey

### *Study Setting and Time Period*

The clinic survey was implemented in 57 clinics in 9 countries (Belgium, Germany, Greece, Italy, the Netherlands, Portugal, Spain, Switzerland, and the United Kingdom) between July 2013 and June 2015. [Multimedia Appendix 1](#) lists the clinics' names.

### *Participants and Eligibility Criteria*

Patients were eligible for inclusion in the study if they were (1) HIV-positive, (2) aged  $\geq 18$  years, (3) foreign-born and resident in the country of recruitment for  $\geq 6$  months, (4) diagnosed within 5 years of the study date, and (5) able to complete, either alone or supported, a CASI in any of the 15 languages available (Amharic, Arabic, Dutch, English, French, German, Greek, Italian, Polish, Portuguese, Russian, Turkish, Tigrinya, Spanish, and Somali). In Switzerland, local eligibility criteria applied (migrants from neighboring Austria, France, Germany, and Italy are excluded due to close linguistic and cultural ties).

### *Sample Size*

The sample size calculation was based on precision and used the standard formula for standard error of a proportion:  $SE = \sqrt{p(1-p)/n}$ . In calculating the sample size, the primary outcome measures were health service use (registered with primary care physician) and the proportion of participants with a previous negative HIV test.

Initially we anticipated recruiting 4000 participants (2000 men and 2000 women) from 2 to 5 clinics in each of 7-9 EU countries (creating about 40 clusters). We considered the within-cluster correlation likely to be relatively weak (eg, 0.005), at least for regression analyses, as the average cluster size may potentially have been large (eg, 75-125). Assuming a design effect of 1.5 for the study, the overall effective sample size would have been ~2670. This sample size would have provided good precision for our estimates. Specifically, within each gender group, our outcomes could be estimated to within 3% across Europe and to within around 8% for each country. As recruitment was slower than anticipated, to a large extent due to the decrease in the number of new HIV-positive migrants in Europe [12], we revised this sample size in December 2014.

The revised target sample size calculation was 2000 participants (1000 men and 1000 women) from all clinics. We recruited participants from a minimum of 2 clinics in each of the 9 countries, with each clinic forming a discrete cluster. We estimated this within-cluster correlation also to be relatively weak (eg, 0.005), at least for regression analyses including

patient and city characteristics as covariates. As the average cluster size was likely to be smaller than first estimates (eg, 40-60), we assumed a design effect of 1.25 for the study and, hence, an overall effective sample size of ~1600. This revised sample still provides good precision for estimates. Specifically, within each gender group, we will be able to estimate our outcomes to within 3.5% across Europe and to within 10% for each country.

### *Sampling Strategy*

The main inclusion criteria for study sites were a sizable migrant clinic population (sufficient to recruit a minimum of 40 study participants in most sites) and the human resource capacity to conduct the study with minimal additional funding. Eligible patients attending participating clinics within the study period were approached by members of their clinical care team or a recruitment researcher to participate in the clinic survey.

### *Variables and Questionnaire Development*

We formed a working group, made up of international experts and EuroCoord collaborators, to act as an expert panel tasked with reaching consensus on survey instrument development and provide overall supervision of the study. Where possible, we adapted questionnaire items from existing survey instruments. New questions were drafted by the core research team and expert panel members.

We validated the questionnaire using cognitive testing (cognitive aspects of survey methodology approach [13]). It was tested in Spanish (in Spain) and English (in the United Kingdom) on 7 black African and 3 Latin American migrants recruited from community-based HIV service organizations. The finalized patient questionnaire is divided into 3 sections: (1) detailed sociodemographic data and extensive migration history data, (2) sexual and HIV risk behavior, including drug use before and after migration, and (3) service use and experiences of living with HIV, including stigma and discrimination. Questions were tailored to reflect the different health care or ethical approval systems in different countries. For example, respondents completing the survey in Portugal were not asked questions about ethnicity or health care costs. There are 90-92 items included depending on current country of residence, although through skipping and filters some respondents answered as few as 43 questions. Most questions were closed and the survey completion time was between 15 and 50 minutes depending on the language selected. The survey was translated from English into 15 languages (see Participants and Eligibility Criteria above) by a professional translation company. These translations were then checked by a different translation company, who back-translated a portion of the questionnaire into English to ensure quality control.

Participating patients' questionnaires were matched to a clinical data form using a unique study number. The clinical data form contains 20 items, including CD4 cell count and viral load (at diagnosis, at antiretroviral therapy initiation, and the latest available); previous HIV-negative tests and viral clade; AIDS-defining illnesses and coinfections; and treatment initiation. Clinical data were completed electronically.

## Ethics

Ethical approval for the aMASE studies was received separately in each participating country (see [Table 1](#)).

## Pilot Study

We piloted the function and reliability of the CASI and the clinical data form in 3 clinics (2 in London, 1 in Madrid) with 115 patients. The pilot study also tested whether recruitment procedures, study implementation, and data collection, storage, and handling methods were feasible and appropriate. Following feedback about the function of the CASI software from recruitment researchers, we redesigned the survey using new CASI software. To facilitate recruitment, the selection criterion of HIV diagnosis in the previous 3 years was increased to 5 years. Based on the results of the pilot study, the survey questions remained essentially the same; however, we redesigned some items to produce a better user experience.

## Study Implementation

The patient questionnaire was administered using tablets, computers, or laptops running Fluidware version 5.0 (SurveyMonkey Canada Inc, Ottawa, ON). Enrollment commenced in participating clinics in July 2013 and was completed in July 2015.

As of August 2015, there were 57 participating clinics in 9 countries: Belgium (n=4), Germany (n=2), Greece (n=8), Italy (n=2), the Netherlands (n=3), Portugal (n=7), Spain (n=18), Switzerland (n=6), and the United Kingdom (n=7).

A study coordinator at the Institute of Health, Carlos III, Spain, was responsible for the overall management of the fieldwork, but in each country a nominated country lead (usually a member of the expert panel) was responsible for collating data across clinics in his or her country. This coordinator actively engaged with all participating centers and country leads to ensure compliance with the study standards, and identified aspects that needed improvement throughout the study period. Where necessary, clinics were supplied with laptops and tablets preloaded with CASI software and instructions for use. Clinics were given a clinic study pack (developed during the pilot study), which detailed the general protocol and maintenance instructions for the CASI devices. Clinic recruiters were able to access an online Web resource with electronic versions of all the required documentation for the study. Incentives were not provided to participants, although some clinics supported travelling costs in the context of their research practices.

Recruitment procedures varied slightly across countries and between clinics, but in general recruitment and consent procedures were as follows.

Eligible patients were identified through clinic databases and their clinical records were flagged. Clinic numbers of eligible patients were noted next to precoded unique study numbers on an enrollment log. Eligible patients were then approached by either members of their clinical care team or a recruitment researcher and provided with a patient information sheet and the opportunity to ask questions. Patients who declined to participate had their age, ethnicity or nationality, and gender noted on the enrollment log. Those who agreed to participate

were asked to complete the CASI/CAPi on site. In most countries, ethical approval for obtaining informed consent through a tick box in the questionnaire was given; however, in Belgium, Switzerland, Greece, and Germany local ethical approval standards required separate consent forms.

Enrollment logs were stored in a locked cabinet; electronic versions of the completed forms were returned to the study coordinator on a monthly basis. Survey data were either captured and then stored directly on a central secure database operated by FluidSurveys (online questionnaire) or stored on the device's hard drive until they were transferred to a secure network in Madrid (offline questionnaire).

## Statistical Analysis

We will explore barriers to accessing health care by using the primary outcomes measures: access to a primary care physician and a previous negative HIV test.

Participating clinics are not necessarily representative of the number of clinics within countries or, indeed, the migrants living with HIV within those countries. For these reasons, the overall sample prevalence of our primary outcome measures, pooled across countries and clinics, may not be informative. We shall give it emphasis in our results only if the prevalence across countries is similar and otherwise focus on the prevalence in each country. We anticipate that associations with the primary outcomes, for example their association with age, will be broadly comparable across countries. However, if associations differ substantially between countries, then we shall investigate this heterogeneity and report an overall measure of association if we judge this to be meaningful. Furthermore, as men and women are expected to have different barriers to accessing care, we will analyze them separately. We will analyze individuals who identify as transsexual separately if numbers are sufficient. We will conduct analyses separately by region of birth if associations differ substantially by region, and we may conduct separate analyses for men who do and do not have sex with men if associations differ substantially between these 2 groups of participants.

Our interest is in associations between the primary outcome measures and each of the following factors: age, gender, region of birth, sexual orientation, immigration status, and age at migration or diagnosis. We will first describe these associations through cross-tabulations. To acknowledge the clustering of participants, we shall analyze associations using hierarchical random effects logistic regression, with a random effect for clinics nested within countries, analyzing factors individually and then jointly in a multiple regression model. We will report associations as odds ratios with 95% CIs.

Within EuroCoord, a group of experts has been established to develop and evaluate a reliable algorithm to determine probable country of infection. The algorithm will incorporate demographic (eg, gender, race or ethnicity, age) and clinical data (eg, CD4 counts, HIV RNA levels, clinical stage according to the US Centers for Disease Control and Prevention) and will be evaluated in simulation studies and in cohorts with well-estimated seroconversion dates. The algorithm will be further elaborated using data from the questionnaire (eg,

migration and HIV testing history, sexual partners pre- and postmigration). CD4 cell counts and viral loads for the study participants will be extracted from the clinical records. Methods for calculating a proxy date for seroconversion rely on clinical parameters with very little, if any, behavioral information informing the model [14]. Our analysis will draw on more detailed information than what is available in routinely collected surveillance data, thus allowing for a more nuanced approach in determining probable country of infection. We will use imputation methods to account for missing data in clinical records. Further details on the methodology used to develop, verify, and apply the algorithm will be published separately.

### **Response Rates**

The age, nationality or ethnicity, and gender of all patients approached to participate in the study were noted on a clinic log. We will analyze these data to assess whether those who agreed to participate are significantly different from those who declined.

### **Community Survey**

#### ***Study Setting and Time Period***

We designed the aMASE community survey to complement the clinic survey and capture data on all migrants regardless of their HIV status. The community survey was available through Web browsers between April 2014 and July 2015.

#### ***Participants and Eligibility Criteria***

All migrants living in the World Health Organization European area (52 countries) aged  $\geq 18$  years, irrespective of their HIV status or current country of residence, were eligible to participate in the aMASE community survey.

#### ***Sample Size***

No sampling frame for migrants in Europe exists, so we used a convenience sampling strategy. The main outcome measures on which we based our sample size estimates were registration with a primary care physician and ever having tested for HIV. The community survey aimed to recruit 1000 migrants, which allows for estimates of outcomes by gender to within 5%. This sample size also provided 80% power to detect a difference of 6% in 1 of the key outcomes (assuming an overall outcome prevalence of 50%) compared with service users (in the clinic study), or smaller differences for less prevalent outcomes.

#### ***Sampling Strategy***

We actively promoted the survey from June 2014 to May 2015 using social marketing and community participatory methods

in 9 countries: Belgium, France, Germany, Greece, Italy, the Netherlands, Portugal, Spain, and the United Kingdom. We targeted some of these countries for active promotion because they were also involved in clinic recruitment. An ongoing survey with African migrants in Switzerland precluded active promotion in that country, and we selected France because it has a large migrant population. A community advisory group (CAG), a group of individuals working for local community-based organizations that provide services to migrant communities or oversee pan-European migrant or HIV networks, was integral to the sampling strategy. The aMASE expert panel selected CAG members with representation from all countries involved in active promotion of the survey. CAG members were contracted to deliver outreach meetings, with the aim of promoting the survey to other organizations within their country. In turn, these organizations promoted the survey to other organizations and their service users and cascaded the study promotion in a method similar to snowball sampling.

### **Variables and Questionnaire Development**

We developed the community survey instrument using an iterative community participatory approach involving the CAG and the expert panel. The expert panel was responsible for the survey content and design and all technical aspects of administering the questionnaire. The CAG ensured that the survey content was relevant to migrant communities within Europe and provided a “real-world” critique of the survey items. The CAG was able to highlight culturally insensitive questions (eg, increasing the number of available gender categories from 2 to 6) or request items that will provide findings that can be quickly translated into policy and practice recommendations (eg, knowledge about access to free condoms). After 4 iterations of the survey development process, we tested the survey CASI for programming inconsistencies. The survey was then translated into 14 languages (identical to the clinic survey with the exclusion of Tigrinya) by a professional translation company. These translations were then checked by members of the CAG or colleagues fluent in the available languages. Almost three-quarters (66/93) of the items in the clinic survey patient questionnaire are replicated in the community questionnaire to allow for comparison between the 2 samples. The remaining items include country-specific questions and topics of interest to the CAG and cover health service use in the country of origin or residence; home testing or sampling for HIV and other infections; mental health; and social determinants of health (eg, housing).

<sup>a</sup>Date of approval letter.

## Ethics

Ethical approval was obtained from the London Bentham Research Ethics Committee (11/LO/1600). Additional approvals were obtained in all countries also undertaking the clinic survey.

## Pilot Study

We carried out a short pilot study with CAG and expert panel members (38 respondents) who completed the survey in a language of their choice. The CASI was revised to improve the quality of translations and make them more suitable for our target population.

## Study Implementation

EuroCoord's primary community partner, the European AIDS Treatment Group (a European network of nationally based volunteer activists), employed a project coordinator to assist the research team in community engagement and chair the CAG. CAG members were provided with a suite of promotional materials including posters, business cards, postcards, and electronic banner advertisements, which were available from the aMASE website. Over 18,000 small media items (3100 business cards; 15,600 postcards) were printed and disseminated to community-based organizations across Europe. The CAG also used additional promotional and recruiting strategies: for example, 12 organizations (in France, the Netherlands, Greece, and the United Kingdom) allowed participants to complete the survey on laptops or other devices on their premises.

We contacted a further 243 community-based organizations identified through a mapping exercise and asked them to promote the survey on their websites and social media pages (eg, Facebook, Twitter). Approximately 300 webpages and apps also carried banner advertisements or links for the community survey, including PlanetRomeo, Grindr, Poz Traveler, and EasyExpat.

All community survey promotional materials referenced the aMASE website, where potential participants were able to select 1 of the 14 survey languages on the initial landing page [15]. Participant information sheets about the community survey were available in all 14 survey languages. Further information with in-depth details about both cross-sectional surveys was available in Dutch, English, French, German, Italian, Portuguese, and Spanish. Individuals who wished to participate in the study clicked through to a separate website, where the survey is hosted by FluidSurveys. All participants provided within-survey tick box consent. Survey data were captured and then stored directly on a central secure database operated by FluidSurveys.

## Statistical Analysis

Statistical analysis will follow similar methods to those outlined for the clinic survey. Direct comparisons between the clinic population and the community population in the primary outcome measures may identify additional barriers to accessing health care, especially HIV testing, treatment, and care. Secondary outcomes explored in the community survey include

chronic illness and infection other than HIV; access to condoms; access to needle exchange programs; and experiences of racism and homophobia.

### Funding

The aMASE study is part of Work Package 14 of EuroCoord, which is funded by the EU's Seventh Framework Programme for research, technological development, and demonstration (under grant no. 260694). The community mobilization and engagement project was sponsored by Gilead Sciences Europe Ltd. [Multimedia Appendix 2](#) lists other funding sources that contributed to the aMASE study.

### Results

By the end of July 2015, recruitment for both clinic and community surveys had concluded. In total, we recruited 2249 participants from 57 HIV clinics as part of the clinic survey and we retrieved 1637 complete responses as part of the community survey. Following data cleaning and analysis, we submitted initial findings and results for peer review in April 2015.

### Discussion

The aMASE study is the first multinational study to specifically sample migrants from across the globe living in Europe. The data gathered will provide not only valuable information about the barriers faced by migrants when trying to access HIV testing, prevention, treatment, and care, but also data about postmigration HIV acquisition. A literature review estimated that postmigration HIV acquisition among migrants from countries with a generalized epidemic range from 2% in Switzerland to 62% among migrant black Caribbean men who have sex with men in Europe [5]. The aMASE study will be the first to estimate postmigration HIV acquisition among European migrants living in Europe, as well as those from endemic regions. These data will provide policy makers and HIV program managers with a sound evidence base on which to develop HIV testing and prevention initiatives for these populations.

There were limitations to this study. Clinics from 9 countries were involved in data collection for the clinic study, and we recruited participants from 57 clinics. We selected these countries in part because they have large migrant populations (including those from Latin America and sub-Saharan Africa); in 2011, the United Kingdom, Germany, Spain, and Italy were the destination countries of 60.3% of all immigrants to EU member states [3]. The selected countries also contain the largest numbers of nonnationals (not including migrants who acquired citizenship in their current country of residence) living in the EU: Germany (7.7 million persons), Spain (5.1 million), Italy (4.4 million), the United Kingdom (4.9 million), and France (3.8 million) [3]. In Greece and Belgium, migrants make up a substantial proportion of the population (7.8% and 11.2%, respectively). Migrants living in France are a notable omission from our clinic sample; however, agreements are in place that will enable us to compare aMASE data with data from similar studies conducted in France.

Participating clinics were not chosen at random and may not be representative of clinics throughout their country of location.

Nonetheless, the majority of sites are located in conurbations with large migrant populations, and the clinic sample is likely to be broadly representative of migrants accessing health care within each participating country. Our clinic (and community) sample is unlikely to be representative of the European migrant population as a whole in terms of such factors as country of residence, region of birth, gender, and sexual orientation. Consequently, a naive analysis of the overall data might underestimate or overestimate the strength of associations with our outcomes in the total population, but we believe our strategy of investigating heterogeneity of associations between countries and conducting analyses separately within subgroups determined by these factors, where necessary, will limit the bias in our findings.

Finally, the long recruitment period for both the clinic and the community surveys may present a challenge to interpreting the data. Migrant populations within Europe can fluctuate and change rapidly. Those recruited at the beginning of the study may represent a different migration cohort with differing barriers to accessing care from those recruited toward the end.

The aMASE clinic survey links self-reported data provided by participants with data from clinical records, which is vital for the accurate estimation of probable country of HIV acquisition. Furthermore, the clinical data will also allow us to estimate factors associated with late diagnosis, recent seroconversion, and hepatitis coinfection, thereby providing insight into the barriers and facilitators to earlier testing and access to care for study populations that have rarely been the sole focus of HIV research in Europe. The clinic survey will also augment the evidence base with regard to distal determinants of health such as poverty and hunger, as well as the sexual health needs of migrants living with HIV.

The aMASE Study as a whole also provides a useful model for community participatory methods in research. The community survey was developed using iterative methods with close communication between the research team, a panel of experienced epidemiologists, statisticians, and HIV clinicians, and an advisory group made up of community activists. Actively involving the CAG in survey development was time consuming and presented logistical challenges for the research team (eg, language barriers, inability to schedule some meetings during the working day). Those issues notwithstanding, the benefits in adopting this strategy were clear shortly after the 2014 European parliamentary elections, in which parties that campaigned on an anti-immigration platform performed successfully. Without the endorsement and support of the CAG, a study about the health of migrants in Europe may have been viewed with suspicion across the political spectrum. A careful balancing act between active promotion on migrant-friendly media and low-level promotion on mainstream media has enabled the CAG and the research team to promote the study without experiencing a significant backlash from anti-immigrant organizations.

Community stakeholders will be actively involved in guiding analysis and disseminating the results of both surveys. A detailed publication agreement has been drafted that gives community-based organizations access to community survey data relevant to their communities. In addition, CAG members

will assist in creating a policy advocacy information sheet based on the results of both surveys. This information sheet will provide community-based organizations with key local and pan-European health policy advocacy points designed to improve access to health care for people living with diagnosed HIV. Involving community stakeholders in this final stage of

the study increases the likelihood that the findings from this study will be incorporated into policy and practice across Europe. The results of this study will improve the understanding of postmigration transmission dynamics and the barriers to health care for migrants in Europe.

## Acknowledgments

This project has received funding from the European Union's Seventh Framework Programme for research, technological development, and demonstration under EuroCoord grant agreement no. 260694.

## Authors' Contributions

IF, DAA, SM, JDA, and FB were the core research team who led the design and implementation of the study. IF wrote the initial draft of the manuscript and DAA, SM, JDA, and FB edited the manuscript. AJC provided the sample size calculations and statistical advice. AVA was our community partner and chair of our working group. FB, JDA, AFG, CW, GT, MP, CS, and HB were on the expert panel and oversaw data collection in their countries. All authors read and approved the final manuscript.

## Abstract

**Background:** Cost-effective and efficient methods to attract people to Web-based health behavior interventions need to be identified. Traditional print methods including leaflets, posters, and newspaper advertisements remain popular despite the expanding range of Web-based advertising options that have the potential to reach larger numbers at lower cost.

**Objective:** This study evaluated the effectiveness of multiple Web-based and print-based methods to attract people to a Web-based physical activity intervention.

**Methods:** A range of print-based (newspaper advertisements, newspaper articles, letterboxing, leaflets, and posters) and Web-based (Facebook advertisements, Google AdWords, and community calendars) methods were applied to attract participants to a Web-based physical activity intervention in Australia. The time investment, cost, number of first time website visits, the number of completed sign-up questionnaires, and the demographics of participants were recorded for each advertising method.

**Results:** A total of 278 people signed up to participate in the physical activity program. Of the print-based methods, newspaper advertisements totaled AUD \$145, letterboxing AUD \$135, leaflets AUD \$66, posters AUD \$52, and newspaper article AUD \$3 per sign-up. Of the Web-based methods, Google AdWords totaled AUD \$495, non-targeted Facebook advertisements AUD \$68, targeted Facebook advertisements AUD \$42, and community calendars AUD \$12 per sign-up. Although the newspaper article and community calendars cost the least per sign-up, they resulted in only 17 and 6 sign-ups respectively. The targeted Facebook advertisements were the next most cost-effective method and reached a large number of sign-ups (n=184). The newspaper article and the targeted Facebook advertisements required the lowest time investment per sign-up (5 and 7 minutes respectively). People reached through the targeted Facebook advertisements were on average older (60 years vs 50 years,  $P<.001$ ) and had a higher body mass index (32 vs 30,  $P<.05$ ) than people reached through the other methods.

**Conclusions:** Overall, our results demonstrate that targeted Facebook advertising is the most cost-effective and efficient method at attracting moderate numbers to physical activity interventions in comparison to the other methods tested. Newspaper advertisements, letterboxing, and Google AdWords were not effective. The community calendars and newspaper articles may be effective for small community interventions.

**KEYWORDS**

physical activity; web-based intervention; Internet; research subject recruitment; Facebook

**Introduction**

Recent reviews and meta-analyses have confirmed the short-term effectiveness of Web-based physical activity interventions [1-3]. However the public health impact of these interventions is dependent on how many people they reach when disseminated. It is more difficult and complex to successfully attract people to participate in Web-based health programs than may commonly be perceived. The Internet is a very competitive environment with hundreds of thousands of websites all vying to attract the attention of a potentially vast audience. To date, a range of methods have been used to attract participants to Web-based health interventions including newspaper advertisements [4], leaflets [5], email [6], and social media [7]. However, limited research has measured the cost-effectiveness of these methods [8,9].

Traditional methods including leaflets, posters, and newspaper advertisements are still commonly used by researchers and health professionals to attract people to Web-based health interventions. This is despite the growing use of Web-based methods, which have the potential to reach larger numbers at lower cost [8]. Email has been successfully used to attract specific groups such as workplace employees to Web-based health interventions when email lists are available [9]. Email is nevertheless inappropriate for a population-wide dissemination as it is becoming increasingly hard to engage people with emails that are not targeted and personally relevant, or not from a trusted source [10]. Internet banners, links on websites, social media, and search engines are popular and effective Web-based marketing methods in the commercial sector [11].

Recent studies have successfully used social media to attract adolescents and adults to nutrition, smoking, and other health interventions [12-14]. Gilligan et al [7] found Facebook advertisements to be 10 times more cost-effective at recruiting mothers of adolescents to complete a survey than traditional media. Furthermore, Morgan et al [15] found Google AdWords to be a cost-effective method for attracting adults to a depression intervention across 6 western countries. Their results also revealed that posts in forums and community notice boards were not effective. A better understanding of how the Internet can be used to attract people to Web-based health interventions will help researchers and public health workers attract large numbers to Web-based health interventions. Therefore, evaluating the cost-effectiveness of Web- and print-based methods to promote Web-based health interventions requires investigation.

Participants of Web-based physical activity interventions reached through traditional print-based methods have typically been Caucasian, female, and educated [16,17]. Internet use in Australia is currently widespread (83%); however, Internet use decreases with lower education and income [18]. It is unknown whether Web-based advertising is more effective at reaching a representative sample than print-based advertising. Facebook advertising provides the advantage of targeted advertising to assist in reaching desired sample characteristics [12,19].

Therefore, further research is required to determine the characteristics of people reached through different print- and Web-based methods for promoting Web-based health interventions.

This study aims to determine the effectiveness (in terms of cost, time investment, and numbers reached) of multiple Web- and print-based methods to attract Australian adults to a Web-based physical activity intervention. It is hypothesized that the Google AdWords and Facebook advertising will reach a larger number of people at a lower cost and time investment per sign-up than the community calendar and the traditional print-based methods.

**Methods**

The current study recorded and analyzed methods to attract people to a Web-based physical activity intervention trial in Australia. Data collection began in March 2014. The intervention itself was part of a randomized controlled trial (RCT) comparing the effectiveness (in terms of engagement, retention, and physical activity changes) of computer-tailored advice only and computer-tailored advice with a brief coaching session in an 8-week intervention. A detailed description of the intervention, measures, and study protocol has been published elsewhere [20]. Participants were excluded from the RCT if they were non-English speaking, pregnant, under 18 years of age, currently meeting the Australian physical activity guidelines (assessed by a single item, “do you currently participate in less than 30 minutes of physical activity on average each day?”), or at risk of injury or ill health from increasing their physical activity (assessed by the Physical Activity Readiness Questionnaire [21]). These criteria are stricter than typical population- or community-based physical activity interventions, so all interested participants’ data were included in the current study, regardless of their eligibility to participate in the following RCT. These numbers are more likely to reflect the effectiveness of strategies to attract people to real-world Web-based interventions that aim to sign up as many people as possible. The research has been approved by the Central Queensland University Human Ethics Committee (H13/04-044). Informed consent to participate in the study was obtained from all participants.

**Stage 1 Sign-Up**

The advertising methods were implemented in the cities of Rockhampton and Mackay, Queensland, Australia. All print-based advertisements including a newspaper advertisement, posters, and leaflets displayed the intervention logo, the CQUniversity logo, the intervention URL and a quick response (QR) code. The QR code directs people to the intervention website when they scan it with a smartphone. Readers were asked “Do you want to get healthy and fit and go in the draw to win some fabulous prizes? You are invited to participate in an online research study where you will gain free access to the ‘My Activity Coach’ program developed by CQUniversity. It will provide you with personalized advice to help you become more active.” The 10x3 cm newspaper advertisements were

printed in a local newspaper (the Morning Bulletin) that has a circulation of 20,000 in the Rockhampton region. The newspaper advertisements contained the same information as the posters and leaflets but in a more concise format, due to space restrictions. A graphic designer assisted with the design of the print advertisements.

The Web-based methods included paid advertisements targeted to Mackay residents on the social media website Facebook and on the Google search engine (Google AdWords). Advertisements were also displayed on Mackay's community websites, including the local newspaper's website (the Daily Mercury) and My Community Connect Mackay at no cost. These advertisements listed the program in the websites' event calendars. Participants could click on the calendar entry to find out more information including a link to the intervention website. The Google advertisements appeared when users searched for terms related to the intervention including fitness, healthy, physical activity, weight loss, and exercise. The Google search engine displays the advertisements that generate the largest number of clicks for each keyword searched. Therefore, each advertisement is competing against similar advertisements linked to the same keyword(s). The advertisement displayed one sentence about the program (see Figure 1) and took people who clicked on the advertisement directly to the intervention website. Multiple advertisements were trialed with different wording. The frequency of the advertisements that generated

the largest number of clicks was increased. A daily maximum spend of AUD \$10 was applied.

Facebook advertising allows clients to create an advertisement with text and a picture that can be targeted to Facebook user's demographics and interests. The advertisements can be displayed as part of the user's newsfeed, or on the right side of their newsfeed. If the Facebook users click on the feed advertisement, they will be taken to the organization's Facebook page, and if the users click on the side advertisement they will be taken directly to the organization's website. Multiple advertisements can be created within a campaign, with the option to target each advertisement to specific demographics such as age, gender, and location, and/or to people who have shown interest in certain Facebook pages. Only side advertisements were used in the current study to promote direct traffic to the intervention website. Only Facebook users who were over 18 and reside in Mackay were targeted. No additional targeting was implemented to avoid biasing the sample of people reached. Multiple advertisements were trialed with different wording and pictures. Facebook increases the frequency of advertisements that generate the largest number of clicks from the target audience. A limit of AUD \$20 per day was applied. The Facebook advertisements displayed a picture and a sentence inviting people to participate in the physical activity intervention (see Figure 2). Both the Facebook advertisements and Google AdWords were checked by an online marketing specialist.

**Figure 1.** Google advertisement.

**Figure 2.** Facebook advertisement.

## Stage 2 Sign-up

### Stage 2a

At the end of May 2014 after 2 months of promoting the intervention, only 22 people had completed the sign-up survey. To increase the number of sign-ups, the advertising methods were extended to include several other Australian towns: Bundaberg, Townsville, and Brisbane in Queensland; Melbourne (Victoria), Perth (Western Australia), and Sydney (New South Wales). The newspaper advertisements and Google AdWords that had a very high cost per sign-up were discontinued. A new method of delivering leaflets to people's homes was also implemented.

### Stage 2b

By August 15, 2014, only 61 people had completed the sign-up survey. Delivering leaflets to people's homes had a very high cost and time investment, so this was discontinued. Furthermore, no additional posters and leaflets were distributed through health care centers. The event listings in the online calendars, however, were continued as they were free and quick to implement. A news article about the program was printed in the Morning Bulletin on September 1, 2014; this was free of cost and took only 1.5 hours to arrange with the newspaper staff. The costly untargeted Facebook advertising was also discontinued. Instead,

new highly targeted Facebook advertising was implemented across Australia. From this point forward, this was the main recruitment method (see Table 1). The advertisements were targeted to gender, whereby the advertisements showed a photo of an active person of the same gender. Furthermore, in order to reach individuals most likely to be interested and with the most to gain from the intervention, individuals who had diabetes, depression, cancer, and heart disease were targeted. To do this, people who were members of Facebook pages and support groups on diabetes, depression, cancer, and heart disease were targeted. These advertisements included a statement relating to the condition the user was connected with. Finally some Facebook advertisements were shown only to individuals over 45 years of age. These advertisements displayed a picture of an active older person. Both feed advertisements that are displayed on the user's newsfeed alongside posts from their Facebook friends and groups, and side advertisements displayed on the right border of the Facebook webpage were used. Different combinations of gender, age, disease, and advertisement location were created resulting in 24 different advertisements (eg, feed advertisement targeted to males over 45 years with diabetes; Figure 3). Initially, a daily maximum spend of AUD \$5 for each advertisement was selected, but this was regularly updated by increasing the maximum daily spend for the advertisements that had the lowest cost-per click to the intervention website.

**Table 1.** Timeline of strategies used to attract people to the intervention website.

Strategies	2014										2015

**Figure 3.** Feed advertisement targeted to males over 45 years with diabetes.

## Measures

### Participant Numbers

The number of times each advertisement was displayed (impressions) were recorded for the Facebook and Google AdWords advertisements. For the newspaper advertisements, the circulation (estimated number of readers) was used as the measure of impressions. The number of first time website visits from each of the Web-based methods was recorded through Google analytics and the number of website visits for each of the 24 targeted Facebook advertisements was recorded through Facebook. After visiting the homepage, individuals were encouraged to complete a screening survey that asked participants, “how did you hear about this program?” Options included “Google search,” “Facebook,” “community calendar,” “newspaper article,” “newspaper advertisement,” “leaflet,” “letterbox drop,” “poster,” or “other.” This was used as the measure of sign-ups. Generating sign-ups is the main goal of the advertisements and is likely to reflect the number of participants reached through real-world interventions that do not have strict eligibility criteria. Participants who selected “other” were excluded from the current analysis.

### Cost

The total cost of each of the methods used to attract people to the intervention was calculated. This included the cost of a research assistant to implement each method based on the Central Queensland University rate of AUD \$35/hr. The money spent on each of the 24 targeted Facebook advertisements was also recorded through Facebook. The time spent implementing

each method was also calculated. This included the time spent planning, executing, and monitoring each advertisement.

### Demographic Characteristics

Participant demographics were assessed only for those people who signed up, were eligible, and who completed the baseline survey (140 out of 278 that signed up). The questionnaire collected participant demographics including gender, marital status, language, income, education, employment, age, body mass index (BMI), and physical activity. Total minutes of physical activity during the previous week was assessed by the validated Active Australia Questionnaire [22].

### Data Analysis

#### Data Screening

All analyses were conducted using SPSS version 20. Significance level was set at  $P < .05$ . All continuous variables were screened for outliers and normality using Fisher’s skewness coefficient. Age, BMI, and total physical activity per week were found to have a significant negative, positive, and positive skewed distribution respectively. A reflect and square root logarithm and square root transformation successfully transformed these variables into normal distributions respectively.

### Participant Numbers

The number of impressions, first time visits to the website, and sign-ups for each advertising method were calculated.

### Cost

Money spent on the recruitment method plus the hours spent implementing the recruitment method times the hourly cost of employing a research assistant (AUD \$35) was calculated and divided first by the number of website visits and second, the number of sign-ups from each recruitment method. Cost per sign-up was the main outcome measure. The time invested in each advertising method per sign-up was calculated as a measure of efficiency.

### Demographic Characteristics

The demographic characteristics of participants reached through the Web-based and print-based recruitment methods were calculated and compared using chi-square analysis for the

categorical characteristics (gender, language, marital status, employment, education, and income) and analysis of variance for the continuous characteristics (age, BMI, and physical activity).

## Results

### Participant Numbers

The strategies implemented in Stage 1 led to 59 sign-ups, and the letterboxing implemented in Stage 2a led to 18 sign-ups. During Stage 2b, the targeted Facebook recruitment led to 184 sign-ups and the newspaper article led to an additional 17 sign-ups (see Table 2 and Figure 4).

**Figure 4.** Hours per sign-up, cost per sign-up, and number of sign-ups for each advertising method.

### Cost

Two newspaper advertisements were printed, which totaled AUD \$446. A total of 8 hours was spent organizing the newspaper advertisements costing \$280 in research assistant time. In total, 1000 leaflets and 150 posters were displayed in 20 health care centers throughout Rockhampton, and 21 health care centers in Brisbane. The leaflets and posters cost AUD \$570.35 and AUD \$154 for printing respectively. A total of 24 hours were spent distributing the leaflets and posters, costing AUD \$840. Another 3500 and 1500 leaflets were delivered to homes in Rockhampton and Melbourne respectively. The printing for these leaflets cost AUD \$990. A total of 41 hours were spent delivering the leaflets, costing \$1435.

The calendar entry in the Daily Mercury's website and Mackay's My Community Connect was free of costs. However, the research assistant spent 2 hours organizing this, costing \$70. A total of AUD \$215 was spent on Google AdWords. The research assistant spent 8 hours developing, implementing, and evaluating the Google advertisements, costing \$280. Untargeted side Facebook advertisements totaled \$1228. The research assistant spent 6 hours developing, implementing, and monitoring these Facebook advertisements, costing AUD \$210. The targeted Facebook advertisements totaled AUD \$7021. The research assistant spent 20 hours developing, implementing, and monitoring these Facebook advertisements, contributing AUD \$700 to the total cost (see Figure 4).

**Table 2.** Time investment, costs, impressions, first time visits, and sign-ups of each advertising method.

	Advertising method	Time, hrs	Cost, \$	Impressions, n	Visits, n	Sign- ups, n	Time per sign-up, mins	Cost per impression, \$	Cost per sign-up, \$
<b>Web-based</b>									
	Community calendar	2	70		20	6	20		12
	Untargeted Facebook	6	1438	119,806	877	21	17	0.01	68
	Targeted Facebook	20	7721	547,507	5372	184	7	0.01	42
	Google Ad-Words	8	495	18,773	34	1	480	0.03	495
<b>Print</b>									
	Posters	12	574	–	–	11	365	–	52
	Health care leaflets	12	990	–	–	15	48	–	66
	Letterbox drop	41	2425	6000	–	18	137	0.4	135
	Newspaper ad	8	726	40,000	–	5	96	0.02	145
	Newspaper article	1.5	53	20,000	–	17	5	0	3
Total		110.5	14,492	752,086	6303	278	1175	0.08	113.11

### Demographic Characteristics

A total of 140 participants out of 278 (50.4%) completed the baseline questionnaire. The remaining 49.6% did not meet the inclusion criteria for the RCT (inactive Australian over 18 years with no health conditions that may affect their ability to safely become more active) or failed to complete the baseline questionnaire. This comparison was conducted instead of comparing all print methods to Web-based methods as there

was a large variance in effectiveness of the Web-based methods and targeted Facebook advertisements were the most effective method at reaching large numbers at low cost. People reached through the targeted Facebook advertisements were on average older and had a higher BMI than people reached through the other methods. They were also more likely to be divorced or widowed and less likely to have never married, which is likely to be due to the older age group (see [Table 3](#)).

**Table 3.** Descriptive summary of participant characteristics reached using targeted Facebook advertisements and all other methods.

Participant characteristics	Targeted Facebook (n=74)	All other methods (n=66)	Comparison
Gender, n (%)			$\chi^2=1.24, P=.27$
Males	19 (26)	12 (18)	
Females	55 (74)	55 (82)	
First language, n (%)			$\chi^2=0.26, P=.61$
English	71 (97)	66 (98)	
Other	2 (3)	1 (2)	
Marital status, n (%)			$\chi^2=6.17, P=.01$
Never married	0 (0)	5 (7)	
Married	50 (69)	46 (69)	
Divorced or widowed	23 (31)	16 (24)	
Employment, n (%)			$\chi^2=3.23, P=.19$
Full time	24 (33)	29 (43)	
Part time/casual	13 (18)	15 (22)	
Unemployed	36 (49)	23 (35)	
Education, n (%)			$\chi^2=1.55, P=.46$
Less than secondary	1 (1)	1 (2)	
Secondary	13 (18)	7 (10)	
TAFE or university	59 (81)	59 (88)	
Income, AUD, n (%)			$\chi^2=1.4, P=.50$
Over \$78,000	24 (49)	28 (50)	
\$31,200-77,999	13 (26)	19 (34)	
Under \$31,199	12 (25)	9 (16)	
Age in years, mean (SD)	59.72 (.57)	50.21 (1.24)	$F_{1,141}=57.20, P<.001$
BMI (kg/m <sup>2</sup> ), mean (SD)	32.0 (.83)	30.36 (1.04)	$F_{1,139}=5.081, P=.07$
Total physical activity (minutes/wk), mean (SD)	161.67 (22.07)	162.84 (24.19)	$F_{1,141}=0.05, P=.83$

### Targeted Facebook Advertising

The three most cost-effective Facebook advertisements at bringing people to the intervention website were (1) a feed advertisement targeting males over 45 years with diabetes, (2) a side advertisement targeting females over 45 years, and (3) a side advertisement targeting females over 18 years. The female targeted advertisements were more cost-effective per website visit than the male targeted advertisements except for the diabetes, depression, and heart-targeted advertisements. The advertisements targeted to adults over 45 years were more cost-effective per website visit than the advertisements shown to all ages. The advertisements targeted to general health were

more cost-effective as a side advertisement, while the targeted health advertisements were more cost-effective as a feed advertisement. Overall, the side advertisements were more cost-effective per website visit than the feed advertisements, except for the diabetes-targeted feed advertisement (see [Table 4](#)). The advertisements targeting females were more cost-effective than the advertisements targeting males. The advertisements targeting general health were more cost-effective than the advertisements targeting specific diseases, and the advertisements targeting adults over 45 years were more cost-effective than the advertisements targeting adults over 18 years (see [Figure 5](#)).

**Table 4.** Cost, impressions, website visits, and sign-ups for each Facebook advertisement ordered by cost per visit.

Facebook advertisement	Real cost, \$	Outcomes			Cost per outcome	
		Impressions	Visits	Sign-ups	Cost per impression, \$	Cost per visit, \$
Feed <sup>a</sup> , diabetes, male	85.49	3805	127	2	0.02	0.67
Side, health <sup>b</sup> , female	2500.92	259,992	3237	53	0.01	0.77

<sup>a</sup>Feed advertisements are displayed on the user's newsfeed alongside posts from their Facebook friends and groups, and side advertisements are displayed on the right border of the Facebook webpage.

<sup>b</sup>Health refers to advertisements that were not targeted to a physical activity related chronic disease.

**Figure 5.** Average number of visits per \$100 spent on each Facebook advertisement target.

## Discussion

### Principal Findings

The effectiveness of the Web-based strategies hypothesized to be the most effective (Facebook and Google AdWords) was highly varied. The results demonstrate the low cost-effectiveness of the Google AdWords (AUD \$495), while the targeted Facebook advertisements were the most cost-effective (AUD \$42 per sign-up) method at reaching a large number of sign-ups ( $n=184$ ). This is line with previous research demonstrating Facebook to be a cost-effective method for recruiting adolescent and young adults to nutrition and smoking interventions in Australia and North America [12-14]. The effectiveness of Facebook advertisements per sign-up may be due to the low

cost per impression and the ability to tailor advertisements to individuals who are more likely to be interested in a Web-based physical activity intervention (eg, females over 45 years). The Facebook advertisements were not as effective when the targeting was not used, confirming that the effectiveness of the Facebook advertisements is partially due to tailoring. Health professionals implementing Facebook advertising in future interventions should target the advertisements to reduce costs; however, they need to be aware that this can bias the sample reached. Researchers and public health professionals must balance cost-effectiveness with how representative the sample reached through Facebook advertising will be. On the other hand, targeted Facebook advertisements can be used to reach underrepresented demographics (eg, people with a mental health

condition) or those most in need of a physical activity intervention (eg, males, people over 45 years), but this may result in a higher cost per click. Although the Facebook advertising was the most cost-effective method at reaching moderate numbers, AUD \$42 is still too costly for population-wide dissemination of interventions. Facebook advertising may need to be used in conjunction with mass media and viral marketing strategies to be cost-effective for large-scale disseminations [23]. Overall, the findings from the current study provide evidence to support the use of targeted Facebook advertising to attract people to a Web-based physical activity intervention.

Facebook advertisements displayed on the right side panel that target females over 45 years and general health were generally more cost-effective at attracting people to the physical activity intervention website. It is not surprising that the advertisements targeted to older females are the most cost-effective as this is the demographic that is typically more interested in physical activity interventions [16,17]. In many physical activity interventions, women outnumber men 60% to 40% [1]. Furthermore, it is not surprising that the smaller side advertisements were more cost-effective than the feed advertisements. The feed advertisements resulted in more clicks per dollar spent. However, the feed advertisements take users to another Facebook page (about the physical activity intervention) and then users need to click again to go to the intervention website itself. It is therefore likely that many people were lost at this additional step. It is surprising, however, that the advertisements targeted to people who had liked Facebook pages about diabetes, heart disease, depression, or cancer were not as effective as the advertisements targeted to general health. This could be due to the people who had liked these pages not having the disease themselves. Alternatively it could be due to a small number of users fitting the target criteria, resulting in a high number of impressions made to the same people (ie, repeated displays of the same advertisement to the same uninterested users).

Participants were asked in the sign-up survey which Facebook advertisement allowed them to find out about the program. Due to 37 out of 140 participants' "not remembering" (26.4%), we did not include the analysis of cost per sign-up for each Facebook advertisement. The result of this analysis suggests that the feed advertisements targeted to specific diseases were the most cost-effective at recruiting participants. This means that more people clicked on the side advertisements per dollar spent, but many decided they were not interested after visiting the intervention website and did not sign up. On the other hand, fewer people clicked on the feed advertisements per dollar spent, but a higher percentage of these people signed up to the intervention making it the more cost-effective for achieving sign-ups. Although we cannot draw any conclusions from this data, it highlights the importance of future interventions to monitor website visits as well as sign-ups to evaluate the performance of each Facebook advertisement. Facebook now allows customers to do this by choosing a "conversion" behavior (eg, clicking on the sign-up button) to automatically track how many people from each advertisement begin the sign-up questionnaire on the website.

The high cost and low effectiveness of Google AdWords was not expected as Google AdWords is an effective marketing strategy in the commercial sector, and the advertisements were shown to people who were searching for information related to the intervention. This means that the advertisements were viewed by people more likely to be interested in physical activity and health, compared to Facebook or print-based advertisements, which are shown to people who are not searching for information on physical activity and health. Further, these findings are inconsistent with Morgan et al [15] who found Google AdWords to be a cost-effective method for attracting adults to a depression intervention across 6 western countries (\$12 per participant). The high cost of the Google AdWords for the current physical activity program could be due to a high level of competition for the AdWords used including exercise and weight loss. Google increases the frequency of the advertisements that generate the most clicks. Our Google advertisements were therefore competing against commercial weight loss and exercise-related companies in the multibillion dollar fitness industry, which are more likely to gain clicks and therefore be shown more frequently.

The newspaper article and calendar cost the least per sign-up (AUD \$3 and AUD \$12 respectively); however, they reached only a small number of sign-ups ( $n=6$  and  $17$  respectively). This is in line with the findings from Morgan et al [15], that community forums and notice boards resulted in few participants. Furthermore, it may not be possible for state- or national-wide interventions to use community forums and calendars as many accept only local events. The only forums that accepted the advertisement for the current project were in Mackay, as Mackay has a Central Queensland University campus through which the program was run. The newspaper article was easy to arrange in Rockhampton where the main campus of the university is located; however, newspapers in other towns were not interested. Although Web-based community forums and newspaper articles did not reach many people, small community interventions may benefit from these methods as they can reach a few additional people for a minimal time and monetary investment.

It is not surprising that the newspaper article and Facebook advertisements required the least amount of time investment per sign-up. The newspaper article was organized by newspaper staff at their expense, so the only time investment was contacting them about the program and answering some interview questions over the phone. The tailored Facebook advertisements can be set up online without any face-to-face meetings or need to manually distribute. Only a small time investment was required to choose appropriate figures and wording for the advertisements and to monitor and adjust them when they were running. The other advertisements needed to be distributed to health clinics (posters and leaflets), delivered to people homes (leaflets), and arranged with face-to-face meetings (newspaper advertisement). This further supports the use of targeted Facebook advertising to attract large numbers to Web-based physical interventions with a wide reach.

There are currently 12 million Facebook users in Australia [24], and the demographics of Facebook users has broadened in recent years [25]. Due to the wide reach of Facebook, Facebook

advertising has reached a representative sample of the target population in many Australian studies [7,26]. It was therefore surprising that people reached through the targeted Facebook advertisements in our study were significantly older than those reached through the other methods. This may have been influenced by the Facebook advertisements that were targeted to people over 45 years. These advertisements were displayed more frequently as they resulted in a lower cost per click. The high prevalence of chronic conditions related to physical inactivity in older adults (eg, osteoarthritis, cardiovascular disease, diabetes, and falls), and the aging population means there is a specific need for physical activity interventions that can reach older adults [27]. The finding that participants reached through targeted Facebook advertising had a significantly higher BMI than participants reached through the other methods may be due to the advertisements targeting individuals with cardiovascular disease and diabetes. It is encouraging that the findings of this study demonstrate the capability of Web-based methods at reaching people most in need of a physical activity intervention.

### Limitations

This study presents data to help researchers and public health professionals understand the cost, effectiveness, and issues surrounding different methods to attract people to a Web-based health intervention. However, the findings have limitations, including that the demographic data were collected only for participants eligible to participate in the RCT and who completed the baseline assessment. Thus, it did not include people who signed up but were not eligible. Further, to ensure enough people participated in the RCT, the amount of funds

allocated to the advertisements was continuously evaluated and directed to the more successful advertisements over the recruitment period (hence Stages 1, 2a, and 2b during the recruitment phase). Therefore, the most successful advertisement method (eg, Facebook ads) was used for longer than the non-successful advertisements (eg, Google AdWords and newspaper ads). The differences in time of year and total amount spent on different advertisement methods may have affected their success.

### Conclusion

Our findings reveal that targeted Facebook advertising is the most cost-effective method to attract moderate numbers to a Web-based health intervention while Google AdWords, despite being a popular marketing method in the commercial sector, was the least cost-effective method. However, the cost of Facebook advertisements are unsustainable for large population-based interventions that seek widespread implementation. Such interventions may need to use mass media in addition to Facebook advertising to reach larger numbers at a lower cost. Community calendars and newspaper articles were the cheapest methods; however, they reached a limited number of sign-ups. These interventions may therefore be beneficial for local community-based interventions. In summary, our findings suggest that Facebook advertising is the most cost-effective method at attracting moderate numbers to physical activity interventions in comparison to the other methods tested. However, it is still too costly for population-based interventions. Further research is needed to determine alternative recruitment procedures more effective at reaching large numbers of participants at low cost.

### Acknowledgments

SA conducted the data collection, carried out the data analysis, and drafted the manuscript. CJ, RP, and CV played a significant role in establishing the study design and drafting the manuscript. ## Abstract

**Background:** Internet interventions may have an important role to play in helping self-quitters maintain an initial period of abstinence. Little is known about the characteristics and utilization patterns of former smokers who use Internet cessation programs.

**Objective:** The overarching aim of this preliminary study was to establish the feasibility of a subsequent randomized trial of the effectiveness of Internet interventions in preventing relapse. Specifically, this study sought to determine the number of former smokers that register on a smoking cessation website, the characteristics of former smokers and their website utilization patterns, and potential predictors of sustained abstinence.

**Methods:** Participants were self-identified former smokers who registered on a free smoking cessation website. Recruitment occurred immediately following site registration. Participants completed Web-based baseline and 1-month follow-up assessments. Website utilization metrics were extracted at 1 month. Descriptive statistics were used to characterize the full sample. Baseline differences were examined between recent quitters ( $\leq 7$  days of abstinence at enrollment) and more established quitters (8+ days of abstinence at enrollment) using chi-square tests and *t* tests. Univariate logistic regression examined demographic, smoking, psychosocial characteristics, and website utilization metrics as predictors of 1-month abstinence.

**Results:** During the 10-month study period, 1141 former smokers were recruited to participate: 494 accepted the invitation, 395 were eligible, 377 provided informed consent, and 221 completed the baseline and fully enrolled (56% of those eligible). At 1 month, 55.7% (123/221) of participants completed the follow-up survey. Mean age was 44.25 years (SD 12.78) and the sample was primarily female (174/221, 78.7%), white (196/221, 88.7%), and had at least some college education (177/221, 80.1%). Slightly more than half of participants (123/221, 55.7%) reported quitting more than a week prior to website registration and 43.9% (97/221) had quit within 7 days of registration. The website features most likely to be used were an interactive Quit Date tool (166/221, 75.1%) and the Community (134/221, 60.6%). Univariate regression models showed that recent quitters, those with higher motivation to remain abstinent, and those who used cessation medication in the past year were more likely to use the Community. Older age, longer duration of abstinence at registration, better health status, and health care provider advice to quit were associated with 1-month abstinence. Website utilization metrics did not predict abstinence, though odds ratios suggested higher utilization was associated with greater odds of abstinence.

**Conclusions:** This exploratory study demonstrated the feasibility of recruiting former smokers to a research study and documented the uptake of an Internet cessation intervention among this group of self-quitters. Results also showed higher levels of website utilization and greater likelihood of community use among smokers early in their quit attempt compared to those with a longer period of abstinence at enrollment. Important areas for future research include identifying former smokers who may be more susceptible to relapse and determining which components of an Internet intervention are most helpful to prevent relapse in the early and later stages of a quit attempt.

**KEYWORDS**

smoking cessation; Internet; relapse prevention

**Introduction**

Identifying strategies to prevent relapse among the millions of smokers that attempt to quit each year remains a public health priority [1]. In 2012, 52.9% of smokers attempted to quit smoking, yet each year, only 5-7% of smokers are able to maintain abstinence for more than 6 months [2]. The majority of smokers relapse within several weeks after a quit attempt [3-6]. Despite decades of research on relapse prevention, a 2013 Cochrane systematic review of 63 studies found little support for the effectiveness of behavioral interventions delivered face-to-face or telephonically, or for pharmacological interventions [7]. As tobacco control policies continue to drive increased quit attempts [8], novel relapse prevention efforts are needed to increase the likelihood that these efforts translate into successful long-term cessation [9].

Internet interventions may be uniquely suited to provide relapse prevention approaches for smoking cessation as they are broad-reaching [10,11], cost-effective [12], and may appeal to individuals who would otherwise not seek cessation counseling. The Internet is a primary source of health information for a majority of adults [13] and is often the first place many people turn to when faced with a health-related question or concern [14]. A timely, on-demand intervention after a smoking lapse is a critical element of an effective relapse prevention approach [15] and one that other treatment modalities like face-to-face and telephonic interventions may be unable to provide. The 24/7 availability of Internet interventions and their ability to surmount geographic and other barriers to treatment use make them a powerful channel through which to address relapse at the time when support is most needed.

In addition, Internet interventions for smoking cessation commonly include social media and Web 2.0 applications that facilitate the exchange of information and support between and among users [16]. Real-time social support from current and former smokers may provide precisely the kind of encouragement, inspiration, and “road-tested” practical advice that former smokers need to prevent relapse [17]. High levels of social support have been associated with better cessation outcomes in a number of studies [18-20], and low levels of support have been conceptualized as a barrier to abstinence [21]. Few studies have examined the role of “offline” social support for relapse prevention [7], and only two studies to our knowledge have explored the impact of online social support through Internet cessation interventions. Schwarzer and Satow [22] found that recent quitters who posted the number of days they had been abstinent in an online bulletin board were less likely to relapse than those who did not post. In addition, posting more messages was associated with a greater likelihood of maintaining abstinence. The authors posited that making one’s intentions to quit visible to an online community may strengthen an individual’s commitment to quit and that active engagement naturally results in continued contact with others, being reminded of one’s intention to quit, and potentially receiving praise. Selby et al [17] found that among individuals who posted

within an online cessation community, the most common type of first posts were help-seeking messages from recent quitters who were struggling to remain abstinent. In this study, we were specifically interested in exploring whether use of an online community for smoking cessation was associated with lower rates of relapse among former smokers.

Internet interventions have shown promise for relapse prevention in mental health and addiction treatment [23,24], and several studies within smoking cessation suggest that there is demand for and utilization of online cessation resources among recent quitters. A study by Borland et al [25] sought to examine the impact of a Web-based intervention among current smokers and recent quitters (defined as quit for <4 days) but did not report outcomes by baseline smoking status. Interestingly, approximately 25% of participants screened for this smoking cessation study reported they had already quit smoking. Similarly, a 2006 study by Cobb and Graham [10] found that 24% of individuals searching for smoking cessation information on the Internet had quit smoking: 17% had quit within the previous 7 days, and 7% had quit more than 7 days prior. In an observational study of the Australian Web-based cessation program “QuitCoach,” Balmford et al [26] found that return visits were most common among those who had just quit when they registered on the site and lowest among those not planning to quit.

These studies and others [11,27,28] suggest that Internet interventions may have an important role to play in helping those who have already quit to maintain an initial period of abstinence or to extend their abstinence. However, to date, few studies have documented the extent to which former smokers use Internet cessation programs or their effectiveness in preventing relapse. The goals of this preliminary study were to explore the feasibility of conducting a randomized trial to evaluate the effectiveness of Internet interventions in preventing relapse. Specifically, we sought to address the following questions: (1) Is it feasible to recruit former smokers to a research study, and what is the monthly recruitment volume?, (2) What are the characteristics of former smokers that register on an Internet smoking cessation website?, (3) How do former smokers utilize an Internet cessation program?, and (4) Are there baseline variables or website utilization metrics that predict a former smoker’s ability to maintain abstinence?

**Methods****Participants**

Participants were individuals who registered on a free smoking cessation website and selected “former smoker” when asked about smoking status (options were “current smoker,” “former smoker,” or “looking for help for someone else”). The only other eligibility criteria were age 18 years or older and US residence, which were gathered during website registration. The study invitation was presented immediately following website registration. Eligibility screening, informed consent, and the baseline survey were administered online. Immediately

following the baseline survey, participants were directed back to the website where they were able to use the site as they desired; there were no additional interventions provided. At 1-month post-registration, participants were asked to complete an online survey to assess smoking status and other related variables. Participants received three email prompts for follow-up survey completion and were offered a US \$20 incentive. The study protocol received human subjects protection approval from Copernicus Group Independent Review Board.

## Intervention

BecomeAnEX is a free smoking cessation website developed and managed by Truth Initiative (formerly American Legacy Foundation) in partnership with the Mayo Clinic Nicotine Dependence Center [11,29]. Consistent with the 2008 Public Health Service Clinical Practice Guideline for Treating Tobacco Dependence [1], BecomeAnEX provides (1) problem-solving and skills training designed to enhance self-efficacy, (2) information and guidance in selecting and using FDA-approved smoking cessation pharmacotherapies, and (3) intra-treatment social support in the form of a large online community. BecomeAnEX guides and supports smokers through the process of planning and preparing to quit through the following interactive features: (1) a Quit Date tool that assists users in selecting a prospective quit date or documenting a retrospective quit date, (2) a Cigarette Tracker exercise to identify smoking triggers, (3) a Beat Your Smoking Triggers exercise (Separation exercise) to identify strategies to dissociate cigarettes from triggers, (4) a Build Your Support System exercise (Support exercise) to identify helpful supporters, (5) a Choose a Quit Smoking Aid exercise (Addiction exercise), in which users indicate their plans for pharmacotherapy use, and (6) Community, which is a large online network of thousands of current and former smokers who communicate through a variety of channels (eg, blog posts/replies, wall posts, private messages). In addition to these interactive features, the site contains static content to prepare for quit day, cope with slips, and prevent relapse; videos about addiction and medication; and a checklist (My Quit Plan) that displays whether each of the site's core components has been used and recommends next steps. The site can be browsed anonymously, but to save information or post content in the Community, visitors must register. To register on BecomeAnEX, individuals must agree to the site's Terms of Use and Privacy Policy. The Privacy Policy makes clear that (1) BecomeAnEX automatically collects information about its users and their use of the site, (2) information is used for research and quality improvement purposes only, and (3) personal information is kept confidential. BecomeAnEX has been promoted through a national multimedia campaign since 2008 [11], with more recent promotional activities focused on paid search advertising that targets current smokers.

## Data Collection and Measures

Data sources for these analyses included (1) a Web-based survey administered at baseline, (2) a Web-based survey administered at 1-month post enrollment, and (3) 1-month website utilization metrics obtained via automated tracking software. Demographic variables included age, gender, race, education, employment, and marital status.

Abstinence-related questions asked when participants decided to quit smoking, their quit date and confidence about the accuracy of that date, and the date of their last puff of a cigarette. These questions were used to calculate the number of days they had been abstinent when they registered on BecomeAnEX. The Abstinence Related Motivational Engagement Short Form (ARME) [30] was administered to assess motivation to remain abstinent. This scale consists of 5 Likert items (1=completely disagree to 7=completely agree): (1) I try to anticipate and prepare for any challenges to being smoke-free (vigilance), (2) The thought of being a nonsmoker still excites me (excitement), (3) At this time, I am still very excited by the idea of being smoke-free (excitement), (4) I spend a great deal of time thinking about becoming or staying smoke-free (cognitive effort), and (5) I am carefully watching out for things that might put me at risk for smoking (vigilance). The short form has demonstrated adequate reliability ( $\alpha=.82$ ) and has been correlated with length of abstinence [31].

Smoking history questions asked about the number of quit attempts made in the past year, and the use of behavioral (books/pamphlets, individual/group counseling, telephone quitline, Web-based interventions), pharmacologic (nicotine patches, gum, lozenges, nasal spray and inhaler, Zyban, Chantix), and alternative (e-cigarettes, switching to chew or snuff, switching brand or cutting back, acupuncture, hypnosis, herbal/laser/other alternative methods) quit methods during the past year. Reports of using "willpower/cold turkey" or "prayer" were coded as unassisted quit attempts.

Health history items included current health status (excellent, very good, good, fair, poor; [32]), history of an illness caused or made worse by smoking (yes/no), and whether the participant had received advice to quit smoking from a health care provider in the past year (yes/no).

Psychosocial measures assessed "offline" social support as potential influences on online Community use. They included the Appraisal and Belonging subscales of the 12-item Interpersonal Support Evaluation List [33], which is a general measure of perceived social support. The Appraisal subscale measures the perceived availability of someone to talk to about one's problems, and the Belonging subscale measures the perceived availability of people one can do things with. Each subscale contains four statements that participants indicate are definitely true, probably true, probably false, or definitely false. One item from the UCLA Loneliness Scale [34] was administered, which asked how often the participants felt that there were people they can turn to (1=Never, 4=Always).

Internet and social media use were assessed with items that asked about frequency and duration of Internet use [35] and frequency of communication with other people via the Internet (eg, via blogs, instant messaging, forums) [36].

Website utilization data were obtained via Adobe Analytics software [37], a customizable Web analytics tool that is used to monitor, report on, and optimize use of the BecomeAnEX website. General utilization metrics examined in this study included number of return visits following website registration, total number of minutes spent on the site, and the number of pages viewed. Data were also extracted on the use of the six

interactive features described above. Because website utilization typically shows a steep attrition curve [38-43], we focused on utilization metrics during the first month following site registration.

Smoking abstinence at 1-month post enrollment was measured as 7-day and 30-day point prevalence abstinence.

### Statistical Analyses

Descriptive statistics were examined to characterize former smokers on sociodemographic variables, smoking history, health status, and psychosocial measures. We also examined baseline differences between recent quitters ( $\leq 7$  days of abstinence at enrollment) and more established quitters (8+ days of abstinence at enrollment) using chi-square tests and *t* tests. Our decision to use 7 days as a cut-point was largely an empirical one. Relapse is most common within the first week after a quit attempt, and prior analyses have shown that the largest proportion of Internet cessation treatment users that self-identify as former smokers report quitting within the past 7 days [3,10,44]. Previous studies of relapse prevention interventions have varied widely in terms of abstinence-related inclusion criteria [45]. Our intent was to determine if there were distinguishing characteristics based on length of abstinence at program enrollment that might suggest that a subsequent effectiveness study should focus specifically on recent quitters.

Website utilization patterns were examined using descriptive statistics. The full sample was characterized, and comparisons between recent quitters and more established quitters were explored. Means and standard deviations were computed for general website utilization variables and compared using two-sample *t* tests. Given that general website utilization data were positively skewed, the median and interquartile range are also reported and differences examined using the Wilcoxon Mann Whitney test.

To identify characteristics of participants who used the Community, univariate logistic regression models examined baseline demographic, smoking history, and psychosocial variables. To identify predictors of 1-month abstinence, univariate logistic regression models examined the association between 30-day abstinence and baseline characteristics (demographic, smoking history, psychosocial measures), website utilization metrics (return visits, time on site, Community use),

and other treatment utilization (behavioral interventions, medication use, alternative methods). Statistical significance for all analyses was set to an alpha of .05. Analyses were performed using SPSS version 21 and SAS software version 9.3.

## Results

### Recruitment and Follow-Up Results

Between November 15, 2012, and September 17, 2013, a total of 1141 consecutive registered users who identified as former smokers were recruited to participate in the study: 494 accepted the invitation, 395 were eligible, 377 provided informed consent, and 221 completed the baseline survey and fully enrolled (56% of those eligible). This represents an available pool of approximately 114 former smokers per month from which to recruit and a recruitment rate of approximately 22 participants per month. At 1-month post registration, 55.7% (123/221) of participants completed the follow-up survey. Survey non-respondents were more likely to have a high school degree or less (OR 2.68, 95% CI 1.35-5.30) and to be black/African American (OR 4.26, CI 1.14-15.97). One-month follow-up attrition was significantly correlated with website utilization. Specifically, those with fewer site visits, time on site, and number of page views were also more likely to be lost to follow-up (all ORs 1.76,  $P < .04$ ).

### Baseline Characteristics of Former Smokers

Table 1 shows the demographic, smoking history, and psychosocial characteristics of the full sample of former smokers. Mean age was 44.25 years (SD 12.78), and the sample was primarily female (174/221, 78.7%), white (196/221, 88.7%), college educated (177/221, 80.1% reporting some college or more), employed full or part-time (149/221, 67.4%), and married or living with a partner (135/221, 61.1%). Two thirds (148/221, 67.0%) reported having an illness either caused or made worse by smoking, and 69.7% (154/221) had been advised to quit by a health care provider in the past year. The average score for ARME was high (mean 29.51, SD 5.69), with the two “excitement” items (“thought of being nonsmoker still excites me,” “I am still very excited by the idea of being smoke-free”) yielding the highest mean values (mean 6.1, SD 1.5 for both items).

**Table 1.** Baseline characteristics of former smokers by number of days quit at enrollment.

Slightly more than half of participants (123/221, 55.7%) were “more established quitters” (days abstinent at registration: mean 358.8, SD 1504.9, range 97-13) and 43.9% (97/221) of the sample were “recent quitters” (days abstinent at registration: mean 3.1, SD 2.0, range 7). One respondent did not provide valid date-based quitting-related responses and the length of their quit at registration is unknown. Recent quitters were younger (mean 40.39, SD 11.82 vs mean 47.33, SD 12.76,

$P<.001$ ) and had higher scores on the ARME (mean 30.46, SD 4.89 vs mean 28.75, SD 6.18,  $P=.03$ ) than more established quitters. No other baseline differences were observed.

### One-Month Website Utilization Patterns and Predictors of Community Use

Website utilization metrics are presented in Table 2. During the first month after registration, participants made an average of

6.61 return visits to the site (SD 17.79; median 2.00), spent 115.69 minutes on the site (SD 433.42; median 28.27), and viewed 82.00 pages (SD 228.33; median 32.00). The most commonly used features were Set a Quit Date (75.1%) and Community (60.6%). There were significant differences between recent quitters and more established quitters across a number of utilization metrics. Recent quitters made more return visits (median 3.00, interquartile range (IQR) 2.00-6.00 vs median 2.00, IQR 1.00-3.00,  $P=.01$ ), spent more time on the site (median 42.33, IQR 18.30-75.90 vs median 25.37, IQR 11.90-39.50,  $P=.02$ ), and viewed more pages (median 39.00, IQR 18.00-88.00 vs median 26.00, IQR 9.00-45.00,  $P=.05$ ), compared to more established quitters. Recent quitters were also more likely than more established quitters to set a quit date on the site (87.6% vs 65.9%,  $P<.001$ ), to visit the Community (70.1% vs 53.7%,  $P=.01$ ), and to engage in the Community both passively (read blog posts: 19.6% vs 8.1%,  $P=0.01$ ) and actively (wrote a blog post: 13.4% vs 4.9%,  $P=.03$ ; wrote on message boards: 10.3% vs 2.4%,  $P=.01$ ; sent private messages: 8.3% vs 2.4%,  $P=.05$ ).

### Predictors of Abstinence

Univariate regression analyses showed that several baseline characteristics were predictive of 1-month abstinence (see Table 3). Older age (OR 1.23, CI 1.05-1.40), self-identification as a more established quitter (OR 4.61, CI 1.87-11.41), better health status (OR 2.59, CI 1.07-6.30), and being advised by a health care provider to quit in the past year (OR 2.25, CI 1.00-5.07) were associated with increased abstinence, whereas 7 or fewer days of abstinence at registration was associated with lower odds of 1-month sustained abstinence (OR 0.17, CI 0.07-0.40). General website utilization metrics (number of return visits, time on site) and community use did not emerge as significant predictors of abstinence, though odds ratios suggested that higher levels of utilization were associated with increased abstinence.

## Discussion

### Principal Findings

This study is one of the first to characterize a sample of former smokers that registered on an evidence-based Internet smoking cessation program, document their website utilization patterns, and explore the factors that predicted maintenance of an initial period of abstinence. Over the 10-month study period, 1141 former smokers registered on the site. This is noteworthy given that all promotional efforts describe the site as a smoking cessation intervention for current smokers. Promotional efforts that specifically appeal to recent quitters may attract an even larger audience, as our data demonstrate that an online cessation program is of interest to recent quitters looking for information and support. The study enrollment rate is comparable to several recent large-scale Internet cessation trials [25,46] and demonstrates the feasibility of recruiting former smokers to participate in research.

In general, this was a sample of very recent quitters, nearly half of whom had quit within the past week and who were very motivated to maintain this initial period of abstinence. Two-thirds reported having an illness caused or made worse by smoking and having been advised by a health care provider to

quit smoking. Participants had made multiple quit attempts in the past year, and the majority had used medication and alternative quit methods during these quit attempts. These characteristics paint a picture of middle-aged smokers who had experienced multiple failed quit attempts using other treatment strategies but who were still engaged in the process of quitting. That the sample was largely female is consistent with reports that women are more likely than men to seek health care information online [13].

Self-identified former smokers were not a homogeneous group when it came to website utilization patterns. Recent quitters (ie, those who had quit in the last week) returned to the site more often, viewed more pages, and spent more time on the site than more established quitters (ie, those who had quit more than a week ago). They were also more likely to use the quit date feature and to participate in the Community both actively and passively. These differences may signal the more precarious nature of their abstinence and the need for different type of guidance and support than those who are more established in their quit. It is noteworthy that of all the website features examined, the most consistent patterns of differences emerged in use of the online Community. Additional research to understand the nature of the posts that former smokers make in blogs and on message boards may help inform more tailored treatment strategies specifically designed for recent quitters versus more established quitters.

Approximately a third of participants who completed the follow-up survey indicated that they had returned to smoking at 1 month. Older age, longer duration of abstinence at enrollment, better health status, and having received advice from a health care provider to quit smoking were predictive of abstinence. These findings suggest that it may be possible to identify former smokers at higher risk for relapse using baseline characteristics, which is consistent with previous research [47]. More intensive or directed intervention for former smokers at greater risk of relapse—potentially leveraging the constant availability of online community support—may be a fruitful line of inquiry for future research.

### Limitations

This study has several limitations. First, the wide confidence intervals in several of the univariate analyses point to small cell counts for several variables. This was a feasibility study primarily designed to determine the available pool of participants for a subsequent trial and to characterize this understudied group of website users. Future research with a larger sample is needed to confirm some of the preliminary associations we have identified. Second, given the exploratory nature of the study, we did not control for the number of statistical analyses conducted so as not to miss important potential relationships. This approach may have increased the likelihood of Type I error. Third, as this was an exploratory study, univariate logistic regression results are unadjusted and the associations noted in the results section may not persist if appropriate adjustments are made. Fourth, assessing abstinence at 1-month post registration provides only an early peek at the potential effectiveness of an Internet intervention in preventing relapse. Studies with a longer-term follow-up are needed to

assess the extent to which the early signals of intervention effect are sustained over time. Finally, slightly more than half the sample was reached for follow-up. Although this degree of attrition is common in Internet-based studies [48], it may have resulted in an overestimate of the proportion of participants who were abstinent in responder-only analyses and may limit the generalizability of these findings. However, our use of automated tracking data ensured that we captured the full extent of website utilization during the study period.

## Conclusion

Our findings suggest that the Internet may be a promising delivery channel for relapse prevention intervention and highlight several important areas for future studies. Additional research should focus on identifying recent quitters who may be more susceptible to relapse and determining which specific aspects of a Web-based intervention are most helpful to recent quitters in preventing relapse. Optimizing Internet interventions to help recent quitters maintain an initial period of abstinence may yield significant benefits for reducing the prevalence of smoking.

## Acknowledgments

## Abstract

**Background:** Text messaging (short message service, SMS) has been shown to be effective in delivering interventions for various diseases and health conditions, including smoking cessation. While there are many published studies regarding smoking cessation text messaging interventions, most do not provide details about the study's operational methods. As a result, there is a gap in our understanding of how best to design studies of smoking cessation text messaging programs.

**Objective:** The purpose of this paper is to detail the operational methods used to conduct a randomized trial comparing three different versions of the National Cancer Institute's SmokefreeText (SFTXT) program, designed for smokers 18 to 29 years of age. We detail our methods for recruiting participants from the Internet, reducing fraud, conducting online data collection, and retaining panel study participants.

**Methods:** Participants were recruited through website advertisements and market research online panels. Screening questions established eligibility for the study (eg, 18 to 29 years of age, current smoker). Antifraud measures screened out participants who could not meet the study requirements. After completing a baseline survey, participants were randomized to one of three study arms, which varied by type and timing of text message delivery. The study offered US \$20 gift cards as incentives to complete each of four follow-up surveys. Automated email reminders were sent at designated intervals to increase response rates. Researchers also provided telephone reminders to those who had not completed the survey after multiple email reminders. We calculated participation rates across study arms and compared the final sample characteristics to the Current Population Survey to examine generalizability.

**Results:** Recruitment methods drove 153,936 unique visitors to the SFTXT Study landing page and 27,360 began the screener. Based on the screening questions, 15,462 out of 27,360 responders (56.51%) were eligible to participate. Of the 15,462 who were eligible, 9486 passed the antifraud measures that were implemented; however, 3882 failed to verify their email addresses or cell phone numbers, leaving 5604 who were invited to complete the baseline survey. Of the 5604 who were invited, 4432 completed the baseline survey, but only 4027 were retained for analysis because 405 did not receive the intervention.

**Conclusions:** Although antifraud measures helped to catch participants who failed study requirements and could have biased the data collected, it is possible that the email and cell phone verification check excluded some potentially eligible participants from the study. Future research should explore ways to implement verification methods without risking the loss of so many potential participants.

## KEYWORDS

tobacco use cessation; text messaging; clinical trial; survey methods; cell phones; telemedicine

## Introduction

Text messaging (short message service, SMS) has been shown to be effective in delivering interventions for various diseases and health conditions, including smoking cessation. There are many similarities in the design of existing text-based cessation interventions. Kong et al [1] conducted a narrative review of 15 text-based smoking cessation interventions and found that all based their motivational messages in cognitive behavioral and social cognitive theories focused on self-efficacy, with roughly half of the interventions tailoring the message content according to baseline questionnaire responses. All studies recruited participants who indicated that they were willing to quit smoking, and seven of the programs recruited young adults 18 to 29 years of age. The reviewed interventions varied in duration and format. All interventions included text messages to participants during the active quit phase, which ranged from 1 to 13 weeks; 10 interventions also included a preparation phase (ranging from 1 to 4 weeks) before the participant reached his or her quit date, and 8 included a maintenance phase during which the number of text messages received decreased over time. Similarly, the number of text messages varied by intervention, from nine messages per day to three per week, with increased frequency during the active quit period. Eleven of the interventions reviewed specifically offered or informed participants about other cessation treatments, including support through email, websites, self-help booklets, and medication, to supplement the text messaging intervention.

When developing smoking cessation studies, researchers also look to previous studies to answer questions pertaining to how study participants should be recruited, what type of data collection strategy would work best for a smoking cessation text messaging program, how frequently the data should be collected, what kind of incentive (if any) should be used, what type of antifraud methods should be used, how long recruitment should last, what response and retention rates can be anticipated, and what level of follow-up is required to retain participants through all data collection activities.

While the review by Kong et al provided details about the key elements of text messaging programs, it did not provide clear answers to these specific issues; however, it did synthesize the general methods used in the 15 studies that were reviewed. This review indicated that recruitment strategies for text-based cessation interventions most frequently used online venues (eg, Google, Facebook, Craigslist; [2-4]), although Free et al [5] reported use of a wide variety of recruitment methods, including radio, billboards, newspapers, and cessation service providers. Kong et al found that data collection tended to be conducted online [3-5] with secondary options including phone [5] and text message [4]. Very few studies reported offering a financial

incentive for data collection efforts. Ybarra et al [4] offered US \$10 to \$20 for completion of post-quit follow-up surveys, but they did not discuss fraud that may have occurred as a result of this financial incentive. Reviews and individual studies often do not provide the details about the operational methods used, and do not highlight the lessons learned from using these methods, resulting in a gap in our understanding of how best to design studies of smoking cessation text messaging programs.

## Study Objective

While some studies provide a general description of study methods, most do not provide the details about operational methods used to conduct a study. The purpose of this paper is to detail the operational methods we used to conduct a randomized trial comparing three different versions of National Cancer Institute's (NCI) SmokefreeText (SFTXT) program (Clinical Trials.gov NCT01885052). In particular, we detail our methods for recruiting participants from the Internet, reducing fraud, conducting online data collection, and maintaining the panel of over 4000 study participants.

## Rationale for the Study

This study was developed to compare three different versions of NCI's SFTXT program, which is designed for smokers 18 to 29 years of age. The current SFTXT program (available at NCI's smokefree.gov website [6]) is an 8-week text messaging program that includes 2 weeks of preparatory messages before a participant's quit date and 6 weeks of motivational support messages after a participant's quit date. For this study, we assigned a quit date 2 weeks post-baseline, as opposed to the real-life application of SFTXT that allows users to choose their own quit date. Program data indicated that 34.1% of participants dropped out of the program within one week after their chosen quit date. Given these data, NCI was interested in determining whether a modified program focusing only on preparatory messages and quit-day support messages would be as effective as the full program. NCI also wanted to determine how these high-intensity motivational messaging programs compared with a low-intensity program that provided only quit date reminders and smoking status check-in messages. Three different versions of the SFTXT program were tested using a randomized three-arm longitudinal study design. The number of texts received varied by study arm, with Arm 1 participants receiving 11, Arm 2 participants receiving 40, and those in Arm 3 receiving a total of 127 text messages. Participants received a variety of types of texts depending on their group assignment. Examples of the types of texts included quit date reminders, tips on staying smoke-free, motivational messages, facts about smoking cessation, mood assessments, and others. The authors can be contacted for a full description of the study, including

details about the intervention components of all three SFTXT programs tested.

## Methods

### Recruitment Goal and Power

To determine the sample size needed to conduct this study, we performed a power analysis [7] assuming a 32% predicted smoking abstinence rate and a 60% wave-to-wave attrition rate. The analytic goal was to detect a 5% difference between any two arms within the experimental design with 80% power and a two-sided test. This power analysis yielded a conservative baseline recruitment size of 4248 (1416 per arm) and a minimum sample size of 435 participants per arm to complete all five surveys.

### Recruitment Methods

#### Advertisements

SFTXT Study participants were recruited from June 26, 2013, through January 8, 2014, using a series of online strategies. Advertisements were posted on Facebook, Craigslist, and Pandora, along with search ads on Google, Yahoo!, and Bing. Additionally, market research firms emailed announcements about the study to their online panel members who smoked, and were within the eligible age group. Individuals who clicked on an SFTXT Study advertisement were directed to a 10-question screener to determine study eligibility.

#### Eligibility Criteria

To be eligible to participate in the study, individuals had to (1) be aged 18 to 29, (2) live in the United States, (3) have smoked on at least 5 of the past 30 days, (4) be at least moderately interested in stopping smoking within the next 30 days, and (5) not be seeking cessation services elsewhere. Given that all study communication was conducted via email or by text message, participants needed to have an active email address and agree to receiving up to 130 messages over 8 weeks on their mobile phones. Only one family member per household was eligible to participate in the study, as determined by a question on the screener questionnaire, and verified using an automated Internet Protocol (IP) address duplication check. Participants could not have a close friend who was already participating in the study. Finally, to be eligible, individuals had to be willing to share their contact information.

Eligible individuals completed an online consent form and were required to provide their email address (entered twice) and mobile phone number, and give permission for the study team to use the email and phone number to send surveys and leave reminder messages. Eligible individuals were also asked for an alternate phone number, but could participate in the study without providing one. Ineligible individuals were asked to complete a four-question exit survey that included demographic questions about sex, race/ethnicity, and education level.

#### Email and Text Verification

To confirm contact information, participants responded to an email verification request and a text message verification request before receiving the baseline survey. This procedure also

verified that a participant could receive both emails and text messages for the study.

#### Incentives

To keep participants engaged in the study, we initially offered a choice of an Amazon or iTunes electronic gift card as an incentive for completing each of the five surveys. We conducted an initial pilot study for 2 weeks in July, 2012. Within the first few days of this pilot, we noticed that similar email addresses were being used to enroll participants. For example, an enrollee might have entered Jane.Doe@gmail.com, and shortly thereafter we would find a similar email address, such as JDoe@gmail.com. Upon investigation, we discovered that the system we created to check for duplicate emails or phone numbers was not working properly. To verify that the second case was associated with the first, we examined the IP addresses from the two cases to see if they were identical. We identified 105 duplicate or fraudulent enrollees, and these cases were notified by email that they were terminated from the study. We stopped the study for 16 days to fix the system for duplication checks, and added more antifraud measures, which are described below. We also decided to stop incentivizing the baseline survey. Instead, we only incentivized the four follow-up surveys at US \$20 per survey.

#### Antifraud Measures

To ensure the integrity of the SFTXT Study sample, multiple antifraud measures were implemented within the screener instrument to prevent two types of behaviors: (1) eligible participants enrolling multiple times in the SFTXT Study (presumably) to obtain multiple incentives (US \$20 for completion of each of the four follow-up surveys), and (2) previously ineligible individuals reenrolling and changing their responses to be within the eligibility criteria.

Our antifraud process included the following measures:

- **CAPTCHA.** CAPTCHA is a technique used to verify that a person, and not a computer, is accessing the website. A common type of CAPTCHA asks a user to type letters or numbers that appear in a distorted image on the screen. This task is very difficult for a computer to perform, making it an effective way to verify that a person is on the other end of the transaction.
- **Honesty pledge.** An honesty pledge can be implemented at the start of a survey to attempt to improve data quality. Users are asked to acknowledge that they intend to answer the survey truthfully. Results from a recent study presented at the American Association of Public Opinion Reporting (AAPOR) suggested that these types of pledges can help reduce the occurrence of straightlining, question skipping, and other types of fraud [8].
- **Hosting the survey on a secure site.** With a secure site, only those with a password can gain access. This mechanism reduces the likelihood that a participant could tell their friends to take the survey to collect incentives. To access each survey, participants needed to enter the username and password that was sent to them with the link to the follow-up surveys.

- *Conducting rigorous data cleaning.* The cleaning process looked for straightlining, anyone completing the survey in an extremely short amount of time, and other such indicators.
- *Duplication checks.* The antifraud process included automated duplication checks of phone numbers, email addresses, and IP addresses. If duplicates were detected, the individual was excluded from the study. To ensure that no lapses occurred in antifraud prevention, retroactive duplication checks were implemented by linking cases to one another through the contact information and IP addresses, which helped to ensure the sample's validity.

## Data Collection

Once participants completed the verification process, they were invited to participate in the study. Study data were collected at five time points: baseline, 3 weeks post-baseline (7 days post-quit date), 8 weeks post-baseline (6 weeks post-quit date), 20 weeks post-baseline (18 weeks post-quit date), and 32 weeks post-baseline (30 weeks post-quit date). Additionally, upon completion of the baseline survey, participants were randomly assigned to one of the three study arms. A quit date was set at 2 weeks after completion of the baseline survey for all study participants.

Participants were invited to complete each survey via an email with a link to the study website. Participants could complete the survey at one time or could save their partial responses and complete the survey later. Participants were required to take the baseline and 3-week follow-up survey within 14 days of the initial email invitation and within 36 days for the 8-week, 20-week, and 32-week surveys, and were classified as survey non-respondents if they did not do so. These participants, however, remained in the study and were invited to complete the remaining questionnaires. Participants who had not completed a survey were emailed reminders on the third, fourth, fifth, sixth, and tenth day after the invitation was sent. If a participant still had not completed a survey, a staff member telephoned them as a final reminder before expiration of the 2-week window for taking the survey.

## Panel Support and Maintenance

To support the study, project team members answered participants' questions about the study via email and telephone. The majority of participant questions focused on the verification process, missing login information, and requests to have incentive gift codes re-sent. This process enabled participants to update their contact information and receive answers to questions regarding existing survey invitations and incentives, which helped to ensure that the intervention was implemented as designed.

Participants were allowed to withdraw from all or parts of the SFTXT Study at any time, including the 2-week period before the assigned quit date. Participants who texted "STOP" in the 2 weeks before the assigned quit date were opted out of the study entirely and received no future text messages or follow-up survey invitations, as they would not have received the intervention. Participants who texted "STOP" after the assigned quit date no longer received the text messages but continued to

receive follow-up survey invitations and were still considered study participants. These individuals could still opt out entirely if they contacted the study director to leave the study completely.

## Statistical Analysis

To be considered a study participant, an individual needed to meet all eligibility criteria, complete the verification process, and complete the baseline survey. Individuals were defined as *verified* if they provided informed consent, pledged to give honest responses, provided an email address and phone number, and verified their contact information. For the baseline survey to be considered complete, individuals needed to respond to essential questions (eg, smoking history, demographics). To assess differences between arms for response and retention rates, we conducted significance testing based on a chi-squared test for differences between Arms 1 and 2, Arms 1 and 3, and Arms 2 and 3. To calculate the response rate for the baseline survey, we used the AAPOR [9] RR6 formula with *noncontact* and *other* set to zero.

## Results

### Participant Recruitment

Participants were recruited over 196 days. Figure 1 presents the steps involved in recruiting and determining the eligibility of study participants, and the number retained and excluded at each step, beginning with initial visits to the SFTXT landing page where the study screener was located. There were 153,936 unique visitors to the landing page, or 785 visits per day on average.

Of those 153,936 unique visitors, 27,360 (17.77%) began the screener. Based on their responses to the screener, 15,462 of 27,360 visitors (56.51%) met the study's eligibility requirements. Failure to provide informed consent excluded 3428 of the 15,462 eligible participants (22.17%). Antifraud measures excluded 2548 of 12,034 participants who provided informed consent (21.17%): 576 (4.79%) refused the honesty pledge, 1312 (10.90%) did not provide contact information, and 660 (5.48%) failed the duplication checks, leaving 9486 of the 15,462 eligible participants (61.35%) who had both consented and passed the antifraud measures. Another 3882 of 9486 (40.92%) eligible participants were sent a verification code; however, they failed to verify their email address and phone number and were excluded based on this requirement.

The remaining 5604 respondents were sent an invitation to complete the baseline survey; 1172 of 5604 respondents (20.91%) did not complete this survey and were excluded from the study. Participants (405 of 4432, 9.14%) were also excluded if they did not receive the intervention. For example, 233 of 4432 faced technical difficulties (eg, undelivered text messages). Participants who texted "STOP" at any point *before* their quit date (n=150) were excluded because they had not received an essential part of the intervention (ie, messages on their quit date) and, depending on the study arm, may have received less than half of the text messages. A small number of participants (n=22) opted out of the study entirely by notifying the project team, typically via email. Those who texted "STOP" after the quit date were retained in the analytic sample.

## Final Sample

A total of 4,027 participants were retained for analysis, including participants who texted STOP *after* their quit date ( $n=236$ ), as they had received the essential quit date messages and most of the intervention at that point. The frequency of texting “STOP” messages sent after the quit date was significantly higher in Arm 3 (153/236) than in Arm 1 (54/236) or Arm 2 (29/236) and significantly higher in Arm 1 than in Arm 2. Of these participants, 41 responded to a survey question asking why they opted out of receiving further text messages, with the majority (51%, 21/41) reporting that there were too many texts or that

the texts were bothersome. Others stated that the texts did not help them quit smoking (10/41), or that they had stopped trying to quit (6/41).

## Response and Retention Rates

Verified and consented individuals (5604 of 9486 eligible participants) were invited to take the SFTXT baseline survey, and 4027 participants subsequently completed it and were retained for analysis (see Table 1). This sample size, which excludes participants who completed the baseline survey but were ultimately dropped from the analytic sample, equates to a response rate of 71.86% (using the AAPOR RR5 formula [8]).

**Table 1.** Response rates by recruitment stage and study arm ( $n=153,936$ ).

Response rate for recruitment stage	Overall		Arm 1		Arm 2		Arm 3	
	n	%	n	%	n	%	n	%
Unique visits to project websites	153,936		—		—		—	
Initiated screener/initiation rate	27,630	17.77	—		—		—	
Completed screener/screener rate	26,057	94.31	—		—		—	
Eligible	15,462	59.34	5041	32.60	5307	34.32	5114	33.07
Verified (baseline survey invitation)	5604	36.24	1828	32.62	1902	33.94	1874	33.44
Completed baseline survey <sup>a,b</sup>	4027	71.86	1313	32.60	1400	34.77	1314	32.63

<sup>a</sup>An AAPOR [9] RR6 formula was used for the calculation, with *noncontact* and *other* set to zero.

<sup>b</sup>Includes all cases retained for analysis.

Retention rates for each follow-up survey were calculated for the analytic sample ( $n=4027$ ; Table 2). Approximately 56.67% (2282/4027) of participants completed all four follow-up surveys, and 19.99% (805/4027) did not complete any of the follow-up surveys. Within each study arm and across arms, retention rates tended to decline as the weeks between baseline and follow-up increased. For example, the retention rate for the 3-week follow-up survey was 74.72% (3009/4027), whereas the retention rate for the 32-week follow-up survey declined to 64.64% (2603/4027). The lowest retention rates in the 3-week and 8-week follow-up surveys were in Arm 1, whereas the

lowest retention rates in the 20-week and 32-week follow-up surveys were in Arm 3.

For the 3-week follow-up, Arm 2 had a significantly higher retention rate than Arm 1 ( $P=.01$ ). There were no significant differences between arms at the 8-week and 20-weeks follow-ups. For the 32-week follow-up, Arm 2 had a significantly higher retention rate than Arm 3 ( $P=.03$ ). Arm 1 was significantly more likely than Arm 2 not to complete any follow-up surveys ( $P=.01$ ). Arm 2 was significantly more likely than Arm 3 to complete all follow-up surveys ( $P=.05$ ).

**Table 2.** Retention rates ( $n=4027$ ).

Follow-up survey	Overall ( $n=4027$ )		Arm 1 ( $n=1313$ )		Arm 2 ( $n=1400$ )		Arm 3 ( $n=1314$ )	
	n	%	n	%	n	%	n	%
3-week	3009	74.72	949	72.28	1071	76.50	989	75.27
8-week	2881	71.54	925	70.45	1024	73.14	932	70.93
20-week	2675	66.42	866	65.96	957	68.36	852	64.84
32-week	2603	64.64	846	64.43	933	66.64	824	62.71
Completed no follow-up surveys	805	19.99	292	22.23	256	18.29	257	19.56
Completed all follow-up surveys	2282	56.67	746	56.82	818	58.43	718	54.64

The proportion of participants who completed each survey on the day the invitation was emailed was highest for the baseline survey (56.16%, 3147/5604) and lowest at the 32-week

follow-up survey (22.80%, 918/4027), as shown in Table 3. Email and telephone reminders boosted the response rate for all five surveys.

**Table 3.** Percentage of the overall sample completing survey by prompt and data collection point (n=4027).

Percent complete	Baseline	3-week	8-week	20-week	32-week
Day invitation sent	56.2	30.9	31.8	24.1	22.8
Day after invitation sent	5.6	8.9	9.0	8.0	7.9
Single email reminder <sup>a</sup>	1.1–2.1	3.8–7.9	1.4–4.7	2.5–5.6	2.3–7.0
Single phone reminder	0.8	3.0	2.6	3.2	2.9

<sup>a</sup>Four email reminders were sent for each survey.

## Representativeness of the Sample

**Multimedia Appendix 1** presents the demographic and smoking history characteristics for the SFTXT analytic sample compared with population estimates from the January, 2011 Current Population Survey (CPS), the most recent survey data available with detailed cigarette smoking information [10]. CPS data are weighted, so counts are not displayed. To create the SFTXT population within CPS, the CPS data were subset down to individuals 18 to 29 years of age who smoked five or more cigarettes per day. The SFTXT sample was predominately female (70.15%, 2825/4027), whereas the CPS population had a more equal distribution of females and males. Compared with the CPS population, the SFTXT sample included more highly educated participants (25.4% vs. 17.3% with a college degree or more), but fewer participants that were employed full-time (39.7% vs. 62.1%). Household income and race/ethnicity characteristics were similar between SFTXT and CPS. In terms of smoking history, the SFTXT sample contained a higher proportion of individuals who tried to quit smoking at least once in the past year (73.8%) compared with the CPS population (60.9%). Average scores on the Heaviness of Smoking Index were higher in the SFTXT sample than in the CPS population, indicating higher nicotine dependence levels among SFTXT participants. **Multimedia Appendix 1** also displays demographic and smoking history characteristics within each study arm of the SFTXT sample. These characteristics did not differ significantly by study arm.

## Discussion

### Principal Findings

When designing this study, we reviewed past studies of smoking cessation text messaging interventions to determine what methods had been successfully used in the past. Unfortunately, few studies provided details about study implementation and the effectiveness of strategies that were used to recruit, retain, and manage study participants and reduce fraudulent entry into the study. Our results help to fill these gaps.

Through online advertising, this smoking cessation study resulted in 153,936 visits to the study's landing page, of whom 27,360 screeners initiated, and 4027 participants were recruited. Antifraud measures prevented, at a minimum, 2448 people from enrolling. Another 3882 respondents were excluded from participating because they did not validate both their email and phone number when sent the verification requests. Of the 4027 participants recruited, 64.64% (2603/4027) were retained across four follow-up waves that extended to 32-weeks

post-intervention. Results from our examination of the effectiveness of the enrollment, data collection, and antifraud methods used in this study can be used to inform the methods and procedures developed for future studies. Although the effectiveness of every procedure we used cannot be quantified, we offer the following suggestions based on experience conducting this study.

First, the online advertising and other recruiting efforts were effective in driving more than 150,000 people to the study website, with over half meeting the eligibility criteria. When compared with CPS data, a higher proportion of our sample was female and had higher levels of educational attainment. However, study participants were heavier smokers and had previously tried to quit in the past year, likely because of our eligibility requirement that participants must be at least moderately interested in quitting.

While the total sample was slightly smaller than our target goal of 4248, our retention rates were higher than anticipated, with 56.67% (2282/4027) completing all four follow-up surveys. We had initially planned for approximately 60% attrition over the four waves of follow-up, for a total of 40% completing the final follow-up survey.

The reason for this higher than expected retention rate may have been the incentive of the US \$20 Amazon or iTunes gift cards offered for completion of each follow-up survey. Future studies could use smaller incentive amounts to see if they would be equally effective in retaining the sample. We recommend incentivizing only follow-up surveys; offering an incentive for a baseline survey that is recruiting participants through online advertising seemed to invite people to attempt to enter the study more than one time so they could get additional gift cards.

Retention rates differed by arm, with Arm 2 having higher retention rates than Arm 1; this result is not entirely unexpected because Arm 2 received significantly more text messages than Arm 1. However, the amount of communication received does not solely explain differences in retention rates by arm, as Arm 3 received significantly more messages than Arm 2. This finding may indicate a threshold for the amount of messaging that keeps participants engaged in both the intervention and the study. In this case, Arm 1 may have been below that threshold while Arm 3 exceeded that threshold.

Multiple email reminders to encourage participants to complete each survey may have positively affected completion rates for each survey. While we are unable to disentangle the effect of these reminders from the effect of the incentives, our findings suggest that the additional email reminders and the single phone

reminder resulted in a small percentage of participants completing a survey, especially for the 32-week follow-up survey, while a single email reminder appears to have prompted 7.0% of the sample to complete that survey. We recommend that researchers who are conducting longitudinal online surveys use multiple email reminders over time to encourage participants to complete each survey.

To receive an invitation to complete each survey, having a correct email address for each participant was necessary. For studies such as this one, we recommend requiring participants to enter their email address two times and programming the data collection instrument to continue only if both email addresses match. However, additional procedures may be needed to ensure that those who are eligible do not have any other barriers to participation. In the overall recruitment process, the largest number of potential participants lost was during phone number and email verification. This number represented a large proportion of the otherwise eligible sample (40.92%, 3882/9486) and, although we sent an email reminding participants to complete the verification process, if their email address was problematic, they would not have received the reminder. Future studies could use both phone and text-based reminders, and should explore other ways to prevent such loss. Without additional research, it is difficult to know all of the possible reasons for so many unverified cases. It is plausible that potential participants did not receive or notice the verification email and/or text, or felt it was too burdensome to go through that process. Others may simply have forgotten. Regardless of the reasons for their dropout, these individuals were known to be eligible and had provided contact information. Additional research could help to determine whether email or phone information is inaccurate, or if reminders to verify (or instructions emphasizing the simplicity of the verification procedures) can help to reduce the number of participants who do not complete the process. In addition, researchers should be mindful of such instances during the recruitment phase, because this type of sample loss incurs unnecessary costs to the recruitment effort.

Previous Internet studies of smoking cessation have found some respondents to be fraudulent [2]. The antifraud procedures we established allowed us to identify more than 5000 cases that

would have been included in the dataset otherwise. Thus, we were able to screen out participants who may have continued to provide bad or duplicate data, and enhance the overall quality of the dataset. The results of this study add further evidence to growing literature that suggests antifraud measures can help deter some respondents who otherwise might have provided less complete or invalid data [8].

## Limitations

Compared with CPS data, our sample was more likely to be female, younger, more educated, heavier smokers, and more likely to have tried quitting in the last year than the general population of smokers 18 to 29 years of age. CPS data did not ask how motivated smokers were to quit, leaving us unable to determine if our sample was more motivated than the general population of smokers 18 to 29 years of age; being moderately interested in quitting was a study requirement. Consequently, the results cannot be generalized beyond this specific sample. Our findings are limited, because we did not design our study to determine the effectiveness of individual study procedures (eg, email reminders, phone reminder, incentives) in retaining participants. Future studies could be designed to conduct experiments to compare these methods.

## Comparison with Prior Work

Our results detail specific methods used to conduct an online longitudinal study of a text-based smoking cessation intervention. Other studies have reported on outcomes, but to date, no other studies provide detailed information about the effectiveness of the operational methods used to conduct the studies.

## Conclusions

The methods described here helped the project team to recruit an overall sample of more than 4000 smokers for the study. Antifraud measures helped to catch participants who tried to collect multiple incentives or were unable to verify their phone numbers or email addresses. This step may have resulted in loss of potentially eligible sample members, but may have contributed to higher retention rates than we originally projected. This tradeoff is a lesson for future studies. Additional research should explore more efficient ways to conduct such verification without risking the loss of so many potential respondents.

## Acknowledgments

Janice Tzeng, Sidney Holt, Marjorie Margolis, and Brittany Zulkiewicz (all with RTI International) helped manage the day-to-day operations of the study, select and track antifraud measures, and manage data collection and documenting implementation of the study. Venkat Yetekuri programmed all data collection instruments, developed and implemented antifraud measures and study processes, and managed data collection.

## Authors' Contributions

Authors (in alphabetical order) all reviewed this manuscript. Erik Augustson (NCI) was the project officer for the study, which RTI International conducted in collaboration with, and on behalf of, NCI. He was responsible for determining the study design, reviewing all data collection instruments, and reviewing the draft and final versions of the manuscript. Derick Brown (RTI International) conducted quality assurance checks of all data, conducted all analyses, and wrote parts of the methods and results sections. Jill Dever (RTI International) oversaw the development and write-up of the study methods and data analyses, and wrote sections of the introduction. Suzanne Dolina (RTI International) wrote the introduction section, parts of the methods section, and

reviewed and provided feedback on all other sections of the manuscript. Bridget Kelly (RTI International) wrote parts of the methods section, the discussion section, and reviewed and provided feedback on all other sections of the manuscript. Sarah Parvanta (RTI International) wrote the abstract, study objectives, and parts of the results. She reviewed and provided feedback on all other sections of the manuscript. Brian Southwell (RTI International) served as a senior advisor on the project and reviewed and provided feedback on the manuscript. Linda Squiers (RTI International) directed the study and coordinated writing, reviewing, and editing of all sections of the manuscript, as well as creation of tables and figures. She also wrote parts of the introduction, methods, results, and discussion sections. Amy Sanders was responsible for overseeing the recruitment of subjects, working with the text messaging vendor, and reviewing the manuscript.

## Conflicts of Interest

None declared.

## Multimedia Appendix 1

Demographics of SFTXT analytic sample compared with Census estimates, overall and by study arm (n=4027).
