Abstract

Background: The recognition of serious pathologies affecting the musculoskeletal (MSK) system, especially in the early stage of a disease, is an important but challenging task. The prevalence of such serious pathologies is currently low. However, in our progressing aging population, it is anticipated that serious pathologies affecting the MSK system will be on the rise. Physiotherapists, as part of a wider health care team, can play a valuable role in the recognition of serious pathologies. It is at present unknown how accurately Austrian qualified physiotherapists can detect the presence of serious pathologies affecting the MSK system and therefore determine whether physiotherapy management is indicated (keep patients) or not (refer patients to a medical doctor).

Objective: We will explore the current ability of Austrian qualified physiotherapists to recognize serious pathologies by using validated clinical vignettes.

Methods: As part of an electronic web-based survey, these vignettes will be distributed among a convenience sample of qualified Austrian physiotherapists working in a hospital or private setting. The survey will consist of four sections: (1) demographics and general information, (2) the clinical vignettes, (3) questions concerning the clinical vignettes, and (4) self-perceived knowledge gaps and learning preferences from the perspective of study participants. Results will further be used for (1) international comparison with similar studies from the existing literature and (2) gaining insight into the participants' self-perceived knowledge gaps and learning preferences for increasing their knowledge level about keep-refer decision-making and detecting serious pathologies.

Results: Data collection took place between May 2022 and June 2022. As of June 2022, a total of 479 Austrian physiotherapists completed the survey. Data analysis has started, and we aim to publish the results in 2023.

Conclusions: The results of this survey will provide insights into the ability of Austrian physiotherapists to make accurate keep-refer decisions and to recognize the presence of serious pathologies using clinical vignettes. The results of this survey are expected to serve as a basis for future training in this area.

Introduction

We live in an aging society. The forecasted increase in the number of people older than 65 years from currently 34.4% to 59.2% by 2070 for the entire area of the European Union will pose great challenges for the health care systems of the European Union member states [1]. A very high increase in health care expenditure is to be expected [1]. In view of the challenges of an aging society, measures are being sought to cope with the increased pressure on the health care system in the future. One measure to relieve the burden on hospitals and to be able to provide the most efficient care for patients, the establishment of primary care units, is currently being propagated in Austria [2]. The core idea of primary care units is that patients are managed in a team consisting of general practitioners and different nonphysician health care professionals (such as nurses, physiotherapists, speech therapists, and occupational therapists) [2]. The expansion of primary health care in Austria is in line with the recommendations of the World Health Organization, which highlights that even though some musculoskeletal (MSK) conditions may require more specialist or surgical management, most conditions of the MSK system can readily and effectively be managed in a primary care setting [3].

MSK conditions that often present with pain and restricted mobility are highly prevalent within the general population [3]. In 2016, low back pain, for instance, was the leading cause of years lived with disability for men in 133 of 195 countries and for women in 104 of 195 countries [4].

Recent data from Denmark demonstrated that the overall prevalence of serious pathologies affecting the MSK system is at present comparatively low (2.3%) [5]. For instance, the prevalence of malignant neoplasms affecting the MSK system was 1.13% [6]. These figures are consistent with those from previous studies that reported a prevalence of metastatic spinal cancer as a serious cause of low back pain below 1% in primary care [7-10]. Another example is osteoporotic spinal fractures. The prevalence of osteoporotic fractures as a cause of vertebral pain in primary care ranges between 0.13% and 0.7% [5,9] but can be as high as 5% in a predominantly older study population [10]. In a progressively aging society, the number of people developing a serious pathology is likely to rise in the future. There is a clear link between advanced age and many cancers [11] such as prostate, lung, bowel, and breast cancer [12,13]. The significance of prostate, lung, thyroid, kidney, and breast cancer is that they account for 80% of all osseous metastases [14]. In addition, 80% of all fractures in women older than 50 years are caused by osteoporosis. One in 2 women and 1 in 5 men over the age of 50 years will experience an osteoporotic fracture [15].

The recognition of serious pathologies affecting the MSK system especially in the early stage of a disease is a challenging task [16]. However, early diagnosis is essential because this significantly improves prognosis and outcomes [16]. It is well known that especially in early stages (prodromal period), there are (if any) few or very vague/nonspecific signs and symptoms of a serious pathology [17]. However, as the disease progresses, these signs and symptoms become more obvious. Physiotherapists work very closely and sometimes over a prolonged period with their patients. They are therefore well suited to monitor the clinical situation of their patients (watchful waiting) [18] and repeatedly screen them for the occurrence or presence of specific signs and symptoms (red flags) that might indicate the presence of a serious pathology. Red flags can become apparent during the interview, physical examination, or treatment of a patient.

To analyze clinical decision-making abilities of medical and other health professionals, researchers make use of clinical vignettes that are concise paper-based or electronic descriptions of actual clinical situations [19]. Vignettes simulate real patients with various ailments and a wide range of different, sometimes complex, symptoms. Based on the clinical descriptions within such vignettes, clinicians are asked to decide about either examination procedures, (differential) diagnosis, or possible treatment options [20]. An additional advantage of vignettes is that they can be easily distributed among a large number of clinicians even with different educational backgrounds or from divergent health care settings [20,21].

Previous cross-sectional studies on qualified physiotherapists in the United States [22-26], Germany [27], Switzerland [28], Denmark [6], on Doctor of Physical Therapy students in the United States [29], and on European final year undergraduate physiotherapy students [30] have raised some concern about the physiotherapists' ability to decide when physiotherapy is indicated (keep), or not (refer), and their ability to accurately detect the presence of serious pathologies based on clinical vignettes. Having said this, numerous case studies and case series within the literature highlight that physiotherapists can become key in the detection of serious pathologies in a clinical setting [31,32].

The ability of Austrian qualified physiotherapists to accurately detect serious pathologies and to determine if a patient is suitable for physiotherapy, or rather needs a more comprehensive medical workup, has not yet been explored. Considering the above-outlined changes to the Austrian health care sector and challenges of an increasingly aging society, this knowledge gap needs to be addressed. To fill this knowledge gap, we propose a cross-sectional web-based survey using validated clinical vignettes [6].

The overall aim of this study is to assess the ability of Austrian qualified physiotherapists to make accurate keep-refer decisions and their ability to detect serious pathologies affecting the MSK system based on 12 clinical vignettes. In addition, we want to explore potential knowledge gaps and learning preferences to acquire more expertise in making keep-refer decisions from the perspective of study participants.

Methods

Overview

The Methods, Results, and Discussion sections will adhere to the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) statement [33].

Ethics Considerations

The project was formally examined by the Commission for Scientific Integrity and Ethics of the Karl Landsteiner Private University, and it was found that in accordance with the set criteria, a further review by the commission was not required (project number: 1021/2022, date April 20, 2022). There were no medical ethical concerns about the conduct of the project.

Eligibility Criteria

To be included in this study, prospective participants need to (1) be registered as qualified physiotherapists with the Austrian Health Professions Registry and (2) work in a hospital or private setting in Austria. Physiotherapists who have not actively treated patients during the last 12 months will not be eligible for this study.

Recruitment Process

The email addresses of physiotherapists registered on the Austrian Health Professions Registry and with a publicly available email address have been collected. The recruitment process will be divided into the recruitment of physiotherapists working in a private setting and physiotherapists working in a health institution.

In the first part, physiotherapists who are working as private physiotherapists will be sent an email with an explanation of the study and a link to take part in the survey. If needed, after 2 weeks, the email will be re-sent to remind physiotherapists of the study.

In the second part, the multidisciplinary team leaders (n=44) of each health institution in Austria will be sent an email with information about the study and will be asked to provide information on the number of physiotherapists currently working for the institution and indicate if they are interested in taking part in the study. If interested, a new email will be sent to the multidisciplinary team leaders containing a link to forward to the physiotherapists to take part in the study.

When the link is activated, the physiotherapists will be taken to a website on the Unipark platform. Information regarding the research aim, eligibility criteria, and the anonymous nature of the study will be available. Consent will be given when participants accept the consent form and click on the “next” button.

Sample Size Calculation

On March 15, 2022, a total of 16,991 physiotherapists were registered on the Austrian Health Professions Registry. Given this population, 376 physiotherapists need to be recruited to retain a 95% CI with a margin of error of 5% [34].

Data Collection Tool

The survey will be constructed on the internet using the web-based survey tool Unipark. It will take 15 to 20 minutes to complete the whole survey. A copy of the survey, except the 12 translated vignettes, is provided in Multimedia Appendix 1.

The survey consists of four sections:

1. Demographic features of participants, for example, age, sex, working experience, and educational level.
2. Twelve vignettes, translated from English to German. After reading each clinical vignette, participants will be asked to decide if this is (a) an MSK condition, which does not need referral to a medical doctor (keep); (b) a noncritical medical condition, which needs referral to a medical doctor, while the patient can be treated by a physiotherapist (keep-refer); and (c) a critical medical condition, which needs immediate referral to a medical doctor and treatment by the physiotherapist should be stopped (refer). The vignettes (used with permission) have been validated by a panel of medical doctors and expert physiotherapists [6].
3. Feedback will be sought from participants on the 12 vignettes. Questions will be asked on
   - how difficult (on a Likert scale from 1 to 5) it is to make keep-refer decisions based on the information presented in the vignettes,
   - the relevance of the vignettes for everyday work (on a Likert scale from 1 to 5), and
   - possible missing information within the vignettes for making accurate keep-refer decisions (open-ended question).
4. Exploration of knowledge gaps and learning preferences to acquire more expertise in making keep-refer decisions and detecting serious pathologies from the perspective of study participants. Questions will be posed on
   - the confidence of participants to conduct clinical examination procedures (such as cranial nerve testing, reflex testing, and auscultation of blood vessels)
   - if participants are interested in learning more about keep-refer decision-making
   - suggestions for content and format of future training sessions to acquire more expertise in keep-refer decision-making (such as learning medium and environment/setting, teaching contents, and educational strategies)
   - any further suggestions and comments (open-ended question).

Pilot Testing

The first draft of this survey was sent to 5 physiotherapists and 4 medical doctors. Participants were asked to comment on their general understanding of the questionnaire and the appropriateness, comprehensibility, and proper sequencing of individual questions. In addition, the participants in the pilot could suggest additional questions that they deemed valuable. For an example, one participant suggested adding a question where future participants will be asked about their confidence in conducting clinical examination procedures (eg, cranial nerve testing) that might be relevant for clinical and keep-refer

XSL•FO
RenderX

decision-making. Another suggestion was to add a question that could aid with the inclusion and exclusion criteria. Participants were therefore, right at the beginning of the survey, asked if they have treated patients during the last 12 months. If the participants answer this question with "no," they will be thanked for their interest and then will automatically be prevented from continuing with the survey. The validity of some of the vignettes in the Austrian health care system was also questioned; therefore, after elaborate discussions, the originally envisioned vignettes by Jette et al [23] were replaced by the more current vignettes of Budtz et al [6]. The feedback from the pilot was collected and incorporated into the existing survey.

Data Management and Analysis

The survey will be constructed online, and progression through the 12 vignettes will be mandatory so that an answer must be entered before one being able to continue. This will allow only completed clinical vignettes to be included in the analysis. Completed surveys will be automatically sent back to the online survey tool Unipark. The data will be stored at the QuestBack server park in Bremen, Germany. After the data collection is completed, the raw quantitative data will then be downloaded onto an SPSS file (IBM SPSS Statistics 28.0). The qualitative data will be exported to a Word document and then imported to a MAXQDA project (MAXQDA 2020). All data will be stored on a secure OneDrive folder to which only the researchers have access through their password protected laptops. The survey will be designed to be completely anonymous; however, there is a small risk that participants will share personal data in the open-ended question in the last section of the survey. If this happens, these data will be anonymized by a member of the research team.

Individual participants' responses for each of the 12 vignettes will be classified as either being correct (Yes) or incorrect (No). Replicating previously used methodology [6,23,25,27-30], definitions of correct answers are as follows:

- For the MSK vignettes: treat the patient without the need for medical referral (keep) or treat the patient with additional medical checkup (keep and refer, also called watchful waiting).
- For the medical noncritical vignettes: choose to start physiotherapy with additional medical evaluation (keep and refer) or refer the patient without physiotherapy management (refer).
- The sole correct answer for medical critical vignettes is sent the patient for medical evaluation without physiotherapy management (refer).

Once the data collection period is finished, the quantitative data will be checked for completeness and outliers. Missing data will be labeled. The Shapiro-Wilk test will be used to examine if the data are normally distributed. If values are normally distributed, the mean (with SD) will be calculated; if not, the median (with IQR) will be calculated. All descriptive statistics, such as age, sex, years of experience as a physiotherapist, and type of expertise, will be collected as categorical data, and the percentage for each category will be calculated.

In the clinical vignettes, the mean percentages (plus SD) of correct keep-refer decisions and actual numbers as well as percentages of participating physiotherapists who manage to accurately answer all vignettes from a specific category will be calculated (MSK vs medical noncritical vs medical critical) [6,23,25,27-30]. If it is not normally distributed, the median percentages with IQR will be presented.

The questions concerning the feedback from study participants on the 12 vignettes, such as "how sure the participants were when answering the clinical vignettes?" and "how relevant the vignettes were for the participants?" will be calculated as percentages for each category.

The questions concerning learning about red flags, such as interest for red flags training, medium of training, and interest of specific assessment techniques, will also be listed as percentages for each category.

The 2 open-ended questions concerning missing information in the clinical vignettes and any other remarks will be analyzed deductively using framework analysis [35] in MAXQDA. The predefined codes were in line with the diagnostic physiotherapeutic process [36]: referral, medical history, and physical examination. Recurrent remarks on additional information, which could help the participants with their clinical decision-making, will be coded and combined into categories to inform the next phase of the study: the development of educational clinical case studies for physiotherapists.

Results

The distribution of the survey took place between May 2022 and June 2022. As of June 2022, a total of 479 Austrian physiotherapists completed the survey. It is anticipated that data collection, analysis, and writing up for a potential publication in a peer-reviewed journal will take 4 to 6 months.

Discussion

Study Strengths

A major strength is that our methodology is in line with previously published studies [6,23,25,27-30]. In addition, we use validated clinical vignettes (with permission) that have already been used in previous research [6,23,25,27-30]. This will give us the opportunity for international comparison.

To the best of our knowledge, this is the first study that examines the ability of Austrian physiotherapists to make accurate keep-refer decisions and to recognize the presence of serious pathologies using clinical vignettes. Moreover, this is the first attempt to explore potential knowledge gaps and learning preferences to acquire more expertise in making keep-refer decisions and recognizing the presence of serious pathologies from the perspective of Austrian qualified physiotherapists. These results will be used to inform future training in this field and should help advance patient safety and interdisciplinary collaboration within the Austrian health care system.

XSL•FO
RenderX

Study Limitations

During the preparation of the study the aim was to collect the email addresses of all physiotherapists currently registered to work in Austria. However, from the private physiotherapists not all email addresses were retrievable on the internet, and 50% of the population will not be contacted. This could have implications on the generalizability of the study.

The limitations of clinical vignettes as a sole instrument for examining clinical decision-making strategies of health care professionals have previously been highlighted [37-39]. However, vignettes have the advantage that they can be distributed to a large pool of potential participants relatively quickly and at low cost. Our approach is in line with previous research using similar methodology [6,22,23,25,27-30]. The participants in this study will have the opportunity to provide feedback on the vignettes, which will be used to develop vignettes validated for the Austrian context.

Acknowledgments

The project team would like to thank the Gesellschaft für Forschungsförderung Niederösterreich m.b.H. (GFF) for the funding provided to carry out the project.

Data Availability

We are aiming to deposit the quantitative data in a GitHub repository.

Abstract

Background: Accidental awareness during general anesthesia (AAGA) is defined as an unexpected awareness of the patient during general anesthesia. This phenomenon occurs in 1%-2% of high-risk practice patients and can cause physical suffering and psychological after-effects, called posttraumatic stress disorder. In fact, no monitoring techniques are satisfactory enough to effectively prevent AAGA; therefore, new alternatives are needed. Because the first reflex for a patient during an AAGA is to move, but cannot do so because of the neuromuscular blockers, we believe that it is possible to design a brain-computer interface (BCI) based on the detection of movement intention to warn the anesthetist. To do this, we propose to describe and detect the changes in terms of motor cortex oscillations during general anesthesia with propofol, while a median nerve stimulation is performed. We believe that our results could enable the design of a BCI based on median nerve stimulation, which could prevent AAGA.

Objective: To our knowledge, no published studies have investigated the detection of electroencephalographic (EEG) patterns in relation to peripheral nerve stimulation over the sensorimotor cortex during general anesthesia. The main objective of this study is to describe the changes in terms of event-related desynchronization and event-related synchronization modulations, in the EEG signal over the motor cortex during general anesthesia with propofol while a median nerve stimulation is performed.

Methods: STIM-MOTANA is an interventional and prospective study conducted with patients scheduled for surgery under general anesthesia, involving EEG measurements and median nerve stimulation at two different times: (1) when the patient is awake before surgery (2) and under general anesthesia. A total of 30 patients will receive surgery under complete intravenous anesthesia with a target-controlled infusion pump of propofol.

Results: The changes in event-related desynchronization and event-related synchronization during median nerve stimulation according to the various propofol concentrations for 30 patients will be analyzed. In addition, we will apply 4 different offline machine learning algorithms to detect the median nerve stimulation at the cerebral level. Recruitment began in December 2022. Data collection is expected to conclude in June 2024.

Conclusions: STIM-MOTANA will be the first protocol to investigate median nerve stimulation cerebral motor effect during general anesthesia for the detection of intraoperative awareness. Based on strong practical and theoretical scientific reasoning from our previous studies, our innovative median nerve stimulation–based BCI would provide a way to detect intraoperative awareness during general anesthesia.

intraoperative awareness; brain-computer interfaces; median nerve stimulation; electroencephalography; general anesthesia

Introduction

Unexpectedly awakening during surgery is a terrifying experience for patients, who fear it, but also for the medical staff, who are worried that the situation may occur under their supervision [1]. This type of phenomenon is called an accidental awareness during general anesthesia (AAGA) [2]. Although its origin is still debated, the reasons and factors favoring AAGA are being studied. This phenomenon appears if the depth of anesthesia, induced by the concentration of anesthetic used, is not deep enough to compensate for all the surgical stimuli related to the operation in progress. The role of the anesthetist is to succeed in inducing an altered state of consciousness, which is complexly intertwined with analgesia and amnesia. Indeed, if the anesthesia is too light, it may result in recovery of consciousness and volitional movement during the operation, which would be very dangerous for the patient [3]. Conversely, if too much anesthetic agent is given, it increases the depth of anesthesia but may lead to problems such as adverse cardiovascular effects, postoperative delirium, and cognitive impairment, increasing the probability of mortality during surgery [4]. Finally, an anesthetic overdose may also increase the symptoms of postoperative nausea and vomiting and thus delay the patient's discharge from the hospital [5].

The rate of AAGA in high-risk practices (eg, obstetric, cardiac, and thoracic) varies from 1% to2% [6]. Considering that hundreds of millions of general anesthesia are performed each year worldwide, new solutions to better prevent this phenomenon are needed [7,8]. AAGA can also cause physical pain [2] and lead to psychological sequelae called posttraumatic stress disorder [1-3], which can last for several years and have severe psychological effects leading to suicide [9,10]. From the economic impact perspective, AAGAs generate direct costs because it is one of the top 3 causes of complaints against hospitals (>US $43,000 per claim) [2,3,11] and indirect costs from the expenses related to the follow-up and psychological support of the patient who has experienced an AAGA. There are currently 2 procedures to monitor the depth of anesthesia based either on the observation of the clinical features (eg, heart rate, temperature, blood pressure, and movement) or electroencephalographic (EEG) analysis. Unfortunately, the first one does not prevent AAGA during surgery may be because such clinical signs observations remain a very indirect way of monitoring the patients' cerebral state not always enabling the anesthesiologist to predict an AAGA before it occurs [12]. Although new devices based on frontal EEG activity indexes are already in use, the studies demonstrating the superiority compared to clinical surveillance or end-tidal anesthetic gas [13-16] are not conclusive. Moreover, several studies consent to the use of BIS as it has been shown that the predictive accuracy is decreased when using neuromuscular blockers [1].

The patients' testimonies show that the first reaction during an AAGA is usually to move to alert the medical staff [2,17]. Unfortunately, during most surgeries, the patient is curarized, which causes neuromuscular block and prevents any movement. Detecting movement intention (MI) is possible by analyzing EEG signals from the motor cortex with a brain-computer interface (BCI). This is based on previous evidence demonstrating that simple MIs are characterized by power spectrum variations (ie, event-related (de)-synchronization called ERD/ERS) in the EEG mu (7-13 Hz) and beta (15-35 Hz) bands over the motor cortex [18] and that electrical stimulation of the median nerve also induces changes in the cortical activity [19,20], which are visible in the EEG signal and which are similar to an MI [21,22]. Interestingly, our preliminary results suggested that when a hand MI coincides with median nerve stimulation (MNS), the ERD/ERS is considerably reduced, and thus the MI can be detected much better by machine learning techniques than an MI without MNS [23-26]. The originality of this BCI paradigm is to exploit this MNS-induced phenomenon to accurately detect the patient's motor intention during an AAGA. Based on these previous results, we envisage a routine procedure where the anesthetized patient is stimulated by electrical pulses delivered at the median nerve position at the wrist, while a BCI device analyzes the ERD and ERS modulations over the motor cortex to detect the intention of movement of the patient. Our previous clinical trial (MOTANA protocol [23]) also includes a condition with MNS and another with MNS accompanied by MI for 3 concentrations of propofol (0, 0.5 µg/mL, and 1 µg/mL). The preliminary results (n=15) highlighted the advantage of a BCI based on MNS from both a functional and an accuracy point of view. First, MNS intrinsically provides a trigger to know when to analyze the signal. Second, the classification accuracy of an MNS-based BCI appeared to be way better than that of a BCI aiming to discriminate a motor imagination from a resting state. More precisely, an MNS-based BCI detected the MI state 15% more accurately. For several subjects, the use of MNS improves performance by more than 20% compared to a standard method [22,25].

These preliminary results also showed that propofol sedation (at 0.5 µg/mL and 1 µg/mL) has no negative impact on the ability of an MNS-based BCI to detect MI. Concretely, at relatively low concentrations, ERD/ERS patterns are still present in the sensorimotor cortex [26]. From these encouraging results, we intend now to verify that the oscillatory activity generated by the MNS remains present during general anesthesia with higher concentrations of propofol. This is in line with the existing literature, suggesting that the detection of MNS under general anesthesia can be achieved as somatosensory cortex maintains a certain activity confirmed by the presence of evoked potentials during sleep or general anesthesia-induced unconsciousness [27]. The cortical regions may still be receptive to information, but their ability to communicate with other regions may be altered during general anesthesia [28]. According to our knowledge, no study has investigated the way in which the cerebral motor activity was modulated with peripheral nerve

XSL•FO
RenderX

stimulation over the sensorimotor cortex during general anesthesia. The aim of this study is to verify that ERD/ERS following MNS is still present and detectable under high doses of propofol with the EEG technique. Such new knowledge will enable the design of an innovative BCI specialized in the detection of intraoperative awareness during general anesthesia.

The first objective of this study is to verify that ERD and ERS patterns induced by MNS can be detected in the cortical motor EEG signal under various concentrations of propofol corresponding to the anesthetic doses required for general anesthesia. The secondary objective is to characterize and understand how the ERD and ERS generated after each MNS will be altered according to each concentration of propofol at the effect site. These results will be discussed in relation to previous results obtained from a protocol investigating the effect of light propofol sedation on EEG signals in the motor cortex. The third objective is to analyze EEG signals offline and try to detect MNS under propofol with new machine learning algorithms. Complementary, the short and middle latency components of the somatosensory evoked potentials (SEPs) will be analyzed for different propofol concentrations. Finally, the long-term goal is to design a BCI that can detect intraoperative awareness during general anesthesia.

Methods

Study Design

The study will be held in an approved location in the operating theaters, at the University Hospital of Bruxelles-Brugmann (Belgium). An anesthetic evaluation will be performed by the study investigator (DS) within 1 month prior to surgery. During this consultation, the study protocol will be explained to the patient, and the different explanatory documents will be given. Only eligible subjects will be enrolled (inclusion and exclusion criteria are listed). Participation is completely voluntary and withdrawal will be always possible at any time without affecting the level of care that will be received. There will be no financial compensation for this study. Each voluntary patient recruited for the study will benefit from the standard of care before, during, and after the surgery. On the day of surgery, and as recommended, the anesthetist will check that there are no current contraindications to perform general anesthesia (ie, failure to fast, fever, occurrence of other medical conditions or disease, unusual blood sample, etc).

Recording a patient's baseline EEG during MNS without an anesthetic drug administered is a prerequisite for the proper functioning of the BCI. It will take place before surgery in a specific quiet room in the postanesthesia care unit. The estimated time to set the EEG headset is 25 minutes, and the estimated time for baseline EEG monitoring is 20 minutes (see Table 1). Painless discontinuous stimulation of the median nerve and recording of the patient's EEG signal will take place throughout the operation. The anesthesia protocol will be left at the discretion of the anesthesiologist, except for obtaining hypnosis, which will have to be performed with propofol using a target-controlled infusion (TCI) pump with the Schnider pharmacokinetic model at the effect site [29-31]. If necessary, neuromuscular blocker agents will be used and monitoring will be performed. Data collection of the propofol site effect target administered to the patient will be directly recorded on a computer. After the surgery is completed, sedation will be discontinued allowing the patient to recover and be monitored afterward in the postanesthesia care unit.

Table 1 shows the registration, intervention, and evaluation schedule.

Considering the SEP stimulation, we consider that nonpainful stimuli will consist of square electrical pulses of 0.2 milliseconds of duration, generated by Micromed device Sd Ltm Stim Energy (Micromed) and delivered through a pair of grass gold cup

XSL•FO
RenderX

electrodes (cathode [−] placed proximally) to the right/left median nerve at the wrist [32]. The intensity will be adjusted for eliciting visible small thumb twitches and without exceeding 50 mA.

Study Population

In this clinical protocol, a total of 30 patients who require scheduled surgery under general anesthesia will be enrolled. For the recruitment of this study, we have designed a flyer that will be disseminated through different media channels. Participation in this experiment will not be remunerated. Patients will be exposed to the same risks of general anesthesia limited to propofol. The doses used in this clinical protocol are the same as those that induce loss of consciousness during conventional surgery.

The inclusion criteria include patients (1) who have received full details of the research organization and have signed our informed consent, (2) aged between 18 and 81 years, (3) scheduled for surgery with the use of total intravenous sedation with propofol, and (4) who are affiliated to a social security regime in Belgium. We shall exclude patients who (1) are allergic to propofol or its ingredients, (2) have a history of an anaphylactic reaction during anesthesia, (3) are female due to the impossibility of checking pregnancy status, (4) are deprived of liberty by a judicial or administrative decision, (5) are under psychiatric care, (6) are unable to give consent and without being subjected to a legal protection measure, (7) refuse to participate in the study, (8) have a BMI below 20 or above 35 kg/m², (9) require surgery for less than an hour, (10) have a pathological history related to the right median nerve, and (11) have any drug addiction.

Ethical Considerations

This research was officially approved by an ethical committee from Belgium (CHU Brugmann, CE 2021/225) and was registered at EUDRACT (2021-006457-56). The study protocol was also registered on ClinicalTrials.gov (NCT05272202). This protocol will follow the principles of the Declaration of Helsinki and the Medical Research Involving Human Subjects Act [33]. Informed written consent will be obtained from all patients before study inclusion. Because involvement of patients is voluntary, the study can be stopped at any time.

EEG Data Acquisition

Motor EEG signals will be collected through the OpenViBE software platform with eego mylab system (ANT neuro) 64-EEG channels, covering the entire scalp at 16,000 Hz and 1 external channel placed on the dorsum of the contralateral hand to the electric stimulation, by means of an adhesive surface electrode. All offline analyses will be performed using the EEGLAB toolbox [34] and Matlab2016a (The MathWorks Inc). The findings will be additionally investigated by applying a Laplacian filter and a mastoidal re-referencing [35]. Then, the EEG signals will be resampled (128 Hz) and epoched into 6-s windows (1 second before and 5 seconds after the MNS). We will compute the ERD/ERS% using the “band power method” [36]. Additionally, SEP will be calculated by averaging epochs extracted from 0.25 to 0.5 with respect to the electric shock.

Statistics

The data processing methods will be similar to those described in the MOTANA protocol [23]. For each patient and each MNS, the maximal value of ERD and ERS max will be, respectively, selected in (0.25;0.5) seconds and (2;4) seconds after stimulation, in accordance with the literature [24,37]. An average over the ERDs max and ERSs max will be performed for each concentration. These 2 values will be, respectively, compared with average ERDs max and ERSs max obtained in the preoperative rest condition with a Student t test (P<.05). To visualize the event-related spectral perturbations with the EEGLAB toolbox, a surrogate permutation test will be used (P<.05; 2000 permutations). In addition to the permutation test, we will apply a false discovery rate correction to show the difference in MNS effect during different concentrations of propofol.

In addition to the event-related spectral perturbation analyses, we will apply 4 different offline machine learning algorithms to detect the MNS at the cerebral level. To do this, these algorithms are based on 4 classification methods in a 4-fold cross-validation scheme. The classification score will be computed for the MNS versus the rest class. Each trial will be segmented into a motor task time window and a resting time window, both lasting 2 seconds. The motor task time window will begin 0.5 seconds after the MNS, and the resting phase time window will begin 3 seconds before the MNS. The first classification method is a linear discriminant analysis method using a common spatial pattern [38] (referred to as common spatial pattern+linear discriminant analysis). For the next 3 classifiers, we will use classifiers that are based on Riemannian geometry. Riemannian geometry-based methods have the advantage of being immune to linear transformations and to be particularly efficient for the detection of motor intentions. For the statistical differences in the latency and topographic voltage of the SEP components, similar permutation tests and post hoc tests will be applied.

Study Duration

The duration of the participation is from 45 minutes before surgery (installation of the EEG cam and the median nerve stimulator) until the end of surgery.

The expected overall duration of the research, including the time required for the completion of the data analysis, is 4 years. The promoter (CHU Brugmann) reserves the right to stop the research (1) if serious, there are significant procedural deviations in the protocol that could impact the statistical analysis of the data, (2) if recruitment of subjects is not adequate, or (3) if a significant issue regarding the safety and rights of the subjects arises.

Data Collection

Data will be collected with a case report form and patient data will be anonymized (ie, a unique study number will be assigned to each individual). The case report form will contain demographic information of the patient, undesirable events which may be experienced during the study, the anesthesia chart will be photocopied at the end of the procedure and anonymized,

XSL•FO
RenderX

and EEG data stored electronically under the supervision of the principal investigator.

Patient and Public Involvement

A total of 30 patients will be involved in the STIM-MOTANA protocol. Patients, patient advisors, and the public were not involved in the development of the research questions or in the design of the study. Patient involvement in the study includes answering survey questionnaires at baseline and at each follow-up. Summaries of study results will be disseminated to study participants via email or mail. The results will be published in international peer-reviewed journals, and summaries will be provided to the funders and patients.

Results

Evaluation Criteria

Primary End Points

A total of 30 patients will be involved in the STIM-MOTANA protocol. We will compute the amplitude of ERD/ERS modulations before and after each MNS during the different phases of anesthesia at 2 different times: when the patient is awake before surgery and under general anesthesia. The primary evaluation end point will be the amplitude of the ERD. According to the Pfurtscheller method, ERD/ERS modulations will be calculated using a baseline taken before each stimulation [36]. The changes in ERD/ERS during MNS according to the various propofol concentrations will be continuously monitored. To compare the motor EEG signal before and after injection of the anesthetic product, we will apply paired statistical tests (Student *t* test).

Secondary End Points

In this project, we need to reach the highest MI EEG detection accuracies as possible, which is necessary in the context of a surgery for which we need a very high true positive rate (ideally all AAGAs are detected) as well as a very low false positive rate (ideally no false alarm). To do so, we will build BCI classifiers based on Riemannian geometry [22,24] a framework in which EEG signals are represented as covariance matrices, which are directly analyzed and classified.

Trial Status

When the manuscript was initially submitted, recruitment had not started. The recruitment began in December 2022. The current protocol version is version 1 and was previously accepted by the ethical committee of the CHRU Brugmann Hospital.

Discussion

Principal Findings

STIM-MOTANA is an interventional study aimed at designing an innovative BCI-based EEG-motor brain activity, which would detect the intention to move of a patient during general anesthesia. STIM-MOTANA is the first study to investigate cerebral motor activity modulations following peripheral nerve stimulation during general anesthesia.

AAGA can occur unexpectedly and is therefore a complication that cannot be easily anticipated and that is only retrospectively diagnosed. The STIM-MOTANA protocol proposes to detect intraoperative awareness reliably by analyzing, in real-time, brain motor activity under general anesthesia with a BCI based on MNS and new machine learning methods. Designing such a BCI presents us with 2 challenges. The first one is to detect the MI of a person who is a victim of AAGA without any time marker presented to the subject (ie, asynchronously) since, during AAGA, it is impossible to ask and know exactly when the patient will intend to move. Unfortunately, the literature clearly shows insufficient classification accuracies and high false positive rates with asynchronous BCI [22]. The second challenge is, therefore, to obtain a high level of accuracy (>90%—the minimum required accuracy according to the clinical application) to ensure a reliable BCI device that can be used in hospitals. To satisfy these 2 requirements, our objective is to design a robust MNS-based BCI. Based on strong practical and theoretical scientific reasoning from our previous studies, our innovative MNS-based BCI would provide a way to detect intraoperative awareness during general anesthesia. The primary limitation of this study is that ERD/ERS habitually generated by media nerve stimulation without anesthetic may disappear for deep levels of anesthesia.

Conclusions

STIM-MOTANA will provide the first protocol study to investigate MNS cerebral motor effect during general anesthesia for the detection of intraoperative awareness. Based on strong practical and theoretical scientific reasoning from our previous studies, an innovative MNS-based BCI used in this study would provide a way to detect intraoperative awareness during general anesthesia.

Acknowledgments

This work was supported by the Brugmann Foundation (Belgium) and the National Funds of Research of Belgium (Belgium). The Brugmann Foundation supported the purchase of the equipment for the electroencephalographic acquisition. The National Funds of Research of Belgium offered a grant for a research fellow (SR) to carry out the experiments and analyses.

Data Availability

The datasets generated and analyzed during the current study will be available from the corresponding author on request. Records of all patients will be kept separately in a secure place in the CHU-Brugmann.

Abstract

Background: Responsive infant feeding occurs when a parent recognizes the infant's cues of hunger or satiety and responds promptly to these cues. It is known to promote healthy dietary patterns and infant weight gain and is recommended as part of the Dietary Guidelines for Americans. However, the use of responsive infant feeding can be challenging for many parents. Research is needed to assist caregivers recognize infant hunger or satiety cues and overcoming barriers to using responsive infant feeding.

Objective: The Learning Early Infant Feeding Cues (LEIFc) intervention was designed to fill this gap by using a validated coaching approach, SS-OO-PP-RR ("super," Setting the Stage, Observation and Opportunities, Problem Solving and Planning, Reflection and Review), to promote responsive infant feeding. Guided by the Obesity-Related Behavioral Intervention Trials model, this study aims to test the feasibility and fidelity of the LEIFc intervention in a group of mother-infant dyads.

Methods: This pre-post quasi-experimental study with no control group will recruit mothers (N=30) in their third trimester (28 weeks and beyond) of pregnancy from community settings. Study visit 1 will occur prenatally in which written and video material on infant feeding and infant hunger and satiety cues is provided. Demographic information and plans for infant feeding are also collected prenatally via self-report surveys. The use of responsive infant feeding via subjective (survey) and objective (video) measures is recorded before (study visit 2, 1 month post partum) and after (study visit 5, 4 months post partum) intervention. Coaching on responsive infant feeding during a feeding session is provided by a trained interventionist using the SS-OO-PP-RR approach at study visits 3 (2 months post partum) and 4 (3 months post partum). Infant feeding practices are recorded via survey, and infant weight and length are measured at each postpartum study visit. Qualitative data on the LEIFc intervention are provided by the interventionist and mother. Infant feeding videos will be coded and tabulated for instances of infant cues and maternal responses. Subjective measures of responsive infant feeding will also be tabulated. The use of responsive infant feeding pre-post intervention will be analyzed using matched *t* tests. Qualitative data will be examined to guide intervention refinement.

Results: This study initially began in spring 2020 but was halted because of the COVID-10 pandemic. With new funding, recruitment, enrollment, and data collection began in April 2022 and will continue until April 2023.

Conclusions: After refinement, the LEIFc intervention will be tested in a pilot randomized controlled trial. The long-term goal is to implement LEIFc in the curricula of federally funded maternal-child home visiting programs that serve vulnerable populations—those that often have infant feeding practices that do not align with recommendations and are less likely to use responsive infant feeding.

KEYWORDS

responsive feeding; infant growth; infant nutrition

Introduction

Infant feeding practices, which include what and how infants are fed, contribute to infant growth and development, and thus, lifelong health [1]. Specifically, healthy infant feeding practices contribute to a healthy weight gain trajectory, which has been associated with decreased obesity later in life [2,3]. Healthy infant feeding practices include not only *what* infants are fed but also *how* infants are fed. The introduction of breastfeeding, breastfeeding until at least 6 months of age, introduction of complementary foods around 6 months and not before 4 months of age, and avoidance of juice and sugar sweetened beverages are recommended examples of *what* infants should be fed [1,4].

The responsive feeding approach is recommended for *how* infants should be fed and has been associated with healthy infant weight gain trajectories [4].

Responsive feeding occurs when a parent (or other caregiver) learns and recognizes the infant's cues of hunger and satiety (Textbox 1) and responds promptly to these cues [5]. Responsive feeding is thought to promote the ability to recognize and respond to internal cues of hunger and satiety [6-10]. This ability to recognize these internal cues and self-regulate intake in response to physiologic need is associated with healthy weight gain during infancy as well as dietary behaviors later in life [8,11]. For these reasons, it is important that parents use the responsive feeding approach when feeding their infant.

Textbox 1. Hunger and satiety cues in infants less than 6 months [5,7].

Hunger signals

- Wakes up and increased alertness
- Moves around
- Smacks lips
- Sucks on fist and fingers
- Cries or fusses
- Opens mouth wide
- Response to rooting reflex

Satiety signals

- Seals lips
- Turns head away
- Decreases or stops sucking
- Spits out nipple
- Falls asleep
- Decreased muscle tone

Three things must be in place for responsive feeding to occur: (1) the child signals hunger; (2) the caregiver recognizes cues and responds promptly; and (3) the child experiences a predictable response to hunger [5]. For this process to occur, caregivers must read their child's nonverbal cues and respond contingently. The degree to which a caregiver responds contingently to a child's communication, whether it is to a child's hunger cues or to bids for social interaction, is widely known to predict a child's language development [12-14]. As such, coaching caregivers to respond to feeding cues could impact overall caregiver responsiveness to their child's communication bids, which could support the child's early language development by extension.

Interventions to promote responsive feeding have shown benefit in preventing rapid infant weight gain and promoting healthy dietary patterns in infants and young children [15-22]. Despite the correlation between responsive feeding and healthy infant weight gain, the successful use of responsive feeding by caregivers is still lacking [23]. Caregivers report that recognition of hunger and satiety cues in their infant is challenging [24,25]. Infant cues can be subtle, and it can be difficult for parents to differentiate reflexive movements such as hand to mouth and rooting. Additionally, recent literature has identified maternal characteristics such as infant feeding beliefs, age, mental health, and the mother's own eating behavior as contributing to the use of responsive feeding [26-29]. Infant temperament and support from health care professionals and family and friends also play a role [23,26]. Therefore, more research is needed to find ways to assist caregivers in recognition of hunger and satiety cues and to overcome additional barriers to promote the use of responsive feeding during infancy.

XSL•FO
RenderX

The Learning Early Infant Feeding Cues (LEIFc) intervention was designed to fill this gap by using a validated coaching approach with the mothers of new infants to promote responsive feeding. The proposed study aims to test the feasibility and fidelity of the LEIFc intervention in a group of mother-infant dyads. We aimed to (1) develop, refine, and test a responsive feeding intervention that can be used within real-world settings to serve mother-infant dyads in the community and (2) design the model with a primary emphasis on responsive feeding, but with a secondary focus on early communication to help caregivers understand the dual benefit of noticing and responding to infant cues.

Methods

Ethics Approval

The institutional review board at Florida State University approved this study (STUDY00002895).

Theoretical Framework

The Obesity-Related Behavioral Intervention Trials (ORBIT) model is used to guide the proposed study [30]. The ORBIT model uses an iterative process and was chosen because the LEIFc intervention is behavioral in nature, in the early stage of development, and focused on prevention of a chronic disease [30]. Testing fidelity and feasibility of the LEIFc intervention study falls into phase I of the ORBIT model as the intervention has been designed but needs to be refined based on preliminary testing. The findings from this initial study will provide the foundation to move to phase II and conduct a proof-of-concept trail.

Study Design and Intervention

This study uses a pre-post quasi-experimental design with no control group to examine the feasibility, fidelity, and social validity of the LEIFc intervention. The intervention was developed based on existing literature regarding enablers and barriers to the use of responsive feeding by caregivers and communication cues present early in life. The multicomponent LEIFc intervention involves maternal education on responsive feeding practices and mother-infant communication while using a family-guided caregiver coaching approach called SS-OO-PP-RR (“super,” Setting the Stage, Observation and Opportunities, Problem Solving and Planning, Reflection and Review) during feeding sessions [31,32]. The SS-OO-PP-RR approach was developed based on adult learning theory and has been successfully used with parents and childcare providers to promote development across domains in infants and young children [31-33]. For the LEIFc intervention, SS-OO-PP-RR was modified to be specific to communication during feeding to promote responsive feeding (Textbox 2). It is used as a guide for the interventionist during the coaching session but will also be used to evaluate the fidelity of the intervention. The objective measure of responsive feeding will occur through video recording of feeding sessions between mothers and infants. Videos will be coded before the intervention and then after 2 coaching sessions between the interventionist and the mother during a feeding session. The subjective measure of responsive feeding will be collected via a self-report questionnaire completed by mothers before and after the intervention study visits.

Textbox 2. The “super,” Setting the Stage, Observation and Opportunities, Problem Solving and Planning, Reflection and Review intervention.

Setting the Stage (SS)

- Asks the caregiver to update how responsive feedings have been going since the last visit—listens, encourages caregiver reflection, and sets up problem-solving as needed
- Shares information related to responsive feeding—connects strategies to the child’s long-term health, well-being, and communication development
- Clarifies responsiveness strategies to use during the session (watching for hunger and fullness cues, using talk and touch during feeding, and stopping when the baby is full)

Observation and Opportunities to Embed (OO)

- Observes the caregiver-child interaction in feeding routine—provides feedback and builds on dyad strengths
- Uses coaching strategies (guided practice, direct teaching, demonstration, and caregiver practice) to help the caregiver embed responsiveness strategies into the feeding routine
- Provides general and specific feedback on caregiver and child behaviors and interactions (links caregiver strategy to child response)

Problem-Solving and Planning (PP)

- Problems solved with the caregiver about appropriate responsive feeding strategies
- Supports the caregiver to identify opportunities to help other caregivers use the strategies (other parents, childcare, and grandparents)

Reflection and Review (RR)

- Asks questions and comments to promote caregiver reflection and review of the feeding routine—identifies what worked for the caregiver and child
- Engages the caregiver to lead development of a “best plan of action” for using responsiveness strategies between visits

XSL•FO
RenderX

Setting and Participants

Mothers of any parity will be recruited from community settings during the third trimester (28 weeks and beyond) of a healthy pregnancy. To be eligible, mothers need to be aged 18 years or older, able to read and speak English, and agree to video recording of an infant feeding in their home. Any medical or congenital condition in the fetus that would interfere with infant feeding or growth (ie, Down syndrome or cleft lip or palate) will be excluded. Mothers will be enrolled in the third trimester and then screened again after the birth of the infant to ensure that mother and infant remain eligible to participate.

An interventionist will be recruited to deliver the LEIFc intervention in the homes of new mothers. He or she will ideally have a background in maternal-child health and may be a nurse, social worker, speech-language pathologist, dietician, or early child development specialist. The interventionist will be trained on the SS-OO-PP-RR approach and the LEIFc protocol. Because the purpose of this study is to test the fidelity and feasibility of the intervention, feedback from the interventionist will be sought as part of the research protocol.

Procedures

Eligible mothers will be identified through community settings such as obstetrician offices, prenatal parenting or birth classes, social media forums that pregnant moms may frequent, and word of mouth. If eligible and interested in the study, study personnel will consent mothers for the study. Once enrolled in the study, the interventionist will implement each study visit (Table 1). Study visit 1 is conducted when the mother is in the third trimester of pregnancy. Written material on infant feeding and infant cues of hunger and satiety is provided. Additionally, 2 short videos, one on infant hunger cues and the second on infant satiety cues, are watched with the interventionist and the mother. Any questions on feeding or communication are answered by the interventionist. Study visit 2 is conducted when the infant is approximately 1 month old. At this visit, a video recording of a feeding session between the mother and the infant is taken with no interaction with the interventionist. The feeding can be from the breast or from the bottle (with breastmilk or formula). Study visits 3 (at infant age of 2 months) and 4 (at infant age of 3 months) are the intervention study visits. At each visit, the interventionist will use the SS-OO-PP-RR tool to coach the mother through the feeding to identify hunger and satiety cues and discuss ways to respond. Each of these visits is also video recorded. The final study visit is at infant age of 4 months when another video recording of the infant feeding session is taken with no coaching from the interventionist.

At study visit 1, demographic data are collected along with the mother's prenatal plans for infant feeding. At study visit 2, birth history is collected along with infant feeding practices, and the mother completes the Infant Feeding Questionnaire (IFQ). During study visits 3 and 4, infant feeding practices are collected. At study visit 5, the mother completes the IFQ and provides feedback on the study itself through a series of qualitative questions.

Table 1. Timing of study visits and procedures.

Study visit	Timing of visit	Components of the visit	Visit location
1	Prenatal (28 weeks or beyond of gestation)	• Education provided on communication with your baby during feeding—videos and written material	Video conferencing platform (Zoom)
2	Infant age approximately 1 month	• Complete Infant Feeding Questionnaire • Video record the mother and baby during a feeding with no coaching • Collect current infant feeding practices	Family home
3	Infant age approximately 2 months	• Video record the mother and baby during a feeding • Provide coaching to the mother during the feeding • Collect current infant feeding practices	Family home
4	Infant age approximately 3 months	• Video record the mother and baby during a feeding • Provide coaching to the mother during the feeding • Collect current infant feeding practices	Family home
5	Infant age approximately 4 months	• Video record the mother and baby during a feeding with no coaching • Complete Infant Feeding Questionnaire • Collect current infant feeding practices	Family home

Outcome Measures

The primary outcome in this study is the use of responsive feeding. This will be measured before (study visit 2) and after (study visit 5) intervention. Data are obtained subjectively through evaluation of the IFQ and objectively through a video review. The IFQ will provide a subjective measure of responsive feeding. This 20-item self-report tool has been validated for use in mothers of infants [29,34,35]. Likert-type scoring is used; higher scores indicate a stronger measure of the construct. Three subscales will be used to measure responsive feeding: use of food to calm, use of food to soothe, and awareness of infant cues.

The objective measure of responsive feeding will be collected via coding of the video session before and after intervention. The research team developed a coding scheme to capture both mother and infant behaviors during the feeding interactions. The coding scheme was adapted from the Responsiveness to Child Feeding Cues Scale [36] to define specific, discrete

XSL•FO
RenderX

maternal behaviors that relate to responding to infant hunger and satiety cues as well as early infant communication acts. Infant behaviors are coded for hunger, satiety, and early communication acts. Research assistants will be trained on the coding scheme and will use existing videos to code with a goal of at least 85% agreement achieved to confirm inter-rater reliability. The coding scheme developed by the team will be used to code the feeding interactions for study visits 2 and 5. Videos will be coded for the number and rate of maternal utterances directed toward the child and responsiveness to the child's vocalizations using the Noldus Observer XT software. The percentage of the interactions spent jointly engaged between the mother and the infant will also be coded.

Infant feeding practices, demographic characteristics (ie, maternal age, marital status, education level, and race and ethnicity), and maternal depression will be considered as covariates. Initiation and duration of breastfeeding and age at complementary food introduction will be extracted from data and tabulated into variables: duration of breastfeeding (any and exclusive) calculated in weeks and age at complementary food introduction calculated in weeks. Demographic data are collected at study visit 1, infant feeding practices at study visits 2 through 5, and maternal depression (via the Patient Health Questionnaire-9) at study visits 2 through 5.

Statistical Analyses

Power analysis for the matched-pair *t* test was conducted. With the lower limit of the medium effect size of 0.5 [37], sample sizes of 27 and 36 provided 80% and 90% power, respectively, under 1-sided directional null hypothesis and the nominal significance rate of .05. We will aim to enroll 30 participants for this feasibility and fidelity study.

Once data are clean, descriptive statistics will be computed and examined. For the primary outcome, benefit will be determined by an increase in responsive feeding codes pre-post SS-OO-PP-RR coaching sessions (visits 2 and 5). IFQ subscale scores will be analyzed using matched sample *t* tests for pre-post coaching sessions to determine the benefit of the intervention. If the assumptions of statistical tests are not clearly met, the Mann-Whitney *U* test would be considered as an alternative. In a future pilot randomized controlled trial (RCT), analysis of covariance (ANCOVA) will be conducted where the difference between treatment and control groups for the postmeasure is examined with the premeasure as a covariate. The use of ANCOVA provides a statistical control in addition to the design control for the premeasure via random assignment in the RCT.

Results

This study was initially designed to begin recruitment in the spring of 2020. Because of the COVID-19 pandemic, all research activities ceased from March to September 2020. The research team modified the protocol to conduct this study with socially distanced measures in place (ie, using videoconferencing platforms for data collection) and began recruitment in October 2020. Two enrolled participants were unable to complete study visits as scheduled, and data collection was unsuccessful. New funding was sought and obtained; recruitment began again in April of 2022 and data collection soon after. It is anticipated that data collection will be complete in April of 2023.

Discussion

Anticipated Findings

Although data collection for this study is ongoing, it is anticipated that the LEIFc intervention will be feasible to implement with and socially acceptable to mother-infant dyads by a trained interventionist. Additionally, it is hypothesized that fidelity of the intervention would need to be refined to better meet the needs of mother-infant dyads, especially those from high-risk populations (ie, minority groups and low socioeconomic status). Qualitative data collected from mothers (visit 5) and from the interventionist (visits 3 and 4) will be used to refine the intervention. Finally, it is hypothesized that there may be a change in responsive feeding before or after intervention; however, it cannot be attributed to the intervention until tested with a control group, in the future planned RCT.

Implications

Childhood obesity rates continue to rise. Data from the National Health and Nutrition Examination Survey (NHANES) found that between 2017 and 2020 (prepandemic), 19.7% of children aged 2-19 years in the United States had obesity [38]. This is up from the previous NHANES data reporting 18.5% of children with obesity [39]. This rise in childhood obesity percentage suggests that efforts in recent years are not enough and more strategies are needed to halt this epidemic. Additionally, there are a higher percentage of children who are non-Hispanic Black, Hispanic, or from families living below the poverty line with obesity (24.8%, 26.2%, and 25.8%, respectively) [38]. Children with obesity are at risk for lifelong cardiometabolic conditions such as hypercholesterolemia, hypertension, and type 2 diabetes [40,41]. Children with obesity are also more likely to have mental health disorders (ie, depression and anxiety) and complications of the pulmonary, orthopedic, and gastrointestinal systems [1,42,43]. The first 1000 days of life, from conception to age 2 years, is a critical period for the development of habits that contribute to one's weight status later in life, such as dietary preferences and behaviors [3,44-46]. Therefore, interventions implemented during the first 1000 days and targeting infants from high-risk groups (those of minority race and ethnicity and low socioeconomic status) have potential to decrease one's obesity risk and subsequent complications. The promotion of responsive feeding is one such intervention that could be used to promote healthy infant weight gain and prevent obesity.

Outcomes

Education on and promotion of responsive feeding should begin prenatally and evolve with the developmental of the child [5]. Research has demonstrated that responsive feeding during infancy helps an individual learn to eat in response to their own internal cues opposed to eating on a schedule [8-10]. The development of this eating pattern early in life may promote healthy eating behaviors lifelong, thus contributing to healthy weight status and prevention of cardiometabolic complications [41]. In addition, this early support for maternal-child

XSL•FO
RenderX

communication may enhance language development during infancy. Infants' earliest communication acts relate to signaling hunger cues, and maternal responsiveness to a child's cues has long been established as an important predictor of later language outcomes [14]. As such, the LEIFc intervention has the potential to support 2 positive outcomes in children—healthy weight gain and positive communication outcomes.

Infant feeding in the first months after birth often occurs in the home, making this an ideal environment to promote responsive feeding [44,46]. Should the LEIFc intervention be successful, implementation in maternal-child home visiting programs would be sought. Maternal, infant, and early childhood home visiting programs, such as Early Head Start and Healthy Start, provide services to families from pregnancy up to the age of 5 years in at-risk communities [47,48]. These programs serve families from low socioeconomic backgrounds that often include those of minority status. Children from these families have higher rates of childhood obesity, cardiometabolic complications, and language delays [38,43]. The implementation of a responsive feeding intervention in these programs has potential to prevent several complications in children who receive this support, making implementation of the LEIFc intervention an important component to maternal-child home visiting program curricula.

Conclusions

The current funded study will test the feasibility and fidelity of the LEIFc intervention in a group of mother-infant dyads. The intervention has potential to promote 2 childhood outcomes: healthy weight gain and early language development. The results of this feasibility study will allow the researchers to refine the intervention and move to phase IIa of the ORBIT model, testing proof of concept of the intervention. If successful, the LEIFc intervention would be expanded to include vulnerable mother-infant dyads enrolled in maternal-child home visiting programs. Once implemented into the curricula of such programs, application and sustainability would be strong.

Abstract

Background: Research on eldercare has been dominated by a provider-oriented perspective, concerned with the conditions and views of care providers. There are striking differences compared with the field of disability studies, where help is framed as part of a larger project of having a daily life and being included in society. Pilot interviews indicate that older people develop active strategies to make care work. These include *practical* preparations, *emotional* activities such as showing an interest in staff members' lives, or *rhetorical* skills in asking for help.

Objective: The aim of this project is to develop empirical and theoretical knowledge of eldercare as a relational practice, accomplished by older people in their daily lives. This perspective will also offer an alternative to ongoing attempts to reduce the user perspective to an issue about older people acting as customers in a market.

Methods: The project will map, investigate, and follow up on care use from the perspective of care users. The project has an ethnographic 2-year longitudinal approach. Data consist of interviews and participant observations with 35 persons (home care users and cohabitating partners) and a diary study with additional 10 care users. Inclusion criteria are people 65 years or older with home care provided by needs assessors. It is preferred that they have had home care between 6 months and 2 years in order to follow a progression in roles, identities, and strategies within home care use.

Results: Between May and October 2022, 25 interviews with home care users were conducted. Data collection with follow-up interviews and observations, analysis, and reporting of findings will be completed by December 2024.

Conclusions: By studying care use in the context of older people's lives the project will add important knowledge about the strategies and adjustments older people apply to make care arrangements work. A user-oriented perspective will further the understanding of how power relations play out in home care over time in relation to the formal rights, categorical belongings, and established norm systems that place the user in superior or subordinate positions.

KEYWORDS

eldercare; user perspective; home care; theory of care use

Introduction

Background

Care has been studied as a relational practice, but above all as a practice for those who *provide* care. This project will shift focus to go beyond the casting of older people as either passive objects or active consumers to provide the empirical and theoretical base for a third route. The point of departure is that older persons act and reason in specific ways to make home care work for them and to ensure that help is provided without friction. This entails thoughts, deliberations, and a range of actions that for older people with home care are part of everyday life:

- Waking up early to prepare the home for visiting care staff

XSL•FO
RenderX

- Learning the home care organizations' technical vocabulary
- Working out which care staff will take out the rubbish as they leave, even if this service is not officially included
- Showing an interest in the personal lives of the care staff and finding common interests
- Deciding whether to go grocery shopping in person or to adapt to buying food online
- Deciding to buy in tax-deductible cleaning and laundry services privately to supplement council-provided home care. (Tax deduction on household services or RUT (rengöring, underhåll, och tvätt [cleaning, maintenance, and washing] were introduced in Sweden in 2007, and RUT service companies increasingly use the term "eldercare" to promote their services.)

Research on home care and other forms of eldercare has been dominated by a provider-oriented perspective, which revolves around the organization, conditions, views, and activities of those who provide the care. This perspective has been developed in theories that define care as a moral, relational practice by which the caregiver interprets the needs of the dependent person [1-6]. Studies of the everyday realities of home care have comprised both providers and users, but as in the excellent thesis by Szebehely [7], the analytical focus and the theorization of eldercare have usually been directed toward the provider side of the relationship. This perspective has also dominated studies of the coordination of care efforts, informal care, and its nexus of formal care [8,9]. Even approaches in the "person-centered" care paradigm share this focus; one review found that most models measured staff members' views [10]. Although the provider-oriented perspective has enlarged our knowledge of the everyday realities of care, few studies have considered the care users' perspectives. The absence of a user-oriented perspective is significant when compared with the field of disability studies. In a review of Swedish research, Erlandsson [11] noted that of 26 Swedish theses about "non-old" people with disabilities, the sole focus of 11 was the person being helped and 2 focused on the provider. By contrast, of the 25 Swedish theses about care for older people, none focused only on the user, whereas the sole focus of 12 was the care provider. The provider-oriented perspective in eldercare is strikingly different from approaches in disability studies. One reason for this is that help for "non-old" people is framed as part of a larger project of daily life and being included in society [11-13]. The provider perspective is crucial in any care situation, but too strong an emphasis on providers plainly risks discounting aspects such as social rights and undermining attempts to resist ageism and exclusion.

This project will address the need for a user-oriented perspective as part of a larger mission to develop a theory of care use. A user-oriented perspective will further the understanding of how power relations play out in home care over time, in relation to the formal rights, categorical belongings, and established norm systems that place the user in superior or subordinate positions. The perspective will also offer an alternative to ongoing attempts to make sense of the meaning of eldercare in a new landscape, where new cohorts of older people become care users, and where marketization has been presented as both a solution and a threat to the welfare state's ambitions [14-16]. Critical approaches have provided valuable knowledge, but in the attempt to combat unrealistic forms of marketization [17], there is an evident risk of downplaying the capabilities of older care users. An alternative route is needed that acknowledges the importance of relations, skills, and adjustments over time.

The project will use qualitative interviews, participant observations, and a diary study to investigate understanding, strategies, and adjustments of older people who use home care, thereby providing a type of knowledge that has so far not been devoted sufficient attention.

Aim and Research Questions

The aim of the project is to develop empirical and theoretical knowledge of home care as a relational practice, as interpreted, accomplished, and negotiated by older people in their daily lives, as part of the formal and informal services available to them:

- RQ1: How do older people navigate, coordinate, and fit care arrangements and other forms of help into their home contexts, daily activities, long-term plans, and social relations?
- RQ2: What practical, emotional, and rhetorical strategies do older people apply in their interaction with care staff?
- RQ3: What types of identities, categorizations, and roles are played out when older people receive home care, and what is the bearing on power relations?
- RQ4: How are users' needs formulated as part of their experience of the eldercare system and their relations with home care staff over time?

The Context of Studies

The studies of the project are situated within several fields of research and investigations, internationally and in the Nordic countries.

A comprehensive body of research theorizes and investigates eldercare, with a strong tradition and prominent research environments in Sweden, Denmark, Finland, and Norway [3,5,18-20]. The research has concentrated on the provision of formal eldercare as part of the social policy of the Nordic welfare states, with studies of the everyday realities, organization, working conditions, needs assessments, and relations between formal and informal care. Research and theories that use this provider-oriented perspective will serve as a backdrop to the project.

A second type of research that informs the project consists of studies that gauge care users' opinions when defining quality of care. The National Board of Health and Welfare's large annual user survey "Vad tycker äldre om äldreomsorgen?" (What do older people think about eldercare?) is the most prominent study from a Swedish horizon [21]. It should be noted that such studies have been criticized for the way they translate quality into numbers. Internationally, qualitative and mixed methods have been used to investigate how the quality of care is measured or the broader issue of quality of life from the perspective of the care user [22].

A third type of research that will feed into the project consists of studies of user participation, originally developed to empower

XSL•FO
RenderX

older people who use health care or social care. This research tradition is anchored in Arnstein's [23] paradigmatic article on the ladder of participation and includes studies of decision-making, power sharing, and the influence of formal interest groups [24]. Notably, however, that participation is usually constructed in eldercare as involvement in care (such as helping get dressed, and sometimes with the aim to achieve help to self-help), whereas the disability field focuses on participation in society and how society's support makes that possible [11].

For the project, the state-of-the-art research builds on what Lloyd [25] calls the personalization agenda, also described as a relational-political interpretation of the capability approach [26]. Acknowledging the relevance of structural conditions and care policies, this research has included studies of power and control over services, relations, time, and the home and its artifacts, and shows that home care can be both enabling and restrictive [27,28]. The approach has also included studies with a phenomenological approach that relate the experience of receiving home care to the meaning to older individuals of home, body, dependence, and relations [29]. Several studies have focused specifically on how older people view, evaluate, and work to establish such relations [30]. Studies using this approach have also addressed the shift to marketization and show that older care users' choices play out in ongoing care and not just at the point when a particular care provider is chosen [31-33].

Drawing on theories in disability studies, the knowledge gained from the project will be used to develop a theory of care. The fact that the nexus of disability and ageing is attracting greater interest, and that concepts such as social rights, discrimination, and exclusion are now being used in policies on ageing, will facilitate the use of a disability lens in the study of home care [11,12,34], bringing a fresh focus on the way home care services enable older people to fully participate in society, or, where relevant, to regard services as restrictive and therefore ageist, with all that the concept of ageism means for the project findings.

The project will take a longitudinal approach. Increased needs frequently entail help from ever-larger numbers of providers, and pilot interviews reveal the efforts made to navigate what is on offer from different providers. Previous studies show that care users adapt their habits to (restrictive) arrangements that they consider to be the conditions of care, but that they also learn what demands and questions to put to care providers, and they try to develop relations that work against and between what is formally granted by the organization [27,28]. The project will provide a unique understanding of how relations, loyalties, skills, and adaptations develop within home care.

Methods

Overview

To address its stated aim and questions, the project will map, investigate, and follow up on care use from the perspective of care users. The mapping will be done with structured interviews with users and in some instances with information from their cohabiting partners and is inspired by existing network studies [35]. The main part of the project will be based on interviews and participant observations. Finally, care use will be followed up using the project's chosen longitudinal approach [36]. This phase of the project will also include a study of care users' diary notes. In its qualitative and longitudinal approach, the project will provide knowledge beyond satisfaction ratings and so will contribute to a well-grounded understanding of eldercare as negotiated by older people in their daily lives, with developing relations and adaptations. By including cohabiting partners, knowledge will be gained about how they too fit care arrangements into their daily lives, and possibly must take on new roles when interacting with home care staff.

Care always occurs within a broader social context of established policies, here in the context of the Nordic welfare state. Policy is realized in everyday practices, and thus a microsociological understanding is crucial when theorizing care use. The project will be theoretically anchored in symbolic interactionism and will use an ethnographic study design to reveal meaning-making, interaction, and the negotiation of identities. The point of symbolic interactionism is that people act toward things based on the meaning those things have for them, and meaning is created in an interpretive process derived from social interaction [37]. In the data analysis, we will make use of theories and concepts developed for the understanding of human service work [38,39] and care work [1,40]. These theories and concepts will be adapted to the care users' positions and perspectives, and the analysis will focus on categorization work (users' categorizations and their evaluations of care staff), empathy, and emotion work, whereas impression management will be studied at the point when older people encounter human service organizations and their representatives (the care staff). This redirecting of analytical focus will be facilitated by the types of comparison to the field of disability studies suggested above.

The theories that the project is designed to develop will increase the understanding of home care use as a *position* and *practice*, anchored in a broader social context but realized in older people's everyday lives. This way of theorizing care could potentially be developed as part of a broader paradigm of help-receiving and care-receiving that reflects people's everyday conditions.

Studies that use a symbolic interactionist approach typically have 2 overarching stages: exploration and investigation [37]. Below, we will first describe how the exploration stage has proceeded, to be followed by the investigation stage, which falls into 3 phases. During the investigation, concepts will become fixed as part of the findings and theory development.

Exploration

The exploration stage has been initiated and conducted through pilot interviews and various contacts with partners for collaboration in the field. The pilot interviews (financed by Helsingborg Council for December 2020 to October 2021) indicate that care users engage in a continuous form of "work"—emotional, practical, and rhetorical activities. Care users use these activities to prepare staff and guide the provision of care, to defend the privacy of their relations and homes, and to avoid depersonalization. Some users carefully prepare their homes and themselves to ensure that care activities run

XSL•FO
RenderX

smoothly. They may display an emotional interest in staff members' personal lives to make themselves visible as individuals. Some users describe rhetorical strategies to adopt the correct organizational and technical vocabulary to get the help they want, to avoid the response "We don't do that," and to develop relations with staff that affect the character of care.

From the exploration stage's pilot interviews and literature review, we have so far identified four themes to be used as sensitizing concepts.

1. Enablement (goals in everyday life, achieved with home care and the navigation and coordination of services)
2. Relations and loyalties (in and beyond the home care tasks)
3. Power and control (over services, space, time, and categorizations)
4. Identity (as affected by receiving care and used to interpret the meaning of care)

The investigation will fall into 3 phases, including empirical studies, collaboration with users and other actors outside academia, and dissemination. The studies of the project are described below, whereas the other activities are described elsewhere in this application.

Stakeholder Involvement During the Exploration Stage

Contacts with members and stakeholders of the field studied are an essential part of the exploration stage, and in the project, such contacts take the form of user involvement and collaboration with actors outside academia. The project uses a model for collaboration and user involvement that focuses on purpose, actor, magnitude, and process [41]. This PAMP (Purpose, Actor, Magnitude, and Process) model (SAPO in Swedish) will guide the development of the project, and below we describe the way the initial stage has proceeded. The purpose of this involvement is to identify relevant questions and sensitizing concepts for further studies, a process similar to what Greenhalgh et al [42] call priority-setting.

Two stakeholder panels have been set up, and additional collaboration has been established with a panel of stakeholder organizations.

Panel 1: Stakeholders With Home Care and Cohabitating Partners

Throughout the project, a user panel of 5 older people with several years of experience of home care will provide feedback on the research process, analysis, and dissemination of results. The panel members have already been involved in the exploration stage, developing research questions and provided valuable feedback on how to strengthen the project's user orientation. Members of the user panel will be part of the project for the entire period (except the dissemination phase) and will be able to influence findings by their validation at regular meetings. The panel consists of persons from the pilot interviews, the current ethnographic study, and professional and personal contacts. Participants have been informed that participation in the panel is voluntary and based on interest to discuss the type of questions that the project investigates. The plan is to have 2 annual meetings. A first meeting was held in May 2022 and a second in November 2022. A lesson so far concerns the frailty of the panel, with a need to recruit new members in case of severe illness or death.

Panel 2: Senior Stakeholders

Throughout the project, a panel of 6 older persons who are interested in the topic of the project will provide feedback on the research process, analysis, and dissemination of results. They will be recruited among senior citizen organizations as well as professional contacts in order to get a balanced distribution of senior citizens. Participants have been informed that participation in the panel is voluntary and based on interest to discuss the type of questions that the project investigates. The plan is to have 2 annual meetings, and the meetings were held in April 2022 and October 2022.

Panel 3: Organizations as Stakeholders

Contact has been established with 3 collaboration partners to act as members of a reference group during the projects. These partners are representatives of Helsingborg Council's eldercare provision; regional and local representatives of the 2 pensioners' organizations, PRO (Pensionärernas riksorganisation, the Swedish national pensioners' organization) and SPF (SPF-Seniorerna, the Swedish association for senior citizens); and representatives of Seniorval (lit. Seniors' choice), a national private provider of information and guidance for older people who apply for home care. During the investigation and dissemination stage, the external partners will be invited for discussions on how to translate our findings into information and programs that are useful for older people who use home care.

The purpose of involving representatives of a local authority and a provider of information—Seniorval—is to achieve direct impact by developing routines and information based on the findings of the project. These actors will be consulted at regular meetings.

Investigation

Phase 1: Mapping Care Arrangements and Investigating Care as a Relational Practice

The first core study will map out the different kinds of care arrangements in older people's everyday lives. Research on informal care has shown that relatives provide a type of managerial care that includes the planning and coordination of help efforts [9], and it has been noted that also older home care users themselves and their cohabiting partners engage in such coordinating efforts [28].

Study 1 will be based on semistructured, qualitative interviews with 25 care users and 10 cohabiting partners, in which the research questions will serve as nodal points for the questions in the interview guide. The first part of each interview will be devoted to a structured mapping of help from the perspective of the care user (including cohabiting partners' perspectives on the help provided in their shared home).

Phase 2: Home Care as Accomplished, Coordinated, and Fitted Into Everyday Life

The second core study will be the most extensive, to be based on interviews and participant observations on several occasions.

XSL•FO
RenderX

Researchers will be present in the users' homes on 2 separate occasions when care staff visit. During these "stay-along observations" (inspired by go-alongs [43]; see also [28]) we will observe and engage in informal field-based interviews with users, staff, and (where present) cohabitating partners. This method will allow us to observe users' preparations and interactions, matched with a fine granularity in the details of care for the necessary contextual understanding of the users' and cohabiting partners' interpretations and strategies.

Study 2 will be based on the interviews conducted in study 1 and on 2 participant observations in the homes of the 25 care users within a month of the first interviews. Instead of accompanying home care staff as they visit various users, we will be present in the users' homes on 2 separate occasions when home care staff visit.

Phase 3: Care Use and Change Over Time

The third stage of the project will follow up on care use using the project's chosen longitudinal approach [36]. On the basis of interviews with care users and additional observations, this approach will provide knowledge of how the user's strategies, perceived needs, and relationships with care staff change. A second study with the same objective will collect data in the form of older care users' diaries. Diary methods can offer a more comprehensive understanding of an individual's everyday activities and thoughts, and the data provided are likely to give a different insight compared with conventional interview approaches [44]. It is also a means of identifying important but seemingly mundane practices, which may be overlooked when relying on "snapshot" approaches such as interviews and surveys.

The follow-up study is based on interviews with all available care users, conducted 16-22 months after study 1. The objective is to gauge how perceptions, relations, and strategies change over time, especially in relation to any alteration in the users' needs and degree of dependence. A total of 10 participants will be chosen for a final round of participant observations.

Diary data will be collected from approximately 10 care users. Each participant will be asked to complete and return a weekly diary for 20 weeks.

Data Collection

Approximately 25 care users from three Swedish local authorities will be included in the project. Additional interviews will be conducted with 10 cohabiting partners. Out of the 35 total respondents, data will thus consist of 60 (25 + 25 + 10) interviews plus 60 (25 + 25 + 10) stay-along observations and diary notes from 10 home care users. The following selection criteria will be used to identify participants: the care user should be 65 years or older and have home care at least twice a week. The project will strive to achieve diversity in the level of care, gender, socioeconomic aspects, and length in experience of living with home care. As part of the effort to map services from a user perspective, 10 participants will be chosen who have home care and combine it with private help through the RUT.

Approximately 10 older people will participate by writing diary notes about their experiences of home care and other forms of care over 20 weeks. The following selection criteria will be used: the care user should be 65 years or older, have home care at least twice a week, and be interested in formulating their experiences in writing. Participants will be recruited through the website Seniorval, where the researchers will advertise for home care users with an interest in documenting their experiences and reflections in diary format.

Home care users with cognitive disorders (dementia) will not be included in the project studies, but the project will develop theory that may be used in future studies of persons with such disorders.

The types of data that are generated are recorded and transcribed interviews, field notes from observations, and diary entries.

Data Analysis

The project will produce a range of findings and is designed to develop a theory of care use. Data will be coded using the NVivo software package, and the steps of qualitative content analysis [45] will be used in the different project studies. Following the tradition of symbolic interactionism, findings will be grounded in the data, guided by the research questions of the project and by the sensitizing concepts identified during the exploration stage. Theories of care work and categorizations that relate to the tradition of symbolic interactionism will inspire the analysis and development of the theory. See also the section on theoretical foundations and guiding tools above.

Ethics Approval

The project plan has been approved by the Swedish authority of ethics approval (2022-00829-02).

The project will focus on how older people interpret and negotiate home care in their daily lives. Thus, it will likely generate sensitive personal data on health. This will be the case, for instance, if interviewees comment and elaborate on illness, disability, dependency, and well-being. The principal investigator and co–principal investigator are familiar with the content and procedures for such applications and the proper procedures that follow ethical approval. Research participants will be provided with written and verbal information about the project's studies, they will be informed that participation is voluntary, and they will be asked to sign a consent form. Data will be anonymized, and publications will not contain information that makes it possible to identify individuals.

The members of the research team have extensive experience in interviewing older people and observations in sensitive contexts. Our experience is that project information and informed consent should be treated as continual practices throughout the research process. Given the project's longitudinal approach, researchers will ask for informed consent at each of the 4 visits. Prior to each "stay-along observation," the researcher will ask research subjects about potentially sensitive situations and how these should be handled. Researchers will not observe situations that are ethically problematic, such as toilet visits and dressing or undressing.

The knowledge gained will benefit older people in a broad sense by shedding light on the everyday realities of those who receive home care. Hitherto, the absence of a true user perspective is

XSL•FO
RenderX

striking. The project is not expected to cause any harm or inconvenience to the research subjects but will hopefully lead to improvements in the long run for older people with home care.

Results

Members of panel 2 participated in a meeting with representatives of the project in April 2022, with the aim to introduce the project. A meeting with panel 1 was held in May 2022, where members of the group provided feedback on an interview guide, through meta-discussions and direct responses to some of the questions. A second meeting with the 2 panels was held in October and November 2022, with the aim to present preliminary findings in order to discuss their validity and relevance.

Between May and October 2022, the first round of interviews (n=25) was finalized. Interviews with partners will be finalized in January 2023, and the first round of observation is expected to be finalized by March 2023. Data collection with follow-up interviews and observations, analysis, and reporting of findings will be completed by December 2024.

Discussion

Principal Findings

The expected main findings of this ethnographic study on home care from the user perspective are that older people use their agency to navigate and fit home care into their daily lives, and that home care enables aging in place but has a number of restricting features that concern the control of time and place.

A user-oriented perspective on eldercare will have an important role in the new landscape of eldercare. This landscape has a theoretical and administrative ambiguity about the content and meaning of eldercare. A revision of the Social Services Act [46] in 2018 allows local authorities to grant older persons home care without an assessment of individual needs. This reform is likely to push the assessment of needs toward the actual meeting between the care user and the care provider, a development at odds with the emphasis on professional needs assessments according to the International Classification of Functioning, Disability and Health–based tool IBIC (Individens behov i centrum [the Individual's needs in center]), previously introduced by Socialstyrelsen [47]. The emphasis on the actual meeting or interaction between the user and provider is also evident in the government white paper [48], according to which older home care users should be offered a personal contact person (*omsorgskontakt*) who is responsible for providing support and managing the personalization of care. However, the actual nature of the position of *omsorgskontakt* is left open. Should it be a member of the professional team that coordinates services for the user, or should it be a care worker who is chosen by the user to perform most services based on their relation and trust? This role ambiguity is also connected to the ongoing marketization of eldercare. Should care be provided by certified, professional care staff, as has been suggested in a government investigation [49] or should Sweden's system for tax deductions for domestic services (RUT), which is increasingly being used and sometimes labeled as "eldercare," be further developed for the category of older people [50]? This system has made it cheaper for older people with higher incomes to buy help and personal care or to top up needs-assessed home care [15]. This development may cause increased social inequality and the exploitation of unskilled workers—private care is now the backbone of eldercare in several European countries. Within the heated debate on marketization, there is even a risk that researchers stress the inability and incompetence of older people as care users to question the relevance of choice models [17]. The third route that the project will develop is needed as part of the ongoing development of eldercare.

Strengths and Limitations

The project has a qualitative multimethod approach using semistructured interviews, observations, and diary notes. A strength in method diversification is a prediction of each capturing different aspects of the subjective experience. An interview is more likely to prime a respondent to evoke stories of critical or otherwise noteworthy events, mostly because of role expectation. The collection of diary notes aims to capture more mundane observations from an older person that may not have made it into an interview answer. The added strength of a period of diary note taking is that the older person will likely be more observant for a period of time. The observations complement the other methods, in that the researchers observe what is happening and prompt a series of short field-based interviews [51] right after a home care visit, which is expected to give slightly different answers when the memory and possibly affect are fresh. The mapping aspect has the strength of combining older persons' experiences with more structured questions from the researcher, contrasting the older persons' subjective experience with references of comparative needs [52].

The main limitation of the project concerns recruitment and inclusion criteria. For the selection of the first 35 older persons for interviewing, the municipal home care managers are needed in order to gain access according to plan. By having municipal managers and home care staff as gatekeepers, there is a risk that older persons who are most likely to have a positive attitude toward home care will be asked to participate. This risk is particularly present when organizations represent fear that the project aims to evaluate the organization and its co-workers rather than exploring the experience of everyday life with home care. Representatives will therefore be informed about the aims of the project and that data will be anonymized when presented in publications. Alternative forms of recruitment based on advertising and snowball sampling will be used as complement, but it should be acknowledged that these methods are likely to result in an overrepresentation of persons being particularly critical. Finally, persons living with dementia and mental illness are excluded from the project for ethical reasons, unless they appear in interviews with cohabiting partners. This excludes an important part of the population who uses home care. These problems of representations will be continuously discussed among members of the research team and presented as limitations in publications of the project.

XSL•FO
RenderX

Conclusions

In this ethnographic 2-year study on home care from a user perspective, we will interview older persons on 2 occasions, conduct participant observations and ask care users to write home care diaries.

By studying care use in the context of older people's lives the project will add important knowledge on the strategies and adjustments older people use to make care arrangements work. A user-oriented perspective will further the understanding of how power relations play out in home care over time, in relation to the formal rights, categorical belongings, and established norm systems that place the user in superior or subordinate positions. The project is expected to contribute empirical and theoretical knowledge on care and is anticipated to have a societal impact on 3 different levels.

First, the quotes and discussions that will be cocreated by respondents and researchers can serve as important consultative data for policy makers. The unique value from a policy design perspective is that the research goes beyond a user-satisfaction focus and gives an older person perspective on how the current welfare delivery is received, interpreted, and negotiated.

The second dimension of contribution is that this research can be read by providers of home care. It may act as consultative data in terms of how the scheduling, staffing patterns, and "the doing" are perceived and how the elderly use their agency to make it fit their life plans. More importantly, it can be used by care staff and other providers of care in order to develop a deeper understanding of everyday practices from the perspective of those receiving help.

The third dimension of the societal impact is an emancipatory one, given that older people who use home care can take part in other persons' stories in order to make sense of their own experiences as well as finding legitimacy, comfort, and courage in knowing that others share aspects of their subjective experiences. A long-term secondary outcome may be a contribution toward mobilization and gaining leverage in maneuvering a quasi-market of welfare provision.

Acknowledgments

The project is based on a pilot study funded by the city of Helsingborg. The project is funded by Swedish Research Council for Health, Working Life and Welfare (FORTE 2021-00506).

Data Availability

All data are qualitative and no data sets have been used. According to the project plan's ethics approval, the transcribed interviews are available to the responsible research team.

Conflicts of Interest

None declared.

Abstract

Background: Living donor kidney transplantation (LDKT) is the best treatment option for patients with kidney failure and offers significant medical and economic advantages for both patients and health systems. Despite this, rates of LDKT in Canada have stagnated and vary significantly across Canadian provinces, the reasons for which are not well understood. Our prior work has suggested that system-level factors may be contributing to these differences. Identifying these factors can help inform system-level interventions to increase LDKT.

Objective: Our objective is to generate a systemic interpretation of LDKT delivery across provincial health systems with variable performance. We aim to identify the attributes and processes that facilitate the delivery of LDKT to patients, and those that create barriers and compare these across systems with variable performance. These objectives are contextualized within our broader goal of increasing rates of LDKT in Canada, particularly in lower-performing provinces.

Methods: This research takes the form of a qualitative comparative case study analysis of 3 provincial health systems in Canada that have high, moderate, and low rates of LDKT performance (the percentage of LDKT to all kidney transplantations performed). Our approach is underpinned by an understanding of health systems as complex adaptive systems that are multilevel and interconnected, and involve nonlinear interactions between people and organizations, operating within a loosely bounded network. Data collection will comprise semistructured interviews, document reviews, and focus groups. Individual case studies will be conducted and analyzed using inductive thematic analysis. Following this, our comparative analysis will operationalize resource-based theory to compare case study data and generate explanations for our research question.

Results: This project was funded from 2020 to 2023. Individual case studies were carried out between November 2020 and August 2022. The comparative case analysis will begin in December 2022 and is expected to conclude in April 2023. Submission of the publication is projected for June 2023.

XSL•FO
RenderX

Conclusions: By investigating health systems as complex adaptive systems and making comparisons across provinces, this study will identify how health systems can improve the delivery of LDKT to patients with kidney failure. Our resource-based theory framework will provide a granular analysis of the attributes and processes that facilitate or create barriers to LDKT delivery across multiple organizations and levels of practice. Our findings will have practice and policy implications and help inform transferrable competencies and system-level interventions conducive to increasing LDKT.

KEYWORDS

transplantation; living donor kidney transplantation; health systems; barriers; resource based theory; complex adaptive systems

Introduction

End-stage renal disease represents a major public health burden. Patients needing dialysis have extremely poor survival rates when compared with the general population [1,2]. This is because these patients have a higher cardiovascular disease burden, greater susceptibility to infections, and demonstrate a decreased response to vaccination [3-6]. The intrusiveness of dialysis can significantly impede normal facets of life, such as work, vitality, and freedom to travel [7].

Kidney transplantation, in particular living donor kidney transplant (LDKT), is widely regarded as the best therapeutic option for patients with kidney failure. When compared with patients undergoing dialysis, those who have undergone kidney transplantation experience a 64%-75% lower risk of death by the first year following transplantation [8-13]. LDKT is a surgery that involves a healthy individual donating one kidney to a patient (recipient) with kidney failure. Given that there is a finite pool of deceased donors in any given year, and that the demand for organs far exceeds its supply [11,14], pursuing LDKT can narrow this gap and provide early access to a transplant. There are also many medical benefits to LDKT. The median survival of a kidney transplant from a living donor is longer than that from a deceased donor [8-11]. Those with LDKT also experience lower rates of acute rejection, spend less time on dialysis, and have an improved quality of life [10,15-21]. Thus, there is considerable interest in increasing the rate of LDKT [15].

Despite its significant benefits, LDKT rates in Canada have stagnated over the past decade and continue to average around 12-14 living donors per 1 million population. This is despite national efforts to increase LDKT, such as the paired kidney exchange program [1,10,22,23]. There are also significant interprovincial variations across provinces. For example, in Quebec, Ontario, and British Columbia, Canada's most populous provinces, <15%, 30%-40%, and 50%-60% of kidney transplants performed annually are from living donors, respectively [11]. Similar trends are noted when comparing the living donor rates per million population across these provinces [1,10,23,24]. The reason for this significant disparity in a country with universal health care is not known.

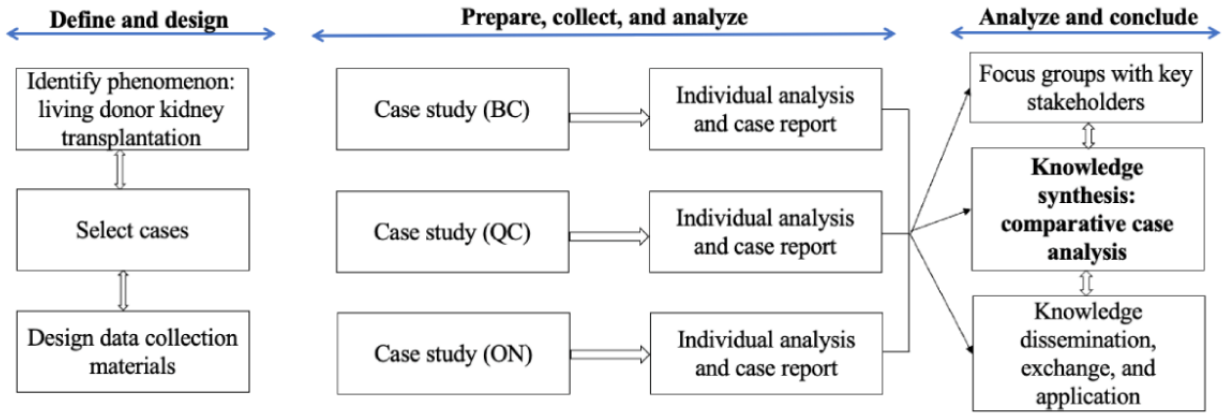
Currently, the impetus of finding living donors is largely placed on the patient, and much of the present work to increase LDKT focuses on patients and addressing these microlevel barriers [25]. We conducted a qualitative study, exploring the perspectives of health professionals on the provision of LDKT [26,27] and identified poor communication between treating teams, absence of consistent guidelines, and lack of resources as barriers. Notably, some of these barriers were more prominent in provinces of Canada that have lower rates of LDKT. This work alluded to the existence of systemic attributes that impede the effective delivery of LDKT, thus driving the need to understand the factors driving these differences to inform system-level interventions to increase LDKT.

As such, the objective of the study described in this protocol is to generate a systemic interpretation of LDKT by identifying the attributes and processes that facilitate the delivery of LDKT in a provincial health system and those that create barriers. We also aim to identify the differences between these attributes and processes by comparing higher- and lower-performing systems. These objectives are contextualized within our broader goal of increasing rates of LDKT in Canada, particularly in lower-performing provinces. Our primary research question is the following: what are the attributes and processes of provincial health systems that account for variability in LDKT rates?

Methods

Research Approach

This study takes the form of a comparative case study analysis as described by Yin [28,29] and illustrated in Figure 1. Case study research is an in-depth, noninterventional examination of a single case over time to investigate a contemporary phenomenon in its natural context [29,30]. Case studies have been identified as the preferred methodology for examining high-performing health systems [31-39]. As quantitative data concerning rates of LDKT across provinces have been well-documented elsewhere [40-4], our study follows a qualitative design to investigate *how* and *why* these differences in performance exist. Qualitative methods have established relevance to answering these questions in health research [43]. Understanding the system as an integrated whole lies in understanding the patterns and relationships between its levels and key players [44]. Our qualitative design will investigate these real-world behaviors and perspectives at multiorganizational levels, in order to understand full system function. Thus, our case study analysis will be explanatory because it will explore and connect how certain attributes and processes of a provincial health system are linked to the provision of LDKT [28]. It will be inductive—that is, allowing



XSL•FO
RenderX

themes and explanations to be derived primarily from a close reading of the data—without trying to fit it into a priori concepts.

Conceptually, our approach is underpinned by an understanding of health systems as complex adaptive systems (CASs). The concept of CAS stems from the complexity theory and takes a dynamic systems approach. A CAS is "an entity composed of many different parts that are interconnected in a way that gives the whole capabilities that the parts don't have on their own" [45]. A provincial health system that delivers LDKT can be understood as a CAS, in that, it is a multilevel, interconnected system that involves nonlinear interactions between people and organizations, operating within a loosely bounded network. CAS approaches have been used increasingly as an analysis and research development tool in health care, with favorable results [44,46,47].

There also exists a tight fit between a CAS approach and case study methodology [44]. Researchers have identified that multiple methods that are often used in case study research lend themselves to understanding emergent elements and system dynamics [44]. Complexity theory also suggests that comparing the best to the worst in multiple case comparison can be a fruitful way of understanding the source of new structural arrangements and patterns of behavior [44,48]. Accordingly, our comparative method entails the comparison and synthesis of the similarities, differences, and patterns across multiple cases that share a common goal [39,49].

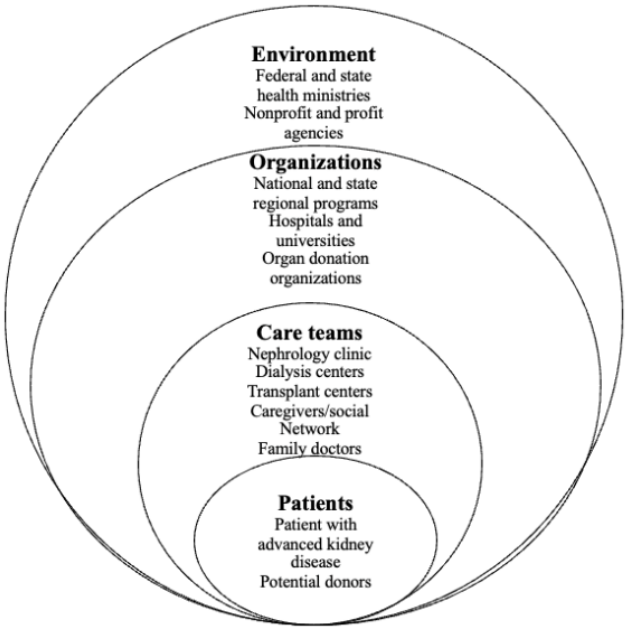


Figure 1. Comparative case study analysis design (adapted from Yin's [28,29] methods of case study research). BC: British Columbia; ON: Ontario; QC: Quebec.

Case Definition

In accordance with the CAS theory, we defined each provincial "case" as the health system involved in facilitating LDKT. Adapted from the 4-level model proposed by leading agencies [50] we mapped a whole-system model of LDKT, composed of macro-, meso-, and microlevels of practice that are interconnected, dynamic, and nested, with the patient at its core (Figure 2) [51]. These levels include organizations, service providers, recipients, and donors, representing the human and nonhuman agents that are implicated in the delivery of LDKT and thus form the elements for our analysis.

Figure 2. Envisioning the health system that delivers living donor kidney transplantation to patients as a complex adaptive system (adapted from the 4-level model proposed by the National Academy of Engineering [United States] and Institute of Medicine [United States] Committee on Engineering and the Health Care System).

XSL•FO
RenderX

Case Selection

We will conduct a comparative case study between British Columbia, Ontario, and Quebec, which represent respectively high, moderate, and low performance in LDKT as defined by the percentage of LDKTs to all transplantation performed annually [11]. These three provinces represent 75% of Canada's population, and over 70% of the patients with end-stage renal disease reside in these provinces. Thus, performance in these provinces significantly influences the country's overall transplant results. Additionally, since these provinces have low, moderate, and high rates of LDKT, we have an ideal case mix to facilitate interprovincial learning, as well as for theoretical replication, reliability, and external validity [28].

Design

Our study follows sequential stages of data collection and analysis (Figure 1). We have conducted independent case studies of the health systems in British Columbia, Ontario, and Quebec using the data collection methods discussed below. Following data collection and independent analysis in all 3 provinces, we have recently conducted focus groups with stakeholders from across Canada, asking their opinions and experiences of the themes derived from the preliminary analysis of these cases. We will now conduct a comparative case study of British Columbia, Ontario, and Quebec. We will use the focus group data to develop and refine the themes from our comparative case study to form a final analysis.

Participants

Participants from different levels of the health system, as shown in Figure 2, were recruited for interviews. As LDKT is organized largely by each province, representatives from federal bodies were invited to participate in focus groups, where we discussed and refined the national relevance of our findings. Table 1 shows a breakdown of participants invited for an interview. The composition of interviewees seen in Table 1 comprises an approach to "studying through," tracing relations among actors, institutions, and discourses across spaces through interview data [52,53]. In accordance with our CAS approach, our participants represent macro-, meso-, and microlevels of practice. As the organizations implicated in LDKT vary among British Columbia, Ontario, and Quebec—for example, Quebec does not have a provincial renal program—the list of participants invited was adjusted accordingly.

Table 1. Types of participants and the numbers that were targeted in each category in each province.

Participant category	Number for each province
Ministry of Health representative	1-2
Organ Donation Organization representatives	2-3
Renal program representatives	2-3
Health care professionals at transplant centers	8-10
Health care professionals at nephrology clinics or dialysis centers	8-12
Living donor kidney transplant recipients	2-4
Living donors	2-4

Recruitment

To recruit participants, purposive criterion sampling was used to invite key leadership at organ donation organizations, provincial renal programs, and transplant centers. Participants were considered to have key leadership roles if they held decision-making authority with interorganizational impact. Thereafter, snowball sampling was used to recruit providers from kidney care clinics and dialysis centers [52,55]. Data gathering continued until data saturation was reached; that is, when new interviews and document reviews did not provide additional information [56].

Data Collection Methods

Semistructured Interviews

Semistructured interviews were conducted to understand the dynamic organization, governance, and care entailed in LDKT delivery and the interdependencies between the elements of each provincial health system. We also sought to understand what aspects of the system variously promoted or hindered patient access to LDKT. Interview guides for professional participants addressed their involvement in facilitating LDKT for patients, their interactions with other professionals in this process, their attitude toward LDKT, and which phenomena helped and which ones posed challenges in their work. Interview guides for donors and recipients of LDKT focused on their experiences of LDKT, their perception of care, and what helped and hindered their care path. Distinct interview guides with open-ended questions were developed for each category of participant with the combined expertise of our research team and preliminary document review (see sample guide in Multimedia Appendix 1). We followed an iterative approach whereby issues or ideas identified by participants were discussed with subsequent participants to enable further definition and refinement of themes [57]. Interviews were conducted remotely in English or French by our bilingual research coordinator (AH). All interviews were digitally recorded and transcribed. Participants were compensated with a CAD $50 (US $37.57) gift card following their participation in the interview.

Document Review

Document review served as complementary data collection to inform our understanding of programs, policies, and resources concerning LDKT in each province and as means of triangulation with interview data [58]. Documents for review were identified in consultation with our collaborators in each province, during interviews, and using web searches of

XSL•FO
RenderX

governmental, organ donation organizations, renal programs, and hospital platforms. Documents were included if they were a policy, guideline, resource, program outline, presentation, announcement, or report pertaining to LDKT. Searches were conducted in both English and French.

Focus Groups

Following data collection in all 3 provinces and the initial coding of individual case studies, we conducted 4 focus groups remotely with the purpose of gleaning opinions about our preliminary themes from key stakeholders (Table 2). Focus groups comprise a small group of people brought together to discuss a particular issue, under the direction of a facilitator [59]. They are widely used in health research and are recognized to produce considerable information in a short space of time [59]. We recruited previous interview participants for focus groups, as well as patients, patient partners, and professionals from other provinces of Canada. In these focus groups, we presented themes from our preliminary analysis of the 3 case studies to participants and asked them about their opinions and experiences. Focus group guides were developed from our initial data analysis and reviewed by the research team. Each focus group lasted approximately 60 minutes, comprised 5-13 participants, and was conducted by the research team experienced in facilitating discussions in this setting (AH and KL). The focus groups were audio-recorded and transcribed. Participants were compensated with a CAD $50 (US $37.57) gift card following their participation in the focus group.

Table 2. Types of participants who were identified for participation in the focus group.

Focus group	Approximate number of participants	Participant types	Language of conduct
1	10-12	A health care professional working in transplantation or nephrology; or a representative from a provincial renal program, organ donation organization, or provincial health ministry, who has previously participated as an interviewee in this study	English
2	4-6	A health care professional working in transplantation or nephrology; or a representative from a provincial renal program, organ donation organization, or provincial health ministry, who works in a province outside of British Columbia, Ontario, and Quebec	English
3	4-6	An LDKT[a] recipient or living donor who has experienced LDKT in the last 7 years and whose preferred language of conduct is English	English
4	4-6	An LDKT recipient or donor who has experienced LDKT in the last 7 years and whose preferred language of conduct is French	French

[a]LDKT: living donor kidney transplantation.

Data Analysis

Individual Case Studies

Data from each case study were analyzed using inductive thematic analysis [43]. Thematic analysis involves identifying and analyzing patterns of meaning [60], and mapping regularities and variations across different accounts [59,61]. It is best suited to studying the processes and attributes of a system because it provides a "map" of the content and patterns across a data set [59], preserving our whole-system approach to understanding LDKT delivery [44]. Interview transcripts were analyzed independently by 2 research associates experienced in qualitative research (AH and KL). NVivo (version 12; QSR International) was used to support data management and analysis.

Transcribed interview data were read and highlighted line-by-line to openly derive preliminary codes that emerged iteratively from the data set. These codes were organized into categories and subcodes to form an initial coding scheme. Codes were then compared across the data set for regularities and divergences and modified accordingly. Through this process of inductive analysis, a coding scheme evolved, which retained strong links with the original data set [62]. The resultant codebooks for each individual case study have been retained as the basis for cross-comparative analysis. Coding, emerging themes, links between themes, and any disagreements between the 2 research associates were discussed at regular research team meetings. Our analytic procedure of documents entailed appraising and synthesizing the data contained in documents, followed by clustering the documents thematically [58]. The 2 research associates compared interview data to verify and corroborate findings from each case study. Analyses from each province are being published as individual case studies as the research progresses.

Comparative Case Analysis

Our comparative analysis will operationalize the resource-based theory (RBT) to compare case study data and generate explanations for our research question. The RBT is a strategic management theory that provides a framework for explaining and predicting the basis of an organization's competitive performance and advantage [63]. RBT involves a broad classification of resources as tangible and intangible assets and aims to assess how resources create strategic advantage by examining how they are combined and managed [64,65]. It is a framework with established relevance in health systems and health management research to understand problems of high organizational complexity [66]. Thus, there is a high level of theoretical congruence between the complexity theory and the RBT, as the RBT engages with the social complexity of how resources—physical, human, and organizational—are combined [67]. The importance of network competence, dynamic capabilities, and strategic alliances between organizations is also well-recognized in this framework for achieving strategic advantage [67-69]. This is particularly pertinent for the study of the CASs that provide LDKT, where management is

XSL•FO
RenderX

distributed between organizations and interorganizational relationships [69]. As such, the RBT provides relevant and useful concepts to understand the full-system function of LDKT, as well as identify the attributes and processes that characterize a high-performing system. Our analysis will follow the principles of RBT, with an emphasis on collaborative organizational relationships, in order to understand and compare the whole-system function of LDKT provision.

Following inductive coding and individual analysis of data collected from British Columbia, Ontario, and Quebec, we will use an RBT framework to analyze and compare our case study data and generate explanations for our research question. To do this, we will organize codebooks from each province into capabilities identified from the RBT literature, following questions stemming from these capabilities to guide our organization (Table 3). According to the RBT, a capability is what can be done as a result of resources working together [70]. We will therefore delineate and compare the attributes and processes from each province that determine their capabilities to deliver LDKT. The same 2 research associates who coded individual case studies will go through codebooks from each case study to extract information about the RBT capacities identified above and assign existing codes to the relevant RBT capability, to build themes. Through an iterative process, we will assign codes to emerging themes, create new themes where needed, and merge themes if they replicate each other until saturation is reached. We will then compare and contrast the themes in each RBT capability among provinces to identify "distinctive competencies" [71]; that is, attributes and processes that exist in certain provinces and not in others. We will compare our focus group data (analyzed using inductive thematic analysis, following the same process described above [43]) to themes from the comparative analysis, adding these data to existing themes where it is concurrent and creating new themes where it diverges. This process will deepen our understanding of the attributes and processes we have identified, and their relevance to other Canadian provinces. Following this approach, we will develop explanations for how resources in each province are deployed to achieve strategic advantage and to explain one province's strategic advantage relative to others in LDKT performance. We will contextualize these capabilities in characteristics described by interviewees that operate externally from the provincial organization of LDKT, which influence delivery. We will situate our analysis in a discussion of these external dependencies.

Table 3. Resource-based theory capacities for comparative analysis.

Capacity	Guiding questions
Resources	What, where, and how are resources deployed in LDKT[a] delivery?
Competition for resources	What competition exists for resources to facilitate LDKT?
Organizational capacity	What are the organizational capacities of the organizations involved in LDKT delivery?
Collaborative capacity	What collaborative capacities exist in and between organizations?
Value creation	What activities create value for LDKT?
Dynamic capabilities	What are the dynamic capabilities of organizations?

[a]LDKT: living donor kidney transplantation.

Ethics Approval

Ethics approval for this study was obtained from the McGill University Health Centre Research Ethics Committee (MP-37-2021-7126/LDKT Case Study). This study is being conducted in accordance with the Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans (2014), and the Declaration of Istanbul.

Results

This project was funded by a grant from a Gift of Life Institute, a Clinical Faculty Development Research Grant from the American Society of Transplantation from 2020 to 2021, and by a Health Research Grant from the Kidney Foundation of Canada. Individual case studies of British Columbia, Ontario, and Quebec were carried out between November 2020 and August 2022. The individual case study findings of LDKT delivery in British Columbia have been published [72,73]. Focus groups were carried out between June and November 2022. The comparative case analysis began in December 2022 and is expected to conclude in April 2023. Writing up of our findings is projected for May 2023, and manuscripts are expected to be submitted for publication by July 2023. A patient partner from Quebec was consulted regarding participant selection, study materials, and analysis and was involved in the publication of the case study [73].

Discussion

Expected Findings

This study aims to produce a system-level understanding of LDKT delivery in Canada's 3 most populous provinces that have variable rates of LDKT, presenting a unique opportunity for comparative analysis. Informed by quantitative data [11], we are using qualitative methods to explain these differences. We want to identify the attributes and processes that facilitate or create barriers to LDKT using the RBT. Our preliminary findings suggest that barriers to effective LDKT delivery exist at different organizational levels of the health system and, critically, in the relationships between these organizations. LDKT delivery is aided by supportive governance organizations with a provincial overview, which increase the collaborative capacities of the system, boost organizational capacity, and

XSL•FO
RenderX

generate value for LDKT across the different organizations involved [72,73].

To our knowledge, a comparative case analysis approach has not been used in the field of nephrology or kidney transplantation. Our approach has implications in these disciplines where there exists a poor understanding of system-level factors leading to inferior outcomes, inequities in access to therapy, and fractured transitions of care. This work also has global implications as LDKT is the main way to obtain a transplant in many countries that lack infrastructure for deceased donation. Based on our preliminary results and background work, we believe that to make significant improvements to LDKT delivery, interventions must target the dynamic relationships between different elements of a system. Much of the current work has focused on microlevel interventions to improve LDKT delivery [25,51], missing the important influence of meso- and macropractices and the dynamic interdependencies that exist between these levels of a health system [51]. Our findings will build on other studies that focus on implementing interventions to improve patient education and comfort on LDKT [16,74-78], and will help reenforce it by informing effective implementation strategies that encompass all levels of a health system.

Limitations

The following limitations to our study may apply. First, our data collection largely pertains to 3 provinces of Canada and our findings may not be applicable to other regions and countries. Nonetheless, it should be noted that Quebec, Ontario, and British Columbia are Canada's most populous provinces and represent 75% of the Canadian population, and our focus group data also go some way to establish the pertinence of our findings to other provinces. Our data also lay the foundations to extend our work across Canada and to other countries. Second, our research will not comprehensively explore the system-level factors leading to disparities in LDKT, such as gender and sex disparities and low rates of LDKT in Indigenous and other vulnerable populations. However, the data collected in this study will inform future systematic approaches needed to address this complex issue.

Another limitation may pertain to the challenge of delineating the "boundaries" of the health systems that form the basis for our cases. Identifying the unit of analysis for case study research has long been identified as a challenge [79], and in the complex field of health care, it may be difficult to differentiate between organizational and system boundaries and their environments [80]. We have delineated our cases by drawing on the extensive expertise of our team and collaborators, many of whom are practitioners in this field, as well as following a snowballing technique to iteratively identify the actors and organizations implicated in LDKT delivery. However, some perspectives may have been missed in this process, for example, family physicians who are primarily involved in living donor care for and may exercise influence over the LDKT process. To mitigate this challenge, we will situate our analysis in a detailed discussion of factors external to the boundaries of our case, which impact LDKT delivery. Where relevant, we will highlight areas for further research. Relatedly, there is some variation in our sample size and organizational representation between cases, given the heterogeneity in how care is structured in different provinces. This may have some impact on how we are able to compare across provinces. Our analysis will include an in-depth discussion of the structural differences in renal care among British Columbia, Ontario, and Quebec to situate our findings. Finally, though we believe our document review serves as useful complementary data collection and triangulation with interview data, we acknowledge that it may not be exhaustive.

Conclusions

LDKT is the optimal treatment option for patients with kidney failure; yet, rates of LDKT have stagnated in Canada and vary significantly across provinces. There is a need to better understand how health systems deliver LDKT to patients. Following our prior work that has suggested system-level differences contributing to variability in LDKT performance, we will generate a systemic interpretation of LDKT delivery by identifying the attributes and processes that facilitate or create barriers to the delivery of LDKT. We will also identify the differences between these attributes and processes by comparing higher- and lower-performing provincial health systems. This qualitative comparative case study analysis is informed by CASs, and data analysis will be carried out in accordance with the RBT. Our findings will have practice and policy implications and help inform specific strategies, regulations, and infrastructure that are transferrable competencies and conducive to promoting the service delivery of LDKT.

Acknowledgments

We would like to thank the Canadian Donation and Transplantation Research Program and the Organ and Tissue Donation and Transplantation committees of Canadian Blood Services for their support in recruitment and grant applications. SS was supported by the McGill University Health Centre Department of Medicine's CAS research funding and now is supported by the Chercheuses-boursières cliniciennes - Junior 1 from the Fonds de recherche du Québec – Santé.

Data Availability

The data sets generated and analyzed during this study are not publicly available, as informed consent to share transcribed data for secondary use beyond this research was not obtained from the participants.

XSL•FO
RenderX

Authors' Contributions

SS conceived, designed, and conceptualized the study. PN, AH, KL, and MCF advised on the methodology, design, and theoretical frameworks. IM, GK, LG, MC, DL, and MP helped with the methods and design and facilitated data collection. AH is the research coordinator and conducted interviews. AH and KL conducted focus groups and are conducting data analysis. AH wrote the first draft of the manuscript. SS contributed to the development of the paper and provided comments for improvement. All authors read and approved the final manuscript.

Conflicts of Interest

SS has received a grant from Amgen Canada to increase living donor kidney transplantation.

Abstract

Background: Tobacco smoking is a major independent risk factor for chronic disease, and the prevalence of smoking among people with behavioral health disorders is 2-fold in comparison with the general population. Smoking rates remain high for various subgroups within the Latine community, the largest ethnic minority group in the United States. Acceptance and commitment therapy (ACT) is a theoretically sound and clinically validated therapeutic approach for several behavioral health conditions with growing evidence of its effectiveness for smoking cessation. Unfortunately, the evidence of ACT effectiveness for smoking cessation among Latine individuals is scarce, and none of the existing studies have tested a culturally targeted intervention for this population.

Objective: This study aims to address the co-occurrence of smoking and mood-related challenges among Latine adults via the development and testing of a culturally tailored ACT-based wellness program: Project PRESENT.

Methods: This study entails 2 phases. Phase 1 consists of the intervention development. Phase 2 entails the pilot testing of the behavioral intervention along with the administration of baseline and follow-up measures to 38 participants. Primary outcomes include feasibility of recruitment and retention, and treatment acceptability. Secondary outcomes are smoking status and depression and anxiety scores at end of treatment and 1-month follow-up.

Results: This study received institutional review board approval. Phase 1 outputs were the health counselors' treatment manual and participant guide. Recruitment was completed in 2021. Phase 2 outcomes will be determined after project implementation and data analyses are complete, which are expected by May 2023.

Conclusions: Findings from this study will determine the feasibility and acceptability of an ACT-based, culturally relevant intervention for Latine adults who smoke and have probable depression and/or anxiety. We expect feasibility of recruitment, retention and treatment acceptability, and reductions in smoking status, depression, and anxiety. If feasible and acceptable, the study will inform large-scale trials, which will ultimately contribute to narrowing the gap between research and clinical practice for the co-occurrence of smoking and psychological distress among Latine adults.

Introduction

Tobacco smoking is a major independent risk factor for chronic disease [1,2]. Although the number of smokers in the United States has declined over the past decades, smoking prevalence remains disproportionately high among individuals with behavioral health disorders [3-5]. For instance, depressive and anxiety syndromes are more prevalent among smokers than nonsmokers [6,7], and smokers with these conditions are more likely to be nicotine dependent [4,8]. Considerable research has assessed the impact of depression and anxiety on cessation outcomes, with a number of studies reporting that depression and anxiety place smokers at increased risk for cessation failure [9-14], with other studies suggesting that the evidence is inconclusive [6,15-18]. Additionally, given the high comorbidity between depression and anxiety [19], the independent contribution of each disorder to smoking cessation remains unclear [11,20,21]. The *Treating Tobacco Use and Dependence Clinical Practice Guideline: 2008 Update* concluded that the evidence is insufficient to determine whether smokers with psychiatric disorders benefit more from tobacco use treatment tailored to their disorder than from standard treatments [22].

Given the link between behavioral health issues and smoking, it would be ideal to identify an intervention that might be especially appropriate for people with behavioral health issues who smoke. Acceptance and Commitment Therapy (ACT) belongs to what is known as "third wave" cognitive behavioral therapy and is positioned as a form of "contextual cognitive behavioral therapy" [23]. An important and unique assumption underlying ACT's treatment approach is that, through conditioning processes, humans learn to avoid thoughts and their accompanying feelings, images, and physical sensations as they would avoid the event itself [24]. This avoidance of aversive private events, called experiential avoidance, is assumed to underlie much of people's suffering, and emotional dysregulation arises from attempts to avoid and alter private experiences that are judged to be aversive [25].

Unfortunately, experiential avoidance often results in an increase in the frequency or intensity of the avoided thoughts and feelings [26] and can generate mood disturbances, including depression and anxiety. An important component of ACT is helping individuals abandon efforts to change their thoughts and feelings and instead engage in an active process of experiencing emotions simply as a constellation of physiological sensations, which have no intrinsic power to harm or hold one back. The goal is the removal of experiential avoidance as a barrier to pursuing valued outcomes (ie, quitting smoking and improving mood).

With respect to substance abuse, behaviors like tobacco smoking are often negatively reinforced via attempts to regulate and control internal, negative experiences [27]. In ACT-based models for the treatment of tobacco use disorders [28], individuals are helped to identify subtle signals of negative affect and to understand that efforts to control or avoid internal experiences are linked to their tobacco use behavior. They are then taught to develop acceptance and willingness to remain in the presence of withdrawal symptoms and aversive internal states associated with triggers to smoke tobacco.

ACT has increasingly shown its effectiveness for treating smoking, depression, and anxiety [23,29-31], and its applicability to diverse populations [32]. However, research on the usefulness of ACT approaches for Hispanic or Latine (hereafter *Latine*, a gender-neutral term) populations, the largest ethnic minority group in the United States [33,34], is limited. Although there are some ACT-related studies that include a considerable proportion of Latine people in their samples [29,35], there is only 1 published study specifically focused on Latine individuals in the United States [36]. However, this study is a secondary data analyses of treatment engagement and efficacy from an ACT treatment not culturally tailored to the population. Moreover, no published studies have specifically addressed smoking cessation among Latine individuals with depressive and anxiety symptomatology.

These gaps in the literature illustrate the need for an ACT smoking cessation treatment that is appropriate for Latine individuals with behavioral health issues. ACT represents a coherent theoretical framework from which to address many of the factors that may present barriers to smoking cessation among Latine individuals with depression and anxiety symptomatology. Hence, the proposed study (ie, PRESENT Wellness Program) aims to improve the health of the Latine community by developing and pilot-testing a culturally relevant ACT-based wellness program addressing smoking, depression, and anxiety among Latine adults.

Methods

Phase 1: Intervention Development: The PRESENT Wellness Program

The PRESENT Wellness Program consists of the ACT-based behavioral treatment component with a participant's guide and nicotine replacement therapy (NRT).

Behavioral Treatment Component and Participant Guide

The techniques used in ACT target the following six main processes [37]: (1) *acceptance*—willingness to experience the natural flow of thoughts, feelings, and sensations (not trying to suppress them); (2) *cognitive defusion*—ability to recognize thoughts and images as just words and pictures, not as real events; (3) *beingpresent*—focus on the present in a nonjudgmental way; (4) *self-as context*—exposure to experiential processes to promote awareness of one's own flow of experiences without attachment to them; (5) *values*—awareness and clarification of personal values and goals; and (6) *committed action*—willingness to behave in line with values and goals, even in the presence of discomfort.

The baseline behavioral treatment was developed using an ACT-based smoking cessation protocol described in existing publications on ACT and smoking cessation [38-40]. This

XSL•FO
RenderX

baseline treatment protocol was then adapted to also address depression and anxiety and to be culturally appropriate for Latine adults. The behavioral health and cultural adaptations were informed by an existing framework for adaptation [41,42], the first author's training on the ACT therapeutic model, and expert consultation. A literature review informed changes to content and to the frequency and duration of sessions.

Adaptations of the baseline protocol to address co-occurring depression and anxiety entailed the proactive inclusion of emotional dysregulation discussions and experiences as part of the treatment. Regardless of participants' initiative to share their experiences with mood management, the health counselor proactively inquires about the person's psychological distress, validates their pain, and highlights that facing discomfort is an inevitable human experience oftentimes necessary for valued living. ACT works to enhance an individual's ability and willingness to experience undesirable or adverse thoughts and feelings, which is expected to assist individuals in developing broader alternatives to mood management. Adaptations of the baseline protocol to be culturally appropriate for Latine individuals started with the labeling of the treatment. For instance, given Latine individuals' stigma related to seeking behavioral health help [43], we chose to call the treatment a "wellness program" so it could be better received by the Latine community. Similarly, we use the terms "health counselor" and "health counseling" to refer to the therapist and the treatment sessions, respectively, to increase openness to the program. Adaptations were also based on the ideas of cross-cultural communication [44,45] as well as the integration of Latine values (eg, familism, personalism, and collectivism) and context (eg, heritage group, acculturation, and enculturation) [46].

The treatment manual includes overall training modules that cover the ACT model, tobacco dependence, depression, anxiety, Latine cultural values, and a session-by-session guideline that includes the core aspects of ACT and their applications for treatment of tobacco dependence and depression or anxiety. The participant's guide mirrored the counselors' treatment manual content in a more simplified manner and includes practice exercises.

The treatment protocol consists of 8 one-hour individual sessions. *Session 1* entails the contextual interview (focused on smoking and psychological distress) and offers didactic information about the effectiveness and use of NRT. The contextual interview is organized around valued domains of living (ie, relationships, health, work, education, and leisure) and the functionality of smoking. Sessions 2-7 focus on each one of the 6 core ACT processes [23,37]. *Session 2* focuses on clarifying participants' overall values and those involved in quitting smoking, as well as the discrepancies between current behaviors and values. *Session 3* focuses on discussing and demonstrating what SMART goals are (ie, specific, meaningful, adaptive, realistic, and timebound) and the development of a preliminary plan to stop smoking, including setting a quit date. *Session 4* introduces participants to mindfulness and helps them notice their internal and external triggers as they occur and to recognize the link between connecting with emotions and the ability to act on them. *Session 5* aims to increase participants' willingness to accept cravings and withdrawal symptoms as a typical experience of the quitting process and develop motivation and skills to deal with them without smoking. *Session 6* helps participants identify and defuse (or to get "unhooked") from thoughts that limit their achievement of quitting smoking and mood-related behavioral goals. In this context, defusion is to see thoughts simply as thoughts rather than as a literal truth that can control one's behavior. *Session 7* guides participants to connect with a transcendent sense of self that is separate from their own internal experience but provides a safe place to observe them. *Session 8* focuses on overall experiences during the wellness program as well as the creation of an individual self-care plan for the future, including value-based actions. All sessions include experiential exercises and metaphors tailored to the participant's situation. Latine-specific issues are incorporated into each session. Participants are instructed to engage in value-based actions as homework assignments between sessions. Table 1 below shows a summary of the session-by-session content with focal exercises [47].

Table 1. Summary of session-by-session content.

Session	Overview of the session	Experiential exercise
1	Contextual interview, explanation of the ACT[a] model and overall wellness program, and didactic information about NRT[b]	Life path
2	Values identification	Bull's eye
3	Goal setting and committed action (quit day is encouraged)	Establishing SMART[c] goals
4	Contact with the present moment	Mindful breathing
5	Acceptance and willingness	The ball in the pool metaphor
6	Cognitive defusion (getting unhooked!)	Hands as thoughts metaphor
7	Self as context (also called perspective taking)	The stage show metaphor
8	Integration and maintenance	Miracle question and Passenger on the bus metaphor

[a]ACT: acceptance and commitment therapy.

[b]NRT: nicotine replacement therapy.

[c]SMART: specific, meaningful, adaptive, realistic, and timebound.

XSL•FO
RenderX

Health counselors with at least a master level degree in clinical or counseling psychology are trained to provide the PRESENT Wellness Program. Specifically, the health counselors undergo about 100 hours of specialized training in tobacco dependence treatment and ACT, including didactic, experiential, and applied training. Before engaging with study participants, health counselors role-play the treatment sessions and have to demonstrate ACT competency, measured by the ACT Core Competency Rating Form [37].

Guideline for NRT Use

NRT is offered as part of the PRESENT Wellness Program. The selected NRT is the nicotine patch because it is frontline therapy for smoking cessation, is safe, well-tolerated, and available over the counter [22]. Also, the nicotine patch has proven effective among smokers with depression and anxiety symptomatology [48]. Participants are given 6 weeks of nicotine patches and are told to start using them 1 week before the quit day, which is encouraged on Session 3. Participants smoking more than 10 cigarettes per day are given 4 weeks of 21-mg patches, 1 week of 14-mg patches, and 1 week of 7-mg patches. Participants who smoke 5-10 cigarettes per day are given 4 weeks of 14 mg patches and 2 weeks of 7 mg patches.

Phase 2: Pilot Testing: Study Design and Participants

This is a longitudinal, 1-arm pre-post feasibility study. A total of 38 participants will be enrolled in the study. The inclusion criteria are ≥18 years of age; self-identify as Latine (of any national group); current smoker (average of >5 cigarettes per day for the past year and carbon monoxide [CO] >6 ppm); motivated to quit within next 30 days; screened positive for probable depression and/or probable anxiety (via a score of >10 in the Patient Health Questionnaire [49-51]; at least marginal health literacy; functioning telephone number; ability to speak English; and physicians' release to participate if taking psychotropic medications. Of note, we chose to recruit only English-speaking Latine participants because it facilitates the supervision of sessions and preparation of materials in only 1 language, maximizing the feasibility of completing the study within the time frame and available resources. The exclusion criteria are contraindication for use of nicotine patch; current use of tobacco cessation medications; current participation in counseling for depression, anxiety, or smoking cessation; being pregnant or nursing; having other current psychiatric disorder that would limit ability to participate; and having a household member enrolled in the study.

Procedures

Recruitment and Screening

Participants are mainly recruited through community outreach, social and print media (eg, local newspaper), flyers, and the ResearchMatch platform [52]. To determine eligibility criteria, interested people complete a phone screening with project staff or complete a self-screening accessed via a QR code located in the study flyer. Individuals who are ineligible or decline participation are given self-help materials and referrals to other cessation programs. Eligible individuals are scheduled for their first appointment.

Baseline Visit

During the in-person baseline visit, study personnel provide a detailed description of the study, answer questions, and obtain informed consent. Enrolled participants complete web-based baseline questionnaires, biochemical verification of smoking status (via a CO test), and their first health counseling session.

Treatment Procedures and Fidelity

The health counseling component consists of 8 one-hour individual sessions (1 in person and 7 by phone) completed within a 3-month period. The initial 2-week nicotine patch is dispensed at the first face-to-face visit and then sent biweekly by regular mail. Participants receive only the number of patches necessary to last 2 weeks, plus several extra patches should a patch fall off or become torn.

Treatment fidelity refers to the extent to which an intervention is delivered as planned. To ensure treatment fidelity, all sessions are recorded and a random sample of at least 15% are coded using the following two forms: (1) an investigator-developed checklist to track fidelity to treatment content per session and (2) the ACT Core Competency Rating Form to determine adherence to an ACT therapeutic approach [37]. The checklist entails a list of all session components (per session), which are marked as covered or not covered. The rating is calculated by assigning 10 points to each component marked as covered and dividing by the maximum number of components in that particular session (see the Multimedia Appendix 1). In the ACT Core Competency Rating Form, the rater evaluates the counselor's competency in ACT on a scale of 1-7, from "never true" to "always true." The supervisor provides written feedback based on the ratings of the rated sessions. Low treatment adherence is addressed by additional training and repeated assessment of adherence on additional cases. Treatment fidelity is attained when 85% or more (ie, ≥8) of the session components were covered and when receiving an overall rating of adequate or above adequate delivery (eg, ≥5) of the ACT essential components.

Follow-up Assessments and Treatment Evaluation

After the final health counseling session, participants attend 2 in-person follow-up visits, at 1-week and 1-month posttreatment, in which they complete a CO test as well as web-based questionnaires about tobacco use, depression, anxiety, and ACT-related constructs. At the 1-month visit, participants rate the degree of acceptability and helpfulness of each ACT component and their satisfaction with the PRESENT Wellness Program.

Financial Compensation

Participants are compensated in the form of gift cards for each of the in-person visits in which they complete assessments (ie, US $30 for baseline and 1 week after end of treatment; and US $40 for 1-month posttreatment follow-up). Thus, participants could receive a maximum total of US $100/person for the completion of assessments and health counseling sessions.

XSL•FO
RenderX

Measures

Primary Outcomes

The primary outcomes of the study are feasibility of recruitment, feasibility of retention, and treatment acceptability. The feasibility of recruitment will be measured by the proportion of participants who consented to participate and attended the baseline session out of the number of individuals who were eligible. The feasibility of retention will be measured by the number of health sessions completed and the rate of follow-up visit completion. Treatment acceptability will be measured by the Program Acceptability Questions (see the Multimedia Appendix 2), an investigator-developed questionnaire rating the degree of acceptability and helpfulness of the PRESENT Wellness Program. The questionnaire contains 7 items categorized on a 5-point Likert scale ranging from "Completely Disagree" to "Completely Agree." Higher scores indicate higher acceptability. A sample item is "This program has helped in my acceptance of my physical cravings, emotions, and thoughts that cue my smoking."

Secondary Outcomes

Smoking Abstinence

Seven-day point prevalence and continuous abstinence will be reported following the Society for Research on Nicotine and Tobacco guidelines [53,54]. *Seven-day point prevalence* abstinence is defined as a self-report of no smoking during the previous 7 days and a CO level of less than 6 ppm. *Continuous abstinence* is defined as a self-report of no smoking since the quit date and biochemically confirmed abstinence at all follow-ups up to and including that time point.

Probable Depression

Probable depression is measured by the Patient Health Questionnaire [49,50], which evaluates symptoms for the last 2 weeks. Items range from not at all (0) to nearly every day (3). The scores for each item are summed to produce a total score between 0 and 24 points. Higher scores indicate higher depressive symptoms. Probable depression is determined by a total score of 10 or above, indicating at least moderate symptoms [50].

Probable Anxiety

Probable anxiety is measured by the Generalized Anxiety Disorder Scale [51], which evaluates symptoms for the last 2 weeks. Items range from not at all (0) to nearly every day (3). The scores for each item are summed to produce a total score between 0 and 21 points. Higher scores indicate higher anxiety symptoms. Probable anxiety is determined by a total score of 10 or above, indicating at least moderate symptoms [51].

Data Analyses

Data analyses in the context of a pilot study are not hypothesis-driven but serve to provide information regarding feasibility and acceptability of the intervention [55]. As such, data analyses will include descriptive statistics (eg, mean tests and proportions) about screening, recruitment, retention, process assessments, and treatment acceptability. We will use descriptive analysis techniques to present participants' characteristics, as well as their scores on secondary outcome measures at the 3 different time points (baseline, 1 week after end of treatment, and 1-month posttreatment).

Ethics Approval

The first author and principal investigator of the study received institutional review board approval from her academic institution, the University of Houston (#00001007).

Results

The outputs of the intervention development (phase 1) were (1) a treatment manual, which guided the health counselors' training, and (2) the participant's guide. Recruitment was completed in 2021. After project implementation and data management and analyses are conducted, the outcomes of the pilot study (phase 2) will be published in a separate paper. Dissemination of outcomes from phase 2 is slated for May 2023.

Discussion

Despite the availability of evidence-based interventions for smoking cessation, there is still a need for interventions focused on individuals with behavioral health challenges, given their high smoking rate and difficulty quitting. Similarly, culturally appropriate interventions for the Latine community, the largest ethnic group in the United States, are greatly needed. To address these gaps, the innovation of the PRESENT Wellness Program lies in the adaptation and testing of an ACT smoking cessation intervention for Latine smokers with clinically significant depression and anxiety symptomatology. This entails refinements and new applications of an existing theoretical and evidence-based clinical approach (ie, ACT) for understudied comorbid conditions (ie, depression, anxiety, and smoking) among an underserved and understudied ethnic minority group (ie, Latine). Besides adaptations in content, the proposed protocol is delivered in a hybrid format, with 1 session in person and the rest by phone, which is expected to address common treatment barriers for Latine individuals (eg, childcare and transportation). All these aspects are strengths of the study.

The implementation of the PRESENT Wellness Program will provide data on the feasibility and acceptability of the intervention as well as preliminary data on the impact of the intervention on decreasing smoking, anxiety and depression, and addressing ACT-related constructs. As primary outcomes, it is expected that recruitment and retention into the intervention is feasible and that the provided treatment is acceptable. For secondary outcomes, it is expected that there is an increase in participants' smoking abstinence and a decrease in depression and anxiety symptoms at the end of treatment and 1-month posttreatment. Our findings will help inform large-scale ACT-based smoking cessation studies for Latine adults with psychological distress and may contribute to a growing body of evidence of the importance of culturally relevant interventions. Findings will be disseminated via professional forums as well as community-accessible venues, such as our laboratory website, social media, and newsletters.

Of note, this pilot study was focused on English-speaking Latine individuals mainly for pragmatic reasons related to study budget

XSL•FO
RenderX

and the feasibility of conducting the intervention and related supervision in only one language. Nonetheless, we acknowledge this is a limitation as excluding Spanish-preferring individuals will reduce the generalizability of findings and the reach of the intervention. We believe there is an urgency to reach Spanish-speaking Latine individuals who smoke and, as such, will work on the translation and linguistic adaptation of the intervention as a next step in this line of research.

Acknowledgments

This pilot and feasibility study is supported by a Mentored Research Scholar Grant in Applied and Clinical Research from the American Cancer Society awarded to the first author (MRSG-15-018-01-CPPB). We are appreciative of Mirna Centeno, from the Health Research Institute, for her graphic designer work while assisting in the development of recruitment materials. Authors are also grateful for the Scholarly Publication Grant of the University of Houston's Underrepresented Women of Color Coalition.

Data Availability

Data sharing is not applicable to this research protocol paper as no clean data sets have been generated for data management or analyses in this study.

Abstract

Background: Living with HIV is a risk factor for severe acute COVID-19, but it is unknown whether it is a risk factor for long COVID.

Objective: This study aims to characterize symptoms, sequelae, and cognition formally and prospectively 12 months following SARS-CoV-2 infection in people living with HIV compared with people without HIV. People with no history of SARS-CoV-2 infection, both with and without HIV, are enrolled as controls. The study also aims to identify blood-based biomarkers or patterns of immune dysregulation associated with long COVID.

Methods: This prospective observational cohort study enrolled participants into 1 of the following 4 study arms: people living with HIV who had SARS-CoV-2 infection for the first time <4 weeks before enrollment (HIV+COVID+ arm), people without HIV who had SARS-CoV-2 infection for the first time within 4 weeks of enrollment (HIV−COVID+ arm), people living with HIV who believed they never had SARS-CoV-2 infection (HIV+COVID− arm), and people without HIV who believed they never had SARS-CoV-2 infection (HIV−COVID− arm). At enrollment, participants in the COVID+ arms recalled their symptoms, mental health status, and quality of life in the month before having SARS-CoV-2 infection via a comprehensive survey administered by telephone or on the web. All participants completed the same comprehensive survey 1, 2, 4, 6, and 12 months after post–acute COVID-19 symptom onset or diagnosis, if asymptomatic, (COVID+ arms) or after enrollment (COVID− arms) on the web or by telephone. In total, 11 cognitive assessments were administered by telephone at 1 and 4 months after symptom onset (COVID+ arms) or after enrollment (COVID− arms). A mobile phlebotomist met the participants at a location of their choice for height and weight measurements, orthostatic vital signs, and a blood draw. Participants in the COVID+ arms donated blood 1 and 4 months after COVID-19, and participants in the COVID− arms donated blood once or none. Blood was then shipped overnight to the receiving study laboratory, processed, and stored.

Results: This project was funded in early 2021, and recruitment began in June 2021. Data analyses will be completed by summer 2023. As of February 2023, a total of 387 participants were enrolled in this study, with 345 participants having completed enrollment or baseline surveys together with at least one other completed study event. The 345 participants includes 76 (22%) HIV+COVID+, 121 (35.1%) HIV−COVID+, 78 (22.6%) HIV+COVID−, and 70 (20.3%) HIV−COVID− participants.

Conclusions: This study will provide longitudinal data to characterize COVID-19 recovery over 12 months in people living with and without HIV. Additionally, this study will determine whether biomarkers or patterns of immune dsyregulation associate with decreased cognitive function or symptoms of long COVID.

Introduction

Background

SARS-CoV-2, the virus that causes acute COVID-19, rapidly spread throughout the world and caused a global pandemic, leading to >6 million confirmed deaths since late 2019 [1]. In early 2020, people with persistent symptoms and new health complications after known or suspected SARS-CoV-2 infection began gathering in online forums and support groups. Working both independently and together, they sounded an alarm in the media for a new, often debilitating, post–COVID-19 syndrome called long COVID [2]. Many other terms for long COVID have been used, including *post-COVID condition*, *long-haul COVID*, *post–acute COVID-19*, *and postacute sequelae of SARS-CoV-2 infection* [3]. Long COVID and related terms generally describe a syndrome encompassing a wide range of symptoms or health conditions that occur after confirmed or suspected SARS-CoV-2 infection that can wax, wane, or persist and can last from weeks to years [3,4].

People with long COVID with interest and skills in research advanced the research agenda by conducting and publishing the first large surveys characterizing the symptoms and time course of long COVID [5]. Dozens of symptoms and sequelae of long COVID have been described since then in survey-based and electronic medical record studies. Commonly reported long COVID symptoms include fatigue, postexertional malaise, difficulties with concentration or thinking (also referred to as “brain fog”), sleep disorders, headache, dyspnea, chest pain, heart palpitations, joint or muscle pain, body aches, anxiety, full or partial loss of taste or smell, among many others. [5-12].

People living with HIV are at a higher risk of severe acute COVID-19 outcomes compared with people without HIV [13-15]. Among people with HIV, those with lower absolute CD4 T cell counts or unsuppressed HIV viral load are at a higher risk of poor acute COVID-19 outcomes [15-17]. However, it is unknown whether living with HIV is a risk factor for long COVID. In addition, it is unknown whether the symptoms, sequelae, or time course of long COVID may differ in people living with HIV compared with people without HIV. People living with HIV are eager to learn the full picture of the risk for long COVID. Although the exact pathophysiological mechanisms contributing to long COVID are currently unclear, some researchers hypothesize that chronic inflammation or immune dysfunction may contribute [18,19]. Chronic inflammation and immune dysfunction are well described in people living with HIV on effective antiretroviral therapy [20]. Whether preexisting inflammation predisposes people living with HIV to long COVID or distorts its presentation needs further investigation. Moreover, some symptoms in individuals with long COVID, such as cognitive symptoms, may overlap with conditions common in people living with HIV, such as HIV-associated neurocognitive disorders.

To investigate long COVID in people living with HIV, we designed a prospective observational cohort study to characterize symptoms, sequelae, and cognitive function formally and prospectively in the 12 months after first SARS-CoV-2 infection in people living with HIV as compared with people without HIV, and as compared with people with no history of SARS-CoV-2 infection both with and without HIV. Because identifying and enrolling a sizeable population of individuals living with HIV with first SARS-CoV-2 infection within the previous 4 weeks would be challenging at any 1 location, and to ensure a study population representative of the demographic and geographic diversity of people living with HIV in the United States, we designed this study to be entirely remotely conducted to allow for enrollment and study participation from any location within the continental United States. Surveys are completed by telephone or on the web, cognitive assessments are administered by telephone, and blood and vital signs are collected via a mobile phlebotomy company. Mobile phlebotomists contracting for this company can meet participants at any location of their choice, for example, home or office.

Study Objectives

This study aimed to characterize symptoms, sequelae, and cognition formally and prospectively in the 12 months following first SARS-CoV-2 infection in people living with HIV as compared with people without HIV at 1, 2, 4, 6, and 12 months after acute COVID-19 symptom onset or after diagnosis if asymptomatic. In addition, people living with and without HIV with no history of SARS-CoV-2 infection were enrolled as controls and completed study events on a similar timeline. The study also aims to identify blood-based biomarkers or patterns of immune dysregulation that are associated with symptoms or sequelae of long COVID.

XSL•FO
RenderX

Other objectives of this study are as follows:

1. To determine baseline host factors correlated with symptoms and sequelae of long COVID.
2. To understand the impact of SARS-CoV-2 infection on quality of life, sleep, fatigue, cognition, mental health, respiratory function, and behavior in the 12 months following infection in people living with and without HIV.
3. To determine whether abnormal orthostatic vital signs are associated with long COVID.
4. To characterize the host response to SARS-CoV-2 infection in people living with and without HIV, including innate and acquired immune responses and circulating levels of immune signaling molecules.
5. To develop a specimen biorepository that includes data and specimens from people living with and without HIV and with and without prior SARS-CoV-2 infection.

Methods

Ethics Approval and Informed Consent

This study was reviewed and approved by the Johns Hopkins University School of Medicine institutional review board (IRB00278774). Written informed consent in English or Spanish was obtained from all participants using either paper consent forms or DocuSign.

Study Design Overview

This study is a prospective, observational cohort study enrolling people living with and without HIV within 4 weeks of first SARS-CoV-2 infection. The study also enrolled people with and without HIV who believed they never had SARS-CoV-2 infection as controls. The study collected health information and specimens from participants at predetermined time intervals through questionnaires, cognitive assessments, and blood draws (Figure 1). This study was designed to enroll participants soon after SARS-CoV-2 infection so that the time course of postacute symptoms and sequelae in the first 12 months could be prospectively investigated and because biomarkers or immune markers of long COVID may only be present early in the postacute period [21]. The study recruited people into the following 4 study arms:

1. HIV+COVID+ arm: people living with HIV with first SARS-CoV-2 infection within the previous 4 weeks.
2. HIV−COVID+ arm: people without HIV with first SARS-CoV-2 infection within the previous 4 weeks.
3. HIV+COVID− arm: people living with HIV who believed they never had SARS-CoV-2 infection.
4. HIV−COVID− arm: people without HIV who believed they never had SARS-CoV-2 infection.

Study Eligibility

We recruited people with and without HIV, who either had first SARS-CoV-2 infection within the previous 4 weeks or who believed they had never had SARS-CoV-2 infection. Adults aged ≥18 years living in the 48 contiguous United States who had the ability to provide consent, who believed they could complete the study events, and who could communicate by telephone in either English or Spanish were eligible. Further eligibility criteria are presented in Table 1.

XSL•FO
RenderX

Table 1. Participant inclusion and exclusion criteria.

Criteria	HIV+COVID+ arm	HIV−COVID+ arm	HIV+COVID− arm	HIV−COVID− arm
Inclusion	• Self-reported HIV infection • Ability to furnish proof of SARS-CoV-2 infection or reasonable certainty that they had SARS-CoV-2 infection • First COVID-19 symptoms or first positive diagnostic COVID-19 test (if asymptomatic) occurred within 28 days before enrollment	• Self-reported HIV-negative status[a] • Ability to furnish proof of SARS-CoV-2 infection or reasonable certainty that they had SARS-CoV-2 infection • First COVID-19 symptoms or first positive diagnostic COVID-19 test (if asymptomatic) occurred within 28 days before enrollment	• Self-reported HIV infection • Never tested positive for SARS-CoV-2 and does not believe they have ever had SARS-CoV-2 infection[b]	• Self-reported HIV-negative status[a] • Never tested positive for SARS-CoV-2 and does not believe they have ever had SARS-CoV-2 infectionb
Exclusion	• A first or only diagnosis of SARS-CoV-2 infection >28 days before contact with study	• A first or only diagnosis of SARS-CoV-2 infection >28 days before contact with study	• Have tested positive for SARS-CoV-2 or believe that they have had SARS-CoV-2 infection at some point in the past regardless of whether they were tested	• Have tested positive for SARS-CoV-2 or believe that they have had SARS-CoV-2 infection at some point in the past regardless of whether they were tested

[a]HIV antigen and antibody test was performed on all participants in this group as part of the study to confirm HIV-seronegative status.

[b]SARS-CoV-2 antinucleocapsid antibody testing was performed as part of this study and must be negative for inclusion in the analyses.

Recruitment

Participants living with HIV came to know about this study through health care providers, social media, and peers in a number of ways. The study coinvestigators and study team emailed and called HIV clinic directors across the 48 contiguous United States and requested permission to hang study flyers in their clinics. The study principal investigator (PI) and coinvestigators established a network of academic investigators and other people interested in HIV and COVID-19 across the United States and kept them abreast of updated flyers and recruitment updates through regular contact. HIV providers who were colleagues of these people were informed about the study by emails or announcements at provider meetings. Emails were sent to the United States HIV Medicine Association and the Infectious Diseases Society of America's Exchange listserves (primarily subscribed to by infectious diseases physicians and providers) every 2-4 months with updated flyers and information about the study to increase study referrals. HIV providers who had heard about the study informed their patients with recent SARS-CoV-2 diagnosis about the study and sought permission for the study team to contact them. This study also reached out to established HIV and substance use study cohorts with information on this research study to disseminate to their study cohort participants. Importantly, this study and people living with HIV aiding this study engaged people living with HIV in the community in numerous ways including social networks, email, and social media. The study worked with the Network for Long COVID Justice to amplify dissemination efforts around this study to several social media sites and web-based media sites popular among people living with HIV. The study worked with several community members to disseminate information about this study through social media channels. The study staff asked the participants who were enrolled to ask their friends and contacts who were eligible to contact our study if they were interested; there was no compensation for this recruitment. Advertisements for the study were posted on Facebook and Grindr. Finally, the study investigators received permission to identify people living with HIV with recent positive SARS-CoV-2 tests within the Johns Hopkins Health System via weekly electronic medical record reports. The study staff called these people with an invitation to hear more about the study.

Participants without HIV heard about this study in a number of ways. Advertisements for the study were posted on Facebook and Grindr. The study worked with several community members to disseminate information about this study through social media channels. Participants were recruited through the Johns Hopkins Institute for Clinical and Translational Research recruitment registry, Hopkins Opportunity for Participants Engagement (HOPE) registry. The HOPE registry is a centralized, institutional review board–approved database that contains the name and contact information of people who have taken a SARS-CoV-2 test within the Johns Hopkins Health System and have expressed interest in participating in research studies. The registry is housed in Research Electronic Data Capture (REDCap; Vanderbilt University), and people who have consented to participate in the registry enter their own data into the registry's web-based intake form, or they have their data collected by recruitment navigators via telephone and entered into the database by HOPE registry navigators. Eligible participants are then matched to each participating study based on the information they have provided and study eligibility criteria. This study's staff then reached out to the people matched to this study to assess their willingness and eligibility for this study. Physical flyers were posted on the Johns Hopkins medical campus.

XSL•FO
RenderX

A study website was developed to provide information for interested people to self-refer via a web-based REDCap Health Insurance Portability and Accountability Act (HIPAA)–compliant form or by contacting the study directly (via email or phone). This website was advertised on social media platforms such as Facebook (including special interest groups such as for lesbian, gay, bisexual, transgender, queer, and others [LGBTQ+] communities in different cities) and Grindr.

Consent

A study coordinator based at Johns Hopkins University held a consent conversation with potential participants by telephone or video call, and consent was signed using DocuSign or paper consent forms. All consent activities were conducted in either English or Spanish. The DocuSign process was approved by the institutional review board and is 21 Code of Federal Regulations Part 11–compliant to obtain a secure electronic signature. This process involved sending the consent form to the participant via an email from DocuSign and providing a participant-specific access code that was required when the participant accessed and signed the consent form. Participants were given adequate time to consider the study and ask questions before signing the consent form. When ready to sign, each participant entered their code, verifying that the person signing the consent was the person whom we spoke with previously, and signed the consent within the DocuSign system. Once the participant had electronically signed, the study team member obtaining informed consent would be notified that the electronic form was ready for their signature. Once signing was completed by all parties, both the study team and the participant could download the signed consent as a PDF. The study team also had access to the audit log and the Certificate of Completion. Documentation capturing details of the consent process was maintained on REDCap.

In instances where DocuSign could not be executed or the potential participant declined to use it, the consent conversation happened in person or by telephone or video call and a paper consent was signed. In these cases, participants were provided with a copy of the paper consent document before the consent conversation either via email, fax, mail, or in person. After the consent conversation, the participants were given adequate time to consider the study and ask questions. The participant would sign, date and time the paper informed consent document. The document was then handed, mailed, emailed, or faxed to the consent designee for their signature, and a copy of the double-signed consent document was handed, mailed, emailed, or faxed back to the participant.

Surveys

Multimedia Appendix 1 [22-48] and Multimedia Appendix 2 provide detailed information about the surveys and the timing of study events. At enrollment, participant demographics, social history, substance use, medical history, medication use, SARS-CoV-2 vaccination status, and HIV history (for people living with HIV only) were recorded. Participants in the COVID+ arms also completed a comprehensive survey on symptoms, mental health, and quality of life via telephone or on the web in the month before having SARS-CoV-2 infection. At each time point after COVID-19 diagnosis (for the COVID+ arms) or after enrollment (for the COVID− arms), participants completed a comprehensive symptom, mental health, and quality of life survey (Multimedia Appendix 1). This survey consisted of several validated tools, which are detailed in the following paragraphs.

Participants indicated the presence and severity (on a scale of "Not at all," "A little bit," "Somewhat," "Very much," or "Quite a bit") of 49 long COVID symptoms. Overall, 34 symptoms derive from the FLU-PRO Plus, and 15 additional symptoms were added based on their frequency of report in a Long COVID Patient Led Research Collaborative survey with input from the patient-researcher authors [5,22]. Dyspnea was assessed using the Modified Medical Research Council (mMRC) Dyspnea Scale, which is used to assess the degree of baseline functional disability because of dyspnea [23]. The Breathless, Cough, and Sputum Scale (BCSS) was used to evaluate the respiratory symptoms common in COVID-19 [24]. The survey also included the Insomnia Severity Index (ISI), which is a 7-item questionnaire assessing the participant's perceived insomnia symptoms and resulting disruption to their lives [25,26]. Participants self-reported the average daily sleep duration in the previous week. Participants completed the Fatigue Severity Scale (FSS), a 9-item questionnaire assessing their perception of the impact of fatigue on their quality of life and activities of daily living [27]. The FSS global fatigue question was used to measure the participants' global fatigue. At each study event, the participants were asked whether they had received a COVID-19 vaccine or had a new infection with SARS-CoV-2 since the previous study event.

The survey included the Patient Health Questionnaire Depression 8-item (PHQ-8) and Generalized Anxiety Disorder-7 (GAD-7) tool to assess the severity of depressive and anxiety symptoms, respectively [28-30]. Participants also completed the computerized adaptive testing for mental health (CAT-MH), which draws upon a bank of >1000 test items aligned with the Diagnostic and Statistical Manual of Mental Disorders (DSM)-5 criteria.[31-33]. The modules completed included the computerized adaptive diagnostic test for major depressive disorder (CAT-MDD; screener for major depressive disorder), the computerized adaptive diagnostic test–Depression Inventory (CAT-DI; assesses depression severity), and computerized adaptive diagnostic test–Anxiety Inventory (CAT-ANX; assesses anxiety severity). The survey also assessed self-reported cognitive problems using the self-assessment section of the General Practitioner Assessment of Cognition (GPCOG). This tool consists of 6 yes or no items relating to participants' perceived difficulty with certain activities owing to cognitive limitations compared with a prior time point [34]. We asked participants to evaluate their current ability to complete the tasks compared with their ability before they had COVID-19 or before enrollment.

Quality of life was assessed using the Short Form Survey (SF-36) and the EuroQuol EQ-5D-5L. The SF-36 contains 36 Likert and binary items relating to the participant's activities and perceptions of health status [35,36]. The EQ-5D-5L assesses general quality of life through 5 dimensions that include mobility, self-care, usual activities, pain and discomfort, and

XSL•FO
RenderX

anxiety and depression [37]. The EQ-5D-5L includes a general health question that asks the participant to provide 1 number from 0 to 100 on a visual analog scale representing their overall health [37]. The Brief Resilience Scale was used to assess the perceived ability to bounce back or recover from stress [38]. Stressor-related questions were also asked to assess general stress levels from daily life during the COVID-19 pandemic (Multimedia Appendix 1).

Participants in the COVID+ arms were administered an additional acute COVID-19 survey at 1 or more months after COVID-19 diagnosis in which the participant was asked to recall the presence and severity of the same 49 COVID-19 symptoms described earlier within the first 14 days of symptom onset or positive testing (if asymptomatic). The survey also queried the type of COVID-19 test taken, sample source, COVID-19 exposure, treatment for acute COVID-19, and whether hospitalization or oxygen was required during acute COVID-19. Reinfection was not uncommon in this cohort, and each participant was asked about reinfection (COVID+ arm) or new SARS-CoV-2 infection (COVID− arm). Each individual with a new SARS-CoV-2 infection since enrollment was administered the same acute COVID-19 survey described earlier one or more months after COVID-19 diagnosis to collect information on the acute course of COVID-19. Further information about the surveys used in the study can be found in Multimedia Appendix 1.

Neurocognitive Assessments

Participants in all arms underwent a telephone-based neurocognitive assessment at 1 and 4 months after acute SARS-CoV-2 symptom onset or diagnosis (COVID+ arm) or after enrollment (COVID− arm). Telephone assessment has been shown to be feasible and provides a valid assessment of cognitive function relative to in-person neurocognitive testing [49-51]. This telephone assessment has been successfully implemented in diverse patient populations, including post–COVID-19 populations [52-54].

A total of 11 cognitive assessments were administered in this study. The Hopkins Verbal Learning Test–Revised (HVLT-R) is a test of new auditory-verbal learning (VL), verbal memory (VM), and recognition discrimination memory (RM) [39,40]. The Oral Trail Making Test part A (OTMT-A) and Oral Trail Making Test part B (OTMT-B) are brief motor-free tests of mental processing speed (part A) and executive functioning requiring sequential set shifting (part B) [39-41]. The Wechsler Adult Intelligence Scale–Fourth Edition (WAIS-IV) Digit Span Forward (DSF) and Digit Span Backwards (DSB) assessments test auditory attention (forward) and working memory (backward) [42-44]. The Calibrated Ideational Fluency Assessment (CIFA) assesses letter-cued and category-cued verbal fluency (VF). Category-cued VF assesses rapid access to semantic information, and letter-cued VF assesses speeded word retrieval in response to phonetic cues [45-47]. The WAIS-IV Information (WAIS-IV IN) test assesses the general fund of knowledge and was only administered once in this study [42-44]. Performance on the WAIS-IV IN is relatively resistant to neurological damage, and scores correlate highly with overall IQ, thereby allowing scores to serve as a proxy for lifelong intellectual functioning [48].

Mobile Phlebotomist Visits and Clinical Laboratory Testing

Participants in the COVID+ arms had mobile phlebotomy visits at a location of their choice at 1 and 4 months after post–acute COVID-19 symptom onset (or after diagnosis if asymptomatic). Participants in the HIV+COVID− arm had 1 mobile phlebotomy visit at either month 1 or 4, provided that they had not had SARS-CoV-2 infection before the visit. Participants in the HIV−COVID− arm could optionally undergo specimen collection at either month 1 or month 4, provided that they had not had SARS-CoV-2 infection before the visit. Anti–SARS-CoV-2 nucleocapsid immunoglobulin G was measured in all participant specimens, and data from participants in the COVID− arm were excluded from analyses if their specimens tested positive for antinucleocapsid antibodies and they were unaware of SARS-CoV-2 infection.

A mobile phlebotomy company that operates in every state of the United States was engaged to (1) measure participant height and weight, (2) measure orthostatic vital signs, and (3) draw ≤50 mL blood. A blood draw kit was shipped to the participants before the date of the blood draw. The kit included a vital sign sheet, a sodium citrate tube, serum separator tubes, EDTA tubes, and a PAXgene blood RNA tube. All tubes were plastic and labeled with the participant identifier and a space for the date and time of collection. In addition, absorbent sleeves to separate tubes, approved shipping materials including an outer cardboard box, and an inner 95-kPa specimen transport bag with appropriate biohazard labeling were included in the blood draw kit.

For the measurement of orthostatic vital signs, the participants were asked to lie down for 5 minutes before the first blood pressure and heart rate measurement. Participants were then asked to stand up, and after 1 and 3 minutes, additional heart rate and blood pressure measurements were recorded. After the measurement of orthostatic vital signs, blood was drawn from the participant by the phlebotomist. After filling, all tubes were inverted gently 6-8 times. The serum separator tubes were kept upright for 30-60 minutes before centrifugation for 15 minutes at 1100-1300 g by the mobile phlebotomist. The tubes were placed in absorbent sleeves and were shipped overnight using International Air Transport Association–approved procedures to the study laboratory (Rush Clinical Retrovirology Research Laboratory, Chicago). When specimens arrived at the laboratory, designated specimens were sent to the study Clinical Laboratory Improvement Amendments of 1988 (CLIA)–certified testing laboratory (Rush Medical Laboratories, Chicago) for testing. If unforeseen shipping delays occurred and blood was received >48 hours after collection, then some of the clinical testing was not performed owing to stability issues (eg, CD4, complete blood count, lipid panel, and D-dimer). The remaining blood was processed on the same day, and serum, plasma, peripheral blood mononuclear cells (PBMCs), and the PAXgene blood RNA tubes were appropriately frozen and stored. An inventory of the biorepository was created and maintained by the study laboratory using the Laboratory Data Management System

XSL•FO
RenderX

(Frontier Science) [55]. The Johns Hopkins REDCap team developed a novel method to directly input biorepository inventory files from the Laboratory Data Management System into the study's REDCap database for seamless and rapid updating of the biorepository in the central database.

Biospecimen Testing

The CLIA-certified study testing laboratory ran the following panel of tests: SARS-CoV-2 antinucleocapsid IgG (Abbott Architect), complete blood count with differential, high-sensitivity C-reactive protein, creatine phosphokinase, D-dimer, lipid panel, HIV fourth-generation antigen and antibody testing (for those who self-reported as HIV-seronegative), and CD4 T cell percentage and absolute count (for those who self-reported as living with HIV). Plasma, PBMCs, and serum were also obtained from all samples. If the blood sample was received by the Rush Clinical Retrovirology Research Laboratory >48 hours after collection, the sample was not sent for complete blood count, CD4 panel, lipid panel, or D-dimer according to the clinical laboratory protocol. The blood sample was still processed for plasma and PBMCs, but in cases where the sample did not separate, plasma and PBMCs were not saved. However, serum was obtained from these samples.

Coronavirus antibodies and select hormones and cytokines were quantified in a subset of specimens. The panel of coronavirus antibodies that were quantified included HCoV-229E Spike, HCoV-HKU1 Spike, HCoV-NL63 Spike, HCoV-OC43 Spike, SARS-CoV-1 Spike, SARS-CoV-2 Nucleocapsid, SARS-CoV-2 NTD. SARS-CoV-2 RBD, SARS-CoV-2 Spike, AY.4, B.1.351, BA.2, BA.2+L452M, BA.2+L452R, BA.2.12.1, BA.3, BA.4, BA.5, and CoV-2 Spike. The hormones and cytokines that were tested were based on what might be important in long COVID from the current literature at the time: interferon (IFN)-β, interleukin (IL)-1RA, IL-1α, IFN-λ1, IL-5, IL-8, interferon gamma-induced protein-10 (IP-10), chemokine (C-X-C motif) ligand 9 (CXCL9), macrophage inflammatory protein (MIP)-1β, vascular endothelial growth factor (VEGF), alpha-1-acid glycoprotein 1 (ORM1), MIP-5, T cell immunoglobulin and mucin-domain containing (TIM)-3, Factor D, lipocalin 2 (LCN2), glial fibrillary acidic protein (GFAP), pentraxin 3 (PTX3), Cortisol, IFN-λ2, transforming growth factor (TGF)-β1, ADAMTS13, complement component 5a (C5a), IFN-γ, IL-1β, IFN-λ3, IL-6, C-C motif chemokine ligand 20 (CCL20), C-C motif chemokine ligand 23 (CCL23), and tumor necrosis factor (TNF)-α [21,56-59]. Most of these analytes were measured with validated assays using commercial plates manufactured by Meso Scale Discovery. Results were analyzed using Discovery Workbench (version 4.0.12; Meso Scale Discovery). The antibody kits were provided by the company.

Data Collection and Management

Database services were provided by the Johns Hopkins University REDCap, a secure, HIPAA–compliant web application for building databases and managing web-based data for research [60]. Almost all data were collected by Johns Hopkins University study staff. A limited number of data points were generated by the mobile phlebotomy company (eg, orthostatic vital signs, height, weight, and status of collection and shipment) and by the study laboratories at Rush University (eg, clinical laboratory test results, status of shipment receipt, and status of sample processing and storage). Study staff at Johns Hopkins University or Rush received data from the mobile phlebotomy company via the phlebotomy secure internet portal and entered it into the REDCap database. The PI of the study was notified of grossly abnormal vital signs or laboratory results and about moderate to high depression or anxiety PHQ-8 and GAD-7 scores. The PI was also notified if the mobile phlebotomist noted any concerning event during the mobile phlebotomy visit. In each case, the PI reached out to the participant to provide basic health advice and guidance and resources for referral to the appropriate health provider.

Outcomes

Primary Outcomes

1. *Time to return to usual health and time to return to usual activities* will be measured using the FLU-PRO Plus instrument where we will assess the days taken to return to usual health and activities after COVID-19 or enrollment.
2. *Fatigue, severity of fatigue, and its effect on activity level* will be measured using the FSS (on a scale of 9-63) and the FSS global fatigue score (on a scale of 0-10) at 1, 2, 4, 6, and 12 months after COVID-19 or enrollment.
3. *Dyspnea* will be measured using the mMRC instrument (on a scale of 0-4) at 1, 4, and 12 months after COVID-19 or enrollment.
4. *Cognitive impairment* will be assessed using age-standardized scores from the 11 cognitive assessments and the GPCOG (on a scale of 0-36) at 1, 4, and 12 months after COVID-19 or enrollment.
5. *Number of symptoms* experienced will be measured using the FLU-PRO Plus instrument and the 11 additional long symptoms in the domains of neuropsychiatry, cardiovascular, and skin (on a scale of 1-5) at 1, 2, 4, 6 and 12 months after COVID-19 or enrollment.

Secondary Outcomes

1. *Orthostatic hypotension and orthostatic tachycardia* will be assessed at 1 and 4 months after COVID-19 or enrollment.
2. *Mental health* will be measured via self-reported measures of depressive symptoms and anxiety using the PHQ-8 and GAD-7 assessments at 1, 2, 4, 6, and 12 months after COVID-19 or enrollment and the CAT-MH at 1 and 4 months after COVID-19 or enrollment.
3. *Quality of life* in the domains of physical functioning, physical limitation of role fulfillment, emotional limitation of role fulfillment, energy and fatigue, emotional well-being, social functioning, pain, and general health will be assessed using the SF-36 and the EuroQuol EQ-5D-5L. The *RAND* 36-Item Health Survey 1.0 scoring method will be used to convert these questions into scores of the 8 QoL domains at 1, 4, and 12 months after COVID-19 or enrollment [61,62].
4. *Insomnia* (presence, severity, and patterns of insomnia) and its interference with daily functioning will be assessed by the ISI (on a scale of 0-28) at 1, 2, 4, 6, and 12 months after COVID-19 or enrollment.

XSL•FO
RenderX

Compensation

All participants were offered compensation for their time and efforts in participating in the study. A compensation of US $25 was offered per blood draw and US $25 per cognitive assessment completed, for a total of up to US $100 (for COVID+ arm) or US $75 (for COVID− arm) if all study events were completed. Participants were compensated in the form of an Amazon or VISA gift card.

Power Calculation

The target enrollment was as follows: 105 participants in the HIV+COVID+ arm, 105 participants in the HIV−COVID+ arm, 45 participants in the HIV+COVID− arm, and 50 participants in the HIV−COVID− arm. This resulted in a total target sample size of 305 participants overall, 210 of whom would be in the post–COVID-19 arms. Using a 2-tailed α of .05 and 10% estimated proportion of persistent symptoms in the comparator group, we estimated that there was 80% power to detect a difference of 15% in new or worsened symptom prevalence between people living with and without HIV after SARS-CoV-2 infection using a chi-square test of proportions.

Statistical Analysis

First, we will calculate the prevalence of persistent symptoms across the entire cohort and new or worsening symptoms compared with pre–COVID-19 symptoms in the 2 COVID-19 recovery arms. We will calculate mean and SD as well as median and IQR of the participant symptom score and quality of life by domain, reporting the statistic that is most reflective of the underlying distribution of the data. We will perform a time-to-event analysis to examine the return to baseline health using a Kaplan-Meier curve to graphically demonstrate COVID-19 recovery. To screen for unanticipated clinical syndromes related to COVID-19, we will also perform an exploratory analysis examining the proportion of participants reporting an abnormality in each item on the symptom checklist. In addition, we will perform cross-sectional cluster analyses at each time point to determine how each symptom relates to the others in each study arm at each time point.

After performing the descriptive analyses for each of the comparator arms, we will compare outcomes between the study arms. For binary outcomes such as new or worsened symptoms, we will report an unadjusted prevalence ratio. For symptom score and quality of life domain scores, we will perform unadjusted linear regression. For return to health, we will perform a time-to-event analysis and use a Cox regression model to estimate hazard ratios. In the next stage of the analysis, we will repeat these models but adjust for covariates including potential confounders (age, sex, race, ethnicity, etc) and effect modifiers (vaccination status and severity of illness).

Finally, we will make comparisons between individuals in each study arm with and without persistent symptoms—we will compare various biological analytes outlined in the *Biospecimen Testing* section among people living with HIV with and without persistent symptoms and among people without HIV with and without persistent symptoms and also describe these analytes among people living with and without HIV who have not had SARS-CoV-2 infection.

Results

The project was funded in early 2021, and recruitment began in June 2021. Data analyses are expected to be completed by summer 2023, and the primary study results are expected to be submitted for publication in 2023. As of February 2023, 387 participants enrolled in this study, 345 of whom completed enrollment and baseline surveys together with at least one other completed study event at month 1, 2, 4, 6, or 12. The 345 participants include 76 (22%) HIV+COVID+, 121 (35.1%) HIV−COVID+, 78 (22.6%) HIV+COVID−, and 70 (20.3%) HIV−COVID− participants.

Discussion

Expected Findings

This study will objectively characterize cognition, symptoms, and sequelae in the 12 months after first SARS-CoV-2 infection in people living with and without HIV. We aimed to replicate the demographic and geographic diversity of people living with HIV in the United States by opening enrollment to people who speak English or Spanish living anywhere in the 48 contiguous United States. As the demographics and medical histories of people living with HIV differ in important ways from people without HIV, we will compare post–COVID-19 cognition, symptoms, and sequelae with postenrollment cognition, symptoms, and sequelae in people living with and without HIV who have never had SARS-CoV-2 infection. We anticipate that people living with and without HIV will have broadly overlapping symptoms and sequelae after COVID. However, given that people living with HIV are more likely than people without HIV to have neurocognitive disease, we anticipate that people living with HIV will be more likely to have subjective and objective cognitive difficulties after COVID than people without HIV [63].

The pathophysiology of long COVID is currently not well defined. Proposed mechanisms include perturbations of immune and inflammatory responses during acute COVID-19, persisting reservoirs of SARS-CoV-2 in tissues, reactivation of latent pathogens such as Epstein-Barr virus, alterations of microbiota, autoimmunity and priming of the immune system from molecular mimicry, microvascular blood clotting, endothelial dysfunction, and dysfunctional signaling in the brainstem [18,19,21,56-58,64-72]. This study will be able to provide evidence to support or refute mechanisms that involve immune dysfunction and persistence of SARS-CoV-2 in plasma by testing samples for cytokines and coronavirus antibody and T cell responses. A central biorepository was created with samples from this study, which could be tested in the future for evidence of the reactivation of latent pathogens, complement activation, and autoimmunity.

Research on the relationship between HIV and long COVID is limited. A US-based electronic medical record preprint using data from TriNetX demonstrated that people living with HIV are more likely to report symptoms and sequelae ≥1 months following COVID-19 compared with propensity score–matched HIV-negative individuals [73]. A moderate-sized cohort study in San Francisco found that HIV is a risk factor for neurological

XSL•FO
RenderX

long COVID [71]. By contrast, a study in South Africa found that people living with HIV were as likely as HIV-negative individuals to report symptoms 6 months after hospitalization for COVID-19 [74]. Studies like ours that have the ability to link symptoms, sequelae, and objective measures such as cognitive testing to biological analytes are needed to help the field understand why people living with HIV might be more likely to develop long COVID symptoms and sequelae.

Strengths

This study was designed to meet the needs of people potentially experiencing long COVID who may be juggling fatigue and other symptoms and sequelae with life, work, and family responsibilities. The major strength of this study is its remote and participant-centric design. Participants could complete every study event from any location of their choice, including their home. This also allowed for the recruitment of a diverse participant population from around the United States who spoke either English or Spanish. In addition, the development of a central biorepository for specimen sharing will serve as a resource for investigators interested in the intersection of HIV and long COVID. Another strength of the study was that our surveys were developed in consultation with patient researchers who were experiencing long COVID.

Limitations

Limitations of the study include study dropout given the extended period of follow-up. To limit dropout, the study staff regularly reminded participants to complete the study events through phone calls, text messages, and emails. Unfortunately, shipping interruptions owing to weather and shipping company errors delayed the delivery of a percentage of specimens and affected which clinical tests could be performed. The survey asking participants to recall symptoms and quality of life in the month before SARS-CoV-2 infection was subject to a recall bias. In addition, as many participants completed the survey on the web in the context of other similar surveys asking about the present time, participants may have reported current rather than pre–COVID-19 symptoms. Questions on alcohol and substance use may have been subject to social desirability bias.

We aim to disseminate results from this study to participants via emails and at least 2 internet calls (with phone numbers and names anonymized by study staff to protect identifying information) so that participants can learn about study findings, ask questions, and provide feedback. We aim to disseminate the results from this study to affected communities by reaching out through the same networks used to advertise the study (social media, community advisory boards, activist groups, informal and formal newsletters, and magazines), ensuring that affected communities hear about science relevant to them.

Acknowledgments

The authors would like to thank all study participants for their time and samples. Major funding for this study was provided by the American Foundation for AIDS Research grant 110180-69-RSCV. Additional support was provided by Johns Hopkins University Center for AIDS Research (P30AI094189). AARA is also supported by National Institute of Allergy and Infectious Diseases K08AI143391. The authors would like to thank all the community members, providers, staff, and other individuals who helped disseminate information about the study, including the Long COVID Justice Network; AIDS Action Baltimore; SisterLove; POZ magazine; Somos Baltimore Latino; the COVID Advocates Advisory Board; The Cranky Queer Newsletter; the Johns Hopkins Institute for Clinical and Translational Research Hopkins Opportunity for Participants Engagement registry; the DC HIV Cohort; and the numerous physicians, researchers, and other individuals who referred participants to the study. The authors would like to thank Hannah Davis and other members of the Patient Led Research Collaborative for Long COVID for providing survey data to inform symptom questions and for reviewing surveys before use. The authors would also like to thank all study staff at all participating study sites. The authors would like to thank Dr Yukari Manabe, Dr Richard Moore, Ms Jeanne Keruly, and Ms Zoe Demko for discussion and support during initial protocol design. The authors would like to thank the Johns Hopkins REDCap (Research Electronic Data Capture) team, specifically Mr Scott Carey, who developed a novel method to directly input biorepository .csv files in the Laboratory Data Management System format into the study's REDCap database.

Data Availability

The data sets generated or analyzed during this study are not publicly available because of the presence of patient identifying information but are available from the corresponding author upon reasonable request pending institutional review board approval.

Conflicts of Interest

Under a private license agreement, TDV is entitled to a share of royalty from the sales of the products described in this study. The terms of this arrangement are being managed by the Johns Hopkins University in accordance with its conflict-of-interest policies. No other authors declare a conflict of interest.

Abstract

Background: In hospitalized patients with COVID-19, the dosing and timing of corticosteroids vary widely. Low-dose dexamethasone therapy reduces mortality in patients requiring respiratory support, but it remains unclear how to treat patients when this therapy fails. In critically ill patients, high-dose corticosteroids are often administered as salvage late in the disease course, whereas earlier administration may be more beneficial in preventing disease progression. Previous research has revealed that increased levels of various biomarkers are associated with mortality, and whole blood transcriptome sequencing has the ability to identify host factors predisposing to critical illness in patients with COVID-19.

Objective: Our goal is to determine the most optimal dosing and timing of corticosteroid therapy and to provide a basis for personalized corticosteroid treatment regimens to reduce morbidity and mortality in hospitalized patients with COVID-19.

Methods: This is a retrospective, observational, multicenter study that includes adult patients who were hospitalized due to COVID-19 in the Netherlands. We will use the differences in therapeutic strategies between hospitals (per protocol high-dose corticosteroids or not) over time to determine whether high-dose corticosteroids have an effect on the following outcome measures: mechanical ventilation or high-flow nasal cannula therapy, in-hospital mortality, and 28-day survival. We will also explore biomarker profiles in serum and bronchoalveolar lavage fluid and use whole blood transcriptome analysis to determine factors that influence the relationship between high-dose corticosteroids and outcome. Existing databases that contain routinely collected electronic data during ward and intensive care admissions, as well as existing biobanks, will be used. We will apply longitudinal modeling appropriate for each data structure to answer the research questions at hand.

Results: As of April 2023, data have been collected for a total of 1500 patients, with data collection anticipated to be completed by December 2023. We expect the first results to be available in early 2024.

Conclusions: This study protocol presents a strategy to investigate the effect of high-dose corticosteroids throughout the entire clinical course of hospitalized patients with COVID-19, from hospital admission to the ward or intensive care unit until hospital discharge. Moreover, our exploration of biomarker and gene expression profiles for targeted corticosteroid therapy represents a first step towards personalized COVID-19 corticosteroid treatment.

Introduction

Background

The emergence of SARS-CoV-2 in Wuhan caused a global COVID-19 pandemic, with a high mortality and morbidity rate worldwide [1]. Over the past years, many efforts have been made to unravel the underlying complex pathophysiological mechanisms and explore various treatment options. Substantial variation exists in systemic and alveolar levels of inflammation between patients, contributing to the heterogeneous clinical course of the disease. This ranges from asymptomatic infection to life-threatening hypoxemic pneumonia. Corticosteroid therapy has the potential to inhibit disease progression and decrease the severity of clinical symptoms and is first-line immunosuppressive therapy in patients with COVID-19 with hypoxia [2].

The main reason for hospitalization of patients with COVID-19 is the requirement of supplemental oxygen therapy because of hypoxemia. In some patients, ground glass opacification and the beginning of consolidations on pulmonary CT scan are observed [3], accompanied by increased parameters of inflammation and coagulation in bronchoalveolar lavage fluid (BALF) and the systemic compartment [4,5]. In case of progressive respiratory failure, patients with COVID-19 will be admitted to the intensive care unit (ICU). These patients have a significantly decreased partial pressure of oxygen in arterial blood–fraction of inspiratory oxygen concentration ratio and frequently fulfill the Berlin criteria of moderate and severe acute respiratory distress syndrome (ARDS) [6]. Analysis of their inflammatory profiles shows a further elevation of proinflammatory cytokines, which is associated with increased mortality [7,8].

For decades, corticosteroids are given to treat patients with non–COVID-19 ARDS because of their strong anti-inflammatory effects [9]. Among patients with COVID-19, the Randomized Evaluation of Covid-19 Therapy (ie, RECOVERY) study showed that low-dose dexamethasone reduces mortality in patients requiring supplemental oxygen therapy or invasive mechanical ventilation but not in patients without respiratory support [10]. Current COVID-19 guidelines recommend a dose of 6 mg of dexamethasone per day for 10 days when oxygen therapy is required, regardless of the level of inflammation or severity of the disease [2]. Unfortunately, a proportion of patients still show progressive deterioration despite this treatment.

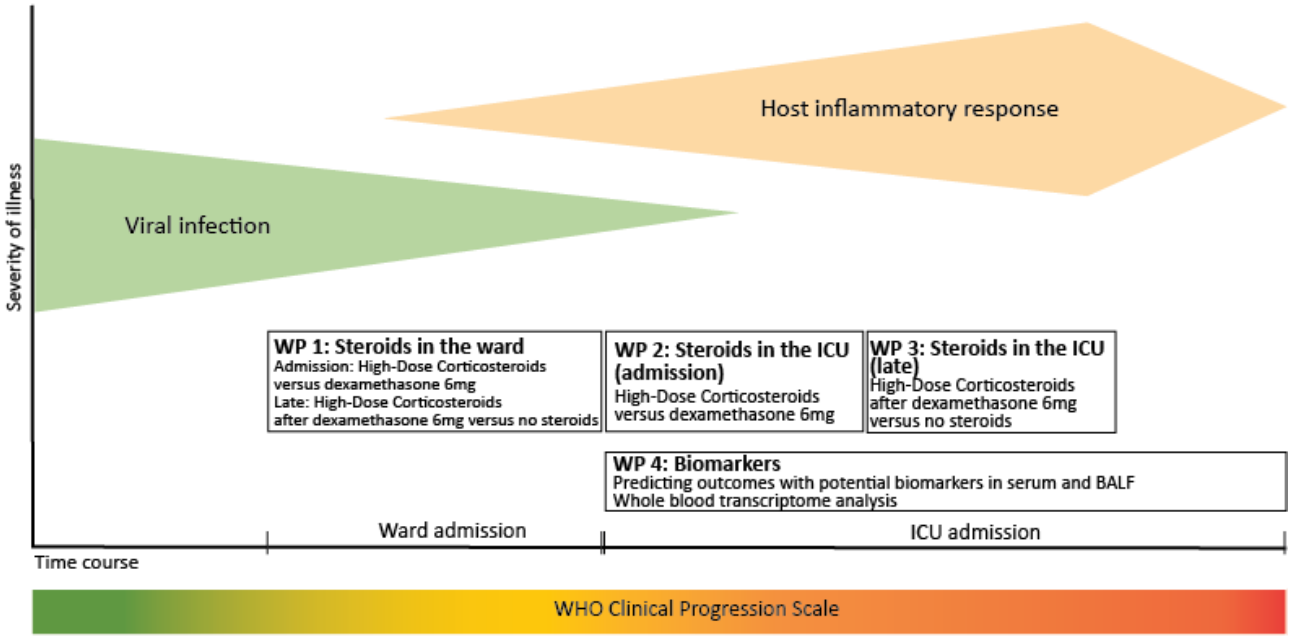
In these dexamethasone-unresponsive patients with COVID-19, corticosteroid therapy is sometimes escalated to a much higher dose. However, large heterogeneity in the type, timing, and

XSL•FO
RenderX

dosing of escalated corticosteroid therapy exists [11]. High-dose corticosteroids are mainly administered during the late phase of the clinical course and in patients with the most severe disease, while earlier administration could be beneficial in preventing disease progression. However, the results of the studies on high-dose corticosteroid treatment for critically ill patients with COVID-19 are contradicting [12-15]. A recent meta-analysis compared high-dose corticosteroids versus low-dose corticosteroids in hospitalized patients with COVID-19 and reported no difference in mortality. Given the low level of evidence, inconclusive trial sequential analysis, and substantial heterogeneity, the authors stress the importance of future research to improve the certainty of evidence [16].

Treatment with high-dose corticosteroids may come at the cost of complications, such as secondary infections due to the immunosuppressive effects. To better predict the response to high-dose corticosteroids prior to therapy, additional diagnostic tools such as serum and BALF biomarker determination and whole blood transcriptome analysis could be helpful [17]. Implementation of these tools may result in a more precise and individualized approach to corticosteroid dosing in clinical practice.

Overall, the optimal dosing and timing of high-dose corticosteroids in hospitalized patients with COVID-19 remains uncertain. Here, we present the study design and methodological considerations of the SELECT (Steroids in Hospitalized Patients with COVID-19 in The Netherlands) study, a multicenter study that aims to study the most optimal dosing and timing of corticosteroid therapy to reduce the morbidity and mortality of hospitalized patients with COVID-19. In addition, we aim to provide a basis for personalized corticosteroid treatment regimens by exploring the predictive value of biomarkers and whole blood transcriptome analysis. We hypothesize that the effect of corticosteroid therapy on outcome is determined by the dosage and timing of administration, as well as the patient's underlying inflammatory state.



Study Aims

Work Package 1: High-Dose Corticosteroid Treatment in the Ward

Work package 1A (WP1A) is used to investigate whether initial treatment with high-dose corticosteroids compared to treatment with 6 mg dexamethasone per day for 10 days, or an equivalent corticosteroid, improves patient outcomes in the ward (Figure 1).

WP1B is used to investigate whether treatment with high-dose corticosteroids compared to no corticosteroids, after treatment with 6 mg dexamethasone per day for 10 days, improves patient outcomes in the ward.

Figure 1. Integration of work packages in the Steroids in Hospitalized Patients with COVID-19 in The Netherlands (SELECT) study. On the y-axis, the viral and host inflammatory response are depicted. On the x-axis, the admission to the ward or intensive care unit (ICU) is shown, and below that, the World Health Organization (WHO) clinical progression scale is displayed as a measure of supplemental oxygen therapy. steroids: corticosteroids; HDS: high-dose corticosteroids; WP: work package.

Work Package 2: High-Dose Corticosteroid Treatment in the ICU

Work package 2 (WP2) is used to investigate whether initial treatment with high-dose corticosteroids compared to treatment with 6 mg dexamethasone per day for 10 days, or an equivalent corticosteroid, improves patient outcomes in the ICU.

XSL•FO
RenderX

Work Package 3: High-Dose Corticosteroid Treatment After Standard Corticosteroid Treatment in the ICU

Work package 3 (WP3) is used to investigate whether treatment with high-dose corticosteroids compared to no corticosteroids, after treatment with 6 mg dexamethasone per day for 10 days, improves patient outcomes in the ICU.

Work Package 4: Biomarker Profiles and Whole Blood Genome Transcriptomes in High-Dose Corticosteroid Treatment

Work package 4a (WP4a) is used to investigate whether biomarker profiles in serum and BALF act as response predictors for high-dose corticosteroids on the outcome.

WP4b is used to investigate whether whole blood transcriptome analysis acts as a response predictor for high-dose corticosteroids on the outcome.

Methods

Definition High-Dose Corticosteroids

High-dose corticosteroids are defined as every treatment with dexamethasone >6 mg daily or an equivalent corticosteroid (Table 1). Regarding prior and continuing use of corticosteroids for other conditions, corticosteroids are considered as part of the COVID-19–related intervention when the high-dose threshold is passed.

Table 1. Equivalent corticosteroids and dosages (total daily dosing)[a].

Drug	Equivalent dose (mg)	Low-dose (mg)	High-dose (mg)
Dexamethasone	0.75	≤6	>6
Cortisone	25	≤200	>200
Hydrocortisone	20	≤160	>160
Prednis(ol)one	5	≤40	>40
Methylprednisolone	4	≤32	>32
Bethamethasone	0.75	≤6	>6

[a]This table shows the equivalent corticosteroids and dosages. The equivalent dose is derived from Farmacotherapeutisch Kompas [18].

Study Design and Setting

The SELECT study is a retrospective cohort study with data from 22 hospitals in the Netherlands, including 4 academic and 18 nonacademic hospitals (Figure 2). Other hospitals may be included as the study progresses and we will use routinely collected electronic data from the participating hospitals. The data sets will contain data on hospitalized patients with COVID-19 from the date the first patient was admitted to the hospital in the Netherlands (March 1, 2020) until data transfer (expected May-December 2023). We will use the heterogeneity in therapeutic regimens in time (ie, first, second, and third epidemiological wave), centers (per protocol high-dose corticosteroids or not), and individual patients in the initial databases to address our aims. In a subpopulation of patients, we will use biobank material collected within the Collaboration on Identification, Understanding and Improved Management of patients with infectious diseases study of the Erasmus MC or collected at the Amsterdam University Medical Center (UMC) within the MERMAIDS-ARI, VIS cohort study or the Amsterdam UMC COVID-19 biobank.

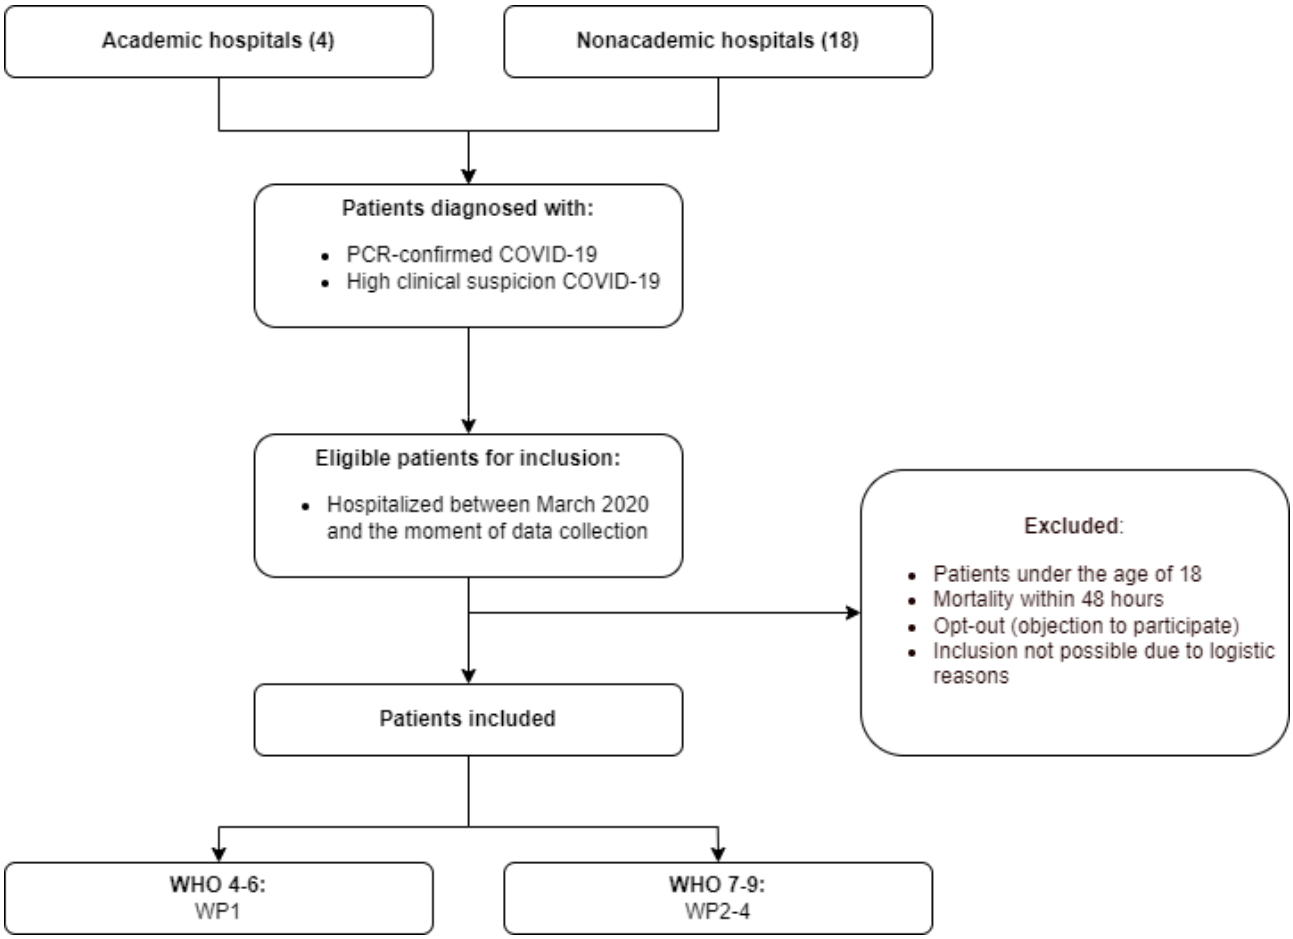
Figure 2. Participating hospitals of the Steroids in Hospitalized Patients with COVID-19 in The Netherlands (SELECT) study. UMC: University Medical Center. MC: Medical Center; OLVG: Onze Lieve Vrouwe Gasthuis.



Patient Selection and Inclusion Criteria

Adult patients (≥18 years) hospitalized with polymerase chain reaction–confirmed COVID-19 or high clinical suspicion of COVID-19 will be included (Figure 3). Pregnant patients and patients receiving corticosteroids for other conditions during or prior to hospital admission are eligible, although a prespecified sensitivity analysis excluding these patients will be performed. Patients who die within 48 hours after admission or patients who object to participate will be excluded from the study. In WP1 and WP4, we will include patients from all SARS-CoV-2 epidemic waves, and in WP2-3, we will include patients from the first and second waves only. Specific inclusion and exclusion criteria for each work package will be applied. In WP1A, patients will be included who are admitted to the ward with a World Health Organization clinical progression scale class of 4-5 [19] (ie, no oxygen or oxygen therapy via a cannula or [non-rebreather] mask). WP1B includes patients who have progressed to the World Health Organization clinical progression scale class of 5-6 (ie, noninvasive oxygen therapy, including conventional oxygen via cannula [non-rebreather] mask, high-flow nasal cannula, noninvasive continuous positive airway pressure, and noninvasive bilevel positive airway pressure) after in-hospital treatment with 10 days of 6 mg per day dexamethasone. The study population for WP2-4 consists of patients admitted to the ICU for a period exceeding 48 hours, who received invasive mechanical ventilation via an endotracheal tube, a tracheostomy, or extracorporeal membrane oxygenation during their ICU stay.

Ethics Approval and Consent to Participate

The study will be conducted according to the principles of the Declaration of Helsinki (64th World Medical Association General Assembly, Fortaleza, Brazil, October 2013) and in accordance with Erasmus MC Research code, Netherlands Code of Conduct for Research Integrity, General Data Protection Regulation, Code of Conduct for Health Research (not subjected to the Medical Research Involving Human Subjects Act [non-WMO]), Code of Conduct for Responsible Use of Human Tissue (Non-WMO), and Medical Treatment Contracts Act. The study was approved by the Medical Research Ethics Committee from Erasmus University Medical Center (MEC-2022-0297) and the local review boards of all other participating centers. Regarding informed consent procedure: within the Erasmus MC, a consent waiver was provided by the Medical Research Ethics Committee for research including patients with COVID-19 due to the pandemic (exception due to emergency situation). Therefore, an opt-out informed consent procedure will be used in the participating centers, and subjects with registered objections to participate will be excluded from the study. This opt-out registration method was approved by the Medical Research Ethics Committee from Erasmus University Medical Center (MEC-2022-0297). Each center is responsible for appropriate informed consent procedures, which are covered in the data transfer agreements. Regarding the biobank data, only biobank material collected within the Collaboration on Identification, Understanding and Improved Management of patients with infectious diseases study of the Erasmus MC (METC number primary application: 2017-0417 and amendment 2020-0222) and samples collected at the Amsterdam UMC within the MERMAIDS-ARI (NL54834.018.15), VIS cohort study (NL73759.018.20), and the Amsterdam UMC COVID-19 biobank will be used.

Data Collection

In WP1, variation in corticosteroid treatment protocols on the ward between centers is evaluated via questionnaires and extraction of data from the electronic patient record. The focus lies on collecting data from centers that use high-dose corticosteroids on the ward directly after admission and subsequently collecting data from centers with low-dose regimens as a comparison. For the data collection of ICU patients (WP2-3), a collaboration with 2 large COVID-19 study groups is started: the Practice of Ventilation in COVID-19 study (ie, PROVENT-COVID) study and the “Practice of Adjunctive Treatments in Intensive Care Unit Patients with Coronavirus Disease 2019” (PROACT-COVID) study [20,21]. The data of

XSL•FO
RenderX

interest will be collected in Castor EDC [22], and it will be imported from each center via a secured data transfer system. Corticosteroid data will be collected on a daily basis including type, dose, and administration route. Regarding biobank WP4, a number of serum biomarker levels were already determined during standard COVID-19 care. In case of missing measurements, the stored samples (Tempus tubes) in the biobank can be used. The BALF was collected during routine COVID-19 care in the Amsterdam University Medical Centers and saved in aliquots at −80 °C for further analysis. SARS-CoV-2 viral load will be measured in BALF by using an in-house reverse transcription polymerase chain reaction. Subsequently, other commercially and generally available biomarkers might be determined in serum and BALF later by using a multiplex assay, such as Luminex. For the whole genome transcriptomes analysis, material was collected and saved in blood RNA Tempus tubes.

Interventions

Patients were administered with >6 mg dexamethasone or an equivalent corticosteroid for a minimum of 3 consecutive days (Table 1). Our study permits the use of other general concurrent interventions, such as venous thromboembolism prophylaxis, fever and glucose control, fluid management, antibiotics, and antiviral drugs. The use of other immunomodulatory agents such as baricitinib, JAK inhibitors, and interleukin 6 pathway inhibitors, as well as antiviral drugs such as remdesivir, is allowed as part of a clinical trial or hospital policy. However, a sensitivity analysis will be performed excluding these patients.

Outcomes

Primary Outcomes

Several outcome parameters will be studied for the different work packages based on the available data. In WP1A, the primary outcome of interest is hospital mortality in patients who do not receive high-flow nasal canule or invasive mechanical ventilation due to restrictions in care, either on medical grounds or advance directives of the patient. In patients who do not have restrictions in care, the need for high-flow nasal canule or invasive mechanical ventilation will be the primary outcome of interest (WHO severity 6-9). In WP1B, WP2, and WP3, 28-day survival and 28-day need for invasive mechanical ventilation will be studied as primary outcomes. In WP4, we will study the response to corticosteroids using the same outcomes.

Secondary Outcomes

Secondary outcomes for the ICU work packages include ICU mortality; in-hospital mortality; hospital length of stay (the number of days from the date of ICU admission to date of ICU discharge or death); mechanical ventilation duration (total duration of mechanical ventilation in days); and ventilator-free days, and alive at day 28. In all 4 work packages, we will evaluate the incidence of general systemic complications during the hospital stay as a secondary outcome, including myocardial infarction, deep venous thrombosis, pulmonary embolus, hyperglycemia, acute kidney injury, and sepsis. The definition of the various general systemic complications is shown in Table S1 in Multimedia Appendix 1.

Statistical Analysis

Data will be analyzed on a convenience sample. No sample size calculations are considered for the study nor will they be provided post hoc [23]. The use of high-dose corticosteroids will be defined as a dichotomous variable (yes or no) in primary analysis and as a continuous variable in secondary analysis.

To study between-center variation in corticosteroid dosing strategy, the proportion of individuals who received high-dose corticosteroids will be compared across hospitals. Determinants of receiving high-dose corticosteroids will be evaluated using a multivariable logistic regression model with study center forced in the model. Whether the effects of significant determinants are different across centers will be tested through a determinant × center interaction term added for each determinant, separately.

In WP1, WP2, and WP3, several statistical analysis approaches will be considered to determine the association between high-dose corticosteroids and outcome, and statistical analyses will depend on the structure of the available data. A multivariable logistic regression model will be used with high-dose corticosteroids as exposure and survival at day 28 as an outcome. Covariates used for adjustment will include age, gender, BMI, smoking status, prior administration of corticosteroids during admission, comorbidity, sequential organ failure assessment score, oxygen saturation, partial pressure of oxygen in arterial blood–fraction of inspiratory oxygen concentration ratio, C-reactive protein, procalcitonin, ferritin, interleukin 6, D-dimer, lactate dehydrogenase, platelet count, lymphopenia, and level of respiratory support. Covariates can be added or removed based on insights from the data set or from the literature. A model might be constructed in which patients are matched on a propensity score based on their probability to receive high-dose corticosteroid treatment. Propensity scores will be determined using a logistic regression model with high-dose corticosteroids as a dependent variable and determinants of high-dose corticosteroids as independent variables. After matching, survival and mortality at day 28 and other outcome parameters will be compared between matched groups using logistic regression. A Cox proportional hazards model might be performed to determine the effect of high-dose corticosteroids on time to death while taking into account the days of administration using time-dependent covariates. Other approaches involving censoring weights for differential loss to follow-up (eg, marginal structural models) or competing risks (eg, joint models) might be explored.

Furthermore, we will use clinical and biological data to perform latent class analysis to search for subphenotypes, which respond more favorably to corticosteroid treatment. This heterogeneity of treatment effect will be evaluated by including the latent class analysis-derived subphenotype, corticosteroid exposure, and an interaction term of the 2 as c-variate in the above-described survival models. Heterogeneity of treatment effect is considered to be present if the interaction term has a *P* value of <.05.

Regarding WP4, patients are randomly selected and cases will be patients treated with high-dose corticosteroids, whereas controls will be patients who were not treated with high-dose

XSL•FO
RenderX

corticosteroids. In WP4a, inverse probability treatment weighting and inverse probability of censoring weights will be used together in a marginal structural model. After we have analyzed the effect of high-dose corticosteroids on mortality and the other outcome measures, we will use this model to determine if the listed biomarkers modify the effect of high-dose corticosteroids on mortality.

In WP4b, we will identify transcriptome features that are differentially altered between cases and controls. Mean transcriptome levels will be compared using an unpaired *t*-test and *P* values will be adjusted for false-discovery rate using the Benjamini-Hochberg procedure. The $\log_2$ mean fold change of levels between cases and controls will also be calculated for each transcriptome. We will define transcriptome features as those with an adjusted *P* value of <.05 and a >2.0 or <–2.0 $\log_2$ mean fold change in level.

Results

The study was funded in December 2021. As of April 2023, data have been collected for a total of 1500 patients, with data collection anticipated to be completed by December 2023. We expect the first results to be available in early 2024.

Discussion

The SELECT study is a retrospective multicenter observational cohort study that aims to determine the most optimal dosing and timing of high-dose corticosteroid therapy in hospitalized patients with COVID-19 and to provide a basis for personalized treatment regimens using biomarkers and whole transcriptome analyses. Increasing insight in the pathophysiological pathways that underlie SARS-CoV-2 infection and the efficacy of high-dose corticosteroid therapy could lead to more precise targeting of high-dose corticosteroid therapy, and as a result, could improve patient outcomes.

The necessity of exploring this matter is underlined by the fact that there is currently no consensus regarding the administration of high-dose corticosteroid therapy in patients with COVID-19.

This study design has several strengths. First, no studies have been performed that evaluate the effect of high-dose corticosteroids throughout the entire clinical course of hospitalized patients with COVID-19. Our study will evaluate the effect of high-dose corticosteroids from hospital admission to the ward or ICU, until hospital discharge. Furthermore, our exploration of biomarker and gene expression profiles for targeted corticosteroid therapy represents a first step toward personalized corticosteroid therapy in COVID-19. By using existing research databases and biobanks, successful data collection is assured, and we will be able to include a large number of patients, which increases the generalizability of the results.

Due to the retrospective study design, some methodological considerations require further discussion. A major issue for any observational study is the fact that treatment modalities are not randomly assigned, but rather likely given based on specific patient characteristics or within-center protocols. This nonrandomized assignment is prone to bias by indication. To correct this bias, our initial analysis step will be the identification of factors that contribute to the allocation of corticosteroid treatment. Subsequently, we will examine several statistical approaches, such as the use of propensity scores at the patient level to minimize treatment indication bias.

The findings of this study could support COVID-19 guidelines and hospital protocols regarding the management of hospitalized patients with COVID-19. Thus far, the translation of predictive biomarkers and whole transcriptome analysis into an applicable bedside tool is highly challenging. We expect to provide valuable tools to guide the dosing and timing of high-dose corticosteroid therapy. Furthermore, the answers to our research questions might be extrapolated to patients with non–COVID-19 ARDS, as the use of high-dose corticosteroids is still a matter of debate in this group of patients. The mortality rate of non–COVID-19 ARDS is even higher than that of COVID-19 ARDS [24], emphasizing the need for improved treatment strategies. Nonetheless, more efforts are required to determine similarities and differences between patients with COVID-19 ARDS and those with non–COVID-19 ARDS to determine whether extrapolation from one group to the other is possible.

In conclusion, our study protocol presents a strategy to gain a better understanding of the optimal dosing and timing of high-dose corticosteroid therapy in hospitalized patients with COVID-19 and thereby improve patient outcomes.

Acknowledgments

We gratefully acknowledge all site investigators of the participating centers. Abstract

Background: In the Canadian province of Saskatchewan, the global COVID-19 pandemic appeared amidst existing social health challenges in food insecurity, housing precarity and homelessness, poor mental health, and substance misuse. These chronic features intersected with the pandemic, producing a moment in time when the urgency of COVID-19 brought attention to underlying shortcomings in public health services.

Objective: The objectives of the program of research are (1) to identify and measure relationships between the pandemic and wider health and social impacts, namely, food insecurity, housing precarity and homelessness, and mental health and substance use in Saskatchewan, and (2) to create an oral history of the pandemic in Saskatchewan in an accessible digital public archive.

Methods: We are using a mixed methods approach to identify the impacts of the pandemic on specific equity-seeking groups and areas of social health concern by developing cross-sectional population-based surveys and producing results based on statistical analysis. We augmented the quantitative analysis by conducting qualitative interviews and oral histories to generate more granular details of people's experiences of the pandemic. We are focusing on frontline workers, other service providers, and individuals within equity-seeking groups. We are capturing digital evidence and social media posts; we are collecting and organizing key threads using a free open-source research tool, Zotero, to trace the digital evidence of the pandemic in Saskatchewan. This study is approved by the Research Ethics Board at the University of Saskatchewan (Beh-1945).

Results: Funding for this program of research was received in March and April 2022. Survey data were collected between July and November 2022. The collection of oral histories began in June 2022 and concluded in March 2023. In total, 30 oral histories have been collected at the time of this writing. Qualitative interviews began in April 2022 and will continue until March 2024. Survey analysis began in January 2023, and results are expected to be published in mid-2023. All data and stories collected in this work are archived for preservation and freely accessible on the Remember Rebuild Saskatchewan project's website. We will

XSL•FO
RenderX

share results in academic journals and conferences, town halls and community gatherings, social and digital media reports, and through collaborative exhibitions with public library systems.

Conclusions: The pandemic's ephemeral nature poses a risk of us "forgetting" this moment and the attendant social inequities. These challenges inspired a novel fusion among health researchers, historians, librarians, and service providers in the creation of the Remember Rebuild Saskatchewan project, which focuses on preserving the legacy of the pandemic and capturing data to support an equitable recovery in Saskatchewan.

Introduction

Background

On March 11, 2020, the World Health Organization declared a global pandemic caused by a new virus, SARS-CoV-2. Due to the uncertainties about the virulence of COVID-19, the disease caused by SARS-CoV-2, and the need to mitigate the expected demand on the health care system, the federal and provincial governments of Canada imposed strict public health restrictions that limited population movement. These new policies helped to slow the spread of COVID-19, but they also had significant social consequences, such as the pivot to remote work and learning and the closure of many small businesses.

In Saskatchewan, a province in central Canada with a population of just under 1.2 million people, the provincial government introduced public health measures with the intention of dampening the initial wave of the pandemic. The transmission of the virus in Saskatchewan was slow during the first 6 months of the pandemic, and the province reported far fewer cases and deaths due to COVID-19 (58.75 and 0.85 per 100,000) than the Canadian average (180.42 cases and 15 per 100,000 deaths) in that time [1]. Like other regions in Canada, Saskatchewan experienced an economic downturn during the first 6 months of the pandemic, losing 5% of its gross domestic product and recording a 5% increase in unemployment [2].

COVID-19 in Saskatchewan

By 2021, COVID-19 cases and deaths in Saskatchewan were trending upward, surpassing the Canadian average in January and remaining above the national rates throughout 2022 [1]. In November 2022, Saskatchewan reported the third-highest death rate among Canadian provinces, with 142 deaths per 100,000, exceeding the national average of 123 deaths per 100,000. Despite high rates of transmission and deaths per capita, the Government of Saskatchewan progressively eliminated public health restrictions, arguing that these protocols hindered economic growth and personal freedom [3]. Subsequently, Saskatchewan became one of the first Canadian provinces to relax all pandemic-related restrictions, first doing so in July 2021 and then again comprehensively easing restrictions during the Omicron wave in February 2022 [3,4].

The 2022 policy reversals coincided with a reduction in pandemic-related data collection and reporting, resulting in limited access to publicly available data and the capacity for the public to understand and interpret the ongoing effects of the pandemic [5]. Beyond prioritizing economic issues over public health, the decision to stop sharing COVID-19 data publicly made the province of Saskatchewan stand apart from other provinces and territories. This, in part, made it an ideal case study for further examination. This shift in priorities during the pandemic also exacerbated preexisting public health needs, namely food insecurity, housing precarity and homelessness, mental health, and substance use.

Since March 2020, the urban centers of Regina and Saskatoon have experienced an increased surge in social service usage [6-8], homelessness, and housing precarity [9-11]. Saskatchewan residents also reported higher rates of food insecurity [12], mental distress, and illness [13-16], and the province experienced a drastic increase in substance use-related deaths [17]. Moreover, the government's decision to stop releasing health data in 2022 led to only a partial understanding of how COVID-19 influenced wider health trends across Saskatchewan.

Remember Rebuild Saskatchewan: A COVID-19 Project

This protocol paper presents our innovative mixed method protocol for a program of research entitled "Remember Rebuild Saskatchewan." This, in turn, consists of 2 constituent federally funded projects: "Build Back Better: Data and equity needed to drive postpandemic recovery in Saskatchewan," funded by Canadian Institutes of Health Research (operating grant 478277), and "Saskatchewan's COVID-19 public archive," funded by Social Sciences and Humanities Research Council of Canada Partnership Development (grant 356339). The objective of the program of research is to identify and measure relationships between the pandemic and wider health and social impacts, namely, food insecurity, housing precarity and homelessness, and mental health and substance use in Saskatchewan. We also aim to identify how the pandemic affected service providers and service users across the province as they navigated (or attempted to navigate) the COVID-19 pandemic. The overall goal is to preserve data and stories in a digital archive and use them, alongside social media and web archives, to create a social history of the COVID-19 response in Saskatchewan, Canada. The findings from this multidisciplinary and community-focused research model will be used to develop policy, programming,

XSL•FO
RenderX

and practice recommendations for policy makers and community-based human service agencies.

Methods

Study Setting and Design

This program of study is set in the province of Saskatchewan, Canada. Our interdisciplinary team blends the expertise of many disciplinary experts, for example, epidemiologists, population health researchers, digital humanists, and medical historians, with the expertise and lived experience of community-based partners to create knowledge and build and share a record of the implications of COVID-19 for the province of Saskatchewan. We use a mixed methods study design, including quantitative survey data collection, qualitative engagements with service providers and individuals from equity-seeking groups through interviews and oral histories, as well as social and digital media record collection and analyses. Our interdisciplinary and mixed methods approach allows us to use diverse and complementary techniques for data collection and analysis and to illuminate the impacts of the pandemic in a multifaceted and evidence-informed manner.

Patient and Public Involvement

The Remember Rebuild Saskatchewan project is heavily community-involved. Because of the limited pandemic-related data in Saskatchewan, we use a bottom-up approach to highlight the impacts and trends of the pandemic and to compare community experiences against a broader provincial population survey. We have partnered with community-based organizations working in food insecurity, housing precarity and homelessness, mental health, and substance use; a task force formed to harmonize a community response to the pandemic; and public sector unions representing nurses and teachers. Community-based organizations and union leaders joined each project as research partners during the initial project conceptualization and aided in the study design through consultation on the development of the public archive and during the Build Back Better survey development. Community partners have shared their stories for the archive, which aids us in the recruitment of frontline staff and people who access services to participate in oral histories and qualitative interviews. Citizens have shared their stories with us, for instance, about those they lost to COVID. We engage community partners quarterly with formal project updates and further consult as needed as the projects progress. Furthermore, partners will be engaged in community events focused on collaborative analysis and knowledge mobilization.

Project: Build Back Better

Overview

Our health research teams are collecting both quantitative and qualitative data to assess the impacts of the pandemic on 4 interrelated areas: food insecurity, housing precarity and homelessness, mental health, and substance use. Given Saskatchewan's huge geographical landscape and the importance of rural and northern communities in addition to its 2 major cities, Saskatoon and Regina, and several midsized urban centers, the team also relies on stratified regional analysis to ensure the relevance of the multiple interacting components of this work across the province. The survey also enables an analysis of how access to services has differed for equity-seeking groups across the province. For our study, we define equity-seeking groups as women; Indigenous populations; youth and older adults; 2-spirited, lesbian, gay, bisexual, transgender, and queer/questioning (2SLGBTQ+) persons; immigrants and refugees; those living in remote and rural or underserved areas; and those living with mental health or disabilities. Our mixed methods approach enables the project to connect survey results with qualitative research analyzing the impacts of the pandemic on service provision by affected frontline workers and health, human, and social service organizations.

Quantitative Methods

Overview

Quantitative data were collected through a population-based cross-sectional web-based survey administered between July and November 2022 (Multimedia Appendix 1). The survey inclusion criteria for the study were the following: (1) a minimum age of 18 years, (2) residing in Saskatchewan, and (3) English language proficiency. We selected the study population for the survey through random probability sampling from the following panels of target populations: the Saskatchewan Community Panel from the Canadian Hub for Applied and Social Research, the Probit Panel from EKOS Research Associates, Inc, and a convenience sample from Voxco's omnichannel cloud. Quotas were implemented to closely approximate the sample to the Saskatchewan population with respect to gender, age, and geographical location; however, postsurvey weights were also calculated and applied to ensure our study sample aligns with provincial demographics.

The survey data address the following research questions: (1) what is the prevalence of adverse mental health status, substance use, home evictions and housing precarity, and food insecurity in Saskatchewan? How has the prevalence of these challenges changed during the pandemic and compared to that before the pandemic? (2) Has the pandemic differentially affected people in equity-seeking groups (Indigenous groups, visible minority or newcomers, 2SLGBTQ+, people with disabilities, etc) and for those with the greatest social and economic needs (unemployed or underemployed and low-income)?

The web-based survey began with general information about the study, resources for support, and an informed consent form for participation. After providing consent, participants were directed to complete the web-based questionnaire. Participants, on average, took 20 minutes to complete the survey. Upon completion, participants were given the option to enter a draw to win one of fifteen grocery store gift cards valued at CAD $100 (US $73.48) each. The survey included 6 sections: demographics, impacts of the pandemic, food insecurity, housing precarity, mental health, and substance use. Measures included in the survey were taken from or adapted from other validated and reliable instruments to ensure consistency and validity of findings, or they were self-drafted collaboratively by the interdisciplinary team.

XSL•FO
RenderX

Demographics

Our survey asked demographic questions to ascertain participants' age, gender and sexual identity, ethnicity, location, immigrant status, disability, and household composition. We asked respondents about their highest levels of education attained. We also queried whether they are engaged in full-time or part-time employment, unemployed, looking for work or not, stay-at-home parenting, retired, studying, unable to work due to disability, and others. If participants indicated employment, they were asked to specify their area of work for their primary job, which included 22 job areas. We also asked whether participants worked in a frontline position to assess the impacts specific to frontline workers during the pandemic.

Impacts of the COVID-19 Pandemic

We measured the impact of the pandemic on participants' health and well-being (both personal and socioeconomic). First, we assessed the current state of health through self-rated physical and mental health questions, positive COVID-19 tests, the severity and duration of COVID-19 symptoms, and the receipt of COVID-19 vaccines and boosters. Participants' personal well-being was assessed through self-rated questions on the quality of life and ability to perform day-to-day activities. We also assessed the pandemic's impact on households' socioeconomic well-being through 6 indicators drafted by the research team, including changes to individual and household employment, income, household finances, and access to financial or community support. In addition, we measured individual and household coping strategies to mitigate economic challenges through 5 indicators adapted from the Canadian Housing Survey [18].

Food Insecurity

We assessed household food insecurity through the Household Food Security Survey Module derived from the Canadian Community Health Survey [19]. Originally developed by the United States Department of Agriculture, the Household Food Security Survey Module is an 18-item standardized and validated module to be used in Canada, consisting of an adult scale (10 items) and a child scale (8 items). These 18 items capture households' experiences of food insecurity over the 12 months preceding the survey, including the quantity, quality, and affordability of food items. Two other questions were developed to assess the quality of the diet and the accessibility of healthy food during the pandemic.

Housing Precarity

Housing precarity was primarily measured by adapting 5 indicators from the Canadian Housing Survey and 8 indicators from the University of California survey of students' basic needs [18,20]. We asked respondents to select any challenges they experienced managing housing finances (rent and mortgage payments) and whether they were due to the pandemic. The survey also captured respondents' precarious housing or homelessness experiences by asking about knowing where to sleep, unsafe sleeping arrangements, and shared accommodations such as CouchSurfing or shelter stays. These indicators also included financial challenges to meet housing needs, such as the inability to pay for housing or utilities, taking on debts to pay for housing costs, or cutting back on other expenses to cover housing costs. If an affirmative response was received to any of these questions, a follow-up question was presented to find out if these challenges were partly or entirely due to financial challenges arising from the pandemic. Our survey also included 7 new questions on moving or finding new housing, reasons for moving, including eviction, and if housing challenges arose from the pandemic.

Mental Health

We measured participants' anxiety, depression, stress, and health-seeking behavior for each mental health condition. Anxiety was assessed using the Generalized Anxiety Disorder 7 diagnostic scale, and depression was assessed using the Patient Health Questionnaire 9 scale [21,22]. In addition, we adapted questions from the Mental Health Commission of Canada and the Canadian Centre of Substance Use and Addiction Leger Questionnaire to assess pandemic-driven stressors (18 questions), ability to handle stressful situations (2 questions), and overall mental health (1 question) [21]. Finally, drawing on questions from the Mental Health Commission of Canada, the Canadian Centre of Substance Use and Addiction Leger Questionnaire, and the Mental Health Research Canada's Mental Health and COVID Tracker poll, we assessed participants' health-seeking behavior through their access to and attitudes about opting for treatments or supports for mental health concerns [21,22]. Questions included whether participants sought treatment from a trained professional, the ease (or difficulty) of accessing these services and reasons for not accessing them, mental health diagnoses from a medical or psychological professional, and the time of receiving a diagnosis. We also included 2 self-drafted questions about participants' feelings about needing help with mental health and for what purpose they sought help or treatment.

Substance Use

We measured participants' substance use in 5 categories: alcohol, tobacco or nicotine, cannabis, prescription medication (opioids, sedatives [benzodiazepines and non-benzodiazepines] and barbiturates, stimulants, and cannabis), and other drug or substance use; self-rated impacts of the pandemic on use of each substance; and substance use concerns, treatments, and supports. We assessed participants' use of each substance using indicators either taken or modified from the Mental Health Commission of Canada and the Canadian Centre on Substance Use and Addiction Leger Questionnaire [21], the Canadian Alcohol and Drugs Survey [23], and the Canadian Nicotine and Tobacco Survey [24] or were self-drafted. We asked about frequency, quantity, and preferences or modes of use for each substance category, where applicable, and these indicators were primarily taken or adapted from the above instruments. We measured the self-rated impacts of the pandemic on substance use through self-drafted questions. We modified an indicator from the Mental Health Commission of Canada and the Canadian Centre on Substance Use and Addiction Leger Questionnaire to measure self-rated concern of use for each substance. If participants indicated some level of concern for one or more of the five substance categories, we asked about seeking treatment or support services from a trained professional, the ease (or

XSL•FO
RenderX

difficulty) of accessing these services, reasons for not accessing services, substance use disorder diagnoses from a medical or psychological professional, and when a diagnosis was received.

Following the closing of the survey, we checked and cleaned the data for outliers to identify if it was skewed in a certain direction. We checked variables with a significant proportion of missing values to see if there was any systematic pattern in the missing data. We conducted a multiple imputation analysis and imputed data for the following variables: location of the residence (5.4%), sex (1.6%), age (3.2%), ethnicity (2.4%), education (3.0%), employment status (1.8%), income (7.1%), and housing insecurity (13.7%).

The final data set, deidentified and cleaned, was shared with the core research team members. Preliminary analyses have been conducted to identify the impact of the pandemic on the overall study population. We presented the findings as frequencies and percentages for categorical variables with associated confidence intervals and means and standard deviations for continuous variables. In addition, we use graphs and maps to present our findings to community partners for ease of understanding key results. Next, we will perform multivariable linear and logistic regression analyses to investigate the risk factors that have intensified households' experiences of food insecurity, housing precarity and homelessness, mental health, and substance use.

Qualitative Methods

The surveys help to provide important quantitative indicators of a broader range of impacts of the pandemic on other public health services, but we also recognize the need to connect the numbers with the stories of how people have experienced this historical moment. We are collecting qualitative data to answer the following research questions: (1) what role have frontline human services agencies played in helping people deal with the challenges of the pandemic? What barriers have hindered access to services? What makes services effective? (2) What do people who access services and service providers believe the priorities for policy and practice implementation should be in the 4 interrelated study areas?

We are collecting data through open-ended interviews with two categories of respondents: (1) service providers from partner agencies (Multimedia Appendix 2) and (2) people who access services within partner agencies (Multimedia Appendix 3). For service providers, we will interview 5 service providers working in agencies in the 4 focus areas (n=20). For people who access services, we will interview 8-10 people per focus area (n=24-32). Interviews last between 30 and 60 minutes, and we provide an honorarium of CAD $25 (US $18.37) to people who access services at participating agencies to compensate for their time and contribution to the project. Service providers will not receive an honorarium as their interviews will be related to their employment at partner agencies, and thus they will be compensated for their time through their workplaces. After the initial interviews, we will consult partner organizations to expand participant recruitment in Regina, midsized urban centers, and rural regions in the province.

Interviews take place in locations that are best suited to individual participants in one of 3 options: in-person at partner or host organizations from which they were recruited; remotely over Zoom, where participants decide where is most advantageous; or remotely over Zoom at partner or host organizations from which they were recruited. Not all people who access services have access to technology for virtual interviews, and some are not comfortable doing interviews in person; thus, we work with host organizations to facilitate an ideal setting for each participant. To further ensure the safety of participants, interviewers completed Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans certification and will complete trauma-informed care training prior to recruiting people who access services.

The analysis of qualitative interview data will begin with the first interview and continue throughout the data collection period. Both inductive and deductive methods of data coding will be used. Reflection on the quantitative data and engagement with the community partners will help us identify the initial coding framework. We will use thematic analysis to identify initial codes in the first rounds of data analysis across the 4 focus areas and begin conceptualizing broad themes [25]. Subsequent iterative rounds of analysis will sharpen our coding into more specific themes. We will also be analyzing for saturation and adapting and updating codes to ensure extracted data reflect participants' contributions as interviews progress. Moreover, we will consult community partners throughout the process. For the data retrieved from people who access services, we will extract common themes across the 4 focus areas as well as stratified thematic analysis for themes specific to equity-seeking groups and other characteristics as the research team identifies emerging themes. For service providers, we will extract themes across the 4 focus areas as well as a broader thematic analysis illuminating common experiences faced by those working in human services during the pandemic.

We use both quantitative and qualitative data to gain a broad understanding of the impact of the COVID-19 pandemic on people's lives and well-being in Saskatchewan. The quantitative data help us identify specific groups of people and areas of concern that are generalizable to the province and comparable with national data sources, and the qualitative data helps to provide a more granular level of detail about impacts on individuals. The qualitative approach allows us to emphasize the intersectionality of the pandemic and other public health needs that are not necessarily readily parsed into categories when it comes to how they were experienced in real time. By allowing participants to describe their encounters in their own words, we seek to enrich our understanding of qualities that include elements of pacing or timing of decisions, to better understand how providers and clients made decisions that prioritized health and economic needs in real time, and how they reflect on the impact of the pandemic and government policies on meeting their basic needs. In combining quantitative and qualitative approaches, we enhance our understanding of the wider impacts of the pandemic, generating a wide range of evidence that is crucial for policymaking in postpandemic recovery.

Project: Saskatchewan's COVID-19 Public Archive

Historians on the team are collecting and analyzing a large archive of academic, oral history, and social and digital media sources to develop a unique digital community archive. The project began as a response to the concern that COVID-19 risked being another forgotten pandemic because of the ephemeral nature of web-based primary sources. We have expanded the project to incorporate new digital methods to increase the capacity to collect digital materials and lay the foundation for writing a social history of the COVID-19 pandemic in Saskatchewan [26]. We began in March 2020 by setting up an Archive-It repository to automatically record a web archive of government, organizations, and media reports related to the COVID-19 pandemic in Saskatchewan. We took inspiration from other jurisdictions engaged in COVID-19 archiving and drew from examples of archives established to capture "disaster responses" that include public memorialization to remember events like Hurricane Katrina in the United States and the 9-11 attacks [27]. Remembering—including analyzing and learning from—COVID-19 requires new theoretical and methodological approaches that capture and preserve the experience for future generations.

We began collecting oral histories in 2020, interviewing local business owners, reporters, and a prominent retired doctor. The new funding and formal partnerships with community organizations allowed us to expand the interviews in the summer of 2022 as we collected perspectives from vaccine scientists, intensive care unit doctors and nurses, frontline workers, employees at a safe consumption site and food banks, justice-involved individuals, and other marginalized racial and ethnic groups of residents. Interviews are conducted using an open-ended interview guide. We plan to expand the scope of these interviews, both by supporting the qualitative research interviews led by the Build Back Better team with at-risk populations and by continuing to seek out oral history interviews with as wide a range of people as possible with unique experiences during the pandemic.

Exploring the Archive-It collection in partnership with the Archives Unleashed project [28], we quickly recognized that we had captured the important institutional experiences via their websites in the province but missed a lot of the social media discussion. We are working to archive large sections of Twitter and Facebook to preserve this public debate. Twitter's application programming interface provides free access to academics, allowing us to record millions of tweets related to the pandemic starting in 2020. We collected every post made by the premier of Saskatchewan during the pandemic, along with all the replies to his tweets, the conversations using the #COVID19SK hashtag, and conversations involving numerous other COVID-19 influencers in the province. Facebook does not provide an application programming interface and actively blocks web crawling software. As a result, it requires manual scrolling of content on the platform. We, therefore, restricted our archiving efforts to focus on the public Facebook page and public posts from a small number of influential accounts commenting on the public health measures. One of these accounts has since been removed from the platform, reminding us again of the ephemeral nature of this material.

Finally, while the Archive-It collection holds thousands of web pages from news outlets, they are not cataloged and are difficult to navigate. To create a more user-friendly repository, we are using citation database software Zotero (Corporation for Digital Scholarship, George Mason University) to catalog stories on the pandemic in Saskatchewan. The collection includes 3200 stories and hundreds of documents generated by community-based organizations responding to community needs during the pandemic. Research assistants work on assigned topics, including homelessness, substance use, nursing, or the start of the COVID-19 pandemic in Saskatchewan. Our research assistants clean the metadata and add keyword tags, including the people mentioned in the news stories, the places discussed, and the main topics and periods of the pandemic, such as "Fourth Wave." The tag categories are carefully managed and edited to avoid using synonyms or the proliferation of tags to the point they become useless. The Zotero database, which includes the HTML code from the original stories, provides another means to preserve web-based content and creates opportunities for text-mining approaches that will help us navigate the much larger Archive-It collection.

Ethics Approval

This study is approved by the Research Ethics Board at the University of Saskatchewan (Beh-1945) and is being conducted in accordance with the guidelines and stipulations of the Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans [29]. Changes to the protocol will be submitted for approval through amendment requests to the Research Ethics Board. Participation in either project is completely voluntary.

Results

The "Build Back Better" and "Saskatchewan's COVID-19 Public Archive" projects received federal funding in March and April 2022, respectively. Survey data were collected between July and November 2022 and are being analyzed with results expected to be published in the fall of 2023. Qualitative interview data were collected between March and June 2023, and 19 interviews have been completed. Qualitative data are being analyzed, with results expected to be published in winter 2024. Initial oral histories and archival data collection began in June 2022 and will conclude in the summer of 2023. Thirty oral histories have been completed. The archive will be continuously updated. On the 3-year anniversary of the first COVID-19 case in the province, we released a new feature on the website: a digital memorial to the lives lost to COVID-19 called "Remember Lives Not Numbers." After reviewing publicly accessible obituaries and media stories about COVID-19 deaths in the province, we created a web-based memorial featuring over 100 entries that honor the lives lost in the province due to COVID-19. This digital memorial includes a public portal, which allows for continued submissions to the site to help expand the reach of this memorial to the hundreds of cases that were not covered in the news media or explicitly mentioned in published obituaries.

Discussion

The global COVID-19 pandemic has been a significant crisis that catalyzed both immediate and long-term changes, prompting collective responses across and within nations, the effects of which are still unfolding (in May 2023). The Remember Rebuild Saskatchewan project has a wide impetus to illuminate what we have learned—both what went wrong and what worked well in our collective responses—and to preserve this legacy for future health crises and events. Our innovative and collaborative program of research harnesses community-engaged research and showcases the strengths of different health, social sciences, and humanities disciplines, and we will produce relevant and accessible quantitative and qualitative findings.

Within "Build Back Better," we expect findings from our general population survey to illuminate disparities in outcomes in the 4 focus areas (food insecurity, housing precarity, mental health, and substance use) in Saskatchewan, where groups such as youth, newcomers, Indigenous peoples, 2SLGBTQ+ individuals, people with low income, or people living with disabilities experience higher rates of negative outcomes. In addition, we expect to elucidate the dual experiences of outcomes during the COVID-19 pandemic—namely, poor mental health and problematic substance use, housing precarity, and food insecurity—which are often experienced together, adding complexity and vulnerability to people's lives.

Our survey design limits our understanding of the depth and intensity of the disruption and negative effects caused by the pandemic, though it captures well the prevalence, scope, and factors associated with these negative effects. We expect our qualitative interview analysis to reveal the depth and intensity of the disruption and negative effects. First, service-providing organizations in Saskatchewan were greatly impacted by the pandemic through modified service provision in accordance with public health guidelines and increased service demand and usage in each of the 4 focus areas. Additionally, we expect interview analysis to reveal that people accessing services in Saskatchewan faced increased barriers to accessing services, such as less access due to shutdowns and public health restrictions, which exacerbated negative health outcomes across the 4 focus areas.

Our COVID-19 public archive is a legacy product and will host the findings from all aspects of our research and outreach, as well as maintain a voluntary submission feature. The Remember Rebuild Saskatchewan findings exist in a freely accessible web-based repository, available on the project website [30]. Creating a public archive enables us to recognize the diversity of the pandemic experience and provides the foundation for future research on the changes we need to implement to build resilience as we prepare for a future with more public health crises. Findings will be available in various formats, such as academic knowledge translation outputs from Build Back Better, the oral his or her or their-stories of various Saskatchewan residents, social and digital news media stories, and audiovisual and creative contributions such as artwork or music. The archive, inclusive of the different components of each project, will be promoted widely to the public at a community event through collaboration with the Saskatoon Public Library in early 2024 and interviews with digital and social media journalists. These events help raise awareness of the projects in addition to facilitating contributions to the archive as the collection continues. We have prepared media releases and policy briefs to further engage the public, media, and policy makers.

We will compile project findings into various academic outputs, including journal articles, research posters, technical reports, conference presentations, and infographics, which will also be stored in the archive. We will additionally host academic contributions from other pandemic-related projects from the Remember Rebuild Saskatchewan team and other research contributions on the province's COVID-19 experience beyond those from the team. In this way, the archive will also act as a research hub for the pandemic in Saskatchewan, offering a repository for data and evidence documenting the multifaceted impacts of the pandemic in Saskatchewan.

Acknowledgments

The members of the Remember Rebuild Saskatchewan Team include, alphabetically: Daniel Adeyinka, Gord Androsoff, Chelsea Brown, Sarah Buhler, Kayla DeMong, Rachel Engler-Stringer, Isobel Findlay, Barb Fornssler, Debra Haubrich, Bonnie Jeffery, Sandra Kary, Jane Macleod, Erin Mathews, Jessica McCutcheon, Tom McIntosh, Mansfield Mela, Jason Mercredi, Nuelle Novik, Gabriela Novotna, Laurie O'Connor, Yolanda Palmer-Clarke, Akela Peoples, Ian Roach, Lenore Swystun, and Len Usiskin.

We acknowledge all those who have already participated in the Remember Rebuild Saskatchewan research (as of May 2023). We also thank our colleagues working in the community who engaged with us with advice and assistance. This project is supported by the Canadian Institutes of Health Research (operating grant 478277) under the competition titled "Addressing the Wider Impacts of COVID-19 on Social, Economic, and Public Health Outcomes and the Social Sciences and Humanities Research Council of Canada Partnership Development" (grant 356339).

Data Availability

Data and stories collected in this work are archived for preservation and freely accessible on the Remember Rebuild Saskatchewan website [30].

Authors' Contributions

NM, ED, and JC conceived, designed, and drafted the research protocols and acquired funding. JD drafted the protocol manuscript. PC, SDG, and members of the Remember Rebuild Saskatchewan Team DA, SB, RE-S, IF, BF, BJ, EM, J McCutcheon, TM, MM, NN, GN, and YP-C critically reviewed the protocols and manuscript for methodological and academic content. CC-C and Remember Rebuild Saskatchewan Team members GA, KD, SK, J Macleod, LO, LU (community partners), CB, J McCutcheon, AP, DH, IR, and LS (knowledge users) contributed content expertise and community knowledge. PC, JD, SDG, and Remember Rebuild Saskatchewan Team member EM will implement the research under the supervision of NM, ED, and JC.

Abstract

Background: In Aotearoa New Zealand, 90% of patients with notified leptospirosis (a zoonotic bacterial disease) have been men working in agricultural industries. However, since 2008, the epidemiology of notified cases has been gradually changing, that is, more women are affected; there are more cases associated with occupations traditionally not considered high risk in New Zealand; infecting serovars have changed; and many patients experience symptoms long after infection. We hypothesized that there is a shift in leptospirosis transmission patterns with substantial burden on affected patients and their families.

Objective: In this paper, we aimed to describe the protocols used to conduct a nationwide case-control study to update leptospirosis risk factors and follow-up studies to assess the burden and sources of leptospirosis in New Zealand.

Methods: This study used a mixed methods approach, comprising a case-control study and 4 substudies that involved cases only. Cases were recruited nationwide, and controls were frequency matched by sex and rurality. All participants were administered a case-control questionnaire (study 1), with cases being interviewed again at least 6 months after the initial survey (study 2). A subset of cases from two high-risk populations, that is, farmers and abattoir workers, were further engaged in a semistructured interview (study 3). Some cases with regular animal exposure had their in-contact animals (livestock for blood and urine and wildlife for kidney) and environment (soil, mud, and water) sampled (study 4). Patients from selected health clinics suspected of leptospirosis also had blood and urine samples collected (study 5). In studies 4 and 5, blood samples were tested using the microscopic agglutination test to test for antibody titers against *Leptospira* serovars Hardjo type bovis, Ballum, Tarassovi, Pomona,

XSL•FO
RenderX

and Copenhageni. Blood, urine, and environmental samples were also tested for pathogenic *Leptospira* DNA using polymerase chain reaction.

Results: Participants were recruited between July 22, 2019, and January 31, 2022, and data collection for the study has concluded. In total, 95 cases (July 25, 2019, to April 13, 2022) and 300 controls (October 19, 2019, to January 26, 2022) were interviewed for the case-control study; 91 cases participated in the follow-up interviews (July 9, 2020, to October 25, 2022); 13 cases participated in the semistructured interviews (January 26, 2021, to January 19, 2022); and 4 cases had their in-contact animals and environments sampled (October 28, 2020, and July 29, 2021). Data analysis for study 3 has concluded and 2 manuscripts have been drafted for review. Results of the other studies are being analyzed and the specific results of each study will be published as individual manuscripts..

Conclusions: The methods used in this study may provide a basis for future epidemiological studies of infectious diseases.

Introduction

Background

Leptospirosis is a neglected zoonotic disease that causes severe febrile illness, renal and hepatic failure, and death [1]. Globally, 1.03 million cases and 58,900 deaths occur annually [2], with a loss of 2.90 million disability-adjusted life years [3]. However, the burden is underestimated [4]. Adding to the disease burden, approximately 30% of patients have symptoms that persist for several years [5,6].

The disease is caused by bacteria of the genus *Leptospira*, which includes >71 species [7] and >300 serovars worldwide [8]. Pathogenic species of *Leptospira* colonize the kidneys of mammals, as well as birds, amphibians, and reptiles [9], and this leads to intermittent urinary shedding. High-risk populations vary spatially and temporally and include those in contact with infected animals (livestock or wildlife) or contaminated environments (water, mud, or soil) [4].

In Aotearoa New Zealand, leptospirosis is a notifiable disease, and its incidence peaked in 1971 with dairy farmers, abattoir workers, and pig farmers identified as a high-risk population [10]. At that time, cattle were the recognized maintenance hosts for serovar Hardjo type bovis and pigs for serovars Pomona and Tarassovi [10,11]. In the early 1980s, cattle vaccines against serovars Hardjo type bovis and Pomona and pig vaccines against serovars Pomona and Tarassovi were developed, and vaccination programs were implemented. Guidelines on the operation of dairy farms were developed, including minimum approved distances between livestock, pigs, and poultry [12]. Awareness campaigns resulted in the increased use of personal protective equipment (PPE) among agricultural workers. Although the guidelines, vaccinations, and PPE appeared to substantially reduce the disease risk in humans [13,14], these preventative measures are only partially effective. Leptospirosis animal vaccines offer strain-specific protection; however, current vaccines do not cover all strains, and noncommercial farmers are often not aware of industry guidelines. In addition, the use of protective equipment does not necessarily prevent infection [15].

Analysis of notification data from 1999 to 2017 showed a decline in leptospirosis cases attributed to serovars Hardjo type bovis and Pomona but an increase in cases attributed to serovars Ballum and Tarassovi [16]. From 1999 to 2017, leptospirosis notifications in abattoir workers were almost exclusively attributed to serovars Hardjo type bovis and Pomona, whereas leptospirosis notifications in dairy farmers were predominantly attributed to serovars Hardjo type bovis and Tarassovi. Occupationally acquired leptospirosis in New Zealand is covered by the Accident Compensation Act 2001. The Accident Compensation Corporation is the Crown entity responsible for enactment of the provisions set out under this Act and manages personal injury including economic, social, and personal costs [17]. However, workplace compensation for leptospirosis cases is challenging for some claimants because of reliance on serological testing and the limited range of automatically eligible occupations [18].

Notification data from 1999 to 2017 also showed that serovar Ballum cases were largely associated with occupations that were not agriculturally based [19]. Our pilot work suggests that wildlife sources [20] and environmental pathways [21] may be increasingly important in disease transmission. A longitudinal survey of wildlife on a coastal dairy farm and bordering forest conducted in autumn and spring for 2 years (from spring 2016 to autumn 2018) determined that the overall prevalence of serovar Ballum in mice, rats, and hedgehogs was 46% (95% CI 39%-52%); 44% (95% CI 26%-62%); and 27% (95% CI 11%-50%), respectively [22]. Metabarcoding of 24 enriched environmental cultures from water, soil, and mud samples taken from the same study site identified pathogenic *Leptospira* in all cultures [21].

Objectives

On the basis of the changes in serovar predominance in the at-risk occupations, as well as an increase in cases with occupations that are not agriculturally based, we hypothesize a change in the epidemiology of leptospirosis in New Zealand. This identified the need to update risk factors and sources of infection, the protocol of which is outlined in this manuscript. The overall aim of this research is to improve the evidence base

XSL•FO
RenderX

to inform effective policies and practices to lower the incidence, health impact, and burden of leptospirosis in New Zealand. The specific aims are as follows:

1. Assess risk factors for leptospirosis in New Zealand, with a focus on activities associated with livestock, wildlife, and pets, as well as environmental and recreational exposure.
2. Assess the effect of preventative measures such as the use of PPE, animal vaccinations, and hygiene practices during high-risk activities.
3. Describe the burden of the disease including the duration, frequency, and severity of symptoms, costs incurred, and support needed by patients.
4. Explore the barriers associated with workplace compensation for occupationally acquired leptospirosis.
5. Assess the potential sources of infection from in-contact animals and environments.
6. Identify the strains of Leptospira causing disease in New Zealand.
7. Establish a cohort of patients for a long-term follow-up study.

Methods

Study Design

This manuscript describes the design and methods of the study titled, "Emerging sources and pathways for leptospirosis—a paradigm shift," an investigator-initiated project that was peer reviewed and funded by the Health Research Council of New Zealand (Multimedia Appendices 1-4).

The key study design is a nationwide frequency-matched case-control study with 4 substudies involving cases only. Studies comprise questionnaire-based investigations (studies 1 and 2), semistructured interviews with a few open questions (study 3), and laboratory-based investigations with testing in our research laboratory (studies 4 and 5):

- Study 1: Case-control survey for all participants (aim 1)
- Study 2: Follow-up survey of all cases (aims 2-4)
- Study 3: Semistructured interviews with a subset of cases who worked in agricultural industries at the time of diagnosis (aims 2-4)
- Study 4: Serological investigations of blood and molecular investigations of blood, urine and kidney samples from in-contact animals and environments of a subset of cases who had regular animal and environmental exposure at the time of diagnosis (aim 5)
- Study 5: Serological and molecular investigations of blood and urine samples from a subset of patients suspected of leptospirosis (aim 6)

Study Location and Period

This is a nationwide study in which the participant recruitment was expected to last for 18 months with the aim of recruiting 150 notified cases starting from July 22, 2019. However, the recruitment period was extended until January 31, 2022, as the New Zealand government–imposed restrictions to manage the COVID-19 pandemic [23] slowed the recruitment process. The extension of the recruitment period allowed an adequate number of cases to be recruited to have sufficient statistical power.

Cases

Case Definition

The case definition for those recruited between July 22, 2019, and October 14, 2020, was the Ministry of Health definition for a confirmed or probable case, that is, a clinically compatible illness with laboratory evidence from a diagnostic laboratory [24].

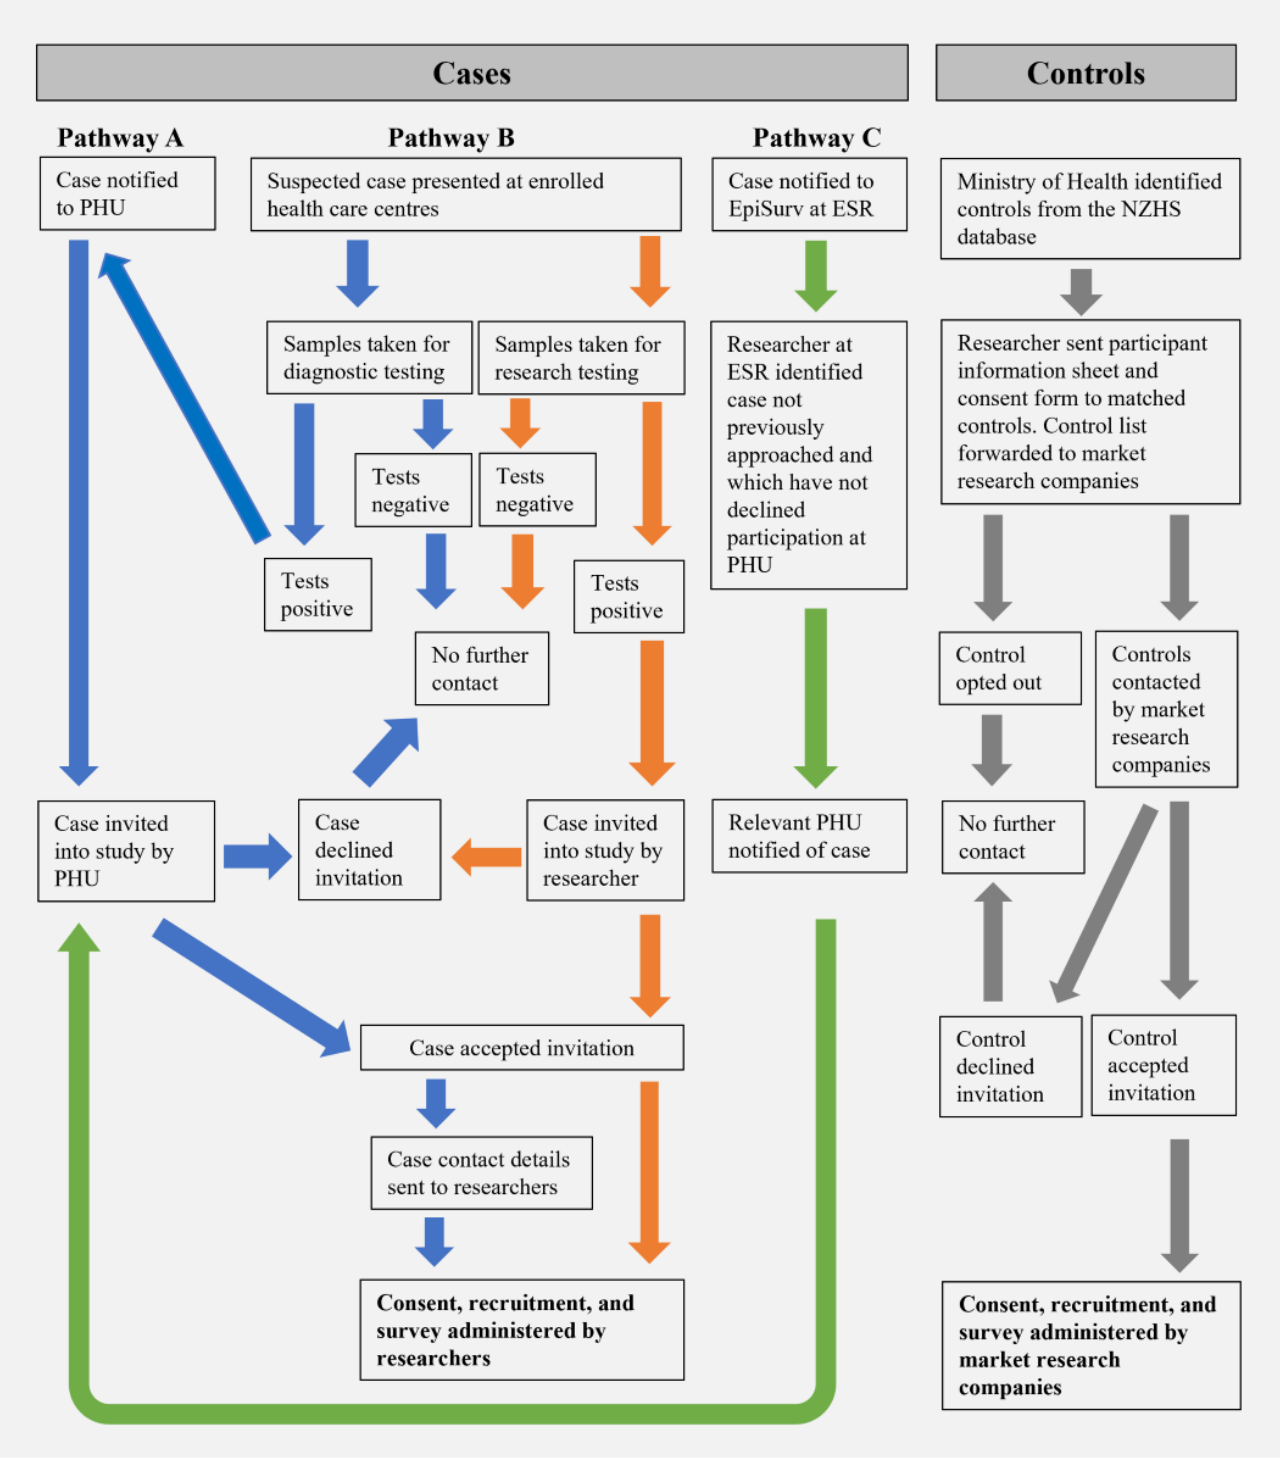
The case definition given in Textbox 1 was subsequently modified for 2 reasons that became apparent during the conduct of study 5. First, the microscopic agglutination test (MAT) requires 2 blood samples, an acute and a convalescent sample, 2 to 3 weeks apart [25], and 77% (10/13) of the patients did not return to provide the convalescent sample, despite consent to enrollment in the study. Most serological samples are prescreened with an immunoglobulin M (IgM) test and forwarded for MAT only if IgM is positive. Given the case number attrition associated with paired blood samples, case definitions were modified to include those that were IgM positive or equivocal at diagnostic laboratories. This occurred from October 15, 2020, until study completion. Second, 9 of the 10 patients suspected of leptospirosis that did not return to provide the second serology sample, tested positive by the polymerase chain reaction (PCR) analysis performed in the research laboratory. Thus, from January 28, 2021, until study completion, the case definition was further broadened to include cases who tested positive for the tests listed in Textbox 1, and the tests were performed at the research laboratory at Massey University.

Textbox 1. Laboratory evidence for confirmed or probable case as per the Ministry of Health definition.

Confirmed case

- Isolation of leptospires from a clinical specimen
- Detection of leptospiral DNA from a clinical specimen using the polymerase chain reaction
- Detection of a ≥4-fold rise in serology titers between acute and convalescent sera using the microscopic agglutination test (MAT)
- Detection of a single raised titer of ≥400 using MAT

Probable case



- Detection of a single raised titer of <400 using MAT

XSL•FO
RenderX

Case Selection

Cases were identified via 3 pathways (A, B, and C) to ensure that all notified cases were given an opportunity to participate in the study (Figure 1).

Figure 1. Study flow diagram of participant selection and recruitment for a case-control study on risk factors for leptospirosis in New Zealand. ESR: Environmental Science and Research; NZHS: New Zealand Health Survey; PHU: Public Health Unit.

1. Notified leptospirosis cases were identified by 12 Public Health Units that represented 20 District Health Boards in New Zealand. Public health officers called all leptospirosis cases to capture demographic and epidemiological data as part of their routine surveillance program for notifiable diseases. This call usually occurred 2 to 4 weeks from when cases first became ill, but the exact time was dependent on the diagnostic tests requested by the attending clinician [26]. Cases who were diagnosed by MAT were called nearer to 4 weeks or later after first becoming ill, because MAT requires 2 samples 2 to 3 weeks apart. At the end of their routine surveillance calls, public health officers informed cases of the study and asked for consent to share contact details with the research team. Cases who did not wish to participate were noted to ensure that they were not contacted again about the study via pathway C.

XSL•FO
RenderX

2. Patients suspected of leptospirosis were identified by clinicians at selected North Island health care facilities. Health care facilities were sampled for convenience based on prior links that had been established between researchers and facility staff and because they were based in regions with a high incidence of leptospirosis, that is, Northland, Waikato, and Hawke's Bay [16]. To increase recruitment of Māori cases (New Zealand's Indigenous population), from January 20, 2021, until the end of the study, an additional health care facility in Hawke's Bay where 76% of service users are Māori was included. Clinicians informed the patients of the study at the time of suspicion of leptospirosis and sought consent to share the patients' contact details and samples with the research team (Multimedia Appendix 5). A scanned copy of the written consent form was kept with patient notes at the clinic, and the original written consent form was sent to the researchers with the patient's samples. In addition to the research samples, samples from these patients were sent to the diagnostic laboratories for standard testing.
3. Recruitment of notified cases from pathway A and suspected cases from pathway B was complemented by monthly check-ins with EpiSurv [27], the notifiable disease surveillance database managed by the Institute of Environmental Science and Research on behalf of the Ministry of Health. These check-ins identified notified cases from pathway A who had not already declined to participate and who were not already enrolled and suspected patients from pathway B who met the case definition after diagnostic testing. The local Public Health Units were informed of these cases and requested to contact them to invite them to participate in the study.

Case Consent and Recruitment

All consenting cases from pathways A, B, and C who met the case definition were sent a participant information sheet and consent form (Multimedia Appendix 6) via either post or email. The researchers called the cases over telephone at least 1 week after sending the information sheet to go through it. Once the researchers had answered cases' queries, they requested and documented verbal consent from them for the following parameters:

- Participation in a
  - case-control survey
  - follow-up survey 6 months after the case-control survey
  - semistructured interview if cases worked in an agricultural industry
- Access to cases'
  - physician's notes associated with leptospirosis
  - leptospirosis diagnostic test results
  - diagnostic DNA samples
- Sampling cases' in-contact animals and environments if cases had regular animal exposure that was not at an abattoir
- Keeping cases' contact details to invite them for the long-term follow-up study

Case Exclusion Criteria

All participants who were aged <16 years were excluded from the study.

Controls

Control Definition

Frequency matching of controls was considered a suitable approach to reasonably ensure that cases and controls were drawn from the same source population. The frequency was based on the distribution of sex and rurality of leptospirosis notifications from January 1, 2014, to December 31, 2018 [27]. During this time, 89.2% (403/452) of cases were males and 63.6% (204/321) lived rurally. However, only 16.29% (766,060/4,699,755) of the New Zealand population lives rurally [28]. Thus, controls were frequency matched as 90% male and 65% rural dwelling, and a 2:1 ratio of controls to cases was planned. Rurality was determined by home address according to the most recent urban or rural classification method by Stats New Zealand [29].

Control Selection

The control population was selected from a database of 18,954 New Zealand Health Survey (NZHS) [26] participants who agreed to be approached for future surveys (Figure 1). This database from the 2016-2017 and 2017-2018 survey periods was provided by the Ministry of Health [30]. The NZHS participants included the usually resident population, that is, they had lived in New Zealand for at least 1 year, with a residence visa or citizenship. Exceptions included the prison population, those who live on small New Zealand islands, and people who have been away from their households for >4 weeks during the NZHS recruitment period.

Control Consent and Recruitment

An invitation letter endorsed by the Ministry of Health and Massey University, together with the participant information sheet and consent form (Multimedia Appendix 7), was posted by the researchers to 1715 NZHS participants that matched our sex and rurality criteria. There was an option to opt out by contacting the research team if they desired. A total of 1613 people who received the invitation for the study and did not opt out of the study had their details sent to the market research companies, Up Market Research and Infield International, who conducted the control surveys.

The market research companies contacted potential controls 6 times during the study period via telephone, verified control eligibility, and obtained verbal consent for participation in the study. Controls were only invited to participate in a telephone survey for the case-control survey (study 1).

Control Exclusion Criteria

The NZHS participants who were aged <16 years and who had an influenza-like illness in the 4 weeks before the control survey were excluded.

XSL•FO
RenderX

Substudy Populations

Study 2: Selection of Cases for the 6-Month Follow-up Survey

All cases were invited to complete a follow-up questionnaire at the time of the case-control survey. The follow-up survey of cases was planned to occur at least 6 months after the case-control survey.

Study 3: Selection of Cases for the Semistructured Interview

Occupational data were collected from all cases who participated in the case-control survey. Participants identified as working in agricultural industries (specifically abattoir workers and farmers) and who were recruited as cases between July 22, 2019, and July 23, 2021, were selected for semistructured interviews. Māori participants were prioritized because they are proportionally overrepresented in the group of people affected by leptospirosis [16].

Study 4: Selection of Cases for In-contact Animal and Environmental Sampling

Animal and environmental exposure data were collected from all cases as part of the case-control survey. Participants identified as having regular non–abattoir-associated animal contact were invited to have their in-contact animals (livestock, pets, and wildlife) and environments sampled.

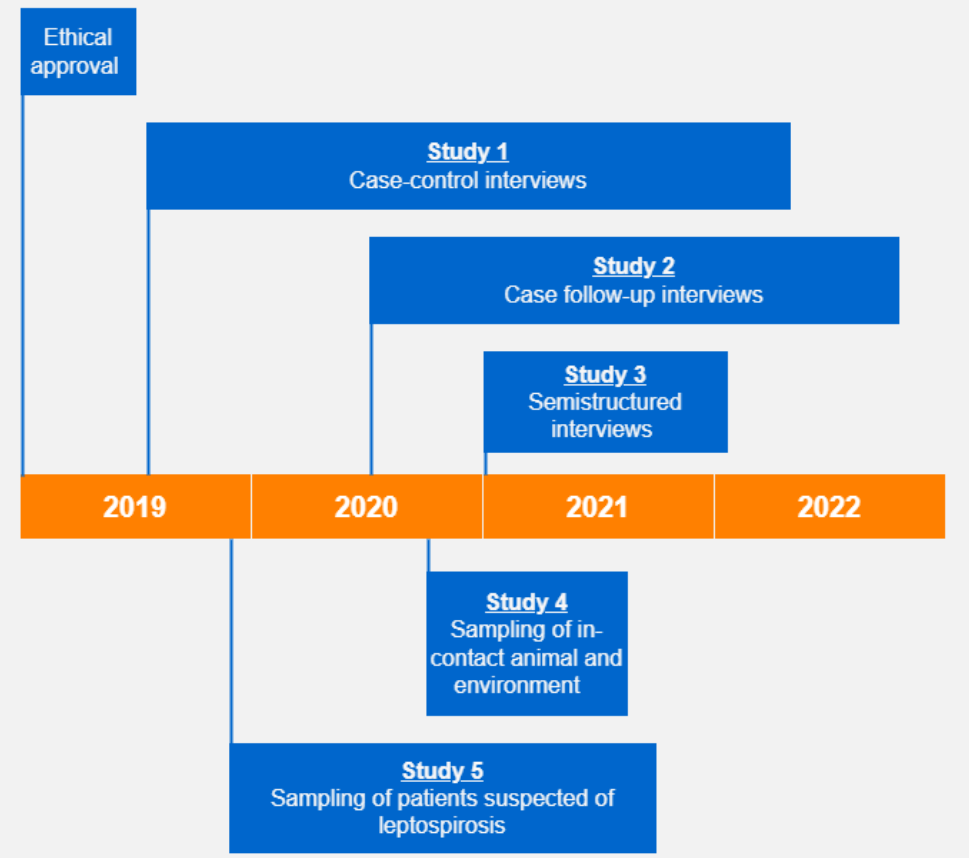
Study 5: Selection of Patients for Sampling

Biological specimens from patients for research testing at Massey University were acquired in two ways.

1. All patients suspected of leptospirosis who were recruited at selected health care facilities (study 5 or pathway B detailed in case selection) provided blood and urine samples to be tested at both diagnostic laboratories and the research laboratory.
2. All cases who met the case definition and agreed to participate in the case-control study provided consent for the researchers to access their diagnostic samples through the diagnostic laboratories. Only DNA extracted from blood, urine, cerebrospinal fluid, and plasma to test for leptospirosis with PCR testing was requested from the diagnostic laboratories.

Data Sources, Collection, and Storage

Overview



Data for this study were sourced from:

- Quantitative telephone interviews using questionnaires (case-control and follow-up)
- Selective transcripts of semistructured interview approved by interviewees
- Physician’s notes
- Biological specimens collected from patients, patients’ in-contact animals, and patients’ in-contact environments. Specimens were processed and tested in the research or diagnostic laboratory.

All data were sourced between July 25, 2019, and October 25, 2022 (Figure 2). Study-specific source documents containing identifiable data were maintained either with a restricted access or in a password-protected network shared drive hosted by Massey University. Information pertaining to the identity of the cases was censored from databases and biological samples and was replaced using unique participant codes. Biological samples were stored frozen at −80 °C.

XSL•FO
RenderX

Figure 2. Study timeline of the 5 studies described in this protocol. Cases in study 1 were asked if they were interested in participating in studies 2 to 4 if they met the study selection criteria. Cases took part in study 2 at least 6 months after partaking in study 1. Cases took part in study 3 after they finished study 1 and study 2 interviews. Study 4 was conducted after study 1 at the earliest convenience. Study 5 participants were enrolled from health care facilities upon presentation.

Study 1: Case-Control Questionnaire

Eligible cases and matched controls answered a case-control questionnaire delivered over the telephone (Multimedia Appendices 8 and 9). The case-control questionnaire was developed to obtain data on exposures. Care was taken during questionnaire content development, via the review of other studies and questionnaire contents, to ensure that appropriate variables and exposures were incorporated. The questionnaire included the following:

- Leptospirosis case report forms used by the Institute of Environmental Science and Research [27] and the Waikato District Health Board [31]
- Questionnaires used in the study of leptospirosis exposure and risk factors in farmers [32], abattoir workers [33], veterinarians [34], veterinary students [35], and livestock [36] in New Zealand
- Questionnaires used for leptospirosis research in Sri Lanka [37], Nepal [38], and Tanzania [39]
- Case-control questionnaires used for other diseases in New Zealand, including campylobacteriosis [40], acute rheumatic fever [41], Legionnaires' disease [42], and Shiga toxin–producing *Escherichia coli* [43]

The case questionnaire also contained additional items including clinical course and outcome, sick leave, and sick leave entitlements as well as emotional well-being questions that were followed up in the substudy surveys. The researchers received training on the delivery of sensitive questions such as the Kessler Psychological Distress Scale (K10) [44] and risk assessment and management skills for interviewing sensitive people.

The case questionnaire was pilot tested by the researchers in 3 cases (patients who had leptospirosis before this study commenced). After piloting, changes were made to the survey questions to remove ambiguities.

Case interviews were conducted by the research team from July 25, 2019, to April 13, 2022, at a time that suited the participants and as soon as convenient after the initial contact. All cases were asked about their exposures in the month before they became ill. Data were collected using the electronic version of the questionnaire and transferred to the database, and 10% of the surveys were checked for data integrity.

All control interviews were conducted by the market research companies: UMR Market Research between October 19, 2019, and February 28, 2021, and Infield International between May 1, 2021, and January 26, 2022. The control questionnaire was pilot tested by the UMR Market Research on 12 controls (participants of the NZHS). The control surveys were conducted in 6 batches, with 50 controls interviewed in each batch. Batched control interviews were conducted in October and November 2019; January and February 2020; January and February 2021; May 2021; August 2021; and January 2022. The lack of control interviews between March 1, 2020, and December 31, 2020, was due to a delay in research during the COVID-19 pandemic.

XSL•FO
RenderX

All controls were asked about their exposures in the month preceding the interviews. Data from the market research companies were received in emails with password-protected Microsoft Excel spreadsheets and transferred to the database, and 10% of the surveys were checked for data integrity.

Study 2: Follow-up Questionnaire

The follow-up questionnaire (Multimedia Appendix 10) was designed to expand on some of the questions from the case-only items in the case questionnaire and to introduce some new items. Follow-up interviews were conducted between July 9, 2020, and October 25, 2022. All symptoms identified in the case questionnaire were further quantified with symptom duration, frequency, and severity scores of 1 to 5, where 1 was mild and 5 was severe. Participants were also asked if they had any new symptoms that they attributed to leptospirosis since their previous interviews. Other questions included following up on current occupation, updates on sick leave, sick leave entitlements, and a repeat of the K10 questions. New items included the costs associated with leptospirosis treatment and support from the workplace, family, and friends during the illness. The follow-up interviews were administered to the cases at least 6 months after the case-control interview and by the same research team. The follow-up questionnaire was pilot tested by the researchers on 4 people who had leptospirosis before this study commenced. Data were collected using the electronic version of the questionnaire and transferred to the database, and 10% of the surveys were checked for data integrity.

Study 3: Semistructured Questionnaire

The semistructured questionnaire (Multimedia Appendix 11) was designed to collect patient experience data to inform the work of 3 groups of professionals: medical professionals (doctors and nurses); public health policy makers (Ministry of Health and Accident Compensation Corporation); and stakeholders in agricultural industries (managers, workers, industry boards, and workers' unions). Semistructured interviews were conducted between January 26, 2021, and January 19, 2022. Cases were asked to share their experiences of the disease; the financial implications; and their advice to workmates, employers, and their community. The semistructured interviews were conducted by the research team that received specific training for this interview. The semistructured questionnaire was pilot tested by the researchers on other researchers in the team who role-played as patients. This helped the researchers to upskill their rapport-building and prompting skills.

Face-to-face interviews were carried out before the COVID-19 pandemic–related movement restrictions were implemented, after which distance interviews using telephone or video calling were used. Data were recorded using Dictaphone for in-person interviews or Zoom (Zoom Video Communications) for distance interviews. Selective transcripts were made from the recordings and sent to the respective interviewees for review and editing with a request to return the transcript within 2 weeks.

Study 4: In-contact Animal and Environmental Sampling

Farm Animal Samples

All farm animal samplings were conducted between October 28, 2020, and July 29, 2021. All live animals were sampled for blood and urine by either the case's veterinarian or a veterinarian serving the area the farm was in. When animals were culled as part of normal farming practices (eg, prime cattle), kidney samples were also collected from the abattoir. On the basis of our earlier studies on leptospirosis in animals, up to 40 livestock of each relevant species were sampled; this allowed the detection of *Leptospira* infection or exposure for a prevalence as low as 15% for any herd or flock size with an error of 5% [45,46] and the isolation of leptospires, assuming a shedding prevalence of 35% and a success rate for isolation of 20% [47].

- Cattle were sampled while restrained in a race or milking shed. Cattle serum was collected from the jugular vein or tail vein with a 20 g needle with a volume not exceeding 10 mL. Urine from cattle was either an opportunistic free catch or collected by perivulval stimulation.
- Sheep were sampled while restrained by hand in a race or a yard. Sheep serum was collected from the jugular vein with a 20 g needle, with the volume not exceeding 10 mL. Urine from sheep was opportunistic free-catch urine or collected by a partial smothering technique. The partial smothering time was restricted to 15 seconds.
- Dogs were sampled while they were restrained by hand. Dog serum was taken from the cephalic or jugular vein with 23 to 22 g needles with the volume not exceeding 5 mL. Urine collection in dogs was by free catch, with an option for the veterinarian to use diuretics.

The samples were sent chilled to the laboratory at Massey University. Approximately 100 µL of urine was cultured in Ellinghausen-McCullough-Johnson-Harris (EMJH) medium, and cultures were kept at 28 °C with shaking and monitored for 13 weeks [48] before being discarded. The rest of the urine was centrifuged at 3000g for 20 minutes, with the supernatant removed [45], and the pellet stored at −80 °C and batch tested. All kidney samples were homogenized in an equal weight/volume of phosphate-buffered saline (PBS); the slurry was then centrifuged at 3000g for 20 minutes, and most of the supernatant was removed, leaving behind 1 mL of liquid [47], which was stored at −80 °C and batch tested. All serum samples were centrifuged at 3000g for 20 minutes, and the supernatant was stored at −80 °C and batch tested [49].

Wildlife Samples

Attempts were made to capture wildlife from farms that provided farm animal samples if the farmers were able to support this work. Wildlife was captured in kill traps, and necropsies were performed by the farmers who were provided with instructions by the researchers. Both kidneys were collected, bagged separately, and frozen upon collection by the farmer. The kidneys were then sent to the research laboratory at Massey University in 1 batch. Kidneys were thawed upon receipt and homogenized in equal weight/volume of PBS; the slurry was centrifuged at 3000 g for 20 min, and most of the supernatant

XSL•FO
RenderX

was removed, leaving behind 1 mL of liquid that was stored at −80 °C and batch tested.

Environmental Samples

Attempts were made to obtain environmental samples from the farms that provided farm animal samples. Where possible, 10 sites (eg, farm dam, muddy paddock) that the participants identified as having contact with during the month before they became ill were sampled. Participants were sent materials and methods outlining how to collect environmental samples from the identified sites. Where possible, a 50-mL specimen bottle was filled with soil, mud, and water from each site. All samples were sent to the research laboratory at Massey University at room temperature and processed within 3 days of receipt. The soil and mud samples were resuspended in 50 mL of PBS, and the supernatant was collected for processing. Soil and mud supernatant and water samples were centrifuged at 3000g for 20 minutes, and most of the supernatant was removed, leaving behind 1 mL of liquid of which 50 µL was cultured in EMJH culture medium, while the rest was stored at −80 °C and batch tested with PCR [21].

Study 5: Human Samples

Samples from patients suspected of leptospirosis were obtained at the patients' usual phlebotomy centers between November 6, 2019, and September 29, 2021. Research samples were collected at the same time as the diagnostic samples and included whole blood, serum, and urine samples. Approximately 100 µL of whole blood and urine was inoculated into the EMJH medium at the laboratories serving the phlebotomy centers. The culture medium and culture protocol were provided to these laboratories by the researchers as part of this study. The rest of the urine was centrifuged at 3000g for 20 minutes; the supernatant was removed, and the pellet was resuspended in RNAlater (Ambion). A total of 5 tubes containing blood culture, urine culture, serum, whole blood, and urine pellets in RNAlater were sent to the research laboratory at Massey University at room temperature. Blood and urine cultures were kept at 28 °C with shaking and monitored for 13 weeks before being discarded. Serum samples were centrifuged at 3000g for 20 minutes, and the supernatant was kept at −80 °C and batch tested. The urine pellet and whole blood were kept at −80 °C and were batch tested. Diagnostic laboratory results for all notified cases in the study were collected from EpiSurv to identify cases that were tested with a diagnostic PCR and to identify the diagnostic laboratories that ran these PCRs. The researchers then acquired the diagnostic sample (DNA) from the respective diagnostic laboratories to perform a research PCR.

Ethics Approval

This study received human ethics approval from the Health and Disability Ethics Committee (reference number 19/STH/80). In addition, this study received locality agreements together with local Māori consultations from 20 District Health Boards. The study received animal ethics approval from the Massey University Animal Ethics Committee (reference number Protocol 19/11).

Data Analysis Plan

Sample Size and Statistical Power

For common exposures (prevalence 30%-70%, such as exposure to flooded paddocks) [35], 150 cases and 300 controls provide more than 80% power for odds ratios (ORs) as low as 1.8, whereas for less common exposures (15%, such as wild deer on or near the farm) [32], this provides 80% power to detect ORs as low as 2.1.

Missing Data

Our approach to handling missing data was to design the answers to the survey questions with contingencies. For sensitive questions such as date of birth, participants could either provide their date of birth, age, or an age range. In addition, the category *unsure* was available to interviewers if participants were asked about the vaccination status of the animals they worked with or the treatment of their work water supply, as employees may not necessarily have this information. The *unsure* category was included in the data analysis.

Study 1: Risk Factors

Descriptive statistics consisted of comparing cases and controls (eg, percentage of respondents within strata and their CIs) according to the demographics and exposure factors present in the questionnaire. Contingency tables were drawn to compare dichotomous and ordinal variables. When applicable, 2 × 2 tables and Fisher exact test were used to calculate the crude ORs and CIs. Ordinal, discrete, and continuous variables with nonnormal distributions were compared using the nonparametric Mann-Whitney-Wilcoxon rank sum test. Boxplots were used to compare discrete and continuous variables. Comparison of independent variables and collinearity was determined using Pearson correlation coefficients. Timelines were plotted to analyze temporal trends and compare interviews of cases and controls.

Multivariable logistic regression models were used to calculate the ORs and CIs. Both crude and adjusted ORs were calculated for each exposure, with adjustment for potential confounders and matching variables. Variables were added in a stepwise manner forming precursor models; this was done separately for each main category of exposure variables, for example, wildlife. Subsequently, the different category precursor models were combined before running a further stepwise backward selection. To assist the decision of variable inclusion or exclusion, the following methods were used: relevance of the exposure in the literature and expert opinion, the Akaike Information Criterion of the model, and sensitivity analysis. Risk factors were initially estimated from a model without occupation, while adjusted for the matching factors (rurality and sex) and other confounders. To provide insight into the effect of occupation, a second analysis was conducted with occupation included.

Study 2: Follow-up of Cases

The proportion of cases with different symptoms at several time points after the onset of symptoms and up to the time of the follow-up interview was calculated. Kaplan-Meier survival curves were used to graphically display the time until symptoms were no longer present [50]. Multivariable logistic regression

XSL•FO
RenderX

models were used as described for the analysis of risk factors to identify possible factors associated with the persistence of symptoms, and crude and adjusted ORs and 95% CIs were calculated.

Descriptive analyses using means, frequencies, and percentages were used to explore how living with leptospirosis had impacted patients' activity participation, ability to cope, capability to return to usual daily activities, and support received from family and friends for recovery.

The K10 scores will be categorized using the method described in the NZHS [51]. Each of the 10 questions was scored from 0 to 4, and for NZHS reporting, psychological distress meant having a score of ≥12. This analysis will allow case K10 scores at both time points from the acute and follow-up surveys to be compared with those of NZHS participants. To assess changes in K10 scores over time, a mixed model repeated measures ANOVA will be used as described previously [52].

Study 3: Semistructured Interviews of Cases

Anonymized selective transcripts were made from the recordings of the semistructured interviews by the interviewer, leaving in what the interviewer considered to be the essential answers to inform the work of 3 groups of professionals. Selective transcripts were used as raw data for content analysis [53]. In this analysis, 3 important choices were made. First, the content analysis focused on *what was said* without the exploration of *what was meant*. Second, the content analysis was inductive, and recurring themes were identified as they emerged from the transcripts. Finally, an issue was considered a recurring theme when approximately one-third of the interviewees mentioned it [54-56].

Studies 4 and 5: Sources of Infection

Attempts to identify the strains of *Leptospira* in human, animal, and environmental samples were as follows:

- Genotyping pure *Leptospira* cultures: DNA extractions from cultures were subjected to *LipL32* quantitative PCR [57] and *glmU* conventional PCR [21] for the detection of pathogenic *Leptospira*. All *glmU* PCR amplicons were sequenced to identify the species and serovars of *Leptospira*. Any culture-negative samples for the pathogenic PCRs were subjected to a 16s PCR [58] to identify saprophytic or intermediate strains of *Leptospira*.
- Genotyping samples: all samples stored at −80 °C from humans (blood, urine, cerebrospinal fluid and serum); animals (urine and kidneys); and the environment (water, soil, and mud) were subjected to DNA extraction and to *LipL32* and *glmU* PCRs as described in the previous paragraph. Samples positive for *glmU* PCR were sent for amplicon sequencing to identify species and serovar of *Leptospira*.
- Serotyping via MAT: all serum samples were serially diluted from 1/24 to 1/3072 and subjected to a MAT assay against 5 serovars belonging to 2 species: *Leptospira borgpeterseneii* serovars Hardjo type bovis, Ballum, and Tarassovi and *Leptospira interrogans* serovars Pomona and Copenhageni. Seropositivity for humans was defined as per the case definition for cases (Textbox 1). Seropositivity for animals was defined as a MAT titer of ≥48, whereas titers of ≥384 indicated likely current or recent infection [59].

Culture media, cultivation of cultures, DNA extraction method, primers, and PCR protocols were as published previously [21].

Results

All participants in this study were recruited between July 22, 2019, and January 31, 2022, and data collection for the study has completed. During this period, a total of 220 cases were notified to ESR, of which 139 were forwarded to us from the Public Health Units; 12 (8.6%) of whom declined to participate, 24 (17.3%) did not meet the case definition, and 7 (5%) were unable to be contacted; thus, 95 (68.3%) cases met the case definition, agreed to participate in the study, and were interviewed. All case interviews were conducted from July 25, 2019, to April 13, 2022. A total of 300 controls were recruited and interviewed: 150 (50%) from UMR Market Research and 150 (50%) through Infield International. Control interviews were conducted from October 19, 2019, to January 26, 2022. A total of 91 cases participated in the follow-up interviews that were conducted between July 9, 2020, and October 25, 2022, and 13 cases participated in the semistructured interviews that were conducted between January 26, 2021, and January 19, 2022. Semistructured interviews were conducted after the participants completed the case (study 1) and follow-up (study 2) interviews. Data integrity checks showed that all responses to the questions in the case-control and follow-up surveys were recorded because of the contingencies put in place to account for missing data. In-contact animal and environmental samples were collected from 4 farms (1 dairy farm, 1 sheep farm, and 2 beef farms) between October 28, 2020, and July 29, 2021. Samples were collected from cattle (16 kidney, 186 serum, and 193 urine samples); sheep (40 urine and 40 serum samples); dogs (12 serum samples); possums (28 kidney samples); rats (6 kidney samples); wild pigs (3 kidney samples); wild rabbits (3 kidney samples); and environmental sources including water (n=10), mud (n=11), and soil (n=15). A total of 20 samples were collected from patients suspected of leptospirosis between November 6, 2019, and September 29, 2021.

Data analysis for the semistructured interviews has concluded, and 2 manuscripts have been drafted for review. Results of the other studies are being analyzed and the specific results of each study will be published as individual manuscripts. All animal and human samples have been tested, and the results returned to farmers and patients by their veterinarians or clinicians, respectively.

Discussion

Principal Findings

This study is the first in New Zealand to quantify the association between leptospirosis and a range of risk factors including contact with livestock, wildlife, and pets; exposure to soil, mud, and water; and the use of PPE and animal vaccination. The identification of risk factors will enable us to design effective intervention strategies to reduce exposure to these factors and thus reduce the disease burden in New Zealand (study 1). Our

XSL•FO
RenderX

assessment of the disease burden for patients is novel, as we included the potential difficulties associated with compensation for occupationally acquired cases. This information may be used to update the compensation policies to adequately support future leptospirosis cases (study 2). The successful follow-up survey of 91 cases and 13 cases from agricultural occupations who shared their experiences in a semistructured interview will provide a new and detailed understanding of the postleptospirosis experience and its burden on individuals and households. This information will help identify the appropriate measures, including social, financial, and emotional measures, to support leptospirosis cases (studies 2 and 3). Furthermore, the data from patients' in-contact animals and environments will provide information on pathways for infection previously not considered important in New Zealand, such as pests or flooding, which will inform (and have informed) health messaging (study 4). Finally, this study identified a large underascertainment of cases, as 70% of patients did not return to provide a second blood sample and did not receive a diagnosis (study 5).

Limitations

It is important to acknowledge the limitations of this study. Case-control studies are generally prone to biases, particularly differential recall, and selection biases. To reduce the impact of recall bias on the findings of this study, both cases and controls were given similar memory aids during the interview and close-ended questions were prioritized over open-ended questions at the analysis stage. Selection bias was reduced by matching only 2 variables (sex and rurality), the major known confounders, to ensure that controls were representative of the case population, as 90% of leptospirosis cases were males and 65% lived in rural areas of New Zealand. By focusing on notified cases, albeit with some broadening of the case definition, the issue of underascertainment, which has previously been estimated at 3-fold where mild cases do not seek medical attention and thus do not receive a diagnosis or get notified [60], was not directly addressed; however, the inclusion in our protocol to (1) enroll and test patients suspected of leptospirosis with a range of research tests (culture, PCR, and serology) and (2) test diagnostic samples with a research PCR will shed light on this hidden burden.

Strengths

One of the strengths of this study was ensuring that all notified cases were given an opportunity to participate in the study by using 3 pathways to identify these cases nationwide (Figure 1). This effort is crucial for a disease uncommon in New Zealand (approximate incidence risk of 2 per 100,000 people) [16] and ensures that the results from this study will provide nationally valid data.

Future Work

Future research goals include following the cohort of patients established in this study (aim 7) in a long-term follow-up study. Furthermore, the underascertainment of cases owing to the requirement of 2 tests identified in study 5 has led us to collaborate with human diagnostic laboratories to develop a PCR test that will require 1 sample for diagnosis and will subsequently be able to type the strain of *Leptospira*.

Conclusions

The dissemination of the study results will occur through scientific and stakeholder channels including publications in international peer-reviewed journals and presentations at international and national meetings. Our stakeholders in the community such as the Meat Industry Association, NZ Meat Workers Union, Department of Conservation, Dairy Women's Network, WorkSafe NZ, Rural Women New Zealand, and district and regional councils will use their websites, social media channels, and publications to deliver key messages. We held a leptospirosis forum in March 2019 that socialized the study with stakeholders and in September 2022 with stakeholders and patients to disseminate the findings of the study. The researchers have summarized the key findings of the study and circulated them to Public Health Units, District Health Board research offices, Māori Health teams, and all participants. These summaries will also be more widely disseminated to the community.

Acknowledgments

The investigators thank the following for their assistance and support with this study: study participants; the Health Research Council of New Zealand for funding this study (reference ID 18/239); medical officers of health from the District Health Boards that worked with us to obtain locality agreement and Māori consultations; Public Health Officers for recruiting cases, clinicians, nurses, and practice managers who assisted with recruitment and sampling of suspected cases; Institute of Environmental Science and Research for allowing monthly surveillance of cases from EpiSurv and for providing diagnostic tests results; laboratory staff in Whangarei Hospital; Waikato Hospital laboratory and Hastings laboratory for specimen collection and processing before transport to the research laboratory; Canterbury Health laboratory and Waikato Hospital laboratory for providing the research laboratory with patient DNA samples used for diagnosing leptospirosis cases in the study, Northland Regional Council for providing traps for trapping wildlife on patient farms; and the Ministry of Health for providing the New Zealand Health Survey database.

Data Availability

The data sets generated during this study are not publicly available, as they are currently unpublished data. Data sets may be available from the corresponding author when they are published on reasonable request.

Authors' Contributions

JB conceived and developed the study design with assistance from SN, JC-E, JM, EV, GP, JD, MGB, DAW, JW, MH, and TQ. MH provided expertise on Māori codes of practice. AF managed the electronic databases. SL managed the laboratory data, and PY provided peer supervision and training on the delivery of sensitive questions. All authors contributed to the drafting and revising of the manuscript. All authors have read and approved the final manuscript.

Abstract

Background: After a dementia diagnosis, Asian Americans experience anxiety, feelings of shame, and other negative effects. Emotional well-being is not only an important aspect of mental health, but also a quality of resilience that helps people bounce back faster from difficulties. However, few studies have addressed issues in developing, implementing, and testing intervention strategies to promote emotional well-being among older adults. Intergenerational solidarity between grandparents and grandchildren has been emphasized in Asian families and is beneficial for the health of persons with dementia. Reminiscence and life review have been identified as potentially effective intervention strategies for helping depression and emotional well-being for older adults.

Objective: This proposed study aims to develop and implement an intergenerational reminiscence approach and evaluate its potential feasibility and effectiveness in improving the emotional well-being of older Asian American adults who have a recent dementia diagnosis.

Methods: An explanatory sequential mixed methods design will be used in which quantitative data will first be collected and analyzed to identify subsamples of participants who report the greatest and least change in emotional well-being; then, these subsamples will be interviewed to further understand why or why not this intervention works for them. Older adults will receive 6 sessions of life review with grandchildren in virtual reality (VR; 1-1.5 hours each week for 6 weeks), aided by pictures and virtually traveling to important places in their life using Google Earth to look around at those places and remember important times. Quantitative survey data will be collected pre- and postintervention and at a 3-month follow-up. Qualitative interviews with selected participants will also be integrated into the study design. The quantitative data from the surveys will be entered into SPSS (IBM Corp) and analyzed using descriptive analyses, Pearson chi-square tests, nonparametric Friedman tests, or nonparametric Wilcox signed-rank tests (2-tailed). The qualitative data will be transcribed by research assistants, coded by the investigators independently, and analyzed with guidance from content analysis software (Atlas.ti; Atlas.ti Scientific Software Development GmbH).

Results: The project was delayed due to the COVID-19 pandemic. Data collection started in late 2021, and 26 participants were recruited as of December 2022. While we are still cleaning and analyzing the quantitative data, the qualitative interviews showed promising results of this intergenerational reminiscence approach in improving emotional well-being among older Asian American adults who have cognitive impairment.

Conclusions: Intergenerational reminiscence provided by grandchildren is promising in improving the emotional well-being of grandparents. VR technology is likely to be accepted by older adults. Future research may consider scaling up this pilot into

XSL•FO
RenderX

a trackable, replicable model that includes more participants and develops a more rigorous study design with control groups to test the effectiveness of this intervention for older adults with dementia.

Introduction

Background

The Asian American population in the United States nearly doubled between 2000 and 2019. Asians now make up about 7% of the nation's overall population, and their numbers are projected to surpass 46 million by 2060, nearly four times their current total [1]. Older Asian immigrants often immigrate to the United States at a late age [2] and experience many challenges related to migration, such as low acculturation, limited English language proficiency, ineligibility for entitlement and welfare programs, family or generational conflicts, and social isolation [3,4]. Older Asian American adults also face numerous challenges and physical, psychological, and mental health problems [5], as well as racial discrimination on a regular basis, especially after COVID-19 [6,7]. As the US population becomes older and more diverse, programs and interventions on how to improve mental health of older immigrants are sorely needed.

In addition, if older immigrants are diagnosed with dementia, they face triple adversity: immigration, aging, and dementia. Immigration is a life-changing event that is often accompanied by elevated stress and adversity; aging adds an additional layer of adversity to immigration, and dementia can lead to experiencing further adverse events. This triple jeopardy poses a trauma risk to older Asian American adults, creating a pressing need to understand how to best restore and preserve their resilience. After a dementia diagnosis, people often experience anxiety, negative impacts on self-esteem, preoccupation with the diagnosis, and hyper-vigilance, which can precipitate a crisis [8]. Asian Americans also report feelings of shame and weakness after a dementia diagnosis; however, they seek fewer formal services for support compared to Whites [9-11], leading to negative emotional and mental health outcomes [12]. Despite vulnerabilities among this population, Asian Americans often attract less research attention, in part due to the "model minority" myth [13].

Despite their overall better physical health, older Asian immigrants have worse mental health outcomes than their White counterparts [14-16]. People who are emotionally well (ie, are satisfied with life, have a positive affect, and find purpose or meaning in life) have a quality of resilience and are able to bounce back faster from difficulties [17]. While there are some studies that have specifically looked at emotional well-being among adults and adolescents [18], few studies have examined emotional well-being among older adults. Prevention and interventions to improve emotional well-being among aging populations have attracted special attention because of its strong correlation with health [19]. Reminiscence and life review have been identified as potentially effective intervention strategies for helping depression and increasing emotional well-being among older adults [20-23]. The literature also asserts the positive impact of an intergenerational approach in achieving positive mental health and emotional well-being among older adults [24-26]. Intergenerational solidarity between grandparents and grandchildren has been emphasized in Asian families [27] and is beneficial for the health of persons with dementia [28,29]. When reminiscence and life review strategies are combined with the intergenerational approach, the mental health benefits for older adults are even clearer and more significant [30]. This approach may also help grandchildren gain more historical and cultural understanding of their grandparents' lived experiences, positively change their views of aging, and increase their bonding with grandparents.

Using technology to help enhance the well-being of older adults is a growing research and practice trend. One recent technological advancement is audiovisual virtual reality (VR), which creates a 3D computer-generated environment to provide an immersive and interactive personal experience [31]. Emerging technologies that allow older adults to socialize across geographic boundaries using a head-mounted display paired with a smartphone have been well accepted by older adults [32]. Studies have also shown the potential of social VR as a powerful reminiscence tool to challenge stereotypes of aging and promote the well-being of older adults [33].

Aims and Research Questions

This proposed study aims to develop and evaluate the potential feasibility and effectiveness of an intergenerational reminiscence approach in improving the emotional well-being of older Asian American adults who have a recent dementia diagnosis. This pilot study is the first to develop and test how social VR can help older Asian Americans improve their emotional well-being and cope with the stress and adversity of having been diagnosed with dementia. It is hypothesized that the resiliencies of family through grandchildren, reminiscence, and technology together will help older adults develop better emotional well-being, which will help them withstand difficulties in the journey of dementia and have better mental health outcomes. The study addresses three specific aims: (1) develop 6 intervention sessions based on the reminiscence and life review theory using VR technology; (2) quantitatively test the effectiveness of this intervention in improving emotional well-being; and (3) qualitatively evaluate the usefulness of this intervention.

XSL•FO
RenderX

Methods

Study Design

An explanatory sequential mixed methods design [34] will be used, involving first collecting quantitative data and then analyzing this data to identify subsamples of participants who report the greatest and least change in emotional well-being. Next, we will conduct qualitative interviews among these subsamples. For the intervention, a single-arm trial will be used in which all the recruited participants are given the intervention and then followed over time to observe their response. This design is used when the objective of the trial is to obtain preliminary evidence of the efficacy of the intervention, but it is not generally used for confirmation of efficacy [35]. Such a design may be desirable when the available participant pool is limited; thus, it is not optimal to randomize many participants to a control arm [35].

Recruitment

Participants in this study will be recruited from immigrant Chinese, Korean, Vietnamese, and Indian families since they are the top 4 minority Asian groups in the greater urban area of Dallas, Texas [36]. The eligibility criteria of the older adult participants include (1) self-identification as Chinese, Korean, Vietnamese, or Indian American and living in the greater Dallas area; (2) age 65 years or older; (3) a dementia diagnosis in the past 12 months (self-reported); and (4) at least one grandchild aged 18 years or older. When both an eligible older adult and his or her grandchild agree to participate in the study, the grandparent-grandchild dyad will be included in the study. The dyads will be recruited through multiple ways, including referrals from facilities or community agencies, flyers posted in Asian grocery markets, announcements posted on Facebook and Twitter, and local churches that service these Asian American groups. Eight dyads from each of the 4 Asian groups are proposed to be recruited (64 total participants).

Procedure

After participants sign the informed consent form, both the older adults and their grandchildren will be offered a VR headset. Training on how to use the VR headset will be offered to grandparents and grandchildren by the research team before the intervention starts. If the grandchildren do not reside locally, Microsoft Teams–based training will be offered. Then, older adults will receive 6 sessions of life review with their grandchildren in VR (1-1.5 hours each week for 6 weeks). The themes will include (1) major turning points in life, (2) family history, (3) life and career accomplishments, (4) history of loves and hates, (5) experiences of suffering or stressful experiences, and (6) meaning and purpose of life. A manual of interaction guidelines will be prepared for the grandchildren to lead the interactions with their grandparents based on the intervention manual proposed by Watt and Cappeliez [37,38] and others, which will outline the implementation of integrative and instrumental reminiscence interventions that promote acceptance of self, conflict resolution and reconciliation, a sense of meaning and self-worth, recalling how one coped with past problems, and drawing from past experience to solve present problems.

The process is a series of discussions using the above themes of major moments in the participants' lives, aided by pictures and virtually traveling to important places in their lives with Google Earth to look around these places and remember important times. Information on important pictures and places will be collected by the grandchildren before the session by asking the grandparents' spouses, their own parents, or the grandparents' caregivers or legally authorized representatives (LARs). Both the grandparents and their grandchildren will participate in the intervention remotely. The VR intervention process is linked to YouTube 360 slideshows, an application that enables 2 or more people to communicate verbally while seemingly in the same shared space despite being physically apart. Participants open the YouTube app and select the video we have created. The videos are slideshows using 360-degree scenery that fits with their personal history and the images provided by their family members. The subjects speak over a speakerphone, talking about their memories, while viewing the same video. The intervention through VR linked to YouTube is not recorded, and the private family account set up for this study does not publicly list any scenery video and is thus private to the participants (grandparents and grandchildren), the older participants' caregivers or LARs, and the research team. Mobile Oculus Quest headsets will be mailed to each participant in the dyads. These headsets do not require a computer and enable an immersive video chat–like experience where participants can do activities together in a virtual world. Some older adults with dementia may need some help from their caregivers or LARs if needed. An eyeglass spacer (a rubber border) comes with every headset provided to the subjects. The interaction process via VR will offer older adults audio as well as visual perceptions and thus increase interactions and engagements while overcoming the limitations of geographical distance between the 2 generations. Pretest, posttest, and 3-month follow-up tests will be performed. Qualitative interviews with selected participants will also be integrated into the study design.

Measurement

The primary outcomes of the study will be the social and emotional well-being of grandparents, and the secondary outcomes are the benefits to the grandchildren.

Primary Outcome Measurements

Primary outcomes among the grandparents include satisfaction with life, emotional well-being, subjective happiness, resilience, depression, and grandparent-grandchild bonds; these are assessed via culturally appropriate standardized instruments before and after the intervention. Demographic information for each dyad, such as age, gender, education, geographic proximity, and self-rated health, are also collected in the pretest survey.

Satisfaction with life is measured by the Satisfaction with Life Scale (SWLS) [39], a 5-item scale designed to measure global cognitive judgments of one's life satisfaction as a whole. Participants indicate how strongly they agree or disagree with each of the 5 items using a 7-point scale that ranges from 7 (strongly agree) to 1 (strongly disagree). The SWLS has shown good reliability and validity and thus has been recommended as a complement to scales that focus on psychopathology or

XSL•FO
RenderX

emotional well-being because it assesses individuals' conscious evaluative judgment of their life by using their own criteria [40].

Emotional well-being will be measured by the Warwick-Edinburgh Mental Wellbeing Scale (WEMWBS) [41], which consists of 14 items that describe participants' experience over the past 2 weeks. The WEMWBS covers positive affect (feelings of optimism, cheerfulness, and relaxation), satisfying interpersonal relationships, and positive functioning (energy, clear thinking, self-acceptance, personal development, competence, and autonomy). Each item is measured using a 5-point Likert scale ("none of the time," "rarely," "some of the time," "often," and "all of the time). Sum scores were calculated with a range of 14 to 70, with a higher score indicating a higher level of mental well-being. The WEMWBS has shown good reliability and validity [41].

The Subjective Happiness Scale (SHS) [42] is a global subjective assessment of whether a person is happy or unhappy. The SHS consists of 4 items, each measured on a 7-point Likert scale ranging from 1 to 7. Sum scores of the 4 items are calculated, yielding a range from 7 to 28. The SHS has been translated to different languages and has shown good reliability and validity.

Resilience of older adults will be measured by the Brief Resilience Scale (BRS) [43,44]. The BRS is one of the best and most highly recommended [44] resilience scales and has shown high reliability and validity in the literature [43,45,46]. Six items are used, each ranging from 1 (low resilience) to 5 (high resilience). After reverse coding 3 items, sum scores are calculated for the final analysis, with a higher score indicating more resilience.

The Geriatric Depression Scale (GDS) [47] short form consists of 15 questions that ask participants to answer yes or no in reference to how they felt over the past week. Of the 15 items, 10 indicate the presence of depression when answered positively while the rest indicate depression when answered negatively. The GDS-15 has been tested and used extensively with the older population and is easy to administer (it takes about 5 to 7 minutes to complete).

Grandparent-grandchild bonds will be measured by 3 questions assessing the quality of their relationship using a scale adapted from the Intergenerational Solidarity Inventory [48]. The 3 questions are as follows: (1) "Taking everything into consideration, how close do you feel to this grandchild?" (2) "How much do you feel that this grandchild would be willing to listen when you need to talk about your worries and problems?" and (3) "Overall, how well do you and this grandchild get along together?" For each question, scores range from 0 to 2 (0="not at all," 1="somewhat," 2="very"). An additive emotional cohesion score was computed, ranging from 0 to 6, with higher scores representing a closer grandparent-grandchild relationship.

Usability of virtual reality technology will be measured by adapting the System Usability Scale (SUS) [49]. The SUS provides a "quick and dirty" but reliable tool for measuring usability. It consists of a 10-item questionnaire with 5 response options (from "strongly agree" to "strongly disagree"). The SUS allows researchers to evaluate a wide variety of products and services, including hardware, software, mobile devices, websites, and applications [50]. In this study, we added "VR" to the 10 statements. In addition, 3 separate questions are asked to evaluate participants' subjective feelings on VR technology (whether they find it comfortable, satisfactory, and effective), with "yes", "no," and "unsure" answers for each question.

Secondary Outcome Measurements

Secondary outcome measurements for the grandchildren include emotional well-being, attitude toward aging, the grandparent-grandchild relationship, and the usability of VR technology. Except for the attitude toward aging, all measurements for the grandchildren will be the same as those for the grandparents.

The young adult volunteers' attitude toward aging will be measured with the Fraboni Scale of Ageism (FSA), which was developed by Fraboni et al [51] and revised by Rupp et al [52]. Participants will be asked to respond on a 4-point Likert scale to 29 statements (1="strongly disagree" to 4="strongly agree"). The FSA has been extensively used among college students and has shown high internal consistency and strong validity [53,54]. Sum scores will be calculated for the final analysis, with higher scores indicating more ageism.

Other Outcomes

Follow-up qualitative interviews are also conducted to explore participants' experience with VR technology and their overall experience and feelings regarding the proposed intervention. We will select 3 dyads from each group for further qualitative interviews (12 dyads total). Each generation's experiences, perspectives, challenges, and suggestions with this intervention will be determined with in-depth interviews (in person or via a phone call lasting for about 45 to 60 minutes). In general, we will use the following probe questions for the in-depth interviews with older adults: (1) "In general, what did you share with your grandchild in the past few weeks?" (2) "Can you describe how your emotional well-being has changed as a result of the intervention program? Please provide a few examples, especially on what part of the intervention helped you most or least when improving your well-being" (3) "How did you feel about the weekly talk with your grandchild?" (4) "How do you feel about the virtual reality technology in this intervention program?" and (5) "What suggestions or advice do you have for this project? Or any suggestion or advice for improving your emotional well-being?" For the grandchildren, we will use the following questions: (1) "In general, what did you talk with your grandparent in the past few weeks? Or what contents did you share with each other?" (2) "Can you describe how your grandparent's emotional well-being has changed as a result of the intervention program? Please provide a few examples, especially what part of the intervention helped you most when improving your well-being" (3) "How did you feel about the weekly talk with your grandparent? Challenges? Ways to overcome?" (4) "How do you feel about the virtual reality technology in this intervention program?" and (5) "What suggestions or advice do you have for this project? Or any suggestion or advice for improving the emotional well-being of your grandparent?"

XSL•FO
RenderX

Statistical Analysis

The quantitative data from surveys will be entered into SPSS (IBM Corp) and analyzed using descriptive analyses, Pearson chi-square tests, Friedman tests, or nonparametric Wilcox signed-rank tests (2-tailed). The qualitative data will be transcribed by research assistants, coded by the investigators independently, and then analyzed with the guidance of content analysis software (Atlas.ti; Atlas.ti Scientific Software Development GmbH).

Ethical Considerations

Prior to commencing the study, all members of the research team successfully completed the Human Subject Protection training and acquired the necessary certification. The study adheres strictly to the guidelines outlined in the Declaration of Helsinki and received approval on July 14, 2020, from the University of Texas at Arlington (UTA) institutional review board (2020-0210). Before conducting the interviews, the participants were provided with clear and comprehensive information regarding the purpose of the study, the procedures involved, the potential risks and benefits associated with participation, the use and anonymization of research data, and the maintenance of confidentiality. Furthermore, the participants were explicitly informed, both initially and through reminders, that their involvement was completely voluntary and that they could withdraw from the project at any point without facing any penalties. The study officially commenced only after participants signed the consent form. The consent form included the contact details of the principal investigator and the institutional review board office, and each participant received a signed copy for their records. Each participant who successfully completes the study is provided compensation in the form of a $110 Walmart gift card.

Each participant is given an ID number. The data obtained for this study has been carefully collected to exclude any personal identifiers. All data files are securely stored in password-protected and encrypted formats on laptops provided by the UTA. These UTA-issued laptops also adhere to encryption protocols mandated by the UTA Office of Information Technology. The encrypted data files will be stored using an approved UTA storage tool, such as OneDrive, to ensure their secure preservation. The utmost priority is given to safeguarding the privacy of the participants involved. A list containing participant names will be maintained securely using author LX's authorized and protected OneDrive account. In the final report, only deidentified data will be included, ensuring anonymity. The data will be retained for a period of 3 years following the conclusion of the study's protocol.

Results

This study was funded by the Rutgers University Asian Resource Centers for Minority Aging Research Center under the National Institutes of Health/National Institute on Aging (grant P30-AG0059304) for a project duration of April 4, 2020, to June 30, 2023. The project was delayed due to the COVID-19 pandemic. Data collection started in late 2021. As of December 2022, 26 participant dyads were recruited, for a response rate of approximately 72% (we approached 36 potential dyads). Among the 26 grandchild participants, 11 were Chinese American, 8 were Vietnamese American, 5 were Indian American and 2 were Korean American. Data for the grandparents at baseline and after the intervention were collected by phone calls by trained bilingual research assistants. Individual grandchild participants entered the data in QuestionPro (Survey Analytics LLC), a centrally supported online survey research tool. The data collected were checked for correctness by means of cross-validation.

After the intergenerational reminiscence intervention was completed, 11 dyads were selected for further qualitative interviews. However, the majority of the dyads interviewed were from Chinese American families. We are currently in the stage of entering, cleaning, and analyzing the quantitative and qualitative data.

Discussion

Principal Findings

The objective of this study is to create and implement a 6-session intervention using VR technology and the reminiscence approach targeting grandparents and grandchildren in Asian American families. By gathering both qualitative and quantitative data, this study aims to assess the effectiveness of the intervention in enhancing the emotional well-being of grandparents and strengthening intergenerational bonds. The research will contribute valuable and up-to-date data to address existing research gaps, particularly by focusing on reminiscence and life review content, incorporating VR technology, and including Asian grandparents who experience cognitive impairment.

Given the various physical, psychological, and mental health issues and instances of discrimination faced by Asian American families [5-7], this study holds significant importance. By focusing on the emotional well-being of older Asian adults, it aims to enhance their life satisfaction, positive emotions, and sense of purpose, all of which contribute to resilience and faster recovery from adversities [17], including the challenges associated with dementia diagnosis. Consequently, this study makes a valuable contribution to the limited existing literature on emotional well-being among older adults, particularly within the context of Asian American families.

Moreover, this research incorporates an innovative approach that combines the positive practice of reminiscence and life review [20-23] with an intergenerational perspective [24-26]. While intergenerational approaches involving younger and older generations have been documented in the literature [24-26], it is worth noting that no previous studies, to the best of the authors' knowledge, have applied this approach specifically to grandparents and grandchildren. This grandparent-grandchild approach holds special significance for Asian Americans, as it aligns with the emphasis placed on intergenerational solidarity between grandparents and grandchildren within their culture. By engaging in this approach, grandchildren can gain a deeper understanding of their immigrant grandparents' lived experiences, from both a historical and cultural perspective. This, in turn, has the potential to positively reshape their

XSL•FO
RenderX

perceptions of aging and strengthen their bonds with their grandparents.

Strengths and Limitations

This mixed methods study is the first to develop and examine an intergenerational reminiscence-based intervention to improve the well-being of older adults in Asian American families with the aid of VR technology. Intergenerational reminiscence provided by grandchildren is a promising approach to improving the emotional well-being of grandparents, as VR technology is likely to be accepted by older adults. This study will help increase intergenerational closeness between grandparents and grandchildren. Findings from this study will also help health or human service providers develop programs to help Asian American families in general.

Limitations of this study include its small sample size and the absence of a control group. Future research may consider scaling up this pilot into a trackable, replicable model that includes more participants and has a more rigorous study design with a control group to test the effectiveness of this intervention for older adults with dementia. In addition, because there are wide differences between different Asian-American groups, it would be better to focus on only one Asian ethnic minority for one research project and compare the differences within that ethnic Asian group. Lastly, this protocol is proposed for in-person interactions between grandparents and grandchildren. Due to the risks and feasibility of conducting an in-person intervention during COVID-19, this project had to be tailored to a telephone-based approach. Future studies may consider comparing the effectiveness of interventions delivered as in-person meetings versus those that use a telephone-based approach.

Conclusions

Intergenerational reminiscence programs have the potential to foster social connection and engagement between grandparents and grandchildren within Asian American families. These programs also serve as a means for grandchildren to gain a deeper understanding of the life experiences of older adults both before and after immigration. By specifically focusing on intergenerational reminiscence between grandparents and grandchildren, a valuable avenue is opened for strengthening generational bonding and relationships. This, in turn, has the potential to enhance the psychological well-being, particularly the emotional well-being, of older Asian immigrant adults residing in the United States. Furthermore, this study will contribute valuable evidence to support future research exploring the feasibility and effectiveness of using VR in interventions or programs designed for older adults with cognitive impairments.

Acknowledgments

LX received support from the Rutgers University Asian Resource Center for Minority Aging Research under the National Institutes of Health/National Institute on Aging (grant P30-AG0059304). Abstract

Background: Many factors influence housing choices among older adults, but far from all have been identified. There is little systematic analysis that has included economic factors and virtually no knowledge about the interplay among perceived costs of moving, health status, and the mobility rate of older homeowners. It is currently unclear whether economic factors influence older adults' willingness to move, and the effects of economic policies on their actual behavior in the housing market are largely unknown.

Objective: The overarching objective of the AGE-HERE project is to develop knowledge of the relationship between health and economic factors that incentivize or disincentivize relocation during the process of aging.

Methods: This project uses a mixed methods convergent design across 4 studies. The initial quantitative register study and subsequent qualitative focus group study will nurture the evidence base and the development of a national survey. The final study will synthesize and integrate the results of the entire project.

Results: Ethical approval for the register study (DNR 2022-04626-01) and focus group study (DNR 2023-01887-01) has been obtained. As of July 2023, data analyses (register study) and data collection (focus group study) are currently being conducted. The first paper based on the register data is expected to be submitted after the summer of 2023. Three meetings have been held with the nonacademic reference group. The qualitative data will be analyzed in the autumn. Based on the results of these studies, a survey questionnaire will be developed and distributed nationally during the spring of 2024, followed by data analyses in the autumn. Finally, the results from all studies will be synthesized in 2025.

Conclusions: Results from AGE-HERE will add to the knowledge base for research on aging, health, and housing and can play a critical role in guiding future policy decisions aiming to balance the housing market. Such developments may lower related social costs and support older adults to maintain active, independent, and healthy lives.

Introduction

Background

The aging population increases the demand for housing adapted to diverse needs that facilitates active and healthy aging [1]. However, this demand is far from met because older adults face a challenging housing market with few choices available [2]. In Sweden, the supply of newly built homes has not kept pace with the increasing demand, and municipalities experience housing shortages [2], which has a major impact on individuals as well as on economic growth. Reforms have been implemented, and further reforms have been discussed. However, the housing policy debate has largely been based on increasing housing construction rather than finding ways to make better use of the existing housing stock.

According to the public debate, older homeowners are concerned about the costs associated with moving (eg, higher rental costs, a monthly association fee, and bank policies) [3]. At the same time, the housing market is experiencing insufficient residential mobility and inefficient relocation chains [2]. However, studies on housing and health in later life seldom incorporate economic factors [4], and how such factors influence older adults' willingness to move is currently unknown. A better understanding of these relationships can play a critical role in guiding future policy decisions aiming to balance the Swedish housing market, which in turn may lower associated economic and social costs as well as support older adults to maintain active, independent, and healthy lives.

Older adults spend more time at home compared to other age groups, and therefore, it is important that the home environment is adapted to suit their needs and preferences. Thus, as people age, housing is associated with health outcomes [5-8]. For example, accessibility problems in the home may lead to injuries and social isolation, which in turn have negative health effects [9]. Yet, research on factors that contribute to residential mobility for those who wish or need to move is sparse [8]. Given that older adults represent a group with varying housing preferences and needs [10,11], more knowledge is needed to support the development of future housing policies that accommodate this heterogeneity.

Recent international research has primarily focused on relocation to residential care facilities [12-14], with disabilities and frailty as predictors of relocation [15]. Situational circumstances such as strong community ties and individual or family health, in combination with social and economic conditions, make housing decisions complex in older age [16]. Thus, negotiating relocation is described as a long process until turning points emerge [17,18]. While these studies primarily focus on the very old, a recent study using register data from the United States showed that factors such as a change in income, years living in the community, and degree of social support are important characteristics for predicting relocations among persons in early retirement age [10]. Adding to this, qualitative research from Sweden suggests that older adults start to have more active reflections regarding their future housing choices and relocations around retirement age [19]. While some studies indicate that retirement triggers actual moves [10,20], we do not know whether economic issues encourage this younger group of older adults to stay in privately owned houses longer, even though those no longer suit their needs and preferences. This knowledge is crucial, especially during times of economic uncertainty and rapid social change, as it can assist policymakers in making informed decisions that support older adults in making suitable housing choices and enhancing their overall well-being.

Turning to the economic situation on a national level, macroeconomic trends such as booms or recessions, usually measured by gross domestic product growth, are likely to influence individuals' behavior in the housing market. This might be especially true for homeowners, as they often have most of their savings invested in the house and can therefore be affected by changes related to the housing market, such as house prices and interest rates [21]. Yet, the majority of studies on this topic focus on the entire population [22] rather than specific age strata, such as older adults. One exception is a study conducted in the United States evaluating lock-in effects due to the financial crash in 2008 and a subsequent major decrease in housing prices. The authors found that the probability of downsizing for adults aged 55 years and older was higher among people with a higher loan-to-value ratio (measured by mortgage loans or value of the house) compared with owners with a lower ratio [23]. Hence, it is likely that economic fluctuations influence households differently, but how such associations develop over time and emerge in a Swedish context remains unknown.

Housing Policy Context

The AGE-HERE project focuses on homeowners aged 55 years and older. In Sweden and most other Organisation for Economic Co-operation and Development (OECD) countries, the most common form of tenure among this age group is single-family home ownership [24,25]. This age group often has most of their savings invested in their house, and other available assets are limited [21], which makes them more vulnerable to changes related to the housing market, such as interest rates or housing prices. As to other economic factors, several have been suggested to encourage this population segment to stay in their current home rather than move. The 2008 Swedish property tax reform lowered the yearly property tax on especially highly assessed property by introducing a low maximum amount, but the capital gains tax was raised from 20% to 22%. Taken together, these changes increased the incentives to stay in large houses rather than moving to smaller ones. In addition, rent control has reduced the supply of apartments, which increases the price of other types of housing, such as owner-occupied housing [3]. Hence, it is likely that the way housing is taxed influences people's relocation behavior, which calls for more research in this area.

Study Objective and Research Questions

AGE-HERE aims to develop new knowledge on relationships between economic factors and health that incentivize or disincentivize relocation among homeowners from an early stage of the aging process (55 years and older). The specific research questions are as follows:

- How did macroeconomic events during the period 1970-2016 affect relocation patterns across time for older

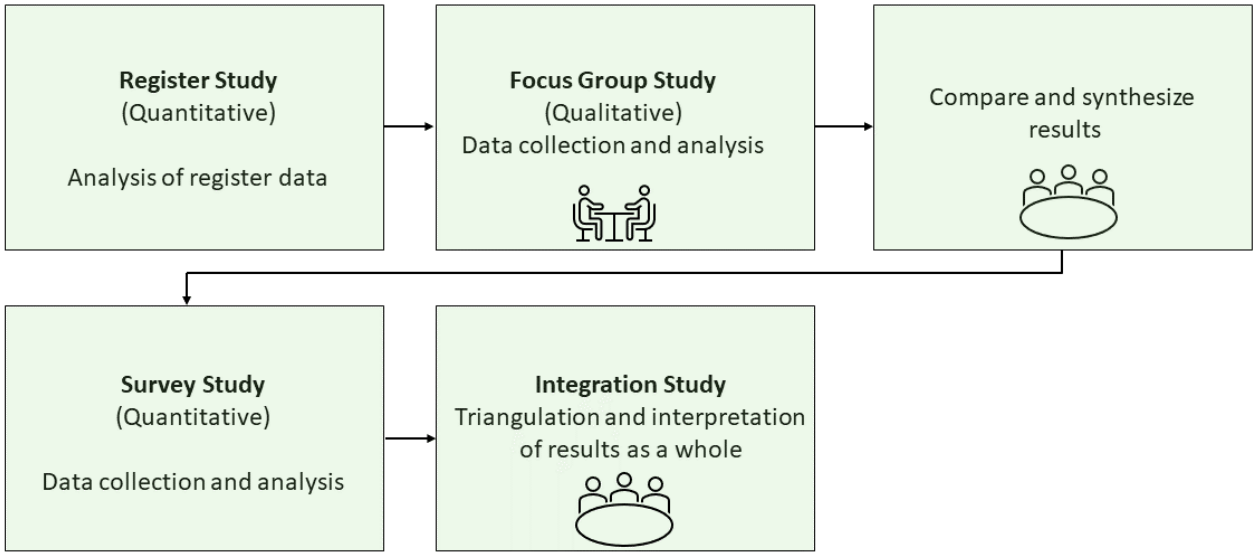
XSL•FO
RenderX

homeowners of different ages? Are there different patterns of relocation depending on civil status and sex?
- In what way did the tax reform of 2008 affect the probability of moving among older homeowners?
- What economic factors predict relocation to different types of housing (eg, condominiums, owner-occupied housing, and rental apartments), taking health factors into account?
- What economic and health factors do older homeowners perceive as important when considering relocation?
- What are older homeowners' preferences and beliefs regarding the economic factors that disincentivize or incentivize relocation?
- To what extent do older homeowners report that economic factors are an important part of the relocation decision process?
- How are economic factors and health related to decisions to move among older homeowners?
- How are the questions above affected by regional differences and housing market structures?

Framework

As a starting point, we will use a framework developed by Roy and coauthors [4] to conceptualize and examine the complexity of factors associated with housing decisions in older age. Covering 6 dimensions—socioeconomic and health, built and natural environment, social, time and space, psychological and psychosocial, and housing economics—this framework is a useful tool to build ties between different research fields [26]. With this framework as the starting point, we will combine several bodies of theories used in research investigating housing decisions in older age: environmental press, migration theory, residential normalcy, and control [4].

Deciding to relocate or not is influenced by individual health factors such as functional limitations and environmental factors [4], which is in line with the environmental press theory stating that the relationship between a person and their environment (social, environment, policy) affects their well-being and behavior [27,28]. Additionally, migration theory covers several domains described by Roy et al [4] and is important to elucidate the place- and people-based push and pull factors that influence older adults' decisions to relocate, particularly after retirement [29]. For example, while investment and housing value may be important for the decision to remain in a current home, stressors such as poor health, safety concerns, mortgages, and tenure status might manifest as push factors leading to a decision to relocate. In parallel, we will draw upon theories relating to the concepts of space (ie, housing, the physical dwelling) and place (ie, a home, with personal meanings) [28]. Thus, the meaning assigned to a home impacts the decision to relocate, and moving into a new home initiates a process of recreating meaning in the new place through living there [28]. These are important aspects in the time and space dimensions as well as in the psychosocial dimension of Roy et al's [4] framework. From an economic perspective, we will use the life cycle hypothesis, which predicts that households favor smooth rather than uneven consumption over their life cycle. In line with the economic factors (eg, mortgages, relocation costs, and taxes) described as important in the framework, the life cycle hypothesis implies that older adults who view their property as part of their retirement savings would sell their property in favor of renting or moving to a smaller, less costly home (ie, to increase the possibility to consume). In addition, tax theory, specifically the principles of tax neutrality and economic efficiency [30], is relevant. For taxes to be efficient, they should be designed so they do not influence behavior (eg, consumption and investments) [30], but when diverse types of housing are taxed differently (as in Sweden), taxes will steer behavior toward types of housing with beneficial taxation. That is, in contrast to the prediction of the life cycle hypothesis described above, the Swedish tax system may disincentivize relocation, so older adults remain in their homes even if that is not what they prefer.



Methods

Overview

AGE-HERE has 4 parts (Figure 1): a register study, a qualitative focus group study, a national survey study, and an integration study. The project is conducted in collaboration with a reference group consisting of nonacademic partner representatives (eg, housing market experts and senior citizen organization representatives) who will provide their input and reflections throughout the research process.

XSL•FO
RenderX

Figure 1. AGE-HERE project design; mixed methods convergent design.

Study Design

AGE-HERE has a mixed methods approach in a convergent design [31]. Results from the initial quantitative and qualitative studies will be used to develop a quantitative national survey. The final study will synthesize and integrate the results of the entire project (Figure 1).

Register Study

To investigate how macroeconomic events and taxes on property and capital gains affect relocation patterns for older homeowners, we will use data from several registers such as the Longitudinal Individual Data Base, a longitudinal database with a representative sample of the population in Sweden (N=300,000) from 1968 to 2016, and the income and taxation register, which provides information related to taxation and income for the entire population of Sweden. To analyze different factors, we will link data from the Longitudinal Individual Data Base and the income and taxation register to register data on health and housing, for example, from the property register, the population register, and the patient register.

Analysis

Tax Reform 2008

Differences-in-difference analysis [32] will be used to study the effects of the tax reform of 2008. Detailed information about taxes and income sources, as well as types of housing and socioeconomic variables, will be used to compare households that were affected to a large extent by the tax reform, that is, those living in highly assessed properties (high exposure group), with those that were less affected, that is, those living in properties worth less (low exposure group). The differences in the number of moves between the high and low exposure groups 2 years prior to the reform (2006) with the differences in the number of moves in the same groups 2 years after the reform (2010) will be compared. As this is not a randomized experiment, 3 methods to adjust for potential systematic differences between the groups will be used. First, we will control for variables such as income, education level, and place of residence that may affect the 2 groups differently. Second, we will use a propensity score matching technique [33] to determine a matched comparison group. Third, we will use a regression discontinuity design to evaluate the effect of the 2008 tax reform. Because the 55 years and above age group is heterogeneous, we will investigate whether different groups are more or less sensitive to economic factors. More specifically, we will compare different subgroups such as age cohorts, retired or working, have been or are receiving sickness payments, marital status, and sex.

Macroeconomic Trends and Health Factors

To evaluate historical trends in the relocation patterns of older adults, descriptive statistics will be used. Means will be described over time for different groups of individuals, depending on age and macroeconomic characteristics for the specific year of the relocations.

To analyze how health factors influence relocation, we will use descriptive and inferential statistics such as odds ratios, mean comparisons, and multivariate regression analyses.

Focus Group Study

To explore how older homeowners reason about their current housing situation in relation to future needs and opportunities to move and what financial and health-related factors they perceive as important in such a decision-making process, data will be collected from a series of focus groups [34] in 4 municipalities across Sweden.

Selection of Municipalities and Recruitment of Participants

Four heterogeneous municipalities have been selected based on demographics (ie, proportion of older adults), local housing market structure (eg, range of housing types, price, rent levels, and new production of housing that matches the needs of older adults), and geographic location.

Participants will be recruited via senior citizens' organizations [19] and through advertisements on social media. The selection of interested participants will be based on similarities dictated by the purpose of the study [34] and heterogeneity among them

XSL•FO
RenderX

(eg, sex, age, and living situation) to explore various perspectives. A total of 64 people will be recruited into 8 groups (ie, 2 focus groups per municipality), with 8 participants in each.

Data Collection

The interview guide will be developed based on findings from the register study, theories underpinning the project, relevant literature, and current media discourse. The groups will meet twice each, and the preliminary results from the first sessions will be used to adapt the interview guide for the second session to allow deeper exploration of the themes that emerge. If a need to contrast different perspectives emerges in the analysis, the participant constellations may change during the second session. Two moderators will lead each group: one will lead the discussions, and one will observe group interactions and listen to the discussions [34]. Sessions will be audio-recorded and last approximately 2 hours. The observing moderator will take field notes on settings and group dynamics as well as pose clarifying questions. At the end of each session, the observing moderator will give a brief summary of the core issues discussed and allow participants to comment and suggest amendments.

Analyses

We will use a constant comparative analytic framework as described by Krueger and Casey [34]. After round 2, audiotapes will be transcribed verbatim. The moderators will read the transcripts and listen to the recordings to get a feel for the dynamics of the discussions and independently code the data. This includes identifying patterns in the data and relationships among concepts. NVivo (Lumivero) will be used as it promotes transparency and validation of coding. To further enhance trustworthiness and reduce potential bias, peer debriefing meetings with all coauthors will be held throughout the analysis process [35].

Survey Study

Overview

The survey study will include a random sample of homeowners aged 55 years and older living across Sweden. In Sweden, approximately 3.71 million people are aged 50 years or older. Within this group, 2.8 million (70%) live in privately owned accommodations: 2.13 million in houses and 710,000 in condominiums [36]. Because men own their homes to a greater extent than women of older age, participants will be stratified by sex and randomly selected from the Swedish national population registry. Using a 95% CI and a margin of error of 4, we estimate a total sample size [37] of 3600 to be representative. We expect a 40%-50% response rate and will therefore draw an initial sample of 7200.

Survey Data Collection Procedures

Results from the register study and focus group study will be used to develop the survey questions in an iterative process involving the nonacademic reference group. The reference group will provide input to ensure the survey length is reasonable, the questions and response choices are clear and understandable, and the items cover the content identified in the previous studies. Sociodemographic questions and established self-rating scales on quality of life, independence, participation, and health will be integrated into the survey to explore the relationships between personal factors, health, and economic factors in decisions to relocate. The survey will be tested in a pilot with a sample drawn from the target population for the main study (n=25), and questions and procedures will be modified based on the results.

A professional survey company will be contracted for the data collection [19]. Potential participants will be sent a postal invitation, which includes a detailed description of the study and instructions for how to opt out. Participants will be able to complete the survey via the internet, using a paper form, or via telephone. Those who have not completed a web-based survey or requested a paper survey after 2 weeks will be contacted by trained interviewers who can conduct the survey using a computer-assisted telephone interview protocol. Data collection will continue until the target sample size is reached.

Analyses

Descriptive statistics will be used to analyze the demographics of each stratum and compare them with national population statistics. If results differ from the population, sample weights to match the population will be created. Weighted sample statistics will be used to describe the prevalence of reported economic incentives or disincentives, and a 2-tailed *t* test will be used to identify sex differences. Univariate and multivariate linear and logistic regression models will be used to assess associations between economic factors, health, and sociodemographic variables.

Integration Study

As a final step, toward the end of the project (in 2025), the results will be merged and interpreted as a whole [31]. The purposes are triangulation (ie, validation based on corroboration between data sets), complementarity (ie, different methods to answer related questions), and expansion (ie, data sources address different aspects of answering questions raised by other data sets) [38,39]. Using an interactive merging strategy, narrative integration and weaving, presenting qualitative and quantitative data together, and forming connections based on specific topics will be used [40]. Analysis meetings involving the reference group will be an integral part. Emerging themes will be explored and developed based on Roy et al's [4] framework, the theoretical underpinnings, relevant international or national reports, policy documents, and legislation.

Ethics Approval

Ethical approval for the register study (DNR 2022-04626-01) and focus group study (DNR 2023-01887-01) has been obtained from the Swedish Ethical Review Authority. We will adhere strictly to the Helsinki Declaration's requirements for research involving humans. Because a systematic examination of ethical considerations is also needed in the survey study, an additional ethical approval will be sought. We will make sure that project staff are trained and supervised on ethical issues, with specific attention to collecting data from older adults. In case participants have questions, contact information of the responsible researchers will be provided for the focus group study and the survey study. In the information letter to study participants, they will be informed about confidentiality and their right to withdraw from the study at any time. Informed consent will be

XSL•FO
RenderX

obtained first after the participants have been given written and oral information on the study's purpose and what participation would entail. All data will be collected and stored in compliance with the requirements of the Ethical Review Authority and the European General Data Protection Regulation.

Results

Ethical approval for the register study and focus group study has been obtained (DNR 2022-04626-01, DNR 2023-01887-01 respectively). Data analyses (register study) and data collection (focus group study) are currently being conducted (July 2023). The first paper based on the register data is expected to be submitted during the summer of 2023. Three meetings have been held with the nonacademic reference group. The qualitative data will be analyzed in the autumn. Based on the results of these studies, a survey questionnaire will be developed and distributed nationally during the spring of 2024, followed by data analyses in the autumn. Finally, the results from all studies will be synthesized in 2025.

Discussion

Principal Findings

This project sets out to investigate how economic and health aspects influence the decision to relocate or not among older adults. By integrating theory and methods from economics and gerontology, we will identify the most influential factors in older homeowners' housing decisions. We expect that economic policies play an important role in the decision to remain in single-family homes even when the home no longer supports older adults with declining health. Furthermore, we expect this decision to also be related to a lack of affordable housing with good accessibility in the Swedish housing market. Although we specifically focus on Sweden, the project has broader geographical implications. Hence, findings can be used to inform the allocation of resources and policy decisions concerning the living arrangements and housing choices of older adults in countries where comparable housing policies are being implemented or intended.

Aging in place has become the norm for most older adults in Sweden as well as in other Western countries, which is supported by society as it is considered less costly to provide home care than care in institutions [41]. Even so, most research on housing and aging does not consider factors that incentivize or disincentivize relocation within the ordinary housing stock; instead, the focus is on people aging with disabilities or frailty, with growing needs for special forms of housing and housing adaptations [14]. Given that aging in place is far from supportive for all older adults [42], future research and policy initiatives should focus on the diverse needs of the heterogeneous aging population [43] and consider aging in the right place [44]. This is important because, with population aging, the share of older adults living with functional limitations and age-related diseases will increase [45], implying that the housing stock needs to be adapted and developed to fit the needs and preferences of this substantial population segment. The dwellings older homeowners tend to live in often have a high prevalence of environmental barriers, and older adults aging with functional limitations experience accessibility problems, which can hinder daily activities and have negative consequences for health and quality of life [9,46,47]. From a societal economic and public health perspective, it is therefore important that municipalities comply with their housing provision responsibility and create conditions for everyone to be able to live in adequate housing [48].

Most older adults in Sweden live in dwellings they purchased much earlier in their lives and are now reticent about selling [49]. This trend is similar to the majority of OECD countries [25]. For example, in the United States, homeownership rates remain unchanged after the age of 55 years [50], and this trend has been relatively stable despite the economic recession and the housing market crash in 2007 [44]. The reluctance to sell contradicts the life cycle hypothesis, which says that older homeowners would sell their property in favor of renting or moving to a smaller, less costly home to start "consuming" or using their equity to support their living costs [50]. While many factors can explain why older homeowners are reluctant to move (eg, attachment to a place), concerns about the associated costs have gained little attention. This has been highlighted by Sweden's largest senior organization, showing that every fifth senior household in Sweden has decided not to move because of the capital gains tax [49]. This means that a substantial number of moves do not happen, which in turn slows down relocation chains and reduces the housing supply for young families who are in need of a larger home.

While there are other recent reports highlighting this issue [51], no scientific efforts have so far been made in Sweden or internationally to understand this complexity in depth. Overall, there is a paucity of studies investigating associations between taxation and decisions to move. Previous studies are based on US conditions and aggregated data [52], where the property tax is local and used to finance local public services and therefore affects the choice to move. As such, the AGE-HERE register study represents a novel approach compared to existing research, as we will study the impact of taxes on housing decisions in older age using high-quality register data. The design of the Swedish property tax, which is national rather than local (and therefore does not interfere with the choice to move), allows us to test this empirically in a valid way. By linking registers with data on taxes, income, and health and using a framework based on a systematic literature review [28], we will be able to analyze a large range of factors. Adding to this, we will observe the number of relocations among older adults historically, which will provide unique knowledge on housing decisions depending on the state of the economy across time.

Turning to the focus group study, previous research conducted in 6 European countries (the United Kingdom, Germany, the Netherlands, Ireland, Italy, and Hungary) has shown that housing choices among older homeowners are highly dependent on the local housing market situation [53], which is seldom considered in research. Our approach in AGE-HERE to collect data in 4 different municipalities across Sweden will provide valuable insights related not only to the range of possible factors that influence older homeowners' decisions to move but also to the role played by preconditions in local housing markets. Local housing markets are heterogeneous and need to be considered

XSL•FO
RenderX

by housing policymakers. For example, in some municipalities, almost the entire housing stock consists of single-family houses, which limits the possibility of moving to a smaller dwelling when needs and preconditions change. In contrast, other municipalities have a large variety of smaller dwellings, both rentals and condominiums. In terms of new production, especially forms of housing that are aimed at the older population, some municipalities have many completed and ongoing projects while others have few. It is not farfetched to believe that such diverse situations will be a huge challenge in the coming years as the share of older people will increase substantially in all municipalities. That is, housing needs will change with population aging, and therefore policymakers need to relate to this diversity of prerequisites when planning for the future.

By better understanding the living conditions of older people from their own diverse perspectives, we can promote a positive development of social relations and enhance full participation in society on an individual level. Additionally, a better functioning housing market would have positive spillover effects on the labor market because relocation chains would function better and on the financial markets because real estate prices would be adjusted, which in turn would affect households' debt levels [3]. Altogether, a better-functioning housing market will enhance not only health and well-being but also the economic performance of society.

Limitations and Strengths

AGE-HERE is conducted in Sweden, but the knowledge gained from the project is expected to be relevant for the development of housing and policies internationally. Hence, population aging is a global phenomenon, and most countries will need to adapt their housing markets to fit diverse needs and expectations.

The data collection for the AGE-HERE focus group and survey studies will be conducted against the backdrop of the COVID-19 pandemic, during a time of high energy prices and inflation. How such periodic effects may influence the data collected will be considered and discussed in all parts of the project.

Conclusions

Results from AGE-HERE can inspire future research and play a critical role in guiding policy decisions aiming to balance the housing market, which in turn may lower related social costs and support older adults to maintain active, independent, and healthy lives.

Acknowledgments

The AGE-HERE project is financed by grant P7/21 from Stiftelsen Länsförsäkringsgruppens Forsknings and Utvecklingsfond. The project is situated in the transdisciplinary Centre for Ageing and Supportive Environments (CASE), which is financially supported by the Faculty of Medicine and Faculty of Engineering at Lund University, Sweden.

Data Availability

The data sets generated and analyzed during the register and survey studies are not publicly available due to a data agreement between Lund University and a third party but are available from the corresponding author or data holder on reasonable request.

Authors' Contributions

MK generated the project idea, designed the project, and wrote the proposals for funding in close collaboration with all coauthors except DD. MK wrote the manuscript, assisted by SMS and DD, with critical reviews from all coauthors. DD and ÅH provided details regarding the register study. All coauthors approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Workers in the salmon processing industry have an increased risk of developing respiratory diseases and other hypersensitivity responses due to occupational exposure to bioaerosols containing fish proteins and microorganisms, and related allergens. Little is known about effective measures to reduce bioaerosol exposure and about the extent of skin complaints among workers. In addition, while identification of risk factors is a core activity in disease prevention strategies, there is increasing interest in health-promoting factors, which is an understudied area in the salmon processing industry.

Objective: The overall aim of this ongoing study is to generate knowledge that can be used in tailored prevention of development or chronification of respiratory diseases, skin reactions, protein contact dermatitis, and allergy among salmon processing workers. The main objective is to identify effective methods to reduce bioaerosol exposure. Further objectives are to identify and characterize clinically relevant exposure agents, identify determinants of exposure, measure prevalence of work-related symptoms and disease, and identify health-promoting factors of the psychosocial work environment.

Methods: Data are collected during field studies in 9 salmon processing plants along the Norwegian coastline. Data collection comprises exposure measurements, health examinations, and questionnaires. A wide range of laboratory analyses will be used for further analysis and characterization of exposure agents. Suitable statistical analysis will be applied to the various outcomes of this comprehensive study.

Results: Data collection started in September 2021 and was anticipated to be completed by March 2023, but was delayed due to the COVID-19 pandemic. Baseline data from all 9 plants included 673 participants for the health examinations and a total of 869 personal exposure measurements. A total of 740 workers answered the study's main questionnaire on demographics, job characteristics, lifestyle, health, and health-promoting factors. Follow-up data collection is not completed yet.

XSL•FO
RenderX

Conclusions: This study will contribute to filling knowledge gaps concerning salmon workers' work environment. This includes effective workplace measures for bioaerosol exposure reduction, increased knowledge on hypersensitivity, allergy, respiratory and dermal health, as well as health-promoting workplace factors. Together this will give a basis for improving the work environment, preventing occupational health-related diseases, and developing occupational exposure limits, which in turn will benefit employees, employers, occupational health services, researchers, clinicians, decision makers, and other stakeholders.

Introduction

Overview

This paper describes the protocol for an ongoing comprehensive study in the salmon industry, comprising collection of information on bioaerosol exposure and health outcomes, as well as health-promoting factors among salmon processing workers. It includes the description of an intervention trial and several substudies.

Background and Previous Research on Salmon Industry Workers

Current knowledge is sufficient to conclude that workers in the fish processing industry have increased risk of developing respiratory diseases and other hypersensitivity responses due to occupational exposure to bioaerosols (ie, bioactive molecules, including fish allergens, enzymes, microorganisms, and endotoxins) [1-3]. We previously reported on an exposure-response relationship between total protein exposure and cross-shift lung function, as well as respiratory symptoms among exposed workers [4]. In addition, we described a case of hypersensitivity pneumonitis caused by proteins from salmon muscle [5]. Impaired respiratory status has also been reported by Douglas et al [6] and Dahlman-Høglund et al [7], and the prevalence of allergy is reported to be 2%-8% [6,8]. Avoidance or reduction of hazardous exposures at the workplace is well established as a key principle for the primary prevention of occupational diseases. For individuals who have developed occupational asthma or hypersensitivity pneumonitis, delayed diagnosis and prolonged exposure may lead to further aggravation and chronification of the disease [9,10]. Early diagnosis with identification of trigger allergens is therefore of great importance.

Hand eczema, representing either an irritant or allergic contact dermatitis, is common in occupations with prolonged use of gloves and wet work [11], and such risk factors are substantial also within salmon processing [12]. Further, contact with fish products after direct contact or deposition of bioaerosols on skin may cause development of irritant contact dermatitis and protein contact dermatitis. Nevertheless, literature concerning skin symptoms within the fish processing industry is scarce [12-14].

As described above, identifying risk factors is a core activity in disease prevention at the workplace. However, there is a growing awareness of the importance of factors influencing well-being at work [15,16]. This implies a shift in focus toward health promotion and more specifically the identification of contributing psychosocial factors. That is, the individual's experience of health-promoting working conditions. To our knowledge, very few studies have so far examined the occurrence of such factors in the working environment in this industry [17].

Background on Salmon Processing and Bioaerosol Exposure

Slaughtering and processing, as well as cleaning and waste handling, generate bioaerosol exposure [4,7,13]. When entering the processing plant, the salmon is stunned before it is killed by cutting the gill arches and transferred to a water tank for exsanguination. Afterward, it is degutted and cleaned of internal organs with a scraper. The salmon is individually assessed and graded according to size and quality. Further on, it is either packed whole in boxes on ice, frozen, or transported to the fileting department. During fileting, the head and backbones are removed. Filets are processed further, depending on the desired end product, for example, removal of skin and cutting to portion sizes. The removed by-products are usually gathered and used for lower-grade foods, such as animal feed or extracted oil.

During salmon processing, bioaerosols are generated along the entire production line outlined above, for example, when water beams hit the fish or surfaces with organic matter. The amount of water used is high in order to meet hygiene requirements and to ensure good workflow. Bioaerosol exposure levels of workers depend on different factors, such as the amount of water used, production activity (number of fish per time unit), distribution mode of water (eg, type and number of water nozzles, jets, spray, high vs low pressure), techniques (manual vs mechanical), type of equipment (open or closed), and shielding for water spray.

It is important to note that fish processing workers are exposed to components that are usually removed from edible parts of the fish before they reach the consumer. Therefore, the importance of specific proteins and epitopes causing allergic sensitization or inflammatory reactions in the occupational setting may be different from what we know from food allergies,

XSL•FO
RenderX

where many proteins are denaturized through food preparation and digestion [18].

Rationale of the Study

Total avoidance of exposure to bioaerosols during salmon processing is not feasible; thus, reduction of exposure is considered the best approach. This is in accordance with the recommendation from the Fifth International Fishing Industry Safety and Health Conference (IFISH5) in 2018 [19] that seafood processing activity that generates excessive bioaerosols must be reduced. To our knowledge, no intervention studies aiming at reducing bioaerosol exposure have been carried out in the salmon industry.

Control measures that aim at reducing bioaerosol generation or increasing bioaerosol elimination are interventions assumed to be efficient in decreasing bioaerosol exposure. Accordingly, the arms of the intervention study that will be described later represent different intervention categories.

Proper exposure assessment, including characterization of bioaerosols, is a prerequisite for establishing preventive measures. Lack of data on the associations between exposure levels and health outcomes has so far prohibited the establishment of occupational exposure limits. A recent European Academy of Allergy and Clinical Immunology (EAACI) position paper [2] addresses the lack of concentration-response data to set internationally accepted occupational exposure limits for airborne food allergens. Also, the progression from allergen exposure to hypersensitivity responses and development of lung diseases, contact dermatitis, and protein contact dermatitis involves a continuum of measurable molecular events, including nonspecific inflammation and immunological responses. More knowledge on mechanisms behind the exposure-induced health outcomes might provide an opportunity for future applications, such as biomarkers for early prediction of disease.

Knowledge on which indicators of health-promoting work environments are present in processing plants in the salmon industry, as well as demographic differences in the perception of health-promotion factors, is lacking. This knowledge is needed both to increase the awareness of and support future health-promoting strategies in this industry.

Aims of the Study

The overall aim is to identify effective and feasible interventions to reduce the exposure to airborne bioaerosols, thereby preventing the development or chronification of respiratory diseases, skin diseases, and allergies among salmon processing workers. Substudies aim to identify and characterize clinically relevant exposure agents, to identify determinants of exposure, and to measure the prevalence of work-related symptoms and disease. Also, the exposure-response relationship between the exposure to individual bioactive agents in bioaerosols and the prevalence of airway symptoms, altered lung function, skin symptoms, and immunological responses indicating hypersensitivity will be investigated. Finally, substudies that aim to identify factors that contribute to a healthy psychosocial work environment in the different processing plants will be conducted.

The data collection will serve multiple stakeholders, ranging from employees, employers, and occupational health and safety personnel to researchers, clinicians, decision-makers, and authorities. Bioaerosol-reducing measures will be assessed, and the most effective approach will be recommended to the industry. In addition, data on exposure characterization, development of better diagnostic tools, follow-up of health examination and symptoms, and the perceived work environment will give new knowledge to basic, clinical, and translational research.

Methods

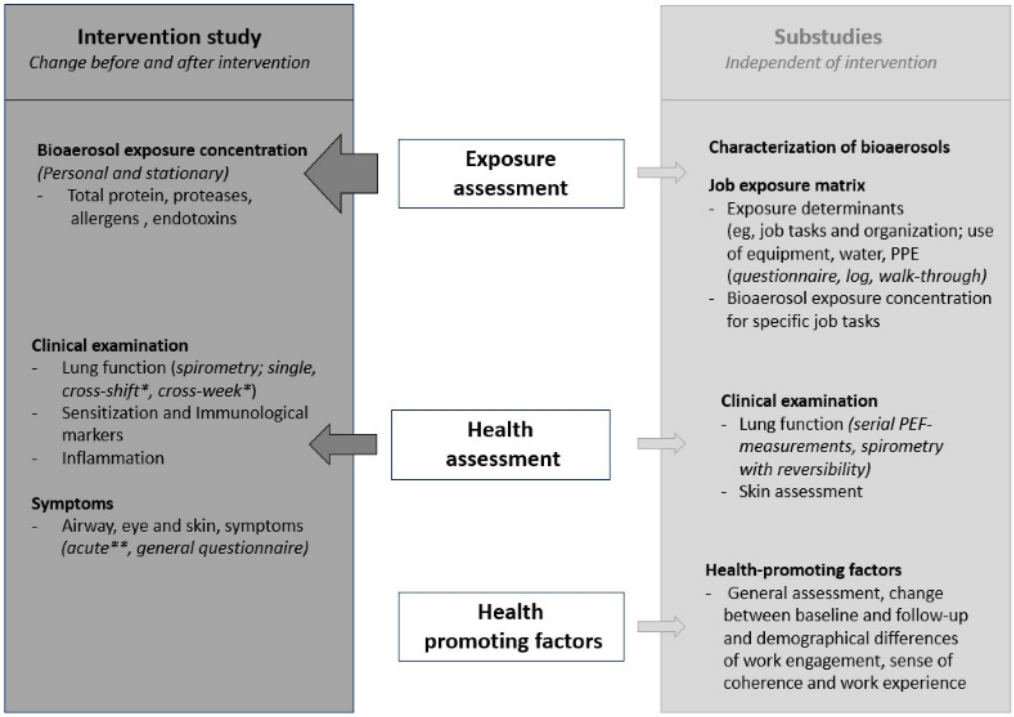
Study Setting and Study Personnel

The study population comprises salmon processing workers from 9 processing plants along the Norwegian coastline, 3 in each of the included geographical areas. The plants are situated in rural areas in western Norway (surrounding area of up to 110 km from Bergen), mid-Norway (up to 190 km from Trondheim) and northern Norway (up to 400 km from Tromsø). The processing plants vary in size, production volume, technology, and number of departments. In some plants the processing line is localized in 1 building, while in other plants the processing steps are separated and localized in several buildings. This can affect both ventilation and other technical solutions which in turn can affect generation and removal of bioaerosols. In some of the factories the processing workers tend to be specialized in specific parts of the processing line (eg, slaughtering, degutting, fileting, and packing), while in others the workers take part in all processes. Shift plans vary in terms of duration of work and breaks. A detailed description of the individual plants, job categories, and tasks will be published in a separate paper.

Study personnel for the fieldwork to gather exposure and health data comprise personnel from the university hospitals and universities of Bergen, Trondheim, and Tromsø. They are competent in occupational hygiene, medicine, nursing, biotechnology, biomedical laboratory science, or sociology, and mainly participate in fieldwork at plants within their own geographical region. Those carrying out health examinations underwent specific training according to study protocols that had been developed within the project group in collaboration with external clinical specialists and in line with national and international guidelines and recommendations. In order to minimize variability in testing techniques, individual study personnel are dedicated to 1 type of health examination whenever possible, and we aim to keep the same personnel within the geographical region and between baseline and follow-up fieldwork.

Data

Overview



This study consists of an intervention trial and related substudies. It will gather extensive information about bioaerosol exposure, health, and work environment for workers in the salmon industry. Fieldwork is carried out at 2 time points that are related to the intervention study: a baseline visit (T_1) and a follow-up visit (T_2). The visits include exposure measurements,

XSL•FO
RenderX

questionnaires, and health examinations, described in more detail below.

For an overview of this comprehensive study, see Figure 1.

Figure 1. Overview of the study with its core, the intervention trial (left side), and its substudies (right side), covering the main topics (middle). Change in health-promoting factors are not part of the intervention study. *Cross-shift and cross-week examinations to be carried out with the same individual before and after shift on Monday and after shift on Thursday; **acute questionnaires to be filled out by the same individual before and after their shift, registering possible symptoms before and during their shift, as well as work tasks. PEF: peak expiratory flow; PPE: personal protective equipment.

Exposure Assessment of Bioaerosols

Sampling Strategy

Full shift personal exposure measurements of airborne bioaerosols are collected in the workers' breathing zone at both T_1 and T_2. Workers are selected based on their work tasks with the aim of covering different areas of the production process. Within each plant, we aim to include 5 job groups in the exposure assessment: workers from slaughtering, fileting, packing, the laboratory or technical department, and the central control room or administration. For the cross-week measurements, 12 workers carry a backpack with personal measuring equipment on Monday and Thursday containing 3 pumps, each connected to a filter containing a sampling head in the workers' breathing zone. The filters are analyzed for inhalable protein, inhalable protease enzymes, fish allergens, and endotoxins. On Tuesday and Wednesday, 12 other workers carry 2 pumps whose filters are analyzed for inhalable protein, inhalable protease enzymes, and fish allergens. Workers register work tasks performed while wearing the backpack, in addition to breaks and other time away from the production area.

Stationary exposure measurements for bioaerosols are performed on Tuesday and Wednesday for a minimum of 6 hours during production. Sampling pumps are placed in plastic containers close to one of the following 3 work stations: cutting of gill arches, degutting, and trimming of filets in plants with filet departments. The filters are analyzed for inhalable protein, inhalable protease enzymes, fish allergens, and endotoxins.

Culturable bacteria and fungi are collected using a microbiological air sampler adjusted to sample 100 L and 250 L or 250 L and 500 L of air. This is done on Tuesday in close proximity to the 3 locations in each plant where the stationary bioaerosol measurements are located.

Temperature and relative humidity are registered every 15 minutes in selected areas of the processing plant throughout the week of data collection using direct reading instruments. The instruments are placed centrally in rooms with salmon production, away from sources of heat or cold.

Analysis of Bioaerosols

Personal and stationary bioaerosol samples are collected and analyzed for inhalable total protein (μg/m^3), inhalable protease enzymes (ng/m^3), fish allergens (as total dust; ng/m^3), and endotoxins (as total dust in endotoxin units; EU/m^3).

Inhalable protein will be quantified by bicinchoninic acid (BCA) assay [20]. Inhalable enzymes will be quantified by zymographic assay [21]. The amount of allergen will be monitored using targeted proteomic analysis using a high-throughput Q Exactive liquid chromatography–mass spectrometry (LC-MS) system [22]. Endotoxin samples will be analyzed using recombinant factor C (rFC) assay [23]).

To identify known and novel allergens, extracts from these filters will be separated by sodium dodecyl-sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and subjected to immunoblotting using sera from workers with immune

XSL•FO
RenderX

globulin E (IgE) reactivity to salmon (>0.1 kU/L). Antibody binding will be graded and presented in allergograms.

Identification of microorganisms to species level will be collected from area sampling on growth media. Quantification and identification of bacteria and fungi will be performed using matrix-assisted laser desorption and ionization-time of flight mass spectrometry (MALDI-TOF MS) as described by Madsen et al [24].

Determinants of Exposure

Determinants of exposure are factors that directly or indirectly affect the environmental concentration of the agent of interest. To register relevant information on potential determinants of exposure to bioaerosols (inhalable protein, allergen, enzymes, and endotoxins) a walk-through survey and meetings with the management during fieldwork to gather technical and process-related information will be performed. In addition, workers carrying the sampling devices will be asked about job tasks performed, number and duration of breaks, and any incidences thought to affect exposure.

Questionnaires

There are 2 types of self-administered questionnaires. The main questionnaire includes questions on demographics, background data regarding health and previous job history, smoking habits, department and job tasks, exposure determinants, respiratory and skin symptoms, allergies, and health-promoting factors. All employees present at work during the T_1 and T_2 visits are intended to be invited to answer this form. Repeated short questionnaires regarding work tasks and acute symptoms from the airways, nose, eyes, and skin will only be filled out by workers carrying out personal exposure measurements.

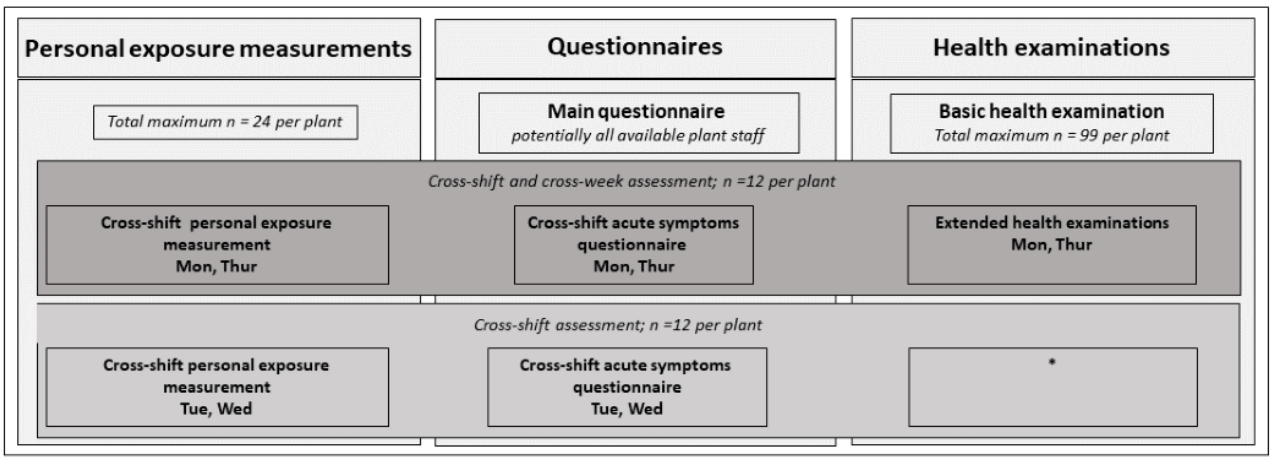
Questionnaires are available in Norwegian, English, Polish, Lithuanian, Slovakian, and Romanian. A Russian version of the main questionnaire is made available at T_2. Validated questions were used whenever possible. For further information, see the “Health Assessment” section.

Distribution of main questionnaires is done either by study personnel, contact persons, or other plant staff, depending on the plant. Those who participate in health examinations usually receive their questionnaire at this time point.

Health-Promoting Factors

Health-promoting factors in the salmon processing industry are assessed in the main questionnaire using a compilation of standardized questionnaire-based instruments, including the Utrecht Work Engagement Scale (UWES) [25], Work-related Sense of Coherence Scale (Work-SOC) [26-28], and Work Experience Measurement Scale (WEMS) [29,30].

Health Assessment



Due to logistical constraints, a maximum of 99 workers at each processing plant are invited to participate in health examinations. They are prioritized based on their work tasks, with production workers being the main focus. For the T_2 measurements, the plants are asked to aim at recruiting workers that participated in the first round when possible. Before the health examinations, participants are to fill out a form ruling out contraindications to examinations and to register their postal address so that pathological findings can be sent directly to the participant.

Health Examinations

Overview

The basic health examinations include skin prick test, spirometry, and blood samples. Workers participating in personal exposure measurements on Monday and Thursday undergo extended health examinations with cross-shift and cross-week assessments that include repeated spirometry, extended and repeated blood samples, and short questionnaires regarding acute symptoms (see Figure 2). Workers participating in personal sampling on Tuesday and/or Wednesday can or cannot undergo basic health examinations, depending on their preference. Health assessments are described in more detail in the following sections.

Figure 2. Overview of the different modes of data collection for both baseline and follow-up visits. Main questionnaires are to be filled out by all available plant staff, whereas exposure measurements and health examinations are restricted in number. All individuals carrying out cross-week exposure measurements on Monday and Thursday also undergo basic health examinations. *These staff carry out cross-shift exposure measurements on Tuesday and Wednesday; they can or cannot undergo basic health examinations.

XSL•FO
RenderX

Lung Function

Spirometry, including forced expiratory volume in 1 second (FEV_1) and forced vital capacity (FVC), is performed as recommended in the American Thoracic Society and European Respiratory Society guidelines [31]. In one of the geographical areas, it is intended to perform a reversibility test in a subsample of participants with abnormal lung function at T_2. In addition, subsamples of about 80 participants with work-related lower respiratory symptoms and 20 participants with no respiratory symptoms from 6 plants are asked to perform serial peak expiratory flow (PEF) measurements for 4 weeks at least 4 times a day. The PEF data will be interpreted with the Occupational Asthma System (OASYS) software [32].

Respiratory Symptoms

Information on symptoms from the lower and upper airways in general, during the past week, or during the past 12 months are collected through the questionnaires comprising standardized questions on respiratory symptoms, allergic status, and malaise from the European Community Respiratory Health Survey (ECRHS). Participants wearing bioaerosol sampling equipment also answer questionnaires on acute symptoms from eyes, upper and lower airways modified from Wasserfallen et al [33] before and immediately after ending the work shift [34].

Hand Eczema and Urticaria

Symptoms of hand eczema and urticaria are assessed through the Nordic Occupational Skin Questionnaire (NOSQ-2002). In 1 of the 3 geographical areas, scoring of hand eczema using the Hand Eczema Severity Index (HECSI) [35] is carried out, and skin barrier function (degree of hydration) is assessed measuring transepidermal water loss (TEWL) [36].

Immunological and Inflammatory Markers

Blood samples are collected for determination of high-sensitive c-reactive protein (CRP), total IgE, as well as specific IgE in a pooled screening test of common inhalant allergens (1 for birch, timothy grass, mugwort, alternaria, and cladosporium, and 1 for cat, horse, dog, mites, and rabbit), as well as IgE against salmon, cod, *Anisakis simplex*, and shrimp. As part of the extended health examinations, peripheral blood leukocytes (total and differential count of lymphocytes, eosinophils, and neutrophils), and CRP are assessed cross-shift and cross-week (Monday and Thursday).

Skin prick tests are performed, including commercial tests for seafood components as well as in-house study-specific extracts from salmon components, to map immunological responses to common seafood components that workers are exposed to. The 10 substances tested comprise commercial cod and salmon with its positive and negative controls, as well as study-specific extracts made in the Tromsø laboratory (2 negative controls, raw muscle, mucous from skin, skin, and cooked muscle).

Figure 2 summarizes the different modes of data collection during fieldwork. For questionnaires and registration cards, see Multimedia Appendix 1. More details on different analytical methods and health assessments will be described in detail in future publications regarding the specific topics.

Specifics for the Intervention Trial

The core of the study is a pragmatic parallel group, 3-arm nonrandomized multicenter superiority trial with a 1:1:1 allocation ratio (ClinicalTrials.gov NCT05039229).

Eligibility and Exclusion Criteria for Individual Participants

All workers employed in, and present at, the processing plants at baseline (T_1) and follow-up (T_2) are eligible for answering the self-administered questionnaire. The numbers of invitees for health examinations and individual exposure assessments are limited to a maximum of 99 and 24, respectively, per plant, owing to logistical, financial, and time constraints.

Pregnant participants are excluded from skin prick testing and spirometry, while persons with a history of heart attack or surgical interventions in the eye, stomach, or chest within the preceding 3 months are excluded from carrying out spirometry testing.

Intervention Groups and Content of Intervention Follow-Up

Overview

While the control group will not receive any intervention, there are 2 different intervention arms that imply measures with the potential to reduce bioaerosol exposure for the employees. These intervention arms represent a general intervention category in which details for the actual intervention are to be developed in collaboration with the factory management and staff. Their involvement ensures local knowledge, including local-specific characteristics, specific location of intervention, other ongoing projects, operation plans, or other aspects that are important to achieve a high effect of intervention measures.

The following sections describe possible alternatives for interventions.

Nozzles Intervention

Nozzles intervention (NZ) is a technical intervention targeting alteration of nozzle types, numbers, or nozzle function along the production line, for example, by manipulation of nozzle dimensions, alteration of operating pressure, or shielding of the nozzle's output stream.

Cleaning of Surfaces Intervention

Cleaning of surfaces intervention (CS) is a behavioral or technical intervention related to cleaning of the workers' personal operating areas (work benches and part of production lines) during work operations or while cleaning floor areas during production hours. This can include increased use of swabbing instead of flushing with water hoses or alterations in use of water hoses for cleaning. Examples for the latter are a reduced flushing frequency, reduction of number of employees executing the work, alterations of hose dimension, or nozzles on hoses.

Control Group

For the control group work is to be carried out as usual without any intervention measures.

XSL•FO
RenderX

Interventions in the NZ and CS groups were to be started between 5 and 8 weeks after baseline measurements at time point T_1. The weeks between T_1 and T_2 are hereafter called "intervention weeks." All 3 arms are followed up in the same way between T_1 and T_2. This includes regular contact by phone or email and 1 physical meeting in intervention weeks 31-36. This midway meeting has a scheduled agenda addressing evaluation of baseline fieldwork, suggestions and input for follow-up fieldwork, status of potential technical changes in the plant, as well as assessment of adherence and employees' experiences of the intervention and study participation.

Adherence to the Trial Protocol and Concomitant Activities

Regular contact, midway meetings, and postintervention measurements are one way of increasing adherence in the intervention groups. Local staff involvement in the eventual design of the intervention also has the potential to increase adherence, especially when behavioral changes are part of the intervention.

Although it was expressed to the plants' management that it is desirable to not engage in any other technical or behavioral changes that could affect the study, there are no restrictions regarding concomitant activities during the study period.

Recruitment of Processing Plants and Individual Participants

Participating plants were recruited through earlier collaboration and by establishing new contacts based on regional knowledge about existing factories.

Each plant has a designated contact person from their own staff who helps with recruitment of individual participants and organization and logistics related to fieldwork at T_1 and T_2; this person keeps in contact throughout the intervention period.

Timeline

Participating factories were recruited during time of funding application. A visit at time point 0 (T_0), 1-3 weeks before baseline measurements at T_1, was used for detailed mapping of the specific factory's infrastructure, a walk-through of the facilities, and for recruiting individual participants through information meetings and distribution of information material. Allocation of intervention groups was done based on this mapping and communicated to the factories in a meeting with company, employee, and safety representatives during the week of baseline measurements at T_1. The companies then had time to discuss details of the intervention activities internally until the expected implementation period (intervention weeks 5-8).

Individual participants are enrolled with individual consent forms for both health examinations and questionnaires. T_1 and T_2 measurements were scheduled within 1 working week (Monday through Thursday). The interval between T_1 and T_2 is set to be 12 months (plus or minus 2 weeks).

Table S1 in Multimedia Appendix 2 gives an overview of the timeline of the intervention study.

Assignment of Intervention

Randomization of intervention arms was not feasible because of different premises of plant infrastructure. The participating plants were therefore allocated to the study arms by the project group, based on meetings and discussion with the local staff and management, and aiming at covering all 3 study arms in each region. Criteria that were taken into account for allocation to a specific arm were prestudy status of awareness and compliance of bioaerosol-reducing behaviors and technical installation, such as use of swabbing; flushing of work areas during work shifts; number, type, and shielding of water nozzles; water pressure; ventilation system; and plans for any alteration of these factors within the study period.

Allocation concealment and blinding was not relevant for obvious reasons.

Data Collection and Management

Database

Study data are collected and managed using REDCap electronic data capture tools hosted at the University Hospital of North Norway (UNN) [37,38]. REDCap is a secure, web-based software platform designed to support data capture for research studies; it provides (1) an intuitive interface for validated data capture; (2) audit trails for tracking data manipulation and export procedures; (3) automated export procedures for seamless data downloads to common statistical packages; and (4) procedures for data integration and interoperability with external sources. The main questionnaire and the questionnaires on acute symptoms are filled out in a self-administered paper form and consecutively scanned into the REDCap database. Analysis results on occupational exposure, inflammation markers (blood), skin examinations, skin prick tests, and spirometry will be put into the system by import or manual plotting.

We use the automatic quality check inherent in REDCap, including checking that critical variables have been entered, checking that the participant has consented, and performing range checks and inspection of outliers. Visual data checks are performed for 10% of the manually plotted data in order to identify transcription errors (skin prick tests and lung function measures). Exposure measurements, differential counts, CRP, and IgE are visually checked (100%) after transfer to Excel (Microsoft Corp) sheets. Excel sheets are imported into RedCap and 10% are checked after this process. In addition, 10% of the main questionnaires that are scanned and directly imported into REDCap will be visually inspected and adjudicated.

The database is administered at UNN and will comprise all the original data from T_1 and T_2, in addition to metadata and syntaxes (statistical coding) for generated variables. Only a limited number of researchers will have access to the data, as well as have permission to do data entries and corrections.

Biobank

Biological specimens (serum and plasma) are transferred and stored in a pseudonymized form in a project specific biobank at UNN for later analyses.

XSL•FO
RenderX

Data Management Group

The project has established a data management group comprising of the principal investigator and leaders of the 6 work packages (WPs). If not covered by the group of WP leaders, each center is represented by up to two other researchers. The data management group will ensure that the publication plan covers the research questions in the protocol, handle applications of data and biomaterial, and make sure that the data management in the project is in compliance with the approvals from the ethical board and General Data Protection Regulation (GDPR). A data management plan further describes data security issues and ethics regarding data management.

Ownership and Use of Data

As this project is a multicenter study, an agreement of ownership and use of data has been completed among the 3 study centers. Agreements between the 3 study centers and the participating plants, ensuring mutual commitment to its collaboration, have also been signed. All data will be archived for 10 years after study termination. Extension of data archives beyond 10 years must seek special approval by the Norwegian ethical committees.

Data Access

The participant-level data set will not be available for public access owing to the GDPR. Metadata and statistical codes (syntaxes) beyond those reported in publications will be available upon reasonable request.

Ethics Approval

This research is carried out in compliance with the Helsinki Declaration of 1975 as revised in 2000, and has been approved by the Regional Committee for Medical Research Ethics North Norway (REK Nord No. 175081). Written, informed consent is obtained from each participant before participation. The consent forms emphasize the right to withdraw from the study at any time without explanation, and that the participants may at any time request that their biological material be destroyed. Information about the study was given orally in an information meeting at T_0 and orally and in written form during fieldwork (T_1 and T_2), with the opportunity to ask questions on-site. Personally identifiable data are entered and analyzed in pseudonymized form by replacing the name with a project-specific identification code, ensuring personal confidentiality. Only the principal investigator and co–principal investigator are given access to a code key that is stored electronically with 2-factor authentication on a safe server at UNN. All personal data will be handled in accordance with GDPR.

The project protocol will ensure that findings reported back to the participants will be analytically valid, clinically significant, and actionable [39,40]. Abnormal lung function measurements, positive skin prick tests, and IgE for salmon-related proteins, and white blood cell count substantially outside the normal range, as well as abnormal white blood cell distribution will be reported back to the participants.

There are ethical concerns related to the common use of workers from outside Norway hired from temporary staff recruitment agencies, as workers with occupational health issues discovered in the project may be lost to follow-up. We will try to avoid this by giving appropriate information at a personal level. All data collection and result analyses will be performed or supervised by experienced investigators trained in good ethical research practices. Scientific and popular scientific publishing will follow the ethical standards for coauthorship and publishing.

Statistical Analysis

Sample Size and Power Analysis

Statistical power was estimated according to the primary outcomes of the project: the change in exposure to inhalable total protein in the breathing zone before T_1 and after T_2 and implementing exposure-reducing interventions in the participating salmon processing factories. A previous study in the Norwegian salmon industry reported a geometric mean exposure of total protein in the processing areas of 2.7 (range 0.76-12.62) μg/m^3 [4]. The study was based on 273 exposure measurements, making it the most extensive study available on assessment of the concentration of total proteins in the salmon processing workers' breathing zone. The crude data allowed us to estimate the corresponding arithmetic mean exposure of total protein (10.0, SD 5.8 μg/m^3). Based on these data we estimated that with a significance level of .05 there is a power of 80% of finding a 40%, 30%, and 20% reduction of exposure in 1 intervention arm if we include 34, 59, and 133 measurements in each of the groups, respectively. Since baseline measurements are performed at all sites before intervention, there will be an even higher statistical power given that we can adjust the exposure levels after intervention for mean baseline values at each site. Based on these calculations, we aimed at including 24 workers with 2 repeated measurements in each of the intervention groups (144 measurements in each group equals a total of 432 measurements) both at baseline and after intervention.

Analysis of Data

Detailed description of statistical analyses will be found in the respective scientific publications. In general, for parametric data displaying a normal distribution, results will be presented as arithmetic means with SDs. For data showing a skewed distribution, as is commonly found for exposure measurement data, the results will be presented as geometric means with geometric SDs. Categorical data will be presented as percentages. In case of missing variables, omission or imputation will be performed depending on the type of data.

In general, risk estimates for the various outcomes with 95% CIs will be estimated using a regression model being appropriate for the analysis in question. The estimates will be adjusted for covariates identified as potential confounders, effect modifiers, and mediators. Tests are considered statistically significant at a *P* value of .05.

Analyses related to the intervention study will be performed according to intention-to-treat, regardless of protocol adherence. Results will be reported in line with CONSORT (Consolidated Standards of Reporting Trials) guidelines.

XSL•FO
RenderX

Intervention Outcomes

The primary outcome, outcome measure (OM) 1, is to evaluate the effect of the interventions (control measures) on reducing salmon processing workers' personal exposure to airborne inhalable total protein (μg/m^3) from T_1 to T_2. Differences in mean concentration of full shift measurements (8 hours) between intervention groups and between intervention groups and control groups will be analyzed.

The secondary outcome measures are the changes from T_1 to T_2 for a range of other exposure and health outcomes. Differences between intervention groups and between intervention groups and control groups will be analyzed. The following secondary outcomes will be assessed:

OM 2: Change of concentration of salmon processing workers' personal exposure to proteases (ng/m^3).

OM 3: Change in total protein (μg/m^3, inhalable aerosol fraction) from stationary measurements in relevant areas of the salmon production line.

OM 4: Change of salmon processing workers' personal exposure to airborne fish allergens, measured by concentration of total aerosol fraction of fish allergens (ng/m^3).

OM 5: Change of salmon processing workers' personal exposure to airborne endotoxins (EU/m^3).

OM 6: Change in salmon processing workers' self-reported symptoms from the upper airways.

OM 7: Change in salmon processing workers' self-reported symptoms from the lower airways.

OM 8: Change in salmon processing workers' self-reported eye symptoms.

OM 9: Change in salmon processing workers' lung function at group level (FEV_1 in percentage of predicted value).

OM 10: Change in salmon processing workers' lung function at individual level (FEV_1/FVC ratio).

OM 11: Change in salmon processing workers' cross-shift lung function (FEV_1).

OM 12: Change in salmon processing workers' cross-week lung function (FEV_1).

OM 13: Incidence of salmon processing workers' sensitization to salmon assessed by serum IgE specific to salmon proteins.

OM 14: Change in salmon processing workers' self-reported skin symptoms.

For more details regarding the intervention study, please see ClinicalTrials.gov NCT05039229.

Other Outcomes of Interest (Substudies)

In addition to outcome measures related to the intervention study itself, substudies will investigate the following:

1. Characterization of airborne bioaerosols from the work environment with respect to inhalable protein, protease enzymes, microorganisms, and microbially derived agents, as well as known and possible novel fish allergens.
2. Development of improved test extracts for seafood allergy diagnostics
3. Exposure-response relationship between bioaerosol exposure and indicators of respiratory health effects, markers of inflammation, and sensitization.
4. Identification of factors that can explain the variation in bioaerosol exposure (determinants of exposure).
5. Evaluation of prevalence and determinants of respiratory work-related symptoms and disease.
6. Evaluation of prevalence of work-related asthma by assessment of respiratory symptoms and work-related airflow limitation by serial measurements of PEF.
7. Cross-shift and cross-week changes in acute symptoms from airways and eyes, as well as inflammatory biomarkers.
8. Status of markers of inflammation and sensitization among salmon processing workers.
9. Presence of indicators of health-promoting working environments in the salmon processing industry, demographical differences in perception, and their consistency through a 1-year follow-up.
10. Evaluation of prevalence and determinants of dermatological work-related symptoms and disease.
11. Objective evaluation of hand eczema and skin barrier function.
12. Investigation of which indicators of health-promoting working environments are present in the salmon processing industry, and whether these are consistent through a 1-year follow-up.
13. Associations between employment conditions and health among migrant workers.

Participant and Public Involvement

Participants and the public have been involved in the design of and recruitment for the study by personal contact and through the reference group. They will be further involved in dissemination activities to ensure that information is given in a way that is clear and easy to understand for the different stakeholders.

Reference Group

The reference group's mandate is to ensure that the project is relevant for the salmon processing workers, is professionally sound and anchored within the industry, and that it is practically feasible and adequately prioritized. Its main role is to give advice in terms of planning, executing, and possibly adjusting the project. The group's purpose it to ensure good collaboration with those who can profit from the project's results, to root the project in the participating factories, as well as to give advice in terms of communication. The reference group does not have any responsibility for the project's progression, goal achievement, or formalities; neither does it have any authority to take decisions. It consists of members of the employer organization the Norwegian Seafood Federations (Sjømat Norge), the employee organization Norwegian Food and Allied Workers Union (Norsk Nærings- og nytelsesmiddelarbeiderforbund), the Norwegian Labour Inspection Authority, an occupational health service, 1 plant

XSL•FO
RenderX

representative from each of the 3 geographical regions, 1 researcher from each of the project group's locations (Tromsø, Bergen, Trondheim), and the principal investigator.

Results

The study was originally planned to begin in fall 2020 but was delayed to September 2021 due to the COVID-19 pandemic. The pandemic further influenced both data gathering and company access due to access restrictions and short-notice sick leaves or quarantines. Among other consequences, this led to delays in baseline measurements, especially in the plants in mid-Norway that had carried out their baseline measurements (T_1) between March and June 2022, 3 months behind schedule.

As the study is still ongoing and data quality checking is not finished, we only have preliminary results from the baseline measurements at T_1. The main questionnaire at T_1 was answered by 740 participants. Due to uncertainties in numbers of distributed questionnaires, it was not possible to calculate a precise response rate, but we estimated its average to be 61% with a range between about 48 (31%) out of 155 and 134 (91%) out of 147. A total of 673 workers participated in the baseline health examinations. Calculating the participation rate is futile, because in several plants there was a much higher number of potential participants than there was capacity to carry out health examinations.

Exposure measurements were undertaken, resulting in over 700 personal measurements (400, 203, and 122 for protein, allergens, and endotoxins, respectively), as well as almost 150 stationary measurements (59, 51, and 34 for protein, allergens, and endotoxins, respectively).

Due to a long time frame of about 2 years between the companies' original consent to participate in the trial and the actual start of the study, technical adjustments were done in several factories before the study start. Thus, the original plan to allocate 3 plants per intervention group was not feasible. One plant planned adjustments to the ventilation system during the intervention period and was therefore not allocated to any of the original intervention groups at T_0. This left only 2 groups for the CS arm, while 3 plants each were allocated to the NZ and control group arms.

Discussion

Preliminary Principal Findings

The response rate could not be calculated precisely as the project group did not have the opportunity to distribute questionnaires personally in all plants. Also, the seafood industry is an industry heavily relying on short-time and temporary labor, making it difficult to keep track of which employees are available for inclusion at any given time, as well as to supply questionnaires in the correct language. Difficulties in calculating exact response and participation rates is a known problem in research concerning occupational health in the seafood industry [41,42], and our average is in line with earlier studies with questionnaires in the Norwegian seafood industry [43].

In general, response or participation rates have been declining steeply over the past decades. It has been suggested to report several types of rates together with careful explanations about how they were calculated, rather than reporting single numbers, in order to give a more nuanced picture of the specific study [44].

Strengths and Limitations

To our knowledge, this is the largest study on a salmon processing worker population assessing exposure to bioaerosols and its associations with respiratory and skin outcomes. Further, it is the first study to strategically test different measures of intervention for reducing bioaerosol levels.

The main strengths of the study include (1) its prospective design, with measurements of bioaerosol exposure and a range of health effects before and after implementation of exposure-reducing measures; (2) its multicenter design and provision of study material in 6 relevant languages, thereby covering a large and representative proportion of workers in the Norwegian salmon processing industry; (3) the large population size, with repeated sampling over consecutive work shifts and with a 1-year interval between measurements, which allows us to assess what affects the variability in exposure; and (4) extensive collection and analysis of active components in the bioaerosols, such as fish allergens, enzymes, and endotoxins, which will allow us to investigate which bioactive molecules and microbial agents are commonly present in bioaerosols produced during salmon processing, as well as respiratory and dermal health and health-promoting factors among salmon industry workers. The repeated measurements design allows analyses of paired samples, reducing the interindividual variation in samples assumed to show small changes in assumed healthy workers.

A special trait of the study is the combination of the assessment of work-related risk factors and work-related health-promoting factors which has so far not been done in the salmon processing industry.

For the health examinations, we cannot rule out a certain selection bias, as participation was restricted due to capacity reasons, as well as because it was voluntary. The latter could result in workers with existing health problems being more prone to participate, in order to find out more about their health, but it could also lead to refusal due to a fear of losing their job. The latter was addressed in the consent form and information meetings, emphasizing that employers of plant staff will not be informed about individual health findings. In any case, it is impossible to say in which direction this possible bias would influence results.

The lack of randomization to interventional categories is in part a weakness, but at the same time a necessary approach in order to make the study feasible. The seafood industry is in constant change and has to react quickly to challenges on the market. Therefore, it is unlikely to meet stable conditions over a longer time period, as this study confirmed. Also, as each plant's infrastructure and needs are so different, it is not feasible to allocate the plants to predefined detailed interventions. Due to limited capacity, it will only be possible to include some of the

XSL•FO
RenderX

participants in the different health examinations, and this will hamper the interpretation of associations between the different outcomes to a varying extent.

Another weakness is the pandemic-related delay in baseline measurements at 3 of the plants, which moved the period under study forward to a timeframe with a potentially lower production rate, warmer weather, and higher probability of pollen exposure outdoors, which could affect exposure measurements, as well as symptoms in the airways and skin. In order to keep circumstances somewhat similar, follow-up measurements at T_2 are planned to be performed around the same time of the year.

All abovementioned factors will be further discussed in future publications for data from this study.

Dissemination Plan

Trial results will be disseminated to participants, the salmon processing industry, researchers, health personnel, authorities, and other interested parties through scientific conferences, publications, reports, and public dissemination measures. There are no publication restrictions, and the results will be disseminated regardless of the magnitude or direction of the effect. Authorship eligibility is determined according to the International Committee of Medical Journal Editors criteria for manuscripts submitted for publication. There is no intention to use professional writers. Data presentation will be performed in a way that ensures confidentiality for individual or workplace-specific data.

Acknowledgments

We would like to thank the project group member Gro Tjalvin from the University Hospital and University of Bergen for her thorough work with the study questionnaires. We further thank all participants for their time spent for collection of exposure measurements, health examinations, and questionnaires and the participating plants for their hospitality, facilitation, and support of the study. We also thank participating staff, other than the coauthors, from the universities and university hospitals of Bergen, Trondheim, and Tromsø for their contribution in data gathering during field studies, as well as Inger Sperstad and Hildegunn Frost from the clinical research department at the University Hospital of North Norway for their help and support with data registration. The project is funded by the Research Council of Norway (project code 302902) with additional funds from the Helse Nord health trust (grant HNF1345-17) and grants from Haukeland University Hospital, Helse Vest health trust, and Borregaard Research Foundation. The publication charges for this article have been funded by a grant from the publication fund of UiT The Arctic University of Norway. The funders had no role in the design or conduct of the study; collection, management, analysis, or interpretation of the data; preparation, review, or approval of the manuscript; or the decision to submit the manuscript for publication.

Authors' Contributions

BEB conceived the study. All authors contributed to the design, planning, and fieldwork of the study, especially BEB, BEH, MRT, ACH, TEE, and MG as work package–leaders of the study. ACH and JK wrote the first draft of the manuscript, supported by the remaining authors.

Conflicts of Interest

None declared.

Abstract

Background: Previous research has suggested that most adults improve their asthma control after a short-term behavioral intervention program to increase physical activity in daily life (PADL). However, the characteristics of individuals who respond and do not respond to this intervention and the medium-term response remain unknown.

Objective: This study aims to (1) identify the characteristics of adult responders and nonresponders with asthma to a behavioral intervention to increase physical activity and (2) evaluate the functional and clinical benefits in the medium term.

Methods: This prospective pragmatic study will include adults with moderate to severe asthma who enroll in a behavioral intervention. All individuals will receive an educational program and an 8-week intervention to increase PADL (1 time/wk; up to 90 min/session). The educational program will be conducted in a class setting through group discussions and video presentations. Behavioral interventions will be based on the transtheoretical model using counseling, incentives, and individual feedback aiming to increase participation in physical activity. Motivational interviewing and guidelines for overcoming barriers will be used to stimulate individuals to reach their goals. Pre- and postintervention assessments will include the following: PADL (triaxial accelerometry), body composition (octopolar bioimpedance), barriers to PADL (questionnaire), clinical asthma control (Asthma Control Questionnaire), quality of life (Asthma Quality of Life Questionnaire), anxiety and depression levels (Hospital Anxiety and Depression Scale), and exacerbations. “Responders” to the intervention will be defined as those who demonstrate an increase in the number of daily steps (≥2500).

Results: In December 2021, the clinical trial registration was approved. Recruitment and data collection for the trial is ongoing, and the results of this study are likely to be published in late 2024.

Conclusions: The intervention will likely promote different effects according to the clinical characteristics of the individuals, including asthma control, age, anxiety and depression levels, obesity, and several comorbidities. Identifying individuals who respond or do not respond to behavioral interventions to increase PADL will help clinicians prescribe specific interventions to adults with asthma.

KEYWORDS

asthma; behavioral intervention; physical activity; responders

Introduction

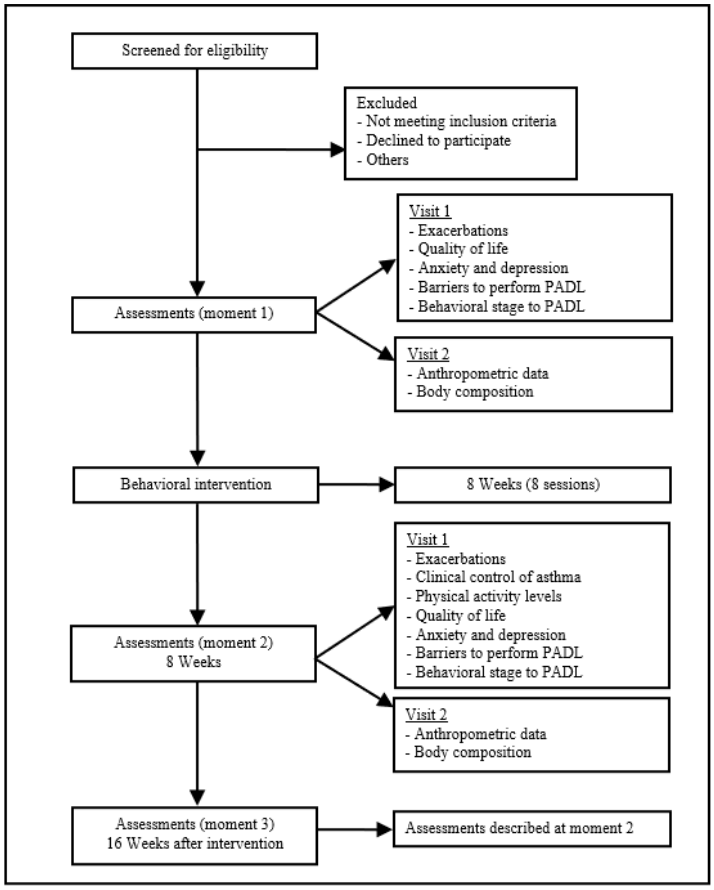
According to the Global Initiative for Asthma (GINA), asthma is a heterogeneous disease characterized by chronic airway inflammation [1]. Asthma is defined by the history of respiratory symptoms, such as shortness of breath, wheezing, chest tightness, and cough, which can vary over time and in intensity, together with variable expiratory airflow limitation [1]. Asthma is a global health problem that affects all age groups. For example, in 2019, about 262 million people were diagnosed with asthma, and 461,000 died from this disease [2]. Moreover, its prevalence is increasing, affecting up to 18% of the population in some countries [1].

Several treatments, both pharmacological and nonpharmacological, are involved in the control of asthma. A supervised, structured exercise program is a nonpharmacological treatment known to improve asthma control [3]. However, despite the proven benefits of exercise, several barriers, such as the lack of space, limited access to pulmonary rehabilitation programs, and decreased motivation to remain physically active after the completion of such programs [4], make interventions to increase physical activity in daily life (PADL) an attractive and viable option [5].

Despite the known benefits of being physically active that have already been shown in this population, individuals with asthma are less physically active than control populations [6]. For instance, a previous study demonstrated that physical inactivity and a sedentary lifestyle are the only extrapulmonary factors associated with asthma exacerbation [7]. In addition, higher levels of physical activity positively impacted the clinical outcomes in this group [6]. Consequently, it is important to develop strategies to modify behavior to increase physical activity and reduce sedentary activities in this population.

The World Health Organization (WHO) recommends that adults perform 150 to 300 minutes of moderate-intensity aerobic physical activity weekly to achieve certain health benefits [8]. In addition, international guidelines [9] and GINA [1] classify, with A-level evidence, people with asthma who engage in regular physical activity to reduce cardiovascular risk and improve their quality of life [1]. A previous study found that a behavioral intervention to increase PADL improves clinical asthma control, sleep quality, and anxiety symptoms in adults with moderate to severe asthma [5]. However, 17% of the individuals did not improve their physical activity level, and 25% did not improve their clinical control after the intervention. Individuals with other chronic respiratory [10], cardiac [11], musculoskeletal [12], and neurological diseases [13] have also been classified as better or worse responders to specific interventions.

Thus, despite the benefits obtained by behavioral intervention aimed at increasing PADL in adults with asthma [5], it is necessary to know the characteristics of responders and nonresponders to guide the management in a more personalized approach. Moreover, the effects of this intervention were only assessed in the short term (immediately after the intervention), and the medium-term effects remained unknown. We hypothesize that the intervention might cause different effects according to the clinical characteristics of the individuals, including asthma control, age, anxiety and depression levels, obesity, and several comorbidities. Therefore, the main objective this prospective cohort study will be to identify the characteristics of adult responders and nonresponders with moderate to severe asthma to a behavioral intervention to increase PADL and evaluate the functional and clinical responses in the short and medium terms.



Methods

Study Design

This prospective cohort study will be conducted at a university hospital that provides specialized asthma treatment. The study protocol was developed following the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist guidelines [14], and the trial was registered at ClinicalTrials.gov (NCT05159076). The study design is illustrated in Figure 1. Individuals with asthma will be enrolled in the trial after a routine medical consultation. Baseline lung function will be checked from the medical records. Eligible participants will undergo an 8-week behavioral intervention protocol to increase PADL and reduce sedentary behavior. First, all included individuals will receive an educational program, followed by an intervention aimed at increasing physical activity. All individuals will be assessed before and after the 8-week intervention and then 16 weeks later. The outcomes assessed will include anthropometric variables, clinical asthma control, health-related quality of life, physical activity levels, anxiety and depression symptoms, exacerbations, body composition, barriers to performing PADL, and physical activity behavioral stages (Figure 1).

XSL•FO
RenderX

Figure 1. Study design. PADL: physical activity in daily life.

Participants

The study will include both male and female adults aged 18 to 65 years with moderate to severe asthma [1] who are not physically active (<150 min of moderate to vigorous physical activity/wk [15] or ≤7500 steps/d) and have partially controlled or uncontrolled asthma (Asthma Control Questionnaire [ACQ] score ≥0.75) [16]. In addition, the following inclusion criteria will be considered: diagnosis of asthma based on the recommendations established by GINA [1], outpatient medical treatment for at least six months, and a stable clinical status for at least 30 days (no hospitalizations, visits to emergency services, or medication changes) [17]. Pharmacotherapy will be maintained throughout the intervention period. After being informed about the possible risks and benefits of the study, participants will be instructed to sign an informed consent form.

Ethics Approval

This study will be performed in accordance with the Declaration of Helsinki. Ethics approval has been granted by the Research Ethics Committee of the Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo (#51929221.7.0000.0068).

Consent to Participate

Written informed consent will be obtained by researchers from all study participants.

Analysis of the Population

Exclusion criteria will include participation in another research study, difficulty understanding any questionnaires, and pregnancy or psychiatric problems that make it difficult to understand the questionnaires and study protocol. If a patient misses any session, they will be contacted by telephone to confirm the reason, and the session will be rescheduled. Attending a total of 6 sessions will be considered the cut-off point to establish patient compliance [18-20]. An intention-to-treat analysis will be performed using the patient's most recent assessment in the case of withdrawal from the study or the absence of data. The intervention will be conducted by a trained physiotherapist who is not otherwise directly involved in the assessments. In case of possible injuries occurring during the intervention period, the individuals will be referred for appropriate treatment.

Procedures

Interventions

The intervention proposed here has been previously performed for individuals with asthma [5]. All individuals will participate in a brief asthma education program with 2 sessions, each lasting approximately 90 minutes. The educational program will be conducted in a class setting in the form of group discussions and video presentations. Educational topics will include asthma pathophysiology, medication and peak flow meter use, self-monitoring symptoms, environmental hygiene [1,21], and physical activity recommendations and benefits [15].

XSL•FO
RenderX

Behavioral interventions will be based on the transtheoretical model using counseling and incentives to increase the practice of physical activity [22,23]. Motivational interviewing, feedback, and guidelines for overcoming barriers will be used to stimulate individuals to reach their goals. Furthermore, individuals will receive a commercially available smartwatch activity monitor (Mi Band 5; Xiaomi) with an alarm that vibrates when the recommended daily number of steps is achieved and if the individual remains sedentary for 60 minutes. The main objective of the behavioral intervention will be to increase the level of PADL at any intensity, and the secondary objective will be to reduce sedentary time. The program will include 8 weekly face-to-face individual sessions, lasting up to 90 minutes each. At the beginning of the protocol, the motivational interview will identify the behavioral stage for physical activity practice using an appropriate questionnaire [24]. In addition, individuals will be asked to complete a daily physical activity diary and sign a contract with the health professional.

The data referring to the respective weeks of use will be reviewed for each behavioral intervention session. Each individual will receive advice based on their smartwatch data. Each session will address different topics related to physical activity practice and sedentary behavior, and individuals will be motivated and encouraged to make behavioral changes. In the last session, a motivational interview will be conducted to identify the individual's behavioral stage, goals achieved, benefits gained, strategies used to overcome the most significant barriers, and proposed attitudes to keep themselves physically active in the long term. The schedule and content of each session are detailed in Table 1. The protocol of Freitas et al [25] will be modified by only changing the activity smartwatch monitor used during the intervention (Mi Band instead of Fitbit) [25].

XSL•FO
RenderX

Table 1. Description of the behavioral change intervention sessions. Reproduced from Freitas et al [25] under CC-BY License [26] . In this study, Mi Band 5 replaces Fitbit Flex 2.

No. Week	Topics covered
Week 1: Lifestyle choices	• Motivational interview to establish an educational diagnosis • Identify the behaviour stage regarding physical activity • Raise awareness of physical activity benefits • Provide the Fitbit Flex 2 and ask them to wear it for at least 3 days each week
Week 2: Why become physically active?	• Raise awareness of the physical activity international recommendations • Deepen the knowledge about the physical activity benefits for patients with asthma • Review Fitbit Flex 2 data of the past week and set one smart weekly goal (number of steps) • Establish the action planning (goal) and sign a contract • Evaluate the confidence of patients in achieving the goal (self-efficacy) • Explain about the use of the workbook, diary and vibration alert
Week 3: Sedentary behaviour	• Raise awareness of the risks of prolonged uninterrupted periods of sitting • Ask them to start monitoring their sitting time (diary in a workbook) • Discuss strategies to stand up/break up the sedentary time, according to the Fitbit Flex 2 vibration function • Review achievement (using the diary and Fitbit Flex 2 data) of the current goal • Discuss progress of the current goal • Set one smart weekly goal (number of steps)
Week 4: Dealing with barriers	• Dealing with barriers (as part of action and coping planning) • Brainstorm the main barriers and possible solutions/modifications • Discuss preferred activities • Invite participants to come up with ideas for walking (progression in duration/intensity) • Congratulate patients on any success (positive reinforcement) and ask them to reflect on any difficulties • Review achievement (using the diary and Fitbit Flex 2 data) of the current goal • Progress the current smart goal (number of steps and sedentary behaviour)
Week 5: Self-control	• Facilitate self-control (how to self-monitor the negative and positive behaviours regarding PA) • Identify the benefits acquired with the lifestyle change and reinforce the commitment to change • Invite participants to come up with ideas to break up the sedentary time • Review achievement (using the diary and Fitbit Flex 2 data) of the current goal • Progress current goal(s) as able/required
Week 6: Setting additional goal	• Review initial goal and discuss the progress of this goal (challenges) • Evaluate the confidence about achieving the new goal (self-efficacy) • Reinforce the health benefits of increased participation in PA and of breaking up sedentary time • Congratulate any success and reflect on any difficulties • Review achievement (using the diary and Fitbit flex 2 data) of the current goal • Set a new smart goal as able/required
Week 7: Being rewarded	• Identify the behaviour stage regarding physical activity • Discuss the change (or not) that was achieved, as well as the benefits acquired with the new lifestyle • Discuss positive reinforcement • Review achievement (using the diary and Fitbit flex 2 data) of the current goal • Set a final goal (number to steps)
Week 8: Goal balance	• Final motivational interview (goal setting, benefits acquired and strategies to overcome barriers) • Reinforce the importance of following through with these changes • Establish a long-term goal to stay physically active

Participant Timeline

The schedule of enrollment, interventions, and assessments is outlined in Table 2. The recruitment of the study participants began in May 2022.

[a]PADL: physical activity in daily life.

Outcome Measures

The primary outcome will be PADL (the number of steps per day) using an activity monitor (by actigraphy). Secondary outcomes will include clinical asthma control, quality of life, body composition and anthropometric data, anxiety and depression levels, asthma exacerbations, physical activity barriers, and behavioral stages for physical activity. This will be a single-blinded (outcome assessor) study in which assessments will be performed before, immediately after, and 16 weeks later.

Primary Outcome: PADL

PADL will be objectively assessed using an activity monitor (ActiGraph GT9X), a device that monitors frequency, intensity, and duration [27] in real time and is considered a sensitive and reliable method [28,29]. This triaxial monitor provides measurements of the amount and intensity of PADL and the monitoring of posture [27,30] through variations in acceleration. The "counts" obtained in a given period of time are linearly related to the intensity of the patient's physical activity in this period [29]. Individuals will be instructed to use the accelerometer, attached to the hip using an elastic belt, for 7 consecutive days. All accelerometers will be initialized to collect data in 60 "epochs" on the 3 axes using ActiLife (version 6.9.5; ActiGraph) software. The following data will be later analyzed using the same software: the number of daily steps and the time spent in sedentary, light, moderate, and vigorous states of activity. Moderate to vigorous physical activity will also be evaluated. Sedentary behavior will be assessed using the same activity monitor.

Secondary Outcomes

Asthma Clinical Control

Clinical asthma control will be assessed using the ACQ, a reliable and validated tool [16,31] that comprises 7 questions [16]. Five questions are related to asthma symptoms (waking up at night, activity limitation, shortness of breath, and wheezing), 1 question is related to rescue medication (short-acting β_2-agonist use), and 1 question is related to lung function (forced expiratory volume prebronchodilator, in percentage of predicted). The questions are scored on a 7-point scale ranging from 0 (no limitation) to 6 (maximum limitation), and the total score is the average of the 7 items, ranging from 0 (totally controlled) to 6 (severely uncontrolled). A cut-off value ≥1.5 indicates poorly controlled asthma, 0.75-1.5 indicates partially controlled asthma, and ≤0.75 indicates fully controlled asthma [16]. A change of at least 0.5 points in the ACQ score is considered clinically significant [32].

Asthma-Related Quality of Life

Health-related quality of life will be evaluated using the Asthma Quality of Life Questionnaire (AQLQ) [33,34]. This questionnaire consists of 4 domains that assess the last 2 weeks: activity limitation, symptoms, emotional function, and environmental stimulation. The AQLQ score ranges from 0 to

XSL•FO
RenderX

7; the higher the score is, the better the quality of life. A difference of 0.5 points is considered clinically significant [35].

Body Composition and Anthropometric Indexes

Octopolar InBody 720 equipment (Biospace) will be used. The weight, fat mass, fat-free mass, visceral adiposity area, and skeletal muscle mass will be calculated. The InBody 720 uses 8 electrodes to assess body composition according to total body water, proteins, minerals, and fat mass. The contact points to connect the electrodes will be cleaned with an electrolytic cloth, according to the manufacturer's instructions. Data will be electronically imported into Microsoft Excel using Lookin'Body 3.0 software (Biospace). Anthropometric data, including height, body weight (Filizola), abdominal, waist, and hip circumference, and waist-to-hip ratio will be measured according to standardized protocols [36,37]. BMI will be calculated by dividing body weight (in kg) by height (in m^2) [38].

Anxiety and Depression

The Hospital Anxiety and Depression Scale (HADS) will be used to assess anxiety and depression symptoms [39]. The HADS is composed of 14 questions divided into 2 subscales, anxiety and depression (7 questions each). Each question ranges from 0 to 3, with a maximum score of 21 points for each subscale. In this study, a cut-off score (≥8) will be used to classify the presence or absence of symptoms of anxiety or depression [40].

Asthma Exacerbations

Asthma exacerbation is defined as an event in which a patient requires urgent action and needs to change the pharmacological treatment [41]. During this study, at least one of the following criteria will be used to define an exacerbation: the use of ≥4 puffs of rescue medication per 24 hours during a 48-hour period, a need for the administration of systemic corticosteroids, an unscheduled medical appointment, and either a visit to the emergency room or hospitalization [21,25,41].

The Behavioral Stage for Physical Activity

The assessment of "readiness to change" will be graded using a questionnaire to evaluate the following behavioral stages for physical activity: *Precontemplation*, *Contemplation*, *Preparation*, *Action*, and *Maintenance* [24,42]. The data will be presented in frequencies.

Barriers to Performing Physical Activity

Barriers to PADL practice will be assessed using a questionnaire that contains the most common barriers in adults [43,44]. The options to answer each question included: never, rarely, sometimes, almost always, and always, and each item score varies from 0 to 4. Higher scores indicate higher barriers.

Sample Size Calculation

A minimum number of 17 individuals in at least one of the groups (responder or nonresponder) was established to detect a difference of 2500 (SD 2500) steps [45] in the primary outcome (α=5%, 1 – β=80%). A sample of 100 participants was established, considering the percentage of nonresponders (17%) as previously observed [5]. Clinical improvement in the ACQ score (≥0.5) [3,32] will be considered a secondary outcome.

Statistical Analysis Planning

Individuals will be stratified as "responders" and "nonresponders" based on an increase of ≥2500 steps [45]. The Kolmogorov-Smirnov test will be used to assess data normality. Cluster analysis will be used to characterize the groups according to individual characteristics. Cluster analysis will be carried out in 2 stages: hierarchical analysis using the Ward method to determine the number of clusters and k-means analysis to group the clusters [46]. Comparisons of clinical, anthropometric, and psychosocial data obtained in the responder and nonresponder groups will be conducted using the 2-tailed *t* test or Mann-Whitney *U* test for continuous variables and the chi-square test for categorical variables. To determine the independent factors associated with the level of PADL (dependent variable, considering clinical control, smoking, obesity, anxiety, and depression as independent variables), multiple linear regression analysis (stepwise forward) will be used. The intra- and between-group comparison at baseline, short term, and medium term will be assessed using the 2-way ANOVA with repeated measures test. The significance level will be adjusted to 5% (P<.05) for all tests. If necessary, intention-to-treat analysis will be performed, as described earlier. SPSS Statistics (version 22.0; IBM Corp) will be used for statistical analysis. Data integrity will be monitored by regularly scrutinizing data files for omissions and errors. Participants will be given an anonymous study ID to protect confidentiality, and only study investigators will have access to the final trial data set.

Results

In December 2021, the clinical trial registration was approved. Recruitment and data collection for the trial is ongoing, and the results of this study are likely to be published in late 2024.

Discussion

Potential Impact and Significance of the Study

The role of exercise training in individuals with moderate to severe asthma has been widely studied in recent years [47,48]. Aerobic exercise training improves physical fitness, health-related quality of life, asthma control, and lung function in this population [46,49]. However, despite the beneficial effects of exercise training, little is known about the behavioral modifications needed to achieve a more active lifestyle [4], and studies have been conducted to address behavioral interventions. Very recently, it was demonstrated that a behavioral intervention aimed at increasing PADL modified the behavior of patients with asthma, resulting in an increase in PADL and improvement in symptoms of the disease [5]. This protocol was developed to identify the characteristics of individuals who respond and do not respond to this type of intervention, which may help guide clinical practice.

XSL•FO
RenderX

Strengths and Limitations of the Study

In addition to the potential to identify the characteristics of responders and nonresponders, this study will also follow up 4 months after training, considered the medium term. These results will allow us to determine if behavioral changes are maintained in the responders over time. The assessment of PADL using accelerometers as a primary outcome is a study strength because it is an objective outcome measure, thus decreasing the risk of bias. The fact that the study will be performed in only 1 hospital center can be considered a limitation.

Contribution and Clinical Applicability

To our knowledge, this will be the first study to assess the characteristics of responders and nonresponders to a behavioral intervention aimed at increasing PADL in adults with asthma. Therefore, the results obtained in the proposed protocol may provide vital information for health care professionals to refer patients with asthma to more specific intervention approaches (behavioral or otherwise) based on their profile as potential responders or nonresponders. Furthermore, this study may clarify whether the potential gains obtained in the short term after the intervention are maintained in the medium term in individuals with moderate to severe asthma.

Conclusion

The behavioral intervention to increase PADL may promote different effects according to the clinical characteristics of the individuals, including asthma control, age, anxiety and depression levels, obesity, and several comorbidities. Furthermore, identifying individuals who respond or do not respond to behavioral interventions to increase PADL will help clinicians prescribe specific interventions to adults with asthma.

Acknowledgments

The Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) sponsored FFdL and CRFC (grants #150845/2021-9 and #312.279/2018-3, respectively). The São Paulo Research Foundation (FAPESP) sponsors FFdL, DHAP, and CRFC (grants #2021/04198-6, #2021/03745-3, and #2018/17788-3).

The study funders (FAPESP and CNPq) are public research foundations and do not have any influence on the study's results, including data collection; the management, analysis, and interpretation of data; or writing of the manuscript.

Abstract

Background: Since they are key witnesses to the systemic difficulties and social inequities experienced by vulnerable patients, health and social service (HSS) professionals and clinical managers must act as change agents. Using their expertise to achieve greater social justice, change agents employ a wide range of actions that span a continuum from the clinical (microsystem) to the societal (macrosystem) sphere and involve actors inside and outside the HSS system. Typically, however, clinical professionals and managers act in a circumscribed manner, that is, within the clinical sphere and with patients and colleagues. Among the hypotheses explaining this reduced scope of action is the fear of reprisal. Little is known about the prevalence of this fear and its complex dynamics.

Objective: The overall aim is to gain a better understanding of the complex dynamic process leading to clinical professionals' and managers' fear of reprisal in their change agent actions and senior administrators' and managers' determination of wrongdoing. The objectives are (1) to estimate the prevalence of fear of reprisal among clinical professionals and managers; (2) to identify the factors involved in (a) the emergence of this fear among clinical professionals and managers, and (b) the determination of wrongdoing by senior administrators and managers; (3) to describe the process of emergence of (a) the fear of reprisal among clinical professionals and managers, and (b) the determination of wrongdoing by senior administrators and managers; and (4) to document the legal and ethical issues associated with the factors identified (objective 2) and the processes described (objective 3).

XSL•FO
RenderX

Methods: Based on the Exit, Voice, Loyalty, Neglect model, a 3-part sequential mixed methods design will include (1) a web-based survey (objective 1), (2) a qualitative grounded theory design (objectives 2 and 3), and (3) legal and ethical analysis (objective 4). Survey: 77,794 clinical professionals or clinical managers working in the Québec public HSS system will be contacted via email. Data will be analyzed using descriptive statistics. Grounded theory design: for each of the 3 types of participants (clinical professionals, clinical managers, and senior administrators and managers), a theoretical sample of 15 to 30 people will be selected via various strategies. Data will be independently analyzed using constant comparison process. Legal and ethical analysis: situations described by participants will be analyzed using, respectively, applicable legislation and jurisprudence and 2 ethical models.

Results: This ongoing study began in June 2022 and is scheduled for completion by March 2027.

Conclusions: Instead of acting, fear of reprisal could induce clinical professionals to tolerate situations that run counter to their social justice values. To ensure they use their capacities for serving a population that is or could become vulnerable, it is important to know the prevalence of the fear of reprisal and gain a better understanding of its complex dynamics.

KEYWORDS

change agency; fear; professional practice; retaliation; social justice

Introduction

As they are in regular contact with patients who are vulnerable or at risk of becoming vulnerable, health and social services (HSS) professionals are often the first to see the systemic difficulties and social inequalities these patients encounter. These professionals are then called upon to act to defend the rights and promote the social inclusion of these patients, in other words, to assume the role of change agent [1-6]. From both a professional [1-6] and an ethical [7] perspective, this role is not optional, it is an obligation. Clinical managers (eg, department heads and coordinators), who are usually HSS professionals [8], also take on this role. In times of uncertainty (pandemic and disaster), it is all the more critical to act as a change agent because of increasing inequities, including in HSS [9,10]. The COVID-19 pandemic revealed or exacerbated existing social and health inequities in populations at risk of increased vulnerability, including seniors and people with disabilities, chronic illnesses, or mental health issues [9,10]. Using their expertise and influence to achieve greater social justice [7], change agents employ a wide range of actions that span a continuum from the clinical (microsystem) to the societal (macrosystem) sphere and involve actors both within and outside the HSS system [11]. To increase social inclusion and justice for people with heightened vulnerability, however, the clinical actions typically mobilized (such as advocating for a patient's choices in a team meeting) are not enough [12]. In light of the systemic issues that persist in HSS, including ableism, ageism, and racism [13], social actions such as advocating to policy-making bodies, serving in an official capacity within an advocacy organization, or speaking out in public [11] are also necessary to stimulate positive systemic change.

Typically, HSS professionals and clinical managers act as change agents in a circumscribed manner, at the clinical level and with patients and colleagues. For example, in a quantitative cross-sectional study [14], the change agency practice of occupational therapist practitioners and clinical managers included little social action (such as public speaking) and rarely targeted higher level actors in their institution (eg, senior administrators or senior managers) or outside it (eg, senior government officials and elected officials). One of the hypotheses suggested to explain the lack of action outside the clinical sphere is the fear of reprisal. This fear emanates from a risk of retaliation, whether this risk is real or not [15]. Reprisals are "action[s] taken by an individual or group to inflict physical, economic, or other harm in response to an action taken by another" (free translation [16]). They include but are not limited to formal sanctions. Instead of taking action, fear of reprisal may lead clinical professionals and managers to tolerate situations that run counter to their social justice values [12]. In an interpretive qualitative study with change agents recognized as such by their peers, participants reported that having a system that "supports" the agency of professionals is one of the essential elements for carrying out change actions [17]. Thus, to ensure they are using their capacities as agents to serve a population that is or could become vulnerable, HSS professionals and clinical managers should not fear reprisals for their actions to improve social inclusion and justice for their patients; rather, they should feel supported in their change efforts.

Some authors [14,18] suggest that a fear of negative repercussions may be rooted in part in how professionals and their managers interpret the duty of loyalty to their employer [19]. Other potential causes associated with the duty of loyalty include the confidentiality agreement that new employees must sign in some HSS settings, disciplinary proceedings for professional misconduct (eg, Carolyn Strom in Saskatchewan [20]), and disciplinary action taken by the employer (eg, nurses suspended without pay [21]). To our knowledge, no empirical study has specifically examined the fear of reprisal associated with change agents' actions, or sought to understand when and under what conditions this fear arises. Some studies that focused on the change actions of professional practitioners and managers did, however, document part of this reality. In particular, an exploratory qualitative study [22] examined the actions of 39 nurses who were politically engaged in their hospital practice setting. Fear of retaliation by colleagues and managers was reported as a barrier to change actions in the clinical setting. Among the types of retaliation used, participants described

XSL•FO
RenderX

"various forms of harassment, violence (often public), confrontation, intimidation or threats, loss of privilege, and abandonment by colleagues...increased monitoring...sudden deterioration of relationships with their superiors, ongoing tensions, and more frequent sanctions such as 'going to [the superior's] office'... [use of] disciplinary notes, various forms of coercion, such as suspensions and dismissal" [22]. Participants spoke of fear-based management to explain their reluctance to voice their opinions within the HSS system. By analyzing 597 anonymous whistleblower reports from outside the HSS system at the beginning of the COVID-19 pandemic, Perron et al [18] were also able to identify retaliation against nurses, including intimidation, threats, and sanctions. These 2 studies shed light on nurses' perceptions of potential or actual retaliation for acting as change agents. However, it is not clear if this view is shared by all HSS professionals and clinical managers. Moreover, since they are also concerned about a fear of reprisal, the perspective of senior administrators and senior managers regarding what constitutes an improper change agent action must be considered. To date, nothing is known about this perspective.

In "professionalizing" HSS university programs, professional competencies, including those related to the change agent role, are being developed and fostered by a longitudinal, gradual, and explicit deployment of learning activities [23]. This deployment takes place in authentic professional situations [24] involving high ecological validity and increasing complexity [23], drawing on transformational learning [25] and critical consciousness [26], and combined with formative (eg, providing feedback) and summative assessments of competencies through programmatic or longitudinal approaches [27]. Both ecological validity and increasing complexity optimize the preparation of future professionals for their actual practice conditions. This preparation is associated with an increased sense of competence in practice [28] and consequently a greater motivation to act [29]. Further, by increasing their critical awareness [30], authentic educational experiences open up learners to professional transformation [31,32] and allow for reflexivity [33], which may assist in developing skills leading to patient advocacy and participation in social justice initiatives in partnership with community stakeholders. To ensure the ecological validity and increasing complexity of authentic educational activities related to the change agent role in HSS university programs, it is important to gain a better understanding of when and under what conditions fear of reprisal and determination of wrongdoing occur, respectively, in professional practitioners and clinical managers and in senior administrators and senior managers. Knowledge of these processes is crucial to better prepare future HSS professionals to incorporate the change agent role in their practices, and hence support high quality, compassionate, and equitable health and social care. Eventually, professionals trained in this way will help to increase social inclusion and justice for people with heightened vulnerability.

Methods

Objectives and Design

The aim of this study is to gain a better understanding of the complex dynamic process leading to clinical professionals' and clinical managers' fear of reprisal in their change agent actions and senior administrators' and senior managers' determination of wrongdoing. More specifically, the objectives are (1) to estimate the prevalence of fear of reprisal among clinical professionals and managers, overall and by profession and practice setting; (2) to identify the factors involved in (a) the emergence of this fear among clinical professionals and managers, and (b) the determination of wrongdoing by senior administrators and managers; (3) to describe the process of emergence of (a) the fear of reprisal among clinical professionals and managers, and (b) the determination of wrongdoing by senior administrators and managers; and (4) to document the legal and ethical issues associated with the factors identified (objective 2) and the processes described (objective 3).

We will use a 3-part sequential mixed methods design [34]. In the first component, a survey, the prevalence of fear of retaliation in the population under study, that is, clinical professionals and managers in HSS in Québec (Canada), will be estimated (objective 1). This type of design has already been used successfully to estimate the prevalence of this fear among Canadian workers according to different types of occupational health and safety advocacy actions [35]. The aim of the second component, a qualitative grounded theory design, will be to identify the factors involved in the emergence of this fear among clinical professionals and managers and in the determination of a wrongful action by senior administrators and managers in HSS in Québec (objective 2) as well as to describe the process of emergence of this fear among clinical professionals and managers and of this determination by senior administrators and managers (objective 3). Finally, in the third component, a legal and ethical analysis, the legal and ethical issues associated with the factors identified and the processes described will be documented (objective 4). Thus for components 2 and 3, there will be 2 study populations in HSS in Québec: clinical professionals and clinical managers, on the one hand, and senior administrators and senior managers, on the other.

Theoretical Background

This study is based on the *Exit, Voice, Loyalty, Neglect* (EVLN) model [36], which presents 4 possible employee responses to unsatisfactory working conditions. This model is relevant to this study because professionals' ability to act to improve social inclusion and justice for their patients is a function of their practice and thus of their working conditions. In the EVLN model, exit induces the professional to leave his or her job while voice leads him or her to speak up to improve the situation. Loyalty reflects his or her decision to wait. Finally, in neglect, the professional gives up trying to improve the situation and disengages or obstructs. The concept of interest here, namely fear, can be met with silence (nonaction; [37]). Depending on the reason for the professional's "silence" [38], the silence will fall under loyalty (expectation) or negligence (disengagement). For example, as a strategy or due to resignation or fear, the

XSL•FO
RenderX

professional may choose not to act (remain silent). The nature of silence can thus vary according to the characteristics of the situation and the moment [39]. Examples of characteristics and moments are the intensity and immediacy of the fear and the person with whom the professional is dealing (eg, senior manager). This finding is independent of the status of the professional (could be a department head); relatively high status workers are affected [40]. Even among workers hierarchically equivalent to clinical managers, actions may vary depending on the severity of retaliation, the coping strategy chosen, the relative organizational statuses of those involved, and the person's gender. All of these contextual elements will be considered in the development of data collection tools for components 1 and 2. The EVLN model will also enrich the interpretation of the results of the 3 components.

Study Components, Data Collection, and Analysis

Component 1: Survey

Overview

Given the common challenges they face, such as labor shortages [41], waiting lists, and wait times [42-44], as well as the at-risk vulnerable populations they serve, nurses, occupational therapists, physical therapists, social workers, and speech therapists working in the public HSS system will be the target population. In fact, these challenges and patient populations may increase the likelihood of acting or intending to act as change agents. To estimate the prevalence of fear of reprisal (objective 1), we will survey this entire population using a web-based self-administered questionnaire that we will develop.

Development, Validation, and Pretesting of the Questionnaire

To develop the questionnaire, we will use 3 alternative sources of information combined with the EVLN model. This will give us recent examples of situations involving fear of reprisal that are highly relevant to our target population. *Source 1:* we will conduct a review of papers citing fear of reprisal by HSS professionals in the Québec media from January 2015 (last HSS reform) to May 2022 using 2 databases: Eureka and the Canadian Business & Current Affairs Database. The former contains papers from Canadian news media, including periodicals, newspapers, and television and radio transcripts; the latter contains news stories, and radio and television transcripts. *Source 2:* We will collate case law from employment and professional tribunals concerning formal sanctions against HSS professionals and clinical managers from January 2015 to May 2022 from the 2 leading legal databases in Québec, CanLII, and Soquij. This source will provide examples of situations that may cause concern. *Source 3:* We will conduct 4 open-ended exploratory interviews, 2 with 2 union representatives and 2 with 2 association representatives, about their experiences with the relevant situations. For all 3 data sources, we will conduct a summative content analysis [45]. This type of analysis leads to an interpretation of the contextual meaning of specific terms or types of content. Supported by the EVLN model, we will then triangulate the distinctive elements of the reported situations, including change agency actions and manifestations of fear of reprisal. Based on these elements, we will develop survey questions focusing on change agent actions that were considered or carried out and the occurrence of fear of reprisal for these actions. The questionnaire will consist mainly of Likert scale questions (4 levels; from 0: not at all, to 3: completely) and closed multiple choice questions. For example, for actions, 1 question could be: "I have thought about making a claim or I made a claim to a manager regarding a situation of concern for my patients." For the associated fear, 2 questions could be "When I thought about advocating or when I advocated to a manager about a concern for my patient, I feared retaliation" and "If you checked 1 to 3, choose which of the following retaliations you feared." The Delphi method will be used to ensure content and face validity of the questionnaire [46,47]. Further, 10 content experts from various fields (law, management, industrial relations, and HSS) will be consulted during (content validity) and after (face validity) construction of the questionnaire. This systematic method of consultation is particularly useful when empirical knowledge is poor [48]. The consultation will be conducted by email and in successive rounds until a consensus of 80% (n=8) of experts for each question is reached. To characterize the profile of participants, a sociodemographic section (eg, occupation, background, and years of experience) will be added to the validated questionnaire as well as an invitation to participate in component 2 of this study. The questionnaire will then be pretested with 5 graduate students in health or management who have experience as a health professional or clinical manager, respectively.

Data Collection

As recommended by Dillman et al [48], the entire target population will be contacted. Our connections and credibility in the professional community (1 researcher from each profession) will facilitate recruitment. To be recruited, individuals will need to hold a professional or clinical management position, be a member of 1 of the 5 relevant professions, understand French, and have at least 6 months' experience in the public HSS system. From their membership lists, 2 unions (one representing nurses and the other representing occupational therapists, physical therapists, social workers, and speech therapists) will send an email invitation to participate in this study and a link to the survey hosted on LimeSurvey (LimeSurvey GmbH). This strategy will also reach clinical managers. A total of 77,794 clinical professionals or clinical managers working in the public HSS system will be reached: 4125 occupational therapists, 2142 speech-language pathologists, 8895 social workers, 2489 physiotherapists (O Dallaire-Turmel, personal communication, August 13, 2021), and 60,143 nurses [8]. Considering the participation rate for recent surveys of the target population (eg, references [49,50]), we estimate that we will obtain a minimum participation rate between 30% (n=23,338)and 45% (n=35,007).

Analyses

To estimate the prevalence of fear (objective 1) and describe the participants, descriptive statistics (means, SD, frequencies, and percentages) will be used, overall by type of participant, and then by setting, profession, and position (professional or managerial). The data will be analyzed in Excel (Microsoft Corp) and SPSS (IBM Corp) and the analyses will be validated

XSL•FO
RenderX

by all team members. The results will shed light on the elements to be studied in greater depth in component 2.

Component 2: Qualitative Grounded Theory

Overview

We will use a qualitative grounded theory design based on a constructivist perspective [51] with 3 types of participants: clinical professionals, clinical managers (department heads, coordinators), and senior administrators and managers. This type of design enables the exploration and definition of a little-known process (fear of reprisal and determination of reprehensible change agent actions) by taking into account all of the factors involved.

Recruitment and Sampling

To recruit our 3 types of participants, we will use three main recruitment strategies: (1) contact with component 1 participants who have indicated an interest in participating in component 2 (clinical professionals and clinical managers); (2) an email invitation from the *Association des gestionnaires des établissements de santé et de services sociaux* (managers) and the *Association des cadres supérieurs de la santé et des services sociaux* (senior managers); and (3) word of mouth through participants already recruited (clinical professionals, clinical managers, and senior administrators). *Association des gestionnaires des établissements de santé et de services sociaux* represents almost three-quarters of all managers in the HSS system [52] and all senior administrators and senior managers automatically become (unless voided) members of *Association des cadres supérieurs de la santé et des services sociaux* [53]. For clinical professionals and managers to participate in this study, the same inclusion criteria will apply as in component 1. In addition, they must have experienced a situation in which their change agency's actions, either planned or carried out, led to a fear of reprisal. For managers to be included, they will have to hold a management position, understand and speak French, and have at least 6 months' managerial experience in the public HSS system. For individuals recruited by convenience sampling and for each type of participant, we will then use a theoretical sampling technique to vary the heterogeneity of the personal characteristics and situations experienced by the participants. This will be done in successive phases with 2 or 3 participants, according to criteria guided by data analysis needs [54]. We estimate that a theoretical sample of 15 to 30 people will be needed for each of the 3 types of participants to achieve theoretical saturation, that is, the point at which data do not add any new properties to the theoretical concepts identified [55]. This saturation is fostered by comparing and contrasting emerging theoretical concepts with different empirical contexts [54,55].

Data Collection

Each participant will be met digitally on a secure platform (Teams) for a 60-90 minute semidirected, audio-recorded, and transcribed interview. This approach will help to recruit participants from across Québec, offer greater flexibility in the timing of interviews and ensure confidentiality. Based on the results of component 1 and the EVLN model, a semistructured interview guide will be developed for each type of participant, validated by 4 methodological experts (grounded theory) and content experts (health and management) and pretested with 3 graduate students in health and management. To promote theoretical saturation, the guides will be refined following the analysis of each interview. To characterize their profile, participants will also complete the sociodemographic section of the web-based questionnaire in component 1. Throughout data collection, memos (collection and analysis notes) will be used to (1) record preconceived notions (logbook), (2) clarify methodological choices (audit trail), and (3) outline emerging concepts and categories (data source). Memos will thus be used as a source and tool for analyzing the data and interpreting the results [51,54].

Tools

Semistructured interview guides will use open-ended questions to address change agent actions reported, factors involved in the emergence of fear of reprisal (clinical professionals and managers) or determination of wrongdoing (senior administrators and managers), and how that fear or determination emerged (process). For example, questions might be "What actions caused you to fear retaliation?" "Describe what led you, as a result of [this action], to determine that it was wrong"; "You told me that [this factor] led you to fear retaliation. What other [factors], if any, contributed to your fear? Explain"; "What actions did you determine to be objectionable? Explain." These questions will elucidate the specific experience of participants while avoiding the use of preconceived categories [51]. Each guide will be developed according to the principles of Vermersch's [56] explicitation technique. This interview technique aims to make participants' experience of actions explicit, which reduces the risks of post hoc rationalization inherent in the retrospective nature of the method used in this study. Thus, respecting explicitation technique principles adds rigor to the chosen design and increases the credibility of the results.

Analyses

The analyses will be carried out independently for each type of participant. Sociodemographic data will be analyzed using descriptive statistics. Data from interviews will be transcribed using the Teams transcription function and transcripts will be verified against the audiotapes. All the data collected will be analyzed according to the constructivist perspective of grounded theory [51] and, to enrich the analysis [57], in relation to the EVLN model. This flexible and open-ended method makes it easier to understand complex processes [54] such as fear of reprisal and the determination of wrongdoing. The data will be analyzed using a constant comparison process [51]. The strategies used are (1) simultaneous data collection and analysis, (2) coding (open and then selective), (3) comparative analysis methods, (4) use of memos to facilitate analysis of the concepts under study, (5) theoretical sampling to refine theoretical constructs and saturate data, and (6) integration of theoretical structure (ie, updating conceptual links) to facilitate the emergence of a process model. Further, 3 models will be developed initially. The 2 models of the fear of reprisal process will then be compared to identify points of convergence and divergence, leading to an integrated model of fear of reprisal. The points of divergence and convergence between the

XSL•FO
RenderX

integrated model of fear and the integrated model of determination of wrongdoing will also be documented to provide a comprehensive picture of these interrelated processes and form a final integrated process model.

Component 3: Legal and Ethical Analysis

To document the legal and ethical issues associated with the factors identified and the 2 processes described (objective 4), the situations described by the participants in the 3 groups will be analyzed from both a legal and an ethical viewpoint. Specifically, the legal analysis will include a collection of applicable legislation as well as jurisprudence from specialized labor and employment tribunals (notably arbitration awards) and disciplinary bodies (decisions of disciplinary committees and the Professions Tribunal) from the 2 leading legal databases (CanLII and Soquij). From an analysis of the circumstances in which courts and tribunals have concluded that the employer's or the professional association's sanctions were justified, it will be possible to identify situations in which fear of reprisal is legally founded. To understand the role played by the actors' understanding or misunderstanding of the applicable law, these situations will then be compared to the factors involved in the emergence of fear of reprisal among clinical professionals and managers and the determination of wrongdoing among senior administrators and managers. On the ethical front, we will first analyze the same situations using Swisher and Royeen's [58] model. This model aims to conceptually organize a situation's ethical issues into 5 categories: dilemma, ambiguity, distress, temptation, or silence. The issues identified can then be deepened by mobilizing deductive ethical theories (deontology and consequentialism) and inductive ethical theories (ethics of care and axiology) using the Quadripartite Ethical Framework [59,60]. The results of this in-depth ethical analysis of situations mentioned by participants will provide clues to the ethical tools to be developed to improve how practicing and future professionals are trained.

Ethical Considerations

The research protocol has been approved by the Research Ethics Board of the Université de Sherbrooke (Comité d'éthique de la recherche – Lettres et sciences humaines; #2022-3473/Carrier). All participants will be required to provide free and informed written consent [61]. Participants will be able to withdraw from this study at any time without any repercussions. They will also be informed of the confidential nature of the data collected and the procedures followed to ensure confidentiality and anonymity. The data collected, both electronically and on paper, will be secured (on a password-protected computer or in a locked fireproof filing cabinet at the Research Centre on Aging) and only the research assistant, research trainee, and principal investigator will have access to them. To ensure they are not lost, electronic data will also be stored on the Université de Sherbrooke's secured institutional platform accessible only through institutional identification and password by the same team members.

Results

This ongoing study began in June 2022 and will be conducted according to an optimal but realistic 5-year timeline that takes into account the uncertain context related to the COVID-19 pandemic (Table 1). Components 1 and 2 will be completed within a 4-year time frame (2022-2026) while component 3 will be completed in the final year. To ensure rapid knowledge mobilization, dissemination strategies will be employed by the entire team throughout this study.

Table 1. Tasks and timeline by component. This table describes the tasks and timeline for each component (C) of the 3-part sequential mixed-method design research over a 5-year period.

Discussion

Strengths and Limitations

Building on established and new collaborations, the research team has all the interdisciplinary expertise required to conduct this study successfully and ensure effective and relevant dissemination and mobilization of the knowledge developed. In fact, a conscious effort has been made to secure complementary expertise and professional networks. Each profession concerned is represented, and each member has a high degree of credibility in his or her profession and strong ties to organizations related to that profession or to senior administrators and managers. This will undeniably facilitate the recruitment of participants, which is the main challenge of this study. The results should lead to a fleshed-out understanding of the fear of reprisal associated with change agent actions, a phenomenon that is apparently growing in HSS.

Broad Implications

Using a sequential mixed-method design, this study will first establish the prevalence of fear of reprisal among clinical professionals and managers in the public HSS system who are particularly involved with the vulnerable population: nurses, occupational therapists, physical therapists, social workers, and speech therapists. Second, this research will identify the factors involved in the emergence of this fear among clinical professionals and managers and in the determination of wrongdoing by senior administrators and managers. Third, the emergence process of this fear among clinical professionals and managers and this determination by senior managers will be described. Finally, this study will document the legal and ethical issues associated with the factors identified and the processes described. This will provide a better understanding of the complex dynamic process leading to professionals' and clinical managers' fear of reprisal in their change agency actions and senior managers' determination of wrongdoing.

The scientific knowledge developed in this study will help to prepare practicing and future professionals to work in real-world settings. In addition, this knowledge will be useful for university programs both in Québec and globally. These results will also be of interest to professional regulatory boards and associations, unions, and management associations, all of which are concerned with their members' continuing education and quality of practice. Moreover, knowledge mobilization strategies will include the organization of forums (eg, training) to encourage the emergence of actions. Finally, the interest of researchers studying other public services potentially affected by fear of reprisal, such as education and the environment, will also be stimulated.

Acknowledgments

We wish to thank Anne-Marie Breton, Étienne Lavoie-Trudeau, and Carine Bétrisey for their contributions to and collaboration in this study. Annie Carrier and Anne Hudon are *Fonds de recherche du Québec – Santé* junior 1 researchers (#296437 and #35581, respectively). Funding comes from the Social Sciences and Humanities Research Council of Canada (SSHRC; #435-2022-1058), and the Faculty of Medicine and Health Sciences, Université de Sherbrooke's institutional funds.

Data Availability

The research team abides by the Research Data Management Plan of the *Université de Sherbrooke*.

Authors' Contributions

AC drafted the French and English versions of this paper. FB, NDC, FM, AH, MEC, AD, and MB helped draft and extensively revised this paper. All authors approved the final paper and are willing to take responsibility for appropriate portions of the content.

Abstract

Background: The toll associated with suicide goes well beyond the individual who died. This study focuses on a risk factor for veteran suicide that has received little previous empirical attention—exposure to the suicide death of another person.

Objective: The study's primary objective is to describe the mental health outcomes associated with suicide exposure among veterans who served on active duty after September 2001 ("post-9/11"). The secondary objective is to elucidate why some veterans develop persistent problems following suicide exposure, whereas others do not.

Methods: This is an explanatory, sequential, mixed methods study of a nationally representative sample of post-9/11 veterans enrolled in Department of Veterans Affairs (VA) health care. Our sampling strategy was designed for adequate representation of female and American Indian and Alaska Native veterans to allow for examination of associations between suicide exposure and outcomes within these groups. Primary outcomes comprise mental health problems associated with trauma and loss (posttraumatic stress disorder and prolonged grief disorder) and suicide precursors (suicidal ideation, attempts, and planning). Data collection will be implemented in 3 waves. During wave 1, we will field a brief survey to a national probability sample to assess exposure history (suicide, other sudden death, or neither) and exposure characteristics (eg, closeness with the decedent) among 11,400 respondents. In wave 2, we will include 39.47% (4500/11,400) of the wave-1 respondents, stratified by exposure history (suicide, other sudden death, or neither), to assess health outcomes and other variables of interest. During wave 3, we will conduct interviews with a purposive subsample of 32 respondents exposed to suicide who differ in mental health outcomes. We will supplement the survey and interview data with VA administrative data identifying diagnoses, reported suicide attempts, and health care use.

Results: The study began on July 1, 2022, and will end on June 30, 2026. This is the only national, population-based study of suicide exposure in veterans and the first one designed to study differences based on sex and race. Comparing those exposed to suicide with those exposed to sudden death for reasons other than suicide (eg, combat) and those unexposed to any sudden death may allow for the identification of the common and unique contribution of suicide exposure to outcomes and help seeking.

XSL•FO
RenderX

Conclusions: Integrating survey, qualitative, and VA administrative data to address significant knowledge gaps regarding the effects of suicide exposure in a national sample will lay the foundation for interventions to address the needs of individuals affected by a suicide death, including female and American Indian and Alaska Native veterans.

Introduction

Background

Suicide is a public health problem that disproportionately affects US veterans. Veterans are 1.5 times more likely to die by suicide than members of the general population, after adjusting for age and sex [1]. Adjusting for age, female veterans are 2.1 times more likely to die by suicide than female nonveterans [1]. Suicide rates are particularly high in the year following military separation and may remain elevated for at least 6 years following separation [2,3].

Groups at increased risk of suicide may also be at increased risk of *suicide exposure*, defined as knowing someone who has died by suicide. It has been estimated that for each person who dies by suicide, 135 others may be exposed, and up to 50% of them may be intimately and directly affected [4,5]. Those exposed to a suicide death are at increased risk for psychiatric disorders, disordered grief, physical disorders, impaired social functioning, and their own fatal and nonfatal suicide behavior compared with those who are unexposed [6-9]. Consequently, suicide prevention strategies recommend *postvention*, which is the provision of services and support to those affected by a suicide death to facilitate their healing [10]. This study characterizes the postvention needs of veterans during the first 6 years after military separation.

Suicide exposure among military populations is an understudied risk factor for suicide. A scoping review of studies based on military samples identified 6 empirical studies of exposure to suicide death and one study of exposure to suicide attempts [11]. Suicide exposure ranged from 47.1% in a sample of 931 veterans living in Kentucky [12] to 65.4% in a sample of 971 active-duty National Guard personnel in Utah and Idaho [13]. Consistent with studies based on civilian samples, studies of suicide exposure in military samples reported high frequencies of mental health disorders, including posttraumatic stress disorder (PTSD) and disordered grief; suicidal ideation; and suicide attempts among those exposed to suicide compared with those who were unexposed [11].

These studies established that suicide exposure is all too common among military populations. However, they leave unanswered questions foundational to preventing and treating mental health and psychosocial problems among those affected by a suicide death. The studies of suicide exposure in military populations were based on geographically distinct or small samples that did not include a sufficient number of female and racial and ethnic minority individuals to examine potentially critical differences based on sex and race. American Indian and Alaska Native individuals serve in the US military at the highest rate per capita compared with other US racial groups and have the highest suicide death rate, yet American Indian and Alaska Native veterans are not represented in these studies [14,15]. Another limitation is regarding the comparison group selected for extant studies in military samples. With 1 exception [16], studies of suicide exposure based on military samples have compared service members or veterans who knew someone who died by suicide with those who did not. Therefore, the comparison group included individuals who were unexposed to any type of sudden death and those exposed to sudden death from other causes such as natural events (eg, cardiac arrest) or unnatural events (eg, combat and vehicular crashes). An understanding of how a suicide loss differs from other sudden and traumatic losses is needed for the design of postvention interventions [17].

There is also an absence of studies of modifiable moderators that could be targeted to promote healing among those affected by a suicide death. Studies of risk factors following suicide exposure has primarily examined sociodemographic variables, such as family and personal history of psychiatric disorders and suicidal behavior, relationship with the decedent (eg, kinship and perceived closeness), and the number of trauma exposures, none of which are modifiable [7,18]. An additional knowledge gap is that we know almost nothing about help seeking following a suicide death and whether the received services and supports (eg, support groups for suicide death survivors) facilitate healing. The 1 study to examine the effect of suicide exposure on mental health treatment seeking in veterans was based on a small university sample [19].

In summary, the numbers of veterans needing intervention following suicide exposure, the types of problems they are experiencing, and the services and supports that might most benefit them are all unknown.

This Study

This paper describes the protocol for a US Department of Veterans Affairs (VA) Health Services Research and Development–funded study on suicide exposure among veterans within 6 years of military separation. Veterans who have served on active duty since September 2011 are known as “post-9/11” veterans. The study’s primary objective is to describe the mental health outcomes associated with suicide exposure among post-9/11 veterans within the first 6 years of military separation, when their risk for suicide is elevated [1,2]. Our sampling strategy aims for adequate representation of female and American Indian and Alaska Native veterans to allow for the examination of associations between exposure and outcomes

XSL•FO
RenderX

within these groups. Our secondary objective is to elucidate why some veterans develop mental health problems following suicide exposure, whereas others do not. Consistent with the socioecological model of suicide prevention, risk and protective factors are grouped at individual, relational, community, and societal levels [20]. We will include 2 comparison groups—those exposed to sudden death for reasons other than suicide (eg, combat) and those unexposed to any sudden death—to identify the common and unique contribution of suicide exposure to health outcomes and help seeking.

Methods

Study Objectives, Design, and Aims

This is a 4-year, explanatory, sequential, mixed methods study of a nationally representative sample of post-9/11 veterans enrolled in VA health care. The study starts with quantitative data collection and analysis (which is the priority of the study), followed by qualitative interviews. Textbox 1 presents the study aims and hypotheses. Primary outcomes comprise mental health problems associated with trauma and loss and suicide precursors (suicidal ideation, attempts, and planning).

Textbox 1. Study aims and hypotheses.

Aim 1 (1 of the 2 primary aims of the study)

- Aim 1 is to evaluate differences in the prevalence of posttraumatic stress disorder; prolonged grief disorder; and suicidal ideation, attempts, and planning among veterans exposed to suicide compared with those exposed to other causes of sudden death and with unexposed veterans. We will also assess whether prevalence differs based on sex and race.

Hypothesis 1

- The prevalence of posttraumatic stress disorder; prolonged grief disorder; and suicidal ideation, attempts, and planning will be high in veterans exposed to suicide compared with veterans exposed to other sudden deaths and with unexposed veterans, after controlling for closeness with the decedent and other covariates.

Aim 2 (1 of the 2 primary aims of the study)

- Aim 2 is to identify the modifiable moderating factors for the association between suicide exposure and negative outcomes and the modifiable moderating factors for the association between suicide or sudden death exposure and negative outcomes relative to those with neither exposure.

Hypothesis 2

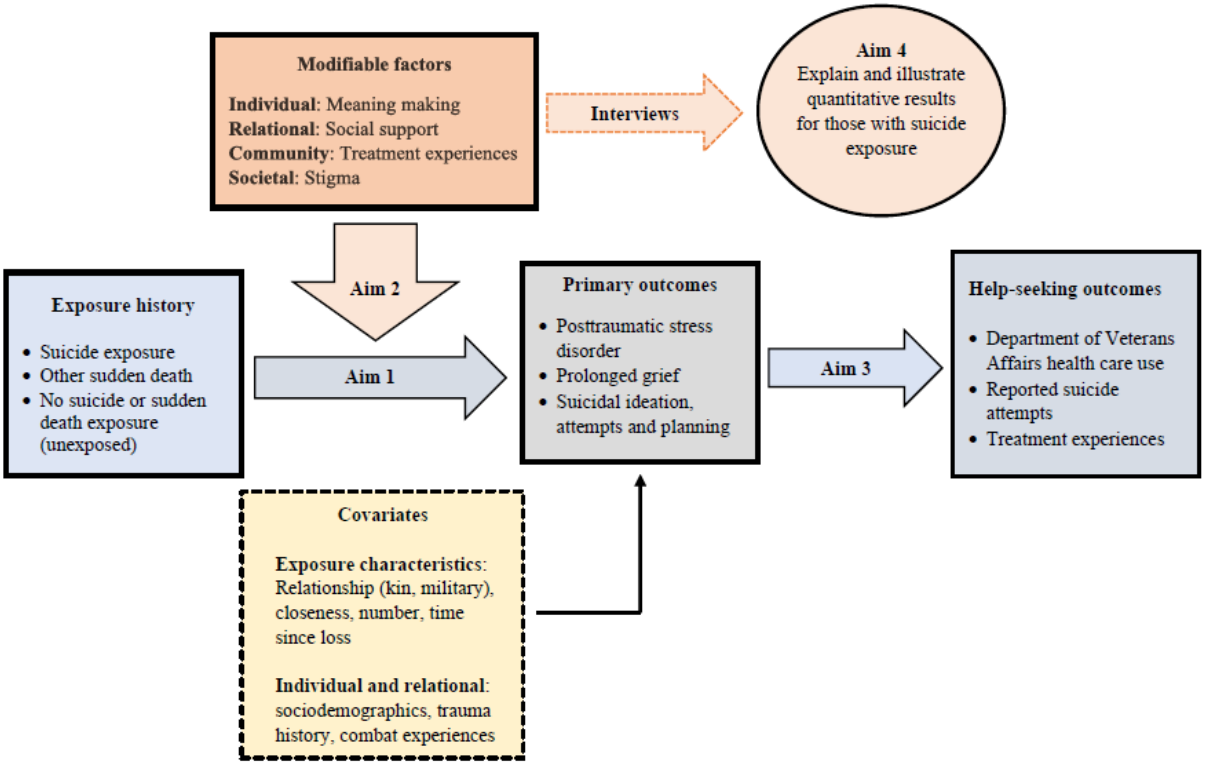
- Social support will buffer, whereas stigma will worsen, the effects of suicide exposure on health outcomes after controlling for closeness with the decedent and other covariates.

Aim 3 (exploratory)

- Aim 3 is to describe the treatment experiences, reported suicide attempts, and patterns of Department of Veterans Affairs service use among those exposed to a suicide death compared with veterans exposed to other sudden deaths and with unexposed veterans. We will also explore differences based on sex and race.

Aim 4 (explains and illustrates aim 2 findings among those exposed to suicide)

- Aim 4 is to contextualize the quantitative findings from aim 2 through interviews with a purposive sample of veterans exposed to suicide. The interviews will focus primarily on modifiable factors at each level of the socioecological model of suicide prevention to better understand the targets for intervention for people affected by a suicide loss.



Primary data collection will be implemented in 3 waves. During wave 1, we will field a brief survey to a stratified random sample drawn from the population of post-9/11 veterans to assess exposure history (suicide, other sudden death, or neither) and exposure characteristics (eg, time since exposure and closeness with the decedent; N=11,400 participants). This will provide prevalence estimates for suicide exposure among post-9/11 veterans. During wave 2, we will survey a stratified random sample of wave-1 participants (4500/11,400, 39.47%) to assess health outcomes, covariates, and moderators. Female and American Indian and Alaska Native veterans will be oversampled in both surveys. During wave 3, we will interview a purposive subsample of 32 participants with a history of suicide exposure to understand how and why potential moderators affect outcomes. We will supplement the surveys and interviews with VA administrative data identifying diagnoses, reported suicide attempts, and health care use.

Conceptual Framework

Figure 1 presents the study's conceptual framework. Aim 1 examines differences in outcomes based on exposure history (suicide exposure, other sudden death exposure, or neither), controlling for covariates. Aim 2 examines the moderating effect of modifiable factors, again adjusting for covariates. Aim 3 explores interventions and supports received for identified mental health problems and whether they differ based on exposure history. Aim 4 will help explain and illustrate aim 2 findings for those affected by a suicide loss to further inform interventions.

Participant Selection and Recruitment and Data Collection

Study Population

The study population consists of post-9/11 veterans within 6 years of military separation, who are enrolled in VA medical care.

Self-Administered Surveys

The wave-1 survey assesses suicide and other sudden death exposure history and willingness to consider participating in a follow-up web-based survey. We used data from the VA's data repository, the Corporate Data Warehouse (CDW), to identify the study population, their sex, and their race and to obtain their contact information. The only exclusion criterion is an invalid US mailing address. Veterans in the study population with a valid US mailing address will be stratified based on sex (male or female) and whether they are American Indian or Alaska Native (yes or no).

To allow time for recruitment following sample identification, the recruitment pool includes post-9/11 veterans within 5 years of military separation. As of February 2023, there were 619,216 post-9/11 veterans who were within 5 years of military separation enrolled in VA health care. Of these, 96.82% (599,522/619,216) had valid US mailing addresses. Of those with a valid mailing address, 19.09% (114,424/599,522) were female (gender is inconsistently reported in VA databases and will be assessed as part of this study) and 1.49% (8939/599,522) were classified as American Indian and Alaska Native. We will oversample female and American Indian and Alaska Native veterans, so that female veterans comprise approximately 30% and American Indian and Alaska Native veterans collectively comprise approximately 12% (4% American Indian or Alaska Native female veterans and 8% American Indian or Alaska Native male veterans) of those recruited. The recruitment pool will be updated every 3 to 6 months.

Wave-1 recruitment material will be sent through the US postal service and include a letter that describes the study, a 2-page questionnaire, a postage-paid return envelope, and a pen and note pad as nonconditional incentives. We will append bright-colored Post-it notes to the survey to encourage participation [21]. The notes will be customized for the 4 demographic strata (American Indian or Alaska Native female individuals, American Indian or Alaska Native male individuals, female individuals from other racial groups, and male individuals from other racial groups). The survey coversheet will include a shortened URL and a QR code that recipients can scan if they prefer to complete the survey on the web and a phone number to call if they prefer to complete it over the phone. We will use repeat mailings, emails, and phone calls to encourage participation among nonresponders. The survey can be completed in <10 minutes, as demonstrated by members of the veteran engagement group who provided feedback about the study material. A sample of 11,400 wave-1 participants should provide a sufficiently large pool of veterans in each exposure group for the wave-2 survey. Although we hope to achieve a response rate >50%, response rates to a survey about suicide exposure in this population are not known and will be evaluated over the course of this study.

The wave-2 survey assesses outcomes, covariates, moderators, and experiences of getting help and support for the suicide, sudden death, or another significant loss. Inclusion criteria are responding to the first survey, having a valid email address (provided on the wave-1 survey or identified though CDW), and indicating willingness to consider participating in the

XSL•FO
RenderX

wave-1 survey. Those who meet these criteria will be stratified based on exposure history (suicide, sudden death unrelated to suicide, or neither) and, within exposure history group, sex and whether they have been identified as an American Indian or Alaska Native so that we can monitor wave-2 survey participation rates based on these characteristics and evaluate the possibility of adjustment in our sampling plan or recruitment strategy. We plan to randomly select 1500 participants with suicide exposure, 1500 participants with sudden death exposure but no suicide exposure, and 1500 participants with neither suicide exposure nor sudden death exposure from the eligible wave-1 survey respondents to participant in the wave-2 survey. The selection within each arm will match the sex and race composition targets of the wave-1 survey.

We will recruit those who meet the above mentioned inclusion criteria through email. The email will include information about the study, a hyperlink to the study website with pictures and information about the study incentives, and a URL for the web-based survey. Nonresponders will receive reminder emails, a postcard, and outreach calls. Participants will be able to choose an incentive valued at approximately US $20 after completing the survey. On average, members of the veteran engagement group completed the wave-2 survey in 45 minutes. The target sample size for the wave-2 survey is 4500 participants, with the goal of approximately even distribution across the 3 exposure history groups. The feasibility of achieving that goal will depend on the prevalence of suicide and sudden death exposure and response rates.

We will use Qualtrics Federal Risk and Authorization Management Program electronic survey software (Qualtrics XM) for the web-based surveys. Participants will access the website using a secure, shortened URL link and unique personal identification number assigned to them; protected health information will be kept behind the VA firewall. The Qualtrics surveys use branching logic, required fields, and pop-up warnings to reduce missing data. Participants' survey responses are stored in a web-based database as the participant progresses through the survey.

Interviews

We will conduct qualitative interviews with a subsample of at least 32 of the participants who have been exposed to suicide. Veterans who indicated on the first survey that they were at least somewhat close to a person who died by suicide within the past 5 years will be eligible for inclusion. The 5-year criterion will help ensure that participants can remember the help they received after the suicide loss.

Veterans will be purposively selected for interview after quantitative data collection and preliminary analyses [22]. Half of the interview subsample will be veterans with clinically significant symptoms based on our primary outcomes; the other half will have no clinically significant symptoms. Our purposive sampling strategy will ensure a demographically diverse group of participants in terms of sex, race, ethnicity, and relationship (family member, fellow veteran, friend, etc) with the decedent. Half of the sample will be women (as self-reported in the wave 2 survey) and at least half will be from racial and ethnic minority groups, with oversampling of American Indian and Alaska Native veterans.

We will use mail and email to initiate the recruitment of our interview sample. The study team will call veterans within 1 week of sending the recruitment material to discuss participation and will repeat attempts to contact those selected for recruitment. We anticipate contacting approximately 64 of the wave-2 responders who meet our interview inclusion criteria, to achieve the target sample size of 32 interview participants.

We will conduct semistructured interviews with participants over the phone or through an approved videoconference platform. A team member will conduct the interview while another manages the logistics and takes notes. The interview will focus on the modifiable factors included in the study's conceptual model and measured quantitatively in the second survey. Veterans will also be asked for recommendations that could help other veterans after a suicide loss. Consistent with the explanatory, sequential, mixed methods design, we will use the quantitative findings to inform the content of the qualitative interviews. The semistructured interview guide will be further refined based on feedback from veterans participating in the study's veteran engagement group and from professional experts in postvention and trauma participating in our advisory panel. Interviews are anticipated to last up to 60 minutes.

Stakeholder Engagement

This study has 2 stakeholder engagement panels to ensure that the work is meaningful and useful to the target population, build trust in the study findings and results, and accelerate the uptake and translation of the study findings into clinical practice [23,24]. The first is a veteran engagement group with experience in consulting to researchers about research projects. At the time of proposal development, the veteran engagement group consisted of 10 veteran members varying in health status and personal backgrounds, including 5 female individuals, 4 post-9/11 veterans, 5 racial and ethnic minority individuals (1 American Indian or Alaska Native, 2 African American, 1 Pacific Islander, and 1 Asian), and 1 Hispanic or Latinx veteran. The veteran engagement group provided feedback about the topic and recruitment material during grant development. During the project, they will meet with the research team at least 3 times to provide feedback about the recruitment materials, survey content, and dissemination to veterans. The second panel comprises staff with roles in VA's suicide prevention program, the Mental Illness Research Education and Clinical Center for suicide prevention, and the National Center for PTSD and an expert in prolonged grief disorder (PGD) from outside the VA. This professional advisory panel provided consultation about the topic and its relevance for VA health care, the study-specific risk management protocol, and the survey measures to assess treatment experiences. They will ensure that the study team is aware of relevant policies and initiatives and assist with dissemination to health care system–level stakeholder groups (clinicians, program managers, and operations leaders), as relevant.

XSL•FO
RenderX

Risk Management

Resources are provided to enhance safety and access to mental health resources for all veterans recruited for participation. For example, the recruitment material and surveys include information (either written instructions or a hyperlink) to access the Veterans Crisis Line. Furthermore, the study team will implement a detailed protocol if participants exhibit concerning behavior or express thoughts of self-directed or other-directed violence in written content on surveys or during phone calls or interviews. This protocol includes administration of the Columbia–Suicide Severity Rating Scale Adult Screener for Primary Care [25] and a warm handoff to the Veterans Crisis Line for a positive screen when possible elevated acute risk is identified.

Measures

Factors considered in measure selection were reliability and validity, use in related studies (to facilitate comparison across studies), veteran engagement panel feedback about relevance and acceptability, and participant burden. Secondary and exploratory measures are included to develop a more comprehensive understanding of the effects of suicide exposure and inform future studies.

Exposure History and Characteristics

Questions assessing suicide exposure history and exposure characteristics were drawn from the Military Suicide Research Consortium recommendations for common data elements and modified for clarity based on recommendations from the study's veteran engagement group.

Suicide exposure will be assessed using the question, "Did you personally know anyone who has died by suicide?"

Other sudden death exposure will be assessed using the question, "Did you know anyone who died suddenly from something other than suicide?" The latter question is followed with an explanation, "By 'suddenly' we mean the death was not expected or occurred within a few days. Causes of sudden death include natural disaster, medical illness (such as cardiac arrest or stroke), combat, car crashes, accidents or homicide."

For each exposure type, we will ask 6 questions. Questions 1 and 2 ascertain the number of exposures and year of the most recent exposure. As individuals may have multiple exposures and closeness to the decedent is related to outcomes [26], the remaining 4 questions ask participants to think of the person with whom they were closest who died by suicide or other sudden death while rating closeness to the decedent (5-point Likert scale ranging from "not close at all" to "very close"), perceived impact of the death (5-point Likert scale ranging from "the death had little effect on my life" to "the death had a significant or devastating effect on me that I still feel"), relationship with the decedent (eg, family member or fellow service member), and year of the death of the person with whom they were closest.

Primary Outcomes

PTSD in the past month will be assessed using the PTSD Checklist version 5, a validated 20-item self-report measure to assess the Diagnostic and Statistical Manual of Mental Disorders–Fifth Edition (DSM-5) symptoms of PTSD, with scores ranging from 0 to 80 [27,28]. Participants will be asked to complete the PTSD Checklist version 5 with respect to "the very stressful experience" that is on their mind and bothers them the most, as assessed using the measure of trauma history described in the following section. At the time of protocol development, a score ≥33 was considered to be indicative of probable PTSD [29].

PGD will be assessed using the 10 items from the Prolonged Grief-13–Revised (PG-13–R) that assess DSM-5 Text Revision symptoms of PGD on a 5-point Likert scale, with total scores ranging from 10 to 50 [30]. PG-13–R is a reliable and valid measure of maladaptive grief response consistent with the new diagnosis of PGD. Participants are asked to complete PG-13–R with respect to the "the death that was the most difficult." Following completion of the measure, participants indicate the cause of the death, year of the death, and relationship with and closeness to the decedent. Those who indicate that the cause of death was suicide or other sudden death will not be prompted to indicate closeness to and relationship with the decedent, as both were assessed in the wave-1 survey. A score ≥30 is indicative of probable PGD [30].

Suicide ideation, *attempts*, and *planning* will be assessed using the 4-item Suicidal Behavior Questionnaire–Revised [31], a measure recommended for population-based surveys because of its utility, appropriateness, and psychometric properties [32]. Item 1 assesses lifetime suicide ideation and attempts, item 2 assesses past-year suicidal ideation, item 3 assesses the threat of suicide attempt, and item 4 evaluates the self-reported likelihood of suicidal behavior in the future. We added an item to identify the person to whom participants communicated the threat of suicide attempt (item 3). Response to each item will be used to evaluate the prevalence of lifetime and past-year suicidal ideation, attempts, and planning. We will also compute total scores (range 3-18). Scores >7 are indicative of possible suicide risk in nonclinical samples [31].

Secondary Outcomes of Functioning

Community reintegration will be assessed using the Military to Civilian Questionnaire, a 16 - item self - report measure of reintegration difficulty across 5 domains of functioning [33]. Items are rated on a 5-point Likert scale ranging from "no difficulty" to "extreme difficulty." Total scores range from 0 to 4, with high scores indicating more reintegration difficulty. The scale's factor structure and association with theoretically related measures support construct validity. We are piloting the inclusion of 2 additional items to assess financial difficulty and housing instability or homelessness.

Physical and mental health–related quality of life will be assessed using the Veterans Rand–12 item health survey, an adaptation of the 36-item Medical Outcomes Study health survey that has been extensively validated in outpatient VA populations [34]. Veterans Rand–12 physical component and mental component summary scores are comparable with 36-item versions and standardized to the US population. Scores range from 0 to 100 (mean 50, SD 10).

XSL•FO
RenderX

Secondary Clinical Outcomes

Depression will be assessed using the 8-item Patient Health Questionnaire, a screening measure to assess the prevalence and severity of depression in epidemiological studies that has strong psychometric properties [35]. Total score ranges from 0 to 24, with scores ≥10 indicative of current depression and scores ≥20 indicative of severe depression.

Anxiety will be assessed using the Generalized Anxiety Disorder 7-Item [36,37]. This scale is based on the diagnostic criteria for generalized anxiety disorder described in the Diagnostic and Statistical Manual of Mental Disorders–Fourth Edition, but there is evidence supporting its reliability and validity as a measure of anxiety in the general population [37]. Scores range from 0 to 21, with scores between 10 and 14 indicating moderate anxiety and scores between 15 and 21 indicating severe anxiety. A score ≥10 will be used to identify probable anxiety disorder [36].

Exploratory Clinical Outcomes

Exploratory clinical outcomes are other known risk factors for suicide among veterans [38].

Sleep disturbance and *impairment* will be assessed using the Patient-Reported Outcomes Measurement System Short Form Sleep Disturbance and Sleep-Related Impairment scales. These two 4-item scales (8 items in total) are rated on a 5-point Likert scale and yield total scores that range from 4 to 20 and can be converted to *t* scores, with high scores indicating great sleep disturbance or impairment [39].

Probable alcohol and *drug problems* will be assessed using the Two-Item Conjoint Screen [40]. This screen was included in the Department of Defense Post-Deployment Health Reassessments. A cutoff score of 1 had 0.80 sensitivity and specificity in patients in primary care.

Pain intensity and interference in the past week will be assessed using the 3-item Pain, Enjoyment of Life, and Activity scale. This scale has been found to have good reliability and construct validity [41]. Participants will also indicate the main causes of their pain (eg, a combat injury or a chronic health problem).

Covariates

Sociodemographics assessed using VA administrative data include sex, age, race, time since military separation, VA disability ratings, psychiatric diagnoses, medical diagnoses, and zip code of home residence. Medical diagnoses will be used to compute the Charlson Comorbidity Index scores using International Classification of Diseases–10th Revision codes [42,43]. Zip code will be used to determine region and rurality, which is associated with suicide risk [44]. These measures are available for responders and nonresponders and will be used to adjust for response bias.

Sociodemographics assessed using self-report include marital status, number of times married, education, employment, sexual orientation, and parental status. We will identify race, ethnicity, and gender identity because these variables are incomplete in administrative data. Those identifying as American Indian or Alaska Native will be asked to specify their nation or tribal affiliation, whether they reside in their reservation homeland, and whether they receive health care through the Indian Health Service. We will assess age of entry into the military, military branch and component, rank, and number of combat deployments. We will use single-item questions to assess mental health treatment history (eg, age of first mental health treatment and receipt over the past 12 months). Those who received mental health care within the past 12 months will be asked to indicate the location of care (VA or non-VA).

Trauma history will be assessed using a modified version of the Trauma Screen from the PTSD Diagnostic Scale for DSM-5. Participants indicate the very stressful events that they have experienced or witnessed at any time in their lives from a list of 8 categories (eg, assault, sexual trauma as adult, or child abuse) [45]. A follow-up question asks which of the endorsed "very stressful experiences" is on their mind and bothers them the most.

Combat experiences will be assessed using the 13 items designed to capture experiences commonly encountered during Iraq and Afghanistan deployments that are included in the Millennium Cohort Study, the largest population-based, prospective study of health and well-being in US military history. Items will be summed (range 0-26), and combat severity will be categorized as no combat (0 items), low combat (1-3 items), medium combat (4-7 items), and high combat (8-13 items), as done in previous studies [46].

Potentially Modifiable Factors

Social support will be assessed using the Postdeployment Social Support Scale from the Deployment Risk and Resilience Inventory-2 [47]. This scale measures the extent to which family, friends, coworkers, employers, and community provide emotional and instrumental support. Each of the 10 items is scored on a 5-point Likert scale, with responses ranging from "strongly disagree" to "strongly agree." Total scores range from 10 to 50. The scale has high internal consistency, and associations with mental health outcomes support its construct validity.

Perceived stigma will be assessed using the 10-item version of the stigmatization subscale from the Grief Experience Questionnaire [48]. Items (eg, "feel like the death somehow reflected natively on you or your family") are rated on a 5-point Likert scale, with responses ranging from "never" to "almost always" and total scores ranging from 10 to 50. Consistent with previous studies [48,49], we modified the stem to elicit reactions following the suicide or sudden death of the closest contact identified in the first survey. Those who have had both suicide and sudden death will be asked to select the death that was most difficult for them. Participants in the unexposed group will not complete this measure.

Meaning making will be assessed using the 6-item Integration of Stressful Life Experiences Scale–Short Form [50]. High scores indicate more adaptive meaning made following a loss. The measure has good internal consistency, test-retest reliability, and convergent validity with scales for psychiatric and bereavement distress. A total score ≤20 may be used as a cutoff for indicating problems with meaning made of loss [51]. We

XSL•FO
RenderX

modified the stem to elicit reactions following the suicide or sudden death of the closest contact identified in the first survey. Those who have had both suicide and sudden death will be asked to select the death that was most difficult for them. Participants in the unexposed group will not complete this measure.

Everyday discrimination, an exploratory measure associated with suicide risk [52], will be assessed using the Everyday Discrimination Scale–Short Version [53]. This scale assesses frequency of exposure to 5 types of discrimination in "day to day life" rated on a 5-point scale ("never" to "at least once a week"). An additional item assesses the main reasons (eg, gender, race, and religion) for discrimination experienced at least "a few times a year."

Help-Seeking Outcomes

Treatment experiences for the loss or losses will be assessed using 14 items developed for this study based on the UK survey by Pitman et al [54] for help seeking and support following suicide and other sudden death exposure and recommendations from the study's advisory panel. Participants indicate whether they received interventions or supports after the loss from a checklist (yes or no) and, if received, how helpful it was to them on a 5-point scale ranging from "not at all helpful" to "extremely helpful." They are asked to describe other types of assistance or support they wish they had received and whether they have participated in "an event or gathering to increase awareness of suicide and suicide loss." Participants are instructed to complete this measure with respect to the suicide or sudden death of the person closest to them, as reported in wave 1, or the loss that was most difficulty for them, as identified for PG-13–R. We will derive four binary outcomes from these questions to indicate (1) receipt of any intervention from a medical professional (eg, therapist or physician), (2) receipt of any support from clergy or spiritual leaders, (3) receipt of any informal support or interventions (eg, community members, elders, friends, and family), and (4) receipt of any support or intervention rated as at least "somewhat helpful."

VA Health Care Use

We will extract CDW data about service use for the 12 months before wave-2 survey completion. Service use will be classified as mental health, primary care, and specialty care. We will use procedure codes to classify outpatient mental health care as individual psychotherapy, group psychotherapy, or other. We will use pharmacy data to identify psychiatric medication prescriptions (eg, antidepressant, antipsychotic, lithium salts, prazosin, and benzodiazepines). We will use data from templated notes to identify the use of evidence-based psychotherapies for PTSD, depression, and insomnia among those who meet the survey criteria for these conditions. Outcomes will be binary (yes vs no for each type of service) and continuous (number of appointments per service category and inpatient length of stay over the preceding 12 months).

Suicide attempts reported to VA clinicians will be extracted from the CDW, based on data automatically generated from the Comprehensive Suicide Risk Evaluations and Suicide Behavior and Overdose Report, either of which VA requires for reporting suicide behavior. We will identify nonfatal events using the self-directed violence classification of suicide attempt with injury or suicide attempt without injury, based on self-directed violence classification guidelines developed by the Centers for Disease Control and Prevention and adopted by the VA.

Analysis

Power

The anticipated wave-2 sample size (n=4500) will provide >90% power for a global likelihood ratio test and for pairwise comparisons for a range of considered differences between exposure history groups in the distribution of a binary outcome (hypothesis 1). The configurations considered for the trio of outcome rates in these calculations comprised differences between the middle rate and each of the lower and higher rates corresponding to approximately half of the middle rate. Among female veterans (anticipated n=900), the study should have >82% power. Among American Indian and Alaska Native veterans (anticipated n=540), the global comparisons will have >82% power. Power for the pairwise comparisons will be limited for comparisons involving an exposure history group with very low representation of American Indian or Alaska Native veterans. Power to detect moderation (hypothesis 2) is determined by sample size, prevalence of the exposure history classification, prevalence of the moderator within each group, and outcome rates for the different combinations of exposure and moderator measures. Under different plausible scenarios for these measures, power to detect the interaction ranges from 0.81% to 0.87%.

As discussed previously, little is known about the response rates of veterans to surveys regarding suicide exposure. The study population is sufficiently large that obtaining ≥10,000 respondents for the wave-1 survey is highly likely by sufficiently increasing the selected sample for this aim. The precision of the estimation of exposure rates among this population then will be less affected by sample response rates and sample size than response bias. For wave 2, we may find that those with no exposure are less willing to participate and that the cohort of wave-1 respondents willing to participate in wave 2 is shifted toward those with suicide or other sudden death exposure. In this event, we will likely need to alter the planned analysis to focus on comparing the suicide and other sudden death exposure groups. However, we would expect that the power available for the analyses will be comparable with or larger than the power discussed previously for analyses within female and American Indian and Alaska Native veterans.

Preliminary Analyses

We will construct nonresponse-adjusted, sample inclusion probability–weighted estimates of the prevalence of suicide exposure, sudden death exposure, and the combination of exposures (exposure to suicide and other sudden death) and the prevalence of the study outcomes. We will use administrative data together with the survey sampling strata to develop logistic regression models for the probability of survey response for each survey. We will then adjust the initial survey weights based on the estimated probability of survey response to generate weights for use in analysis. If there is <3% of missing data for

XSL•FO
RenderX

the survey items required for a particular analysis, we will further adjust the weights within classes of individuals with similar response propensities from the same stratum to address missing data. If the amount of missing survey items exceeds 3%, we will use the available survey and administrative data in a chained sequence of regression analyses to impute missing survey items [55]. We will then use the imputed data to implement the weighted analyses described in the following section.

Aims 1, 2, and 3

For aim 1, we will use nonresponse-adjusted, sample inclusion probability–weighted logistic regression analyses for the outcomes with sampling strata and exposure categories as explanatory measures. We will conduct global Rao-Scott likelihood ratio tests to assess the differences in prevalence of the primary outcomes between exposure history groups followed by tests for pairwise differences between groups (hypothesis 1). To assess whether associations between exposure and outcomes persist when adjusting for covariates, we will expand these models to include closeness to the decedent or decedents, an interaction between exposure history group and closeness, and the sociodemographic and trauma history covariates. If there does not appear to be an interaction, we will simplify the model. We will also expand the analyses to include interactions of exposure history group with number of death exposures, time since exposure, and time since military separation to examine whether associations vary with these covariates. We will summarize the differences between exposure history groups using model-estimated odds ratios and CIs.

To assess whether the differences between exposure history groups vary with sex and race, we will use similar Rao-Scott likelihood ratio tests to compare weighted logistic regression models incorporating exposure history, sex or race, the respective interaction with exposure, closeness of decedent, and sociodemographic and trauma history covariates with models that do not include the exposure by sex or exposure by race interaction. Additional analyses will examine the differences in total scores (continuous measures) for the outcomes, modifying the abovementioned analyses to use weighted multiple linear regression models. Similar likelihood ratio tests will be used and the differences between exposure history groups will be summarized with model-estimated least square mean differences and corresponding CIs. We will also conduct a similar set of analyses to explore whether the prevalence of the outcomes differ based on the use of VA services (any and mental health) in the previous year.

For aim 2, we will add the potential modifying factor (eg, social support or stigma for hypothesis 2) and the interactions with exposure history and with decedent closeness to the model developed for aim 1. We will use Rao-Scott likelihood ratio tests to assess whether the association between exposure history and a given outcome varies across levels of the moderating factor or across levels of exposure and decedent closeness. If we obtain significant results for a test of an interaction between exposure and a moderator, model-estimated associations between the moderator and the outcome within exposure history groups and additional pairwise contrasts between exposure history groups conditional on the various values of the moderator will be examined.

For our exploratory aim 3, we will create summary measures of treatment experiences, reported suicide attempts, and VA service use and then, similar to aim 1, construct weighted estimates of the prevalence of these treatment measures, along with 95% CIs, in the exposure history groups and compare these using weighted logistic regression analyses with Rao-Scott likelihood ratio tests. Within exposure history groups, among those we have identified as meeting the survey criteria for the clinical conditions, we will estimate the population rates of receiving VA mental health care (yes, no, number of sessions, type of therapy, and report of attempt) during the year before the survey using finite population sampling domain estimation methods. We will then assess whether these vary based on sex and race.

Aim 4 Qualitative Analysis

We will use a qualitative data management software package to facilitate the coding and retrieval of qualitative themes. Coders will apply a priori–determined, first-level codes that correspond to the interview domains (eg, social support, professional help, and stigma). We will use a constant comparative analysis approach in which we begin to review data as soon as the first interviews are conducted to permit the identification of emerging issues to be included where appropriate in the ongoing interviews. We will review all proposed codes in weekly meetings to derive an initial codebook. We will elaborate upon the codebook and adjust content as each interview is reviewed, through practice coding and interview reviews until we have finalized the code list. Before independent coding, we will practice coding as a team until we reach consensus and record all decisions to create an audit trail. In addition, we will double code at least 20% of the transcripts, ensuring that each coder codes at least one of the transcripts of each of the other coders and ensure acceptable interrater reliability. Discrepancies will be resolved in team meetings. After coding is complete, we will produce code reports that include all subcodes for each selected first-level code and by veteran mental health status (clinical vs nonclinical interview groups). We will use the code reports to synthesize patterns of responses related our domains of inquiry into larger themes.

For aim 4, interpretation will involve the identification of differences in modifiable factors across our clinical and nonclinical groups. For example, we will examine whether veterans who differ in outcomes describe differences in how people in the community supported them or in their treatment experiences. We will examine convergence and expansion across the quantitative and qualitative data [56].

Ethical Considerations

The Minneapolis VA Health Care System Insitutional Review Board (IRB) granted this protocol (reference number 1676462) an exempt determination under category 2 (research that involves surveys or interview procedures) subparts 2 (disclosure would not be harmful) and 3 (IRB conducts limited review to make the required determination that there are adequate provisions to protect the privacy of participants and to maintain

XSL•FO
RenderX

the confidentiality of data). The IRB also granted a Waiver of Health Insurance Portability and Accountability Act Authorization for all study procedures involving the collection or use of protected health information. The overseeing Research and Development Committee has reviewed and approved all amendments or modifications to study procedures and materials.

Results

This project began on July 1, 2022. The study team includes experts in suicide exposure, suicide prevention, traumatic stress, epidemiology, survey development and methods, statistics, programming, and VA administrative data. A veteran engagement group and an advisory panel of professional experts provide additional guidance throughout the study. Milestones so far include the identification of the sampling frame, implementation of the first phase of the stratified random sampling plan, refinement and preparation of the recruitment material and surveys, and piloting of survey methods in a sample of approximately 800 veterans to identify and resolve challenges before scaling up. Pilot enrollment began on May 1, 2023.

The study's funding period will end on June 30, 2026. The veteran engagement group will help us identify the findings that are most important to veterans, including study participants and dissemination vehicles (eg, the study website, publications for service members and veterans, and veterans service officers). We will collaborate with the professional advisory panel to disseminate key findings to VA operational stakeholders and clinicians. Findings will be disseminated to the scientific community through publications and presentations.

Discussion

Summary

This is the only national, population-based study of suicide exposure in veterans and the first one designed to study differences based on sex and race. It is an initial, crucial step in addressing the dearth of studies of suicide risk in American Indian and Alaska Native veterans and fills the knowledge gaps identified by the US National Alliance for Suicide Prevention, including the need for reliable and valid estimates of suicide exposure and the impact of exposure to suicide [17]. This information is needed to identify postvention strategies and interventions that address the needs of those affected by suicide loss or combinations of suicide, other losses, and trauma and whether these needs differ based on sex and race.

We are prioritizing outcomes associated with trauma and loss. However, the rich data set this study creates may yield novel information about the effect of suicide exposure on health and functioning that have not been hypothesized. Analyses involving secondary and exploratory measures and VA health care use may pave the way for full understanding of the effects of suicide loss and help identify those at risk for being most affected. As such, we anticipate that this data set will lay the foundation for studies that go beyond the aims of this project. Possibilities for future studies include epidemiologic studies of outcomes beyond those we are able to examine as part of this project (eg, the longitudinal course of physical and mental health effects of suicide loss and other sudden death) and, alternatively, studies that prioritize qualitative data collection and analysis to obtain a more complete understanding of risk and protective factors following exposure to suicide or other sudden and traumatic death.

A challenge for studies in this area is that veterans may have been exposed to >1 suicide or other sudden death from combat or other reasons [9,16]. Consistent with previous studies, we are asking participants to focus on the suicide and sudden death of the person with whom they were closest because this is the loss that is likely to have the most significant effect on them [26]. Relatedly, participants may have PTSD owing to the suicide exposure or another stressor, and they may have PGD owing to suicide exposure or another death. To provide more clarity regarding the sources of their symptoms, we are asking participants to specify and use as a referent the trauma and death that was the most difficult for them. However, participants may have difficulty in separating their response to 1 loss or trauma from their responses to others. In our analyses, we will examine the timing, number, and combinations of exposures in an effort to better understand how multiple losses and trauma of different types interact to affect outcomes.

We are assessing exposure history through survey because we are not able to ascertain exposure history through medical records. Challenges associated with survey data collection include the possibility that response rates may be lower than expected and vary based on exposure history, sex, or race. In anticipation of these potential problems, we will recruit in batches, closely monitor participation rates, and adjust the recruitment methods and the sampling plan in an effort to approximately achieve the desired number of wave-1 and wave-2 responders per stratum. In the analysis, we will use inverse probability weights to help account for differential responses and weigh estimates back to the population. We will also report all results with CIs as measures of precision, irrespective of *P* values, so that our results can still lay a foundation for future studies.

We also recognize that the prevalence of suicide exposure, other sudden death exposure, and neither may be different than expected based on previous studies with veterans from earlier service eras [12]. If the wave-1 survey does not provide an adequate number of veterans in each exposure history group for our second survey, we may have to adjust our analysis plan. This may occur if, for example, the proportion of post-9/11 veterans unexposed to either suicide or sudden death is very low.

This study does not allow us to examine the longitudinal course of symptoms in our exposure history groups, an important topic with clinical implications. Unfortunately, additional waves of data collection would not be feasible within the funding mechanism's budget cap. We will, however, be able to evaluate the effect of time since exposure in our analyses. A limitation associated with our sampling strategy is the lack of inclusion of post-9/11 veterans who are not enrolled in VA health care and are at high risk for suicide [1]. However, as not all enrolled veterans use service regularly, we will be able to compare those

XSL•FO
RenderX

who have with those who have not used VA health care in the previous year.

Despite these limitations, this study addresses knowledge gaps and will direct VA and the field toward an understanding of the most critical outcomes among veterans exposed to suicide and the mechanisms that may lead to deleterious outcomes and lay a foundation for the development and implementation of effective postvention interventions.

Conclusions

This study addresses an understudied risk factor for suicide—suicide exposure. Integrating survey, VA administrative, and qualitative data to address significant knowledge gaps regarding the effects of suicide exposure will lay the foundation for interventions to address the needs of post-9/11 veterans affected by a suicide death, including female and American Indian and Alaska Native veterans. By advancing the scientific understanding of suicide loss compared with other sudden deaths, findings have the potential to also inform postvention research and interventions more broadly.

Acknowledgments

This study is funded by the US Department of Veterans Affairs Health Services Research and Development (grant SDR 21-046).

Conflicts of Interest

None declared.

Abstract

Background: Military services provide a unique opportunity for studying resilience, a dynamic process of successful adaptation (ie, doing well in terms of functioning and symptoms) in response to significant adversity. Despite the tremendous interest in positive adaptation among military service members, little is known about the processes underlying their resilience. Understanding the neurobiological, cognitive, and social mechanisms underlying adaptive functioning following military stressor exposure is essential for enhancing the resilience of military service members.

Objective: The primary objective of the Advancing Research on Mechanisms of Resilience (ARMOR) longitudinal study is to characterize the trajectories of positive adaptation among young military recruits in response to basic combat training (BCT), a well-defined, uniform, and 10-week period of intense stress (aim 1), and identify promotive and protective processes contributing to individual variations in resilience (aim 2). The secondary objective is to investigate the pathways by which neurobehavioral markers of self-regulation assessed using electroencephalography and magnetic resonance imaging contribute to adaptive trajectories (aim 3).

Methods: ARMOR is an ongoing, prospective longitudinal cohort study of young military recruits who recently joined the National Guard but have not yet shipped out for BCT. Participants (N=1201) are assessed at 5 time points over the initial >2 years of military service beginning before BCT (baseline) and followed up at 2 weeks and 6, 12, and 18 months after BCT. Participants complete web-based questionnaires assessing vulnerability and protective factors, mental health, and socioemotional functioning at each time point and a battery of neurocognitive tests at time 0. A subset of participants also complete structured diagnostic interviews and additional self-report measures and perform neurobehavioral tasks before and after BCT during electroencephalography sessions and before BCT only during magnetic resonance imaging sessions.

Results: This UG3/UH3 project was initially funded in August 2017, with the UG3 pilot work completed at the end of 2018. The UH3 phase of the project was funded in March 2019. Study enrollment for the UH3 phase began on April 14, 2019, and ended on October 16, 2021. A total of 1201 participants are enrolled in the study. Follow-up data collection for the UH3 phase is ongoing and projected to continue through February 2024. We will disseminate the findings through conferences, webinars, open access publications, and communications with participants and stakeholders.

Introduction

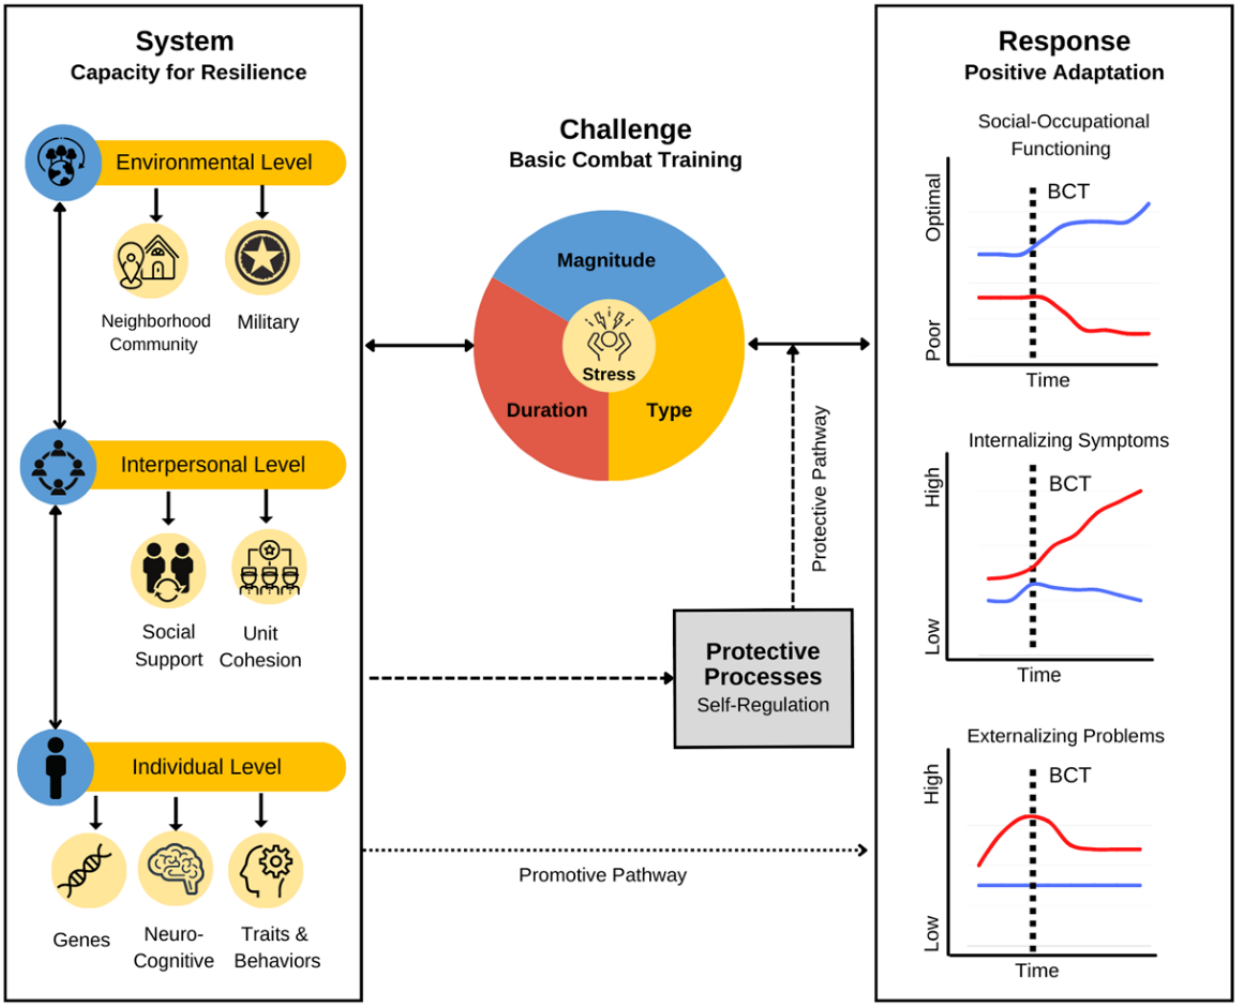
Background

Across the military career life cycle, service members are at a considerable risk for exposure to stressors that may impact their health, well-being, and performance [1-3]. Extensive research has identified factors that contribute to the risk for psychopathology (eg, posttraumatic stress symptoms and depression) following combat exposure and other military-related stressors [4-6]. However, mounting evidence suggests that most individuals show resilience, adapting successfully to risk and adversity [7,8]. Understanding the neurobiological, cognitive, and social mechanisms underlying successful adaptation following military stressor exposure is essential for designing prevention and intervention strategies to enhance resilience in military populations [9]. However, the mechanisms and processes that facilitate resilience following military stressors remain poorly understood.

Most studies on resilience within the military context have operationalized resilience as a static, trait-like attribute or have relied on cross-sectional designs [10]. One-time assessments of adaptation, adversity exposure, and resilience, particularly through self-report questionnaires, provide very limited insights into risk and protective processes and their influence on later mental health outcomes. There is now a growing consensus that resilience is a multidimensional and dynamic process that unfolds over time in response to a challenge [11-14]. We define resilience as the capability of a system to adapt successfully through multiple processes to challenges that threaten the system function [12]. In addition, the resilience of an individual draws on support from systems beyond the individual, including supportive relationships, such as battle buddies or a supportive unit [15,16]. Variations in the nature and timing of adversity exposure also influence how individuals adapt, and it is ideal to assess adaptive functioning before, during, and following exposure to well-described uniform stressors. Basic combat training (BCT) provides a systematic and relatively uniform challenge with known timing, so assessments of adversity, potential vulnerabilities, and protective influences, as well as adaptive functioning, can be performed before, during, and following a well-described period of challenge. Therefore, our approach to operationalizing resilience calls for a prospective, longitudinal study that tracks the adaptation of military service members over time with assessments before and after BCT and related, well-defined challenges.

A growing body of longitudinal research with military populations has identified distinct latent classes (groupings) of service members demonstrating similar trajectories of adaptation over time [7,8,17]. This literature suggests that there is significant heterogeneity in people's responses to comparable stressors. However, these studies have generally examined trajectories following deployment and across the transition from military to civilian life [18,19]. Little research has focused on young military recruits from the outset of their military careers. During the initial years of military service, recruits are faced with numerous challenges (eg, moving away from home, separation from family and friends, dramatic changes in the living environment, and intense military training) as they are encultured into military life. Moreover, for most recruits, this transition from civilian to military life occurs within the context of the transition from adolescence to emerging adulthood [20]. Identifying potential contributing factors linked to risk and resilience early in military service may be particularly useful for effectively intervening in service members during this key developmental transition. Longitudinal studies have also examined a limited number of outcomes in isolation (eg, posttraumatic stress disorder [PTSD], depression, and alcohol use). Our conceptualization of resilience as a multidimensional process in which a person may show successful adaptation within some domains but not others [21] calls for research that assesses multiple outcome domains (eg, internalizing symptoms, externalizing problems, and social-occupational functioning) over time. Finally, prior research has investigated the role of demographic characteristics (eg, age and gender), psychological factors (eg, neuroticism and self-efficacy), and environmental factors (eg, social support and subsequent life stressors) in differentiating individuals who manifest resilience from those who exhibit maladaptive trajectories [8,18,19]. Few studies have integrated neurobehavioral paradigms into longitudinal cohort studies [7,22], so the neurobiological, cognitive, and behavioral processes contributing to trajectory membership remain largely unknown.

Drawing on the aforementioned literature, the Advancing Research on Mechanisms of Resilience (ARMOR) study was established at the Minneapolis Veterans Affairs Health Care System (MVAHCS) and the University of Minnesota-Twin Cities (UMN) [23]. The overarching goal of this prospective, longitudinal cohort study with an embedded laboratory substudy is to develop a comprehensive, multilevel model of resilience to guide the development of prevention and intervention



XSL•FO
RenderX

strategies for military trainees and potentially other young people facing significant life challenges.

Figure 1 presents the basic conceptual model guiding this study [24]. It recognizes that individuals are embedded within a complex system of risk and protective factors that span multiple levels, from individual neurobiological and behavioral factors to social and broader environmental factors. This multisystemic perspective acknowledges the dynamic and reciprocal relationships among these influences and their joint impact on resilience [25]. The model also emphasizes potential pathways to risk and resilience in the face of adversity (shown as blue and red lines in response to BCT). Challenging life experiences in the past and at present, including childhood adversity or trauma and exposure to military training, can heighten the risk of developing psychopathology. As illustrated by the dotted line in Figure 1, promotive factors, such as cognitive ability and social support, directly contribute to positive adaptation, regardless of the risk level. The dashed line in Figure 1 illustrates how protective factors can act as buffers against the detrimental effects of adversity. In the ARMOR study, the focus is on investigating self-regulation as a key protective process contributing to resilience.

Self-regulation comprises 3 distinct but interrelated neurocognitive processes involving affect, behavior, and cognition, which together can facilitate adaptive responding to adversity [26]. Attentional control involves the ability to concentrate and sustain attention despite distractions, inhibitory control refers to the regulation of maladaptive behavior in favor of goal-directed actions, and behavioral flexibility enables the adaptation of behavioral strategies to meet environmental demands. Previous studies using laboratory-based paradigms have identified significant associations among these self-regulatory processes and measures of trait resilience, implying their potential as stress-buffering mechanisms [27]. However, few studies have examined neurobiological, cognitive, and behavioral processes in relation to resilience trajectory membership [7].

Figure 1. Integrated multilevel model of resilience for military service members. Conceptual model of resilience as a dynamic process in response to the challenges of basic combat training (BCT). Risk and protective factors across multiple levels (individual, social, and environmental) are depicted in the box on the left. Promotive and protective pathways are depicted with dashed and dotted lines, respectively. Positive (blue) and negative (red) responses to the challenges of BCT are shown in the graphs in the box on the right. Objectives

The primary objective of the ARMOR study is to characterize the trajectories of adaptation among young military recruits in response to BCT over the first 2 years of military service (aim 1) and identify promotive factors and protective processes contributing to individual variations in adaptation (aim 2). The secondary objective is to investigate whether neurobehavioral markers of self-regulation are predictive of resilient and nonresilient trajectories (aim 3).

Methods

Study Design

ARMOR is a prospective, longitudinal cohort study of young military recruits, including those aged 17 years at study entry, that investigates the mechanisms contributing to manifested resilience across multiple levels of analysis (neural, cognitive, behavioral, and social). The study includes the following two components: (1) a web-based longitudinal survey component, including self-report measures presented via Qualtrics (Qualtrics International Inc) and neurocognitive tests administered using the Penn Computerized Neurocognitive Battery (PCNB); and (2) a laboratory substudy component consisting of clinical diagnostic interviews, additional self-report questionnaires, and a series of performance-based tasks involving electroencephalography (EEG) and magnetic resonance imaging (MRI) assessments. We aimed to enroll a cohort of at least 1200 young military recruits who recently enlisted in the Minnesota Army National Guard. Participant recruitment began on April 14, 2019, and ended on October 16, 2021. Data collection is ongoing and is expected to continue into 2024. As shown in Figure 2, participants were assessed at baseline (time 0) before exposure to a uniform military challenge (BCT) and are currently being followed up at 4 time points (study is ongoing): 2 weeks following return from BCT (time 1) and at 6 months (time 2), 12 months (time 3), and 18 months (time 4) after BCT. A subset of participants from the longitudinal cohort (123/1201, 10.24%) completed the laboratory substudy procedures before shipping out for BCT (before BCT) and after returning from the training (after BCT).

Figure 2. Advancing Research on Mechanisms of Resilience (ARMOR) study timeline. BCT: basic combat training.

Context and Setting

This study aims to investigate mental health and adaptive functioning among young military recruits before and immediately after BCT and beyond, offering a unique opportunity to study resilience in response to a well-defined, naturally occurring, and uniform military stressor. BCT is a mandatory, intensive, and 10-week training course that all military recruits must successfully complete. The training environment is highly structured and characterized by low personal autonomy, with strict discipline enforced by drill instructors [28]. One distinctive aspect of BCT is the deliberate introduction of numerous stressors into the training environment, designed to prepare recruits for the challenges they will face in future military life [29]. These challenges include prolonged separation from family and friends, dramatic changes in the living environment, extreme physical demands, mental challenges, and simulated combat. This process is believed to foster unit cohesion and cultivate a strong sense of mental and physical toughness known as the *warrior ethos*. Previous research has shown that BCT has positive effects on cognitive performance, mood, and physical fitness [30-34], and it is associated with increased unit cohesion over time, which, in turn, leads to reduced psychological distress and improvements in tolerating training stressors [35].

XSL•FO
RenderX

Although most military recruits successfully adapt to the challenges of BCT, some recruits experience it as highly stressful. A considerable percentage (approximately 20%) of National Guard recruits fail to complete BCT [36]. This suggests that although BCT is a uniform stressor experienced by all recruits, its impact and perceived stressfulness vary among individuals. A study of Swiss Armed Forces recruits participating in a 21-week BCT course found that higher perceived stress at the beginning of the training was associated with greater mental distress and poorer military performance at later stages [37]. Previous studies focusing solely on BCT completers have overlooked valuable data from a significant minority of individuals who exhibit reduced resilience.

To comprehensively understand how BCT influences adaptive functioning and study resilience processes over time, we use a prospective, longitudinal research design with data collection before and after the relatively uniform stressor of BCT. This design makes it possible to capture changes within participants over time and allows us to test the temporal order of variables. Longitudinal designs permit stronger inferences about causal effects, although not with the rigor of a randomized controlled trial. Our design also provides insights into the underlying mechanisms contributing to individual variations in resilience and lays the groundwork for studying the impact of unforeseen events, such as the COVID-19 pandemic and military deployments, on resilience trajectories. By evaluating the perceived frequency and intensity of stressor exposure during BCT, we capture the individual experiences of military recruits. Furthermore, our focus on young, healthy participants at the beginning of their military careers, *before* significant exposure to military stressors, enables us to take a developmental approach to studying resilience within a military context. Finally, the integration of a laboratory substudy within our research design provides an opportunity to conduct in-depth, multilevel assessments of a subset of the cohort. This laboratory substudy allows us to investigate neurobehavioral markers of self-regulation that may predict resilience trajectories, enhancing our understanding of the underlying mechanisms associated with resilience in the context of military training.

Participants and Recruitment

The enrollment of participants in this study was based on specific inclusion criteria. Individuals aged ≥17 years who were newly enlisted members of the National Guard and had been assigned a ship date to complete BCT during the study period were eligible for participation. Exclusion criteria included a history of prior military service or any previous experience with BCT.

To recruit participants, a consecutive approach was used within designated National Guard Recruitment Sustainment Program (RSP) units across the state until the target sample was reached. The research team recruited participants between April 2019 and October 2021 using briefing presentations held during drill events at military posts. The relevant Army National Guard command provided the research team with a list of all potentially eligible military service members. During the briefings, interested individuals were provided with a study packet, which included a consent or assent letter, a "Help Us Keep in Touch" locator form, a "What to Expect Next" card illustrating the study design in layperson's terms, and a randomly generated unique study ID number. Throughout the recruitment process, detailed documentation was maintained. This included recording the total number of eligible military service members approached as well as the number of participants enrolled, those who refused to participate, and those found to be ineligible based on the inclusion and exclusion criteria.

Ethical Considerations

This study was reviewed and approved by the institutional review boards of the UMN (STUDY00004470) and the MVAHCS (VAM-18-00334/1594664). All study procedures were also approved by the relevant military command. All participants provided informed consent. Participants were provided with a letter that explained all the procedures, risks, and benefits. This information was verbally presented during the briefings, and participants indicated their consent to take part in the survey component by entering a unique study ID number to begin the web-based survey. A waiver of the requirement to document consent for the survey component of this study was granted. The survey component of this study was also provided an approval to include individuals aged <18 years under 21 CFR 50.51/45 CFR 46.404. From the subset of participants aged ≥18 years taking part in the laboratory substudy, written informed consent was obtained before participation in any laboratory study procedures. Participants in the longitudinal survey component of the study will be compensated up to US $150 for the completion of all the currently planned survey waves (US $25 for the time-1 survey, US $35 for the time-2 survey, US $40 for the time-3 survey, and US $50 for the time-4 survey). Owing to military regulations, articipants were not compensated for participating in the baseline (time 0) survey. Participants in the laboratory component were compensated up to US $400 for the completion of both the pre-BCT and post-BCT visits.

Survey Data Collection Procedures

For the web-based survey component conducted at baseline (time 0), participants were asked to complete a battery of self-report questionnaires on Qualtrics as well as select tests from the PCNB. Time-0 data were collected using study Chromebooks (Google LLC) in classrooms at local armories. Participants were instructed to log into a secure web-based Qualtrics platform using their unique study ID for authentication. Most participants completed the baseline data collection procedures within 90 to 120 minutes.

As exposure to BCT is required for continued follow-up, participants are monitored over the course of the study and retrospectively excluded if they are discharged before exposure to BCT. Participants' exposure to BCT is verified before the initial follow-up wave (time 1), and those eligible to continue study participation are invited to complete the battery of self-report questionnaires at each follow-up time point. All follow-up assessments are completed outside the drill training. Participants complete either a confidential web-based survey of the battery of computerized self-administered questionnaires linked to the participants' study ID or a paper-and-pencil version of questionnaires marked with the participants' study ID.

XSL•FO
RenderX

To ensure the continuity of follow-up assessments, we adapted the longitudinal retention model developed by Scott and colleagues [38] to engage and maintain contact with participants from enrollment to the final follow-up time point. During enrollment, participants were asked to provide detailed contact information, BCT ship and return dates, and full contact information for 3 alternate contacts who can help the study team locate the participant if needed. Study engagement will be maintained between follow-up waves through periodic communication (ie, newsletters and greeting cards), and survey nonrespondents will be contacted to encourage survey completion.

Measures

Self-Report Variables

Table 1 lists the self-report questionnaires administered via Qualtrics at baseline and at each follow-up time point. This battery of measures assesses 8 domains (internalizing symptoms, externalizing problems, social-occupational functioning, health, self-regulation processes, supportive relationships, personality, and vulnerability or risk factors). Although most questionnaires are repeated across all time points (time 0 to time 4), as they are critical for tracking outcome trajectories and resilience processes, some are completed only at time 0 (ie, personality) or time 1 (ie, BCT stressor exposure), as they do not require repeated assessment.

Outcomes

Primary outcomes include trajectories of internalizing symptoms, externalizing problems, social-occupational functioning, and global adaptive functioning. Secondary outcomes are self-reported self-regulatory processes, neurobehavioral markers of self-regulation, and ecologically valid markers of functioning extracted from administrative military records.

Neurocognitive Measures

Table 2 lists the neurobehavioral functions and major cognitive domains assessed by tests from the PCNB administered at baseline. Neurocognitive tests measure performance accuracy (eg, proportion of correct responses) and speed (eg, median correct response time) in major cognitive domains [64].

Table 2. Neurobehavioral functions and domains assessed using tests from the Penn Computerized Neurocognitive Battery at baseline in the Advancing Research on Mechanisms of Resilience longitudinal study.

Neurobehavioral Function	Domain	Test
Executive control	Attention	Penn Continuous Performance Test
Complex cognition	Language reasoning	Penn Verbal Reasoning Test
Episodic memory	Face memory	Penn Facial Memory Test
Social cognition	Emotion differentiation	Penn Emotion Differentiation Test

Laboratory Substudy Procedures

A subsample of the longitudinal cohort (123/1201, 10.24%) was recruited for a laboratory visit, both before and after BCT. Laboratory participants were selected based on their responses to baseline self-report measures and a predictive algorithm developed in the pilot UG3 phase of this project (details reported elsewhere; S Noorbaloochi et al, unpublished data, 2023). This strategy was intended to provide a subsample enriched with participants at a relatively high risk of maladaptive functioning (~72/123, 58.5%) compared with a low-risk group (~48/123, 39%). Participants were briefly screened via phone call, and those reporting contraindications to MRI due to the potential presence of metal in the body (eg, participants employed as a metal worker or participants with implanted medical devices) or due to problems with being in enclosed places were excluded.

Data for the laboratory substudy were collected during an 8- to 9-hour combined pre-BCT laboratory visit to the MVAHCS and UMN Center for Magnetic Resonance Research and during a 4- to 5-hour post-BCT laboratory visit at the MVAHCS. During the pre-BCT and post-BCT laboratory visits, participants completed a structured clinical interview (1-2 hours) with a trained master's level assessor under the supervision of a licensed clinical psychologist (CRE or PAA). The Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) was used to diagnose lifetime mental disorders and determine whether the disorder is "current" [65]. The Clinician-Administered PTSD Scale for DSM-5 was used to diagnose PTSD [66]. Participants also completed a battery of self-report measures assessing constructs related to self-regulation (Table 3).

XSL•FO
RenderX

Table 3. Self-report measures administered in the Advancing Research on Mechanisms of Resilience laboratory substudy before and after basic combat training (BCT).

Participants were asked to complete an EEG session to measure resting-state neural function as well as brain responses during cognitive tasks. We used electrodes embedded in an elastic cap to record electrical activity from 128 scalp sites. The precise physical location of the electrodes was recorded in 3D space with respect to auricular and nasion landmarks so that EEG recordings could be integrated with the corresponding structural MRI data. To measure eye movements for the detection of bioelectrical artifacts, vertical electro-oculograms were recorded from above and below the right eye, and horizontal electro-oculograms were recorded from near the outer ocular canthi. Left and right forearm electromyographs and electrocardiograms were recorded to identify and reduce artifacts and quantify the aspects of muscle contraction associated with button presses. EEG signals were digitized at the rate of 512 Hz with 0.5-200 Hz low frequency and 200 Hz high frequency bandpass filters. Each participant completed assessments of visual acuity and handedness as well as provided information about medications, alcohol consumption, caffeine consumption, and sleep in the last 24 hours. Self-report ratings of emotional state were assessed before and after EEG recording sessions using the Positive and Negative Affect Scale [71].

At the pre-BCT laboratory visit only, MRI data were collected at the UMN's Center for Magnetic Resonance Research on a 3T (Siemens) Prisma scanner using a 32-channel birdcage head coil with foam pads to minimize head movements. Sequences included T1-weighted Magnetization Prepared-Rapid Gradient Echo, T2-weighted Sampling Perfection with Application optimized Contrast using different flip angle Evolution, diffusion-weighted MRI, resting-state functional MRI (fMRI), and task-based fMRI.

Neurobehavioral Assessments

Overview

During the EEG session at the pre- and post-BCT visits, participants were asked to perform a series of neurobehavioral tasks applying paradigms to assess attentional control (dot-probe paradigm) [75,76], emotional inhibitory control (go or no-go paradigm) [77,78], and feedback processing (gambling decision paradigm) [79]. In addition, participants were asked to complete a video game–based task applying the Pavlovian-instrumental generalization paradigm [80] to assess adaptive versus maladaptive avoidance in the face of a physical threat.

Dot-Probe Task

Attentional bias is assessed using the dot-probe task [75,76]. Participants passively inspect rapidly presented face pairs with neutral, happy, or angry and threatening expressions. The face pairs disappear and are replaced by a blank space on one side of the screen and an asterisk (target probe) on the other. Participants are instructed to respond as quickly as possible to indicate the side on which the target probe appeared.

Emotional Go or No-Go Task

Inhibitory control is assessed using the emotional go or no-go task [77,78]. Participants view a series of rapidly presented visual targets and nontargets. Participants are instructed to press a response button for each target presented ("go trials") and to avoid pressing the button for each nontarget ("no-go trials"). Errors (response to no-go trials or failure to respond to go trials) are accompanied by visual (red bar in the center of the screen) feedback. The task is completed in 3 blocks with adaptive response timing windows to increase task difficulty based on performance. Participants are provided with visual feedback on task points earned or lost, which is displayed on the screen every 20 trials. During the second block, time windows are shortened to increase the task's difficulty just beyond what is feasible for participants. Points awarded during the second block for correct responses are also significantly reduced.

Gambling Decision Task

Error and performance monitoring is measured using the gambling decision task [79]. For each trial, participants are presented with 2 adjacent squares, each enclosing a number (5 or 25). Participants are instructed to choose between the 2 squares and then receive feedback (the chosen box turns red or green to signify either a win or a loss, with the winning and losing colors counterbalanced across participants). Winning and losing squares are preprogrammed in a randomized manner such that participants must make guesses and will be unable to detect a true pattern using the task feedback. Thus, the task assesses participant biases toward risk-taking following the experience of loss.

Farmer Task

While in the MRI environment, participants completed the farmer task [80]. In this gamified task, the participant is asked to take on the role of a farmer whose task is to travel between

XSL•FO
RenderX

a shed and garden to harvest crops. Two different roads connect the shed to the garden: (1) a short road and (2) a long road. Traveling the short road is perilous (contingently associated with an electric shock; 3-5 mA for 100 ms) but allows the farmer quick travel from shed to garden, thereby assuring a successful harvest. Conversely, traveling the long road is always safe (never associated with shock) but often prevents the farmer from arriving at the garden before "wild birds" eat the crop.

Before each trial, a stimulus is presented to the participant that they learn can indicate whether the short road will deliver the electric shock. Specifically, participants learn, through fear conditioning, that shock is predicted by a visual ring of extreme size (conditioned danger cue: CS+) but not by rings of the smallest size (conditioned safety cue: CS–) displayed on the screen. During the game, rings of intermediary sizes, presented in the absence of a shock, serve as generalization stimuli. The task captures fear generalization and subsequent instrumental avoidance by assessing task-based behaviors in response to generalization stimuli that are similar (but not identical) to CS+. Decisions to "unnecessarily" avoid during safe cues is considered *maladaptive* because danger (threat of shock) is not a realistic possibility, and avoiding unnecessarily compromises performance on the task. Adaptive responding is operationalized by higher rates of decisions to push through (ie, low levels of avoidance) when encountering safe yet danger-resembling cues.

DNA Samples

All participants enrolled in the longitudinal study were asked to provide a DNA saliva sample at baseline, which is stored for future analysis. Participants in the laboratory substudy are also asked to provide a blood sample to be stored for future research.

Administrative Data

The study team will work with the local National Guard to extract administrative data capturing sociodemographic and service-related variables (ie, Armed Forces Qualification Test score, training dates, and military discharge). Administrative data from military records will be deidentified and matched by participant ID.

Sample Size and Power Analysis

Sample size was calculated based on the primary objective of the study (aims 1 and 2) using structural equation models of various hypothesized structures (nested and longitudinal). This demand resulted in a sample size that could provide sufficient power to test such hypotheses across varying df. Control of root mean square error of approximation (RMSEA) was the criteria used for our sample size and power calculations. According to MacCallum and colleagues [81], RMSEAs of 0.01, 0.05, and 0.08 indicate excellent, good, and mediocre fit, respectively. Table 4 presents the required sample sizes and the corresponding powers for df=2 and df≥5, assuming a null RMSEA of 0.05 and an α of .05. Assuming a retention rate of 65% to reach an effective sample size of 780, we needed to recruit 1200 participants. Note that for n=780, structural equation models with df≥5 would have an expected power of at least 0.909. The column for df=2 demonstrates that for df smaller than 5, the power for our feasible sample size drops below conventional 0.80.

Table 4. Power estimates (chi-squared test for root mean square error of approximation=0.05).

Sample size	Estimate (*df*)	Estimate (*df*)
700	0.567 (2)	0.878 (5)
800	0.619 (2)	0.916 (5)
1000	0.707 (2)	0.961 (5)
1200	0.776 (2)	0.982 (5)

Data Management

Data collected via the web-based survey platform (Qualtrics) administered at the UMN will be downloaded securely into the study databases stored on a shared server at the MVAHCS, with access limited to authorized study personnel. Qualtrics includes a complete suite of features to support Health Insurance Portability and Accountability Act compliance, including a full audit trial, user-based privileges, and integration with the institutional Lightweight Directory Access Protocol (LDAP) server. Hard copy surveys will be double entered and checked for consistency. Laboratory substudy data (ie, neuroimaging and EEG data) will be stored in secure databases held on servers at the UMN and will be available only to lead investigators of each substudy component and the principal investigator. Administrative data will be transferred directly from the Minnesota Army National Guard to a secure server at the MVAHCS via secure data transfer. At the MVAHCS, the data will be accessible by a named Center for Care Delivery and Outcomes Research (CCDOR) Data and Statistics Team member. This individual will deidentify the personal information, match records with the study ID number, and transfer them to a shared server for the study. The study ID numbers will be used for data transfer, communication, and analysis purposes to protect confidentiality. Participant contact information linked with the study ID number will be stored in an SQL server database that will be created on internal Department of Veteran Affairs (VA) web servers. Only individuals with a need to access the data, as vetted by the principal investigator, will be granted access. Access to contact information will be obtained through Windows authentication (ie, personal identity verification card and password for the network).

Statistical Methods

Aim 1 will characterize adaptation among young military recruits over the first 2 years of service. Consistent with a hierarchical concept of the structure of resilience, we will use latent growth mixture modeling to identify the latent trajectories of adaptation and its indicators. We will apply latent growth

XSL•FO
RenderX

mixture modeling at the level of internalizing symptoms, externalizing problems, and social-occupational functioning as well as an overall model that simultaneously embeds all 3 domains into a model of adaptive functioning. We hypothesize that at least three trajectories (one showing resilient adaptive functioning or low pathology and the other two showing new-onset and chronic distress) will emerge for each domain assessed (internalizing symptoms, externalizing problems, social-occupational functioning, and global adaptive functioning).

Note that all remaining analyses for aims 2 and 3 will be conducted on the trajectory class membership data for each of these 4 domain outcomes to test for the specificity of resilience mechanisms**.**

Aim 2 will identify the promotive factors and protective processes contributing to individual variations in adaptation. We will apply structural equation modeling and Bayesian network analysis to detect and identify the latent constructs and the dependency structure between different domains. We will also examine the effects of protective and vulnerability factors on membership in different trajectory classes. We propose to investigate this in 2 complementary ways. First, in our structural equation modeling, we will augment the measurement submodels of the most parsimonious latent growth structural mixture models accepted in aim 1 with the indicators of protective and vulnerability measurements (Tables 1 and 2) and evaluate the change in the relationships (coefficients) that indicators have with the latent trajectories. We will treat potential predictors as moderators or mediators, depending on their hypothesized role in the model, and we will test their contribution to the model by change in model fit indices using the Akaike information criteria (AIC), the Bayesian information criteria (BIC), root mean squared error (RMSE), and goodness-of-fit (G^2) also known as the likelihood ratio test. Second, the trajectory class membership assignment in aim 1 will be used as dependent variables (resilient vs nonresilient or distressed trajectories), and protective and vulnerability factors will be used as predictors in random intercept multinomial logistic mixed models that will provide a quantitative picture of the unique contribution of these measures. We hypothesize that the risk factors listed in Tables 1 and 2 will predict membership in nonresilient or distressed trajectory classes, whereas protective or promotive factors will predict membership in the resilient or nondistressed trajectory classes. All analyses will be estimated within the propensity classes that adjust for any possible lack of imbalance and will be performed on both complete cases and 5 imputed data sets.

Aim 3 will investigate whether neurobehavioral markers of self-regulation assessed using a series of performance-based tasks involving EEG and fMRI assessments are predictive of resilient and nonresilient trajectories. EEG recordings will be put through an independent component analysis–based processing pipeline to isolate and remove noisy time segments, signal artifacts (eg, eye movements), and bad electrodes. Recording epochs centered around the onset of task stimuli will be extracted for the analysis of event-related potentials and time-frequency energy. Given that this study focuses on conflict monitoring and bottom-up covert attention, we plan to examine brain responses at midline frontal (eg, FCz) and lateralized posterior electrodes (eg, PO7 and PO8), respectively. We will quantify brain response metrics such as feedback-related negativity and θ-band (4-8 Hz) oscillations, which we predict will be associated with trajectory class membership. fMRI data collected during the farmer task will be analyzed using an event-related design to model blood oxygenation level dependent (BOLD) fluctuations due to stimuli onsets using Analysis of Functional Neural Images software [82]. Functional activation maps will be computed by regressing each voxel's fMRI response time course onto an ideal response function for 5 stimulus types: the danger cue, 3 classes of safety cues with parametrically varying levels of perceptual similarity to the danger cue, and a control condition including a safety cue with no perceptual similarity to the danger cue [83]. We will focus particularly on fMRI responses to these stimuli in brain areas associated with fear reactivity (anterior insula and dorsomedial prefrontal cortex) and fear inhibition (ventromedial prefrontal cortex and anterior hippocampus). Fear-related brain activations to safety cues resembling danger cues (relative to safety cues without danger-cue resemblance) will be used as predictors of maladaptive avoidance (costly or unnecessary avoidance of safe cues perceptually resembling danger cues). Finally, these brain and behavioral responses, as well as their moderation by protective (eg, social support, military cohesion, and self-regulation) and vulnerability factors (eg, BCT stressors and anxiety traits), will be used as predictors of trajectory class membership.

Handling of Missing Data

Every effort will be made to maximize the completion of data and responding across waves in the longitudinal survey (aims 1 and 2). However, the data collected at each wave will be subject to various random missingness. At the end of each wave, the mechanism of missingness for each measured variable will be assessed, and an imputation model appropriate to that variable (predictor, response, or adjustor covariate) will be identified. Appropriate imputation methods based on variable characteristics (eg, linear regression for continuous variables, multinomial logit models for categorical models, and propensity matching based on multiple predictors) will be used. After selecting a relevant model and, more importantly, deciding on the predictors of missingness, 5 imputed data sets will be constructed for each wave. The relevant analyses will then be based on the combined inferences derived from these 5 imputed data sets.

Results

This UG3/UH3 project was reviewed by the National Institutes of Health (Multimedia Appendix 1) and initially funded in August 2017. The UG3 pilot phase for establishing the feasibility of the larger prospective longitudinal study was conducted between August 2017 and December 2018 and is reported elsewhere [23]. The UH3 phase of the project was funded in March 2019. Study enrollment began on April 14, 2019, and ended on October 16, 2021. A total of 1201

XSL•FO
RenderX

participants are enrolled in the study; follow-up data collection is ongoing and projected to continue through February 2024.

Discussion

Aims of the Study

ARMOR targets a gap in resilience research by providing a rich longitudinal database to assess resilience as a dynamic process of successful adaptation in response to significant adversity and identify the processes underlying resilience. Specifically, this study will characterize the trajectories of adaptation (ie, resilient vs nonresilient) among young US Army National Guard recruits in response to BCT beginning at career onset and spanning 2 subsequent years (aim 1) and identify promotive factors and protective processes contributing to individual variations in adaptation (aim 2). ARMOR will also investigate whether neurobehavioral markers of self-regulation are predictive of resilient versus nonresilient trajectories (aim 3).

Strengths and Limitations

This study takes a longitudinal, multilevel approach to examine the mechanisms underlying individual variations in resilience trajectories. Through the assessment of recruits before BCT and follow-up across 4 time points after BCT, the design provides an opportunity to map individual trajectories in response to exposure to a naturally occurring, uniform military challenge. Although previous research has identified numerous resilience factors, most existing longitudinal studies have relied almost entirely on self-report. This study uses an embedded laboratory substudy design that integrates novel laboratory-based experimental paradigms for assessing dynamic self-regulatory processes into a large, prospective, and longitudinal study. This approach will enable us to explore whether neurobehavioral markers of self-regulation assessed using a series of performance-based tasks involving EEG and fMRI assessments are predictive of resilient versus nonresilient trajectories. A final strength is the involvement of military stakeholders in the study design. Beginning at the early planning stage, members of the local National Guard command were involved in the research process, providing feedback on relevant research questions and consultation on the feasibility of the study methods. The selection of the outcome measures was informed by their priorities and military experience. The local National Guard command also facilitated the study team's access to military personnel and allocated training time for the investigators to present information about the study to potential participants and collect baseline data.

Despite these strengths, ARMOR has several limitations. The nature of our study design, incorporating in-person laboratory visits for a subset of the cohort, required that participants reside within a limited geographical area. Therefore, it was necessary to limit the recruitment of participants to the National Guard of a single state. Although we will investigate the influence of demographic characteristics on our findings, the results may not be generalizable to all military service members from other states or to all military branches.

Although we attempt to be exhaustive in our assessment of the risk and protective processes relevant to resilience in the context of military stress, it is possible that some relevant variables may not be assessed. For example, we recognize that collecting data from other informants, such as peers, commanders, or family members, would provide information on the influence of environmental factors on resilience. However, collecting such data would be prohibitive in terms of cost and time given the number of participants we are studying. However, we obtained permission from military service members to access military and VA administrative records so that these sources of information (eg, ecologically valid markers of functioning from administrative military records) can be accessed and analyzed in the future.

A key challenge for any longitudinal study is the retention of participants over time. This can be particularly difficult when participants are both young and highly mobile, as is the case in this study. We have taken steps to ensure a satisfactory response rate so that the study will be adequately powered to detect small effects in analyses testing our major hypotheses. Although follow-up survey data collection continued throughout the COVID-19 pandemic, all in-person research activities, including participant recruitment, baseline data collection, and laboratory visits, were suspended from March 2020 to early August 2020. During this period, some participants returned from BCT but were unable to complete in-person laboratory visits.

As of March 2020, over half (755/1201, 62.86%) of the ARMOR participants had been recruited and assessed at baseline before the pandemic outbreak. All remaining participants were enrolled and completed baseline measures after the pandemic outbreak between August 2020 and October 2021. This presents a rare opportunity to conduct a "natural experiment" in which recruits who have completed the stressful but potentially resilience-enhancing BCT before the pandemic can be compared with those who have not. For details outlining the collection of additional COVID-19–focused surveys through supplemental funding from the National Center for Complementary and Integrative Health, see the Multimedia Appendix 2 [1,31,38,44,45,48,84-127].

Conclusions

The ARMOR study provides a rich data set to identify the predictors and mechanisms of resilient and nonresilient outcomes in the context of military stressors. Understanding the neurobiological, cognitive, and social mechanisms underlying adaptive functioning following military stressor exposure is essential for enhancing the resilience of military service members. The findings from our study will facilitate the understanding of the mechanisms underlying self-regulatory processes implicated in resilience and thus provide a foundation for the development of prevention and intervention strategies that help to promote positive adaptation and resilience among young military recruits. Specifically, the findings of this study may support the optimization of mindfulness-based interventions, which focus on increasing the awareness of one's thoughts, emotions, and actions to improve specific aspects of executive functioning, including attention, cognitive control, and emotion regulation.

Acknowledgments

The authors wish to acknowledge Dr Christopher Erbes, who passed away on May 30, 2021. Dr Erbes served as a principal investigator in this project and contributed to the overall design and conceptualization of the study. The authors would also like to thank Amit Sethi for his assistance with creating and revising the figures in this manuscript. The content is solely the responsibility of the authors and does not necessarily represent the official views of the Departments of Veterans Affairs, Army, or Defense or the National Institutes of Health (NIH). Generative artificial intelligence was not used in the writing of any portion of the manuscript. MAP received funding from the National Center for Complementary and Integrative Health (NCCIH) of the NIH (award UH3AT009651). JDS received funding from the National Institute on Drug Abuse (award T32DA050560). This work was also supported by the resources and the use of facilities at the Minneapolis Veteran Affairs Health Care System, Minneapolis, Minnesota. The authors would like to express their gratitude to the National Guard service members volunteering to participate in this study. This work was supported by the NCCIH of the NIH (grant UH3AT009651).

Data Availability

Data sharing is not applicable to this paper, as it does not report on any data generated or analyzed during this study.

Authors' Contributions

MAP was responsible for the overall conception and design of the study and led manuscript writing. CAM made substantial contributions to the acquisition of data and critical revision of the manuscript. MH made substantial contributions to the acquisition of data for the study and review of the manuscript. EHC made substantial contributions to the analysis and interpretation of data and the review of the manuscript. PAA made substantial contributions to the acquisition of data and critical revision of the manuscript. NDD made substantial contributions to the acquisition of data and critical revision of the manuscript. KOL made substantial contributions to the acquisition of data and critical revision of the manuscript. SL made substantial contributions to the development of the Farmer Task, acquisition of data, and critical revision of the manuscript. JDS made substantial contributions to the critical revision of the manuscript. SRS made substantial contributions to the acquisition of data and critical revision of the manuscript. ASM contributed to the conception and design of the study and critical revision of the manuscript. SN contributed to the conception and design of the study, analysis and interpretation of data, and critical revision of the manuscript. All authors have provided final approval of the manuscript for submission.

Abstract

Background: Semivolatile organic compounds (SVOCs) comprise several different chemical families used mainly as additives in many everyday products. SVOCs can be released into the air as aerosols and deposit on particulate matter during use by dispersion, evaporation, or abrasion. Phthalates are SVOCs of growing concern due to their endocrine-disrupting effects. Human data on the absorption, distribution, metabolism, and excretion (ADME) of these compounds upon inhalation are almost nonexistent.

Objective: The goal of this study is to develop a method for repeated inhalation exposures to SVOCs to characterize their ADME in humans.

Methods: We will use diethylhexyl phthalate (DEHP), a major indoor air pollutant, as a model SVOC in this novel protocol. The Swiss official Commission on Ethics in Human Research, Canton de Vaud, approved the study on October 14, 2020 (project-ID 2020-01095). Participants (n=10) will be repeatedly exposed (2 short daily exposures over 4 days) to isotope-labeled DEHP (DEHP-d4) to distinguish administered exposures from background exposures. DEHP-d4 aerosols will be generated with a small, portable, aerosol-generating device. Participants will inhale DEHP-d4-containing aerosols themselves with this device at home. Air concentrations of the airborne phthalates will be less than or equal to their occupational exposure limit (OEL). DEHP-d4 and its metabolites will be quantified in urine and blood before, during, and after exposure.

Results: Our developed device can generate DEHP-d4 aerosols with diameters of 2.5 µm or smaller and a mean DEHP-d4 mass of 1.4 (SD 0.2) µg per puff (n=6). As of May 2023, we have enrolled 5 participants.

Conclusions: The portable device can be used to generate phthalate aerosols for repeated exposure in human studies.

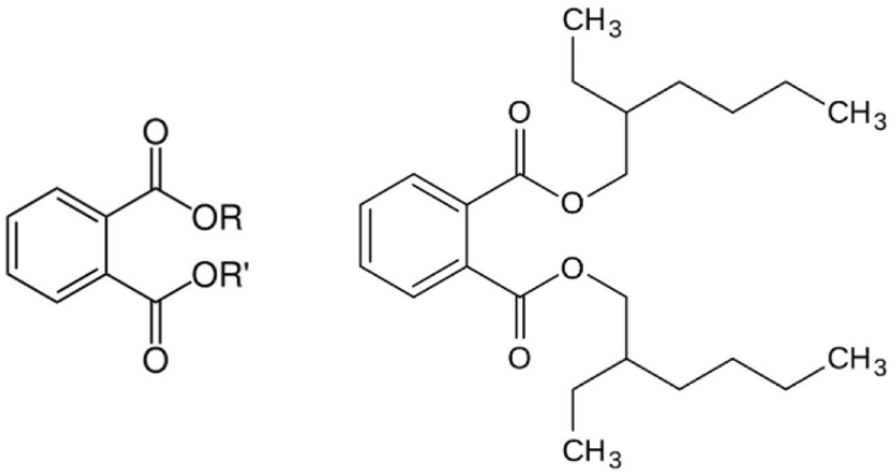
Introduction



The general population is exposed every day to semivolatile organic compounds (SVOCs) through inhalation [1-4], but few data exist on the internal (eg, blood) concentrations of these compounds when inhaled. One reason for this lack of data is the absence of a device to aerosolize SVOCs for controlled human exposure over several days. These compounds cannot be tested in common devices used for volatile chemicals such as solvents in whole-body exposure chambers. SVOCs are found in the air as liquid aerosols and deposited onto solid particles that are easily resuspended in the air and directly available through inhalation [5]. They are used as active ingredients in pesticides, cleaning agents, and personal care products, as well as additives in materials such as plastics, floor coverings, furnishings, and electronic components [4]. More than a thousand SVOCs are high-production-volume chemicals (HPVCs) [6]. Many of these have been associated with adverse health effects and have since been removed from commercial use [7,8]. Some are presumed (category 1B) endocrine-disrupting chemicals (EDCs) [9,10], including, among others, phthalates [11-14], brominated flame retardants [15], bisphenol A [16], nonylphenol [17], and some pesticides [18]. SVOCs are found in higher abundance indoors than outdoors [19,20] and are detected in both blood and urine collected from the general population [21]. This confirms the omnipresent and concurrent body burden.

Phthalates are a specific family of SVOCs used to impart flexibility to polymer plastics (ie, plasticizers) [22]. Phthalates are not covalently bound to the polymer matrix. Therefore, they can migrate to the surface and be slowly released into the air [21-24]. Phthalates with short alkyl chains, such as diethyl phthalate (DEP), have the highest vapor pressures and can also be released in the air in the vapor phase. Phthalates with long alkyl chains, such as diethylhexyl phthalate (DEHP), have lower vapor pressures and tend to adsorb to aerosol particles or dust [23] (Figure 1). DEHP has been reported to be the most abundant phthalate in house dust, with measured concentrations up to 5.3 mg/g [24,25].

Children and adults living in industrialized countries are estimated to spend around 17-19 hours and 21 hours per day indoors (ie, at home and in the working environment), respectively [26]. There is considerable concern regarding phthalate exposures because several epidemiological studies have shown associations between exposures to some phthalates and retarded male reproductive development [11,12], altered semen quality [13,14], endometriosis [27,28], and respiratory diseases in children [29]. When inhaled, phthalates can reach the alveoli, be absorbed into the blood, and then be distributed to potential target tissues, where they may trigger an effect. Therefore, absorption rates (ie, rate at which the molecule enters blood), internal doses (ie, parent compound concentrations in blood), as well as metabolic and elimination rates (ie, rate of metabolites' formation and elimination, usually in urine), are important toxicokinetic parameters to accurately determine the total exposures in the human body and, thus, potential risks to the population. Although urinary metabolite ratios were reported to be different between humans and animals [30-34], these toxicokinetic parameters have not been studied in humans exposed to phthalates through inhalation as a single exposure route. The few human toxicokinetic studies conducted with phthalates were mainly after ingestion [35-38]. A total of 2 human studies have been conducted on phthalates, including simultaneous exposure through the skin and inhalation routes [39,40]. These studies only provided estimated toxicokinetics (absorption, distribution, metabolism, and excretion [ADME]) for the inhalation route. Since inhalation is considered a significant indoor route of exposure for some phthalates [41], toxicological studies need to be performed to understand phthalates' ADME through this exposure route. However, a procedure to expose healthy participants to SVOCs is lacking due to the absence of devices for human studies with SVOCs through inhalation. We aim to fill these gaps by describing the required steps to obtain human ADME data after inhalation. The SVOC selected in this study is DEHP, a model SVOC due to its major presence in the indoor environment (air and dust) and human populations (urine). This study is divided into 2 parts. Part I describes the dosing procedure and how to generate aerosols at environmentally relevant phthalate concentrations with a device suitable for chronic inhalation exposure. Airborne phthalate aerosols will be produced based on the technology of commercially available "electronic nicotine delivery systems" (ENDS), which have proven efficacy in generating aerosols for human use [42,43]. ENDS are generally used to generate nicotine or flavored aerosols from highly viscous liquids such as glycerol (viscosity=1412 mPa·seconds) making this technology suitable for viscous chemicals such as some phthalates. Part II provides the study protocol for participants exposed to ring-deuterated DEHP for several days. Unisanté has strong expertise in toxicological studies with healthy participants and has adapted its protocols for repeated, at-home exposure. We will show the results of the first participant here as proof of concept.

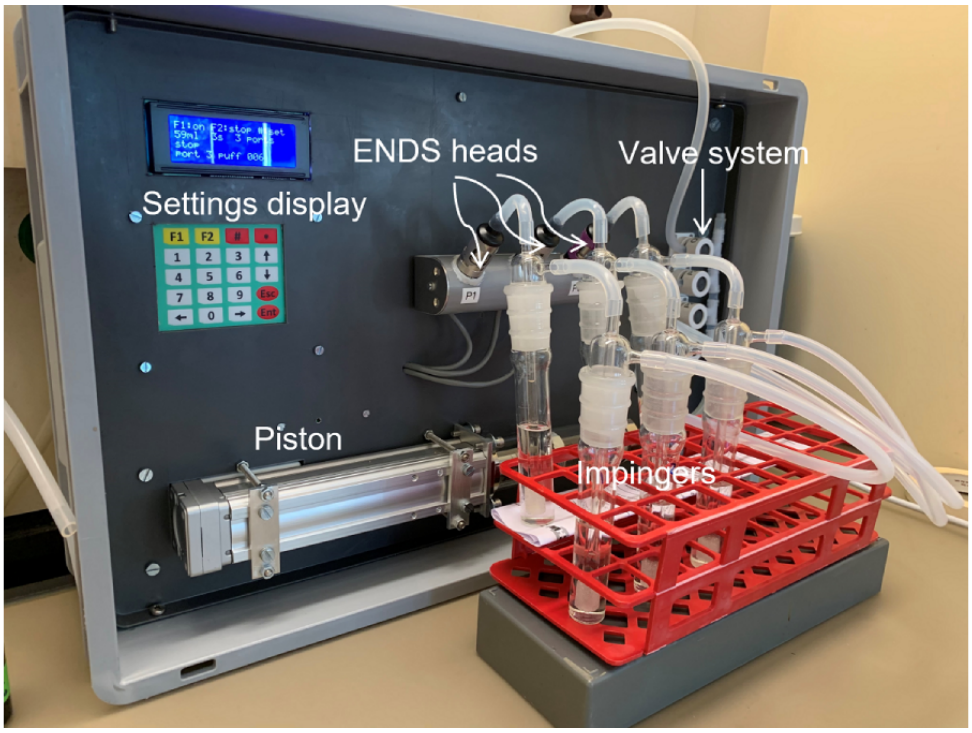
Methods

Part I: Dosing Protocol

Portable Dosing Device

The commercial ENDS "Endura T20-S" (Innokin) was chosen as the portable dosing device for participants' exposure to DEHP. ENDS consists of a battery-powered heated coil that functions as a thermal atomizer, a mouthpiece, and an e-liquid tank. Generally, the e-liquid is mainly composed of nicotine, flavoring agents, and ethanol in a base of propylene glycol (PG) and vegetable glycerol (VG). Base composition can vary from a PG/VG ratio of 20/80 to 70/30 and is typically 50/50. When the user activates the heated coil by pressing a button on the ENDS, the e-liquid is vaporized, releasing a flavored nicotine-containing aerosol called a "puff." The user inhales this aerosol through the mouthpiece.

E-Liquids



Aerosols generated by ENDS are complex mixtures containing volatile and semivolatile gases (mainly PG and glycerol) and nonvolatile particles (mainly glycerol, PG, and nicotine) [44,45]. The e-liquid formulated in this study is composed of glycerol (purity 99.5%, Hänseler Swiss Pharma), PG (PG 0 mg/mL nicotine, Revolute), ethanol (absolute for analysis EMSURE, Supelco, Merck), and DEHP. Ring-deuterated DEHP (DEHP-d4, CAS# 93951-87-2, Sigma Aldrich) is used to differentiate exposures generated in our experiment to environmental and laboratory DEHP contaminations.

Aerosol Generation and Vaping Machine

To adapt the ENDS to generate DEHP aerosols at controlled concentrations, we used a vaping machine that was developed in the Unisanté laboratory in collaboration with the University Centre of Legal Medicine of Lausanne (CURML) [46]. The purpose of the vaping machine was to replicate the puffing behavior of an individual using an ENDS according to the method n°81 recommended by the Cooperation Centre for Scientific Research Relative to Tobacco (CORESTA) [47]. This method describes the requirements for the generation and collection of e-cigarette aerosols for analytical testing purposes and led to an ISO (International Organization for Standardization) standard (20768:2018). Our vaping machine included 3 ports, each for an ENDS head (e-liquid tank, atomizer, and mouthpiece), a power supply, a piston syringe, a pinch-valve system, and silicon tubing (Figure 2). The machine was equipped with its own power supply, which replaced the individual ENDS batteries. This provided a steady-state power of 12 W throughout all experiments. The replacement of the ENDS battery by the machine's power supply precisely controlled puff duration during the experiments. The piston, in combination with the pinch valve system, controlled the puff volume, that is, the volume leaving the ENDS. Puff volumes were trapped by n-hexane in subsequent glass impingers (with P1 porosity fritted nozzle tip, joint connection NS 29/32, Bistabil, Sigma Aldrich) for analytical analysis. Puff duration (3 seconds per puff), volume (55 mL per puff), and frequency (30 second between puffs) were set up as per CORESTA criteria. Tests were carried out in triplicates. Control tests served to verify that the entire setup was not contaminated by DEHP-d4. A total of 3 ENDS with 0.8-ohm atomizers were used for all the experiments. New atomizers were used in each experiment.

XSL•FO
RenderX

Figure 2. Aerosol generation tests with our vaping machine. A total of 3 electronic nicotine delivery systems (ENDS) heads were directly screwed onto the vaping machine. Each ENDS head was attached to 2 sampling bottles (impingers) in series by silicon tubes. The impingers were attached to the valve system of the vaping machine and could be set to a specific vaping volume, duration, and frequency through the display at the top left.

E-Liquid Formulation and Testing Conditions Optimization

A first series of tests was carried out on the vaping machine to optimize the e-liquid formulation for generating stable aerosol concentrations as well as trapping conditions. We prepared several formulations with different PG/VG ratios (from 0/100 to 50/50), different ethanol amounts (0%-10%), and different DEHP amounts (0.002%-0.3%, w/w) to determine e-liquid formulations that allowed DEHP to be dissolved in the e-liquid and aerosolized by the atomizer. For each ENDS, DEHP-d4 was quantified in the n-hexane of all impingers. The number of impingers (2 and 3), impinger volume (20 and 100 mL), and n-hexane volume in each impinger (13, 50, 75, and 80 mL) were tested for optimal DEHP-d4 trapping conditions.

DEHP-d4 Mass Balance and Aerosols Concentrations

We carried out a second series of experiments with the vaping machine to determine mass balance and confirm DEHP-d4 concentration in the aerosols. DEHP-d4 was quantified in the n-hexane of all impingers, in the e-liquid before and after the experiment, and in an acetone/ethanol (50/50 v/v) mixture (acetone, suitable for high-pressure liquid chromatography [HPLC] ≥99.9%, Sigma Aldrich) that was used to extract DEHP-d4 from disassembled ENDS parts at the end of the experiment by the Central Environmental Laboratory of the Ecole Polytechnique Fédérale of Lausanne (EPFL).

DEHP-d4 Stability in E-Liquid

The stability of the DEHP-d4 concentration in e-liquid was an important control step for the participants' safety and to avoid any exposure concentration variability between the participants. The stability test for DEHP-d4 in the e-liquid was performed on the e-liquid stored at room temperature for 1 week and frozen at –20 °C for 2 weeks.

Aerosol Particle Mass Distribution in E-Liquid

A portable optical particle counter (aerosol spectrometer, model 1.109, GRIMM) was used to determine the mass distribution of e-liquid particles in the aerosols and assess deposition in the respiratory system [48,49]. Aerosols were generated by equipping the vaping machine with ENDS. The e-liquid used for these tests was composed of a PG/VG ratio of 50/50 with 1% ethanol and was not spiked with DEHP-d4. A total of 6 puffs of aerosol (55 mL×6=330 mL) were diluted in ambient air in a 3 L sampling bag (Tedlar sampling bag, Nutech Instruments Inc). The dilution in ambient air simulated the aerosol dilution in inhaled air by an individual puffing, assuming a 55 mL puff and a 500 mL tidal volume (330 mL/3000 mL=55 mL/500 mL). The particle size distribution profile was then measured. A control test was performed with ambient air.

DEHP-d4 Exposure Concentration

The concentration of DEHP-d4 in the e-liquid (percentage by weight) was set at a value that produced DEHP-d4 concentrations for participant exposures (C_{exp}, mg/m^3) at or below the Swiss occupational exposure limit (OEL) for DEHP (2 mg/m^3) [50]. The OEL is set at concentrations that, based on available scientific data, should not produce health effects in workers exposed to a substance in the air every day for a workweek throughout their working lifetime (in Switzerland: 8 hours per day, 5 days a week, for 40 years). C_{exp} was calculated based on the following equation:

XSL•FO
RenderX

where M_{puff} was the mass of DEHP-d4 in the aerosols generated in a puff by ENDS coupled with the vaping machine (µg per puff), p was the number of puffs per minute that an ENDS user would consume per minute (puff per minute), V_{tidal} was the human mean tidal volume (0.5 L of air per inhalation [51,52]), and IE was the number of inhalations/exhalations per minute.

Part II: Human Toxicological Study Protocol

Participant Sample Size and Selection

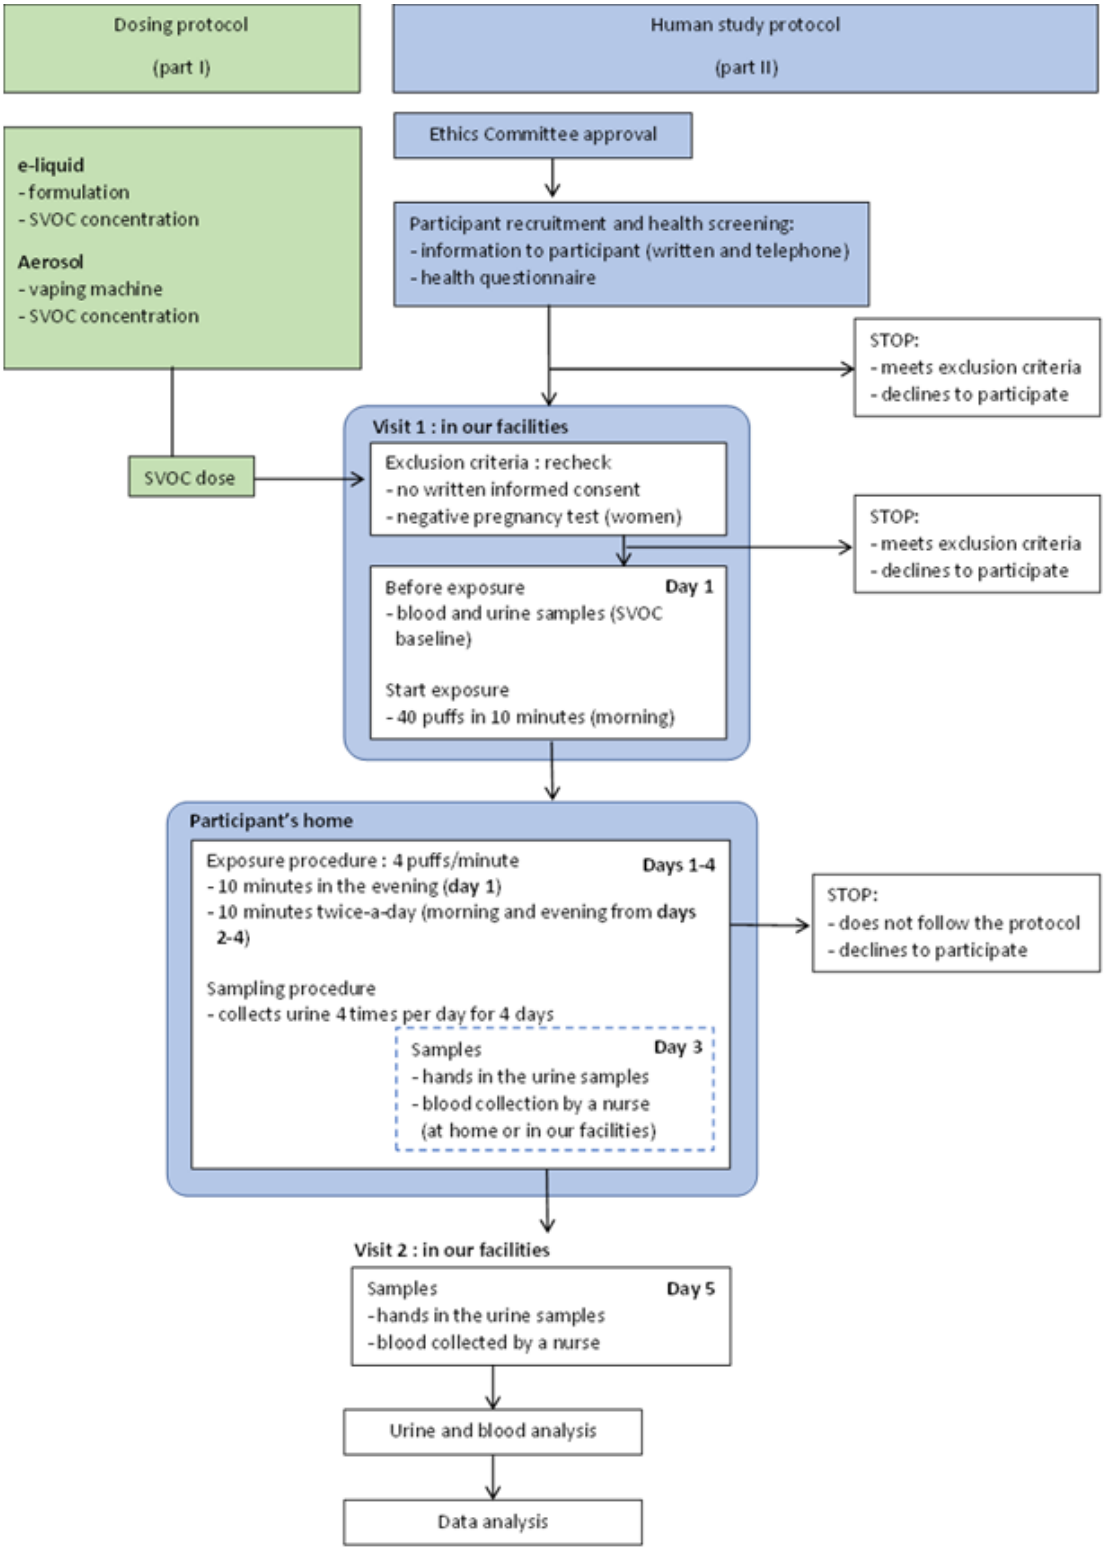
A maximum of 10 participants (N=10) will be recruited for repeated exposure to DEHP. Participants who are interested in the study will be checked for eligibility through a short general health questionnaire. These questions are about smoking status, age, BMI, alcohol consumption, general health status, and current job (to exclude the possibility of exposure to phthalates at work). The eligibility criteria are described in Textbox 1.

Textbox 1. Inclusion and exclusion criteria approved by the Ethical Committee. The inclusion criteria "able to understand the procedure" mean the presumed ability of the participants to understand or discern the written and oral explanations during the first visit. This capability will be assessed as follows: by asking the participants to repeat what they understood about the study; by asking questions to the participants and assessing their answers (eg, studied molecules, number of visits, right to accept or reject participation in the study, etc).

Inclusion criteria

- Aged between 18 and 65 years old.
- Men and nonpregnant women (negative pregnancy test).
- Nonsmoker (vaping is authorized).
- Not under a medical regime.
- BMI between 18 and 25.
- Not exposed to phthalates at work.
- Able to understand the procedure.
- Has signed the consent form for research project participation.

Exclusion criteria



- Aged 18 years or younger.
- Pregnant women.
- Smoker (cigarette, pipe, and cigar smoker).
- Under a medical regime.
- BMI below 18 or greater than 25.
- Exposed to phthalates at work.
- Not capable of understanding the procedure.
- Has not signed the specific consent form for research project participation.

Participant Timeline

The flowchart in Figure 3 shows the steps from participant screening and visits through exposure periods until data analysis. Briefly, an initial contact with the participant will be established by email to explain the study and obtain informed consent. Then, a phone call will be made to check if the inclusion and exclusion criteria are met and to get answers for a short general health questionnaire. If the inclusion criteria are met, the participant will be invited for a first visit. At this visit, the participant will sign the written informed consent. Women of reproductive age will also undergo a pregnancy test. Then, the participant will be given an aerosol-forming device and, after being instructed on how to use the device, will undergo the first inhalation exposure under the supervision of a research team member (see "Participant Exposure" section). A blood and urine sample will be collected before the first exposure (baseline) and will serve as baseline concentrations (control). Blood will be drawn again 30 minutes after the first exposure. Then, participants will follow the expected vaping schedule with DEHP-d4-spiked e-liquid and collect spot urine samples 4 times throughout the day (morning, midday, evening, and night) for the 4 days of exposure. Blood and urine collecting times are shown in Multimedia Appendix 1.

XSL•FO
RenderX

Figure 3. Flowchart of recruitment, screening, visits, interventions, sampling, and analysis. SVOC: semivolatile organic compound.

Blood and Urine Analysis

The Laboratory of Clinical, Forensic, and Environmental Toxicology, University Hospital of Liege, will determine DEHP-d4 and its metabolites concentrations in blood. The quantified metabolites will be deuterated mono(2-ethylhexyl)phthalate (MEHP-d4), deuterated mono(2-ethyl-5-hydroxyhexyl)phthalate (5OH-MEHP-d4), and deuterated mono(2-ethyl-5-oxohexyl)phthalate (5oxo-MEHP-d4). The Institute for Prevention and Occupational Medicine of the German Social Accident Insurance, Institute of the Ruhr-Universität Bochum (IPA), will quantify DEHP-d4 metabolites in urine, as described in Koch et al [53]. The metabolites quantified by the IPA laboratory will be MEHP, 5OH-MEHP, 5oxo-MEHP, and mono(2-ethyl-5-carboxypentyl)phthalate (5cx-MEPP).

XSL•FO
RenderX

Participant Exposure

Participants will use the portable aerosol-forming device themselves, first in our facilities (day 1) and then at home (days 1-4). The e-liquid will have a PG/VG ratio of 50/50 with 1% (w/w) ethanol and 0.02% (w/w) DEHP-d4. The participants enrolled in the study will press a button on the ENDS battery. The coil will heat the e-liquid, generating an aerosol with DEHP concentrations less than or equal to the OEL.

The e-liquid will be prepared in advance for DEHP-d4 quantification analysis and will be stored at room temperature during the exposure week. A fraction of the e-liquid will be sent to the analytical laboratory of EPFL to confirm the DEHP-d4 concentration in the e-liquid, and the rest will be frozen at –20 °C until use. On the day of the first exposure to DEHP, the e-liquid will be defrosted. A vial with a weighted amount of e-liquid sufficient for 1-week exposure (ie, reserve) will be prepared for each participant. This vial will be stored at room temperature at the participant's place, where they will use it to refill the ENDS e-liquid tank when needed. Therefore, a stability test is required to verify DEHP-d4 concentration after several days of storage at room temperature. This step is also important for the relevance of the study. On day 5, the participant will return the ENDS and the e-liquid vial, which will be weighed to calculate the exact amount of e-liquid puffed by the participant, hence the amount of puffed DEHP-d4.

Statistical Analysis

Standard descriptive statistics (ie, scatter plots, box plots, means, and SD) will be performed to describe the within-participant evolution of parent compound and metabolite distribution and elimination over time. Absorption and elimination rates will be estimated for each of the participants using standard nonlinear regression methods (hockey plots, piecewise linear regression models, or exponential models). These rates will be compared while accounting for potential effect modifiers (eg, age and gender) using mixed models.

Ethical Considerations

This study protocol has been approved in Switzerland by the official ethics committee of the Canton de Vaud for research studies with humans (Commission cantonale d'éthique de la recherche sur l'être humain, CER-VD, October 14, 2020, project ID 2020-01095). This study will be carried out at the Department of Occupational and Environmental Health at Unisanté, Lausanne (Switzerland).

This study is in compliance with the Declaration of Helsinki [54], the Swiss legal requirements for scientific research involving human beings [55,56], the Human Research Ordinance (HRO) [57], and the legislation relative to data protection (Swiss Biobanking Platform [SBP]). The Cantonal Ethics Committee of Vaud (CER-VD) approved the first version of the study on October 14, 2020 (project ID 2020-01095). The protocol described in this study is Version 8 of September 14, 2021.

The study is presented to any subjects who contact us for recruitment by phone and through a written participant information sheet. Participants also receive 2 consent forms, one for this study and one for possible future studies. If they agree to participate in the study, they need to sign the informed consent form before being exposed. The information sheet and the consent forms have been approved by the CER-VD.

All health information and biological samples related to this study will be part of a biobank that follows the current Swiss legal requirements for data protection and will be performed according to the Swiss HRO, Article 5. The SBP approved the study on January 21, 2021 (Vita Label N° Unisante_2101_1).

The results from this study will be communicated at scientific meetings and submitted for publication in peer-reviewed journals.

Results

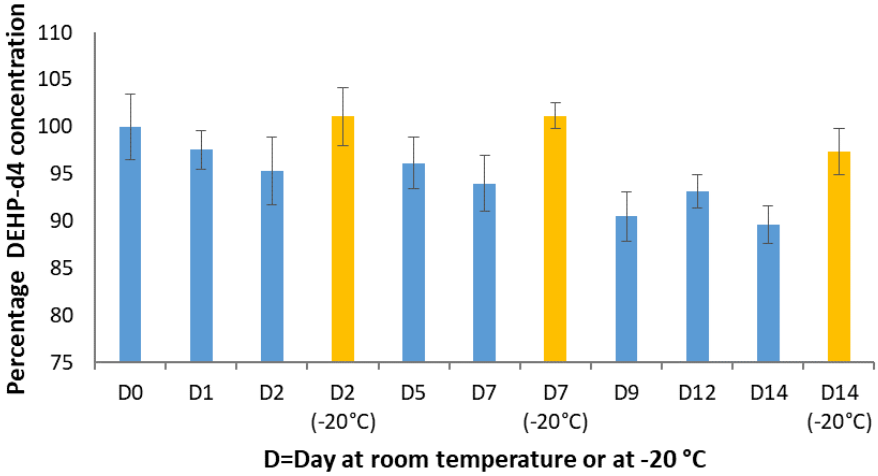
Here we will present results for the portable aerosol-forming device (Part I) and anticipated results with the participants (Part II).

Part I: Dosing Protocol

E-Liquid Formulation and Testing Conditions Optimization

The optimized e-liquid formulation had a PG/VG ratio of 50/50 with 1% (w/w) ethanol and 0.02% (w/w) DEHP-d4. Ethanol was necessary to dissolve DEHP-d4 and then create a homogeneous solution with PG/VG. The mean recovery in impingers was 89% (SD 5%) of the mass of aerosolized DEHP-d4 (n=5). The optimized number of impingers, impinger volume, and n-hexane volume in each impinger were 3 mL, 125 mL, and 80 mL, respectively. The number of puffs per experiment (n=36) was set to produce 2 dm^3 of aerosol, a volume that generated quantifiable amounts of DEHP-d4, and that was a submultiple of 1 m^3 (the volume used to define the OEL), which simplified calculations.

DEHP-d4 Mass Balance and Aerosol Concentrations



Total DEHP-d4 mass mean recovery for e-liquids, ENDS heads, and impingers was 100% (SD 22%; n=4). A DEHP-d4 concentration of 0.02% (w/w) in the e-liquid was confirmed by chemical analysis and produced aerosols containing 25.4 (SD 3.4) mg/m^3 DEHP-d4 (median 26 mg/m^3), corresponding to a mean of 1.4 (SD 0.2) µg DEHP-d4 per puff (n=6).

DEHP-d4 Stability in E-Liquid

The results of the stability test (Figure 4) showed a decrease in DEHP concentration of about 10% when the e-liquid was stored at room temperature. This loss may be explained by slight adsorption of the DEHP to the recipient wall or analytical error (up to 10% is considered in the error range of the analytical method). Therefore, the concentration of DEHP was stable when the e-liquid was stored in the freezer at –20 °C.

XSL•FO
RenderX

Figure 4. Percentage of isotope-labeled diethylhexyl phthalate (DEHP-d4) concentration over 14 days of storage at room temperature (blue) and at –20 °C (yellow). Note that the y-axis starts at 75%.

Aerosol Particle Mass Distribution in E-Liquid

The aerosol particle size distributions are shown in Figure 5. Table 1 lists the particle means expressed in terms of environmental (PM10, PM2.5, and PM1) and occupational (inhalable, thoracic, and respirable) mean mass concentrations. Most of the particles in the diluted ENDS-generated aerosols were at the respirable mass fraction level, with a diameter of 2.5 µm or smaller.

Figure 5. Mean (n=48) particle counts per cubic meter of air measured in ENDS-generated aerosol containing propylene glycol/vegetable glycerol (PG/VG=50/50), 1% ethanol, 0.02% DEHP-d4 (blue line with diamond marks). Gray line and squared marks represent the control (ambient air). Error bars represent the ± SD. Particles with diameters larger than 3 µm were 0.0003% of total counts.

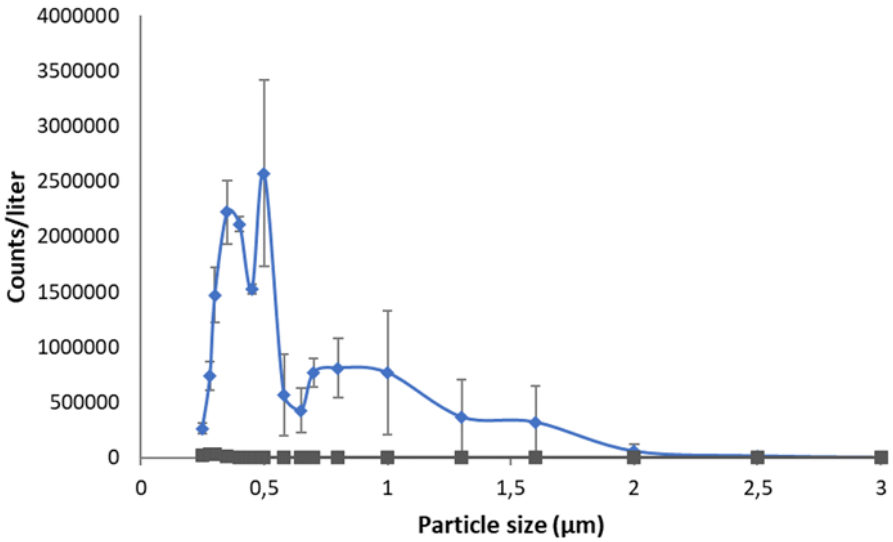


Table 1. Mean mass concentrations (µg/m3) corresponding to the aerosol fractions of PM10, PM2.5, and PM1 (PMX: 50% of particles exhibit an aerodynamic diameter below the indicated numbers 10, 2.5, and 1 microns, respectively) as well as the inhalable, thoracic, and respirable fractions (50% of particles exhibit an aerodynamic diameter below the indicated numbers 100, 10, and 4 microns, respectively) as per European Standard EN 481:1993 definitions.

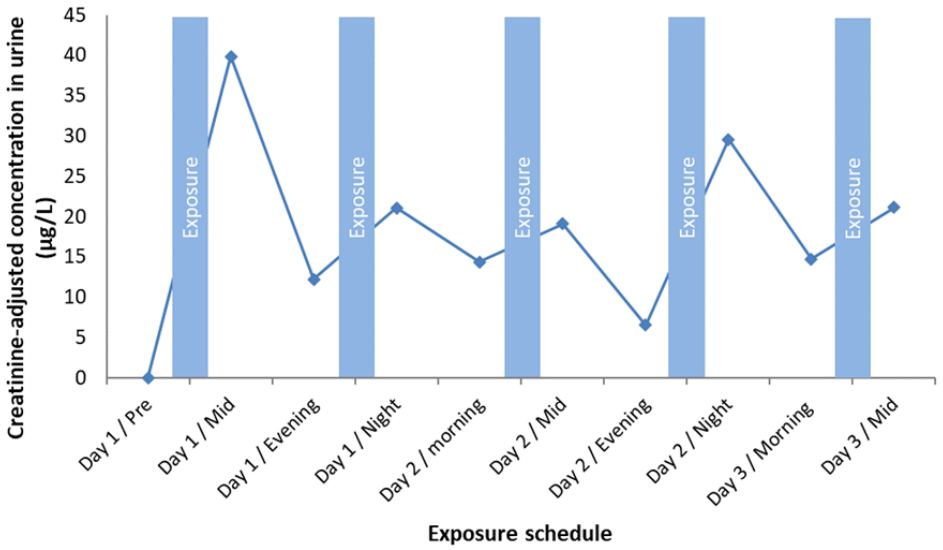
	PM10 (µg/m^3)	PM2.5 (µg/m^3)	PM1 (µg/m^3)	Inhalable (µg/m^3)	Thoracic (µg/m^3)	Respirable (µg/m^3)
Diluted aerosol, mean (SD)	6325 (4363)	6192 (4213)	2634 (728)	6325 (4363)	6325 (4363)	6217 (4245)
Control, mean (SD)	4 (1)	4 (1)	4 (1)	4 (1)	4 (1)	4 (1)

DEHP-d4 Exposure Concentration



We observed that on average, an individual puffs 4 times per minute and inhales and exhales 12 times per minute (data not shown). Therefore, a 0.02 % (w/w) DEHP-d4 concentration in the e-liquid generating an aerosol with 1.4 µg per puff of DEHP-d4 led to an estimated exposure concentration C_{exp} of 0.9 mg/m^3 over a 10-minute exposure, which was below the OEL. Assuming that a participant puffed 40 times on average

XSL•FO
RenderX

over the 10-minute exposure duration twice a day (80 puffs per day), the predicted DEHP-d4 dose for a week of exposure was 0.45 mg.

Our first participant could not complete the exposure week because some e-liquid leaked out of the ENDS, preventing our control of the puffed dose. Therefore, results for this participant are shown in Figure 6 as proof of concept. Our results from our first participant showed quantifiable amounts of DEHP-d4 in this participant's urine. DEHP-d4 was quantified in the e-liquid by chemical analysis before participant exposure (0.019%, w/w). The participant was asked to puff 40 times over 10 minutes twice a day. After five 10-minute exposure periods over 3 days and minor leaking, 2.52 g of e-liquid were used, corresponding to 0.47 mg DEHP-d4. This amount was in line with the DEHP-d4 predicted dose and led to exposure concentrations lower than the OEL but still sufficiently high to quantify DEHP in urine and to elucidate the urinary elimination kinetics. However, C_{exp} led to concentrations below our limit of quantification (LOQ) for blood.

Figure 6. Urinary concentration of the sum of isotope-labeled diethylhexyl phthalate (DEHP-d4) metabolites (MEHP-d4, 5OH-MEHP-d4, 5oxo-MEHP-d4) quantified for 1 participant.

Part II: Human Toxicological Study Protocol

As of May 2023, we have enrolled 5 participants. Following the whole protocol, participants will be able to generate aerosols with controlled DEHP concentrations using the ENDS and the prepared e-liquid at home for several days.

Discussion

We developed a method to generate aerosols containing controlled concentrations of SVOCs of toxicological relevance (ie, DEHP in this study) for controlled human exposure studies. Aerosols were generated by a portable and easy-to-use device (ENDS). Our results showed that DEHP in the e-liquid was stable for the duration of the study and that ENDS-generated aerosol particles were in the respirable range. Therefore, DEHP was likely to reach the alveoli, be absorbed, and enter the systemic circulation. Knowledge of human toxicokinetics after SVOC aerosol inhalation exposures will help regulatory agencies set new exposure limits and new requirements for toxicity reporting from manufacturers or suppliers because the data are human data instead of animal data. Some e-liquid leaking occurred with our first participant. This will be prevented by asking the next participants to keep the ENDS at home in a vertical position.

In the near future, our portable aerosol device will be used to study biomarkers of phthalate exposure in humans and the influence of these chemicals on a panel of readouts related to human health. We believe that this protocol with a take-home device has an easy approach, and we therefore anticipate that participant compliance rates to the exposure protocol will be high. The potential limitations of this protocol are the risks of missing part of the dose in blood and urine because only DEHP metabolites, not the parent compound, are quantified in these fluids, and participants are asked for spot urine samples, not 24-hour urine collection for every day of exposure. We hope this protocol will help other researchers design human inhalation studies of environmental substances that can contribute to the large data gap that exists today.

The results of this study will add new and important human data on the toxicokinetics of SVOCs such as DEHP upon repeated, inhalation-only exposures. Understanding phthalate toxicokinetics upon repeated exposure will help researchers understand possible phthalate accumulation in the body (if any) and improve models estimating internal exposures from external exposures, as well as interpret biomonitoring results from the general population, where urine is often collected at different times.

Authors' Contributions

ER contributed with conceptualization, methodology, investigation, validation, writing the original draft, and visualization; NBH contributed with conceptualization, methodology, writing, review, and editing; FB contributed with validation, resources, methodology, and formal analysis; DG contributed with validation, resources, methodology, and formal analysis; CP contributed with resources and validation; CC contributed with resources and validation; HMK investigation, resources, writing, review, and editing; AB contributed with methodology, conceptualization, resources, writing, review, and editing; GS contributed with methodology, conceptualization, writing, review, and editing; MB contributed with conceptualization, methodology, visualization, supervision, project administration, funding acquisition, writing, review, and editing.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Blood and urine sampling design. The exposure period is shown in grey. On day 1, blood and urine will be taken to provide baseline data (controls). Then, the first exposure starts and will be repeated twice a day, in the morning and in the evening. On day 3, participants return to our facilities to hand out day 1 to day 3 urine samples and for blood sampling. The last exposure is on day 4. On day 5, participants hand out urine samples from day 4 and the morning of day 5; a postexposure blood sample is collected at our facilities.

Abstract

Background: Community violence is a persistent and challenging public health problem. Community violence not only physically affects individuals, but also its effects reverberate to the well-being of families and entire communities. Being exposed to and experiencing violence are adverse community experiences that affect the well-being and health trajectories of both children and adults. In the United States, community violence has historically been addressed through a lens of law enforcement and policing; the impact of this approach on communities has been detrimental and often ignores the strengths and experiences of community members. As such, community-centered approaches to address violence are needed, yet the process to design, implement, and evaluate these approaches is complex. Alternatives to policing responses are increasingly being implemented. However, evidence and implementation guidance for community-level public health approaches remain limited. This study protocol seeks to address community violence through a resilience framework—Adverse Community Experiences and Resilience (ACE|R)—being implemented in a major US city and leveraging a strategy of community organizing to advance community violence prevention.

Objective: The objective of this research is to understand the impact of community-level violence prevention interventions. Furthermore, we aim to describe the strategies of implementation and identify barriers to and facilitators of the approach.

Methods: This study uses a hybrid type 1 effectiveness-implementation design. Part 1 of the study will assess the effectiveness of the ACE|R framework plus community organizing by measuring impacts on violence- and health-related outcomes. To do so, we plan to collect quantitative data on homicides, fatal and nonfatal shootings, hospital visits due to nonaccidental injuries, calls for service, and other violence-related data. In Part 2 of the study, to assess the implementation of ACE|R plus community organizing, we will collect process data on community engagement events, deliver community trainings on community leadership and organizing, and conduct focus groups with key partners about violence and violence prevention programs in Milwaukee.

Results: This project received funding on September 1, 2020. Prospective study data collection began in the fall of 2021 and will continue through the end of 2023. Data analysis is currently underway, and the first results are expected to be submitted for publication in 2024.

Conclusions: Community violence is a public health problem in need of community-centered solutions. Interventions that center community and leverage community organizing show promise in decreasing violence and increasing the well-being of community members. Methods to identify the impact of community-level interventions continue to evolve. Analysis of outcomes beyond violence-specific outcomes, including norms and community beliefs, may help better inform the short-term and proximal impacts

XSL•FO
RenderX

of these community-driven approaches. Furthermore, hybrid implementation-effectiveness trials allow for the inevitable contextualization required to disseminate community interventions where communities drive the adaptations and decision-making.

ACEs; community organizing; community violence; implementation-effectiveness trial; resilience

Introduction

Community violence is a persistent problem impacting public health. Community violence impacts the overall mental and physical health of neighborhoods, towns, and collective spaces. Risk factors associated with violence and community trauma include community poverty, community disadvantage, and disorganization [1]. Research framed through social disorganization theory, sometimes referred to as "broken windows theory," has suggested that disorder within a community can impact mental health and contribute to stress in individuals [2]. Among youths and adolescents, the impacts of community violence are particularly strong [3]. Violence, including experiencing physical violence and being a witness to violence, is considered an adverse childhood experience that can significantly impact children's future physical and behavioral health [4]. Different types of violence against youths, such as child abuse and neglect and community youth violence, often share the same risk and protective factors [5].

Protective factors, contrasted with risk factors, are increasingly seen as key to effective community-level violence prevention interventions. In taking a strength-based approach, which highlights protective factors, there is an opportunity to center the role of community members and their experiences while moving away from risk-framing approaches [6]. Strength-based approaches to community violence prevention are those that consider community relationships as a positive, protective factor against violence. Resilience theories, along with constructs of collective efficacy and social cohesion, have allowed for an expanded understanding of how to consider structural-level interventions leveraging protective factors to address community violence [7].

Interventions conducted at the community level can impact multiple individuals, particularly youths, at once [8]. Community-level interventions can interrupt patterns of violence at the structural level, preventing exposure to violence at an early age, and can move beyond school-based approaches commonly targeting youth [9]. Furthermore, community-level interventions developed through an asset-based framework, rather than deficits, have gained wider understanding and evidence. One community-level primary prevention strategy that has been explored in the context of community resilience is community organizing [10]. Community organizing can be defined as a process in which people affected by common concerns aim to build their power together and identify solutions for those shared concerns by mobilizing [11,12]. Community organizing, in the context of community violence prevention, seeks to address issues of social cohesion and isolation by building up relationships within communities and having communities lead the violence prevention strategies. Community organizing has been incorporated into interventions seeking to address domestic violence [13], as well as a way to empower youth in the violence prevention space [14,15].

It is difficult to implement community-level interventions and measure their effects, because of the complexity of intermingled contextual and temporal factors. Community-level interventions are often not broadly disseminated nor scaled up because they are developed according to the unique demographic characteristics of the community, as well as the unique characteristics of the practitioners or other persons leading implementation. Community-level interventions may also occur at a particular moment in time that cannot be easily incorporated into statistical models to determine intervention impacts. Hybrid trials seek to address these problems by allowing for implementation-related data collection to be incorporated into the study design [16]. Thus, this study uses a hybrid type 1 implementation-effectiveness trial; these are typically conducted early in the intervention development process and have the primary aim of evaluating the effectiveness of an intervention while allowing for the collection of implementation-related data to improve dissemination and intervention uptake.

Adding to the complexity of researching community-based interventions is the appropriate selection of statistical approaches to analyze community-level outcomes captured as interrupted time series data. Statistical decisions include the choice of analytic model (eg, autoregressive integrated moving average vs regression), if and how to account for autocorrelation and seasonality, if and how to correct for a small sample size, and aligning the statistical strategy with the available data, such as the number of time points. Reporting the planned analytic strategy a priori in protocol papers is important for avoiding bias due to a selected approach, as well as engendering confidence in the results [17].

Promising structural interventions that account for these methodological and implementation issues to address community violence have emerged in recent research. Cure Violence, a violence prevention intervention adapted from "Chicago Ceasefire" that was developed in the mid-1990s, framed violence as a communicable disease [18]. Through adaptations and implementations in multiple cities over the last 3 decades, the impacts of Cure Violence have been mixed [19]. The research has allowed for an evolved understanding of the importance of changing community norms around violence, in addition to the physical acts of violence [20,21]. Another study building on Chicago Ceasefire, the CeaseFire 365 intervention, effectively reduced gun violence in Baltimore while identifying the importance of measuring nonviolence-related outcomes to

XSL•FO
RenderX

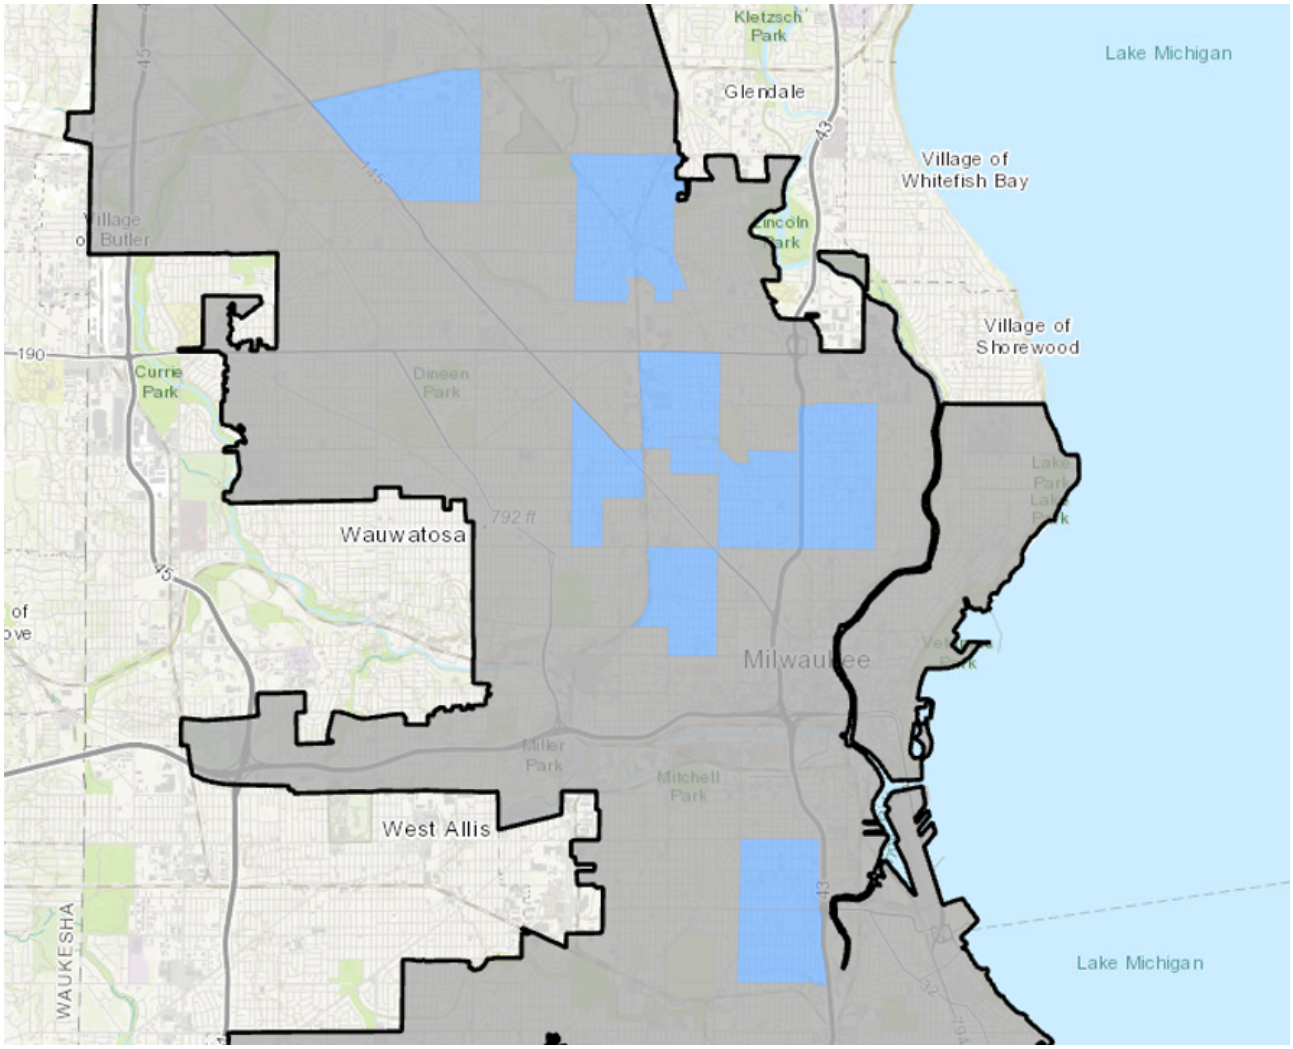
determine impact. The intervention included weekend "ceasefires" in which community events and public meetings sought to communicate a stop to violence during specific times [22].

Building on previous experiences and challenges of Cure Violence and similar community violence prevention interventions, the Prevention Institute (PI) and the University of California San Francisco, developed the Adverse Community Experiences and Resilience (ACE|R) framework as a community-level approach to violence prevention. The ACE|R framework uses community-specific data combined with an underlying evidence-based understanding of how adverse childhood experiences impact adolescents and communities [10]. In 2016, PI introduced the ACE|R framework to over 150 community partners and residents in Milwaukee during a time when the Milwaukee Blueprint for Peace—a call to action for violence prevention—was in development. The PI partnered with the Milwaukee Office of Violence Prevention (OVP) to facilitate the development of the Milwaukee Blueprint for Peace using the ACE|R framework, including having residents identify the leading risk and resilience factors related to violence in Milwaukee. These factors were solicited through community conversations, roundtable discussions, and web-based surveys. Residents and community organizations shared input on the emerging vision and principles in alignment with the ACE|R framework through those same forums. Through this citywide organizing and mobilization approach to comprehensive planning, a shared set of goals, strategies, and indicators was identified and formally launched in 2017 as the Blueprint for Peace.

The primary objective of this study is to assess whether community organizing and mobilizing residents to act on the Blueprint for Peace increases the effectiveness of the ACE|R framework to reduce community-level measures of child abuse and neglect and youth violence in 4 select communities, compared with having no community organizing in the 6 remaining select communities. The secondary objective is to explore the barriers to and facilitators of implementing community organizing as a strategy for increasing support for the sustainability of the Blueprint for Peace and the reduction of community-level violence in Milwaukee.

Methods

Study Design



To meet the objectives of this study, the proposed research design is a hybrid type 1 effectiveness-implementation design using a mixed methods approach, leveraging both quantitative and qualitative methods to measure the effect of the ACE|R plus community organizing on communities and collect data on the implementation of community organizing. We present the details of the proposed study in two parts: part 1 describes the proposed study to measure the effectiveness of the ACE|R plus community organizing, and part 2 describes how we will measure the implementation of the ACE|R plus community organizing.

Setting

This proposed study will take place in Milwaukee, Wisconsin, where the Blueprint for Peace was first launched in 2017. Blueprint for Peace participants in the development process selected 10 communities as the neighborhoods to prioritize and focus on violence prevention efforts (Figure 1). This study focuses on 4 of the 10 selected communities, hereafter referred to as the "select communities."

XSL•FO
RenderX

Figure 1. Map of Milwaukee, with the 10 communities where the Blueprint for Peace Initiative has been implemented highlighted in blue.

Intervention—Blueprint for Peace and the Resident Leadership and Advocacy Training

The proposed study uses the ACE|R framework plus community organizing as a strategy to directly address the need for community-level action to prevent child abuse and neglect and youth violence. Intervention communities will receive training and technical assistance that integrates the ACE|R framework, community organizing and mobilization, and operational knowledge of the Milwaukee Blueprint for Peace**.** The goal of this intervention element is to prepare residents and other interested parties in the community (eg, community-based organizations and faith-based organizations) to understand and be prepared to act on (organize or support) structural community-level change in support of the Blueprint for Peace. The ACE|R plus community organizing trainings (hereafter referred to as “resident leadership and advocacy training”) consist of 5 modules that ground participants in the knowledge of systemic trauma and then cover ways to address neighborhood violence through community-designed solutions. The details of each of the training modules are presented in Table 1.

XSL•FO
RenderX

Table 1. Content details for the 5 modules that make up the resident leadership and advocacy training.

Module	Module title	Module objective	Example content
1	Systematic and Historical Trauma (Adverse Community Experiences and Resilience)	Learn about systematic and historical trauma through the recognition that the impact is cumulative and reverberates across neighborhoods for generations	• Defines adverse childhood experiences • Defines trauma
2	Social Determinants of Health and THRIVE[a]	Explore community factors—people, places, and equitable opportunities—that influence health, safety, and well-being in their neighborhoods	• Defines the social determinants of health inequities and describes how socioeconomic factors and neighborhood characteristics shape behaviors • Identifies strategies to address community-level factors and move toward health equity • Discusses the role of neighborhood, home, and work environments in determining health and the quality of life
3	Addressing and Preventing Community Trauma and Healing	Learn ways to address community trauma through healing	• Healing as a starting point for community and system transformation, including activities to explore opportunities for healing and identify strong examples of how community healing is already taking place in the neighborhood • Strategies for healing • Strategies to address community trauma
4	Building Resident Leadership and Voice, Navigating Systems from Civic Engagement to Movement Building	Identify the steps of effective community action, including needs and issue assessment and strategic planning	• Defines key components of a toolkit specific to Milwaukee city and county processes • Outlines opportunities for shifting power by elevating community ownership, creating community change, such as shifting policy, and influencing decision makers. • An overview of the Blueprint for Peace and the goal areas, including discussion and activities, to map how it is connected to existing neighborhood efforts and neighborhood goals that support the blueprint
5	Resident Leadership in Action—Needs and Opportunity Assessment	Identify actions they will take to implement community action	• Readiness assessment designed to guide and support communities in determining capacity-building needs • Readiness assessment to build a plan for community mobilization of assets that accelerates community-level violence norms change and collective action toward a public health approach to violence prevention

[a]THRIVE: Tool for Health & Resilience in Vulnerable Environments.

Part 1: Effectiveness of the ACE|R Framework Plus Community Organizing

To define and determine the effect of a community violence prevention intervention, the first part of this study will be an effectiveness study of the ACE|R framework plus community organizing. This part will include using an idiographic clinical trial research design that captures within-community changes to analyze the Blueprint for Peace–related activities and outcomes, including child abuse and neglect, youth violence, and other violence-related outcomes (Textbox 1).

XSL•FO
RenderX

Textbox 1. Key measures to evaluate the implementation and effectiveness of Adverse Community Experiences and Resilience (ACE|R) plus community organizing through outcome constructs.

Outcome constructs and tracked measures

- Increased community organizing
  - Events led by individuals trained in community organizing
- Long-term development of safe and healthy communities
  - Homicides
  - Nonfatal shootings in select neighborhoods
  - Fatal shootings in select neighborhoods
  - Firearm-related injuries
  - Arrests due to violence among youths younger than 18 years
  - Arrests due to child maltreatment
  - Calls for service in selected communities
  - Nuisance, vacant, and blighted properties abated in select neighborhoods
  - Poverty rate in select neighborhoods
- Reduced adverse childhood experiences
  - Children hospitalized for confirmed and suspected child abuse or violence-related injury
  - Children at the emergency department for confirmed and suspected child abuse or violence-related injury
  - Home removals
- Reduced child abuse and neglect
  - Child protective services referrals
  - Child maltreatment reports
  - Rate of child victims per 1000 children
- Increased social cohesion
  - Block clubs in select neighborhoods
  - Resident-led events in select neighborhoods
- Increased awareness of violence prevention strategies
  - Neighborhood perceptions of safety, resilience, and access to resources and services
  - Awareness of neighborhood assets, resources, and programming among neighborhood residents

Unlike randomized controlled trials, which use large samples and randomization to control confounding influences, the idiographic clinical trial will manage differences by collecting control data and treatment data from the same community. Differences between control and treatment phases are quantified as change at treatment onset (ie, phase intercepts) and change over time (ie, phase slopes). Blueprint for Peace activities include events, workshops, and trainings that provide communities with strategies and resources to reduce violence. Counts and descriptions of Blueprint activities will be collected in the 4 select communities monthly. The 4 selected communities are defined by geographically bounded areas that city government agencies provided to the research team (Figure 1). Milwaukee is a safe and resilient city where the lives of all residents are valued, promoted, and protected. Outcome measures were derived from the following six overarching goals of the Blueprint for Peace [23], (1) stop the shooting, stop the violence; (2) promote healing and restorative justice; (3) support children, youth, and families; (4) promote economic opportunity; (5) foster safe neighborhoods; and (6) strengthen capacity and coordination of violence prevention efforts.

Data Analysis

Primary analysis of outcome measures will use intensive hierarchical modeling with maximum likelihood estimation, a multilevel linear model that has evolved for use in small-sample clinical trials [24]. This approach can capitalize on both change from baseline (preintervention) to treatment phases of time series data and differences between communities that do and do not receive an intervention.

Recent developments in intensive hierarchical modeling for small samples allow for evaluation models that (1) control for

XSL•FO
RenderX

biases due to small samples, (2) estimate intervention impacts that are quantified in terms of phase "jumps" and slopes, (3) use thorough power analysis using Monte Carlo simulation, and (4) have the ability to model and test complex causal inferences [24,25]. For intensive hierarchical modeling of the ACE|R plus community organizing impacts, time series data are clustered within communities; the effect of community organizing is quantified at level 1 as change over time, with aggregate models across communities being analyzed at level 2. Corrections to statistical testing and parameter estimates (to account for small sample sizes) will include the Satterthwaite degrees of freedom [26] and use full information maximum likelihood estimation for statistical testing of parameters but estimate model parameters using restricted maximum likelihood.

Differences between baseline and treatment phases will be estimated within the 4 select communities; community-level factors that may enhance or attenuate the impact of resident leadership and advocacy training will be explored using between-select communities fixed effects. An additional contrast will be to compare the changes in the 10 select communities to matched communities in Milwaukee outside the study.

Part 2: Implementation of the ACE|R Framework Plus Community Organizing Strategy

To address the objective of improving the research-to-practice gap, the second part of the study is the collection of data on the implementation of community organizing, as well as neighborhood perceptions of safety, resilience, and access to resources and services. This includes awareness of neighborhood assets, resources, and programming among neighborhood residents. Data sources include community members and resident leaders who have received training on how to deliver training on ACE|R and Blueprint for Peace activities. Data collection activities include focus groups and surveys.

Recruitment

Recruitment of community residents will occur in collaboration with PI, OVP, and community organizations including neighborhood associations in the 10 select neighborhoods. Materials for recruitment will be cobranded to reach community residents in venues like community centers, food pantries, flea markets, and social service organizations. Social media outreach will take place on the web through Instagram and Facebook. In addition to recruitment in the broader community, those participants who have completed the resident leadership and advocacy training will be referred to the community resident focus groups.

Focus Groups With Community Members

We plan to conduct focus groups within the select communities every 6 months to better understand the implementation of the Blueprint for Peace and community organizing as a strategy. At least 1 focus group in each select community will occur, with community residents recruited through convenience sampling, resident advisory committees, and local advertisements.

Those who agree to participate in the focus groups will undergo informed consent procedures and receive a US $40 gift card (their choice between Walmart, Amazon, or 2 local Milwaukee vendors) as part of their participation. Focus groups with community participants will be conducted through Zoom or in person in private or semiprivate spaces convenient for the participants (eg, community center) by research staff trained in qualitative methods. Focus groups will be digitally recorded and transcribed verbatim using a third-party service. Once the transcript is returned, it will be autocoded in NVivo (version 12; QSR International). Theme identification will occur for each question on the focus group transcripts.

Trainings and Community Events

In addition to focus groups with community members, we plan to collect data on the resident leadership and advocacy training conducted by the PI and the events delivered by those trained on resident leadership and advocacy, as well as events hosted by the city of Milwaukee as part of the Blueprint for Peace. Data will be collected through information provided by those trained (through surveys), as well as regular monthly meetings with the Milwaukee OVP.

Guided by the Consolidated Framework for Implementation Research (CFIR), we will use the data from these trainings and community events to better understand key CFIR domains: outer setting, inner setting, intervention characteristics, and process. These data will allow for the definition of specific strategies for improving intervention implementation (Table 2).

Table 2. Data sources informing implementation of Adverse Community Experiences and Resilience (ACE|R) plus community organizing through the use of the Consolidated Framework for Implementation Research (CFIR).

CFIR domain	Domain description	Goal	Data source
Outer setting	Characteristics outside the program and program delivery staff (eg, OVP[a] and PI[b])	Identify elements external to the program (eg, media) that might shape implementation barriers and facilitators	Community outreach event log
Intervention characteristics	Elements of the program that might cause barriers to implementation and sustainability	Facilitate adaptations of the program and program delivery	PI training tracking
Process	Actions taken during the implementation and delivery of the program that can be defined	Develop strategies that facilitate the implementation of the intervention	Community outreach event log and PI training tracking

Ethical Considerations

There is strong evidence that the trauma of community violence impacts those living in these communities, including health effects on youth and adolescents [27]. Importantly, those who are both in the community and engaging in intervention delivery are also greatly impacted [28]. Given these considerations, we will engage community members through focus groups and surveys on trainings to better understand the norms of violence as well as the mental and physical impacts. We will make every effort to support those participating in the study and provide mental health support, as requested. This study has been approved by the institutional review board of Advarra (#0217719). The proposed study will be performed in accordance with the Declaration of Helsinki.

Informed consent will be obtained from all the participants or legal guardians of participants for the community focus groups through signing a digital consent form. Those who attend the focus group will receive a US $40 gift card (participants may choose between Walmart, Amazon, or 2 local Milwaukee vendors). For the community focus groups, the audio of each of the focus groups will be recorded, transcribed, and anonymized. All data are securely stored on the RTI International server, and all electronic files containing identifiable information are password protected, with access limited to study staff. Only aggregate data will be shared with study partners. Focus group recordings will be destroyed as soon as the project is completed.

Results

This project received funding on September 1, 2020. Prospective study data collection began in the fall of 2021 and will continue through the end of 2023. Data analysis is currently underway, and the first results are expected to be submitted for publication in 2024.

Discussion

Expected Findings

This study aims to understand the impacts of a community-centered violence intervention. Our goal is not only to determine the impact of community organizing on community violence prevention but also to determine the feasibility and acceptability of such a strategy. This intervention centers the community, leveraging community member strengths, experiences, knowledge, and wisdom.

A key strength of this study is the engagement with government and community partners, along with the use of existing community infrastructure. Using the ACE|R framework plus community organizing to identify approaches to strengthen the city's implementation and impacts of the Milwaukee Blueprint for Peace engages resident leaders within an existing policy initiative. We will use our findings to further build the evidence for this approach, including identifying the barriers to and facilitators of implementation as faced by the community and its partners.

The first limitation of this study is the impact of COVID-19 on staffing, recruitment, and data collection. Labor markets have shifted widely during the pandemic; as such, identifying research support staff in Milwaukee may prove difficult. Such impacts are also being seen by other nonprofit organizations and government agencies. Because of our partnerships with the Milwaukee OVP, we may see impacts on its structure and the OVP-led community engagement activities. Recruitment at in-person events is difficult because, despite relaxed COVID-19–related restrictions, there continues to be less in-person interaction; remote events are also challenging as recruiting avenues because of scheduling conflicts and a lower engagement than at in-person events. Because conducting focus groups remotely is difficult, we aim to incorporate in-person focus groups once local Milwaukee officials have determined that it is safe to do so.

Beyond the impacts of COVID-19, an additional limitation with a community-level intervention is the possibility of contamination bias—that is, bleeding of the intervention into control communities. With extensive reporting and regular team meetings with the OVP, the PI, and our community partners, we hope to account for this bias but recognize that it cannot be completely avoided.

Conclusions

Our hope is that this approach will further strengthen the evidence that not only should community violence be viewed as a public health problem but also that there are ways to address it as such with a community-level approach that centers communities as agents of community transformation. How to implement these types of programs and the methods of measuring their impact remain mixed. The role of resident leaders is pivotal for understanding the effects of the intervention on community violence and the impacts on the leaders themselves in delivering and implementing the intervention. Results from this study will provide a road map for how other communities can implement community organizing within the ACE|R framework and further community violence prevention efforts.

Acknowledgments

We wish to thank our community partners—including the Milwaukee Office of Violence Prevention, Safe & Sound, and the Medical College of Wisconsin—and the broader Milwaukee community for all their support. This study was funded by the National Center for Injury Prevention and Control, Centers for Disease Control and Prevention (5R01CE003191-03). The funders had no role in the design of the study or the writing of the manuscript.

Abstract

Background: A global trend is to move rehabilitation closer to people's neighborhoods and homes. Still, little attention has been given to how the built environment outside the hospital setting might impact rehabilitation and recovery for stroke survivors.

Objective: The overarching objective of this project is to develop conceptual models of built environments that support stroke rehabilitation and recovery outside the hospital setting. Specifically, the project will explore factors and characteristics of the built environment that support people with stroke and their families and identify innovative built environments that can be designed for local health care. The project will examine facilitators and obstacles for implementing built environmental solutions and evaluate the potential benefits, feasibility, and acceptability.

Methods: The project uses a mixed methods design approach with 3 phases. In phase 1, factors and characteristics of the built environment for rehabilitation will be identified. Based on the results from phase 1, phase 2 will involve co-designing prototypes of environments to support the rehabilitation process for people with stroke. Finally, the prototypes will be evaluated in phase 3. Qualitative and quantitative methods will include a literature review, a concept mapping (CM) study, stakeholder interviews, prototype development, and testing. The project will use multidimensional scaling, hierarchical cluster analysis, descriptive statistics for quantitative data, and content analysis for qualitative data. Location analysis will rely on the location-allocation model for network problems, and the rule-based analysis will be based on geographic information systems data.

Results: As of the submission of this protocol, ethical approval for the CM study and the interview study has been obtained. Data collection is planned to start in September 2023 and the workshops later in the same year. The scoping review is ongoing from January 2023. The CM study is ongoing and will be finalized in the spring of 2024. We expect to finish the data analysis in the second half of 2024. The project is a 3-year project and will continue until December 2025.

Conclusions: We aim to determine how new environments could better support a person’s control over their day, environment, goals, and ultimately control over their recovery and rehabilitation activities. This “taking charge” approach would have the greatest chance of transferring the care closer to the patient's home. By co-designing with multiple stakeholders, we aim to create solutions with the potential for rapid implementation. The project’s outcomes may target other people with frail health after a

XSL•FO
RenderX

hospital stay or older persons in Sweden and anywhere else. The impact and social benefits include collaboration between important stakeholders to explore how new environments can support the transition to local health care, co-design, and test of new conceptual models of environments that can promote health and well-being for people post stroke.

KEYWORDS

stroke rehabilitation; built environment; person-centered; participation; self-efficacy; meaningful activities; accessibility; participatory co-design; good quality and local care

Introduction

Overview

The Built environments to support rehabilitation for people with stroke from the hospital to the home (B-Sure) initiative aims to create conceptual models of environments designed specifically to support the rehabilitation of stroke patients, from hospital settings to their homes. The project addresses the fundamental transformation of health care to provide care and rehabilitation close to the person or at home, that is, good quality and local health care [1-3]. Exploring how the built environment can support these new care policies is important to enhance a person's potential to live an active life. Surprisingly, little consideration has been given to how the built environment might influence rehabilitation and recovery for people with stroke. Developing new, more supportive environments may be a crucial factor in the success of local health care innovation.

Background

Stroke is a highly prevalent and debilitating brain injury that causes disability in adults [4,5]. In Sweden alone, an estimated 25,000 people are affected annually [6], while globally, stroke affects over 15 million people yearly, resulting in over 5 million deaths [5]. People with stroke often have long-lasting rehabilitation needs, and recovery is known to be complex, with several care providers involved [7-9]. The effects of stroke can be profound and lead to a range of activity and participation limitations [9-11], such as reduced quality of life, social isolation [12-14], and adverse events such as falls [9,15]. Many patients and families describe the support provided poststroke as poor and not patient-centered [16-18] and report poor engagement in their care and treatment decisions [7,19]. In addition, the role and importance played by the built environment to support rehabilitation outcomes have been largely ignored, especially when patients return home [20,21].

Rehabilitation aims to restore a person's functional capacity and societal participation after injury [22]. Effective health care services support a person's independence, participation, and self-directed capacity as people return to the community after a stroke. Recovery after a stroke is best supported when the person and their family or care network feel empowered to take responsibility for their rehabilitation, recovery goals, and activities [22,23].

There is a general need for improvements in the rehabilitation environments. Hospital environments, even specialized rehabilitation hospitals, make patients feel bored and lonely and inhibit independence and control [24-26]. These shared experiences can influence recovery and disempower individuals from leading or engaging in meaningful recovery. Studies show that patient outcomes vary between rehabilitation facilities [27], possibly partially due to the differences in the built environment [28,29]. The design of rehabilitation environments may impact the recovery of people with a stroke, affecting their function in the long term [30]. For society, this can increase disability expenditure and reduce productivity by hampering people's ability to participate fully [26,30]. It is worth noting that in most design strategies in rehabilitation, the built environment has not undergone empirical testing or evaluation.

New Places for Health Care

Moving care and rehabilitation to peoples' neighborhoods and in the home is a global development [1]. In Sweden, the reform, "good quality and local health care" is described as a new service [3] with more outpatient care and less but highly specialized inpatient care. This requires an empowered, more self-directed patient with control over their care and rehabilitation. The care must be person-centered and needs to switch from traditional 1-way expert providers to shared decisions with the patient [31,32]. Health care is far from fulfilling the demands of person-centered care and shared decision-making [33,34]. The Swedish government argues that the reform has implications for the building sector as they must be involved in policy discussions to avoid the risk when expensive new inpatient hospital building projects with large climate footprints are realized. At the same time, care and rehabilitation should move closer to patients or into their homes [3].

Developing local health care systems will require innovative approaches to living environments and care provision. These approaches must prioritize providing safe and dignified care, healthy working environments for health care staff, and support for continued independent living despite disability [35]. To achieve these goals, new models of care that promote health and rehabilitation in alternative settings may be necessary, such as rehabilitation hotels, small recovery homes, and day rehabilitation environments. Web-based care and technology, such as telerehabilitation, may also be critical in creating effective transition pathways between different care environments [36-38]. To achieve this, it will be important to develop simple systems for monitoring progress and requesting appointments with health care teams, which can be embedded into the built environment of these care settings.

XSL•FO
RenderX

Our starting point was to ask whether the alternative care environments, between hospital and home, might better support people with rehabilitation needs and avoid the current negative effects of hospital-based rehabilitation. While rehabilitation at home may suit some more mildly affected individuals with stroke and their families, it is impossible for others. Our goal is to explore built environment solutions for individuals who require more support or for individuals unable to readily or immediately go home. This direction aligns with the 2030 Agenda for Sustainable Development to ensure cities are inclusive, safe, resilient, and maintainable and promote well-being for all [39]. We believe the design and development of built environments can support recovery for people with stroke but also benefit others with similar needs and functional challenges, for example, multiple sclerosis or Parkinson and those sensitive to obstacles in their environment, including older people.

Despite the growing trend of rehabilitation at home, earlier research has neglected the role of the environment in this transformation, creating a significant knowledge gap [40]. This gap undermines the effectiveness of rehabilitation at home. There is a pressing need for an in-depth exploration of the environmental factors that impact rehabilitation outcomes, including innovative methods and solutions. An integrative mixed methods approach and participatory design can offer a comprehensive understanding of the importance of the environment for rehabilitation at home. By using these approaches, it will be possible to generate robust evidence on the impact of environmental factors on rehabilitation outcomes, inform the development of guidelines and policies for local care and rehabilitation, and enhance the effectiveness of rehabilitation at home.

Objectives and Research Questions

B-Sure aims to explore the essential factors in a built environment that supports stroke survivors and their families during rehabilitation. The specific research questions include (1) what are the most important factors in a built environment that supports people with stroke and their families in their rehabilitation process? (2) What do innovative built environments for local health care and rehabilitation look like? (3) What are the significant facilitators and obstacles for implementing various built environmental solutions? (4) How do stakeholders evaluate different built environment solutions regarding their potential benefits, feasibility, and acceptability?

Theoretical Framework

We will use several theories and frameworks to conceptualize and explore the interaction between a person and the environment. For example, the Person-Environment-Occupation model [41] and the International Classification of Functions [42] show that the environment comprises many facilitating or hindering factors external to the person. These factors include features of the built environment (eg, stairs and doors), natural environment (eg, surfaces outdoors), and objects. The models describe that a good fit between a person's (P) functional abilities and the demands of environmental factors (E) leads to positive outcomes such as increased independence and overall well-being [43-45]. Hence, to optimize rehabilitation outcomes, it is important to use a person's environment and be aware of facilitating and hindering factors.

B-Sure is also based on theoretical components of self-efficacy in which the person is seen as capable, with unique experiences, expectations, needs, and resources. Self-efficacy is a key construct from Bandura's theory of social cognition [46]. It is defined as "people's beliefs about their capabilities to produce designated levels of performance that influence events that affect their lives." Self-efficacy beliefs can determine how people feel, think, motivate themselves, and behave concerning their health. For example, self-efficacy influences motivation and health behaviors by determining people's goals, how much effort they invest in achieving them, and their resilience when faced with difficulties or failure.

In addition, B-Sure is based on the framework of Living-Lab and co-design [47], that is, a close collaboration between stakeholders in the design development process. One of the major challenges in planning and architectural practices today is the communication gap between the design team, the various levels of user groups, and the wide array of specialized consultants in the process.

Methods

Study Design

B-Sure has a mixed methods approach [48], including participatory co-design [49,50]. The project has 3 phases. In phase 1 a literature review, concept mapping (CM), and interviews will be done. In phase 2 the results from phase 1 will be used to co-design prototypes of environments to support the rehabilitation process for people with stroke. Finally, phase 3 will evaluate the prototypes obtained with the co-design process. The process will be iterative, enabling knowledge accumulation and increased common understanding between stakeholders and researchers, and contributing to solid knowledge production.

Phase 1: Identify Factors

Overview

Phase 1 involves 3 primary methods of data collection. First, a rapid scoping review [51] will be conducted to synthesize relevant knowledge of essential environmental factors. Second, a participatory mixed methods approach called CM [52] will engage stakeholders in mapping conceptual areas related to the built environment's importance for home rehabilitation. This process will involve collecting qualitative and quantitative data through generated statements, which will then be synthesized and sorted. Finally, interviews with diverse stakeholders will be conducted, covering sociodemographic data and open-ended questions related to identifying crucial factors for promoting the rehabilitation process of people with stroke and their families within the built environment.

Participants

Participants from five stakeholder categories will be recruited for the CM and the interviews: (1) people with stroke; (2) relatives or significant others; (3) health care staff; (4) government, including officials responsible for the operation of health care environments and stroke rehabilitation in the

XSL•FO
RenderX

region and municipalities; and (5) industry practitioners, including architects and other designers working within the health care contexts and home environments. We will strive to recruit 20 individuals from each category for the CM study and 3-5 people from each category for the in-depth interviews.

People who have had a stroke and their relatives will be recruited locally and regionally through advertising on several portals: hospital notice boards, stroke units, outpatient wards, the STROKE National Association's website, and social media. Participants meet the criteria to participate if they are willing to give written informed consent, have a diagnosed stroke, are 18 years of age and older, or care for someone who has had a stroke. We will use a strategic selection procedure with maximum variation to ensure we get a broad description of experiences from the participants regarding age, gender, time since stroke, ethnicity, and geographical location. Staff with clinical experience in rehabilitation after a stroke will be recruited through the research group's contacts, email lists, and targeted personal emails. We will strive to have a balance between different professionals and regional distribution. We will also recruit representatives from the region, municipality, and real estate owners through our network and collaborators.

Analysis

We will use multidimensional scaling analysis and hierarchical cluster analysis for the CM of quantitative data [53] and qualitative content analysis [54] for the interviews and CM. The NVivo software (QSR International) [55] will be used to aid the qualitative analyses and promote the validation and transparency of the coding.

Phase 2: Co-Design Prototypes or Models of Environments

Overview

This aspect of the research will be carried out within the framework of a Living Lab [47] using an iterative and learning co-design approach to engage stakeholders. Building on Phase 1, we will use the well-established Double Diamond method [56] as a guide for the workshop, previously used by the research group [57]. The method includes a three-step process: (1) idea generation, (2) modeling a prototype, and (3) testing and discussing. The research team will facilitate the sessions. Each co-design session is scheduled to continue the work of the previous session. The sessions will be combined with meetings with an advisory committee to guide the progression of the developing prototype. We will use tools and techniques that combine narratives, creativity, and imagination (scenario planning, group discussions, world cafe, individual work, collective sessions, and mock-ups) to ensure we reach all participants based on their characteristics and to guarantee that power is shared within the group.

We will be running 2 co-design processes, 1 in a dense city area and 1 in a rural area. The process will consist of 5 co-design sessions of 3 hours, which will take place over 6 months.

In this process, we will also use a geographic information system (GIS) method [58]. Through the analysis, we can visualize optimal places with the highest possible accessibility for the population. To perform the analysis, we will collect network data for transport systems, information about the population, government thresholds, and rules. Sensitivity analysis of optimal places will be done where the population's place patterns alternate (according to gender, socioeconomic status, and health status). Furthermore, a rule-based modeling method will be used to work out the optimal places where the identified needs from the literature study and the interviews will be used as criteria and matched with environments in the urban area and in the rural area.

Participants

Participants from five stakeholder categories (not included in phase 1) will be recruited: (1) persons with stroke; (2) relatives or significant others; (3) health care staff; (4) government, including officials responsible for the operation of health care environments and stroke rehabilitation in the region and municipalities; and (5) industry practitioners, including architects and other designers working within health care contexts and home environments. We will strive to have at least 2-4 people from each group. They will be recruited in the same way as in phase 1.

Data Collection

The data will be obtained from (1) notes taken by the team, (2) prototypes produced by each group, and (3) notes taken after the working sessions via a meeting with the research team to share their impressions.

Analysis

A qualitative content analysis [54] supported by using NVivo software [55] will be used. To enhance the mixed methods approach of CM a qualitative GIS method [58,59] will be used to spatially analyze and contextualize the CM results. Open access Swedish spatial data (ie, street network files and geocoded health services) will be triangulated with the CM results using qualitative GIS methods to provide a layered, grounded theory understanding of the meaning and experiences of the stakeholders. A qualitative GIS approach offers a deeper understanding of the context and meaning of the situations that influence person-place interactions and the social factors that relate to the perception and interactions.

Phase 3: Evaluation of the Prototypes

Overview

The third phase will evaluate the different prototypes or models of different environmental solutions according to benefits, feasibility, and acceptability. This is a matter of observing future user and stakeholder discussions when confronted with the prototypes, aiming to identify possibilities and challenges with the prototypes.

A combination of think-aloud and focus group interviews will be used. The think-aloud method is frequently used to reveal views from users when they encounter potential solutions [60]. In general, this method aims to capture a systematic process of thinking aloud and analyze this process to gain a deeper understanding of the feasibility of the developed models or prototypes. The sessions will be filmed to allow for transcription

XSL•FO
RenderX

of the communications and permit us to associate them with the prototypes.

Participants

A sample of potential users and stakeholders will be recruited. We will base the sample on the 5 stakeholder groups and recruit 2-3 people from each group.

Analysis

The transcriptions will be coded to identify possibilities and challenges with the prototypes and content analysis will be used [54].

Patient and Public Involvement

B-Sure study aims to achieve active engagement and empowerment of persons with stroke, health care professionals, decision makers, and other stakeholders by developing partnerships that emphasize equal power while acknowledging different roles and responsibilities. The collaborative nature of the research design supports a strong patient and public involvement approach. We are actively working in collaboration with stroke organizations and stroke units where the research questions for the study have emerged. This ensures that the research aligns with the needs and perspectives of stroke survivors, their families, and the wider community. During the initial phase, individuals with stroke, family members, and relevant stakeholders, including representatives from stroke organizations and stroke units, will contribute their insights and lived experiences to identify key factors and characteristics of the built environment for rehabilitation. The co-design phase will adopt a participatory approach, actively involving stroke survivors, their families, stakeholders, and representatives from stroke organizations and units as partners in developing prototypes for rehabilitation-supportive environments.

To generate and disseminate knowledge, an iterative Integrated Knowledge Translation approach will be used, with participants and researchers functioning as cocreators. Practical implications of cocreators include the terms “knowledge user” and “stakeholder,” as defined by the International Association for Public Participation Spectrum of Public Participation [60]. The study will evaluate the level of participation using this framework [61].

Dissemination

Our participatory approach involves engaging knowledge users and researchers as partners throughout the study. We will create knowledge products that feature the review results, interviews, and co-design process. These products will include recommendations for improvements in stroke care and presentations for health care leaders, clinical teams, and policy makers. Additionally, we will produce traditional academic outputs like conference presentations and publications.

Ethical Considerations

The study has ethics approval from the Swedish Ethical Review Authority (2023-02337-01 and 2022-04231-01). The project will adhere to ethical guidelines outlined in the Helsinki Declaration. Informed consent will be obtained. Written and oral information on the study purpose and what participation would entail will be given before the informed consent. They will also be informed about confidentiality and their right to withdraw from the study at any time. The design of B-Sure is inherent, iterative, and dynamic. This means participants will be able to keep discussions about ethical issues along the way.

Results

The B-Sure is a 3-year project which started in January 2022 and is planned to continue until December 2024. The project was funded in November 2022, ethical approval was obtained in March 2023. Data collection is planned to start in September 2023, and the workshops later in the same year. The scoping review is ongoing from January 2023. The CM study is ongoing and will be finalized in the spring of 2024. We expect to finish the data analysis in the second half of 2024.

Discussion

Principal Results and Social Benefit

We aim to determine how new environments could better support a person’s control over their day, environment, goals, and ultimately control over their recovery and rehabilitation activities. This “taking charge” [22] approach would have the greatest chance of transferring the care closer to the patient's home. By co-designing with multiple stakeholders, we aim to create solutions with the potential for rapid implementation. The project’s outcomes may be scaled up and target other persons with frail health after a hospital stay or older persons in Sweden and elsewhere.

B-Sure will provide knowledge about how buildings and environments in society can support the new care landscape with more care and rehabilitation outside the hospital. The project can thus contribute to improved, strategic, and maintainable planning of environments in society. We will examine this issue from the perspective of the needs of people with stroke in their recovery and rehabilitation phases. Stroke is common, and the affected individuals have complex health needs. As acute care shortens, rehabilitation and recovery will increasingly happen in the community or at home.

We will use Living-Lab and participatory co-design, where the users (patients, relatives, and professionals) and other key stakeholders such as decision makers in the health service and municipalities, architects, and building planners will be involved. There is a need for collaboration between the users, the building sector, health care, regions, and municipalities to develop innovative and maintainable environments that can support the transition to local health care. Overall, there is a great need for investments in health care environments, which affects the resource space for care. Poor design that is not supportive of the end users, entails significant costs for the patients, the government, and health care and risks contributing to large climate footprints as the buildings reduce the chance of being maintainable. In addition, we know that traditional planned building projects are often stuck in conventional thinking and risk cementing old care structures and obstacles between the care providers while innovative solutions are needed.

XSL•FO
RenderX

It is still uncommon for more developed, innovative collaboration between the stakeholders when planning and developing facilities [62]. The Swedish government has drawn attention to this [63]. It intends to map and analyze how these investment projects related to the ongoing development of health care at a national level and how facilities can contribute to the national development of health care and increased socioeconomic efficiency.

We expect that the knowledge produced by B-Sure is critical to fill this gap. The impact and social benefits include (1) Collaboration between important stakeholders (patients, health care, and building sector) to explore how new environments can support the transition to local health care. (2) Co-design and test new conceptual models of environments that can promote health and well-being of people poststroke. (3) Conduct a participatory design process that can create conceptual models where the built environment is included as an important part of rehabilitation. (4) Stimulate the establishment of a strong national network that can strengthen the development of high-quality rehabilitation environments.

With the B-Sure approach, new knowledge and results will be disseminated locally, nationally, and internationally by our broad stroke rehabilitation and architecture network. We will initiate and participate in knowledge transition activities such as conferences and seminars. Most importantly, we have designed the project to include persons with stroke, relatives, staff, and actors from society, enabling rapid user feedback and the spread of results to a wider public. We will initiate and be involved in knowledge transition activities such as conferences and seminars as contributing to a collaboration between health care, region, and municipalities is the goal to generate knowledge and bilateral development.

Strengths and Limitations of This Study

The study aims to examine the specific requirements of individuals with subacute stroke during their recovery and rehabilitation phases, emphasizing the crucial role of built environments in facilitating innovative care approaches beyond the hospital setting.

This project will foster collaboration among key stakeholders, including stroke survivors, health care professionals, the building sector, and policymakers. This collaborative effort will explore how the built environment can effectively support the transition toward the new health care landscape with local health care, thereby driving the development of optimal rehabilitation environments.

The research findings will not only enhance the knowledge base for individuals with stroke, health care providers, building sectors, policymakers, and educational institutions but also underscore the critical significance of the built environment.

These findings will pave the way for introducing groundbreaking solutions in health care services and communities. Although implementing these solutions may encounter challenges, the research team ensures maximum buy-in by actively involving key representatives from relevant institutions and units as integral research team members. This approach ensures a comprehensive and well-rounded perspective in addressing the complexities of optimizing the built environment for stroke rehabilitation.

Abstract

Background: Black cisgender gay, bisexual, and other sexual minority men (SMM) and transgender women (TW) continue to be heavily affected by HIV. Further research is needed to better understand HIV prevention and care outcomes in this population. In particular, there is a need for research examining the impact of substance use and sleep health on HIV prevention and treatment outcomes among Black SMM and TW.

Objective: This paper outlines the study methods being used in the recently launched follow-up study to the Neighborhoods and Networks (N2) study, which we refer to as N2 Part 2 (N2P2). N2P2 aims to address this gap in the literature, build off the findings of the original N2 study, and identify socioenvironmental determinants of health, including whether neighborhood and network factors mediate and moderate these relationships.

Methods: Building on the N2 cohort study in Chicago from 2018 to 2022, N2P2 used a prospective longitudinal cohort design and an observational-implementation hybrid approach. With sustained high levels of community engagement, we aim to recruit a new sample of 600 Black SMM and TW participants residing in the Chicago metropolitan statistical area. Participants are asked to participate in 3 study visits across an 18-month study period (1 visit every 9 months). Four different forms of data are collected per wave: (1) an in-person survey, (2) biological specimen collection, (3) a daily remote ecological momentary assessment for 14 days after each study visit, and (4) data from electronic health records. These forms of data collection continue to assess

XSL•FO
RenderX

neighborhood and network factors and specifically explore substance use, sleep, immune function, obesity, and the implementation of potential interventions that address relevant constructs (eg, alcohol use and pre-exposure prophylaxis adherence).

Results: The N2P2 study was funded in August 2021 by the National Institute of Drug Abuse (R01DA054553 and R21DA053156) and National Heart, Lung, and Blood Institute (R01HL160325). This study was launched in November 2022. Recruitment and enrollment for the first wave of data collection are currently ongoing.

Conclusions: The N2P2 study is applying innovative methods to comprehensively explore the impacts of substance use and sleep health on HIV-related outcomes among an HIV status–neutral cohort of Black SMM and TW in Chicago. This study is applying an observational-implementation hybrid design to help us achieve findings that support rapid translation, a critical priority among populations such as Black SMM and TW that experience long-standing inequities with regard to HIV and other health-related outcomes. N2P2 will directly build off the findings that have resulted from the original N2 study among Black SMM and TW in Chicago. These findings provide a better understanding of multilevel (eg, individual, network, and neighborhood) factors that contribute to HIV-related outcomes and viral suppression among Black SMM and TW.

Introduction

Background

Black cisgender gay, bisexual, and other sexual minority men (SMM) and transgender women (TW) continue to be heavily affected by HIV, with both groups at increased vulnerability for HIV acquisition [1-8]. Despite accounting for <1% of the US population, Black SMM constituted 28% of newly diagnosed HIV cases in 2020 [1]. Black TW also experience disparately high rates of HIV prevalence, with a recent systematic review estimating HIV prevalence to be 14.1% among TW, overall, and 44.2% among Black TW, in particular [9]. Despite these long-standing inequities, much of the research on HIV among SMM and TW has been conducted among racially and ethnically diverse samples, and, in some instances, focused on comparing Black and White populations. In contrast, this study focuses exclusively on Black SMM and TW as a more intentional, effective, and efficient research approach that recognizes the nuanced challenges faced by these communities.

Within this context, intersectionality theory provides a framework for understanding and examining the ways in which intersecting societal oppressions have multiplicative effects on health outcomes among multiply marginalized people. Indeed, in a society structured by White supremacy, cisnormativity, and heteronormativity, Black SMM and TW experience multilevel, interrelated oppressions that directly impact their life experiences, including factors related to HIV prevention and care [10-13]. It is important to recognize that Black SMM and TW experience these oppressions in distinct ways [14]. However, in certain local contexts (eg, Chicago), there is also a significant overlap of social and sexual networks as well as neighborhood-related factors between Black SMM and TW [15-17]. Given the long-standing health inequities experienced by Black SMM and TW [4,9,18,19], such as those related to HIV prevention, care, and its determinants, research to further understand salient issues in the lives of these multiply marginalized populations is urgently needed.

Current research on HIV prevention and care should be responsive to a dynamic biomedical landscape. Specifically, HIV pre-exposure prophylaxis (PrEP) represents an unrealized yet potentially critical tool for ending the HIV epidemic (EHE) [20] and reducing inequities [21-28]. Although PrEP awareness and use have been increasing [29-32], there has been limited uptake of PrEP among marginalized populations, especially Black SMM and TW [33-38]. For example, in 2020, among those for whom PrEP is recommended, only 9% of Black individuals were on PrEP (as opposed to 66% of White individuals) [39]. Similar levels of suboptimal PrEP uptake have been noted in TW populations as well [26]. Antiretroviral therapy (ART) is another critical tool for EHE as it functions to maintain undetectable levels of HIV viral load among people living with HIV [40]. Achieving sustainable levels of effective ART adherence is critical for HIV prevention and treatment, as research demonstrates that viral load is associated with onward HIV transmission [41], such that no HIV transmission events occur when viral loads are below a certain threshold (eg, undetectable=untransmissible) [42]. However, evidence indicates that many Black SMM and TW face challenges in achieving sustained viral suppression, including factors such as stigmatizing experiences, depression, anxiety, intimate partner violence, and financial stressors [43-48].

Further research is needed to better understand HIV prevention and care outcomes among Black SMM and TW, including the impact of prevalent behaviors such as substance use. Recent findings indicate that cannabis use, including heavy cannabis use, is highly prevalent among Black SMM and TW. For example, in the Neighborhoods and Networks (N2) study among Black SMM and TW in Chicago (mainly the south side of Chicago) [49], two-thirds of participants currently use cannabis (past month), half of whom use cannabis daily [50], similar to other studies among Black SMM and TW [48,51,52]. Cannabis use also likely increased during the COVID-19 pandemic [53,54], including for Black SMM and TW [50]. Thus far, however, there have been mixed findings as to whether cannabis use impacts HIV-related outcomes [55,56]; although among

XSL•FO
RenderX

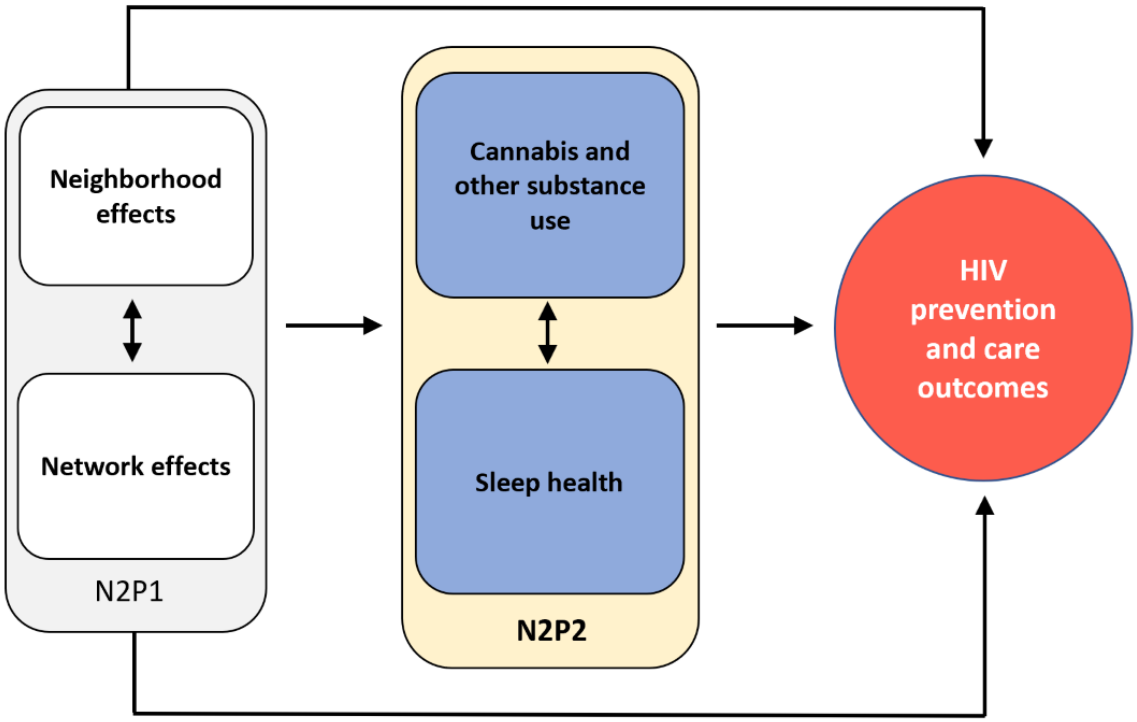
Black SMM and TW, studies have shown that cannabis use is associated with HIV acquisition [51], being connected to an HIV transmission cluster [57], and decreased HIV testing [58]. The impact of cannabis use on the PrEP care continuum has not been studied as much, although initial results suggest that there may be an association [55,59-61], including a few studies on Black SMM [59,60]. Additional substance use behaviors among Black SMM and TW (beyond cannabis use) are also potentially relevant to understanding HIV-related outcomes. Alcohol misuse, including heavy drinking and binge drinking, is prevalent and has been shown to negatively impact HIV-related outcomes, including in Black SMM and TW [62-64]. Increasing methamphetamine use among Black SMM and TW is also a growing concern [65,66], especially given its negative impact on HIV prevention [67,68], the acquisition of other sexually transmitted infections (STIs) [69-71], and HIV treatment outcomes [72,73].

There are critical gaps in our understanding of substance use among Black SMM and TW, including identifying its socioenvironmental determinants as well as its impacts on HIV-related outcomes. Further research into whether substance use impacts HIV-related outcomes should also focus on potential mechanisms (eg, biological vulnerability [74-79] and neurocognitive impacts [80-82]), which will help identify potential intervention points along causal pathways and enhance external validity, which can also help inform future intervention and implementation strategies [83]. When studying HIV prevention and care among Black SMM and TW, it is also critical to take contextual factors into account [84,85], particularly those operating at multiple socioecological levels [86]. Neighborhood and social factors have been shown to be associated with HIV-related outcomes in general populations as well as among intersectional minoritized populations, such as Black SMM and TW [87]. One especially important issue is policing and police brutality, as research has demonstrated that Black SMM and TW frequently encounter law enforcement [88,89], and the presence of police has been linked to be various HIV-related outcomes, including among Black SMM [90].

Sleep health is another salient factor in the lives of Black SMM and TW, as studies have found a high prevalence of sleep problems (eg, excessive or short sleep) [91,92], and this has worsened during the COVID-19 pandemic [93]. Sleep health has been found to be associated with HIV-related outcomes in the general population [94] as well as in samples of sexual and gender minority groups [95,96]. Research regarding the relationship between sleep and HIV outcomes among Black SMM and TW is scant, although 1 study from our team has demonstrated that poor sleep health is associated with lower PrEP adherence among Black SMM [93].

Generally, there have been limitations to the collective research that has been conducted, thus far, on substance use, sleep health, and their impacts on HIV-related outcomes among Black SMM and TW. First, most studies used cross-sectional data and relied on self-reporting (which are subject to social desirability bias). Studies that use objective measures, such as biological specimens and data from electronic health records (EHRs), allow researchers to assess the accuracy of self-report data and minimize self-report bias. Furthermore, most studies have used retrospective measures, which summarize across periods and are subject to recall bias [97]. Prospective data, especially granular data, can be collected using innovative methods such as ecological momentary assessment (EMA) [97,98], which captures day-to-day and event-level variation of experiential, spatial, and behavioral data in real time. Longitudinal studies that include objective, prospective, and granular measurement of relevant constructs and that evaluate mechanisms and context will allow us to better study these complex constructs and how they interrelate among Black SMM and TW.

Objectives



To overcome these limitations, we are conducting a prospective study to explore the impact of substance use and sleep health on HIV-related outcomes among a well-characterized HIV status–neutral cohort of Black SMM and TW in Chicago, Illinois. The study objectives are conceptualized in Figure 1, and the primary objectives are summarized as follows:

1. Determine the causal effects of substance use (eg, cannabis use and stimulant use) and sleep health on HIV outcomes, including acquisition, prevention (eg, HIV testing, PrEP uptake, and PrEP adherence), and care outcomes (eg, retention in care and viral suppression).
2. Assess whether associations between substance use, sleep health, and HIV prevention and care outcomes vary by contextual characteristics (eg, individual-, network-, and neighborhood-level constructs) and are mediated by relevant constructs (neurocognitive impacts and biological vulnerability).

To prioritize the potential expedited translation of study findings into public health impact, which is of critical importance among populations such as Black SMM and TW that experience long-standing health inequities, we will use an innovative observational-implementation hybrid approach [99]. The observational-implementation hybrid approach prioritizes the collection of implementation data while conducting observation research. This paper outlines the study methods being used in the recently launched follow-up study to the N2 study [49], which we refer to as N2 Part 2 (N2P2).

XSL•FO
RenderX

Figure 1. Conceptual model for the Neighborhoods and Networks Part 2 (N2P2) study. Originally looking at the neighborhood and network factors of HIV-related outcomes in the Neighborhoods and Networks Part 1 (N2P1) study, we have now launched the N2P2 study to expand our understanding of substance use, sleep, and HIV-related outcomes.

Methods

Study Design

Building on the N2 cohort study in Chicago, which was completed between January 2018 and June 2022 (N=412), the N2P2 study uses a prospective longitudinal cohort design and aims to recruit a sample of 600 Black SMM and TW participants residing in the Chicago metropolitan statistical area (MSA). Following updated recommendations for labeling hybrid studies [100], we will apply an observational-implementation hybrid approach in the context of the cohort study design [99]. Following an initial baseline assessment (conducted in person), participants are asked to participate in 2 subsequent in-person visits every 9 months, totaling 3 visits across an 18-month study period. The participants are also asked to participate in a daily remote EMA survey occurring for 14 days after the in-person study assessment. As has been our long-standing practice for work with this heterogeneous community in Chicago, we are using an HIV status–neutral approach with Black SMM and TW to increase inclusivity and minimize the risk that participation in the study could disclose HIV status [101]. The HIV status–neutral approach (also known as an integrated continuum) is a person-centered approach that uses the same treatment approach for all individuals, regardless of HIV serostatus. This approach has been noted as a strategy that works toward achieving health equity among marginalized populations and is in line with ongoing calls for prioritizing the social determinants of health in health equity research [101,102]. Relatedly, all study procedures are identical for participants regardless of their HIV serostatus.

Hybrid Observational-Implementation Approach

As part of the observational-implementation hybrid approach, we are preparing to conduct multiple activities as part of N2P2 that will provide data on implementation constructs related to evidence-based interventions that address salient health issues impacting Black SMM and TW. For example, we are currently collecting data that will inform how to improve the delivery of evidence-based interventions to reduce alcohol use among Black SMM and TW who could benefit from reducing their drinking. Specifically, we are developing a Discrete Choice Experiment (DCE) [103,104] to determine preferences for alcohol interventions among N2P2 participants who have an Alcohol Use Disorders Identification Test-Consumption score ≥4 [105,106]. DCE's are a preference elicitation method that asks participants to complete multiple-choice tasks (eg, paired comparisons of profiles A vs B) with different levels and combinations of questions to compare various attributes (ie, key intervention design features). The DCE that we are currently developing will ask N2P2 participants for their preferences regarding the delivery of several evidence-based alcohol interventions, including pharmacotherapy [107,108], behavioral therapies [109,110], and mobile health interventions [111,112]. Attributes that will be included in the DCE tasks include type of intervention, person delivering the service, delivery settings, and communication platforms. We will consult with the N2P2 community advisory board as part of the formative work for

XSL•FO
RenderX

refining the DCE, and it will be incorporated into the second wave of N2P2 data collection using a logic step in the survey.

In addition to the DCE on preferences for alcohol intervention delivery, we will also apply a human-centered design approach [113] to a subsample of N2P2 participants to create journey maps of Black SMM and TW experiences as they access HIV prevention and care settings. We are also using the same approach to understand the experiences of health care providers as they deliver HIV prevention and care services to Black SMM and TW. These data will then be used to inform how to tailor alcohol interventions to be more contextually informed to better suit the needs of Black SMM and TW and how to integrate them into community-based and clinical HIV prevention and care service settings. In subsequent waves of data collection, we plan to explore the collection of data on implementation constructs related to evidence-based interventions that address cannabis use, such as cognitive behavioral therapy. In addition, as recruitment settings for N2P2 seeds include HIV testing and substance use treatment facilities, and referral participants are likely to have accessed these services as well, we will also collect data from N2P2 participants about their experiences with these interventions. Collectively, these data can be used to better understand the implementation of evidence-based interventions and related determinants.

Recruitment

Soft-launch recruitment for N2P2 commenced in September 2022. Respondent-driven sampling (RDS), a systematic form of snowball sampling that leverages existing social networks, is being used for recruitment [114]. RDS has previously been used to sample marginalized populations [115], including Black SMM and TW [49,116]. A total of 60 nonrandomly selected "seed" participants will be recruited from a variety of community sources with attention paid to diversity in geography and prior involvement in research and substance use (eg, recruiting seeds who use methamphetamine) [117,118]. In the cohort before N2, uConnect (n=612), we achieved a representative sample using approximately 60 seeds, which generated a large sample (n=620) [119]. Although a diverse sample was generated, homophily was achieved across several demographics in fewer waves (including some nonproductive seeds) given the inclusion criteria based on race, geography, and age. We hope to replicate a successful RDS in N2P2. Study facilitators will monitor the recruitment process and track referrals along recruitment threads. During recruitment, participants will receive a flyer with a unique identifier code, allowing them to be added to the study, which will also be used to indicate who referred them. For each additional individual that a participant successfully recruits to the study, the participant will receive US $30 compensation (up to a maximum of 6 additional participants) via cash or an electronic money transfer service of their choice (eg, PayPal, Cash App, and Venmo). Recruitment materials were developed to increase awareness of the study among the community, including the development of an N2P2 study logo (Figure 2).

Eligibility criteria for inclusion in the N2P2 study include (1) assigned male sex at birth, (2) identify as being Black or African American, (3) aged 18 to 34 years, (4) report of at least 1 sexual encounter with another man or transgender woman within the past year, and (5) currently residing in the Chicago MSA with no plans to move or relocate during the proposed study period. Individuals who are unable to provide informed consent are excluded from participating in the study. Individuals who screen eligible will then be scheduled for an appointment at the study site, the Village, the Chicago Center for HIV Elimination's, off-campus community service and research space that has served Chicago's South Side community for over a decade and that specializes in HIV prevention and care services [120].

Regarding the eligibility criteria, we made a conscious decision to be inclusive in the N2P2 study and engage Black TW as well as Black SMM. There are multiple reasons for this decision. First, the environments in Chicago in which both Black SMM and TW predominantly live include hyper-segregated neighborhoods that create similar exposures that are major drivers of HIV [121-123]. In addition, networks are often similar and overlapping with social networks including members of the house or ball community and sexual networks including many SMM. Indeed, research has shown that Black SMM and TW are members of social and sexual networks that are associated with HIV-related outcomes in nuanced ways [15-17,124-127]. In addition, many Black TW transition later than their White counterparts, and they identify at younger ages as SMM [128-130]. The reasons for this are complex, but the situation is likely not helped by most adolescent gender programs across the United States (including in Chicago), which underuse gender-affirming hormone therapy [131,132]. Finally, the decision to intentionally include both Black SMM and TW in the N2P2 study was made with community input, including from participants in the original N2 study, and with the understanding that social and sexual networks among Black SMM and TW in Chicago significantly overlap [126,133]. Importantly, community input highlighted increasing inclusivity, with particular attention needed to ensure that survey materials, procedures, and protocols are culturally tailored and gender affirming, with appropriate skip patterns and language to ensure that community members feel included and respected.

We recognize that transgender individuals describe themselves in a variety of different ways; for the purposes of our study and in congruence with established research on TW with HIV [134,135], we define TW as individuals who were assigned male sex at birth and have a feminine gender identity. We acknowledge that it is important to note that Black SMM and TW are distinct populations that experience unique social contexts and challenges related to substance use, sleep health, and HIV-related outcomes [14,136]. Indeed, studies have demonstrated that compared with Black SMM, Black TW experience substantially higher rates of financial instability, incarceration, and HIV and STIs [137,138].

RenderX

Figure 2. Neighborhoods and Networks Part 2 (N2P2) study logo.

Procedures and Measures

Assessments are conducted every 9 months for 3 waves. Assessments are conducted in person in private interview rooms at an off-campus research and service space, The Village, which is located in the same building that has been engaging Black sexual and gender minority community members for >20 years. Four different forms of data are collected at each assessment: (1) a self-report survey, (2) biological specimen collection, (3) the administration of a daily remote EMA survey, and (4) extraction of EHR data. The prospective design of N2P2 enables the study team to alter and expand future surveys based on preliminary findings, including measuring relevant implementation issues, as per the hybrid observational-implementation approach [99]. After completing the survey, blood samples are drawn by trained study staff and screened for HIV antibodies to determine participant HIV serostatus. To encourage engagement with community members from all backgrounds, reduce barriers to entry, and increase accessibility, participants have the option to complete assessments remotely on Zoom (Zoom Video Communications), thus reducing the in-person requirement of participation to only collection of the biospecimens, which are scheduled at a separate date and time following survey completion. At the end of the assessment, survey technicians confirm contact information, schedule follow-up visits, provide instructions on completing the daily EMA survey, and disburse compensation for completion of the survey (US $100) and provision of biological samples (US $50) in cash or other preferred mechanism for compensation. Finally, as we did for the original N2 study [139], we continue to seek permission to access EHR data and health department data of each participant via release of information forms and subsequently link these data with the participant's study identification number. Details on each type of data collection are described in the following sections.

Self-Report Survey

Overview

The self-report survey was developed by the study investigators in tandem with the University of Chicago Survey Laboratory. Of note, certain constructs from N2 Part 1 continue to be used in this N2P2 study, allowing for robust longitudinal analyses. Trained survey technicians obtain written informed consent before participants complete a survey using computer-assisted participant interview (CAPI) technology. Self-report survey measures assessed using CAPI technology are described by construct in the paragraphs below and summarized in Table 1.

HIV Care

Self-reported HIV care outcomes include ART adherence and linkage to HIV care, which are assessed using validated measures [144,159].

PrEP Cascade of Care

To assess self-reported PrEP outcomes, we are providing participants with an adapted description of PrEP used successfully with samples of SMM and TW vulnerable to HIV [160]. The PrEP cascade of care measures include *current PrEP use* [144], *PrEP modality* (pill or injection), *PrEP initiation and discontinuation, and PrEP adherence* [159].

Cannabis Use and Other Substance Use

Cannabis use is being assessed via multiple validated and reliable measures that describe the frequency of use [151], modes of use [151], timing of use [151], risk of disordered use [152], motivations for cannabis use [153], and reasons for seeking cannabis treatment (if sought out by participants) [154]. The use of other substances such as alcohol, stimulants, heroin or opiates, and nicotine is also assessed and described in terms of frequency, method of consumption, and risk of disordered use [105,155,156].

Sleep

Sleep health outcomes include the self-reporting of sleep duration [157], sleep quality [157], and sleep-related problems (eg, apnea and trouble falling asleep or insomnia) [158].

Sexual Behavior

We are measuring partnered sexual behavior in the past 3 months [161], including characteristics of sexual partners (eg, gender, relationship type, HIV status, PrEP use, and undetectable viral load), sexual acts, and condom use.

Moderating Variables

Additional relevant individual-, network-, and neighborhood-level characteristics will be assessed as moderators of the impact of cannabis use on PrEP outcomes. Individual-level characteristics will include sociodemographics, reasons for using cannabis, cannabis use expectations, intersectional discrimination [148], and race-based harassment [147]. Obesity will also be assessed as a potential moderator for analyses involving sleep health as an exposure variable. Social and sexual network characteristics will include the racial and ethnic composition of network members, network size, network substance use, and network PrEP use. Neighborhood-level characteristics will include socioeconomic disadvantage, racial and ethnic composition, and locations of dispensaries. Many of these measures were captured in the original N2 study. Whenever feasible, preexisting N2 data will be used.

Covariates

Data are being collected on the following relevant sociodemographic variables: age, ethnicity, sexual orientation, sexual attraction, socioeconomic status (eg, education, income, and employment), current living situation (eg, housing instability), nativity, relationship status, mental health, history of incarceration, health insurance status, and existing or recent STIs (eg, chlamydia, gonorrhea, and syphilis).

Biological Specimen Collection

Collected blood samples are screened on site for HIV and syphilis, after which the plasma from each sample is objectively measured for quantitative levels of cannabis metabolites via liquid chromatography–tandem mass spectrometry [74]. These metabolites will also be measured using solid-phase extraction and gas chromatography–negative ion chemical ionization mass spectrometry [162]. The detection of cannabis metabolites in plasma will be used to confirm self-reported cannabis use by the study participants. In addition, we will explore the utility of using plasma levels of tetrahydrocannabinol to stratify participants into cannabis use groups (eg, heavy user or moderate user) [163]. Cytokine and chemokine levels are also assessed in the systemic circulation (plasma samples) using the Human Inflammation Panel via the LEGENDplex assay (BioLegend, Inc), which measures 13 different cytokines or chemokines, including those relevant to HIV infection [164].

After instruction by study staff, the participants also self-administer 3 rectal swabs and 1 oral swab. The 1 oral swab and 1 of the 3 rectal swabs are tested on site for chlamydia and gonorrhea nucleic acid amplification tests [165]. The remaining 2 rectal swabs are evaluated for the levels of proinflammatory cytokine and chemokine in the rectal mucosal secretions. Finally, participants are asked to provide a urine sample, which is used to conduct on-site toxicological screening of marijuana, methamphetamine, opioids, and cocaine as well as chlamydia and gonorrhea nucleic acid amplification tests. Participants who test positive for HIV or STIs or who are interested in PrEP, primary care, or substance use treatment are linked to care with services available in the same building as the data collection. A summary of the biological measures is presented in Textbox 1.

XSL•FO
RenderX

Textbox 1. Biological data in Neighborhoods and Networks Part 2 data collection.

Constructs and measurements

- Cannabis use
  - Biological presence in blood or urine samples
- Other substances
  - Biological presence in blood or urine samples
- Sexually transmitted infections
  - Biological data for chlamydia, gonorrhea, or syphilis in urine, blood, saliva, or rectal mucosa samples
- Inflammation
  - Biological data on cytokine and chemokine levels in systemic circulation and rectal mucosa

EMA Survey

The EMA survey is administered over a 2-week period following the in-person assessment. If participants are unable to complete the EMA survey using their personal phone, the study team sends the EMA survey via email. Participants receive a daily notification through their cell phones at the same time each day asking to complete the brief survey. The participants have 2 hours to complete the survey. Participants receive an additional reminder notification 1 hour before the survey expires as well as personalized reminder text messages from the study staff. Daily assessments (rather than more frequent assessments) were chosen to minimize participant burden, based on feedback from community members who participated in the original N2 study. Participants receive US $2 for each daily survey completed within the first week and US $3 for each daily survey completed during the second week. The participants also receive a US $5 bonus if all 14 days are completed. The EMA survey includes multiple measures regarding policing, substance use, HIV outcomes, and mental health. Example questions and response options from the EMA survey are listed in Table 2.

Table 2. Ecological momentary assessment survey measures in Neighborhoods and Networks Part 2 data collection.

Measure	Example question	Example response options
Policing	"In the past 24 hours, did you encounter someone in law enforcement that:"	"(Select all that apply) Pushed or grabbed you?; Followed you?; Made you feel unsafe?; etc."
HIV outcomes	"In the past 24 hours, did you take a daily PrEP[a] pill"	"Yes; No"
Cannabis use	"In the past 24 hours, how many times did you use cannabis?"	"(Numerical drop-down selection) 1-7+"
Other substance use	"In the past 24 hours, did you use any of the drugs listed below?"	"Heroin (Smack, Junk, Dope); Fentanyl (China White, China Girl, Tango); Benzos; Methamphetamine (Speed, Meth, Crystal, Crystal Meth, Ice, Crank); Cocaine (Coke, Snow, Crack, Rock); Prescription opioids; Unknown combination of opioids; Other; None of the above"
Alcohol use	"In the past 24 hours, how many drinks of alcohol did you have?"	"(Numerical drop-down selection) 1-7+"
Anxiety and depression [145]	"In the past 24 hours how often were you bothered by the following problems (if at all)?"	"Not at all; Several times throughout the day; More than half the day; Nearly all day"

[a]PrEP: pre-exposure prophylaxis.

EHR Data

Overview

As we did for the original N2 study [139], we continue to seek permission to access the EHR data of each participant via release of information forms from a local partnering health clinic and surveillance data from the health department and subsequently link these data with the participant's study identification number. The outcomes described in the following subsections will be extracted from participants' EHRs (Textbox 2).

XSL•FO
RenderX

Textbox 2. Electronic health record data in Neighborhoods and Networks Part 2 data collection.

Constructs and measurements

- Viral suppression
  - Biological viral load
- Retention to HIV care
  - Missed visit proportion
- Pre-exposure prophylaxis (PrEP) outcomes
  - PrEP persistence and type of PrEP product

Viral Suppression

Viral suppression data will be obtained from the participants' EHRs. Viral suppression is defined as having a viral load of ≤200 HIV RNA copies/mL.

Retention to HIV Care

Retention to HIV care is measured by calculating a missed visit proportion, or the proportion of total scheduled visits (eg, nonacute appointments with an ART-prescribing provider) that are missed across the 27-month follow-up period [166,167]. Appointment and visit history to calculate the missed visit proportion will be collected from each participant's EHR. To permit longitudinal analyses, we will divide the 27-month follow-up period into three 9-month sections and record, for each participant, whether they completed or missed their scheduled appointment during that section.

PrEP Outcomes

Several PrEP-related outcomes will be obtained from the participants' EHR data, including PrEP persistence, which will be measured in several ways (eg, number of dedicated PrEP visits and number of prescriptions for PrEP) [168]. The type of PrEP product will also be collected, although we expect limited uptake of long-acting injectable PrEP in this community owing to a number of social and structural barriers; notably, these barriers are repeatedly observed with each new biomedical advance purportedly developed for community members classified as most vulnerable [169,170].

Data Management

Each N2P2 participant receives a unique study identification number, which is used to link all 3 forms of the primary data into a centralized database in the same manner as our original N2 study [139]. Data will be analyzed with the aim of maintaining participant anonymity. Access to the participant identification number, which links data to unique identifiers, will be restricted to designated members of the research team. All survey, biological, EMA, and EHR data will be uploaded to the encrypted University of Chicago servers and will be backed up on a weekly basis.

Data Triangulation

For data triangulation, objective measures will be prioritized, using previously validated decision rules for combining objective biomarker data with self-reported measures, an approach that has been used in other studies with regard to substance use [171,172] and that we will adapt as needed. This approach will allow us to account for the limitations of respective measures (eg, inaccuracy of self-report [173] and varying rates of metabolizing substance use [174]) and also allow us to identify relevant categories, as has been done in other studies [74,175]. Using multiple measures to assess constructs, particularly those regarding sensitive topics, is superior to relying on a single method [176].

Statistical Analyses

The longitudinal design of N2P2 will allow researchers to evaluate changes in constructs over time as well as cross-sectional, series cross-sectional, and longitudinal associations between exposures and outcomes [177]. We will use generalized linear models to evaluate the associations between relevant exposures and outcomes. These models will include the appropriate time-invariant and time-varying covariates to adjust for confounding of each exposure-outcome relationship. In addition, we will apply generalized estimating equations to account for repeated measures within individuals across study visits. For analyses that assess mediation, we will use statistical tests that leverage the latest statistical methodological advances in the causal inference field and that test for and estimate the effect of mediation (ie, the natural indirect effect). Our inferences will support a causal mediation interpretation if the covariates effectively control for confounding in 4 key relationships: the impact of the candidate exposure on the outcome, the effect of the candidate exposure on the candidate mediator, the influence of the candidate mediator on the outcome, and if the candidate exposure has no impact on any confounding variables related to the effect of the candidate mediator on the outcome. We recognize that this approach is among various mediation analysis methods, and we will also consider other commonly applied approaches [178]. To assess effect modification, we will conduct regression analyses by adding 2-way interaction terms (eg, cannabis use × moderator) to the previously described generalized linear models. We also plan to evaluate cross-level interactions to determine whether our 2-way interaction analyses vary by other variables in the associations between our candidate exposures and outcomes. We further plan to use additional modeling approaches, including egocentric analysis, mesolevel sociometric analysis, multilevel (affiliation network) modeling, 2-mode person or place network modeling, synergistic place or network models, and spatial autocorrelation regression modeling. In

XSL•FO
RenderX

some analyses, moderating variables that are considered confounders will be adjusted for as covariates.

Power Calculations

We have adequate power to address our primary study aims. With a planned baseline sample size of 600 Black SMM and TW with 80% attrition over the study period and assuming α=.05 and power=0.80, we estimate that we will have 80% power to detect Cohen *d* effect sizes of 0.40 in differences of continuous HIV-related outcomes (based on distributions of those outcomes in N2 baseline data) in the highest versus lowest quintiles of exposure in the cohort. This is a conservative calculation, as it does not account for the adjustment of covariates, which can serve to increase power. To maximize the sample size and minimize potential selection bias as a result of loss of participants who do not attend all follow-up waves, we will use a pooled analysis approach and include participants who attend at least 1 of the 3 waves over the study period. A total of 600 participants will contribute 1800 potential observations across waves. This approach has been used in our prior work and in other cohort studies to efficiently maximize analytic capabilities [179]. Moderation analyses may not be optimally powered, especially to examine cross-level interactions. Mediation analyses may also not be optimally powered. However, to mitigate power issues, we plan to dichotomize sociodemographic characteristics when possible and appropriate [180]. Moreover, the potential mechanisms linking study exposures to HIV-related outcomes will be the focus of future research proposals (ie, adequate power will be prioritized).

Governance and Organizational Study

Research strategies and protocols for the N2P2 study were developed using a community-based participatory approach [181] where study staff members regularly meet with the community advisory board to guide the study. These meetings involve receiving community feedback on survey assessments and protocols, presenting progress reports on the study, discussing preliminary data, and determining the best practices for dissemination to community members and policy makers. In addition, 1 staff member who is from the Chicago Black SMM and TW community further guides community engagement through periodic social events and social media development. Moreover, we have also created a scientific advisory board to provide expert feedback on the overall study design and methodology of N2P2, thereby supporting the collection and analyses of high-quality data.

Ethical Considerations

This study was conducted in accordance with the guidelines of the Declaration of Helsinki. The N2P2 study protocol has been approved by the institutional review board (16-1419) of the University of Chicago (institutional review board of record), and a reliance agreement has been established with Columbia University. Written informed consent is required from all participants before participation in the study. Benefits to participation in the study include sharing the results of HIV serostatus and STI testing at multiple time points as well as referral to relevant health services when necessary (substance use treatment and mental health).

Results

The N2P2 study was funded in August 2021 by the National Institute of Drug Abuse (R01DA054553 and R21DA053156) and National Heart, Lung, and Blood Institute (R01HL160325), and approved by the institutional review board in September 2022. Data collection was launched in November 2022. As of manuscript submission, 431 participants have been enrolled. Recruitment and enrollment for the first wave of data collection are currently ongoing.

Discussion

Expected Findings

In summary, the N2P2 study applies innovative methods to comprehensively explore the impact of substance use and sleep health on HIV-related outcomes among an HIV status–neutral cohort of Black SMM and TW in Chicago. This study applies an observational-implementation hybrid design to prioritize the expedited translation of findings into public health impact, a critical priority among populations such as Black SMM and TW that experience long-standing inequities with regard to HIV and other health-related outcomes owing to systemic racism, homophobia, and transphobia. N2P2 directly builds on the findings of the original N2 study among Black SMM and TW in Chicago. These findings contribute to a better understanding of how multilevel (eg, individual, network, and neighborhood) factors are associated with HIV prevention and care outcomes among Black SMM and TW [139,182,183]. Relatedly, the N2 COVID-19 study contributed additional findings related to factors associated with PrEP and ART use, among other health outcomes and health behaviors, at the initial peak of the COVID-19 pandemic [50,184-186].

A major goal of the N2P2 study is to inform the implementation of evidence-based practices that already exist to address many of the issues that we are studying. For example, we observed a high prevalence of heavy drinking in the original N2 study, which aligns with other studies among Black SMM and TW [187]. We also observed from the N2 COVID-19 study that alcohol use increased among Black SMM and TW during the pandemic [50], as it did among the general population [188,189]. However, very few individuals who could benefit from alcohol treatment receive it [190,191], despite the availability of multiple evidence-based interventions [107], indicating a clear implementation gap. Therefore, in this observational cohort study, we are working to incorporate elements of implementation science related to evidence-based interventions that address alcohol use. We have named this the *hybrid observational-implementation approach*, and we have previously described how this practical approach can be applied to observational epidemiologic research to make it more consequential by contributing more directly to the growing implementation science movement [99]. This may also help to make the research pipeline more efficient and faster [192] and help observational research achieve its intended public health impacts, an innovation that is especially important for health

XSL•FO
RenderX

equity research. In future waves of the N2P2 study, we intend to expand this work to address other salient health issues, particularly those that we learn about through findings from the existing N2 study data, or in the upcoming waves of N2P2 data collection.

In addition, given the longitudinal nature of our data collection, we are able to continue examining COVID-19 as well as recently emerged STI threats (eg, mpox [193]), evolving STI epidemics such as syphilis, and other infections that disproportionately impact these communities (ie, meningococcus). This can be an important extension for future N2P2 waves, as it is known that there are clear racial and ethnic differences in new and emerging infectious disease epidemics, including among Black SMM and TW [194,195].

Maintaining meaningful community engagement at each step of the research process and enhancing those efforts are top priorities in the N2P2 study, an approach used in the original N2 study. For example, community members provided iterative feedback that has informed this study's design. In addition, the study team organized several community dinners and social events (eg, study relaunch event at the Village) to share the findings of the original N2 study and further strengthen community trust and inclusion. We aim to continue prioritizing shared decision-making and using innovative community-based research approaches (eg, crowdsourcing and human-centered design) as the N2P2 study progresses forward [196].

Relatedly, many papers from the original N2 study were led by trainees and early-stage investigators (eg, postbaccalaureate research coordinators, master's-level students, PhD students, and postdoctoral fellows), including those who hold minoritized identities, particularly trainees who hold the same intersectional identities as those in the N2 study. This has enhanced our ability to situate interpretations of data in the community context and obtain high-quality data. For example, because many research coordinators hold similar intersectional identities as N2 study participants, we were able to build trust with the community. This hopefully will contribute to less misclassification in self-reported measures and a greater willingness to adhere to study protocols. In N2P2, we plan to continue this work, especially because we recognize the harms that can arise from power differentials between researchers and study participants [197]. We view this component of our work as part of our intersectional and health equity–focused research program, which aims to ultimately achieve better health outcomes among Black SMM and TW [198,199].

Finally, we note that the N2P2 study currently does not have funding for recruitment in the Southeastern United States, which was a component of the original N2 study. We are actively working to acquire funding to study Black SMM and Black TW in the Southeastern sites included in N2, including New Orleans and Baton Rouge, given that the burden of the domestic HIV and AIDS epidemic is heaviest among Black SMM and TW living in that part of the country [200].

Strengths and Limitations

The N2P2 study has some limitations. First, our sample of Black SMM and TW is sampled exclusively from the Chicago MSA and may have limited generalizability to other geographic contexts, such as smaller cities or rural areas. We decided to continue our focus on the Chicago MSA as >80% of the US population lives in urban settings [201]. Chicago shares similar contextual and environmental characteristics with many other hyper-segregated EHE jurisdictions in the United States, such as Houston and Detroit. In addition, owing to the duration of the cohort, our study's ability to assess causality may be limited by participant loss to follow-up. This limitation is particularly significant for minoritized populations such as Black SMM and TW because of the structural barriers that these groups experience. For example, in the original N2 study cohort, 70% of the participants had an annual income of <US $25,000 and 35% reported unstable housing. These structural barriers have also been shown to be related to HIV-related outcomes [48], and they also serve as barriers to participation in research. To mitigate this challenge, participant retention is prioritized within the study's community integration efforts as well as through protocol-based approaches such as recording participant contact information and consistent efforts to connect with participants and remind them of their engagement with the study. Moreover, owing to social desirability bias, it is possible that substance use, sexual behaviors, and PrEP and ART nonadherence are underreported. We aim to reduce the effects of this bias by obtaining objective biomarker data and using CAPI to collect potentially sensitive information. Finally, we recognize heterogeneity in Black SMM and TW and the importance of meaningful intersectional analyses; however, because we are not intentionally focusing on this heterogeneity, we may have limited power for subgroup analyses such as by ethnicity and socioeconomic status. For example, in the original N2 study, although we have variation in socioeconomic status, only 6.6% of the sample reported being Latinx or Hispanic ethnicity. We are also making efforts to ensure variability in other factors that are related to health, such as our intentional geographical sampling approach, and collect data on experiences that are relevant to Black SMM and TW, such as membership in the house or ball community and other queer family structures.

Conclusions

These limitations are offset by many notable strengths. In N2P2, we are using a unique and innovative approach to simultaneously explore multiple salient questions about what potentially drives the long-standing HIV-related inequities experienced by Black SMM and TW [1,9]. Combining resources to conduct a comprehensive study, such as N2P2, marks a potentially more efficient use of resources, one that may reduce the logistical challenges associated with establishing independent cohorts to address each of these topics independently. The inclusive HIV status–neutral approach minimizes potential stigmatization and enhances the potential to connect participants with relevant HIV prevention and treatment services. Furthermore, the multiple innovative methods that are being used to collect primary data in N2P2, including EMA, biobehavioral overlap, preference elicitation, and human-centered design, will allow a more holistic understanding of how substance use, sleep, and HIV-related outcomes interrelate. Similarly, because of the pressing need for additional research on the HIV epidemic, specifically within Black SMM and TW communities, the study

XSL•FO
RenderX

findings from N2P2 may have a substantial potential public health impact. As such, the N2P2 study provides a pivotal opportunity to better understand the impact of substance use and sleep on HIV among Black SMM and TW, which may inform the development of future evidence-based culturally relevant interventions and policy approaches.

Acknowledgments

The authors thank the participants for engaging in this research. The Neighborhoods and Networks Part 2 (N2P2) study is funded by grants from the National Institute on Drug Abuse (R01DA054553, multiple principal investigator [MPI]: DTD and JRK; U2CDA050098, principal investigator [PI]: JAS and the National Heart, Lung, and Blood Institute (R01HL160325, MPI: DTD or JAS). The N2P2 study is further supported by several pilot awards from the HIV Center for Clinical and Behavioral Studies (P30MH043520, PI: Remien), the National Center for Advancing Translational Sciences (UL1TR001873, PI: Reilly), and the New York University Center for Drug Use and HIV Research (P30DA011041, PI: Hagan) to JRK. JRK is also supported in part by grants from the National Institute on Alcohol Abuse and Alcoholism (K01AA028199), the National Institute on Drug Abuse (NIDA) (R01DA057351 and R21DA05315), and the National Institute on Mental Health (P30MH043520). YTC is supported in part by a grant from the National Institute on Drug Abuse (R03DA053161). Duncan was supported in part by grants from the National Institute on Minority Health and Health Disparities (R01MD013554 and R01MD013554-S1); the National Institute on Mental Health (R01MH129198); the National Institute on Drug Abuse (5P30DA011041-24); the National Heart, Lung, and Blood Institute (R01HL160325); and the National Institute on Allergy and Infectious Diseases (UG3AI169658). JR and the Center for Human Toxicology receives funding from NIDA (75N95019C00016) to support the development and validation of a bioanalytical assay for measuring cannabinoids. The work described herein is the sole responsibility of the authors and does not represent the official views of the National Institutes of Health or its institutes.

Data Availability

Once data are collected, they will be stored in a public repository hosted by Data Commons. In addition, investigators can obtain data via an email request to the Neighborhoods and Networks Part 2 staff.

Authors' Contributions

JRK, JAS, and DTD were responsible for conceptualization of the project. The methodology was developed by JRK, JAS, and DTD. Formal analysis was conducted by EA, AH, and CM. JRK, JAS, DTD, IM, MD, HH, and EA. Resources were provided by JAS. Data curation was conducted by HH, EA, and AH. JRK, BD, TM, and DTD prepared the original draft of this manuscript and IM, MD, HH, EA, AH, JP-B, Y-TC, DE, JM, JR, CM, BM, GJ-L, HJR, SSM, CG, DSH, AWC, SS, JAS, and DTD revised and edited the manuscript. JRK, JAS, and DTD supervised the project with project administration by IM, MD, HH, and JAS. Funding acquisition done by JRK, JAS, and DTD.

Abstract

Background: Chondrocytes are the primary cells responsible for maintaining cartilage integrity and function. Their role in cartilage homeostasis and response to inflammation is crucial for understanding the progression and potential therapeutic interventions for various cartilage-related disorders. Developing an accessible and cost-effective model to generate viable chondrocytes and to assess their response to different bioactive compounds can significantly advance our knowledge of cartilage biology and contribute to the discovery of novel therapeutic approaches.

Objective: We developed a novel, streamlined protocol for generating chondrocytes from bone marrow–derived mesenchymal stem cells (BMSCs) in a 3D culture system that offers significant implications for the study of cartilage biology and the discovery of potential therapeutic interventions for cartilage-related and associated disorders.

Methods: We developed a streamlined protocol for generating chondrocytes from BMSCs in a 3D culture system using an "in-tube" culture approach. This simple pellet-based 3D culture system allows for cell aggregation and spheroid formation, facilitating cell-cell and cell–extracellular matrix interactions that better mimic the in vivo cellular environment compared with 2D monolayer cultures. A proinflammatory chondrocyte model was created by treating the chondrocytes with lipopolysaccharide and was subsequently used to evaluate the anti-inflammatory effects of vitamin D, curcumin, and resveratrol.

Results: The established protocol successfully generated a large quantity of viable chondrocytes, characterized by alcian blue and toluidine blue staining, and demonstrated versatility in assessing the anti-inflammatory effects of various bioactive compounds. The chondrocytes exhibited reduced inflammation, as evidenced by the decreased tumor necrosis factor-α levels, in response to vitamin D, curcumin, and resveratrol treatment.

Conclusions: Our novel protocol offers an accessible and cost-effective approach for generating chondrocytes from BMSCs and for evaluating potential therapeutic leads in the context of inflammatory chondrocyte–related diseases. Although our approach has several advantages, further investigation is required to address its limitations, such as the potential differences between chondrocytes generated using our protocol and those derived from other established methods, and to refine the model for broader applicability and clinical translation.

Introduction

Background

The burgeoning field of regenerative medicine has placed a considerable focus on the differentiation of bone marrow–derived mesenchymal stem cells (BMSCs) into chondrocytes [1,2]. This area of research is critical for advancing our understanding of cartilage repair and regeneration and for developing novel therapeutic strategies [3]. Therefore, it is essential to consider the optimal environment for these sophisticated cellular processes. Although cell culture plates have been the standard for differentiation experiments, recent evidence suggests that using tubes for differentiation may better simulate the native chondrocyte habitat and foster more accurate cell-cell and cell–extracellular matrix (ECM) interactions [4]. Consequently, research has shifted its focus toward tube-based, 3D culture systems that more accurately simulate native tissue conditions [5].

Several studies have highlighted the superiority of tube-based culture over conventional 2D cell culture plates. A comparative analysis is presented in Table 1. The rationale behind this innovative approach lies in the unique characteristics of the chondrocyte ECM and the intricacies of cartilage tissue formation. By using tubes for differentiation, we can create a 3D environment that better mimics the native milieu of chondrocytes, fostering improved cell-cell and cell-ECM interactions. This shift in methodology not only enhances our understanding of chondrogenesis but also has the potential to accelerate the development of novel therapeutic strategies for cartilage repair and regeneration.

Table 1. Comparison of 2D and 3D cell culture methods.

	Type of cell culture		Key references	Advantage of tube-based cell culture used in this protocol[a]
	2D	3D		
Cell-cell interactions	Limited	Enhanced	Breslin and O'Driscoll [6]	Enhanced cell-cell interactions
Cell–extracellular matrix interactions	Restricted	More accurate	Cukierman et al [7]	Improved mimicry of in vivo conditions
Spatial organization	Flat and monolayer	Complex and multilayered	Edmondson et al [8]	Better representation of tissue architecture
Cell polarization	Mostly absent	Prominent	Théry [9]	Improved cell polarity and functionality
Cell signaling	Altered and oversimplified	More realistic	Bissell and Radisky [10]	More accurate signaling pathways
Cell migration and invasion	Less accurate	Closer to in vivo	Friedl and Alexander [11]	Improved evaluation of cell migration and invasion
Cellular morphology	Flattened and simplified	More in vivo–like	Ravi et al [12]	Enhanced representation of native morphology
Stiffness	High stiffness (approximately 3×10^9 Pa)	Low stiffness (>4000 Pa)	Krausz et al [13]	Low stiffness reduces durotaxis, augmenting cell growth and proliferation and reduction of cellular stress, which may alter gene expression
Gene expression	Altered	More physiologically relevant	Duval et al [14]	Improved gene expression profile
Cellular functions and responses	Limited and oversimplified	More complex and accurate	Edmondson et al [8]	Better simulation of in vivo functionality
Differentiation and stem cell maintenance	Reduced fidelity	Enhanced fidelity	Hockemeyer and Jaenisch [15]	Improved maintenance of cell identity
Cell viability and proliferation	Unreliable representation	More accurate representation	Langhans [16]	Better assessment of cell growth and survival
Drug sensitivity	Less predictive	More predictive	Imamura et al [17]	More accurate drug sensitivity when compared with the 2D system but not as superior when compared with complex 3D techniques such as organoids and scaffold-based systems
Drug exposure	Nonphysiological	Closer to in vivo	Badr-Eldin et al [18]	Improved drug exposure over the 2D system; but when it comes to in vivo mimicry, it may not be as superior as complex 3D techniques such as organoids and scaffold-based systems
Ease of imaging	Enables simple imaging owing to their monolayer structure	Requires sophisticated imaging protocol owing to the complex and multilayered structure	Temple et al [19]	Ease of imaging is high in 2D over 3D cell culture systems, although in-tube–based 3D cell culture systems involving a single type of cell, imaging is relatively easy with high replicability over complex 3D techniques such as organoids and scaffold-based systems
Technical complexity	Low	Higher and varies according to the type of 3D culture system being used	Cacciamali et al [20]	In this protocol, complexity is moderate when compared with a 2D culture system

XSL•FO
RenderX

	Type of cell culture		Key references	Advantage of tube-based cell culture used in this protocol[a]
	2D	3D		
Scalability	High	Variable and technique dependent	Fang and Eglen [21]	Depends on the 3D cell culture technique but is relatively high for tube-based 3D cell culture techniques. Scalability is especially restricted in scaffold and matrix and microfluidic 3D models
Reproducibility	High	Variable and technique dependent	Duval et al [14]	Typically higher than other 3D cell culture techniques
Cost of experimentation	Low	High—varies with technique	Khalil et al [22]	Typically higher than 2D cell culture techniques, varies with technique but lower when compared with scaffold or matrix, organoid, and microfluidic 3D models
Cost of maintenance	Low	High—varies with technique	Raic et al [23]	Typically higher than 2D cell culture techniques, varies with technique but lower when compared with scaffold or matrix, organoid, and microfluidic 3D models.

[a]The 3D tube-based method for culturing chondrocytes demonstrated in this protocol offers advantages over 2D culture plates, such as enhanced cell-cell interactions, improved extracellular matrix production, and more physiologically relevant cellular responses. Although this tube-based approach is relatively simple compared with other 3D methods such as scaffold-based systems, hydrogels, and organoids, it still possesses many benefits of 3D cell culture systems.

Furthermore, investigating the response of the differentiated chondrocytes to proinflammatory stimuli such as lipopolysaccharide (LPS) is a vital aspect of understanding the intricate mechanisms of cartilage tissue degeneration and inflammation. By creating a proinflammatory model using LPS with the differentiated chondrocytes, we can delve deeper into the cellular and molecular responses that occur during inflammatory conditions such as osteoarthritis. This knowledge is crucial for the development of targeted therapies to mitigate inflammation and promote cartilage regeneration.

Objective

In this concise research protocol, we outline an uncomplicated approach to differentiate BMSCs into chondrocytes within a 3D culture system. Subsequently, we establish a proinflammatory model using the differentiated chondrocytes for further investigation. This succinct research protocol not only provides a valuable contribution to the field of cartilage tissue engineering but also offers a practical foundation for researchers seeking to explore the potential therapeutic applications and underlying molecular mechanisms in chondrocyte-based proinflammatory models.

Methods

Reagents and Equipment

The different reagents and equipment that were used in this study are presented in Textbox 1 in the form of a list for ease of use and reference by researchers.

XSL•FO
RenderX

Textbox 1. Reagents and equipment used in this study.

Cell culture

- Reagents
- Human BMSC line (Addexbio, United States [24])
- Complete MesenCult-ACF Chondrogenic Differentiation Medium (Stem Cell Technologies, Canada [25])
- Phosphate-buffered saline (PBS; Gibco, United Kingdom [26])
  - Mesenchymal stem cell growth media (MSCM; Himedia, India [27])
  - Fetal bovine serum (Himedia, United States [28])
  - Penicillin-streptomycin solution (Himedia, India [29])
  - Trypsin and ethylenediaminetetraacetic acid solution (Himedia, India [30])
- Equipment
  - Automated cell counter (DeNovix, Cell Drop, United States [31])
  - Microfuge 20 centrifuge [32]

Histological section of pellets

- Reagents
  - Dimethyl sulfoxide [33]
  - Neutral-buffered formalin (TissuePro, United States [34])
- Equipment
  - Microtome (Leica RM2255, Germany [35])

Staining of chondrocytes

- Reagents
  - Toluidine blue ($C_{15}H_{16}N_3S^+$; Abcam, United States [36])
  - Alcian blue ($C_{56}H_{68}C_{14}CuN_{16}S_4$; Abcam, United States [37])
- Equipment
  - Olympus BX63 microscope (Japan [38])

Creation and evaluation of proinflammation model

- Reagents
  - LPS (Thermofisher Scientific, United States [39])
  - Vitamin D (calcitriol; 1,25-dihydroxyvitamin D3 [1,25(OH)2D3]; Abcam, United States [40])
  - Curcumin (MedChem Express, Ukraine [41])
  - Resveratrol (MedChem Express, Ukraine [42])

Cytokine expression study

- Reagents
  - Tumor necrosis factor-α (TNF-α) enzyme-linked immunosorbent assay (ELISA) kit (Abcam, United States [43])
- Equipment
  - Microplate reader (Hidex, Finland [44])

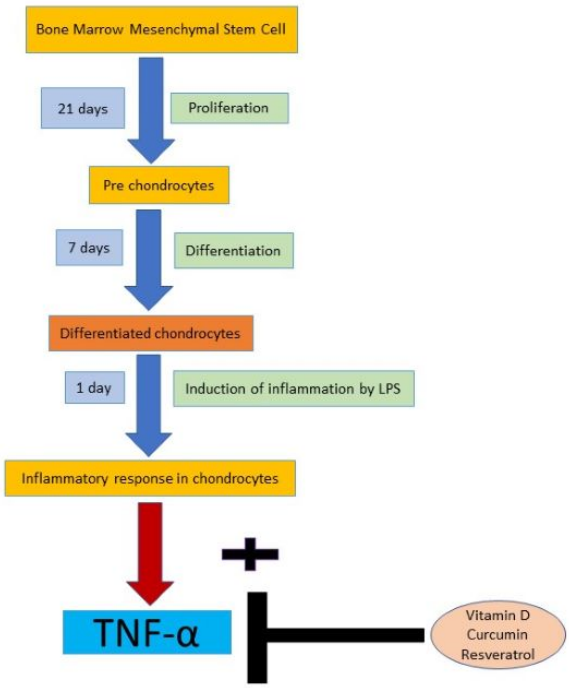
Ethical Considerations

In this study, we conducted experimental procedures exclusively using in vitro methodologies with commercially available cell lines. The absence of animal models or samples, patient samples or data, and the recruitment of human participants ensured minimal risk associated with our research. As such, this study falls under 1 of the exempt review categories defined by the institutional review board regulations of Mohammed Bin Rashid University. For further information and clarification, the institutional review board of the Mohammed Bin Rashid University can be reached at irb@mbru.ac.ae.



As our experiments were conducted using commercially purchased cell lines and did not involve human participants, there was no requirement for informed consent or the inclusion of minors, eliminating the need for parental or guardian consent. In addition, our study did not involve the use of medical records or archived samples. As no human participants were involved, the need for a language waiver was not applicable.

In summary, our study focused on in vitro experiments using commercially available cell lines, negating the involvement of human participants. Consequently, no participant consent was required, and the need for consent, as well as a language waiver which is often required for addressing a form or an agreement while obtaining consent, was waived by the ethics committee. This study complies with human subject research ethics review, exemptions, and approvals, although it primarily involves observations of public behaviors or secondary analyses of research data.

As this study did not involve human participants, the privacy and confidentiality protection descriptions for human participants research, such as statements about data anonymity or deidentification, were not applicable. In addition, because our research did not involve human participants, there was no compensation type or amount provided for human participants research.

The workflow underlying the proof-of-concept study is shown in Figure 1.

Figure 1. Workflow of this study. LPS: lipopolysaccharide; TNF-α: tumor necrosis factor-α.

Preparation of Human Bone Marrow Mesenchymal Stem Cell Line for Cell Culture

Upon receiving the human BMSC line in liquid nitrogen, they were immediately washed with PBS to ensure that the cells were free from the cryoprotectant dimethyl sulfoxide. The washed cells were then cultured in MSCM supplemented with 10% fetal bovine serum and 1% penicillin-streptomycin antibiotic solution. After the addition of MSCM, the cells were kept in an incubator at 37 °C and 5% carbon dioxide. The cell culture medium was replaced with fresh medium at an interval of 3 days, and their confluency was appraised. Once the cells reached 90% confluence, the proteolytic enzyme trypsin was added to dislodge the adherent cells from the culture flask. Trypsinization was performed using trypsin and ethylenediaminetetraacetic acid solution. The detached cells were subcultured for further growth in MSCM.

Cell Culture

In this study, we cultured cells as pellets in 15-mL tubes, instead of using a monolayer culture. Although we did not use a matrix gel or scaffold, our cell culture system can be categorized as a "simple 3D cell culture system." In this pellet culture system, cells are aggregated and allowed to form spheroids or clusters, promoting cell-cell and cell-ECM interactions that more closely resemble the in vivo cellular environment compared with traditional 2D monolayer cultures [45].

XSL•FO
RenderX

This pellet culture system has several advantages over the 2D cell culture system. First, the 3D cell culture system provides a more physiologically relevant environment for the cells, allowing for better simulation of in vivo conditions, including nutrient diffusion, oxygen gradients, and cell signaling (Table 1) [8]. Second, cell behavior, morphology, and gene expression profiles are often more representative of in vivo conditions in 3D culture systems compared with 2D monolayers (Table 1) [14]. As a result, the pellet culture system may provide more accurate insights into cellular responses to various stimuli, such as drug treatments or the presence of inflammatory molecules, which can be beneficial for therapeutic development and disease modeling.

It is worth noting that although the pellet culture system described in this study represents a simple form of 3D cell culture, more complex 3D culture systems using scaffolds or matrix gels can further enhance the recapitulation of the in vivo microenvironment and may provide additional benefits for various applications [46].

After 5 passages of subculture (passage 5), the BMSCs were used for chondrogenic differentiation. For chondrogenic differentiation, 2×10^6 BMSCs (estimated using an automated cell counter) were pelleted in 15-mL polypropylene tubes after centrifugation at 1000 rpm for 10 minutes. In total, 2 mL of complete MSCM chondrogenic differentiation medium was added to the cell pellet, from which 0.5 mL of the cell suspension was added to each 15-mL polypropylene tube (4 in total) for "in-tube" differentiation. Each of these tubes was centrifuged at 1000 rpm for 10 minutes at 25 °C. Caps of the tubes were gently loosened, and the tubes were incubated at 37 °C in the presence of 5% carbon dioxide to ensure that there were no alterations in the pH of the cell culture media. After 3 days of incubation, 0.5 mL of complete MSCM chondrogenic differentiation medium was added to the tubes, followed by incubation at 37 °C in the presence of 5% CO_2 for 3 days. After incubation, the cell culture medium was carefully aspirated from each tube, and 0.5 mL of fresh MSCM chondrogenic differentiation medium was added. The tubes were further incubated at 37 °C in the presence of 5% CO_2 for 21 days, with intermittent replacement (at 3-day intervals) of cell culture medium with fresh MSCM chondrogenic differentiation medium. After each change of cell culture medium, the differentiating cell pellets were gently "flicked" to ensure that the pellets did not adhere to the tube surfaces. After 21 days of incubation, the cell pellets, which were at the stage of chondrogenic differentiation to prechondrocytes, were further incubated for 7 days.

Cryopreservation of Differentiated Chondrocytes

Chondrocytes intended for cryopreservation were centrifuged at 1000 rpm for 10 minutes. The cells were then resuspended in the freezing medium and transferred into suitable sized cryovials. The pellets were kept at −80 °C overnight, followed by storage in a liquid nitrogen tank for long-term use.

Preparation of Histological Section From Cell Pellet

The pellet was transferred to a histology cassette, followed by fixation in 10% neutral-buffered formalin for 24 hours. The cassette along with the pellet were then transferred to 70% ethanol, followed by dehydration in graded ethanol series (25%, 50%, 75%, 90%, 95%, and 100% for 3 minutes each). The clarification steps were carried out in xylene and embedded in paraffin, following a standard embedding protocol. Cell pellets containing chondrocytes were sectioned (6 µm) using a microtome. The sections were mounted on slides. The sections were deparaffinized in 3 changes of xylene, followed by rehydration of the slide sections using a decreasing alcohol series (100%, 95%, 90%, 75%, 50%, and 25% for 3 minutes each), followed by a final rinse with deionized water for 5 minutes.

Toluidine Blue Staining

Toluidine blue solution was prepared by dissolving 0.1 g of toluidine blue in 100 mL of deionized water. The pH of the solution was adjusted to 4. Following the preparation of slides (as described in detail in the *Preparation of Histological Section From Cell Pellet* section), the slides were stained with toluidine blue and kept for 2 minutes at room temperature. The slides were carefully rinsed with water for 1 minute, followed by dehydration in a graded ethanol series (25%, 50%, 75%, 90%, 95%, and 100% for 3 minutes each). The slides were incubated in xylene for 5 minutes to improve visibility by removal of impurities, and mounted in mounting solution. The slides were then observed using a microscope.

Alcian Blue Staining

The alcian blue solution was prepared by dissolving 1 g of alcian blue in 3% acetic acid. The pH of the solution was adjusted to 2.5. The preprepared slides (as described in detail in the *Preparation of Histological Section From Cell Pellet* section) containing 6-µm sections of the pellet were placed in 3% acetic acid solution for 3 minutes. The slides were placed in a 1% solution of alcian blue for 30 minutes. The slides were then washed with running water for 1 minute, followed by dehydration in a graded ethanol series (25%, 50%, 75%, 90%, 95%, and 100% for 3 minutes each). The slides were incubated in xylene for 5 minutes to improve visibility by removal of impurities, and mounted in mounting solution. The slides were then observed using a microscope.

Microscopic Analysis

The Olympus BX63 microscope was used to analyze the staining protocol. The microscope is equipped with Olympus DP80 camera (resolution of 4080 × 3072 pixels and pixel size of 6.45 × 6.45 µm) with Cell Sens Dimension 2.3 software (Olympus Soft Imaging Solutions GmbH). Images were acquired with 20X (numerical aperture 0.45; 1920 × 1200 pixels; 465.079-nm/pixel resolution in both x-axis and y-axis) and 40X (numerical aperture 0.6; 1920 × 1200 pixels; 232.54-nm/pixel resolution in both x-axis and y-axis) objective lenses.

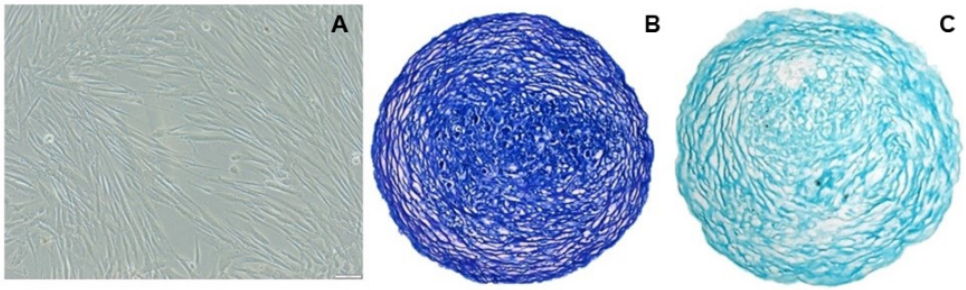
Creation and Evaluation of the Proinflammation Model

LPS was used to stimulate inflammation in the differentiated chondrocytes to create the proinflammation model. LPS was administered at 10 µg/mL concentration to the differentiated chondrocytes to induce inflammation. The cells were incubated in an incubator at 37 °C and 5% CO_2 concentration for 1 day.

XSL•FO
RenderX

To validate our proinflammation model, we evaluated the anti-inflammatory effects of vitamin D, curcumin, and resveratrol by their dose-dependent inhibition of TNF-α. After 1 day of LPS treatment, LPS-treated chondrocytes were treated with various doses of vitamin D (calcitriol) at 0, 0.01, 0.02, 0.12, and 0.25 µM. Curcumin and resveratrol were used at various concentrations (0, 25, 50, 75, and 100 µM). Following treatment with these nutraceutical leads, the cells were incubated at 37 °C and 5% CO_2 concentration for 1 day.

Cytokine Expression Study



Expression of TNF-α was assessed in LPS-treated chondrocytes with or without vitamin D, curcumin, and resveratrol. The chondrocyte supernatants were collected by centrifugation at 5000 rpm for 10 minutes. Concentrations of TNF-α were determined through the use of a commercially available ELISA kit. The assay was performed in accordance with the manufacturer's guidelines. The plates were precoated with human TNF-α. TNF-α levels were measured using a microplate reader at 450 nm, with a reference wavelength of 620 nm. All experiments were performed independently 3 times. All data were reported as mean (SD).

Results

Qualitative Evaluation of Differentiated Chondrocytes

Chondrocytes successfully differentiated from human BMSCs (Figure 2A) after culturing in a chondrogenic differentiation medium. The quality of the differentiated chondrocytes was assessed histologically using 2 different dyes: toluidine blue (Figure 2B) and alcian blue (Figure 2C).

Figure 2. Qualitative analysis of the differentiated chondrocytes. (A) Differentiated chondrocytes obtained from bone marrow–derived mesenchymal stem cells after 28 days; (B) differentiated chondrocytes stained with toluidine blue, and (C) differentiated chondrocytes stained with alcian blue.

Qualitative assessment of successful chondrogenic differentiation of BMSCs was pursued using toluidine blue staining, where the cationic dye specifically binds to the sulfate groups of proteoglycans. A well-differentiated chondrocyte will stain purple owing to the presence of proteoglycans in the ECM, as observed in this study (Figure 2B). The expression of proteoglycan (aggrecan), type II collagen and type X collagen after 21 days of differentiation, was confirmed in the chondrocytes by alcian blue staining (Figure 2C).

Creation of Proinflammatory Chondrocyte Model and Its Evaluation

Following the generation of high-quality chondrocytes from BMSCs, inflammation was induced in the chondrocytes to generate a "proinflammation model." Inflammation was induced using LPS, a biomolecule of predominant abundance in the outer membrane of gram-negative bacteria, which is a key pathogenic stimulator for the dysfunctions. During septicemia, circulating LPS, as a pathogen-associated molecular pattern (PAMP) stimulates the innate immune system, leading to local or systemic inflammatory responses. It has also been shown that LPS also stimulates nonimmune cells and initiates the severe inflammatory responses through dedicated receptors. In particular, the innate LPS–pattern recognition receptor, that is, the Toll-like receptor 4 (TLR4), is extensively expressed in cardiomyocytes, which leads to a severe LPS-induced inflammatory response in cardiomyocytes irrespective of the involvement of immune cells [47,48]. TLR4 is also extensively expressed in chondrocytes [49]. Building upon this foundation, we postulated that LPS can trigger proinflammatory reactions in differentiated chondrocytes independent of immune cell participation.

To assess inflammation, the levels of TNF-α in LPS-treated chondrocytes versus LPS-naive chondrocytes (control) were investigated. TNF-α holds particular significance in comparison with other cytokines, with respect to inflammation in chondrocytes. This is primarily because of its well-established role as a key mediator of inflammatory processes in various cell types, including chondrocytes. Several studies have demonstrated the crucial involvement of TNF-α in the pathogenesis of cartilage degradation and osteoarthritis [50-52].

First, TNF-α has been shown to directly promote the production of other proinflammatory cytokines, such as interleukin-1β (IL-1β) and interleukin-6, which subsequently contribute to the inflammatory cascade in chondrocytes [50,53,54]. This amplification of the inflammatory response highlights the central role of TNF-α in this process.

Moreover, TNF-α has been found to induce the expression of matrix metalloproteinases (MMPs) in chondrocytes [55]. MMPs are enzymes responsible for the degradation of the ECM in cartilage tissue, thereby playing a crucial role in cartilage breakdown and the progression of osteoarthritis [56].

In addition, TNF-α can inhibit the synthesis of cartilage matrix components, such as aggrecan and type II collagen, further impairing the structural integrity and function of the cartilage [57,58]. This effect on cartilage homeostasis further underscores the importance of TNF-α as a marker for assessing inflammation in chondrocytes.

XSL•FO
RenderX

In light of these findings, focusing on TNF-α as a marker for evaluating inflammation in chondrocytes is well justified, as it serves as a reliable indicator of the extent of cartilage degradation and the inflammatory status of chondrocytes in various pathological conditions.

Following the addition of LPS, differentiated chondrocytes were incubated for 24 hours, following which the level of TNF-α was assessed by ELISA. LPS-treated chondrocytes expressed 40% more TNF-α, when compared with the LPS-naive chondrocytes (control population of cells treated with PBS instead of LPS).

Investigating the Effects of Vitamin D, Curcumin, and Resveratrol on Chondrocytes Derived From the "In-Tube" Culture System

After successfully establishing a proinflammatory chondrocyte model, we evaluated its applicability for characterizing potential therapeutic candidates. In this context, we investigated the impact of vitamin D, curcumin, and resveratrol in ameliorating the expression of TNF-α in the proinflammatory chondrocyte model (Table 2).

Table 2. Anti-inflammatory response of vitamin D, curcumin, and resveratrol at different doses in the generated proinflammatory chondrocyte model. (Note: Increasing concentrations of the bioceuticals attenuate tumor necrosis factor-α [TNF-α] expression, although vitamin D exhibits the highest potency of inhibition).

Doses (μM)	Percentage of TNF-α expression, mean (SD)	TNF-α expression reduction at max assessed dose (%)
Vitamin D		66.1
0	100 (0.2)	
0.01	88 (2.3)	
0.02	72 (1.7)	
0.12	58 (1.9)	
0.25	33.9 (0.9)	
Curcumin		61.9
0	100 (0.8)	
10	88.4 (2.9)	
25	72.9 (5.8)	
50	59.7 (1.2)	
75	44.3 (6.4)	
100	38.1 (2.4)	
Resveratrol		45.3
0	100 (1.9)	
10	92.3 (2.4)	
25	88.2 (6.8)	
50	76.2 (3.7)	
75	63.0 (5.9)	
100	54.7 (3.0)	

Although the effects of vitamin D on TNF-α are well described in the literature, our study focuses on the unique "in-tube" 3D culture approach for differentiating BMSCs into chondrocytes. This novel method offers significant advantages over traditional 2D culture systems (Table 1), such as improved cell-cell interactions, increased ECM production, and more physiologically relevant cellular responses. Given the unique nature of the "in-tube" culture system, it is essential to verify whether the well-known anti-inflammatory effects of vitamin D on TNF-α are maintained. Using vitamin D in our protocol, we aim to assess the reproducibility and consistency of its effects in an innovative 3D chondrocyte model.

Moreover, the inclusion of vitamin D serves as a positive control to validate the effectiveness of our proinflammatory chondrocyte model, as its effects on TNF-α reduction are well established. By demonstrating that vitamin D effectively reduces TNF-α levels in our "in-tube" culture system, we can confirm the suitability of the model for investigating other potential therapeutics, such as curcumin and resveratrol.

In summary, the use of vitamin D in our protocol is justified by the need to validate the "in-tube" 3D culture system's ability to replicate well-known anti-inflammatory effects as well as to provide a positive control for evaluating the effectiveness of other nutraceuticals, such as curcumin and resveratrol. The inclusion of vitamin D, along with curcumin and resveratrol, expands our understanding of the potential therapeutic leads for inflammatory chondrocyte–related diseases in the context of our unique 3D culture model.

XSL•FO
RenderX

Vitamin D, specifically its active form, 1,25-dihydroxyvitamin D3 (1,25(OH)2D3), has been shown to exert anti-inflammatory effects in various cell types, including chondrocytes. It modulates the production of proinflammatory cytokines, such as TNF-α and IL-1β, and suppresses the expression of MMPs, which are involved in cartilage degradation [59]. In addition, vitamin D promotes chondrocyte differentiation and enhances the synthesis of ECM components such as type II collagen and aggrecan [60]. Thus, vitamin D can be used to assess the effectiveness of anti-inflammatory agents in a proinflammatory chondrocyte model.

Curcumin, the bioactive component of turmeric, has demonstrated potent anti-inflammatory, antioxidant, and chondroprotective properties [61]. Studies have shown that curcumin can inhibit the expression of proinflammatory cytokines, including TNF-α, IL-1β, and interleukin-6, as well as MMPs in chondrocytes [62-64]. Furthermore, curcumin suppresses the activation of the nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB), a key transcription factor involved in the regulation of inflammation and cartilage destruction [63]. Therefore, curcumin is an ideal candidate for assessing the efficacy of anti-inflammatory interventions in a proinflammatory chondrocyte model.

Resveratrol, a polyphenol found in grapes, red wine, and other plant sources, exhibits strong anti-inflammatory and antioxidant properties. Research has shown that resveratrol can attenuate inflammation in chondrocytes by inhibiting the production of proinflammatory cytokines and reducing oxidative stress [65]. Moreover, resveratrol suppresses the activation of NF-κB and the expression of MMPs, which are implicated in cartilage degradation [63]. Given its well-documented anti-inflammatory and chondroprotective effects, resveratrol is an appropriate choice for evaluating the performance of anti-inflammatory agents in a proinflammatory chondrocyte model.

In summary, vitamin D, curcumin, and resveratrol possess anti-inflammatory and chondroprotective properties, which make them suitable for assessing the effectiveness of potential therapeutic interventions in a proinflammatory chondrocyte model.

Chondrocytes treated with LPS were exposed to varying concentrations of vitamin D, curcumin, and resveratrol. Each of these nutraceuticals effectively mitigated inflammation, as evidenced by the inverse relationship observed between TNF-α levels and the administered doses of vitamin D, curcumin, and resveratrol (Table 2). This finding has significant implications, as it highlights the potential therapeutic utility of these bioactive compounds in alleviating inflammation and promoting cartilage health in the context of inflammatory chondrocyte conditions. Furthermore, the successful demonstration of the anti-inflammatory effects of vitamin D, curcumin, and resveratrol in this model validates their utility for screening and evaluating other potential therapeutics.

Discussion

Principal Findings

In summary, we have described a straightforward and efficient protocol for generating a large quantity of viable chondrocytes derived from BMSCs in a simple pellet-based 3D culture system. This approach, although not using a matrix gel or scaffold, allows for cell aggregation and spheroid formation, facilitating cell-cell and cell-ECM interactions that better mimic the in vivo cellular environment compared with 2D monolayer cultures. However, it is important to note that the pellet culture system is a simple form of 3D cell culture. More complex 3D culture systems using scaffolds or matrix gels can further improve the recapitulation of the in vivo microenvironment, providing additional benefits for various applications.

This approach can also be used to evaluate the effects of potential therapeutic agents on the inflammatory response of chondrocytes. Importantly, this protocol is accessible to all laboratories, including those without readily available patient samples. Furthermore, this “proinflammatory model” can be used to investigate therapeutic targets for diseases involving chondrocytes, such as osteoarthritis.

A notable aspect of this model is its versatility, as it has been effectively used to assess the anti-inflammatory effects of various bioactive compounds such as vitamin D, curcumin, and resveratrol (Table 2). This adaptability allows researchers to explore a wide range of potential therapeutic leads in the context of inflammatory chondrocyte–related diseases, ultimately expanding our understanding of these compounds’ mechanisms of action and their potential for clinical application.

The established model offers several advantages over the existing methods reported in the literature. First, unlike some chondrogenesis models that recommend the use of synthetic or hybrid scaffolds [66], this model does not require scaffold presence. For instance, Sofu et al [67] demonstrated chondrogenesis using a hyaluronic acid scaffold. The incorporation of scaffolds not only adds multiple steps to the experimental process but also increases costs.

Second, our novel chondrogenic differentiation protocol uses an “in-tube” culture system, which reduces the need for cell splitting. Consequently, this minimized the cells’ exposure to degradative enzymes, ensuring the production of higher-quality cells (Figure 2).

Third, by significantly reducing the number of cell-splitting steps, our protocol minimizes human intervention in the chondrogenic differentiation process. This reduction in intervention subsequently decreases the risk of bacterial contamination, genetic alterations, and phenotypic instabilities [68]. Overall, the proposed protocol offers an accessible, cost-effective, and efficient method for generating chondrocytes and for assessing potential therapeutic leads in the context of inflammatory chondrocyte–related diseases.

The chondrocytes derived through this “in-tube” protocol also have diverse applications:

XSL•FO
RenderX

- Tissue engineering and regenerative medicine: The derived chondrocytes can be used for the development of engineered cartilage constructs for cartilage repair and regeneration, particularly in conditions such as osteoarthritis and focal cartilage defects.
- Drug screening and development: The chondrocytes can serve as an in vitro model for evaluating the efficacy and safety of novel therapeutic compounds targeting cartilage-related disorders, potentially accelerating the drug discovery process.
- Disease modeling: The derived chondrocytes can be used to establish in vitro models for investigating the molecular and cellular mechanisms underlying various cartilage-related diseases, providing valuable insights into disease pathogenesis and progression.
- Personalized medicine: By generating patient-specific chondrocytes from autologous BMSCs, our protocol could facilitate the development of personalized treatment strategies tailored to individual patients' needs, thereby improving therapeutic outcomes and reducing the risk of adverse effects.

Limitations

Nevertheless, certain aspects of the developed model warrant further investigation. One of the limitations of our proposed protocol is the potential difference between chondrocytes generated using our method and those derived from other established protocols or directly isolated from humans or laboratory animals. Although our simple 3D cell culture system facilitates cell-cell and cell-ECM interactions that more closely resemble the in vivo cellular environment compared with traditional 2D monolayer cultures, it is important to recognize that this system is not as advanced as more complex 3D culture systems using scaffolds or matrix gels. These more sophisticated systems can further improve the recapitulation of the in vivo microenvironment and provide additional benefits for various applications.

Another aspect to consider is the use of single-cell transcriptomics to compare the gene expression profiles of chondrocytes generated using our protocol with those isolated directly from humans or laboratory animals. This analysis would help to validate the methodological strength of our approach and provide valuable insights into the similarities and differences between the generated chondrocytes.

Another limitation of our protocol is that the pellet culture system, although beneficial for cell aggregation and spheroid formation, may not be suitable for all cell types or for studying specific cellular behaviors. Certain cell types may not adhere or proliferate well in this system, and the lack of a defined matrix or scaffold may limit the ability to investigate cell-matrix interactions and cellular migration.

In addition, our protocol has not been extensively tested for scalability, which could be a concern when attempting to generate large quantities of chondrocytes for applications such as tissue engineering or regenerative medicine. Further optimization of the protocol may be required to ensure that the system can be effectively scaled up to meet the demands of these applications.

Moreover, in response to an inflammatory microenvironment, chondrocytes adapt their physiology by modulating the expression of cell surface proteins, collectively referred to as the "surfaceome" [69], and the assortment of transporters and ion channels, known as the "channelome" [70]. It is crucial to determine whether the chondrocytes obtained using this new protocol exhibit surfaceome and channelome profiles consistent with those found in physiological conditions.

In addition, other potential limitations of this study should be acknowledged. For instance, further research is necessary to validate the long-term stability and functionality of the generated chondrocytes in both in vitro and in vivo settings. Moreover, it would be beneficial to explore the effects of other inflammatory mediators on the chondrocytes derived from this protocol to determine their applicability in a broader range of inflammation-driven scenarios. Finally, a comprehensive assessment of the safety and efficacy of the tested bioactive compounds is essential before transitioning to clinical applications. By addressing these limitations, the model used in this study can be refined and expanded to provide a more robust foundation for future research on inflammatory chondrocyte–related diseases.

Conclusions

In conclusion, the development of our novel, streamlined protocol for generating chondrocytes from BMSCs in a 3D culture system offers significant implications for the study of cartilage biology and the discovery of potential therapeutic interventions for cartilage-related disorders. The "in-tube" culture approach not only allows for the efficient production of viable chondrocytes but also provides a versatile platform for evaluating the anti-inflammatory effects of various bioactive compounds, as demonstrated by the decreased TNF-α levels following treatment with vitamin D, curcumin, and resveratrol. This accessible and cost-effective model holds promise for advancing our understanding of chondrocyte function in cartilage homeostasis and its response to inflammation, which is critical for unraveling the progression of cartilage-related diseases and identifying novel therapeutic strategies. Although our findings contribute to the growing body of knowledge in the field, further investigation is needed to address the limitations of the model used in this study, refine its applicability, and facilitate its translation into clinical practice. By doing so, this innovative approach may ultimately pave the way for the development of more effective and targeted therapies for a range of cartilage-related disorders, ultimately improving patient outcomes and quality of life.

Abstract

Background: Due to interconnected structural determinants including low maternal health knowledge, economic marginalization, and remoteness from low-capacity health centers, ethnic minority women in remote areas of Vietnam face severe maternal, newborn, and child health (MNCH) inequities. As ethnic minorities represent 15% of the Vietnamese population, these disparities are significant. mMOM—a pilot mobile health (mHealth) intervention using SMS text messaging to improve MNCH outcomes among ethnic minority women in northern Vietnam—was implemented from 2013-2016 with promising results. Despite mMOM's findings, exacerbated MNCH inequities, and digital health becoming more salient amid COVID-19, mHealth has not yet been scaled to address MNCH among ethnic minority women in Vietnam.

Objective: We describe the protocol for adapting, expanding, and exponentially scaling the mMOM intervention *qualitatively* through adding COVID-19–related MNCH guidance and novel technological components (mobile app and artificial intelligence chatbots) and *quantitatively* through broadening the geographical area to reach exponentially more participants, within the evolving COVID-19 context.

Methods: dMOM will be conducted in 4 phases. (1) Drawing on a review of international literature and government guidelines on MNCH amid COVID-19, mMOM project components will be updated to respond to COVID-19 and expanded to include a mobile app and artificial intelligence chatbots to more deeply engage participants. (2) Using an intersectionality lens and participatory action research approach, a scoping study and rapid ethnographic fieldwork will explore ethnic minority women's unmet MNCH needs; acceptability and accessibility of digital health; technical capacity of commune health centers; gendered power dynamics and cultural, geographical, and social determinants impacting health outcomes; and multilevel impacts of COVID-19. Findings will be applied to further refine the intervention. (3) dMOM will be implemented and incrementally scaled across 71 project communes. (4) dMOM will be evaluated to assess whether SMS text messaging or mobile app delivery engenders better MNCH outcomes among ethnic minority women. The documentation of lessons learned and dMOM models will be shared with Vietnam's Ministry of Health for adoption and further scaling up.

Results: The dMOM study was funded by the International Development Research Centre (IDRC) in November 2021, cofacilitated by the Ministry of Health, and is being coimplemented by provincial health departments in 2 mountainous provinces. Phase 1 was initiated in May 2022, and phase 2 is planned to begin in December 2022. The study is expected to be complete in June 2025.

Conclusions: dMOM research outcomes will generate important empirical evidence on the effectiveness of leveraging digital health to address intractable MNCH inequities among ethnic minority women in low-resource settings in Vietnam and provide

XSL•FO
RenderX

critical information on the processes of adapting mHealth interventions to respond to COVID-19 and future pandemics. Finally, dMOM activities, models, and findings will inform a national intervention led by the Ministry of Health.

Introduction

Maternal, Newborn, and Child Health Inequities Among Ethnic Minority Women in Vietnam

Despite Vietnam's remarkable progress in improving maternal, newborn, and child health (MNCH) outcomes during the era of the Millennium Development Goals, increasing evidence demonstrates that ethnic minority communities living in remote areas have not benefited equally from this progress—MNCH inequities between the Kinh (ethnic majority group in Vietnam) and ethnic minority communities have in fact widened [1-3]. There are 54 ethnic groups in Vietnam, with the Kinh majority representing 85% (98 million) of the national population and 53 ethnic minority groups representing the remaining 15%. In Vietnam, as in other Southeast Asian countries, the term "ethnic minority" is commonly utilized by government bodies for populations who may elsewhere be classified as Indigenous peoples. As government authorities in Vietnam do not recognize Indigenous identity in programs or reports, this paper utilizes the terminology "ethnic minority."

Among ethnic minority populations, 75% live in 13 provinces in the northern mountain and central highlands regions, which are known for high concentrations of poverty [3]. Ethnic minority populations in Vietnam have higher total fertility rates, adolescent birth rates, and infant and child mortality rates and lower life expectancies [1,4,5]. An analysis of data from 4 recent censuses of Vietnam showed that at all survey time points (2000, 2006, 2011, 2014), the proportions of women who received skilled antenatal care and who gave birth with assistance from skilled staff were significantly higher among Kinh, higher economic status, and urban populations, highlighting clear structural inequities in health access for ethnic minority women in remote settings [2]. Vietnam's overall progress on MNCH indicators obscures severe disparities among marginalized ethnic minorities: in 2020-2021, 95% of all live births in Vietnam were delivered by a skilled birth attendant, yet this figure was only 37.7% among Hmong minority women [4]. Data from the same 2020-2021 national survey show that the percentage of women who received at least four antenatal care visits during pregnancy was 88.2% among the Kinh and Hoa, 62.3% among the poorest quintile, and 10.6% among the Hmong [4].

Shaped by decades of structural deprivation and social exclusion, specific factors contributing to the profound MNCH disparities faced by ethnic minority populations are limited access to education, economic marginalization, remote and rural residence (where there are fewer and lower capacity health centers and a documented shortage of health workers [5,6]), limited access to MNCH information, low reproductive health knowledge, language barriers, and poor access to and uptake of perinatal care services [2,3,5,7,8]. A 2021 study found that economic marginalization and living over 5 km from the nearest health facility were associated with having fewer than 4 antenatal care visits [7]. Importantly, documented inequities along ethnic lines in health care seeking and utilization, MNCH, nutrition, and oral health and hygiene suggest that minority ethnicity alone is a critical determinant impacting health outcomes [9]. Taken together, this evidence highlights how the confluence of ethnic minority status and related facets of socioeconomic exclusion has shaped severe and intractable MNCH inequities among ethnic minority women in Vietnam.

mMOM 2013-2016

To address MNCH disparities among ethnic minority women in remote areas, the "mMOM" project (2013-2016) piloted and evaluated a low-cost mobile health (mHealth) intervention in Thai Nguyen province, northern Vietnam. mMOM was developed by the Institute for Population, Health and Development in Hanoi (PHAD) and Simon Fraser University (SFU) in Vancouver and funded by the International Development Research Centre (IDRC) from Canada. The project aimed to determine whether integrated use of an electronic health information system, low-cost mobile technology, a user-provider interaction model, and behavior change communication (BCC) via SMS text messaging could improve access to MNCH information and services among perinatal ethnic minority women and their families. Developed using templates from the Mobile Alliance for Maternal Health [10] and adapted for local acceptability, mMOM administered 2 SMS text messaging programs for pregnancy and postpartum periods, featuring information, education, and communication (IEC); reminder; and BCC messages designed to support maternal health and to promote deeper interaction between ethnic minority women and the health care system. Participants were registered in mMOM according to their specific week in pregnancy/new motherhood and received tailored information on healthy fetal and infant development 2-3 times weekly via SMS text messaging. Additional details about the mMOM project development and protocol are available elsewhere [11,12].

Between 2013-2016, the mMOM intervention built and implemented an integrated mHealth platform, which sent timely IEC, reminder, and BCC text messages to 961 participating women in 8 communes in Thai Nguyen toward stimulating ethnic minority women's demand for quality perinatal care. In

XSL•FO
RenderX

midterm and final qualitative evaluations assessing mMOM's acceptability and impact involving over 60 participants, women expressed satisfaction with the intervention's quality, timeliness, and convenience, and health workers reported increased efficiency and quality of care [12]. The mMOM project increased care seeking from ethnic minority women and promoted increased contact and strengthened relationships between participants and health providers, demonstrating the potential of mHealth to address the marginalization of ethnic minority women from the health system in this setting [12].

Need for the Current Study

Broader Geographic Area

Despite these findings and mMOM's promise in promoting MNCH among structurally marginalized ethnic minority women, the intervention's impacts were limited due its pilot nature and implementation in only 8 communes in a single province in Vietnam. Implementing an adapted and scaled version of the intervention across a broader geographic area, thus reaching more participants, is necessary to generate robust empirical evidence on the potential of mHealth to improve MNCH health equity in Vietnam and to build models that can be replicated and utilized for country-level mHealth projects.

SMS Text Messaging Versus Mobile App

Despite the high penetration of mobile services in Vietnam (143 mobile subscriptions for every 100 people in 2020 [13]), the application of mHealth for MNCH in Vietnam remains limited, with the exception of a current notable study examining a mobile app to promote early initiation and exclusive use of breastfeeding [14]. In alignment with this current research, given the rapid expansion of telecommunication technology and coverage of 4G network ever since mMOM was completed in 2016 and extensive smartphone uptake and usage even in remote areas [15], the potential impacts of mobile app–based MNCH delivery (rather than SMS text messaging based) among ethnic minority women must also be investigated and compared.

COVID-19, Exacerbated Health Inequities, and the Salience of mHealth

Current gaps in mHealth research and utilization in Vietnam were rendered even more salient by COVID-19, which exacerbated existing inequities in health access and outcomes globally—particularly for communities already marginalized from health systems including ethnic minority populations, women, immigrants, refugees, and people in rural/remote areas [16-20]. The pandemic underscored the urgency of research and development surrounding digital health interventions in the context of physical distancing restrictions and overloaded health facilities to maintain health access and prevent deepening health disparities amid COVID-19. The pandemic impacts have also been gendered and intersectional: globally, perinatal women represent a vulnerable population who have faced poorer maternal health outcomes and increased mental health concerns including heightened postpartum depression amid COVID-19 [21,22], and these disparities have been shaped by economic and class status, ethnicity, and geographic location [17,19,22-26]. This emerging evidence and calls for virtual and digital health programming to support perinatal women during the pandemic [21] suggest an urgent need for mHealth interventions that support maternal mental health and broader MNCH in Vietnam through the evolving COVID-19 crisis and beyond.

Objective

Despite mMOM highlighting the potential of mHealth to promote MNCH among ethnic minority women in Vietnam, existing severe MNCH inequities among ethnic minority women, and digital health approaches becoming even more salient amid COVID-19, mHealth has not yet been leveraged or scaled to address MNCH in Vietnam. Thus, the objective of this paper is to describe the protocol for adapting, expanding, and exponentially scaling the mMOM intervention *qualitatively* through the addition of COVID-19–related MNCH guidance and novel technological components (a mobile app and the use of artificial intelligence [AI]) and *quantitatively* through its expansion over a broader geographical area to reach exponentially more participants. This protocol details the adaptation of the 2013-2016 mMOM intervention (SMS text messaging intervention reaching 8 communes in 1 district with 900 participants) to the dMOM intervention (SMS text messaging, mobile app, and AI intervention reaching 71 communes in 5 districts with 9000+ participants), within the unique pandemic context.

Methods

Overview

The dMOM project will be conducted in 4 phases: (1) updating, adapting, and expanding the mMOM intervention; (2) scoping study and rapid ethnographic fieldwork; (3) dMOM intervention implementation and incremental scaling; and (4) intervention evaluation and documentation of lessons learned. A series of smaller studies conducted through project phases 2-4 will gather evidence on different dMOM facets and models to inform replication and scaling at the country level.

Phase 1: Updating, Adapting, and Expanding the Intervention

For phase 1, the mMOM project components will be (1) updated and adapted to respond to COVID-19 and its impacts and (2) expanded to include a mobile app and AI chatbots to more deeply engage participants. To adapt the intervention to serve perinatal women's unique vulnerabilities and needs through the pandemic and beyond, a literature review of publications on MNCH amid COVID-19 will be undertaken by a multidisciplinary team. Institutional and governmental guidelines on pregnancy during COVID-19 as well as peer-reviewed manuscripts, conference abstracts, and case studies will be screened and reviewed, with relevant information extracted to inform, revise, and update the original mMOM intervention content. As a result, the IEC, reminder, and BCC messages in the SMS text messaging packages and the mobile app content will include critical information (i.e., on COVID-19 risk awareness, testing, vaccinations, and maternal mental health) to support healthy pregnancies and newborn care during the pandemic and postpandemic contexts and ensure that the dMOM intervention reflects international and country-level

XSL•FO
RenderX

institutional guidance on MNCH during COVID-19. Particular attention will be paid to emerging evidence and institutional guidelines surrounding COVID-19, mental health, and postpartum depression among perinatal women [21,22,27]. Finally, the mMOM BCC messages will be updated to target not only ethnic minority women and women living in remote mountainous areas, but also perinatal women in less remote areas, given the novel constraints in MNCH care accessibility and isolation from health services engendered by the pandemic.

To offer participants a more nuanced, customizable, and lower-cost avenue for engaging with the intervention, the dMOM app will be developed in partnership with computing science consultants to leverage smartphone capabilities and provide a more complex variety of functions to improve MNCH access and health outcomes among perinatal ethnic minority women. Similar to the mMOM SMS text messaging intervention, the dMOM mobile app will provide person-centered, tailored, and timely information according to women's specific stage of pregnancy/new motherhood. However, the dMOM app will feature more information per message/interaction (messages will not be subject to SMS text messaging character limits); photo, audio, and video messages to increase engagement with participants; and audio-photo messages as an important accessibility consideration for women with limited literacy and/or disabilities. The dMOM app also will reduce the cost of project participation (there are no associated costs after app installation, unlike SMS text messaging fees) and support health promotion activities among village health workers through the digitalization of traditional, familiar, and culturally acceptable IEC materials (i.e., MNCH posters and educational cartoons) and their inclusion in the app to reach a broader audience.

An assessment of how AI chatbots (automatic dialogue system) can be leveraged in dMOM to promote MNCH care and support project scalability and sustainability will be conducted through a literature review and consultation with AI experts who are members of the research team, and relevant components of existing uses of AI for MNCH will be extracted and adapted for use in the dMOM app. AI chatbots will be developed and piloted, with information collected to train AI models to correct SMS text messages, assess MNCH risks, and provide advice that is responsive to women's inquiries and enables them to quickly act in a health emergency situation requiring expertise from a health professional. dMOM will utilize the richer technological capacities offered by a mobile app and AI chatbots and evaluate their effectiveness in improving the quality of MNCH BCC.

Phase 2: Scoping Study and Rapid Ethnographic Fieldwork

For phase 2, a broad scoping study using mixed methods and rapid ethnographic fieldwork will be conducted at the project outset to involve key stakeholders in the intervention's codevelopment from its initial stages. The scoping study will begin with preliminary engagement meetings with the Ministry of Health, provincial and district health departments, women's health service providers, community advocacy groups for women and ethnic minority populations, local authorities, village chiefs, and individual women to ensure that the intervention is shaped by key institutional and community voices.

The scoping study will apply mixed research methods including in-depth interviews; focus group discussions led by trained project staff; and survey questionnaires with pregnant and postpartum ethnic minority women, family members, and health workers at diverse levels. It will assess (1) unmet MNCH needs among ethnic minority women and their newborns; (2) roles of husbands, family members, and broader community members as well as their gendered power dynamics impacting MNCH care; (3) existing MNCH communication mechanisms, gaps, and MNCH health service utilization; (4) the extent of mobile phone use of ethnic minority women in the new districts in Thai Nguyen and Dien Bien provinces (i.e., districts not covered in the mMOM project) and social and cultural factors impacting phone ownership and usage; (5) literacy and language barriers to receiving SMS text messages and using apps; (6) technical capacity of commune health workers and health centers surrounding mHealth utilization and technical constraints (i.e., power outages and mobile network coverage); and (7) long-term, multilevel impacts of COVID-19 on MNCH access and outcomes, ethnic minority health, and broader socioeconomic status of remote communities. The study will also include a rapid ethnographic review of gendered determinants; ethnicity-based barriers; and other key social, cultural, economic, and political factors that may hinder or facilitate project outcomes, as well as in-depth interviews with other potential stakeholders (i.e., corporate and technological institutions and government bodies) at district and provincial levels to explore partnership opportunities and policy constraints to project implementation and scaling up.

Within the broader scoping study, 2 smaller intersectionality and digital health uptake studies will take place. The intersectionality study will explore ethnicity, gendered power relationships, geographical and social distancing, and other interconnected determinants of MNCH outcomes and mHealth applicability, not in isolation but how they interact dynamically with one another to shape severe health disparities among ethnic minority women in northern Vietnam [28,29], particularly as impacted by COVID-19. This intersectionality study will utilize a participatory action research and people-centered approach—identified as critical contributing factors to the uptake and success of mMOM [12]—toward codeveloping and continually refining the intervention in interaction with community members to ensure that it is culturally sensitive, sustainable, and responsive to community needs [30]. The digital health uptake study will explore digital health accessibility and acceptability in geographically and/or socially remote settings, especially among ethnic minority women. Given current research gaps on digital health preferences among ethnic minority groups, the study will investigate participants' preferences for either the mobile app or SMS text messaging intervention; factors at individual, family, and societal levels informing their preferences; and potential solutions to increase uptake among ethnic minority women in remote areas toward reducing digital health inequity.

XSL•FO
RenderX

Ethics Approval

Trained commune health staff will obtain oral informed consent from focus group and in-depth interview participants prior to their participation in the scoping study. The study has been approved by an institutional review board at PHAD, which is registered with and uses ethical protocols of the Office for Human Research Protections of the United States Department of Health and Human Services (2023/PHAD-DMOM-01). Project data are subject to privacy and security protocols of the Office for Human Research Protections. Participants in the focus groups and in-depth interviews will be remunerated 100,000 Vietnamese Dong (~US $4.20) for their expertise, time, and travel.

The scoping study's findings will be used to refine the scope of work, project activities (e.g., modifying the research design, updating intervention content, and selecting additional ethnic minority languages), and timeline in alignment with implementation capacities at the village and commune health center levels. The study's involvement of stakeholders in shaping the dMOM intervention from the project outset is expected to increase their interaction with the project and empower and strengthen ethnic minority women and their families' increased engagement in MNCH care [30]. It will also provide a critical opportunity for stakeholders to express COVID-19–related concerns regarding the intervention's operation so that these concerns may be accounted for and mitigated.

Phase 3: Intervention Implementation and Incremental Scaling

Upon completion of the first 2 study phases (updating and adapting the intervention content, developing the mobile app, and undertaking the scoping study), for phase 3, the dMOM intervention will be implemented and incrementally scaled. As the project plan will be informed by, updated, and revised based on the scoping study to ensure the intervention's accessibility and acceptability to the target population, the below protocol represents only a general guideline. Implementation will be initiated with project staff conducting a training-of-trainers activity to (1) train commune health workers as dMOM project implementors including on health management information system operations and dMOM integration and (2) enable them to train village health workers in the intervention's routine operation (i.e., registering participants, using the mobile app, and operating and monitoring the dMOM system). First, the updated SMS text messaging intervention will be implemented in Dinh Hoa, Thai Nguyen (the original mMOM intervention site) to initiate the intervention and troubleshoot potential challenges related to human resources, project staff training, and health management information system operation. This initial implementation period limited within 1 district will also provide critical ongoing engagement and continuity of the intervention while the dMOM app is being developed and ease the introduction of the dMOM app. Subsequently, the dMOM mobile app will be piloted in Dinh Hoa and 2 new districts in Thai Nguyen province (one remote and one urban district—Vo Nhai district and Song Cong city) and 2 districts (Muong Cha district and Dien Bien Phu city) within the even more remote and mountainous Dien Bien province, where ethnic minorities constitute 82.6% of the population [31]. To compare the relative acceptability, uptake, and MNCH impact of the dMOM mobile app to the SMS text messaging intervention, an equal number of communes in each district will be randomly assigned with the use of either the dMOM app or mMOM SMS text messaging to assess each component's feasibility among participants. Although the 2013-2016 pilot mMOM intervention reached 961 perinatal women across 8 communes in 1 district, the dMOM intervention will be implemented across 71 communes in 5 districts of 2 provinces, aiming to reach approximately 9000 women participants over a 30-month period.

Phase 4: Intervention Evaluation and Documentation of Lessons Learned

For phase 4, dMOM will be evaluated to assess whether SMS text messaging delivery or mobile app delivery engenders the most improved MNCH health-seeking behaviors and outcomes among ethnic minority women. The dMOM evaluation will involve data collection via multiple channels. Demographic and socioeconomic data will be collected by commune health staff at the intervention onset intervention when participants are registered. Monitoring and evaluation indicators on health-seeking behaviors and pregnancy and birth outcomes will be collected via automatic individual data collection and questions posed to participants within the dMOM app. The SMS text messaging and app systems will also be mined for back-end information regarding user statistics. Finally, qualitative in-depth interviews and quantitative survey questionnaires will be administered online or in-person, depending on COVID-19–related factors and feasibility. Data from these sources will be analyzed using thematic analysis in NVivo for qualitative data and regression models in Stata (StataCorp) or R (R Foundation for Statistical Computing) for quantitative data and triangulated to examine how they expand upon one another and explore both intended and potential unexpected outcomes of the intervention, aiming to improve the credibility, integrity, and utility [32] of the research to multilevel policy institutions in Vietnam and internationally. The documentation of lessons learned will be conducted and shared with Vietnam's Ministry of Health and the public for adoption and further scaling up; upon project completion, the models developed and refined in dMOM will inform a national mHealth project led by the Ministry of Health, representing a scaling of components of the dMOM project to the country level.

During the evaluation phase, a smaller scalability study will draw on the data collected as part of all dMOM components and assess different scenarios associated with several scaling-up strategies. This study will identify factors that may facilitate or constrain effective and ethical scaling of dMOM models and will investigate the potential of the private sector as a financing mechanism to sustain a broader mHealth intervention for MNCH.

Results

The dMOM study was funded by the IDRC in November 2021, cofacilitated by the Ministry of Health, and is being coimplemented by provincial health departments in the 2

XSL•FO
RenderX

mountainous provinces of Thai Nguyen and Dien Bien. The intervention received approval from and completed a memorandum of understanding with Vietnam's Ministry of Health in May 2022. Phase 1 (literature review and updating, adapting, and expanding intervention components) was initiated in May 2022, and phase 2 (scoping study and rapid ethnographic fieldwork) is planned for December 2022. The entire study is expected to be complete at the end of June 2025.

Discussion

Expected Findings

This paper describes the protocol for adapting and exponentially scaling the mMOM intervention *qualitatively* through the addition of novel technological components (i.e., mobile app and the use of AI chatbots); *quantitatively* through its expansion over a broader geographical area; and in its *scope* through deep, ongoing engagement with the Ministry of Health toward the replication of the dMOM models at the country level. This protocol details the expansion of the pilot mMOM SMS text messaging intervention in 8 communes with 900 participants to an SMS text messaging, mobile app, and AI intervention in 71 communes reaching 9000+ participants.

This research will contribute to bridging current gaps in mHealth research and utilization in Vietnam, which were rendered even more salient by COVID-19 and exacerbated existing inequities in health access particularly for ethnic minority populations and people in rural/remote areas globally [16-20]. Our protocol and study aim to respond to research calls for virtual and digital health programming to support perinatal mental health and broader MNCH in Vietnam through the evolving COVID-19 crisis and beyond [21]. Through the dMOM intervention's development, implementation, and evaluation of a mobile app for MNCH amid COVID-19, the project aims to contribute to urgently needed evidence on the application of digital health during the pandemic context, particularly in maintaining health access and promoting health equity among women, ethnic minority populations, remote communities, and other intersecting populations globally who are the most vulnerable to the negative socioeconomic and health impacts of pandemics.

Limitations

Although this study will be conducted within a broader geographical area than the pilot mMOM study, it will only involve ethnic minority populations who are in contact with the health system, as commune health workers will only recruit women who present at the health center. As such, it is possible that the project may exclude members of the target population who are not known to health workers due to extremely remote residence, poverty, or language barriers.

Study Implications

The outcomes and findings of the dMOM study will be relevant to future research on the applicability and use of mHealth and AI for MNCH for ethnic minority communities and for improved MNCH and health-seeking behaviors among other structurally marginalized populations and populations living in remote settings.

Conclusions

This paper outlines the development of the dMOM intervention and its planned expansion and scaling amid the COVID-19 context. The dMOM research outcomes will generate important empirical evidence on the effectiveness of leveraging digital health to address intractable MNCH inequities among ethnic minority women and women living in remote areas and low-resource settings in Vietnam, build models for utilization and replication in country-level mHealth projects, and provide critical information on the processes of adapting mHealth interventions to respond to COVID-19 and other future pandemics.

Abstract

Background: Considering the prognosis of femur fractures worldwide, the ageing of our society, and the problems in adherence to treatment found in these patients, it is believed that mobile health can have a positive impact on the process and quality of care.

Objective: We aim to evaluate the effectiveness of a pharmacological educational nurse intervention with Myplan app with regard to knowledge, adherence to pharmacological treatment, and positive mental health of patients with femur fractures.

Methods: A nonrandomized, quasi-experimental study will be carried out with a pretest-posttest control group. It will include 278 older patients diagnosed with femur fractures, with a Glasgow Coma Scale of 15 and access to mobile devices. Patients with psychological pathologies and cognitive impairment or patients treated in isolation will be excluded. Study variables are as follows: sociodemographic variables (AdHoc Form), patient experience (Patient Experience Questionnaire-15), adherence to pharmacological treatment (Morisky-Green questionnaire), and positive mental health (Positive Mental Health questionnaire). The measurements will be taken 24 hours after admission, upon discharge, and 25 days after discharge.

Results: Enrollment commenced in October 2022. Data collection will be completed in April 2023.

Conclusions: The results of this study will offer evidence of the effectiveness of a pharmacological educational nurse intervention by means of a free smartphone app. If its efficacy is demonstrated and the results are acceptable, it could mean an improvement in the care of patients with femur fractures, and this technology could be used to guide other training interventions in patients with other pathologies.

Introduction

Overview

The estimated amount of femur fractures by 2050 is 6 million worldwide. Due to the increase in life expectancy, the incidence of femur fractures in people older than 65 years is close to 4-6 cases per 1000 inhabitants per year in Spain, Catalonia, being the region with the highest incidence of femur fractures [1]. It has been shown that the population experiencing this type of fracture exhibits a high degree of complexity, causing an increase in morbidity, mortality, and subsequently, health care expenditure [2]. It is, therefore, necessary to establish an adequate health care quality, where the affectivity of the treatment and the safety of the patient are guaranteed [3].

There is evidence of the relationship between a good patient experience and both direct and indirect clinical results, which leads to better prognosis, faster discharges, and lesser use of medication [4,5]. Another important factor is the relationship between positive mental health and capacity for self-care. The more positive patients' mental health is, the better their ability for self-care will be, and vice versa [5-7]. Another key factor, as the literature indicates, is health education for patients regarding their illness and its treatment. The more knowledge they have, the better their health and ability for self-care will be [8,9]. We usually find education studies focused on patients diagnosed with chronic diseases [10], but we rarely find studies that evaluate the effectiveness of education and information in relation to medication adherence.

When informing patients about medication, the term "10 rights" [11] regarding the safe administration of medication should also be mentioned—inform the patient about the medication that is being used, how it must be taken, what it is being used for, and what secondary effects or adverse reactions may derive from its use. The importance of this point stands out in two aspects: (1) the patient's health education regarding all the medications they take, so they understand everything related to the care of their illness; and (2) the potential detection of errors on the patient's part, acting as the last filter just before the administration of the drug by the nurse. This point is so important that not informing patients is considered a medication error in some studies [12].

Prescription of medication is one of the most common interventions in clinical practice [13], and it has a significant repercussion in the time used by nurses in administrating medicines, which takes up a substantial part of their workday. Cleveland Hospital applies one of the innovative strategies in administration of medicines, named the Ask3/Teach3 initiative [14]. In this strategy, the patient is informed about the medicine, but its secondary effects are also inserted into that same conversation with the patient.

Studies in medical literature describe that the introduction of educational tools related to medication in health care organizations is linked to a decrease in hospitalization, admissions into emergency rooms, and readmissions [15]. Patients nowadays have a very close relationship with technology, as has been shown in various published studies that prove the use of apps improves health management [16,17]. Mobile health (mHealth) has opened the doors to new forms of relationships between nurses and patients, providing numerous benefits for both parties with regard to accessibility and optimization of time in office and improvement of therapeutic adherence. The mass use of web-based devices by patients older than 65 years (ie, the population sector with the highest probability of requiring medical care) has had a very positive influence in this regard [18].

It is described that there is a lack of adherence due to the complexity of the treatment, its secondary effects, lack of trust in the treatment, and the relationship between health care professionals and patients [19]. The lack of adherence can lead, firstly, to a lack of treatment effectiveness, and secondly, to a potential increase in the secondary effects of the treatment, a problem that affects 50%-60% of patients with chronic diseases. It is estimated that 20%-50% of patients do not take their medication as prescribed [20]. The index of medication adherence in these patients is only 50% [21]; therefore, improving medication adherence would result in a decrease in morbidity, mortality, and expenditure in medical care [22]. Treatment adherence is also linked to patients' emotional well-being, the mental strength with which they face the situation, and ultimately, their level of positive mental health [23,24]. It has been observed that interventions are needed to improve lack of treatment adherence [25]. No studies have been found in medical literature on the subject of pharmacological adherence and patients with femur fractures.

One of the tools developed to complement patient education is mHealth, described by the World Health Organization (WHO) in its 2015 Global Observatory for Health report (reviewed in 2016) [26] as the use of mobile devices, such as smartphones, personal digital assistants, and patient monitoring devices, in medical practice and public health.

The WHO believes that mHealth can contribute to achieving coverage of health care at a global level, making it accessible to remote populations and communities with health service deficits. This is one of the strategic lines of the government of Catalunya. At the same time, the WHO recognizes that it is not very costly to supply these areas with mobile technology infrastructures [27].

Based on this evidence, this study proposes to respond to the needs raised so far, with the development and evaluation of a pharmacological educational nurse intervention based on a smartphone app (MyPlan app) and with regard to knowledge,

XSL•FO
RenderX

pharmacological treatment adherence, and positive mental health of postoperative patients with femur fractures.

Objectives

The primary objective of this study is to evaluate the effectiveness of a pharmacological educational nurse intervention with MyPlan app in the experience of medical assistance, pharmacological treatment adherence, and positive mental health of patients with femur fractures at the Hospital Clínic de Barcelona. We also intend to compare the pre-post intervention effectiveness in the study variables 24 hours after admission, upon discharge, and 25 days after hospital discharge.

Methods

Study Context

This study aims to test the nurse intervention with the added support of mHealth by creating personalized medical care and a 3-stage follow-up plan to improve the patient's experience, adherence, and positive mental health.

Scope of Study

This project estimates the application of this approach in the Institute of Traumatology and Orthopedics of the Hospital Clínic de Barcelona between October 2022 and April 2023.

Design

This protocol describes a nonrandomized, quasi-experimental study with a pretest-posttest control group.

Participant Selection and Recruitment

Eligible participants will be identified in the hospitalization unit through the observation of a census by the principal investigator (PI) with a nonprobabilistic sample (according to the patients' willingness to participate).

The sample calculation will be made by taking into account the total number of patients treated in the traumatology service for a femur fracture diagnosis during 2020. Approximately 494 patients are admitted annually with a femur fracture diagnosis. GRANMO software (version 7.12; IMIM Medical Informatics Unit) will be used with a 95% CI and a maximum indeterminacy of P=.5, accounting for a 15% loss, for a final recommended sample of 278 subjects to ensure a sufficient sample size for the analysis of the different variables.

Inclusion and Exclusion Criteria

The criteria for inclusion are as follows: (1) femur fracture diagnosis, (2) 18 years of age or older, (3) knowledge of Spanish language, (4) 24-hour admission into the traumatology unit, (5) awareness level of 15 on a Glasgow scale, (6) access to mobile devices, (7) ability to participate in the pilot study, and (8) ability to provide written informed consent personally or to obtain consent via a legal representative. Criteria for exclusion are as follows: (1) presence of psychological pathologies or cognitive impairment and (2) treatment in isolation during hospitalization.

Ethics Approval

This study has been approved by the Regional Health Research Ethics Committees of the Hospital Clínic de Barcelona (HCB/021/0341).

All questionnaires are confidential, and all patients must sign the informed consent according to the current Spanish legislation. In compliance with the current law on data protection and guarantee of digital rights, no data will be shared without express authorization, preserving patients' confidentiality and anonymity of their identity at all times. Their participation will be voluntary, and their anonymity will always be preserved. This will be achieved by anonymizing the names or any personally identifiable information.

Intervention

The final app is named MyPlan. it is based on a platform developed by the nonprofit organization Trilema, with the support of Amgen laboratory. The app is user-friendly and intuitive, and it allows patients to see their updated medication plan on their mobile phones at all times in a safe and private environment (Figure 1). One of its main functions is the daily (Figure 2) and monthly (Figure 3) calendar, and it also features reminders and allows adding programmed activities (eg, medication times, check-ups, and appointments). MyPlan is also a tool that supports treatment, allowing patients to plan and validate individual medication intake (Figure 4).

To ensure that the intervention works as expected and patients are able to access the app, the PI has a private area in MyPlan (Figure 5), where every individual patient is registered with a personal username and password. The PI will also add their individual medication plans so that patients are able to view them on the app.

The nursing pharmacological education intervention will be performed by a single nurse (an employee of Hospital Clínic de Barcelona) and the PI. This intervention consists of 4 sessions (Figure 6). First, the nurse will introduce themselves to the patient as the professional who will carry out the training session. Subsequently, patients will be informed about the intervention and its objectives. They will be introduced to MyPlan app, which will be downloaded on their smartphone, and a username and password will be generated for them (30 minutes). Then, the prescribed treatment and any questions from the patient about it will be discussed and reviewed (20 minutes). Finally, the session itself will be evaluated (10 minutes), using the Morisky-Green scale, as well as the PI's review of the patient's use of MyPlan during the admission, making sure they have pressed "OK" at the time they were taking the medication according to the prescription.

XSL•FO
RenderX

Positive mental health will be promoted in every session by giving patients the opportunity to explain how they are feeling, telling them that it is normal to feel sadness and frustration during hospitalization, but also encouraging them to think about the small daily achievements like decrease in pain or improvement in mobility. If the negative feelings persist, the patient will need to ask for help. The nurse will constantly encourage the patient to try to maintain a positive mindset and think that the final outcome will be good. The patient must value the positive things they have in life and cultivate interpersonal relationships. They will receive help in trying to find activities that will help them achieve a state of mental relaxation. This action will be evaluated by using the Positive Mental Health questionnaire.

The patient's experience will be measured with the Patient Experience Questionnaire-15. These tools have been added into MyPlan, making it agile to fill them out and export their data.

Procedure

Following the inclusion and exclusion criteria defined in the study, the patient will be requested to answer the different questionnaires described in the "measurement tools" section.

The PI will download the MyPlan app for the patient and explain its function to them. The PI will also manually transcribe the treatment that has been prescribed for the patient's hospitalization time. The medication that must be administered to the patient and the medication schedule will be added into the app. The PI will also carry out a basic training session for each medicine prescribed to the patient, including what the drugs are for and their possible adverse effects.

During hospitalization, the same procedure will be repeated every day from Monday to Friday. A minimum of 4 sessions, as described above, will be held to educate the patient and improve their knowledge in pharmacology and autonomy upon discharge. The PI will maintain an individual registry in a Microsoft Excel spreadsheet that will contain all adverse drug reactions notified in the patient's clinical history. These data will be extracted from the information in the Systems Applications and Products in Data Processing bed chart (there is a shortcut icon for adverse drug reactions notifications), which is filled in by the medical professionals in charge of any given patient during hospitalization when applicable. As soon as the patient has been deemed fit to be discharged, the treatment prescribed for the time after discharge will be explained to them using the app (we will restrict the explanations to those pertaining to the treatment specified in the discharge report). It will be explained to them that they can use the app during the 30 days following discharge, as long as their primary care doctor does not make modifications to the treatment. For this reason, the patient's history will be reviewed daily by the PI to make sure there have been no consultations that have resulted in a change in the medication; 25 days after discharge, the PI will contact the patient via the MyPlan app to ask them to fill out the questionnaires and remind them that the study will end 5 days later (ie, 30 days after discharge). A message will be sent to the patient via the app 30 days after discharge to thank them for participating in the study, and their access to the app will be blocked, considering that the intervention has concluded.

Demographics and Baseline Functioning

Background data about the participants will be collected in the first session of the nursing pharmacological education intervention with the objective of evaluating any significant differences in the results after completion of the test. This background data will include age, gender, nationality, level of education, cohabitation status, caregiver, treatment, time of hospitalization, number of previous hospitalizations, evaluation of own health, and adverse effects.

Pilot Study

A pilot study will be carried out for the duration of a month with 20 subjects. The objective will be to evaluate the questionnaires' complementarity, clarity, and understandability. The patients selected for the pilot study will meet the criteria for inclusion. Once the pilot has concluded, modifications to the questionnaires will be made if necessary. The possibility to create a leaflet for the handling of the MyPlan app and the time frame for patient assistance via the app will be discussed.

Measurement Tools

The following measurement tools have been validated:

- Patient Experience Questionnaire-15, adapted and validated for Spanish language [28,29]: this questionnaire will allow us to explore patients' perception with regard to the educational process and their participation in the decision-making processes during their hospitalization.
- Morisky-Green Questionnaire [30]: this questionnaire will allow us to evaluate patients' treatment adherence. It is comprised of 4 binary questions that will reflect the degree of compliance in patients as well as information regarding the causes of noncompliance.
- Positive Mental Health Questionnaire [31]: this scale evaluates mental health from a positive viewpoint. It is comprised of 39 items, which are distributed across 6 categories: personal satisfaction, prosocial attitude, self-control, autonomy, problem-solving and self-actualization, as well as interpersonal relationship skills. Their measurement is made via Likert-type answers with the following range: "always or almost always," "frequently," "sometimes," and "never or almost never." It is validated among the general population in favorable psychometric values, with global reliability of 0.88 and variance of 45%.
- Forms for collection of sociodemographic and clinical variables.

Data Analyses

The statistical analysis will be made using Stata (version 15; StataCorp). It will consist of obtaining the differences between different data collections (24 hours after admission, upon discharge, and 25 days after discharge) for every variable considered in this project as a performance measurement of the intervention. Efficacy, effectiveness, and efficiency indicators will be based on the study of change from before the intervention to after the intervention (ie, before the intervention; upon discharge; and the last control, 25 days after discharge at home). These will be based on relative indexes (ie, change percentages) and reliable change indexes (ie, Jacobson-Truax coefficient as

XSL•FO
RenderX

well as alternative indexes, such as Tsu, Hagerman-Arrindell, and Speer-Greenbaun indexes). The difference in quantitative measurements in different phases will be based on factorial analysis (ANOVA). These will provide the main effects of change for all different phases. They will also provide the reliability intervals of the averages and the differences of proportion as measures to be assessed, as well as that of standardized indexes, such as Cohen *d*.

Results

Enrollment was initiated in October 2022 and will be completed in April 2023.

The main contribution of this protocol is a detailed description of a nursing intervention with the support of a smartphone app that will generate knowledge about patients' experiences, their adherence, and their positive mental health. The protocol is registered with ClinicalTrials (NCTT05669040).

Discussion

Expected Findings

One of the strong points of this study is the linear evaluation of the intervention (ie, 24 hours after admission, upon discharge, and 25 days after discharge), which can demonstrate the effectiveness of assisting the patient throughout the process. Another important finding may be related to the impact of the intervention on the quality of care because it could contribute to early detection and prevention of medication errors, minimizing both the associated complications that these patients may have and hospital re-admissions. Finally, another potential strength of the study is that the intervention can be extrapolated to different specialties in the hospital, which would contribute to the improvement of care for all patients.

The main result will be to generate a change in the medication administration process, implementing the nursing pharmacological education intervention. The secondary result will be related to the patient's hospital experience, the increase in treatment adherence, and the improvement of positive mental health. The expectation is to generate patient empowerment and a reduction in the number of consultations and hospital admissions derived from some adverse effects of the pharmacological treatment.

Potential Limitations and Implications

The main limitation of this study is that the sample is not randomized. Another limitation presented is the selection of patients included in the study according to the level of awareness and cognitive capacity as well as the ability to understand and use the MyPlan app.

The training nurse's time availability to train and educate patients in their pharmacological treatment is another limitation to take into consideration.

Conclusions

The results of this study will offer evidence of the effectiveness of a nursing pharmacological educational intervention that uses a free smartphone app. If its efficacy is demonstrated and the results are acceptable, it could mean an improvement in the care of patients operated for femur fractures and guide other training interventions in patients with other pathologies.

Acknowledgments

The authors would like to thank the University of Barcelona, the Hospital Clínic de Barcelona, the Traumatology Service, and the patients who participated in this study. We also extend our thanks to the Amgen laboratory for allowing the use of MyPlan app for this study.

Data Availability

The data confidentiality and availability disclaimer is included in the information sheet that is distributed to study participants and is explained to them prior to signing the informed consent form.

Authors' Contributions

All authors contributed to the design and writing of this article, and they all read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Black boys and men from disinvested communities are disproportionately survivors and perpetrators of youth violence. Those presenting to emergency departments with firearm-related injuries also report recent substance use. However, young Black men face several critical individual and systemic barriers to accessing trauma-focused prevention programs. These barriers contribute to *service avoidance*, the exacerbation of violence recidivism, substance use relapse, and a revolving-door approach to prevention. In addition, young Black men are known to be digital natives. Therefore, technology-enhanced interventions offer a pragmatic and promising opportunity to mitigate these barriers, provide vital life skills for self-led behavior change, and boost service engagement with vital community resources.

Objective: The study aims to systematically adapt and pilot-test Boosting Violence-Related Outcomes Using Technology for Empowerment, Risk Reduction, and Life Skills Preparation in Youth Based on Acceptance and Commitment Therapy (BrotherlyACT), a culturally congruent, trauma-focused digital psychoeducational and service-engagement tool tailored to young Black men aged 15-24 years. BrotherlyACT will incorporate microlearning modules, interactive safety planning tools for risk assessment, goal-setting, mindfulness practice, and a service-engagement *conversational agent* or chatbot to connect young Black men to relevant services.

Methods: The development of BrotherlyACT will occur in 3 phases. In phase 1, we will qualitatively investigate barriers and facilitators influencing young Black men's willingness to use violence and substance use prevention services with 15-30 young Black men (aged 15-24 years) who report perpetrating violence and substance use in the past year and 10 service providers (aged >18 years; any gender; including health care providers, street outreach workers, social workers, violence interrupters, community advocates, and school staff). Both groups will be recruited from community and pediatric emergency settings. In phase 2, a steering group of topic experts (n=3-5) and a youth and community advisory board comprising young Black men (n=8-12) and service providers (n=5-10) will be involved in participatory design, alpha testing, and beta testing sessions to develop, refine, and adapt BrotherlyACT based on an existing skills-based program (Achieving Change Through Values-Based Behavior). We will use user-centered design principles and the Assessment, Decision, Administration, Production, Topical, Experts, Integration, Training, and Testing framework to guide this adaptation process (phase 2). In phase 3, a total of 60 young Black men will pilot-test the adapted BrotherlyACT over 10 weeks in a single-group, pretest-posttest design to determine its feasibility and implementation outcomes.

XSL•FO
RenderX

Results: Phase 1 data collection began in September 2021. Phases 2 and 3 are scheduled to start in June 2023 and end in September 2024.

Conclusions: The development and testing of BrotherlyACT is a crucial first step in expanding an evidence-based psychoeducational and service-mediating intervention for young Black men involved in violence. This colocation of services shifts the current prevention strategy from telling them *why* to change to teaching them *how*.

Introduction

Background

Youth violence and substance use co-occur as a public health double threat. Youth violence encompasses a range of behaviors, including dating violence, actual or threatened violence, physical fighting, web-based and school bullying, threats and assault with weapons, homicide, and firearm-related and gang-related violence [1,2]. Similarly, substance use is linked to violent incidents, even as persistent substance use (of marijuana and alcohol) is associated with youth violence perpetration and victimization [3,4]. Although the evidence is conflicting [4,5], youth violence and substance use share transdiagnostic risk and protective factors [4,6] and underlying mechanisms that cross-cutting preventative measures can address. Moreover, these socially costly issues are linked to multiple adverse physical, social, and health effects, such as low quality of life, subpar academic and social functioning, mental health disorders, and suicide risk [4].

Young Black men and boys from disinvested communities are disproportionately survivors, perpetrators, and witnesses of youth violence and homicide [7-9]. Recent Centers for Disease Control and Prevention data reports homicide as the primary cause of death for Black boys and men (aged 10-24 years), and firearms were involved in 94% of these incidents [9-11]. During the pandemic, firearm homicide rates in the United States rose to its highest level since its peak in 1994 [12]. Black boys and men aged 10 to 44 years saw the largest increase in these adjusted rates from 2019 to 2020, followed by Native American individuals, aged 25 to 44 years [7,12]. Consequently, Black youth are 14 times more likely and Hispanic youth are 3 times more likely than White youth to die from firearm-related violence [12].

More than 700,000 urban youths (aged 10-24 years) present to emergency departments (EDs) each year with nonfatal assault-related injuries [4,13,14]. Approximately 20% of these youths report substance use within 3 hours of an assault-related injury [3,14,15]. Despite this, service gaps continue to hamper violence and substance use prevention efforts for underserved, urban, and low-income youth. Outside the juvenile and criminal justice systems, racial and ethnic minority youth report critical barriers to obtaining behavioral health services across the continuum of prevention, treatment, and recovery. These barriers include but are not limited to neighborhood disadvantage, racism, homelessness or temporary housing, unemployment, discrimination, peer and gang pressures, transportation issues, program fees, the lack of culturally relevant services, and competing demands on time to attend clinic or group-based rehabilitation sessions [16-18].

Similarly, violence prevention programs in hospital EDs, schools, juvenile justice facilities, child welfare systems, faith-based and street outreach initiatives continue to have substantial wraparound effects in reducing violence [19,20]. However, in resource-limited communities, these programs lack 24/7 staff coverage, follow-up services, and trauma-informed training and report high employee turnover [16-18,21]. Furthermore, injured young Black men perceive hospital violence intervention programs—and other formal institutions—as places of interface with law enforcement and thus avoid using these services [16,22-24], even though EDs are increasingly recognized as a critical intervention venue for youth at risk for future violent injury [4].

Similar to contexts where these services exist, sociostructural barriers can also impede youth willingness to use them. These barriers include and are exacerbated by experiences of police bias and violence, treatment stigma [16,17,25-27], racial trauma, and a historic mistrust of legal and medical systems linked to the systemic discrimination and overt criminalization of Black men and boys [16,28-30]. In addition, the language (and culture) of formal therapy centering on Western-centric curricula [31] and gender norms that frame help-seeking as a *weakness* have also been identified by young Black men as impediments to service use despite the high prevalence rates of trauma exposure among these underserved groups [32,33].

These barriers have created substantial service gaps [17]. In addition, they have exacerbated treatment inequities, leaving young Black men involved in violence in underserved communities to adopt ineffective coping techniques, such as service avoidance or *opting out* [22]. Service avoidance takes the form of deliberate attempts to avoid or disengage from formal treatment or rehabilitation programs perceived to be associated with *feds* or that place them *in the system* [22], whereas *opting out* from preventative programs can manifest as early dropouts, noncompliance, nonparticipation, tardiness, and absenteeism even when the court system mandates program completion. Consequently, persistent service-avoidant behaviors contribute to violence recidivism, substance use relapse, and a revolving-door approach to prevention. Therefore, improving youth access to and trust in existing violence and substance use prevention interventions is critical.

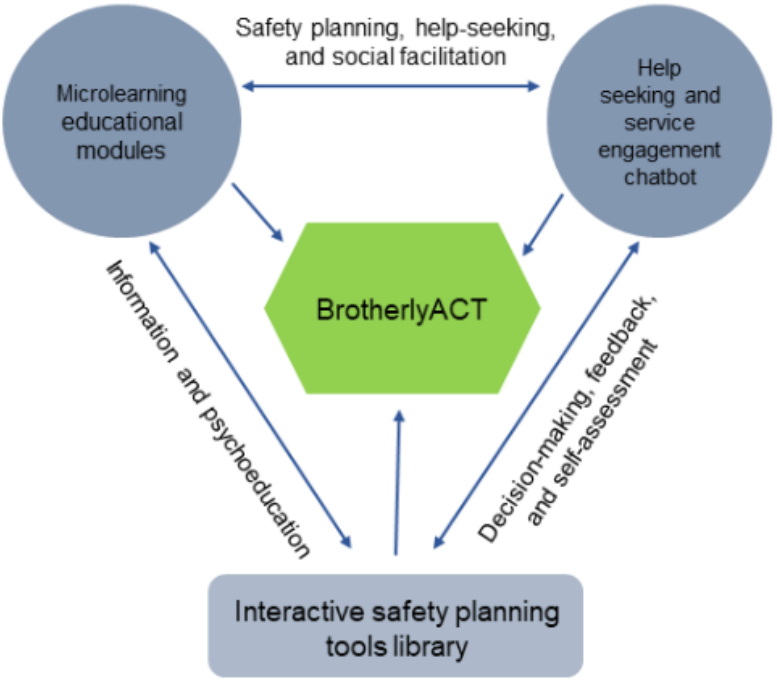
Technology-Enhanced Interventions to Reduce Barriers to Co-occurring Violence and Substance Use Prevention



Technology-enhanced interventions can empower underserved and low-income youth to overcome some of these barriers [18]. Studies show that young Black men favor digital interventions as digital natives in a *tech-saturated* world [34-37]. Even after controlling for age, parent education, and family composition (single vs 2-parent households), Black youth have higher cell phone ownership rates and internet use (ie, hours per day) than Hispanic and White adolescents [36]. Therefore, technology-enhanced interventions can simultaneously mitigate these barriers and broaden the access to trauma-focused therapies. From a prevention science standpoint, engaging at-risk young Black men in this digital landscape—by meeting them where they are—is a promising and pragmatic approach to early prevention of substance-related violence [37-39]. This strategy can potentially reduce service avoidance while boosting the availability, accessibility, and personalization of evidence-based interventions [37-39]. Notably, technology-enhanced interventions can serve the "treatment curious" (those at early risk who have not sought out formal services but who can benefit from a low-stakes digital tool that highlights the risks and consequences of youth violence) and the "treatment veterans" (or returning citizens who are chronically involved *in the system* and familiar with violence and substance use services). Innovative public health and equity-focused interventions promoting health equity and positive service engagement for at-risk and underserved young Black men are needed to address the gaps and barriers identified previously.

This study aimed to systematically adapt and pilot-test Boosting Violence-Related Outcomes Using Technology for Empowerment, Risk Reduction, and Life Skills Preparation in Youth Based on Acceptance and Commitment Therapy (BrotherlyACT), a culturally congruent, trauma-focused digital intervention tailored to Black boys and men aged 15 to 24 years. BrotherlyACT will incorporate microlearning modules, interactive safety planning tools for risk assessment, goal-setting, mindfulness practice, and a service-engagement *conversational agent* or chatbot to connect young Black men to relevant services.

Overview of BrotherlyACT

To address these gaps and barriers, we developed a protocol for adapting and pilot-testing BrotherlyACT. It is envisioned as a multilevel, multicomponent, web-delivered, and app-delivered intervention to promote psychoeducation, safety planning, and service-engagement self-efficacy to reduce the risk and effects of co-occurring youth violence and substance use among low-income Black boys and men (aged 15-24 years). BrotherlyACT will comprise three main components (as depicted in Figure 1): (1) microlearning psychoeducational modules (or brief lessons framed as learnable *life skills* in an interactive curriculum) organized around the 6 fundamental acceptance and commitment therapy (ACT) principles (intrapersonal focus); (2) a safety planning tools library with resources to facilitate risk assessment, goal-setting and tracking, and mindfulness practice (interpersonal focus); and (3) an SMS text messaging–styled service-engagement chatbot or *conversational agent* to promote help-seeking, self-advocacy, and access to a curated list of national and local violence and substance use prevention programs and services (interactional focus). The need for these three components emerged out of interest from young Black men and service providers working with teens involved in violence to help them (1) develop self-efficacy to practice help-seeking while accessing trusted services on their own, (2) create a supportive motivational climate for underserved youth to feel comfortable seeking help, and (3) identify safe people and resources in their communities.

Figure 1. Boosting Violence-Related Outcomes Using Technology for Empowerment, Risk Reduction, and Life Skills Preparation in Youth Based on Acceptance and Commitment Therapy (BrotherlyACT) components.

XSL•FO
RenderX

Theoretical Rationale

BrotherlyACT is based on several theoretical and conceptual models. The intervention's psychoeducational modules will adapt an existing theory-driven and skills-based manualized intervention (Achieving Change Through Values-Based Behavior [ACTV]) with motivational, informational, and behavioral activation strategies [40-45]. These brief or microlearning psychoeducational modules will cover topics on help-seeking, substance use, conflict resolution, nonretaliation, healthy relationships, gun and gang refusal skills, mindfulness (putting a *brake* on emotional reactivity), and positive future orientation and coping.

The original ACTV curriculum comprises 5 modules designed for violence reduction with incarcerated men and women using group sessions [38-44]. In addition to feedback from young Black men and service providers, the other components of BrotherlyACT were informed by the Capability, Opportunity, and Motivation to Change Behavior model [46], which proposes 3 elements that are vital to sustainable behavior change: capability, opportunity, and motivation [46]. *Capability* refers to an individual's abilities and skills, such as physical, cognitive, or technical skills, and considers situational and background risk factors that precipitate youth violence. *Opportunity* refers to the presence or availability of resources and opportunities that enable the individual to engage in a particular behavior, such as access to information, social support, or resources, and practice self-direction and decision-making. *Motivation* refers to the individual's desire or willingness to engage in the behavior, which may be influenced by factors such as attitudes, beliefs, values, or goals. Capability and opportunity jointly influence motivation [46], contributing to lasting behavior change. Taken together, the Capability, Opportunity, and Motivation to Change Behavior model helped to clarify individual, community, and structural risk factors (eg, service avoidance and emotional avoidance) that may be targeted by BrotherlyACT.

We hypothesize that through improved behavioral and cognitive skills and service-engagement self-efficacies, BrotherlyACT can reduce key psychological avoidant mechanisms (emotional avoidance and service avoidance) and increase motivation, capability (eg, self-efficacy to create and use a safety plan), and opportunity (eg, knowledge about service options). These improved conditions will, in turn, reduce the risk and effects of violence and co-occurring substance use among low-income young Black men involved in violence.

ACTV Approach

ACTV is an evidence-based psychotherapy based on ACT [47-52]. ACT is a third-generation cognitive behavioral therapy (CBT) based on the philosophy of functional contextualism and Relational Frame Theory [53]. ACT differs from other CBT-based approaches because it is based on a unified model of human behavior change and psychological growth. It is focused on helping individuals develop a different relationship with their thoughts and emotions instead of trying to change them directly. For example, CBT aims to help individuals identify and change negative or irrational thoughts, whereas ACT holds that pain and discomfort are a fact of life—something we must become comfortable with if we wish to live a happy, fulfilled life. ACT aims to increase *psychological flexibility* or "the process of contacting the present-moment fully as a conscious human being and persisting or changing behavior in the service of chosen values" and reduce *emotional avoidance* (unwillingness or perceived inability to remain in contact with difficult internal experiences and efforts to delay gratification and live a value-based lifestyle) [47-52]. Therefore, ACT encourages flexibly responding with openness and acceptance of our thoughts and emotions rather than trying to directly change their form or frequency and then shifting our attention (with practice) to what is most important in our lives. Of note, >20 meta-analyses and >900 randomized trials, with 12,477 participants, have shown that ACT is effective for a wide range of target conditions, with effect sizes ranging from small to medium for depression, anxiety, substance abuse, and chronic pain and small to large effects for increasing psychological flexibility in general [53,54].

ACTV was developed by a coauthor (AZ) and has been rigorously tested in multiple randomized effectiveness trials, feasibility studies, and pilot studies in collaboration with the Iowa Department of Corrections [38-44]. A series of effectiveness trials compared ACTV with the traditional Duluth or CBT model. A 1-year postintervention comparison of community-based ACTV vs the Duluth and CBT models (widely used globally in rehabilitation programs for abusive men) found that ACTV significantly reduced new charges, domestic assault charges, and violent charges for men who were mandated to complete a domestic violence intervention program (N=3474) at 12 months after treatment [42]. In addition, this effect was maintained for both program completers and dropouts [40]. A recent 5-year survival analysis of ACTV participants corroborated a previous study with 1-year outcomes, showing ACTV participants being less likely to acquire new violent or domestic abuse charges at year 5 (χ^2_1=6.8, *P*=.009) but with no difference in general criminal charges between ACTV and Duluth or CBT participants (χ^2_1=0.3, *P*=.60) [40]. In addition, control participants acquired new charges faster than intervention participants [40]. Although effective for reducing partner and criminal violence, ACT (and ACTV) has not been adapted for cross-cutting violence and substance use prevention with at-risk youth or for digitally enhanced delivery.

However, trauma-focused therapies, such as ACTV, remain inaccessible to youth who are economically disadvantaged and belong to a racial and ethnic minority group (eg, Black and Latinx youth) [54]. These interventions are typically developed, adapted, and evaluated with White, high-income populations [55-57]. In addition, White youth who are involved in violence are more likely than their non-White counterparts to be diverted to rehabilitative therapy [58]. In comparison, young Black men who are involved in violence are substantially more likely to be transferred to more punitive alternatives (eg, transferred to adult court) or other forms of detention [58]. Interventions addressing these issues similarly use Western-centric theories for individualistic violence prevention and emphasize racial and socioeconomic distinctions between treatment facilitators,

XSL•FO
RenderX

program curricula, and men referred to these programs, resulting in a *therapeutic mismatch* [31].

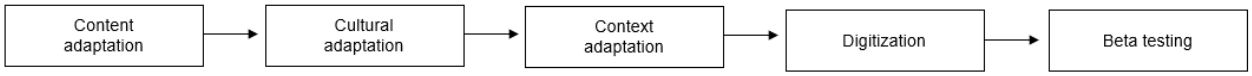
User-Centered Design for Technology-Enhanced Interventions

User-centered design (UCD) is a general term for design methodologies in which end users are involved in the iterative process to shape the design of an intervention and contexts for its implementation [59-61]. UCD strategies can be put into practice quite fast, enabling us to swiftly determine user needs and create appropriate interventions to address these needs.

UCD methods are important, as they can uncover new information that is not revealed by conventional techniques, improve user experience, and ensure that we obtain representative participant response to match a predetermined usability requirement. In addition, users develop a sense of ownership for the product [59]. Contextual interviews, think-aloud protocols, cognitive walk-throughs, semistructured cognitive interviews, and acceptability or feasibility surveys are some of the UCD techniques we will use with key stakeholders as we develop BrotherlyACT.

The development of BrotherlyACT using UCD principles reimplements the design and adaptation methodologies from our previous studies with young men who are involved in violence and affected by trauma [34,62]. In more recent studies, we have used UCD methods in the design of a mobile clinical decision support app for urinary tract infection in long-term care [63,64] and in understanding the usability and function of consumer-grade wearable devices [65].

Several iterations of BrotherlyACT will be produced and tested for usability. Early studies indicate a need for cross-cutting interventions for violence co-occurring with other risky behaviors. Young men in these studies confirmed the suitability of, and the potential to explore further, the use of digital methodologies as a primary prevention tool [34]. Participants listed the following as intervention *must-haves*: individualized feedback, compelling firearm injury testimonials, inspiring tales of other young men who have successfully avoided violence and substance use, humanlike chat capabilities, actual stories and violence-related testimonials, pictures and videos of people similar to them, and mechanisms to monitor behavior change. This feedback substantially informed the proposed BrotherlyACT intervention [34].



Methods

Overview

The development of BrotherlyACT will occur in 3 phases. In phase 1, we will collaborate with Black boys and men (aged 15-24 years) and service providers (aged >18 years; any gender) to identify social and structural barriers and motivators influencing youth violence and substance use prevention. Black boys and men (aged 15-24 years; n=25-30) and their service providers (n=10) will be recruited from clinical (pediatric ED) and community-based settings in the West and South sides of Chicago—2 areas with historically high violence burden and persistent economic disadvantages, but with much promise and a wealth of community-based programs [66-69]. Sessions will include participatory focus groups, in-depth one-to-one interviews, and wish listing activities (ie, listing intervention must-haves).

In phase 2, we will use content and cultural adaptations of the ACTV curriculum using the 8-stage Assessment, Decision, Administration, Production, Topical, Experts, Integration, Training, and Testing (ADAPT-ITT) framework [70,71]. Finally, in phase 3, we will assess the feasibility and acceptability of BrotherlyACT. Overall, 60 young Black men (not part of phase 1 or 2) will remotely pilot-test BrotherlyACT for 10 weeks to determine feasibility and implementation outcomes. An outline of the study stages is shown in Figure 2.

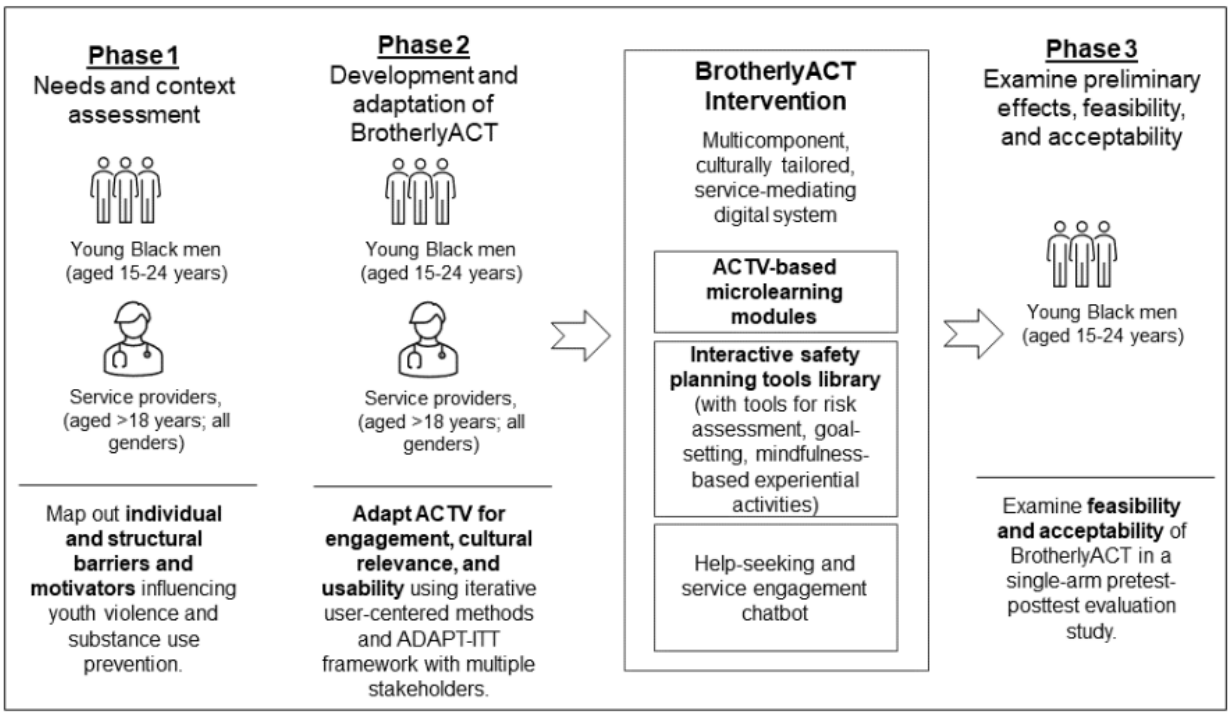
Figure 2. Outline of study phases.

Ethics Approval

All study phases have been approved by the Rush University Medical Center institutional review board (IRB; Office of Research Affairs number 21122902-IRB01). In addition, we have received recruitment-only IRB approval from the Stroger Cook County Hospital (study 22-087R). Each participant will provide informed consent before recruitment into the study and receive a copy of the signed form as a PDF. They will also be informed that their participation is voluntary and that they may withdraw from the study at any time. Furthermore, permission will be sought to audio-record and take notes during the interviews. All study data will be deidentified and kept confidential according to IRB protocols at designated study sites, with Rush IRB being the primary study site.

Study Design, Participants, and Recruitment

Phase 1—Risk and Needs Assessment



Overview

This phase will involve formative, qualitative research using individual web-based interviews and focus group discussions with key informants (young Black men and service providers). This needs elicitation phase will identify social and structural barriers and motivators influencing youth violence and substance use prevention services among Black boys and men (aged 15-24 years) and their service providers (including but not limited to health care providers, street outreach workers, social workers, violence interrupters, community advocates, and school staff). In separate focus groups and individual interviews, we will include community barrier mapping and graphic facilitation sessions (ie, displaying ideas expressed during meetings on a

XSL•FO
RenderX

whiteboard with text and imagery). Young Black men and service providers will describe (1) sociostructural targets to improve young Black men engagement with violence prevention services, (2) culturally salient needs, (3) knowledge of existing resources (eg, where, how, and why young Black men seek assistance), and (4) preference for digital behavior change interventions. In addition, we will age-stratify all interviews (15-17 years and 18-24 years) to account for differences in risk taking, peer culture, developmental age, and self-identity. The service providers and young Black men will not interact in the same sessions. Instead, separate sessions will be scheduled for service providers so that young Black men may openly communicate their experiences and account for developmental, background, and age differences without bias. Sessions will be conducted in person, via phone, or via secure video chat (Zoom; Zoom Video Communications Inc). The outline of the study design is shown in Figure 3.

Figure 3. Outline of study design. ACTV: Achieving Change Through Values-Based Behavior; ADAPT-ITT: Assessment, Decision, Administration, Production, Topical, Experts, Integration, Training, and Testing; BrotherlyACT: Boosting Violence-Related Outcomes Using Technology for Empowerment, Risk Reduction, and Life Skills Preparation in Youth Based on Acceptance and Commitment Therapy.

Study Setting

Study sessions will occur concurrently, with Zoom, phone (phases 1 and 2), and in-person options for participation (phase 3). Only in Chicago, where the study researchers are based, will participants be able to undergo in-person procedures in pediatric EDs and community-based centers, if they prefer. We have chosen to start with young Black men in 1 major high-risk city (Chicago) to establish proof of concept before expanding to other cities with a high violence burden (Detroit, Baltimore, Camden, and Oakland) in the future.

Consent and Assent Process

Black boys aged 15 to 17 years will assent, and Black men aged 18 to 24 years will consent. Participants can electronically assent or consent on a Health Insurance Portability and Accountability Act–compliant e-consent platform. The informed e-consent form will include information about the study's aim, procedures, confidentiality, and risks and benefits of participation and the safety and risk mitigation protocols. Alternatives for contacting the study team (ie, text, calls, and emails) will accommodate participant needs and account for digital divides, internet bandwidth issues, and digital health equity concerns (eg, privacy and data safety concerns). We will not collect written documentation of youth assent and consent to safeguard the participants' confidentiality. We will waive parental consent as this study poses low risk, according to federal laws (45 Code of Federal Regulations 46), Section 116 (d) [72]. Waiving parental consent does not affect the rights and welfare of our participants. Low rates of young Black men enrollment when parental consent is mandated have impeded previous studies.

Moreover, young Black men with low risk (less substance use; little to no violent history) are oversampled when parental consent is mandated (individuals with high risk or great use of violence and substances are less likely to join owing to this reason). Waiving parental consent may reduce sampling biases and dishonest reporting by participants, as adolescent participants may fear their parents discovering their participation in the study. Ineligible participants will be redirected to the end of the survey, where they will find resources (eg, crisis helplines and suicide hotlines) to help young Black men obtain the needed services. In addition, once the e-consent form is submitted, participants can print or save a copy of the informed assent and consent form before moving on to the web-based survey. Importantly, there is no more than minimal risk involved in completing the brief web-based sociodemographic questionnaire, and the participants' responses will remain completely

XSL•FO
RenderX

anonymous (no IP addresses will be automatically logged in REDCap [Research Electronic Data Capture; Vanderbilt University]).

Consent Process for Service Providers

Service providers will be required to verbally consent at the beginning of each session. Service providers will be informed about the voluntary nature of this study, that all questions are optional, and that the session will be audio-recorded. As a part of the consenting process, service providers will be informed that they will not have access to any young Black men's data, even if they come from the same organization.

Data Analysis for Phase 1

Focus groups and interviews will be audio-recorded and transcribed verbatim by an independent transcriptionist. Transcripts from the study sessions will be recorded (with permission after informed consent), transcribed verbatim, and analyzed by 2 research team members using qualitative description, low-abstraction, and low-inference approach to closely interpret the data [73-75]. Qualitative description is ideal for describing phenomena of the participants' experience and language and is well suited for needs and risk assessment with susceptible populations [73-75]. After sorting, rearranging, and comparing codes, we will form categories and subcategories by pooling codes based on commonality, divergence, and logical parsimony [60,61,76]. Primary themes will be identified based on data generalizations and supplemented by participant excerpts [73,74]. Qualitative analysis software will be used to develop codes and a codebook. Approximately 10% of all transcripts will be double coded as pilot transcripts and reviewed for intercoder reliability or consistency to ensure high coder agreement (κ>0.80). In addition, *wish list* data will be analyzed according to a multilevel content analysis using an inductive six-phase process [76]: (1) coding of data sources (ie, focus group and interview transcripts), (2) reflexive note taking and bracketing, (3) cross-examination to discern similarities and variations in data, (4) observing commonalities and differences among the data, (5) identifying stable generalizations from the data, and (6) comparison of results with established literature.

Inclusion and Exclusion Criteria

Black boys and men invited to participate are eligible if they identify as male, irrespective of sexual orientation; identify as Black or African American; are aged between 15 and 24 years (inclusive); report having internet access; and are able to assent or consent to participation. We have received an IRB waiver of parental consent, as this study presents minimal risk. Those who are actively suicidal or homicidal, not medically stable, intoxicated during recruitment, and cognitively unable to provide informed consent; have impairments (such as emergent injuries); or are in police custody or incarcerated during the study enrollment will be excluded. Service providers will be adults (1) aged >18 years (all genders), (2) with experience in working with racial and ethnically diverse youths, (3) of any race or ethnicity, and (4) who are able to speak and read in English.

Recruitment Plan

Recruitment will be based on the Strategies to Recruit, Engage, and Retain Children in Behavioral Health Risk Factor Studies (REACH) model [77]. Strategies will include distributing flyers in high-traffic areas frequented by adolescents (eg, youth-serving agencies, festivals, churches, not-for-profit organizations, sports centers, reentry resource fairs, and barbershops). Our partner organizations will assist in recruitment using channels they deem appropriate for reaching the youth they serve. Partner organizations include The Urban Male Network and the Chicago Black Therapists Network (a network of 140 Black therapists). Both programs support underserved Black youth with mentoring and mental health services. We will also recruit through clinical research platforms, such as ResearchMatch (funded by the National Institutes of Health) [78] and The New Normal. We will work with 2 urban pediatric EDs: John H Stroger, Jr Hospital of Cook County (IRB approved), a level-1 trauma hospital that treats approximately 120,000 adults and children annually; and the 62-bed pediatric ED at Rush University Medical Center. Social media will support broadcast recruitment (via Instagram and Facebook advertisements). Service providers will be recruited via direct email to relevant organizations, word of mouth, and snowballing. Study materials will refer to the *Youth Health and Safety Study*.

A community champion familiar with the West and South sides of Chicago will advise and facilitate recruitment in these communities. Similarly, clinical research assistants in each ED or in-patient trauma unit will enroll participants presenting with assault-related or violence-related injuries who meet our eligibility criteria. All study staff will be trained in research compliance, motivational interviewing, trauma-informed research and data collection, and sensitivity training. After obtaining consent, young Black men will complete a survey on REDCap to assess their eligibility. Participants' compensation will be graded, ranging from US $25 to US $40, with the amount increasing for each study session completed. Service providers will receive US $50 for each session they complete.

Retention Plan

Similarly, we will use the REACH model [77] to maximize participant retention. These strategies will include the following: (1) obtaining the names, phone numbers, and email addresses or SMS text messages of several (at least 3) individuals (ie, friends, parents, and siblings) as alternate safe contacts to keep in touch with participants; (2) after each study communication, the participant will be provided with study contact information; (3) gift card compensation and train or bus passes will be provided for in-person meetings; and (4) a secured database for organizing follow-up contacts. When the app is developed and ready for testing (ie, phase 3), retention plans will include offering participants access to a password-protected study website with instructions on how to safely use the app and maintaining periodic contact throughout the study to assess for safety and confirm planned or unplanned changes to contact information.

Phase 2—Adapt and Optimize BrotherlyACT

Overview

Pertinent themes from phase 1 will inform the adaptation of the ACTV curriculum into a microlearning format in BrotherlyACT. This stage will be focused on iteratively

XSL•FO
RenderX

developing all 3 components of BrotherlyACT tailored to young Black men affected by violence and substance use. The microlearning modules will draw on the evidence-based ACTV intervention by adapting, modifying, or adding modules directly relevant to young Black men's unique experiences in noninstitutionalized contexts. UCD principles and the 8-stage ADAPT-ITT framework will guide this adaptation process. The ADAPT-ITT framework is an 8-stage sequential guide to intervention adaptation, particularly in resource-poor settings [70,71]. Overall, 2 phases of stakeholder adaptations will occur at this stage. Stage 1 will focus on content and cultural adaptations and alpha testing. Then, stage 2 will comprise context adaptations and beta testing. UCD efforts will be informed and guided by our previous study using this methodology.

Stage 1

Overview

This phase of adaptation and optimization will involve *content* and *cultural* adaptations (ie, ADAPT-ITT stages 1-5; refer to Table S1 in Multimedia Appendix 1) and will conclude with alpha testing with topic experts and a multidisciplinary steering group (n=8-10; including the codeveloper of ACTV). This steering group will alpha test using semistructured cognitive interviews and several acceptability and feasibility questionnaires, including the 10-item System Usability Scale (SUS) [79]. The SUS can heuristically capture the perceived ease of use of BrotherlyACT (usability) and learnability (the ease with which users understand the intervention curriculum and layout). The SUS score is stable, with as few as 5 participants testing it. The SUS score must average at least 68 out of 100 (68 is the universal average acceptable score) [79,80]. The SUS is highly reliable (Cronbach α=.90), with scores >70 indicating *good* usability [80].

Content Adaptation

In sessions lasting 60 to 90 minutes, adaptation will focus on altering the noncore components of the ACTV curriculum, including language; simplifying ACTV modules while retaining its therapeutic values; and providing examples, case studies, and metaphors relevant to young Black men. Adaptation will also refine BrotherlyACT to determine which core components must be maintained or excluded (eg, therapeutic jargon). Specifically, we will systematically adapt ACTV skills-based modules into a paper-based microlearning curriculum (draft 0) that will be evaluated and refined independently.

Participants will be taught and will read each of the modules in the ACTV curriculum. Following each module, debriefing sessions will be completed to assess acceptability. Participants will then discuss and recommend (1) vital components to be retained, excluded, emphasized, or condensed to ensure that the adapted curriculum is appropriate for young Black men based on age, context, and community setting; (2) how to structure the module's learning objective in line with Bloom Taxonomy (to improve knowledge, life skills self-efficacy, and motivation to learn); (3) the modules' voice, tone, and pacing; (4) engaging formats for lesson practice and rehearsal (eg, true or false factoids, card sorting exercises, multichoice questions, and quizzes); and (5) module length. The paper-based curriculum will be drafted based on this feedback using Microsoft Word.

Next, adaptation plans will focus on how BrotherlyACT's clinical goals (eg, life skills self-efficacy) will map to BrotherlyACT's other in-app components and pragmatic features (safety planning toolkit and service-engagement chatbot). Overall, curriculum adaptations will consider logistical issues, such as intervention workflow, and what point-of-care organizational and community capacities are required for BrotherlyACT to be successfully implemented.

Cultural Adaptation

This step is vital, as identity, racial socialization, and culture are central themes in minority youth decision-making to seek and use prevention services and to facilitate great sustained engagement in treatment. Culturally adapted interventions must consider racial socialization messaging, beliefs, cultural values, contexts, and racial barriers that affect young Black men. We will also plan to incorporate culturally salient factors (ie, spirituality, Black masculinity, family support, fatherhood, a community, or *village mentality*) into draft 0. These factors influence help-seeking among young Black men [81]. In addition, we will incorporate relevant media (eg, videos of reformed young Black men), providing cultural and community icons as role models, and positive ethnic pride messaging (eg, messages countering the myth that Black boys are prone to violence). Cultural adaptation will necessitate modifying elements of draft 0 based on 8 cultural domains (language, contexts, symbols, metaphors, content, concepts, goals, methods, and context) through the lens of the Ecological Validity Model [82].

Stage 2

This phase of adaptation and optimization will include *context* adaptations, digitization, and *beta testing* of BrotherlyACT by a youth and community advisory board (YCAB).

Context Adaptation

The paper-based curriculum (*draft 0*) will be optimized into a digitized curriculum (ie, interactive web-accessible and app-accessible format) as part of BrotherlyACT (*draft 1*). Using UCD principles that incorporate youth needs [59-61,72,83], the YCAB (young Black men [n=8-12] and service providers [n=5-10]) will alpha test draft 1 for contextual acceptability, esthetics, understandability, relevance, and cultural salience. This wireframe version will not have color or graphics and will concentrate on content flow, functionality, and priority using sketches and layouts of interfaces with clickable components, buttons, and dropdowns. This stage of adaptation will increase BrotherlyACT's suitability to be digitized.

Next, our technology partner (Hekademeia Research Solutions [84,85]) will build a prototype of BrotherlyACT (*draft 2*), beginning with the adapted curriculum. This version will be functional and reflective of the final intervention. The original ACTV is a standardized manual in a predetermined sequence of modules across 24 weeks, which may restrict its flexibility in digital format. Therefore, BrotherlyACT will allow for the nonsequential deployment of interactive micromodules (that can be completed in 5-7 minutes) in response to the urgency of

XSL•FO
RenderX

youth violence and the immediate skills needed and to fulfill real-world needs in high-violence, high-vigilance contexts. We will reconvene confirmatory focus groups with our YCAB to inform a finalized version of BrotherlyACT (*draft 3*—a high-fidelity prototype).

Beta Testing

The YCAB will beta test draft 3 in 2 consecutive sessions (broken into 2 rounds to reduce the cognitive load on participants) and build on findings from iterative sessions. Each session will last 30 to 90 minutes to identify usability problems early, quickly, and economically to find areas for improvements and to recommend content and features to retain or remove (ie, with sufficient features and functionality for testing). The YCAB will click portions (eg, buttons on the interface) on study iPads or personal phones. They will observe, rate, and clarify content tone and esthetic issues using a semiscripted usability protocol, including *cognitive walk-throughs* (to identify content and phrases not understood or interpreted as intended in modules and app pages) based on scripted cognitive tasks. *Theater testing* will be used to clarify their cognitive processes as they react to questions about content ("what comes to mind when the app asks you if you want to redo a module?"), paraphrase or summarize app-related elements (eg, text), and identify technical issues (eg, glitching or slow-loading pages) [71].

Phase 3—Clinical Trial

Overview

Overall, 60 young Black men (not part of phases 1 and 2) will be recruited to a single-group, pretest-posttest study of the finalized version of BrotherlyACT. This pilot test will determine its early feasibility outcomes (the feasibility of recruitment and retention methods; feasibility of module co-design with youth by observing fidelity to and deviations from the study protocol; completion of outcome measures; and satisfaction, appropriateness, cultural relevance, feasibility, and acceptability of the intervention). We will also ascertain the implementation outcomes for a large trial (ie, adherence, sustainability, and usability).

Assessments will be taken at baseline (T0) and after the intervention (T1) at 10 weeks, with SMS text message prompts to complete modules and study sessions. Given the exploratory nature of this study and its focus on feasibility, acceptability, and implementation outcomes, phase 3 data analyses will not be designed to have a specified level of statistical power. Nonetheless, with sample size of N=60, pretest-posttest correlation of 0.60, and α^2 (tailed)=.05, we estimate 80% power to detect a pretest-posttest change of Cohen $d \geq 0.33$ (a small to medium effect). We will use mean imputation on the missing items in the event of participant loss. Participants who leave the study will be compared with those who stay to identify any differences in baseline and follow-up data for descriptive purposes and to determine if data are missing at random.

Data Analysis for Phase 3

Pretest and posttest scores will be compared to see if participants improved, stayed the same, or deteriorated on each outcome scale. Data will be checked for missing data patterns, distributions of outliers, and variable distributions to ensure that they meet the assumptions of planned analyses. For baseline characteristics, descriptive statistics will be generated. We are limited in attributing postintervention change without a control group to the intervention. Thus, the effects observed are preliminary. All statistical analyses will be conducted using SAS. Initial data analysis will be performed to check for data quality, including allowable ranges and errors.

Generalized linear models will analyze the pretest and posttest survey measures using repeated measures analysis. As this pilot study is exploratory, we will use a P value <.05 to denote significant findings but not adjust for multiple tests, given the pilot nature of the study. Exploratory analyses will examine differences in rates of pretest-posttest change by baseline characteristics, including recruitment site (pediatric ED vs community). To test such moderation effects, terms for the moderator and for the moderator × time (before and after) interaction will be added to the models described previously. Significant interactions will be graphed to aid interpretation. At the end of the 10-week study period, participants will complete exit interviews via the web individually and will complete the SUS. Additional open-ended process interview questions will focus on young Black men's perceptions of BrotherlyACT and the research experience. As part of this study, responses to exit interview questions will be recorded with permission and thematically analyzed in a qualitative phase before being combined with pretest and posttest findings.

Results

Phase 1 data collection began in September 2021. Phases 2 and 3 are scheduled to start in June 2023 and end in September 2024. The entire study is expected to be completed by the end of 2025.

Discussion

Expected Findings

Using a mixed methods study format, subjective and objective feasibility and acceptability data will be compared. This will ensure that survey data can be quantified and contribute to our qualitative understanding of the curriculum's practicality and acceptability.

Few antiviolence technology-enhanced interventions exist, and even fewer studies have studied the acceptability, usability, and engagement of a life skills and mindfulness coaching intervention for co-occurring youth violence and substance use among young Black men. The extent to which existing technology-enhanced interventions are used for violence prevention has been limited to supporting the work of street outreach workers [86]. We expect that BrotherlyACT will prove to be acceptable and usable by young Black men affected by violence. Furthermore, findings from the development of BrotherlyACT will be useful for a future definitive trial. This trial will validate an expanded version of BrotherlyACT across clinical and community-based settings for young Black men in Chicago and other cities with a high prevalence of youth violence. Clinical outcomes will be determined after we evaluate how well BrotherlyACT works (ie, reduction in violence and

XSL•FO
RenderX

substance use, perceived likelihood of involvement in violence and problematic behaviors, self-efficacies to plan for a positive future, use of ACT and life skills, and likelihood of using service options). The success of this intervention in different deployment contexts (eg, in a hospital vs a community setting or web-based vs face-to-face setting) will be evaluated as part of the implementation analysis. BrotherlyACT will be tested (1) with referred (vs recruited) young Black men, (2) with an organic deployment by service providers (vs research staff), and (3) in comparison with conventional care in future effectiveness trials.

On the basis of previous application of qualitative methods [34] and UCD [34,59,62], we anticipate that our study will highlight the benefits of technology-enhanced modalities for addressing motivation and self-efficacy to reduce and prevent co-occurring violence and substance use among at-risk young Black men. Studies so far support an association between substance use and violence [4,5], with a consensus that substance use can increase both the frequency and severity of violence [4-6]. A common substance implicated in violent experiences when misused is alcohol, with the suggestion that eliminating hazardous drinking would reduce general violence by 44% [5]. Such findings have led many researchers to focus on developing integrated intimate partner violence and substance use interventions [4-6].

However, this study is the first stage in developing and evaluating a technology-enhanced intervention for reducing co-occurring violence and substance use among Black boys and men aged 15 to 24 years in a high-violence setting. We are using an existing theory-driven and evidence-based intervention (ie, ACTV) that has been proven to reduce violence. This approach eliminates the need for expensive additional investments in developing a new intervention from other data sources, which may face significant feasibility issues and require considerable time. Extending ACTV to noninstitutionalized juvenile samples exposed to youth violence is a logical next step. Addressing our research objectives squarely will drive innovation in violence prevention and identify settings, conditions, and limitations for situations where digital solutions are inapplicable or even detrimental.

Furthermore, crime prediction technologies, digital surveillance tactics, and facial recognition software have all been known to target and penalize Blackness [86]. Therefore, we approach this study through a transformative justice lens, mindful of how technology affects Black communities. We hold ourselves and our team accountable in our quest for ethical and dignified technology-enhanced interventions. We remain responsible to young Black men, who will support this process and, eventually, use BrotherlyACT.

Strengths and Limitations

This study and our approach have some limitations. As our study only includes young Black men, we cannot generalize our results to other groups of young men (such as Hispanic; tribal; and lesbian, gay, bisexual, transgender, queer, and more youth) who are disproportionately affected by violence and substance use. Furthermore, using a single sample group for pretest and posttest will not infer causative relationships and will limit the causal attribution related to the proposed intervention. However, our goal at this stage is to develop and pilot-test BrotherlyACT for preliminary feasibility and acceptability. We have evaluated the power of our sample size using suggestions and guidelines for conducting pilot studies contained in the existing literature.

Nevertheless, it is possible that our sample size is very small, which could influence the results we receive. Regarding cultural adaptation of the intervention to young Black men, it can be challenging to present diverse groups with a unified view of *culture*. Some participants may find that traditional values conflict with their convictions or that generic cultural values may not adequately capture the particulars of their own cultural experience. Therefore, we intend to develop BrotherlyACT's architecture to be adaptable to user requirements and capable of rapid, iterative adjustments. Moreover, young Black men who have perpetrated violence and use illicit substances are a self-selecting population that may not feel comfortable reporting their substance use and histories of violence, thus necessitating the use of novel recruitment tactics.

Conclusions

At the individual level, studies show that life skills are a vital tool and coping strategy for adolescents in high-trauma contexts. Life skills have been used for decades to prevent violence and aggression in adolescents, particularly those in their early to middle adolescence. However, there is compelling evidence that low-income urban youth have few opportunities to observe, learn, or practice the actionable skills required to deal with the heightened levels and severity of the stressors they face. Accordingly, there is a need for combining multilevel strategies, such as psychoeducation and safety planning (at the individual level), with service engagement at the community level. There is also a dire need for easily accessible and youth-endorsed interventions that allow young people to acquire and practice these abilities as they plan for a values-based life. Improving Black adolescents' access to skill-building resources and connecting them to already existing and trusted services is a critical and urgent public health need, the absence of which has resulted in a revolving-door approach to youth violence and substance use prevention.

Data Availability

Study data sets will be deposited in publicly available repositories (where available and appropriate), as dictated by our funders, or presented in the main paper or additional supporting files whenever possible. Using a community-engaged approach ensures that the research findings are owned by the community, sustainable, and widely disseminated. Therefore, the dissemination of results in the community will be considered along with community input on how Boosting Violence-Related Outcomes Using Technology for Empowerment, Risk Reduction, and Life Skills Preparation in Youth Based on Acceptance and Commitment Therapy can be integrated into existing violence prevention programs, policies, and resources for schools, clinics, and community-based settings serving young Black men. Furthermore, service providers can use the adapted Boosting Violence-Related Outcomes Using Technology for Empowerment, Risk Reduction, and Life Skills Preparation in Youth Based on Acceptance and Commitment Therapy curriculum (paper or digital version) as a brief intervention resource to help at-risk and underserved adolescents in various contexts.

Abstract

Background: Cisgender Black women in the southern United States are at heightened risk for HIV and adverse sexual and reproductive health outcomes. Mobile health interventions that target HIV risk while being adapted to the needs and lived experiences of Black women are remarkably limited.

Objective: The study aims to refine *SavvyHER*, a mobile app for HIV prevention, with Black women residing in high HIV incidence areas of Georgia and evaluate the feasibility, acceptability, and usability of *SavvyHER*. This paper describes the procedures implemented to conduct this research.

Methods: Community-based participatory research tenets guide this multiphase study to finalize the development of what we hypothesize will be an effective, sustainable, and culturally relevant HIV prevention and optimal sexual health and reproductive wellness app for Black women. This multiphased, mixed methods study consists of 3 phases. The first phase entails focus groups with Black women to understand their preferences for the functionality and design of a beta prototype version of *SavvyHER*. In the second phase, an app usability pretest (N=10) will be used to refine and optimize the *SavvyHER* app. The final phase will entail a pilot randomized controlled trial (N=60) to evaluate the app's feasibility and usability in preparation for a larger trial.

Results: Findings from preliminary focus groups revealed educational content, app aesthetics, privacy considerations, and marketing preferred by Black women, thus informing the first functional *SavvyHER* prototype. As we adapt and test the feasibility of *SavvyHER*, we hypothesize that the app will be an effective, sustainable, and culturally relevant HIV prevention, sexual health, and reproductive wellness tool for Black women.

Conclusions: The findings from this research substantiate the importance of developing health interventions curated for and by Black women to address critical HIV disparities. The knowledge gained from this research can reduce HIV disparities among Black women through a targeted intervention that centers on their health needs and priorities.

KEYWORDS

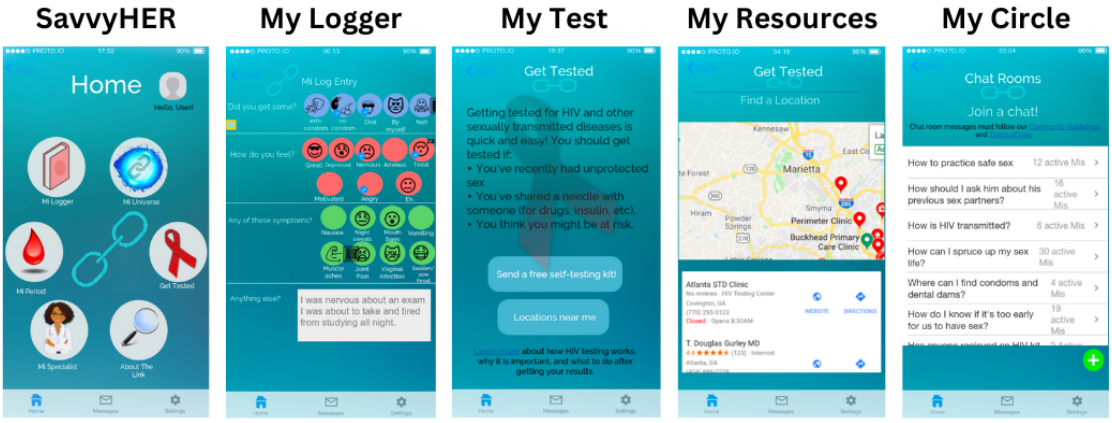
Black women; CBPR; community-based participatory research; HIV; human centered design; mhealth; pilot usability study

Introduction

Black women in the United States are disproportionately affected by HIV. In fact, this group accounts for 60% of new HIV infections among women in the nation, despite only making up 15% of the female population [1-6]. A total of 8 out of 10 states with the highest incidence of HIV diagnoses are located within the southern region of the United States (hereinafter called "the South") [7] and regrettably, Black women also comprise 67% of all HIV diagnoses in this area. Numerous barriers contribute to the increased risk of HIV among Black women which have been well cited in the literature. These barriers often include structural barriers (eg, income inequality, housing insecurity, incarceration, low health care access, and medical racism), social and environmental barriers (eg, small sexual networks, community stigma, intimate partner violence [IPV], and social support), and personal barriers (eg, low knowledge of and access to pre-exposure prophylaxis [PrEP], low self-perceived HIV risk, stigma toward HIV, and medical mistrust). While research often focuses on addressing HIV risk among Black women of lower socioeconomic status, the risk of HIV extends beyond this sub-group. College-educated Black women and Black women of higher socioeconomic status remain at higher risk of HIV due to factors such as limited partner availability, small sexual networks, and health care provider bias. However, they are oftentimes not represented in HIV prevention and larger sexual and reproductive health (SRH) studies [8-10].

Reducing the burden of HIV among Black women requires innovative methods that acknowledge and address the multiple interrelated social and structural factors that promote HIV susceptibility among Black women. PrEP offers an HIV prevention method for women that is discreet, minimizes the need for partner consent, and has no adverse effect on contraception or conception [11-13]. While there is a plethora of PrEP awareness and adoption research that focuses on men who have sex with men (MSM), Black women are overlooked in PrEP literature [14,15]. Studies that have investigated PrEP attitudes exclusively among women have found that while most women have low PrEP knowledge and awareness, they generally respond positively to the idea of using PrEP for HIV prevention [16,17]. Black women's willingness to consider PrEP depends greatly upon social understandings—whether it is seen as an effective, healthy, and socially acceptable HIV prevention strategy—in addition to cultural and structural factors [18-20]. The heightened risk of HIV acquisition among Black women living in the South combined with the lack of PrEP awareness among Black women confirms the need for innovative, affordable, accessible, and tailored HIV interventions for this group.

Previous research highlights the benefits of using mobile health (mHealth) technology to promote sexual and reproductive health [21-23]. A growing body of literature has reported Black women's acceptability toward mHealth interventions, including the use of smartphones for health promotion among Black women of reproductive age [19,24-26]. Although Black women are engaged by mobile apps, little to no mobile apps have been developed for the purpose of HIV prevention in Black women [27,28]. Therefore, our research team is developing an mHealth intervention entitled *SavvyHER* (Sexual/HIV Health Electronic Empowerment Resource), a mobile app developed for Black women by Black women which addresses HIV prevention and SRH among Black women living in the South.



Methods

Formative Work

SavvyHER has been developed based on formative work conducted with Black women living in a high-priority region of the South [19]. We solicited input about the most relevant social inequities hindering or prohibiting HIV prevention through focus groups with Black women. This work gathered Black women's preferences for the functionality, format, and design of a mobile HIV prevention app tailored for Black women. Black women in our formative work specified the following: (1) lack of access to culturally targeted and gender-considerate health care; (2) gender-based power differentials in couple relationships that limit women's ability to negotiate HIV-protective actions with their male sex partners (eg, condom use); (3) unreliable HIV prevention education and limited access to HIV prevention resources; and (4) susceptibility to other sexually transmitted infections (STIs) and chronic illnesses. Women desired content pertaining to women's sexual and reproductive health, including HIV prevention, comprehensive health information relative to the health disparities of the Black community, and linkage to women of color health care providers. Preliminary wireframes were developed using findings from our formative work (Figure 1). In addition, the research team conducted a separate study evaluating perspectives from health care providers regarding challenges and facilitators to PrEP initiation among Black women. This work has helped to guide message framing within the preliminary *SavvyHER* app [18].

Theoretical Frameworks

Social Cognitive Theory of Mass Communication

The *SavvyHER* study is grounded in the Social Cognitive Theory of Mass Communication (SCT-MC) [29]. This theoretical framework has been successfully used as a foundation for computer-assisted and internet-based health promotion interventions. SCT-MC applies the SCT to technologically based interventions, postulating that critical mechanisms for behavior change can occur through mass media technology [30]. The constructs of SCT-MC include cognitive factors, situational (ie, environmental) factors, and behavioral factors, with an emphasis placed on symbolic modeling and the notion that people's perceptions of reality depend upon the media's symbolic environment, which can contribute to new ways of thinking. Symbolic modeling exerts greater influence in populations that look to media-based images to discern what is and is not reality [31]. SCT-MC also posits that experiences (real or vicarious) facilitate the expansion of knowledge and awareness of causal relationships. Thus, SCT-MC is ideally suited to guide mobile-based interventions focused on behavioral knowledge, behavioral acceptance, and the cultivation of supportive social networks. We will operationalize the SCT-MC to address the health communication priority of using media to improve women's sexual and reproductive health outcomes, focusing on HIV prevention behaviors. As SCT-MC has been used in numerous studies to explore the behavioral acceptance of communications interventions among minority communities, the case can be made for using SCT-MC to evaluate feasibility within a group that has been relatively understudied. Research guided by this framework has identified the benefits of using mobile apps to deliver evidence-based health messaging and training [32,33].

Community-Based Participatory Research

This study uses community-based participatory research (CBPR) principles to promote the efficacy, sustainability, and cultural relevance of *SavvyHER* as an HIV prevention app. CBPR is well-suited for addressing health disparities within historically marginalized communities, as it reduces the power dynamic between researchers and participants and fosters shared learning. As a result, CBPR empowers individuals to voice their needs and concerns and facilitates shared learning between researchers and participants [30,34,35]. In order to establish trust and build capacity in our priority community, we ensured that our study team was composed of researchers who identify as Black women to reflect the community we serve. Literature highlights the effectiveness of insider research, or rather, research conducted inside a community to which the researcher also belongs, as a means of "challenging existing structures of power and creating opportunities for the development of innovative and effective solutions to the problems facing society" [36]. In addition to well-established CBPR practices, our team draws on 4 principles of Black feminist epistemology: (1) lived experiences; (2) dialogue; (3) the ethics of caring; and (4) personal accountability [37]. By centering Black women in this project, *SavvyHER* is curated *for and by* Black women to effectively meet this group's needs [38]. In following CBPR principles, we have assembled a community advisory board (CAB) to steer project priorities, implementation, and dissemination. The multidisciplinary CAB has a total of 8 members and includes HIV clinicians, SRH advocacy representatives, social workers, educators, and nonprofit organizations consisting of Black women.

SavvyHER App Design and Development

Industrial and technology designers have used human-centered design (HCD) to facilitate innovation [39-41]. Key principles of HCD are the following: (1) the design is driven and refined by user-centered evaluation; (2) the process is iterative; (3) the design addresses the whole user experience; and (4) the design team includes multidisciplinary skills and perspectives. Although not explicitly a research methodology, HCD employs qualitative and quantitative research methods and encourages health innovators to design technology by focusing on how users can, want, and need to use it. This process begins with the identification of health needs, rapid prototyping, and iterative design and development. Once a prototype is created, it is tested and refined based on the user's experience. The purpose of this approach is to move away from traditional methods of involving users during the latter phases of the prototype and instead regard users as active contributors from the beginning of the design process.

Like other health interventions, mobile health apps face challenges in terms of uptake, engagement, efficiency, and confidentiality. These challenges can be mitigated by ensuring that the intervention content is developmentally appropriate, comprehensible, and comfortable to use. We have chosen an HCD approach to increase the usefulness and use of the app,

XSL•FO
RenderX

encourage HIV protective behavior, and promote optimal HIV prevention practices. Additionally, there may be potential risks of abuse during discussions in the app's virtual peer support communities. The research team will designate chat room moderators to be trained to monitor for abuse. Abuse will be defined in the app-use policies conveyed to participants in the orientation. Examples of these policies might include: no sending of identifying information such as phone numbers or addresses; no posting of links; etc. These policies will be drafted with the CAB. Another potential risk is that women may experience psychological and emotional distress while recounting sexual experiences or discussing sensitive health topics. The research team includes clinicians with experience counseling patients on sensitive health topics. The research team will follow institutional review board (IRB) reporting procedures in the instance that participants experience psychological and emotional distress and will refer participants to local SRH clinicians for support services as needed.

The current version of *SavvyHER* was derived using recommendations from the CAB and based on our preliminary studies [19,42,43]. The app uses text, video, still frames, and other features to convey tailored health messages. The interactive portions of *SavvyHER* are primarily click and swipe functions. Our research team ensured the readability of the app content is no higher than sixth grade level, using the Flesch-Kincaid readability score [44]. *SavvyHER* contains a variety of app features, reflective of the SCT-MC constructs, that were developed based on our formative work with Black women (see Table 1).

Table 1. *SavvyHER* mobile app's features informed by SCT-MC (Social Cognitive Theory of Mass Communication) constructs.

SCT-MC constructs and their descriptions and functions	App feature	Addresses barriers to HIV prevention services
Personal		
Reliable resource for health resources and tools tailored for Black women; addressing Black women's priority SDOH[a] issues	*My Resources*	Unreliable or unknown health information sources; HIV risk perception; resource insecurities characterized as SDOH
HIV prevention plan; health promotion; Health communication messaging	*My Logger*	HIV risk perception: global prevention information that is perceived to be irrelevant to Black women
Maintain interaction with the user; self-monitoring	*My Logger* *My Resources*	Not the focus of HIV prevention efforts
Environmental		
Digital expertise through conversational interface providing consult regarding reproductive health concerns. Health communication messaging	*My Resources*	Stigma; cultural representation and sensitivity; choice of information dissemination modality, resource accessibility

[a]SDOH: social determinants of health.

[b]PrEP: pre-exposure prophylaxis.

My Logger integrates a self-tracking and preventive health messaging feature that incorporates symbolic modeling, behavioral knowledge, behavioral acceptance, and the cultivation of supportive social networks. Participants are encouraged to journal about any sexual or reproductive health encounters, appointments, indicators of social instability associated with HIV risk behaviors (eg, IPV [45,46] and changes in employment and housing), and descriptive anecdotes in the journal section of *My Logger* [47].

My Test consists of two components: (1) a GPS locator for HIV testing and PrEP clinics; we leveraged the existing application programming interface (API) of the HIV.gov testing locator to provide a centralized place for identifying testing and prevention sites; and (2) to make commodity ordering available to participants. Participants can order condoms and STI testing kits through an in-app widget.

My Resources gives participants access to a multimedia resource kit consisting of videos, current events, news feeds, podcasts, and support groups related to women's health, reproductive health, and HIV prevention. In addition, the study team has and will continue to generate health messages, like 1- to 2-minute video clips and infographics.

My Circle is a digital environment for women to connect, extending opportunities for peer modeling, learning, and support. In the moderated web-based groups, women share sexual health goals they are pursuing in the app, use messaging features to provide support around these goals and in their lives more broadly, and share insights they have found meaningful through

XSL•FO
RenderX

the educational messaging components of the app to support peer learning (eg, through buttons that let them easily share information gained through the *My Logger* and *My Resources* features).

Study Design

The pilot feasibility trial will consist of 3 distinct phases in which data collection, analysis, and interpretation will occur separately for each phase. The procedures were modeled after other successfully implemented HIV app development procedures [48-50]. The first phase included qualitative focus group discussions (FGDs) with participants; the second phase involved a pilot of the *SavvyHER* app with a select number of participants; and the final phase will consist of a randomized controlled trial in which participants will be randomized to either the *SavvyHER* intervention arm or the control arm. At the time of this manuscript, phases I and II were complete. Phase III will be initiated during second quarter of 2023. This design approach was deemed appropriate as it allows for further refinement of the *SavvyHER* app using the data obtained from phase I and phase II before the randomized controlled trial in phase III.

Recruitment and Eligibility

Eligibility criteria are consistent throughout all phases of the study. Participants must meet the following inclusion criteria: (1) be 18-45 years of age; (2) self-identify as Black and African American; (3) be assigned female sex at birth and identify as female; (4) PrEP-qualified based on CDC criteria for residence in high HIV incident areas—reside in Fulton, Cobb, Gwinnett, or Dekalb counties; (5) sexually active within the last 6 months; (6) HIV-negative; and (7) own a smartphone. While the *SavvyHER* app is designed by Black women for Black cis women, we anticipate the unique needs of transgender women. The first iteration of the *SavvyHER* app focuses on cis women; future iterations of the app will incorporate the needs of trans women.

A combination of both passive and active recruitment approaches is used to achieve study enrollment goals for all phases. Passive recruitment involves the distribution of flyers through local SRH organizations, clinics, and social media. Active recruitment efforts incorporate the assistance of SRH clinicians who will refer eligible patients to the study as well as targeted advertisements. All digital and print recruitment communications encompass a QR code—a scannable barcode—that guide interested participants to a web-based questionnaire and a brief description of the study [51]. If eligible, participants provide their contact information (eg, by calling or texting the study phone) for a research team member to contact them to establish an intake meeting for the completion of the baseline assessments and group assignment.

Phase I: Focus Group Discussions

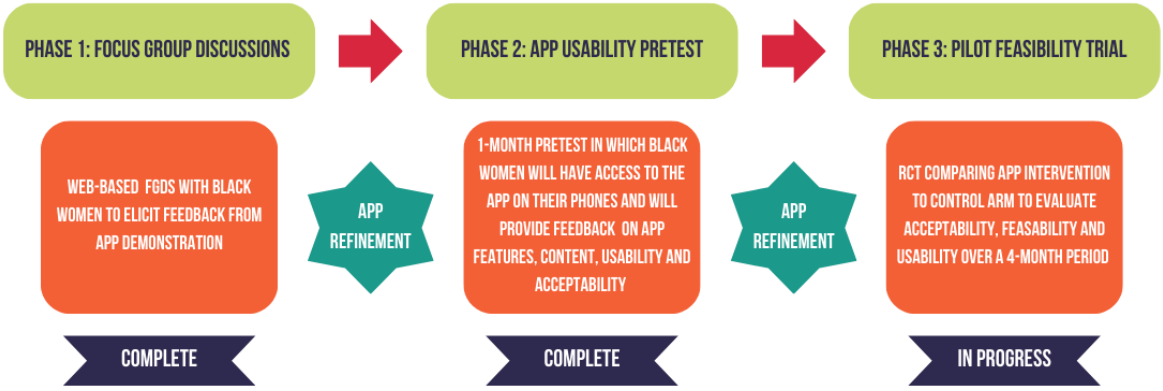
Phase I of the study consisted of qualitative data collection through web-based FGDs on Zoom. FGDs were structured in which participants were shown the app and guided through the app's content and features. After demonstrating the app, participants were asked questions regarding the preferences of each of the *SavvyHER* features, along with questions inquiring about the design of the overall app and features, navigability, and usability.

Phase II: App Usability Pretest

Phase II, or the app usability pretest, involved a 1-month pilot test of the *SavvyHER* app with 10 Black women. During a web-based enrollment session, study staff used a checklist to walk participants through procedures for downloading and using the app. Participants were encouraged to use all *SavvyHER* app components over the pilot period, including the HIV and STI test kit ordering feature. Participants completed a weekly questionnaire to provide feedback on the functionality, technical performance, errors encountered, feasibility, acceptability, and overall experience of using *SavvyHER*. Upon completion of the 1-month pretest, participants completed an exit interview through Zoom. Interviews provided further context in regard to the quantitative survey findings to obtain rich insight on app acceptability, feasibility, usability, concerns and challenges in using *SavvyHER*. Exit interviews were audio-recorded and are being transcribed for analysis by the research team. Findings from the app usability pretest will then be used to inform the final version of the *SavvyHER* app for the pilot feasibility trial in phase III.

Phase III: SavvyHER Pilot Feasibility Trial

After the *SavvyHER* app is refined and optimized using feedback from phase II under the guidance of the CAB, we will evaluate the feasibility, acceptability, and usability of the *SavvyHER* app through a pilot feasibility trial in phase III. This intervention will include a total of 60 Black women who will be recruited and randomized into the intervention group (N=30) or the control group (N=30). The sample size was determined based on feasibility objectives and measures and general guidelines for path analysis, which recommend a sample size of 10-20 participants per study concept while accounting for attrition. Interested participants will provide their contact information, and a research team member will follow up with a baseline assessment and group assignment. After baseline assessments are completed, participants will be randomized 1:1 to either intervention or control using a randomization schedule generated by our statistician using a permuted block procedure [52]. Allocation concealment will be employed before the randomization of participants. Once participants are assigned to groups, blinding will occur, in which researchers involved in data analysis will be blinded to the groups in which participants are enrolled to reduce observer bias and bias in data analysis and interpretation [53]. To restrict access to the *SavvyHER* app to the intervention group, participants will be provided with a single-use registration code that will need to be entered to gain access to the app. Study team members will teach participants how to download the app and navigate app features such as reminders.



Each participant will have 4 months to engage with the app, with e-reminders at time intervals preferred by the participants (a minimum of 3 times per week) through push notifications. We will ask that participants schedule reminders during their peak times of cell phone use. Participants will also be prompted to take a weekly survey to provide app feedback similar to the weekly survey in phase II. Research staff will complete 2-month

XSL•FO
RenderX

check-ins through phone call or video chat with participants in both the intervention and control conditions. At month 4, all participants will complete an endline survey in addition to an exit interview. Procedures for exit interviews are the same as those used in phase II. Participants will be remunerated for completion of the baseline assessment and for completion of the endline survey and exit interview. Furthermore, the CAB will review all feedback given and deliberate on what improvements or changes should be made to the *SavvyHER* app.

The control condition will be a 1-time web-based women's health counseling session with a health care provider. Participants will be given information on (1) STI and HIV prevention; (2) family planning; and (3) general health promotion (eg, exercise and diet). The control condition provides access to HIV prevention materials that are publicly available but that do not offer the dynamic and individually customized features of the health communication and new media research approach proposed herein. The control group will not have access to the *SavvyHER* app until after the study has concluded. See Figure 2 for a visual depiction of *SavvyHER* study procedures.

Figure 2. *SavvyHER* study procedures. FGD: focus group discussion; RCT: randomized controlled trial; *SavvyHER*: Sexual/HIV Health Electronic Empowerment Resource.

Data Collection

All assessments are taken through REDCap, a secure platform for constructing web-based surveys and databases [54]. Participant data is stored under a unique study ID number to ensure security and privacy. In order to inform intervention testing, we collect data on the number and yield of screened participants enrolled, recruiting sources that generated the largest number of enrolled individuals, effective recruitment used for successful enrollment, elapsed time from first contact to enrollment, amount of app interactions, and technological challenges or glitches. Feedback on content and delivery is elicited through REDCap surveys and focus group sessions or interviews, which both undergo qualitative data analysis, also known as coding. Additionally, we collect data on participants' ownership of smartphones and preferred app formats. These measures will help determine the time, resources, and workload necessary for implementing the HIV prevention mobile app for Black women. Moreover, with this data, we can assess whether users perceived the app as beneficial and whether alternatives (in app content and delivery) can be determined.

All participants provide demographic information through REDCap surveys. Primary outcome measures focus on the feasibility, usability, and acceptability of the *SavvyHER* app in addition to the control group procedures. Feasibility metrics will be determined by meeting predefined benchmarks specific to retention, screening, and interaction with app features. Examples include the number of weekly app sign ins, time spent using the app, and its features. Usability and acceptability will be assessed with the system usability scale (SUS) and a 30- to 45-minute exit interview that queries participants' experience with study procedures [55]. Because this is a feasibility study, we do not propose a statistical analysis of changes in behavior (eg, PrEP initiation, HIV testing) among users of the *SavvyHER* mobile app. Secondary measures collected in phase III include information on social determinants of health (eg, health care access near her location, employment status, housing status, transportation access, and social support), sexual health history and knowledge, self-perceived discrimination, mental health status, experiences of intimate partner violence, PrEP stigma, racism, and discrimination, personal media and technology use, as well as web-based health information seeking. The completion of the end line survey will also indicate the feasibility of study procedures (eg, retention). A summary of primary and secondary measures is displayed in Table 2.

XSL•FO
RenderX

Table 2. *SavvyHER* study outcome measures.

Measure	Questionnaire or survey	Weekly survey	Baseline or end line survey
Demographics	• Name, age, race and ethnicity, gender identity, county of residence, relationship status, education, household income	✓	✓
Social determinants of health and women's sexual health history	• Your current life situation [56,57] • Protocol for responding to and assessing patients' assets, risks, and experiences (PRAPARE) [58] • A guide to taking a sexual history [59]		✓
Primary outcomes			
Usability/acceptability	• System Usability Scale (SUS) [60,61]	✓	✓
Feasibility	• Average number of app sign ins per week; number of minutes spent using the app weekly; sexual health tracking entry, home test kit ordering, number of app glitches; 40% of participants using My Logger, My Test, My Resources and My Circle		✓
Secondary outcomes			
HIV knowledge	• Human Immunodeficiency Virus- Knowledge Questionnaire (HIV-KQ AG) [62]		✓
HIV risk	• PrEPa information and self-screening tool for women [63]		✓
HIV and PrEP stigma, PrEP intention or initiation	• Brief HIV PrEP stigma scale (HPSS) [64]		✓
Self-reported racial/ethnic discrimination	• Everyday racial/ethnic discrimination scale [65]		✓
Depression	• Patient health questionnaire-2 (PHQ-2) [66] • The patient health questionnaire (PHQ-9) [67]		✓
Self-reported social media use and technology use; attitudes toward technology use	• The media and technology usage and attitudes scale (MTUAS) [68]		✓
Information seeking	• Web-Based Health Information Seeking [69]		✓
Usability assessment of *SavvyHER*	• Health information technology usability evaluation scale (Health-ITUES) [70]		✓
User experience of *SavvyHER*	• User experience questionnaire [71] • User experience questionnaire short from (UEQ-S) [71]		✓

[a]PrEP: pre-exposure prophylaxis.

Data Analysis Plan

Quantitative Analysis

Data will be downloaded from REDCap into STATA (StataCorp). Exploratory and descriptive analyses will be conducted for all study variables. Variables will be examined for normality in addition to means, SD, range, and medians. The literature on effect size estimates, from pilot studies and National Institutes of Health (NIH) recommendations, confirms that attempting to obtain valid estimates of effect sizes cannot be statistically justified [72-78]. We have identified feasibility and acceptability as the primary outcomes of this pilot. We have indicated target metrics that will substantiate feasibility, and we will use both quantitative survey and qualitative interview data to determine the acceptability of both the mobile app and the control condition. For all outcome measures (eg, PrEP knowledge), a mean score and 95% CI will be calculated, and distributional assumptions will be assessed. The mean change in outcome measure scores between pretest (T0) and posttest (T1) will be compared (paired samples *t* test) for trends in the expected direction or no change. A paired samples *t* test will be conducted to evaluate the mean change in outcome measure scores between pretest (T0) and posttest (T1) within groups. *t* Tests will also be used to compare variables before the intervention among the 2 groups. To compare differences between intervention and control groups, a 2-way analysis of covariance (ANCOVA) will be used in which covariates will be controlled for. All statistical tests will be performed at a 95% CI with an alpha of .05.

XSL•FO
RenderX

We will use mobile app analytics (eg, Google Analytics) to assess trends in app engagement, such as duration and number of app/module/social media forum engagement, clicks, modules viewed/completed, GPS solicitation, and correct or incorrect responses to questions. Analytics data will be collected as categorical and continuous variables. Continuous variables will be transformed into categorical variables, and multivariable logistic regression will be conducted to evaluate the relationship between usage characteristics and primary outcomes using STATA.

Qualitative Analysis

All interviews will be audio-recorded and transcribed using Otter.ai software. Transcribed interview data will be reviewed for overall impressions of the content, materials, activities, and delivery of the *SavvyHER* app. Once transcribed, transcripts will be transferred into Dedoose, a qualitative and mixed methods data analysis platform [79,80]. Our analytic strategy employs a hybrid approach involving concept-driven coding as well as open coding, thus combining the deductive and inductive coding methodologies [81]. Deductive coding denotes the curation of premade codes or themes that are applied to raw data as a means of categorizing quotes for interpretation [82]. Our initial codebook will consist of feedback themes we want to capture regarding the *SavvyHER* app, such as feasibility, acceptability, and usability. Research team members will apply the preset codes to the interview transcripts in an iterative process. Simultaneously, research team members will be creating new codes inductively, or rather, allowing new themes to emerge from the data itself for further analysis [83].

Ethics Approval

Ethical approval for this study was obtained through Emory University's IRB (STUDY00002857). Before enrolling in the study, the research team will discuss the purpose of the study, study procedures, and risks and benefits with participants. Participants who agree to participate in the study will provide informed consent to a member of the research team. For the quantitative portion of the study, written informed consent will be obtained from participants. For the qualitative phase, oral informed consent will be obtained. Participants will be provided a unique study ID upon enrollment, and all data will be deidentified to maintain confidentiality. Survey data is also password protected in REDCap. Focus group transcripts and recordings are password protected in digital files. Only study team members on the IRB will have access to data files. Participants will receive compensation for completion of the baseline assessment (US $50) and for completion of the exit interviews (US $80) for a total of US $130.

Results

Numerous works discuss the gap between scientific discovery and real-world application [84-88]. Literature points to the lack of cultural competency in translational public health research as the source of this gap [88-91]. Our research team and community stakeholders will center on culturally sound, reciprocal knowledge translation, otherwise known as 2-way translation of knowledge. Two-way translation of knowledge involves the creation and distribution of information from academia to the public as well as from the public to academia [91]. In adhering to CBPR approaches, our research team will copresent findings from this project to study participants and other community stakeholders. Disseminating results will not occur for the sole purpose of reporting outcomes but to empower community members to take part in the contextualization of the study findings that guide the development of the *SavvyHER* app. Thus, fostering social action toward mitigating HIV disparities among Black women. The outcomes of the analysis for phase I and phase II will be reported in a future manuscript.

This study was funded in August 2021; data collection is ongoing (we had several phases, and we are currently starting our pilot randomized controlled trial phase now).

The numbers recruited as of submission of the manuscript for this study: a total of 17 participants were recruited for the focus group discussions from December 2021 to March 2022 and met the eligibility criteria to participate. A total of 13 Black cisgender women participated in focus group discussions (phase I). A total of 10 participants enrolled in the study's single-arm "technology usability pretest." Among the participants, 8 completed the quantitative and qualitative analyses, which were all components of phase II. We are currently recruiting for phase III, the pilot randomized controlled trial. We aim to recruit 60 (30 in the intervention arm and 30 in the control arm of the study).

The data analysis for the single-arm "technology usability pretest" is currently completed and under review for publication. Furthermore, the data for the pilot randomized controlled trial will be analyzed once the study has concluded. We project that results will be published in the fall of 2024.

Discussion

Overview

Although Black women are a priority population concerning HIV in the southern United States, few public health interventions are curated for prevention and treatment among this group. Black women experience some of the highest rates of HIV acquisition due to broader social forces and systems embedded in discrimination. In order to mitigate the disproportionate impact of HIV among Black women, novel and effective strategies must support Black women's capacity to protect their own health [92]. We anticipate that the *SavvyHER* intervention will address barriers in HIV prevention and broader SRH disparities among Black women by providing access to culturally responsive resources, educational materials, and health services that otherwise would be difficult to acquire given the limited awareness and extensive structural barriers that this community faces. Several studies have begun to explore the benefits of digital platforms in addressing HIV burdens at local and global levels. A review conducted by Cao et al [93] indicated that digital health interventions have demonstrated feasibility in increasing PrEP uptake and optimizing clinical interventions for target communities. It is critical, however, for such interventions to be adequately adapted toward demographic profiles including age, gender identity, sexual orientation, race, and ethnicity [94-96]. As reported by Budhwani et al [97],

XSL•FO
RenderX

acceptability testing and adaptation that are underpinned by user feedback significantly increase the likelihood of intervention relevance, satisfaction, and acceptability in new populations of interest. As previously described in our methods, our team will be conducting this study in various phases to ensure that *SavvyHER* is adapted to ensure a strong fit between the intervention and the community being targeted [98,99]. To date, several studies have described the benefits of CBPR in the literature, particularly in creating interventions that reflect community priorities and perceived needs [96-98]. The research teams' approach of including a diverse array of community stakeholders through CBPR practices, coupled with involving community stakeholders throughout all phases of the research process, can greatly aid in generating awareness and buy-in toward the app on a larger scale [96-98]. Previous literature highlights the need for centering Black voices as a means for discovering knowledge and developing innovative pathways toward advancing health equity [100,101]. The *SavvyHER* mHealth study is spearheaded by Black women for Black women given that they are underrepresented in public health studies as participants and as researchers [102]. By substantively integrating feedback from Black women at the various phases of this study, our team is continuously refining the *SavvyHER* app to ensure that the content, design, and navigation are effective for HIV prevention and treatment among Black women.

Strengths and Limitations

We have developed a rigorous plan to explore the feasibility, usability, and acceptability of an HIV prevention app for Black women and a strong control comparison. However, potential problems could occur, such as technological glitches, feature imbalances, infirm backend support, irrelevant content, and low engagement, which may be limitations to this study. We have built in questions about all procedures for the focus groups and alternative methods to deal with problems that might arise during the study. This study has low external validity given the randomized controlled trial design and the fact that it is limited to Black cisgender women in the metro-Atlanta area. Therefore, generalization to Black women residing in other areas of Georgia or women of other racial or ethnic identities is limited. This study is strengthened through ensuring that researchers are blinded to which participants are assigned to the intervention and control arms. Thus, observer bias will be mitigated, which will help maximize the validity of the results. Another limitation is the potential for social desirability and recall bias during data collection. Qualitative interviewers will be trained to reduce the likelihood of these biases occurring. While the surveys that will be used contain items from previously validated surveys, the overall survey itself has not been validated, which may contribute to some measurement bias. Measurement bias will be reduced, however, through administering surveys at various time points and coupling Google Analytics data with survey data. Lastly, there may be retention issues with the app; however, we have employed reminders and intrinsic motivation strategies to counter this potential issue.

Future Directions

Future directions for the *SavvyHER* app involve the integration of mHealth and telemedicine. mHealth solely allows for self-health monitoring, in which app users can take charge of overseeing their health without the guidance of a health care clinician [103,104]. Incorporating telehealth into *SavvyHER* permits not only patient self-monitoring but also clinician-to-patient and clinician-to-clinician interactions. The telehealth structure authorizes the electronic exchange of personal health information that can be used for full-spectrum remote patient care [105,106]. Previous research notes that clinician-level factors affect uptake, as does the adherence support that patients receive [17,107-109]. In forthcoming iterations of *SavvyHER*, we will create clinician-specific functions and coaching that address culturally relevant SRH concerns for Black women. Testing would comprise of a 3-arm study that would assess a control group, a mobile app user-only group, and a group where *SavvyHER* has a health clinician and patient interaction feature.

Abstract

Background: Hepatitis C is a disease with a strong social component, as its main transmission route is via blood, making it associated with lifestyle. Therefore, it is suitable to be worked on from the perspective of public health policy, which still has a lot of room to explore and improve, contrary to diagnoses and treatments, which are already very refined and effective.

Objective: An interactive gamified policy tool, designated as Let's End HepC (LEHC), was created to understand the impact of policies related to hepatitis C on the disease's epidemiology on a yearly basis until 2030.

Methods: To this end, an innovative epidemiological model was developed, integrating Markov chains to model the natural history of the disease and adaptive conjoint analysis to reflect the degree of application of each of the 24 public health policies included in the model. This double imputation model makes it possible to assess a set of indicators such as liver transplant, incidence, and deaths year by year until 2030 in different risk groups. Populations at a higher risk were integrated into the model to understand the specific epidemiological dynamics within the total population of each country and within segments that comprise people who have received blood products, prisoners, people who inject drugs, people infected through vertical transmission, and the remaining population.

Results: The model has already been applied to a group of countries, and studies in 5 of these countries have already been concluded, showing results very close to those obtained through other forms of evaluation.

Conclusions: The LEHC model allows the simulation of different degrees of implementation of each policy and thus the verification of its epidemiological impact on each studied population. The gamification feature allows assessing the adequate fulfillment of the World Health Organization goals for the elimination of hepatitis C by 2030. LEHC supports health decision makers and people who practice patient advocacy in making decisions based on science, and because LEHC is democratically shared, it ends up contributing to the increase of citizenship in health.

Introduction

Background

Hepatitis C virus (HCV) is 1 of 6 oncogenic viruses, as established by the World Health Organization (WHO) [1]. Its transmission occurs primarily through infected blood, with which one may come in contact through injection drug use, unsafe injection practices, unsafe health care, and the transfusion of unscreened blood and blood products [2]. Estimates indicate that approximately 20% to 30% of the patients initially infected manage to control the acute infection, whereas approximately 75% develop chronic hepatitis C (CHC) [1,3-5].

Hepatitis C is recognized as a major public health concern, with an estimated 58 million people having CHC infection worldwide [1]. A substantial proportion of chronically infected individuals eventually develops cirrhosis or liver cancer. Approximately 190,000 people die annually from hepatitis C–related events, mostly cirrhosis and hepatocellular carcinoma (HCC) [1].

The introduction of new direct-acting antiviral (DAA) drugs dictated a paradigm change in the treatment of hepatitis C. These new drugs are much more effective and safer than their predecessors, achieving cure rates of ≥95% [6,7]. This paradigm change enabled the contemplation of disease elimination.

In May 2016, the World Health Assembly adopted the first "Global Health Sector Strategy on Viral Hepatitis, 2016-2021" [8]. The strategy encompassed a vision of eliminating viral hepatitis as a public health problem. This is encapsulated in the global targets of reducing new viral hepatitis infections by 90% and reducing deaths due to viral hepatitis by 65% by 2030 [8]. The strategy includes raising awareness; promoting partnerships; mobilizing resources; formulating evidence-based policy and data for action; preventing transmission; and scaling up screening, care, and treatment services [8]. However, in each country, several obstacles must be overcome to accomplish the WHO's goals, many of which are related to the implementation of health policies on hepatitis C [9-12].

The effective means to eradicate hepatitis C already exist (eg, therapeutics, national health services financing therapeutics, harm-reduction services, and hepatitis C health care services), but it is still necessary to persuade decision makers by providing robust policy-relevant information that allows the implementation of necessary measures.

An interactive gamification policy tool, designated as Let's End HepC (LEHC), was created to help stakeholders understand how different political decisions may affect the evolution of hepatitis C in their country. The objective was to create an easy and intuitive high-level communication tool to support decision-making with the aim of formulating hepatitis C eradication policies.

Currently, the tool is fully functional in Portugal, Spain, Austria, Romania, and Bulgaria and is being implemented in other countries. The policy tool is based on an epidemiological model that allows assessing the impact of the degrees of implementation of 24 public health policies (PHPs) on the evolution of hepatitis C epidemiology over time, throughout the cure cascade. The system allows for consultation in cross-platforms, such as computers, smartphones, and tablets. Several health outcomes were defined, and it is possible to observe the impact of the degree of implementation of each policy or set of policies on these health outcomes (eg, hepatitis C incidence, hepatitis C prevalence, diagnosed individuals, individuals linked to care, individuals on treatment, cured individuals, individuals with compensated cirrhosis and decompensated cirrhosis [DC], individuals with HCC, individuals requiring liver transplants [LTs], and individuals with liver-related deaths) and consequently to eliminate hepatitis C by 2030. The model contemplates the evaluation of 5 population groups at risk and the total country's population (the sum of all populations at risk). Some policies are specific to a particular population group, thus impacting only that specific group. Therefore, the policy tool may prove to be a useful resource to support evidence-based policy-making by the involved countries' national health authorities.

Hepatitis C Modeling

In the past decades, several studies have developed mathematical models, including Markov chains, related to the natural history of hepatitis C, such as the work of Salomon et al [13,14]. The focus has been the modeling of incidence and prevalence rates, transmission routes, disease burden, and other factors that could be fundamental to the determination of when elimination could be achieved in different countries. Modeling in this area gained momentum with the introduction of DAA as a new effective treatment for hepatitis C in 2014 and the WHO's targets for the elimination of hepatitis C by 2030.

Razavi et al [15] calculated the total number of individuals infected with HCV, including those newly infected with HCV, those diagnosed with HCV infection, and those cured of HCV infection, in 2013 among 16 countries. They also assessed disease burden by forecasting the disease progression and the total number of individuals at each stage of liver disease in each of the 16 countries between 1950 and 2030. Hatzakis et al [16] developed a mathematical model focused on characterizing the population infected with HCV and deaths due to hepatitis C during the same period.

In 2015, the Polaris Observatory HCV Collaborators developed hepatitis C disease burden models for 100 countries [17], with 59 models being approved by experts in each country. Using the Markov chain component in these models, which analyzed hepatitis C prevalence and genotype distribution studies published after 2013, it was possible to calculate both disease burden and disease prevalence in each country.

In 2017, Scott et al [18] conducted research on when Iceland could achieve the WHO's elimination targets. This research was done by developing a mathematical model with a dynamic compartmental nature and performing liver disease assessment related to hepatitis C progression. The model's targeted indicators were injecting drug status, age, and position of the individual in the HCV cascade of cure. This model comprised the analysis of hepatitis C policy implementation in the country while identifying key targets for elimination and factors that could hinder the WHO's objective.

XSL•FO
RenderX

Chhatwal et al [19] described the importance of components for the mathematical modeling of hepatitis C, such as demographic features, the natural history of the disease, and incidence. This was illustrated for the forecast of hepatitis C burden in the United States, with the comparison of different approaches and strategies to achieve the elimination of the disease by 2030.

Models of hepatitis C have also been developed in Catalonia and applied to PHPs focused on primary health care [20], including a model involving the national health system [21].

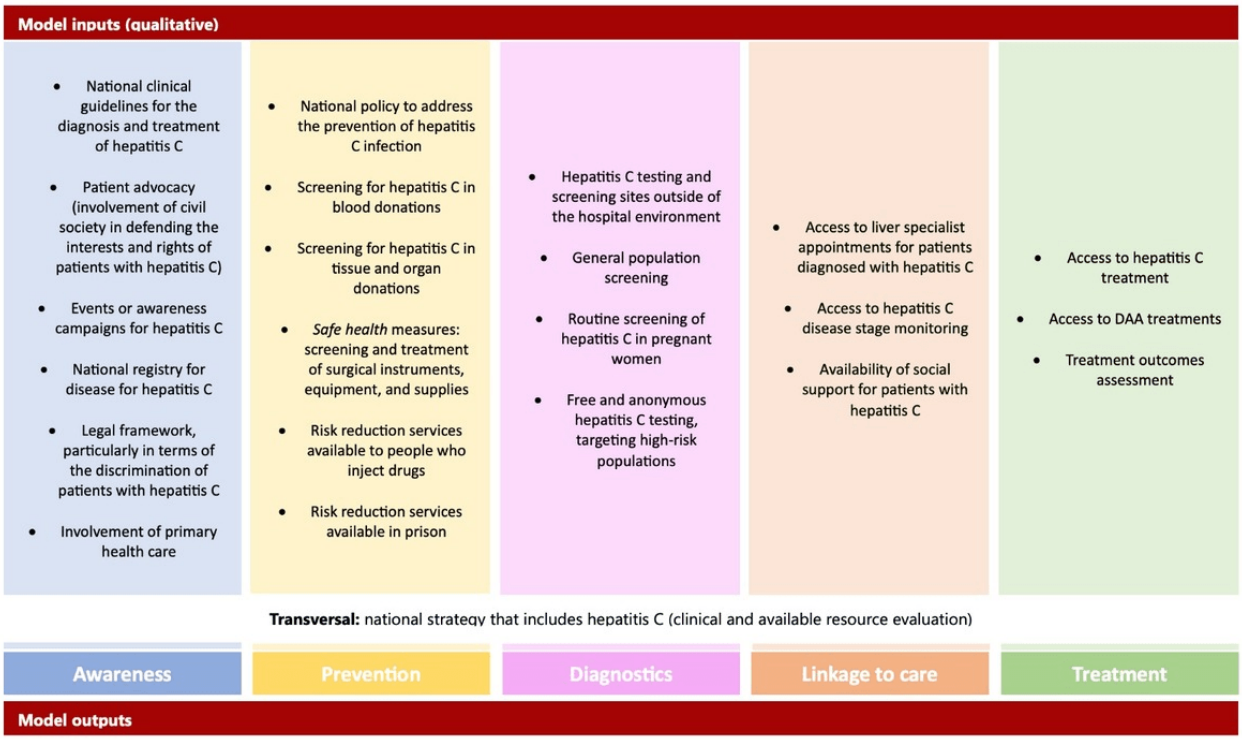
In 2019, Tordrup et al [22] modeled the costs of resources and interventions necessary to attain the elimination goal for viral hepatitis in 67 low-income and middle-income countries.

More recently, Razavi et al [23] used Markov chains to forecast the different outcomes related to hepatitis C incidence, prevalence, diagnosis, and treatment, among others, in 45 high-income countries in relation to their progress toward the WHO hepatitis C elimination goal.

Methods

Inputs

For the construction of the LEHC model, the following elements were reviewed, discussed, and validated: (1) each PHP; (2) the acceptable fluctuation ranges of the PHP impact on epidemiology; (3) the application scales on which each PHP would be measured; (4) the identification of national specificities of each country where LEHC would be implemented and necessary adaptations for the modeling process; (5) the discussion of the main sources of published or unpublished statistical data and their qualification; (6) the explanation of the adaptive conjoint analysis (ACA) and its importance as an individual response; and (7) the creation of channels of permanent communication between the national researchers, scientific partners, and National Advisory Board (NAB) and the scientific coordination team of the LEHC model.



The PHP pool used in the LEHC model was obtained through literature review and in-depth interviews with experts in hepatitis C and the reviewed articles' authors. Three subsequent deliberation sessions of 4 hours each, followed by decision-making, were held with the Portuguese NAB on February 22, 2017, to have an in-depth discussion of the final PHPs to be included in the model. According to a cure cascade reading, a total of 24 PHPs and their application scales were selected.

First, the scientific coordination team of the LEHC model application met with the scientific partners of each country involved in the project in a first moment to discuss the PHPs. Second, there was a meeting with the NABs of each country selected by the corresponding country's scientific partner.

In sum, the epidemiological model considers 24 PHPs and corresponding scales that may impact HCV-related health outcomes in each population group being studied and discussed by approximately 50 national experts in hepatitis C.

Five groups of policies were defined based on the literature review and expert opinion (Figure 1): awareness, prevention, diagnostics, linkage to care, and treatment.

Figure 1. Final qualitative policies of the public health tool and respective outcomes. DAA: direct-acting antiviral.

Each policy was classified into 1 of these 5 groups, thus having a direct positive impact on specific outcomes (Figure 1). Owing to their importance and relevance across the cure cascade, some policies were considered transversal, impacting all the outlined

XSL•FO
RenderX

outcomes. Each policy has several possible degrees of implementation, ranging from not being available in the country to being available but not fully to being fully available. Each of these degrees results in a different impact on the model outcomes.

Tool Outputs and Outcomes

The impact of the implementation degree of the 24 health policies can be assessed by analyzing 3 groups of indicators: hepatitis C cure, disease stages, and disease elimination within the tool.

The first group comprises the distribution of individuals throughout the cure cascade, in terms of incidence (number of new hepatitis C–positive cases), prevalence (total number of hepatitis C–positive cases), number of diagnosed individuals, number of individuals linked to specialized care, number of individuals on treatment, and number of cured individuals.

The second group comprises the distribution of individuals through the disease stages, number of individuals with compensated cirrhosis, number of individuals requiring LTs, number of individuals with HCC, and number of individuals with liver-related deaths.

The third group comprises the disease elimination (considering cutoffs of 90% in new CHC infections and 65% in mortality) [24].

These outcomes can be evaluated over time (from 2015 to 2030) for a country's total population and each of the population segments considered in the model: (1) individuals who receive blood products, (2) prisoners, (3) people who inject drugs, and (4) individuals who are infected through vertical transmission and the remaining population (total population excluding the other 3 population groups).

Core Model

One of the principal components of the model is an adaptation of the Markov model for the natural history of CHC infection and the impact of treatment, as published by Salomon et al [14]. This model, including stages of Metavir fibrosis and long-term complications such as compensated cirrhosis, DC, HCC, and LT, is widely adopted in the international literature on the cost-effectiveness of hepatitis C treatment and screening.

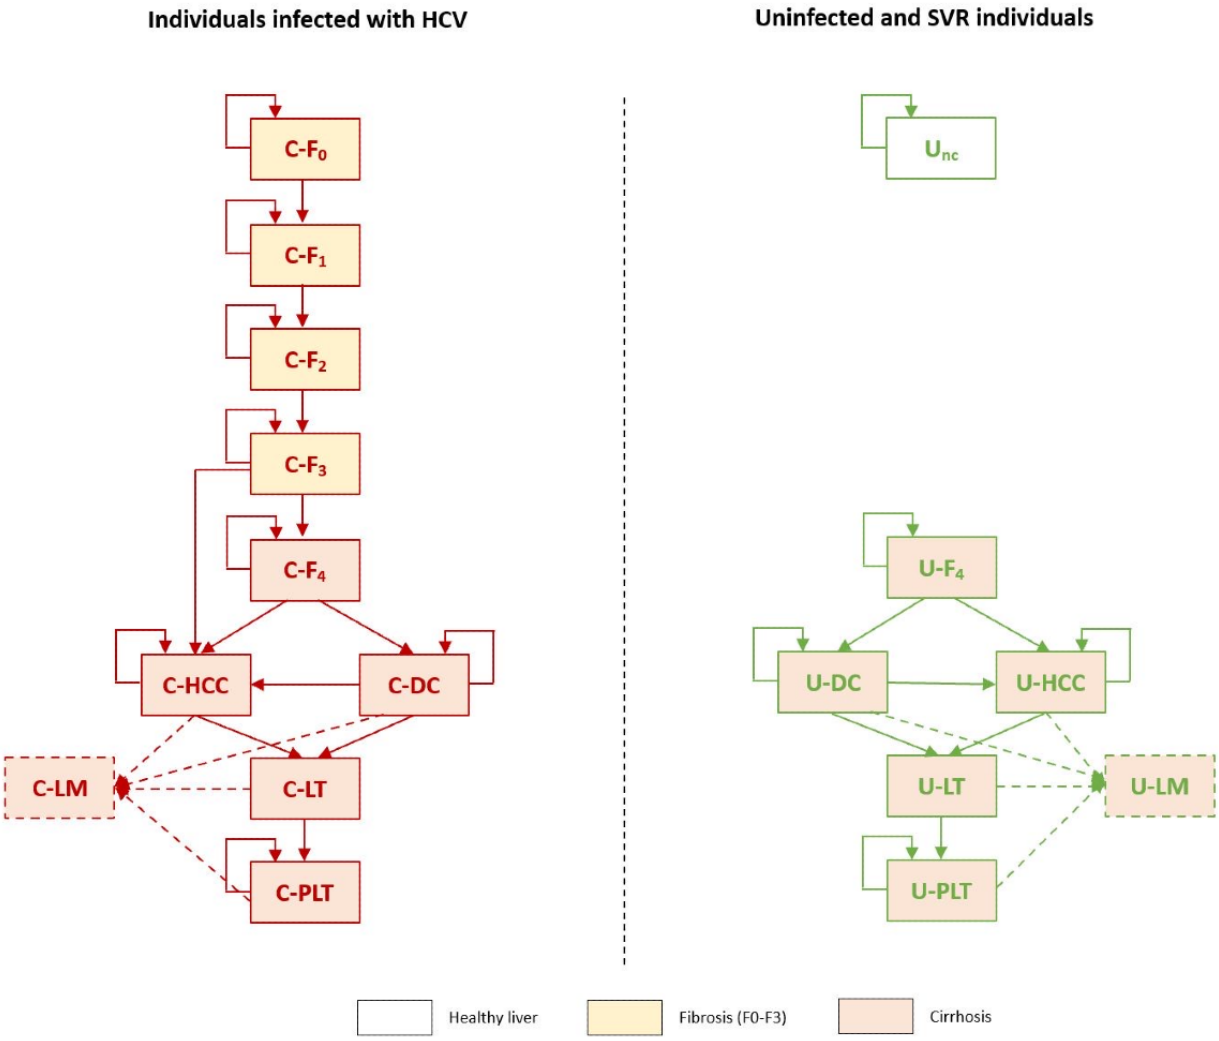
To be able to calculate the impact of different health policies on the epidemiology of CHC within a population, the aforementioned Markov model was augmented by a cascade of infection, diagnosis, and treatment (referred to as the cure cascade in the remainder of the manuscript). This cascade further divides the population into uninfected individuals, individuals who are infected but not diagnosed, individuals who are diagnosed but not retained in care, individuals who are retained in care but not treated, individuals who are treated but do not achieve subsequent sustained virologic response (SVR), and individuals who are treated and achieve subsequent SVR.

On the basis of these 2 main linked components, all individuals of a particular population subgroup (stratified by age and gender) can be represented in a set of mutually exclusive states through which individuals move over time, much in line with the auxiliary epidemiological model reported in the study by Salomon et al [14].

The impact of different policy measures on the epidemiology of hepatitis C was determined through ACA. For each of the policy measures and their implementation levels, the relative weight was determined based on the total impact on the different steps of the cure cascade.

ACA has proven to be a powerful health decision-making tool because it can go further than the traditional conjoint analysis: the computer adjusts the question following the respondent's previous answer, instead of having hard cards; determines the relative importance of attributes; and associates the preference of choice to its importance [25], as safety procedures are set in place, defined by International Society for Pharmacoeconomics and Outcomes Research. There are 10 International Society for Pharmacoeconomics and Outcomes Research health use safety criteria [25], which were followed in this study. Multiple ACA applications have been developed in recent years in the health field: quality-adjusted life year studies [26], clinical decision-making [27], and choice of prescription [28].

Macrolevel Description of the Conceptual Modeling Framework



CHC Disease Progression

In terms of CHC disease progression, the population is divided into 2 similar, but distinct, sets of health states with different transition probabilities between their respective states:

1. The first set of health states (left side of Figure 2) corresponds to individuals infected with HCV. This set represents the natural progression of CHC for untreated individuals (or individuals treated but without SVR).
2. The second set of health states (right side of Figure 2) corresponds to uninfected individuals and includes states for cirrhosis's natural progression in individuals with SVR.

XSL•FO
RenderX

Figure 2. Schematic of the Markov model for the progression of chronic hepatitis C. C: chronically infected; DC: decompensated cirrhosis; HCC: hepatocellular carcinoma; HCV: hepatitis C virus; LM: liver-related mortality; LT: liver transplant; nc: noncirrhotic; PLT: post–liver transplant; SVR: sustained virologic response; U: uninfected.

For the natural progression of CHC, mutually exclusive health states for Metavir fibrosis stages (F_0-F_4) and long-term complications (DC, HCC, and LT) are considered. Individuals progressing to LT pass through a tunnel state representative of the year of transplant, after which they move to a post-LT (PLT) for the remainder of their life. Possible transitions between the health states are identified by arrows (Figure 2).

The health state U_{nc} represents individuals who have never been chronically infected or attained SVR before reaching compensated cirrhosis (F_4). Individuals who attained SVR after reaching compensated cirrhosis, although technically cleared of the virus, are considered to have had irreversible damage to the liver and face disease progression states similar to those faced by individuals chronically infected with cirrhotic (Figure 2).

No explicit health state for acute HCV infection was considered, as it was deemed not to add extra value to the model. For the same reason, no explicit health states for individuals with SVR in Metavir fibrosis stages F_0 to F_3 were considered. Generally presenting with reversible damage to the liver, these individuals are assumed to eventually clear fibrosis [29].

Irrespective of the health state, all individuals experience an age- and gender-dependent general mortality risk [30]. Individuals in the DC, HCC, and LT or PLTs are targeted by liver-related mortality in addition to general mortality.

The annual probabilities of transition between the different health states were obtained from the international literature and are listed in Table 1.

XSL•FO

U-HCC	U-LM	.51	Assumed to be the same as that for C-HCC to C-LM
U-LT	U-LM	.15	Assumed to be the same as that for C-LT to C-LM
U-PLT	U-LM	.05	Assumed to be the same as for that C-PLT to C-LM

[a]C: chronically infected.

[b]F0-F4: Metavir stages.

[c]HCC: hepatocellular carcinoma.

[d]DC: decompensated cirrhosis.

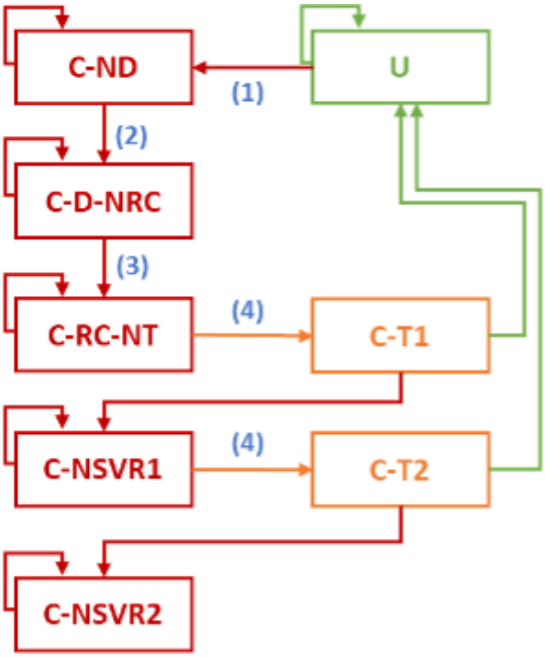
[e]LT: liver transplant.

[f]LM: liver-related mortality.

[g]PLT: post–liver transplant.

[h]U: uninfected.

It should be noted that for individuals with SVR, the probabilities of transition from HCC to LT and from DC, HCC, LT, and PLT to liver-related mortality were assumed to be the same as those for the natural progression of the disease because no evidence was found to contradict the natural history of hepatitis C by Salomon et al [13,14]. However, scientific evidence suggests that the transition probabilities from DC to HCC and from DC to LT reduce after achieving SVR. Therefore, these transition probabilities were calculated by applying the same ratio found between the transition probabilities of the corresponding stages for patients without SVR [35].



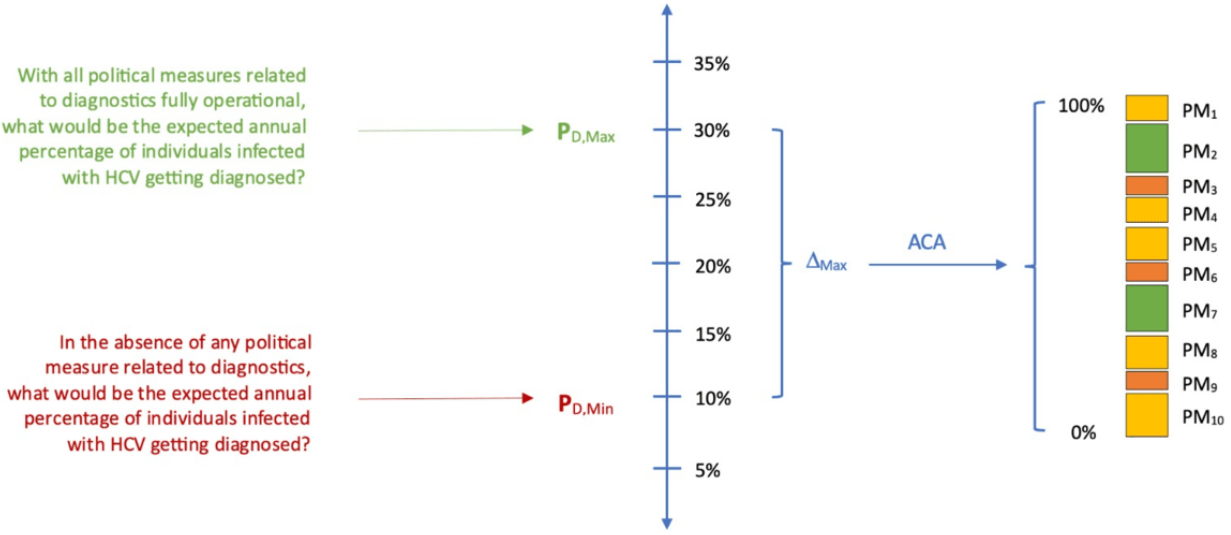
XSL•FO
RenderX

Cure Cascade

Concerning the cure cascade, the population was further divided into individuals who are uninfected, individuals who are chronically infected but not diagnosed, individuals who are diagnosed but not retained in care, individuals who are retained in care but not treated, individuals who are treated but do not achieve subsequent SVR, and individuals who are treated and achieve subsequent SVR (ie, uninfected). For the ease of modeling retreatment, the key to distinguishing the pre-DAA era from the post-DAA era, individuals without SVR after the first course of treatment are eligible for a second course of treatment.

In Figure 3, possible transitions between the different states of the cure cascade are identified by arrows.

Figure 3. Schematic of the Markov model for the cure cascade of chronic hepatitis C. C: chronically infected; D: diagnosed; ND: not diagnosed; NRC: not retained in care; NSVR1: no sustained virologic response after first treatment course; NSVR2: no sustained virologic response after second treatment course; NT: not treated; RC: retained in care; SVR: sustained virologic response; T1: first treatment course; T2: second treatment course; U: uninfected (including individuals with sustained virologic response); 1: annual incidence; 2: annual probability of diagnosis; 3: annual probability of being retained in care; 4: annual probability of treatment.



The distribution of individuals across the different states of the cure cascade is highly dependent on the annual incidence of CHC infection (transition 1 in Figure 3), the annual probability of being diagnosed (transition 2), the annual probability of being retained in care (transition 3), and the annual probability of being treated (transition 4). These probabilities are considered variable from country to country or from population subgroup to population subgroup and are impacted by the modeled policy measures.

Impact of Policy Measures

The policy measures considered in the LEHC health policy tool are of a qualitative nature. Their impact on the CHC cure cascade was quantified via a 2-step process. For example, the policy measures' impact on the annual probability of diagnosis will be considered (Figure 4). The quantification of the policy measures' impact on the remaining steps in the cure cascade followed equivalent steps.

XSL•FO
RenderX

Figure 4. Conceptual model behind the quantification of individual policy measures' impact on the cure cascade (exemplified with the annual probability of diagnosis). ACA: adaptive conjoint analysis; HCV: hepatitis C virus; PMi–ith policy measure.

In the first step, an expert panel was asked to address 2 important questions:

1. In the absence of any policy measure related to diagnostics, what would be the expected annual percentage of individuals infected with HCV getting diagnosed ($P_{D,Min}$)?
2. With all political measures related to diagnostics fully operational, what would be the expected annual percentage of individuals infected with HCV getting diagnosed ($P_{D,Max}$)?

The difference between these 2 values defines the maximum impact ($\triangle_{Max}$) the policy measures can have on the annual probability of diagnosis (Figure 4).

In the second step, each policy measure's contribution to the maximum impact was determined. A simple solution could be to assume that this amount is equally distributed across the policies in question. In the case of 10 policy measures impacting diagnostic rates, this would mean that each policy measure's implementation would add one-tenth of $\triangle_{Max}$ to the annual rate of diagnosis starting at $P_{D,Min}$. However, it is highly unlikely that policy measures related to patient advocacy will have the same impact on annual diagnosis rates as those related to general population screening.

Conjoint analysis techniques were used to determine a more realistic relative weight of each policy measure (and their level of implementation) on the maximum possible impact. These techniques are ideally suited to quantify the relative importance of different, often qualitative, attributes considered important for decision-making. The same expert panel that was requested to pronounce itself on the maximum impact of the policy measures on the annual probability of diagnosis was consulted to determine these relative weights using the commercial ACA Sawtooth Software (Figure 4) [36].

It is important to note that the global policy impact defined for the LEHC project is solely a temporary solution based on an average value, as it is thought that each policy will have an inherent impact that may differ from those of the others. The found solution was based on a qualitative approach resulting from a consensus among hepatitis C experts to fill the gap of no quantitative studies being found on each of the 24 PHPs considered for the LEHC model. Considering this, further research is necessary to identify the impacts of each of the studied PHP, which requires various research lines encompassing elements such as different cultures and legislations in different countries. Nonetheless, the developed work in the LEHC project provides a basis for discussion toward future research, having defined a maximum policy impact of 30% in the model. Although defining the global impact of PHP is not within this study's scope, it is still important to identify it as a possible limitation.

Model Initialization

On the basis of the 2 main Markov model components of the LEHC health policy tool (CHC disease progression and CHC cure cascade), all individuals of a particular population subgroup (further stratified by age and gender) can be represented in a set of mutually exclusive states through which they move over time.

Starting from the current (ie, 2017) configuration of individuals over the different model states, the health policy tool aims to assess the viability of eliminating CHC infection by 2030, under different scenarios of policy measure implementation, in the different countries and population subgroups being assessed. Elimination is defined as a percentage reduction in CHC prevalence between 2015 and 2030 above a certain high threshold (eg, 90%).

Given the complexity of the model, considering simultaneously up to 9 progression health states, 8 cure cascade states, 7 age groups, and 2 genders, it is easily understood that the population is stratified over up to 1000 mutually exclusive model states at each point in time. Knowing that a large part of the population with CHC is suspected to be undiagnosed in many countries, it is highly unlikely to find any country or population subgroup

XSL•FO
RenderX

where an exact or approximate distribution of all individuals over these many states might be available.

An informal back-calculation [37] approach was used to infer a plausible current configuration of individuals over the different model states. To this end, the best possible qualitative, quantitative, longitudinal, cross-sectional, and historical data available for each population subgroup were used. On the basis of these data, the informal back-calculation involved choosing parameter values (such as incidence and diagnosis rates), observing how closely the model simulations for the most recent years are aligned with the scarce data available, and adjusting accordingly.

Population Groups

The model integrates 5 different populations (Table 2) that are susceptible to HCV infection. These populations are dynamic inside each group but are considered mutually exclusive.

Table 2. Population groups included in the epidemiological model.

Group	Definition
Remaining population	This population includes the country's overall population, excluding all the individuals from the remaining population groups (people who inject drugs, prisoners, and people who use blood products).
People who inject drugs	This population represents the national population of injectable drug users. Note that this population does not include drug users who do not inject drugs. As there is a significant overlap between people who inject drugs and prisoners, as a great number of prisoners are also people who inject drugs, and as it has been assumed that the different groups in the model are mutually exclusive, it was defined that this population group only includes the people who inject drugs who are not incarcerated.
Prisoners	This population includes convicted prisoners with sentences >1 year. As the model was constructed on an annual basis, all the preventive prisoners and convicted prisoners with penalties <1 year were excluded.
People who receive blood products	This population includes individuals who have received blood transfusions or blood derivate products.
Individuals infected through vertical transmission	This population is included within the remaining population group. It represents all individuals who were infected through mother-to-child transmission during birth.
Total population	This population is composed of the whole country's population, meaning that it is the sum of all other population groups.

To simulate the epidemiological evolution of hepatitis C for the retrospective period between 1950 and 2016 (model initialization), a series of prespecified inputs must be collected from the available literature for each of the different population groups. Some of these inputs are also required prospectively for the period between 2017 and 2030. For all the missing information, a series of assumptions must be made. The methodology for data gathering, followed for data processing, is described below.

Demography

Demography refers to the population size over the years. For the remaining population, it consists of the resident population size of a country and the number of live births to estimate the changes in population size over time, every year between 1950 and 2018, stratified by gender and age classes.

The other population groups consist of the total number of individuals belonging to each one per year from 1950 to 2030 stratified by gender and age class.

Turnover

Turnover refers to the number of people who enter (turnover in) or exit (turnover out) the population group each year per age group between 1950 and 2030.

For the remaining population, turnover in consists only of live births. Turnover out should be equal to the number of people who enter other population groups.

For people who inject drugs, turnover in consists of people who start injecting drugs each year. By contrast, turnover out consists of all individuals who stop injecting drugs each year, thus leaving this population and becoming part of the remaining population.

For prisoners, turnover in consists of arrested and incarcerated people during that year, whereas turnover out consists of all individuals released from prison during that year, thus becoming part of the remaining population.

For patients receiving blood products, turnover in consists of people who enter the population each year. As people never stop being ex-transfused, it was assumed that there is no turnover out for this population other than mortality, which is a structural component of the model.

Background Mortality

Background mortality refers to the annual probability of death in each population group per year between 1950 and 2030 stratified by age group and gender.

Hepatitis C Incidence

Hepatitis C incidence refers to the number of new chronic HCV infections in each population group per year between 1950 and 2018 stratified by gender and age class. In the remaining population, all new infections occurring in the other population groups should be accounted for.

Hepatitis C Prevalence

Hepatitis C prevalence in the remaining population refers to the predicted prevalence of chronic HCV infections over the years, stratified by gender and age class. Only patients with CHC, who do not belong to any of the other population groups should be considered.

XSL•FO
RenderX

Hepatitis C prevalence in the other population groups refers to the total number of chronic HCV infections in each population per year between 1950 and 2018 stratified by gender and age class.

Diagnosis

Diagnosis refers to the annual probability of an infected individual being diagnosed in each population group per year between 1950 and 2018 according to gender, age group, and disease stage.

Retain in Care

Retain in care refers to the annual probability of a diagnosed individual being retained in care in each population group per year between 1950 and 2018 according to gender, age class, and disease stage.

Treatment 1

Treatment 1 refers to the annual probability of an infected individual being treated for the first time against hepatitis C if already retained in care in each population group between 1950 and 2018 according to gender, age group, and disease stage.

Treatment 2

Treatment 2 represents the patients' second treatment against CHC and should only consider DAA class therapies. It refers to the annual probability of an infected individual being retreated if retained in care and previously treated in each population group according to age and disease stage for the years between 1950 and 2018.

SVR in Treatment 1

SVR in treatment 1 represents the probability of a patient achieving an SVR in the first treatment against HCV in each population group for the period between 1950 and 2030.

SVR in Treatment 2

SVR in treatment 2 represents the probability of a patient achieving an SVR with the retreatment with DAA therapy (treatment 2) in each population group for the period between 1950 and 2030.

Ethical Considerations

In compliance with Portuguese legislation, our study did not involve access to patients' clinical data, personal interactions with them, individual medical records, or consultations with hospital databases. Our research solely relied on elements published in peer-reviewed scientific literature or official state reports. As a result, ethical committee approval was not necessary.

Results

The construction of the LEHC model had to proceed with an adaptation to the practice, involving the construction of proxies in the modeling process. The LEHC model comprised an average production time of 3000 hours per country, considering all the interventions, from data collection to obtaining a fitting.

The model was applied to a set of countries; studies in 5 of these countries have already been completed or are currently under publication process [38-42], and those in the remaining countries are in different conclusion phases, with data being available on the LEHC website for the period between 2017 and 2019.

The double imputation model allowed the assessment of a set of indicators such as LT, incidence, and deaths year by year until 2030 in different risk groups.

Initial feedback from decision makers in pilot countries suggests that the modeling tool was helpful for the politicians. The tool allows people to simulate even seemingly strange or counterintuitive solutions with privacy simply to verify data movements' sensitivity. The simulation processes enabled the health decision makers and the politicians to provide answers about the tool's performance limits and illustrate with concrete, measurable, and externally verifiable facts [38-42].

Discussion

Principal Findings

It was possible to create a gamified system in which even people who are not experts in the field of hepatitis C can have an informed opinion and simulate different technical solutions for their country. This technological opacity solution allows people to use a modeling tool without the need for knowledge about medicine or mathematics. The gamification of the tool allows people to get an idea of which policies can be invoked and the corresponding degree of application by testing different scenarios. This process enables people to be knowledgeable about the impact of policies on different populations and the country as a whole.

The "democratization" provided by gamification puts citizens involved in patient advocacy on the same level as people linked to patient associations and other civil society members (patients, family members, and employers, among others). This is due to allowing the discussion with a technical basis regarding the impact of policies that can be implemented and the practical limitations in contexts with a strong will to eliminate hepatitis C by 2030.

Similarly, for politicians and health system decision makers, the gamification of scenarios allows an instantaneous simulation of each policy's impact on the main health indicators explained earlier.

Limitations

Several types of limitations were identified throughout LEHC, and some of them are highlighted subsequently.

Model Construction

In terms of model construction, there were many requests from politicians and health system decision makers to add a component of financial analysis to the routines and simulation algorithms, which is not very complex. However, it was not possible to take this step because of the lack of funding for this component. This would also further increase the number of statistical series to be collected and worked on, which would not be feasible with the available resources. Nevertheless, we consider that this new functionality would be very advantageous, as it would allow countries to simulate the policy itself and

XSL•FO
RenderX

verify the financial impact that one option has in comparison with another, although it may only be in order of magnitude.

How countries collect and systematize their data varies enormously, complicating and sometimes even preventing direct comparability between identical statistical series. In addition, there is still a need to unify the systematics and ontologies related to hepatitis C (at least at the European level). Even at the country level, the existence of autonomous regions means that there are different health conditions, health legislations, and assistance rights of citizens existing in parallel, making it difficult to obtain a national framework. The solution we found was to work with only 1 region, for example, as was the case in the United Kingdom, where LEHC was applied to England (study on which is almost complete but not finalized), or to work in all autonomous regions, as was the case in Spain, by creating unification proxies, which required tremendous effort and caused great difficulty. In our reading, the only solution for the future will be to create an LEHC at 2 levels, national and regional, for countries that have autonomous health systems. If this option is to be chosen, the efforts made for a country should be multiplied by the number of autonomous regions in that country, provided that all the regions have detailed data for hepatitis C.

Model Application

It must be noted that no country managed to have all the necessary data for the LEHC model. When the series existed in >1 bibliographic source, they were almost always partial or contradictory. There was a need to produce hundreds of proxies with the support of local research teams and validate the data with the NABs based on international experts' experiences.

Even the statistical series available on hepatitis C and populations with risk behaviors for this disease have always been incomplete in terms of the model's requirements. Specific data often focused on specific populations. Even when considering a population with risk behaviors, data sometimes represented specific time periods, specific regions, or different data collection methodologies, which necessitated enormous efforts in finding common denominators.

Another limitation of the model was that the experts constituting the NABs often seemed to be comfortable assessing the impact of some of the modeled policies but not the others. An important predictor of this difficulty was the professional experience of NAB members with specific populations.

Comparison With Prior Work

This work differs from the existing models, as it targets the simulation of PHPs focused on hepatitis C in an innovative way by using gamification processes, allowing citizens to simulate PHP application in the disease, a possibility that until now has been reserved for specialists. The epidemiological modeling in LEHC was seamlessly integrated into decision-making processes through a unified solution.

As in previous works mentioned in the literature review [15,18-21,23], modeling allowed obtaining a set of indicators, as explained above. Similarly, as stated in the appointed application articles for this model [38-42], although there were differences in the year of elimination of hepatitis C (according to WHO criteria), these were not structural until the COVID-19 pandemic. It must be noted that COVID-19 represents a threat to allocated efforts to achieve the elimination of hepatitis C by 2030, with the disease elimination programs being highly impacted [43-45]. In addition, the results that were different were essentially because of distinct assumptions regarding the implementation intensity of PHPs, which points toward an interesting concurrent validity.

Conclusions

The LEHC model combines epidemiological mathematical modeling in its classic sense with the modeling of political decision-making in a single solution. It can simulate different policies with different implementation degrees, thus allowing the anticipation of results concerning different options, making it a potential tool for political decision-making on hepatitis C.

One of the main conclusions is that the tool is able to generate solutions that can be specific for each reality, in which each country ends up needing a set of specific PHPs to address the need to eliminate hepatitis C by 2030. This means that there is an enormous cultural component in the sense of diverse lifestyles, legislations, and social history in general, which the LEHC tool, with its adaptive flexibility, responds to.

This does not mean that the values provided by the LEHC tool should be understood as exact numbers from the past or the future. Like all models, LEHC depends heavily on the quality of the input data, and it was very clear to the authors that there is unlimited dominance in the data from all countries, namely for highly specific data, such as information about people who inject drugs. Therefore, this explains how even the largest organizations have made epidemiological corrections of 40% to 50% in recent years. In our reading, this limitation does not remove the merit and interest of the LEHC tool, and on the contrary, it encourages research and may also be a call for research.

The general meaning of PHP turns out to almost always be the intensity of its use and the potential consequences that can be gained by intensifying it. This is where LEHC provides invaluable help to decision makers and patient advocates, as per feedback that has been collected from these 2 social groups.

The integration of the tool into a gamification system allows anyone interested in hepatitis C to forecast both the current policies that appear as standard and those that are intended to be tested to seek alternative paths. Therefore, it is legitimate to point LEHC as a patient advocacy tool.

Hepatitis C is going through a very problematic phase, discovering millions of cases that still exist outside the health systems; those that were in the area of knowledge in general have already been integrated into the processes of diagnosis and treatment. Because those who remain outside the system are socially opaque, they cannot not be integrated into treatment using just the usual clinical and public health measures because if that were possible, after 8 years of efforts by the health systems, these people would already have been treated.

XSL•FO
RenderX

We have to get out of the standard practices and find social forms based on social segmentation, with PHPs that cover beyond the usual spheres of health to capture the tens of millions of people who are outside. If such a strategy is not adopted, we will somehow be doomed to have viral reservoirs in uncertain parts of the social system, which will feed the reinfections of those who have already been treated as well as disseminators among those who are not yet sick.

LEHC being an integrated and articulated structure of PHPs can make a very positive contribution to join all the other structures that are currently being developed throughout the disease cure cascade.

Acknowledgments

Gilead Sciences Europe Ltd is providing financial support for data collection, web design, and IT-related processes in the Let's End HepC project. Manuscript authorship, the national advisory boards that contributed to this study, and scientific and academic work are not sponsored.

Authors' Contributions

RB-L, HL, BV, JF contributed to study concept and design. HL, BV, and JF were involved in data acquisition. BV, JF, HL, TC, and HB were involved in data analysis and study supervision. HL, HB, and DF drafted the manuscript and provided administrative support. RB-L and HL critically revised the manuscript for important intellectual content. All the authors approved the final version of the manuscript for publication.

Abstract

Background: The increasing use of smartphones, wearables, and connected devices has enabled the increasing application of digital technologies for research. Remote digital study platforms comprise a patient-interfacing digital application that enables multimodal data collection from a mobile app and connected sources. They offer an opportunity to recruit at scale, acquire data longitudinally at a high frequency, and engage study participants at any time of the day in any place. Few published descriptions of centralized digital research platforms provide a framework for their development.

Objective: This study aims to serve as a road map for those seeking to develop a centralized digital research platform. We describe the technical and functional aspects of the ehive app, the centralized digital research platform of the Hasso Plattner Institute for Digital Health at Mount Sinai Hospital, New York, New York. We then provide information about ongoing studies hosted on ehive, including usership statistics and data infrastructure. Finally, we discuss our experience with ehive in the broader context of the current landscape of digital health research platforms.

Methods: The ehive app is a multifaceted and patient-facing central digital research platform that permits the collection of e-consent for digital health studies. An overview of its development, its e-consent process, and the tools it uses for participant recruitment and retention are provided. Data integration with the platform and the infrastructure supporting its operations are discussed; furthermore, a description of its participant- and researcher-facing dashboard interfaces and the e-consent architecture is provided.

Results: The ehive platform was launched in 2020 and has successfully hosted 8 studies, namely 6 observational studies and 2 clinical trials. Approximately 1484 participants downloaded the app across 36 states in the United States. The use of recruitment methods such as bulk messaging through the EPIC electronic health records and standard email portals enables broad recruitment. Light-touch engagement methods, used in an automated fashion through the platform, maintain high degrees of engagement and retention. The ehive platform demonstrates the successful deployment of a central digital research platform that can be modified across study designs.

Conclusions: Centralized digital research platforms such as ehive provide a novel tool that allows investigators to expand their research beyond their institution, engage in large-scale longitudinal studies, and combine multimodal data streams. The ehive platform serves as a model for groups seeking to develop similar digital health research programs.

Introduction

Background

The increasing use of smartphones has provided an opportunity for the growth of mobile health apps for studying health and disease. These apps enable engagement with participants throughout the day, remotely, and at a high frequency. They allow for the collection of patient-reported outcomes measures (PROMs) through surveys, the assessment of social media use, website tracking, and the examination of patterns of phone use [1]. Similarly, wearable and connected devices for ambient sensing are increasingly accepted and used in the United States [2]. Commercial and custom devices can collect physiological data from users continuously and without active input.

Digital technologies are increasingly used to help overcome the limitations of traditional research, such as limitations to recruiting sufficiently large and diverse cohorts and tracking day-to-day changes in participant conditions [3,4]. Remote digital study platforms represent a subset of digital platforms comprising a patient-interfacing digital application that enables multimodal data collection from a mobile app and connected sources. They offer an opportunity to recruit at scale, acquire data longitudinally at a high frequency, and engage study participants at any time of the day in any place [5,6]. These multimodal platforms collect PROMs, provide study content such as videos or other engagement tasks, and collect objective environmental and connected device data. They can enable the electronic onboarding of participants through an e-consent process and establish individual baselines that allow for the construction and forecasting of individual patient trajectories [7].

Many app-based studies and platforms often suffer from low rates of retention and adherence [8-11]. Factors such as perceived utility, value, convenience, and usability have been identified as barriers to use [12]. However, a centralized and agile digital research platform offers an opportunity to improve engagement and mitigate many factors that drive low adherence rates. Through the concerted development and expansion of a central modifiable research application, usability and engagement tools can be optimized across the platform. This mitigates the need to develop single-use applications, enabling the successful growth of digital research across disciplines. The ehive studies platform is the centralized digital research application of the Mount Sinai Health System (MSHS) in New York. It is a proof-of-concept platform that incorporates the elements and features most necessary across studies, uses recruitment and retention features, outlines data collection elements, and assures patient privacy and safety. It serves as a potential model for other health systems and organizations seeking to develop centralized digital research programs.

Overview

Here, we describe the ehive research platform and its features to provide a road map for the development of similar infrastructure. In the following sections, we first describe the technical aspects and functionalities of the ehive platform, including participant consenting procedures and privacy protection. Then, we provide information about ongoing studies hosted on ehive, including usership statistics and data infrastructure. Finally, we discuss our experience with ehive in the broader context of the current landscape of digital health research platforms.

Methods

Digital Platform Development

The MSHS (New York, New York) includes the Icahn School of Medicine at Mount Sinai and 8 hospitals in the New York metropolitan area. It comprises the largest health system in New York City, with one of the most diverse patient populations in the United States [13]. The Hasso Plattner Institute for Digital Health at Mount Sinai (HPI.MS) was founded in 2019 and represents an international academic collaboration between the Hasso Plattner Institute for Digital Engineering in Potsdam, Germany, and the MSHS in New York City, United States [14]. The COVID-19 pandemic highlighted the need for a digital alternative to the in-person studies conducted by the MSHS, which was seen as an imperative future direction. To meet this need, HPI.MS launched the ehive digital research platform in early 2020 with the initial goal of creating a platform to support multiple studies and study types. The initial design of ehive drew upon the prior experiences of the digital health and clinical research faculty, who were charged with its development. The ehive platform is overseen by a program within HPI.MS called the Digital Discovery Program (DDP [15]). The DDP is responsible for maintaining ehive and determining which studies will use the platform and how the platform will be modified and evolve over time. Although the DDP determines the short- and long-term goals of the app, input is solicited from researchers using the app and study participants. Study-specific modifications are undertaken during the planning and development phase of each study, which can be applied across the platform. Any unsolicited feedback from the participants using the app is evaluated by the DDP and incorporated into future modifications.

This multimodal digital platform can be used on both iOS (Apple Inc) and Android (Google LLC) mobile devices and is designed to support multiple independent research studies via the collection of remote consent and PROMs and integration of data from commercial and custom wearable devices, electronic health records (EHRs), and biobanks.

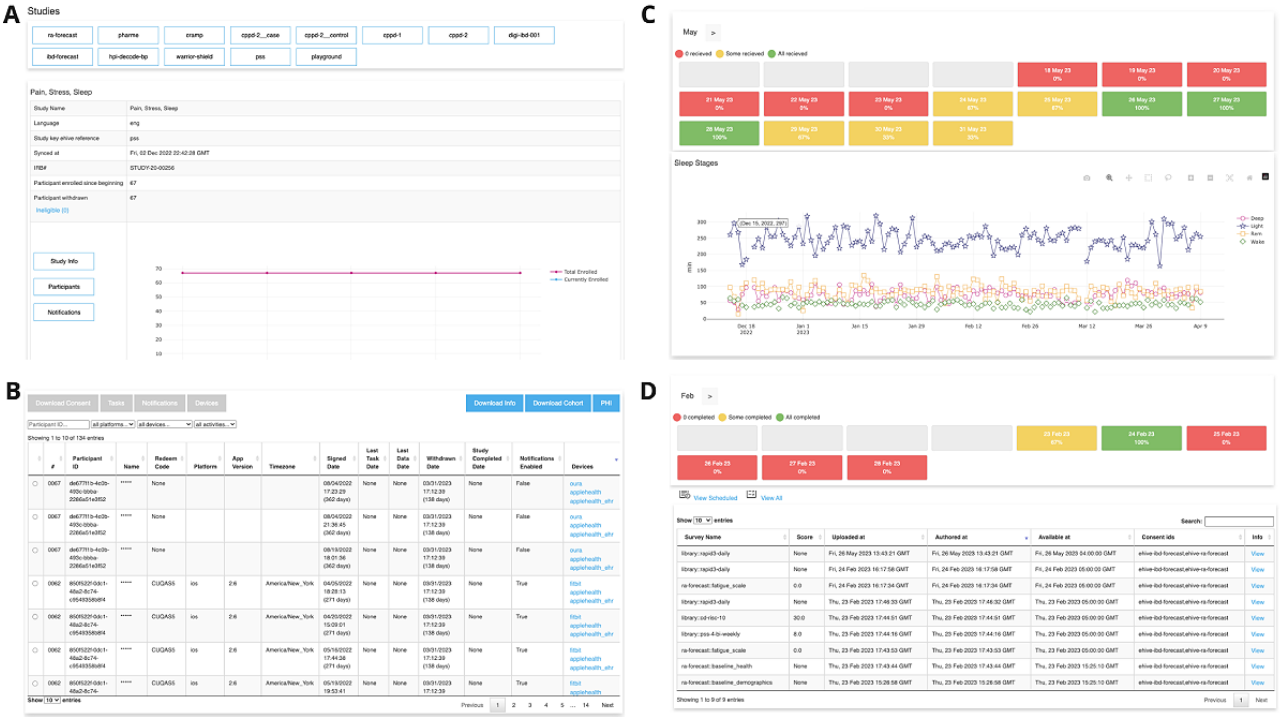
Recruitment, Retention, and Monitoring

Research participant recruitment and retention is challenging and an important determinant of research success [16]. Digital tools such as email messages, SMS text messages, websites, and smartphone apps are increasingly used to assist with participant recruitment and retention and help eligible participants find potential studies [17]. The ehive platform was developed with unique capabilities to assist investigators with study recruitment, including bulk messaging through the EPIC EHR system and standard email portals. The lists of potential study participants meeting the specified inclusion criteria can be generated through a data warehouse system hosted by Mount Sinai. This system collates identified and deidentified data from the EHR, including email addresses. Using this infrastructure, investigators can run queries through the EPIC system to find participants who meet the study eligibility criteria. Through ehive, investigators can send automated recruitment messages to the EPIC MyChart messaging inbox of this cohort. Alternatively, ehive can send automated messages via email using prespecified email distribution lists collected from the data warehouse. These 2 approaches allow for broad engagement with potential participants, enhancing study visibility throughout the health system. This facilitates the recruitment of diverse participant populations, the lack of which is a significant limitation in many digital studies. The ability to engage with individuals across the health system ensures that a large population of patients can become aware of specific studies relevant to them, including patient populations that may be difficult to reach via traditional recruitment methods and across socioeconomic statuses.

Participant retention and engagement are key drivers of data quality and research study success. Over half of the participants in digital studies stop participating after the first week [18]. Frequent light-touch reminders for participants to engage in study activities are often used in digital studies to maintain compliance [12]. The ehive platform was developed with several light-touch features. Smartphone push notifications are generated at customizable frequencies, in customizable language, and at modifiable times of the day to remind participants to complete study tasks and use their connected devices. The app can send modifiable email messages to participants that welcome them to the study, thank them for participating, and remind them to maintain engagement. The ehive app is designed for automated compliance monitoring using customizable engagement thresholds for each study, which generate these customized push notifications or emails for participants or study staff. This permits the passive monitoring of a large number of study participants and initiates re-engagement if compliance drops below the specified thresholds. Depending on the specific study, the app allows participants to tailor their ehive experience based on their daily schedule, providing them the option to customize when they receive notifications and which notifications they receive.



Research Dashboard

A central ehive dashboard is available to monitor participant engagement across studies (Figure 1). The dashboard allows the visualization of ongoing and completed studies and can be tailored to grant specific personnel access to specific studies. Access is granted via invitation, and the dashboard is accessible only through the MSHS virtual private network. The Azure Active Directory manages dashboard log-ins, and role access is managed by an honest broker who has administrative access to the dashboard. The dashboard has multiple features, including an interface for participant and study team communication, a data review feature, and a feature for visualizing data trends based on the information collected from wearable devices and PROMs. Access to each feature can be granted based on the role of the user in each study, as specified in the institutional review board (IRB) approval. This allows research coordinators to actively interact with study participants through custom push notification features or emails, which can be generated within the dashboard. In addition, this allows researchers to interact with the data in a deidentified or an identified fashion based on the study requirements.

Various customizable features allow the study team to change the consent language, task language, and task scheduling as well as to add and remove integrated wearable devices. Customization can be done seamlessly and does not require the release of an app update. This agile solution enhances user experience by allowing researchers to correct errors and provide real-time feature deployment without triggering app updates. Major app updates are available on digital stores (Apple App Store [Apple Inc] and Google Play [Google LLC]), and participants are automatically notified to manually update the app. The ehive team encourages a soft launch of each study to enable the identification and correction of any problems. After the enrollment of the first several participants, study compliance and data quality can be reviewed to enable early modifications of task language or schedules before full-scale enrollment is undertaken. Each data point collected through ehive is time-stamped. All changes to the consent procedure, tasks, or other study components are stored in a change log within GitHub. Using the time stamp associated with study data and the change log, data versions can be tracked and evaluated during the analysis phase.

Figure 1. The ehive study dashboard for participant monitoring. (A) Individual studies can be selected to gather study details and visually track enrollment and compliance. (B) Participant information can be visualized for each study, which is provided as an interactive list with participant contact information, unique study IDs, date and time of enrollment, withdrawal date, copies of each signed consent form, and information on patient-reported outcomes measures (PROMs) and wearable data. (C) Wearable device data trends can be visualized for each participant, including sleep and heart rate variability data. (D) Survey data from each participant can be visualized.

Downloading ehive and Providing e-Consent

The ehive app can be downloaded free of charge from the Apple App Store and Google Play and is designed for users to remotely onboard themselves (Figure 2). The introduction screen allows individuals to view publicly available studies and publications generated from research conducted on the platform. This interface allows users to explore publicly available studies and join these studies if they meet the eligibility criteria. Non–publicly available studies are not visible in the ehive app unless potential participants are provided with a link and log-in credentials to reveal and unlock the study on their ehive dashboard.

The consent process is customizable for each study and can include a brief study introduction; an eligibility screener; and, subsequently, an e-consent review and signature process (Figure 3). The eligibility screener verifies that the participant meets the study criteria. This verification of inclusion and exclusion criteria matches user's answers to questions locally on the phone and does not store this information as study data, as this is done before the study consent process. The subsequent e-consent process incorporates visualizations on the interface to explain concepts, communicate the impacts of the study, and highlight the benefits and risks to participants. This process allows potential participants to read and learn about the study information at their own pace, with the option of contacting the study team with questions at any point. A review of the concepts of e-consent is followed by a series of comprehension questions that assess the participant's understanding of the key aspects of the study. The e-consent process allows participants to move back and review any material again, as needed. If potential participants fail the study concept quiz 3 times, they are deemed ineligible for the study, and the study is locked to future enrollment. This can be manually reset by the study team if required. Once the study concept quiz is completed by a potential participant, the IRB-approved consent form is available for review and electronic signature. A signed pdf version of the consent form is then generated and stored in the app for future reference. Depending on the study requirements, the e-consent process can be performed either solely by the participant or can involve a study coordinator (Figure 4).

After the e-consent form is signed, participants can review and select the data streams to be shared with the research team through a data control permission process (Figure 5). Data streams can range from wearable device data to other modalities such as EHR data. If a participant is enrolled in a second study, the app will notify them regarding the need to once again select the data streams to be shared. Permission for wearable data access is provided at the study level, which allows the participant to use the same or additional devices and decide which data to share for each study. This places data-sharing control in the hands of participants and allows them to customize their choice for each study. This permission is modifiable and can be edited or revoked by participants at any time.

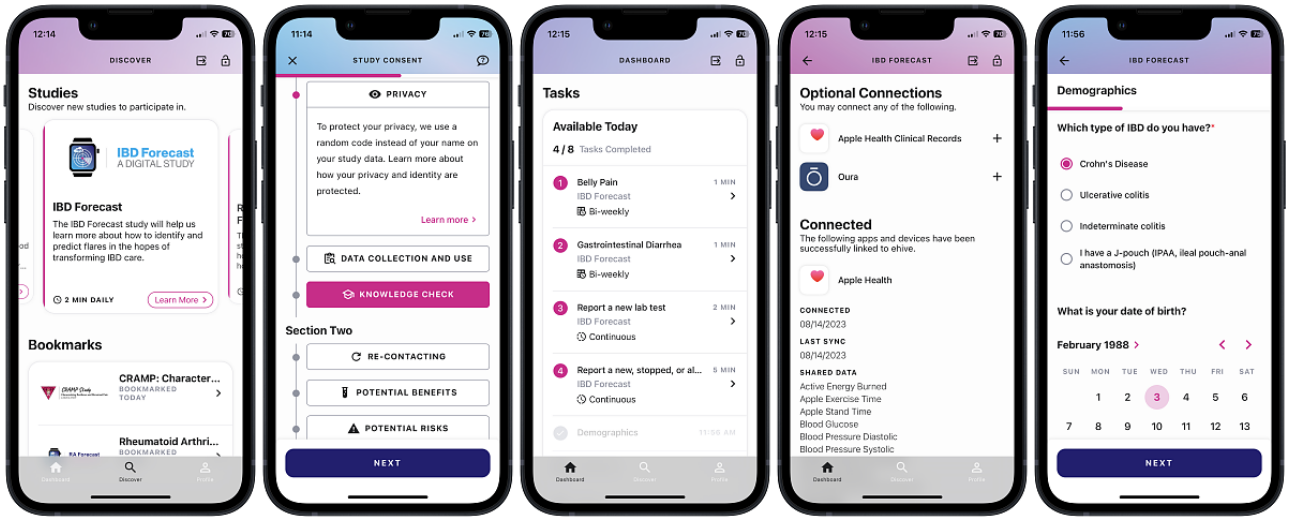
RenderX

Figure 2. An overview of the major features of the ehive app. Participants can scroll through the available studies, provide consent for studies that interest them and whose eligibility criteria they meet, complete daily tailored study tasks, and share wearable and other health data. IBD: inflammatory bowel disease.



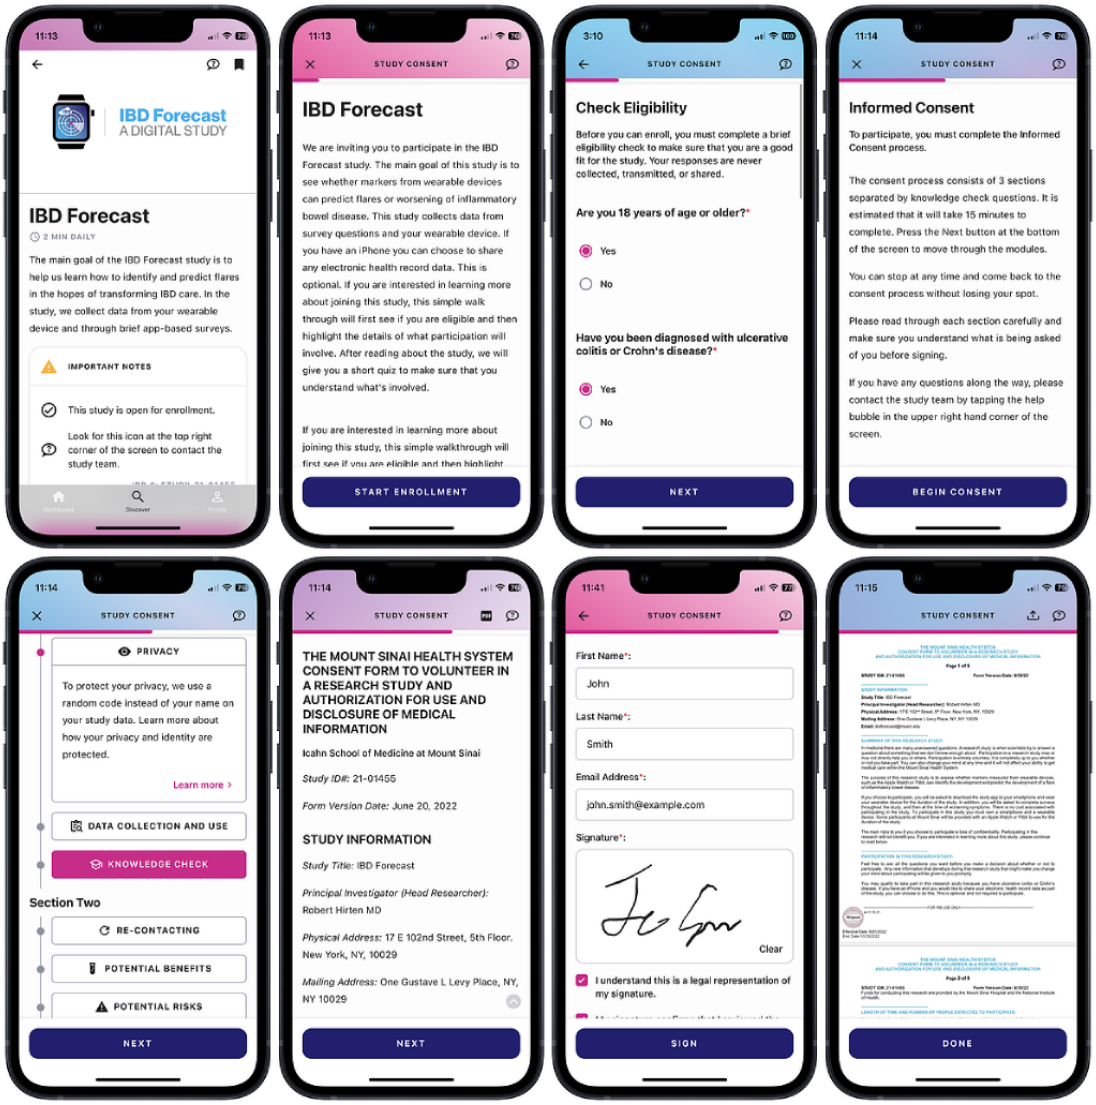


Figure 3. The sample e-consent process in ehive. A brief introduction to the study is provided, followed by participants checking whether they meet the eligibility criteria. If inclusion and exclusion criteria are met, participants are taken through the consent form and required to complete a study comprehension quiz. If this is successful, participants can read through the institutional review board–approved consent form and provide an electronic signature. A pdf version of the signed consent form is generated and available for review. IBD: inflammatory bowel disease.

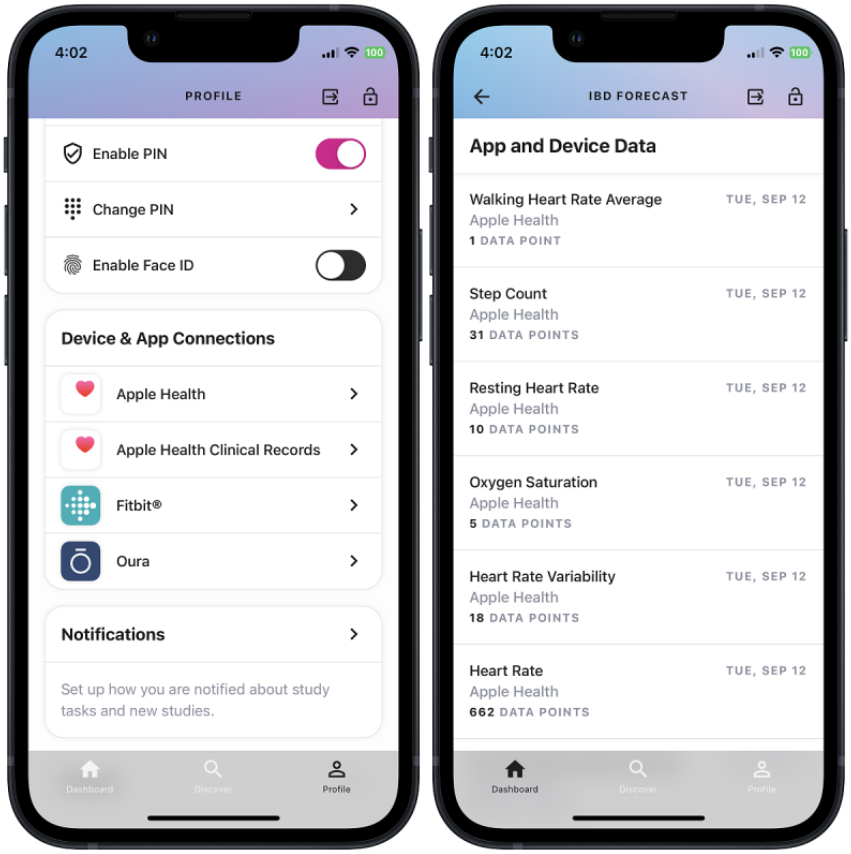

XSL•FO
RenderX

Figure 4. The consent flow for prospective study participants. The consent flow consists of 6 main screen groupings: (A) selection of the study, (B) review of detailed study information, (C) eligibility screening, (D) walkthrough of consent details and knowledge checks, (E) consent document review and signature, and (F) enrolled patient-facing study dashboard. Studies that are fully remote and have no active research coordinator participation include consents using each of these groups. Consent flow is indicated by the solid line in the flow diagram. The consent process of studies using an active research coordinator may skip certain groups if desired by following the dashed line on the flow diagram. CRC: clinical research coordinator; IBD: inflammatory bowel disease.

XSL•FO

Figure 5. Study integration with external data sources, such as wearable devices. Participants can link connected devices to the ehive app and choose which device data to share with the study team. Participants can verify that app and device data have been shared with the study team. IBD: inflammatory bowel disease.

Ethical Considerations

All ehive studies that involve human participants require separate approval from relevant IRBs. Ongoing IRB approval is required for the study to remain active on the platform. Approval is needed for any secondary analyses of research data, for the sharing of data outside the study team, and during the data extraction and analysis period. Each study incorporates its own IRB-approved data-sharing and consent framework. Compensation is individualized for each study. The ehive platform is itself approved by the IRB at the Icahn School of Medicine (STUDY-21-01500) to assure compliance of its consent and data storage approaches with relevant institutional guidelines for the ethical conduct of research. All the data presented in the subsequent sections were approved by the Mount Sinai IRB.

Patient-Facing Dashboard and Tasks

Study participants can manage individual study activities on their smartphone via ehive's patient-facing dashboard. This user-friendly interface provides an overview of the study tasks and activities as well as a list of completed tasks and future tasks. Participants can also access a summary of the types of device data they are sharing with the study team. Additional features include detailed information about the study's IRB approval, contact information of the study team, and the signed consent form. Participants can withdraw from the study through the app.

Through the task list on the ehive dashboard, participants can complete custom or standardized surveys as well as view videos and educational content. Additional integration with the EHR is possible. Participants can grant permission for the EHR to be read via Apple's HealthKit. When connected, EHR data are pulled directly from the HealthKit database into the ehive platform via Fast Healthcare Interoperability Resources (FHIR). Currently, this interface allows participants to visualize the data collected from connected devices or scored survey results. However, in the future, it is planned to enable the visualization of wearable metrics by participants within the patient-facing dashboard. Depending on the specific study, this information can be masked to minimize bias.

The ehive app is designed to collect multimodal data, including PROMs. PROM questionnaires are delivered as study tasks, with participants' responses saved directly in the ehive database in the FHIR Questionnaire Response format. New questionnaires are created using a configuration file that is deployed to the ehive server and added to a study's task schedule. Questionnaires are created, scheduled, modified, and deployed without requiring an app update. The ehive app has built-in support for 23 question types (ie, multiple select, year, yes or no select, drag or drop reorder, text, etc) and branching logic to show or hide questions based on the participant's responses. The ehive backend is integrated with the REDCap (Research Electronic Data Capture; Vanderbilt University) platform, enabling it to write and read questionnaire responses with REDCap, if requested by the study team. Previously used

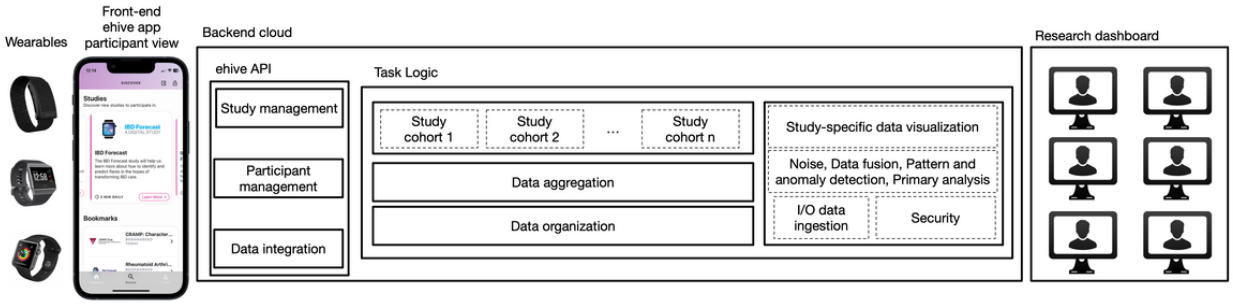
XSL•FO
RenderX

surveys are stored in a data library to allow for ease of use in future studies.

Data Integration

The ehive platform is integrated with external data sources using two primary mechanisms: (1) via a web application programming interface (API) or (2) via a software development kit (SDK). For security purposes, ehive integrates only with web APIs that implement the Open Authorization 2.0 (OAuth 2.0) protocol. OAuth 2.0 is an authorization standard that enables a third party to request a service on behalf of the resource owner. Using the OAuth 2.0 protocol, the resource owner retains full control of an individual's log-in credentials and the shared data. When initiating a request to share data, ehive specifies exactly which scopes (data types) the study is interested in. The participant chooses which of these scopes he or she wishes to authorize, and then the external service releases a short-lived access token and a refresh token. The access token grants temporary access to the authorized data. After the access token expires, a new access token may be released using the provided refresh token. These tokens are stored in the database and used for server-to-server communication, allowing ehive to pull external data without continued interaction with the ehive mobile app. The study participant can revoke ehive's access at any time, whereupon the refresh token will be invalid, no new access tokens will be released, and no more data will be obtained from the participant.

OAuth 2.0-enabled web APIs are ubiquitous among commercial and research-grade wearable device companies. As the authorization logic is identical among external services and all API methods are simple http requests, little effort is required to integrate with a new data source. In addition, web APIs can be used to integrate data for any service that chooses to expose an API (eg, device data, genetic data, and social media data). SDKs are primarily used to integrate wearable devices. Unlike web APIs that permit server-to-server communication, SDKs require specific code to be bundled with the ehive mobile app to handle communication with the device. Using an SDK is significantly more complicated than using a web API. There are few similarities among SDKs, even among those from the same manufacturer (eg, HealthKit and SensorKit [Apple Inc]), making meaningful abstraction impossible. Furthermore, using SDKs can lead to imbalances between platforms because some SDKs are only available on iOS (eg, HealthKit), whereas others are only available on Android (eg, Samsung Health [Samsung Electronics]). Additionally, iOS and Android require the use of different programming languages and tools. Therefore, when an SDK is to be made available on iOS and Android devices, it must be implemented separately for each platform. These complexities prolong the time required to integrate a new SDK into platforms such as ehive. In addition to the primary integration mechanisms discussed earlier, ehive has access to unique data set integrations only available within the MSHS, such as genomic and proteomic biobanks. This data integration is automated and does not require any action on the part of participants.



Multi–data sets such as pathology data, radiology images, EHR in Observational Medical Outcomes Partnership format, and genetics data are stored in a different environment within the MSHS called AIR.MS for efficiency and security purposes [19]. They can be accessed and integrated with ehive data with IRB approval and participant consent. The ehive platform collects information such as medical record numbers, name, sex, date of birth, and zip code. When the bootstrapping process is initiated in both environments, a lookup table with the hash value of the medical record number, the date of birth, and a random value is exchanged between the 2 domains using a public or private key exchange protocol. After the bootstrapping process, when a new patient is added to AIR.MS, a unique hash value is inserted into the AIR.MS lookup table. The same steps are performed on ehive when a new participant signs in to assess whether he or she is in MSHS. A new record is added to the ehive lookup table. If the security of the lookup table is compromised, a new public or private key is generated, and a random value is shared. Both AIR.MS and ehive must then recompute their lookup tables for future matching between the data sets. Principal investigators (PIs) interested in using multiple data sets from both environments must be granted access and have IRB approval. Once access is granted, a software agent returns the number of data points available for the time range requested by the PI. The PI can then verify the data quantities returned and decide whether they meet the criteria to build the cohort. If the cohort meets the PI criteria, an automatic process deploys a new virtual machine accessible to the researchers on the IRB who have valid Mount Sinai Azure Active Directory credentials. The virtual machine has automated access only to the data requested by the PI.

Data Infrastructure

The ehive backend runs on Health Insurance Portability and Accountability Act–compliant Azure cloud infrastructure (Figure 6). It uses Docker (Docker Inc) and a microservice architecture pattern to simplify the maintenance and deployment of new features. Each service has its database, which contains the data required to perform its duties. No sensitive information is stored within the microservices themselves. Database access keys and API keys are stored in Azure Key Vault, and all data are stored in an encrypted Postgres database. A flexible Postgres service that scales dynamically to meet the current workload is used to improve performance and availability. App-related data are stored primarily using relational database techniques. However, PROMs and data from external integrations are stored directly in JavaScript Object Notation format. Using JavaScript Object Notation, the ehive mobile app and backend can communicate using the FHIR standard. This design choice allows ehive data to be interpretable by other health organizations, a benefit of which is the possibility of generating interoperable data analyses and merging with EHR and other health data sources.

XSL•FO
RenderX

Figure 6. The ehive platform encompasses a front-end patient-facing smartphone app, backend cloud, and research dashboard. External to the ehive digital ecosystem are third-party apps and wearable devices. Their integration to ehive is mainly through the REST application programming interface paradigm. When data integration through the REST application programming interface is unavailable, as with Apple Watch, ehive accesses the data through software development kits. The ehive data architecture is based on Azure cloud, managed by the Mount Sinai Health System. Investigators interact with the collected data, the study's status, and the study's configuration through the research portal that runs on the Azure cloud. IO: input-output.

Data shared with ehive are authorized on a per-study basis. If a participant is enrolled in multiple studies that request the same data integration, the participant will be asked to provide authorization for each study individually. This process provides transparency and control, allowing participants to decide which data are accessed by each study. Gaps in wearable device data can occur for several reasons. For example, this can occur (1) when the device runs out of battery and is unable to sync with the app's backend, (2) when the participant ceases wearing the device, or (3) when a data sync fails for unforeseen technical reasons. It is vital to the success of each study to minimize gaps in the collected data. Several services run on the backend of ehive to check whether new data are available and whether any gaps exist. In case of a sync failure, the backend will make ad hoc data requests to fill in any missing data. When the gaps cannot be filled via ad hoc requests, an automated message is delivered to participants, notifying them of the issues with their device use patterns.

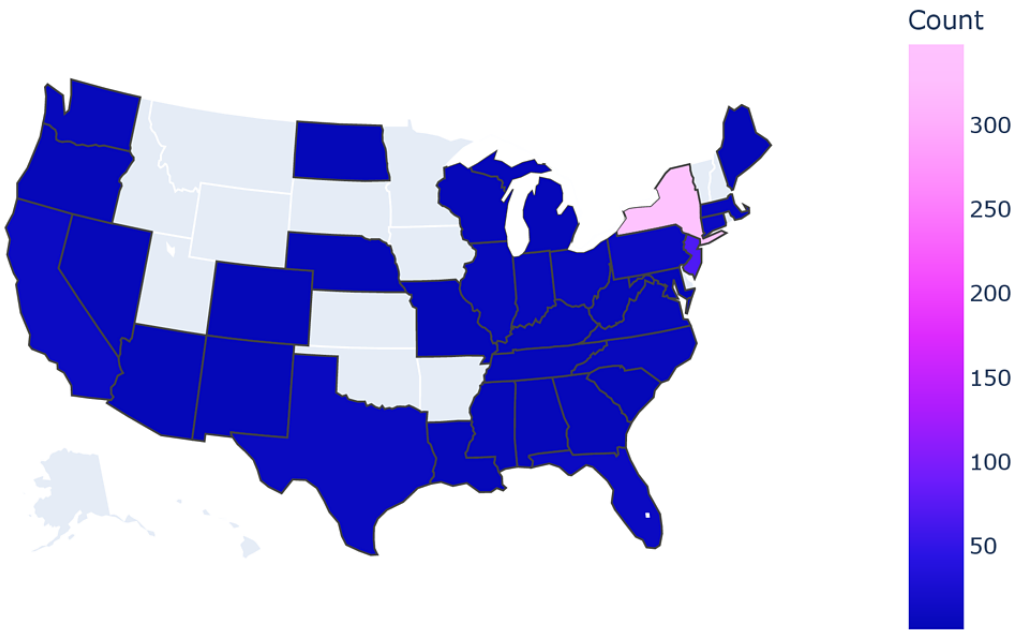
Results

The ehive Platform

The ehive platform was launched in 2020 and has since hosted 8 ongoing or completed studies, with 7 additional studies planned for launch. This study composition is 6 observational cohort studies and 2 clinical trials. The observational studies encompass a range of disease and health states. These include studies recruiting healthy health care workers throughout the MSHS for the development of algorithms to predict COVID-19 infections, studies for understanding the psychological well-being of health care workers during the COVID-19 pandemic, and studies aimed at developing machine learning algorithms to predict psychological states from passively collected wearable data. Beyond the MSHS, the platform has hosted 2 national studies enrolling individuals with chronic diseases from across the United States aimed at predicting disease exacerbations using wearable device data [20,21]. The clinical trials hosted on ehive are fully digital. The Warrior Shield study was such a siteless trial, which enrolled 127 health care workers and aimed at building resilience using digital interventions that modified heart rate variability. The physiological effects of the intervention were monitored using wearable devices.

Participant Recruitment and Engagement

Through January 2023, a total of 1484 participants downloaded the ehive app, with 1044 (70.35%) of them meeting the inclusion criteria for study enrollment. Over 51 million wearable device–based data points have been collected and over 132,241 surveys have been conducted through the ehive app. This demonstrates ehive's ability to recruit across multiple studies and the digital ecosystem's ability to simultaneously run multiple individual cohort studies and clinical trials. Importantly, ehive-based studies have engaged with and recruited diverse populations. For example, the Warrior Watch study, which developed machine learning algorithms aimed at predicting COVID-19 infections, enrolled 297 participants across racial and ethnic groups (Table 1) [22]. Although most ehive study participants are centered around the New York City metropolitan area, individuals across 36 states within the United States have enrolled (Figure 7).



Participant engagement and the use of the ehive platform have steadily increased as the number of studies supported by the app have increased. In addition, modifications that enhance engagement and retention have been continually made and improved, as discussed earlier. The app has an average of 148 (SD 11.43) unique daily users over a 7-day period (April 2023; Figure 8). Highlighting the role that light-touch engagement measures play in the interaction with ehive, we found that measures such as push notifications result in a marked increase in user engagement shortly after being implemented (Figure 9). This highlights the ability of these light-touch measures to remind and engage participants in ongoing studies that require either daily or sporadic tasks within the app.

Table 1. The ehive platform has enrolled diverse patient populations. The demographic profile of the participants enrolled in one ehive study, the Warrior Watch Study, is described to highlight participant diversity (n=297).

Characteristics	Value
Age (years), mean (SD)	36.3 (9.8)
Sex (female), n (%)	204 (68.7)
Race, n (%)	
Asian	73 (24.6)
Black	29 (9.8)
White	108 (36.4)
Other	43 (14.5)
Hispanic ethnicity, n (%)	44 (14.8)

Figure 7. The number of individuals participating in ehive-related studies in each state in the United States.

XSL•FO

Discussion

Principal Findings

There are limited descriptions of centralized digital research applications in the literature to help guide their development. The ehive app represents such a model that can be used to grow digital health research. Here, we provide an overview of the infrastructure and design of ehive, which was developed to help mitigate many of the limitations that have historically impacted digital studies. This platform has successfully hosted 8 observational studies and clinical trials that include over 1044 participants across 36 states. Such a centralized digital ecosystem fosters the opportunity for conducting digital health research at scale across multiple studies, participant populations, and data modalities.

The advent of the COVID-19 pandemic has highlighted the need to be able to perform research remotely and engage traditionally underrepresented patient populations. The ehive platform represents a model that academic and other institutions can use to meet these needs and grow research opportunities in an increasingly remote and digital world. The modifiability of platforms such as ehive enables multiple types of study that incorporate various data streams to be conducted. This includes opportunities for the digitization of clinical trials, which has been increasingly emphasized by industry and funding agencies, including the National Institute of Health [6,23]. Digital solutions present an opportunity to streamline clinical trial costs, improve efficiency through investigator support, provide novel physiological data streams, and offer new end points. In addition and as demonstrated, they enable expanded study recruitment, compliance monitoring, and enhanced automated retention modalities [24].

Such platforms enable the integration of multimodal data streams, including wearable outputs, biobank specimens (ie, genomic and proteomic biobanks), EHR outputs, and PROMs. The integration of multiple data streams allows data sources to complement each other, amplifying the derived information beyond each individual data stream [25]. The ability of centralized digital research platforms to add multiple data modalities that can evaluate information on different scales results in improved predictive ability and the potential for artificial intelligence and machine learning techniques to unlock novel capabilities. Although this is implemented at scale in large biobanks, such as the United Kingdom biobank or the National Institutes of Health All of Us initiative, centralized digital platforms, such as ehive, enable this performance on a modifiable and tailored basis [26,27]. An additional benefit of a central research app is that capital improvements in the app are translated across studies, thereby optimizing institutional or organizational investment in digital research infrastructure. This allows the entire digital ecosystem to benefit from system upgrades and modifications and avoids the duplication of effort and, thereby, costs that would occur if similar improvements were applied to single-use apps.

However, only limited descriptions of such platforms are available in the literature. Published descriptions of modifiable central digital research platforms focus on specific study types. For example, the StudyU platform is a customizable app that enables clinicians and researchers to design and implement N-of-1 trials. This unique platform is similar to ehive to the extent that it leverages its centralized features to host individual studies that capitalize on central app developments [28]. However, descriptions of fully modifiable centralized platforms that can support multiple studies and study types are lacking. In academics, such platforms include the myPHD app from Stanford University, whereas in industry, the evidations research app and Apple Research app (Apple Inc) have similar capabilities [11,29,30]. However, robust descriptions of their capabilities have not been published.

The modifiability of the ehive research ecosystem enables its evolution and expansion over time. Several future app developments are planned. Given the importance of participant compliance and engagement, ehive updates are focused on maximizing this aspect of the app. A micropayment system is planned, which will allow participants to easily track their study progress and acquire points or monetary compensation after hitting study milestones. This feature will enable the automatic payment of participants through ehive, mitigating the need for study coordinators to track and remit compensation. In addition, an expansion of the patient-facing dashboard is planned. This will enable participants to not only track their wearable data in aggregate but also download their granular wearable data during the study period. This will increase participant engagement with the app, enable participants to share their data with their doctors if needed, and convey the impression that the collected data are being engaged with and used by the researchers. Further scaling of the ehive platform through research collaborations with academic and industry partners as well as through the exploration of platform licensing options is also planned.

A strength of the ehive platform is the ability of individual studies to use existing features or develop new ones. However, this app has several important limitations. Although we have worked to develop light-touch measures to maintain engagement with the app, we still note that participant engagement decreases over time. Although this is a limitation in all studies, ongoing efforts are needed to continually improve how participants interact with the app. Our planned micropayment system and an improved patient-facing dashboard will hopefully further engage participants. Another limitation in studies hosted on ehive is restrictions on data access. Wearable device companies often have limitations on the type and granularity of data that can be accessed. In addition, there can be intellectual property limitations on the downstream uses of these data, which can impact the ownership of the study results and algorithms. This highlights the need for greater collaboration between device companies and health researchers as well as solutions in which raw data access can be obtained for reasonable compensation. An additional limitation is that if study participants do not have automatic updates turned on, the ehive team has to manually reach out to participants to have them update the app. Although this happens infrequently if there is a major app update that impacts a large number of participants, it can be a significant limitation. Finally, there are significant costs related to running and maintaining a centralized research platform that require upfront institutional investment. Although subsequent

XSL•FO
RenderX

app-driven revenue streams can support ongoing operations, the initial development costs often require external support.

Conclusions

The ehive app is a promising proof-of-concept centralized research solution for complex health care systems that see value in building a secure mobile health research platform that can support multiple studies. It is a novel tool that offers investigators the capability to expand their research beyond their institution, engage in large-scale longitudinal studies, and combine multimodal data streams. It serves as a model for groups seeking to develop similar digital health research programs.

Data Availability

The data sets generated and analyzed during this study are not publicly available. This is because the data summaries presented represent the composites of individual datasets from multiple studies. Each study has its own restrictions on data access.

Authors' Contributions

RPH, MD, MZ, and EG developed the study concept. RPH, MD, KL, and MZ assisted with the drafting of the manuscript. RPH, MD, KL, MZ, EG, GO, JR, IE, EA, EB, GNN, TJF, and ZAF critically revised the manuscript for important intellectual content. RPH, MD, KL, MZ, EG, GO, JR, IE, EA, EB, GNN, TJF, and ZAF provided final approval for the version of the manuscript to be published and agree to be accountable for all aspects of the work. All authors approved the authorship list. All authors had full access to all the data in the manuscript and had final responsibility for the decision to submit it for publication. RPH, ZAF, KL, and MD have verified the presented data.

Conflicts of Interest

RPH has served on the advisory board of Bristol Meyers Squibb. EB reports consultancy agreements with Deloitte and Roland Berger; ownership interest in Digital Medicine E Böttinger GmbH, EBCW GmbH, and Ontomics, Inc; receives honoraria from Bayer, Bosch Health Campus, Sanofi, and Siemens; and serves as a scientific adviser or member of Bosch Health Campus and Seer Biosciences Inc. GNN reports employment with, consultancy agreements with, and ownership interest in Pensieve Health and Renalytix AI; receives consulting fees from AstraZeneca, BioVie, GLG Consulting, and Reata; and serves as a scientific adviser or member of Pensieve Health and Renalytix AI. ZAF discloses consulting fees from Alexion, GlaxoSmithKline, and Trained Therapeutix Discovery and research funding from Daiichi Sankyo, Amgen, Bristol Myers Squibb, and Siemens Healthineers. ZAF receives financial compensation as a board member of and an adviser to Trained Therapeutix Discovery and owns equity in Trained Therapeutix Discovery as a cofounder. All other authors declare no other conflicts of interest.

Abstract

Background: The worldwide prevalence of type 2 diabetes (T2D) has increased in the past decade, and it is projected to increase by 126% by 2045 in Africa. At the same time, mobile phone use has increased in Africa, providing a potential for innovative mobile health interventions to support diabetes care.

Objective: This study aimed to apply the Behavior Change Wheel (BCW) framework to develop text messages to influence food literacy in adults with T2D in urban Kenya.

Methods: The 8 steps of the BCW framework guided the development of text messages: (1) Define the problem in behavioral terms; (2) select target behaviors; (3) specify the target behaviors based on who needs to perform the behaviors, what needs to change, and when, where, how often, and with whom; (4) identify what needs to change; (5) identify intervention functions; (6) select policy categories; (7) select behavior change techniques (BCTs); and (8) select the mode of delivery. Recent exploratory studies in Kenya and other low- and middle-income countries provided information that was used to contextualize the intervention.

Results: In step 1, the behavioral problem was defined as unhealthy dietary patterns among adults with T2D. In step 2, based on a qualitative study in the target population, the target behavior was selected to be evaluation of reliable sources of information, and selection and preparation of healthy food. In step 3, unhealthy dietary patterns were selected. In step 4, 10 domains of the Theoretical Domains Framework were identified, and in step 5, 5 intervention functions were linked to the domains and unhealthy dietary patterns were specified. In step 6, communication and regulations were identified as policy categories, while in step 7, 9 BCTs were selected from the Behavior Change Technique Taxonomy version 1. In step 8, the most suitable mode of delivery was determined to be mobile text messages. A total of 36 mobile text messages were developed based on the 9 BCTs.

Conclusions: This study shows the step-by-step application of the BCW framework to develop mobile text messages to influence food literacy in adults with T2D.

Introduction

Worldwide, the prevalence of diabetes has been on the rise in the past decade, with more than half a billion people with diabetes in 2021, of which more than 90% had type 2 diabetes (T2D) [1]. Currently, in Africa, 24 million people have diabetes, and it is projected that this prevalence will rise by 126% to 55 million in 2045 [1]. This projected rise in the African region will be the highest compared to all other worldwide regions [1]. In Kenya, 3% of adults aged 20-79 years have diabetes, with a higher prevalence in urban (3.4%) compared to rural (1.9%) areas [2]. Further, in Kenya, older age (60-69 years) is associated with a higher incidence of diabetes [2]. In addition to the rising prevalence of T2D in Kenya, only 36.6% of patients achieve glycemic control [3]. Glycemic control in diabetes is defined as glycated hemoglobin (HbA_{1c}) levels of <7% (53 mmol/mol) [4]. Poor glycemic control increases the risk of the development and progression of micro- and macrovascular complications in people with diabetes [5]. As such, achieving glycemic control soon after diagnosis is an important goal in the management of diabetes. In addition to diabetes self-management medical actions, a recent prospective analysis showed that optimization of dietary patterns is an effective strategy to achieve glycemic control [6]. Poor dietary quality has been assumed to be associated with a lack of food-related knowledge and skills [7]. However, food literacy has been used to improve dietary behavior associated with healthy dietary patterns [8,9]. Food literacy enables the application of information about food choices and critical reflection on the effect of food choices and has the potential to prevent disease, promote optimal health, and sustain the environment [9,10].

As the prevalence of T2D is on the rise, mobile phone subscription in low- and middle-income countries (LMICs) has been on the rise in the past 2 decades. Recent data show that mobile cellular subscriptions per 100 people in LMICs and Kenya rose from nearly 0% in 2000 to 104% and 123%, respectively, in 2021 [11]. This increase in mobile phone subscriptions in LMICs has resulted in a commensurate rise in the use of mobile health (mHealth) in behavior change interventions [12,13]. Optimization of glycemic control in adults with T2D through a food literacy intervention requires behavior change. Therefore, a systematic approach to developing an intervention and its subsequent implementation and evaluation was used [14]. In this study, we used the Behavior Change Wheel (BCW) framework [15] to systematically develop intervention components. Given that the BCW framework has been used widely to design and evaluate several behavior change interventions [16-20], we used it to develop text messages. Specifically, the BCW framework helps in the systematic identification of target behaviors that need to be changed to improve health outcomes and to select appropriate intervention functions, policy categories, and behavior change techniques (BCTs) based on the analysis of the sources of behavior (capability, opportunity, and motivation) [14].

The BCW is a 3-stage comprehensive framework for designing complex interventions (Figure 1) that integrates behavior theory by using expert consensus and a validation process [14]. The BCW framework has been designed to help understand and select relevant mechanisms of action for an intervention [15]. The BCW framework uses the 3-layered capability, opportunity, motivation for behavior (COM-B) model (Figure 2) to analyze and diagnose behavior. The first, core layer of the COM-B model is further expanded to physical and psychological capability, social and physical opportunity, and automatic and reflective motivation. According to Michie et al [15], core domains are needed to increase the likelihood of performing the target behavior. COM-B is supported by the Theoretical Domains Framework (TDF), which describes 14 constructs from 33 behavior change theories [21]. The second layer of the BCW framework is composed of 9 intervention functions: education, persuasion, incentivization, coercion, training, enablement, modeling, environmental restructuring, and restrictions. These intervention functions indicate how an intervention changes behavior and are linked to a taxonomy of 93 replicable BCTs (Behavior Change Technique Taxonomy version 1 [BCTTv1]) [22]. The third, outermost layer of the BCW framework is composed of 7 policy categories that can be applied to support the delivery of the intervention functions. Although text messaging is increasingly used in health care and the demand for interventions based on theory, existing text messaging interventions often overlook the theoretical basis for their development [23,24]. This study therefore aimed to apply the BCW framework to develop text messages to influence food literacy in adults with T2D in urban Kenya. The specific objectives of this study were to (1) define the problem affecting adults with T2D in behavioral terms, (2) define the intervention and implementation options of the identified target behaviors, and (3) develop text messages to influence food literacy in adults with T2D in Kenya.

Figure 1. Stages and steps in the BCW. Adapted from Michie et al [15]. BCW: Behavior Change Wheel.

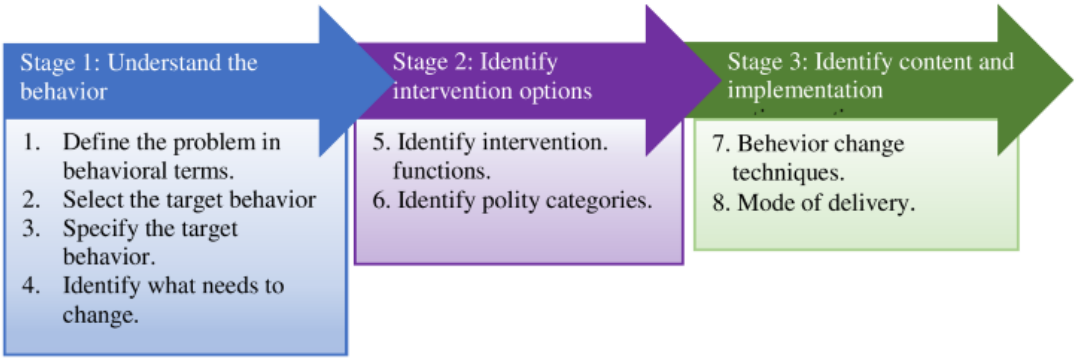

Figure 2. The COM-B model. Adapted from Michie et al [15]. COM-B: capability, opportunity, motivation for behavior.

Methods

Study Design

Developing this intervention involved 3 stages of the BCW framework: (1) understanding the behavior and user preferences, (2) identifying intervention options, and (3) identifying content and implementation options. These stages were further subdivided into 8 steps and are further explained in detail later (Figure 1). The process of intervention development was iterative and was conducted by the research team (authors MM, FK, PY, RV, TB, JLK and CM). The team consisted of dieticians, nutritionists, public health specialists, and an endocrinologist.

Stage 1: Understanding the Behavior and User Preferences

Step 1: Define the Problem in Behavioral Terms

Defining the problem in specific behavioral terms included an in-depth description of the target population and the specific behavior [15]. We used the recent and contextually relevant literature [25-27] to refine our understanding of the target population's dietary behavior to optimize glycemic control from health providers' and patients' viewpoints.

Step 2: Select Target Behaviors

Target behaviors were selected by applying a systems analysis approach, as recommended by Michie et al [15]. First, we used the list of facilitators of and barriers to healthy dietary behavior in adults with TDM from our previous phenomenological qualitative study conducted in Kenya [28]. In that study, 30 male and female respondents were interviewed through mobile telephones, revealing that facilitators of and barriers to healthy dietary behavior are related to food literacy. We ranked the various facilitators and barriers based on the number of thematic nodes (collection of references about a specific theme) generated by NVivo software (Lumivero). Table 1 shows the ranking of thematic nodes.

XSL•FO
RenderX

Table 1. Ranking of thematic nodes.

Food literacy component	Number of nodes	Rank of priority
Plan	42	4
Prepare	60	3
Select	168	2
Eat	171	1

Second, we used the criteria recommended by BCW guidelines to prioritize the target behaviors. The criteria include the following considerations: (1) the relative impact of the behavior, (2) the likelihood of changing the behavior, (3) the potential for spilling over into other relevant dietary behaviors, and (4) the ease of measurement of the behavior. Finally, we categorized each selected behavior as very promising, promising, unpromising but worth considering, or unacceptable based on guidance by Michie et al [15]. These decisions were made by consensus by the expert panel and then tabulated for each selected behavior.

Step 3: Specify the Target Behavior

Step 3 involved specifying the context in which the target behavior will occur by asking specific questions: Who needs to perform the behavior? What needs to be done differently to achieve the change? Where and when do they need to perform the behavior? How often and with whom did they perform the behavior? To answer each of these questions, we used the findings from our qualitative study conducted on the target population [28].

Step 4: Identify What Needs to Change

Step 4 involved 2 substeps: (1) behavioral analysis using the COM-B model and (2) identification of what needs to change using the TDF.

In substep 1 of behavioral analysis, we mapped the specified target behavior from step 3 to the COM-B component and further explored what needed to happen for the target behavior to occur and whether there was a need for change to select and eat food known to contribute to glycemic control.

In substep 2, after determining what needs to change, we linked the behavior that needed to change based on BCW and TDF guidelines [15,29]. The TDF consists of 14 domains: knowledge; skills; memory, attention, and decision processes; behavioral regulation; social/professional role and identity; beliefs about capabilities; optimism; beliefs about consequences; intentions; goals; reinforcement; environment context and resources; social influences; and emotion. The domains identified in this step were tabulated and summarized to include the following aspects for the specified behavior: (1) COM-B component, (2) what needs to happen for the target behavior to occur, (3) whether there is a need for behavior change, (4) the domain linked to the COM-B component, and (5) relevance of the domain.

Stage 2: Identifying Intervention Options

Step 5: Identify Intervention Functions

Intervention functions were mapped onto each of the theoretical domains identified in step 4 [15]. The intervention functions that would most likely affect behavior change were selected based on the COM-B and TDF behavior analyses conducted in step 4. The relevant intervention functions were then assessed using APEASE (acceptability, practicability, effectiveness, affordability, side effects, and equity) criteria of the BCW framework [15]. The assessment included checking how the selected intervention functions meet the 5 components of the APEASE criteria.

Step 6: Select Policy Categories

The policy categories included communication/marketing, guidelines, fiscal measures, regulation, legislation, environmental/social planning, and service provision, which guide decisions made by authorities that help support and enact interventions [15]. We mapped the policy categories onto the intervention functions identified in step 5 using the APEASE criteria [15]. The selection of relevant policy categories was based on the matrix of links between intervention functions and policy categories described by Michie et al [15] and the APEASE criteria. The decisions on the APEASE criteria were informed by our understanding of the context, as revealed by our qualitative study [28].

Stage 3: Identifying Content and Implementation Options

Step 7: Identify BCTs

Based on the intervention functions identified in step 5, we selected BCTs from the BCTTv1 [22] and the APEASE criteria. The BCTTv1 is a standardized terminology used to specify the active ingredients of behavior change interventions and consists of 93 unique BCTs [22].

Step 8: Select the Mode of Delivery

The mode of delivery was guided by the taxonomy of the models of delivery for intervention functions that involved communication. Based on the taxonomy of the models of delivery, we selected the mode of delivery by using the findings from our qualitative study [15,30]. The taxonomy is structured into binary options, where we selected the most practical option using our understanding of the context and the target population [28].

Testing the Feasibility of the Intervention

The BCW guidelines recommend that developed behavior change interventions be tested for feasibility. As such, we were guided by the Medical Research Council (MRC) framework that illustrates the steps to be followed in the development and evaluation of behavior change interventions [31].

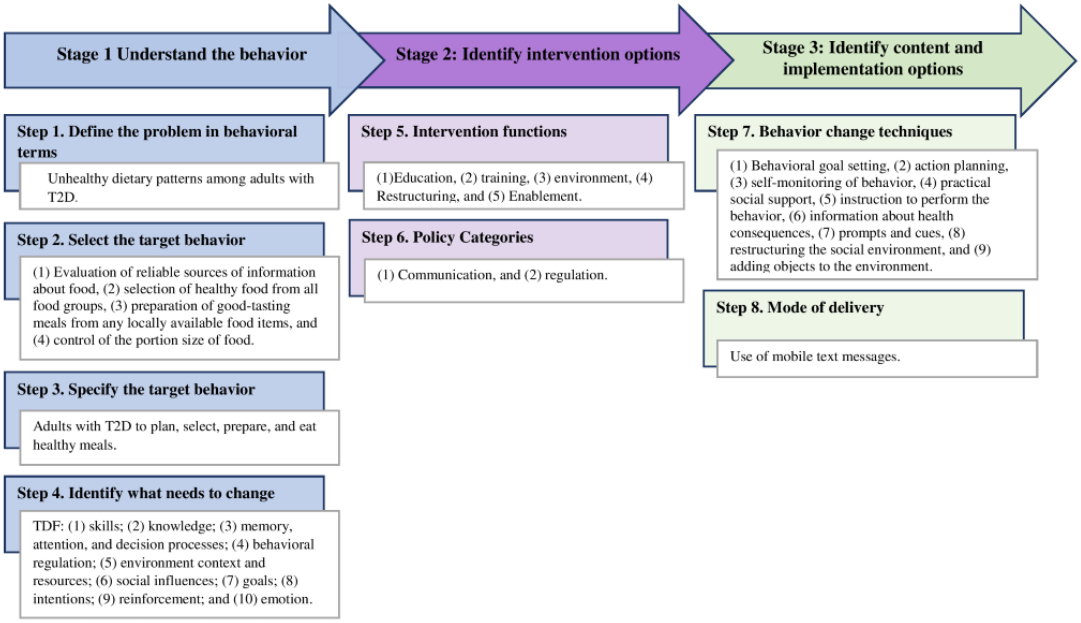
Ethical Considerations



This being a study on the development of text messages to enhance food literacy in adults with T2D, human subjects were not directly involved. However, studies [25,27,28,30] that provided evidence in the development of this study sought ethical approval.

Results

Summary of Findings

Figure 3 summarizes findings from the 8 steps of the BCW framework.

Figure 3. Summary of findings from the steps in the Behavior Change Wheel.

Stage 1: Understanding the Behavior and User Preferences

Step 1: Define the Problem in Behavioral Terms

In defining the problem in behavioral terms, we considered findings from existing evidence in LMICs [25,27] and our previous studies [28,30]. The existing literature, however, is limited by the fact that it was conducted in different settings and that most of these studies lacked the rigor for replication in other settings [26]. Our qualitative study of facilitators of and barriers to healthy dietary behaviors among adults with T2D revealed the following facilitators: knowledge of healthy food choices, gardening, self-efficacy, food preparation skills and eating at home, education by health care workers, food availability, proximity to food-selling points, and family support. The barriers included tastes and preferences of food, health conditions barring the intake of certain foods, random eating of unhealthy food, socioeconomic status, seasonal unavailability of fruits, food safety concerns, and inaccurate beliefs and information about food and diet. In a systematic review of self-management of diabetes in sub-Saharan Africa, which included 43 studies, most of which were observational, there were misconceptions about and gaps of knowledge in what entails healthy food [27]. Further, the review found that interventions on dietary behavior led to relevant improvements in healthy eating habits. Another systematic review of adherence to diabetes self-care behaviors in LMICs found that adherence to dietary recommendations ranged from 29.9% to 91.7%, while consumption of fruits and vegetables averaged 3 times per week, although the portion sizes were not revealed [25]. In summary, the key gaps identified in these studies were related to our qualitative study [28], showing that dietary behavior is associated with food literacy. Food literacy is “the interrelated combination of knowledge, skills and self-efficacy on planning for meals, selecting foods, preparing food, eating and evaluating information about food with the ultimate goal of developing a lifelong healthy, sustainable and gastronomic relationship with food” [32]. Food literacy enables the application of information about food choices and critical reflection on the effect of food choices and has the potential to prevent disease, promote optimal health, and sustain the environment [9,10]. As such, the fundamental components of food literacy can be applied to positively influence behaviors required for healthy diet patterns. In practical terms, food literacy comprises planning, selection, preparation, and eating of food [33]. Based on these findings, we defined the problem in behavioral terms as unhealthy dietary patterns among adults with T2D.

Step 2: Select Target Behaviors

Based on a system analysis, we selected the following as target behaviors: evaluation of reliable sources of information about food, selection of healthy food from all food groups, preparation of good-tasting meals from any locally available food items, and control of the portion size of food (Table 2).

Based on the findings of our qualitative study on the same population [28], we prioritized the target behaviors in Table 3.

XSL•FO
RenderX

Table 2. Identification of target behaviors.

Facilitator/barrier	Contextualized target behavior (components of food literacy) [33]
Access to reliable sources of information about food	Evaluation of information
Access to healthy food from all food groups	Selection of healthy food
Preparation of good-tasting meals from any locally available food items	Preparation of healthy meals
Control of the portion size of food	Eating a healthy diet

Table 3. Prioritization of the target behaviors.

Potential target behavior relevant to improving food literacy	Impact of behavior change[a]	Likelihood of changing behavior[b]	Spillover score[c]	Measurement score and means of measurement[d]
Evaluate reliable sources of information about food.	Very promising	Promising	Very promising	Promising (identify sources of reliable information)
Select healthy food from various sources to ensure varied consumption from all food groups.	Very promising	Promising	Very promising	Promising (proportion of healthy foods accessed)
Prepare healthy and good-tasting meals from locally available food and ingredients.	Promising	Unpromising but worth considering	Very promising	Promising (healthy and good-tasting meals prepared)
Consume a controlled portion size of food.	Promising	Promising	Promising	Promising (number of meals eaten that fit the plate model[e])

[a]Likely impact if the behavior were to be changed.

[b]Ease of likelihood to change dietary patterns.

[c]Likelihood of having an impact on other behaviors that may support a change in dietary patterns.

[d]Measurability either by routine data or through new data collection procedures.

[e]Plate model: a visual method for teaching meal planning, where the dinner plate serves as a pie chart to illustrate the proportions of the plate that should be covered by various food groups [34].

Step 3: Specify the Target Behavior

The target behavior was specified by answering the following questions, as illustrated in Table 4:

- Who? (Adults with T2D)
- Where? (At home or work)
- When? (When planning, selecting, eating, or preparing food)
- How often? (Every time or most of the time during consumption)
- With whom? (Either alone or with the family)

Table 4. Specification of the target behavior.

Specification	Description
Target behavior	Adults with T2D[a] to plan, select, prepare, and eat healthy meals
Who needs to perform the behavior?	Adults with T2D
What is to be done differently to achieve the desired change?	Plan, select, prepare, and eat healthy meals
When is it to be done?	Whenever eating
Where is it to be done?	At home, at work, or away from home
How often do they need to do it?	Every day
To whom do they need to do it?	Alone or with family or friends

[a]T2D: type 2 diabetes.

Step 4: Identify What Needs to Change

Identification of what needs to change was informed by findings drawn from the opinions in our qualitative study [28], in addition to recent and contextually relevant findings from Uganda [26]. Table 4 summarizes what needs to change based on the behavioral diagnosis using the COM-B model. A total of 10 TDF domains were identified: skills; knowledge; memory, attention, and decision processes; behavioral regulation; environmental context and resources; social influences; goals; intentions; reinforcement; and emotion. The behaviors diagnosed were further expanded to illustrate their relevance (Table 5).

XSL•FO
RenderX

Table 5. Behavioral analysis and application of the TDF[a] in diagnosis.

COM-B[b] component and what needs to happen for the target behavior to occur	Is there a need for change?	TDF domain linked to the COM-B component	Relevance of the domain
Physical capability			
Search and access healthy food from all food groups.	Yes	Physical skills	Explain how to search for and access healthy food from all food groups.
Prepare healthy meals using locally available food ingredients.	Yes	Physical skills	Explain how to prepare healthy meals using locally available food ingredients.
Be able to serve controlled portion sizes using the plate model.	Yes	Physical skills	Explain how to serve controlled portion sizes using the plate model.
Psychological capability			
Know how to distinguish between reliable information and myths.	Yes	Knowledge	Create knowledge of various food groups and food sources.
Know where to search for reliable information.	Yes	Knowledge	Create knowledge on where to search for reliable information.
Know various food groups and locally available health food sources.	Yes	Knowledge	Create information on food groups and locally available food sources.
Advanced planning skills to ensure the availability of healthy food.	Yes	Memory, attention, and decision processes; behavioral regulation	Enable action-planning skills.
Know foods to avoid for optimal glycemic control.	Yes	Knowledge	Help in decision-making on the type and quality of healthy food.
Know the composition of the plate model.	Yes	Knowledge	Enable the serving of healthy portions of food.
Physical opportunity			
Be aware of where to get healthy foods (shops, markets, home garden), and establish or maintain kitchen gardens.	No: food is accessible in the target population.[c]	N/A[d]	N/A
Use the mobile phone or computer to search for information, where possible.	No: the proportion of the target population using smartphones or computers is low.[c]	N/A	N/A
Have the necessary cooking equipment.	No: patients commonly cook at home.[c]	N/A	N/A
Use smaller plates when serving food.	Yes	Environmental context and resources	Search and use a smaller plate to serve food.
Social opportunity			
Call health care workers when searching for information.	No: patients have access to health care workers during clinic visits.[c]	N/A	N/A
Challenge cultural beliefs regarding food choice.	Yes	Social influences	Understand that some cultural values are unhealthy.
Awareness to family members involved in meal preparation on the preparation of healthy meals.	Yes: some families provide support to adults with T2D.[a]	Social influences	Social support in the selection, preparation and eating of healthy food.
Change cultural habits regarding food portion size.	Yes	Social influences	Change perceptions on the amount of food to be eaten.
Reflective motivation			
Intend and prioritize seeking clarification of information when needed	Yes	Intentions	Encourage the intention to search for information through reliable sources.

XSL•FO
RenderX

COM-B[b] component and what needs to happen for the target behavior to occur	Is there a need for change?	TDF domain linked to the COM-B component	Relevance of the domain
Establish routines and habits to eat healthy meals	Yes	Goals	Develop routines to eat healthy meals.
Intend to purchase and eat healthy food	Yes	Intentions	Encourage the intention to purchase and eat healthy food.
Plan to cook healthy meals	Yes: The target population cooks most meals at home.[c]	Goals	Plan to cook healthy meals.
Plan to serve healthy portion sizes	Yes	Goals (action planning)	Enable service of healthy portion sizes.
Automatic motivation			
Desire to look for information when in doubt	Yes	Reinforcement	Reinforce the habit of searching for reliable information.
Establish meal plans to ensure the intake of healthy meals	Yes	Emotion	Plan for healthy meals.
Establish routines and habits of serving healthy portions of food	Yes	Reinforcement	Have the desire to serve healthy portions of food.

COM-B component and TDF[c] domain linked to it	Intervention function	Selected BCT
Physical capability		
Physical skills	Train how to search for and access healthy food from all food groups.	Instruction to perform the behavior
Physical skills	Train how to prepare healthy meals using locally available food ingredients.	Instruction to perform the behavior
Physical skills	Train how to serve controlled portion sizes using the plate model.	Instruction to perform the behavior
Psychological capability		
Knowledge	Educate where to search for reliable information.	Information about health consequences
Knowledge	Educate on various food groups.	Information about health consequences
Knowledge	Educate food local foods in various food groups.	Information about health consequences
Knowledge	Educate about food groups and locally available health food sources.	Information about health consequences
Knowledge	Educate foods to avoid for optimal glycemic control.	Information about health consequences
Knowledge	Train on the composition of the plate model.	Instruction to perform the behavior
Behavioral regulation	Train or enable planning for and accessing healthy food.	Instruction to perform the behavior
Memory, attention, and decision processes	Enable the distinction between reliable information and myths.	Information about health consequences
Memory, attention, and decision processes	Enable decision-making on the type and quality of healthy food.	Action planning
Physical opportunity		
Environmental context and resources	Enable environmental restructuring to use a smaller plate to serve meals.	Adding objects to the environment
Social opportunity		
Social influences	Enable environmental restructuring to modify cultural beliefs on food that affect the choice of food.	Restructuring the social environment
Social influences	Enable to challenge sociocultural habits regarding food portion sizes.	Practical social support
Social influences	Enable awareness creation among family members involved in meal preparation on how to prepare healthy meals.	Practical social support
Reflective motivation		
Intentions	Educate how to clarify information, when needed.	Prompts and cues
Goals	Enable establishment routines and habits to eat healthy meals.	Behavioral goal setting
Goals	Enable establishment routines and habits of observing optimal portion sizes when serving food.	Behavioral goal setting
Goals	Enable planning to serve correct portion sizes.	Behavioral goal setting
Goals	Enable planning to cook healthy meals.	Action planning
Intentions	Educate to prioritize the purchase and eating of healthy food.	Self-monitoring of behavior
Beliefs and consequences	Educate on foods to avoid for optimal glycemic control.	Information about health consequences
Automatic motivation		
Reinforcement	Persuade to look for information when in doubt.	Practical social support
Goals	Enable to establish meal plans to ensure the intake of healthy meals.	Practical social support

[a]COM-B: capability, opportunity, motivation for behavior.

[b]BCT: behavior change technique.

[c]TDF: Theoretical Domains Framework.

Step 6: Identify Policy Categories

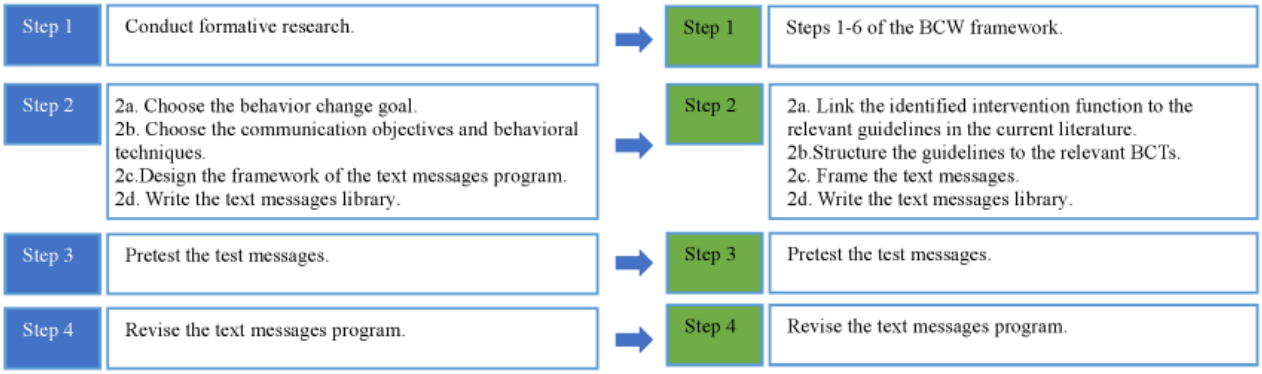
Policy categories were selected based on our qualitative study after analysis using the APEASE criteria: (1) Most participants (90%) had an income of less than 400 euros (US $ 422.27) per month, and this had limited the control of fiscal decisions; (2) all participants owned a basic mobile phone; and (3) the process of developing guidelines by the Ministry of Health in Kenya is

XSL•FO
RenderX

structured and involves multiple stakeholders, making it likely to be limited by time. Based on this, we identified communication and regulation as the most practical policy categories.

Stage 3: Identifying Content and Implementation Options

Step 7: Identify BCTs



BCTs are the "irreducible, observable, and replicable components of an intervention designed to redirect behaviour" [35]. In this study, we selected 9 BCTs from the taxonomy of behavior change [36] to develop intervention content aimed at influencing dietary behavior (Table 5). These BCTs included behavioral goal setting, action planning, self-monitoring of behavior, practical social support, instruction to perform the behavior, information about health consequences, prompts and cues, restructuring the social environment, and adding objects to the environment.

Step 8: Select the Mode of Delivery

Based on findings from our qualitative study [28], most of the adults with T2D in the target population owned and used mobile phones. Additionally, our systematic review revealed that using text messages in LMICs is associated with a clinically significant effect on HbA_{1c} levels, in addition to being cheap and easy to use irrespective of socioeconomic status, and is not affected by racial disparities [30,37,38]. As such, we selected mobile text messages as the mode of delivery [28].

The text messages were developed based on Abroms et al's [39] 4 steps for developing a text messaging program: (1) formative research, (2) design, (3) pretest, and (4) revision. In this study, we modified steps 1 and 2, as shown in Figure 4. Specifically, we modified step 2 to include 3 substeps: (2a) linking the identified intervention function to relevant Kenyan and international guidelines and recommendations for a healthy diet [42-47], (2b) structuring guideline content to the relevant BCT, and (2c) gain- or loss-framing the text message. Gain-framed health promotion messages emphasize the benefits of engaging in a certain behavior, while a loss-framed message emphasizes the consequences of failing to participate in the behavior [46]. The messages were developed through a consultative process that included MM, CM, and FK. Table 7 illustrates a sample of the developed text messages.

Figure 4. Adaptation of the message development. Adapted from Abroms et al [39].

XSL•FO
RenderX

Table 7. Sample text messages to be used in the mHealth[a] intervention.

COM-B[b] components and what needs to happen for the target behavior to occur	BCT[c]	Mobile text messages
Physical capability		
Be able to select healthy food	Instructions on how to perform the behavior	• To meet nutrient needs within calorie limits, choose a variety of nutrient-dense foods across and within all food groups in recommended amounts. Energy-dense foods include vegetables, fruits, whole grains, beans, nuts and seeds, and lean protein when prepared with little or no saturated fats, added sugars, and sodium. • There are 5 food groups: (1) vegetables and legumes or beans; (2) fruit; (3) lean meats and poultry, fish, eggs, nuts and seeds, and legumes or beans; (4) grain (cereal) foods, mostly whole-grain or high-cereal fiber varieties; and (5) milk, yoghurt, cheese, or alternatives, mostly reduced fat. • Most processed carbohydrate foods release glucose more quickly than whole-grain carbohydrates. Eat whole-grain carbohydrates, which produce a slower rise in blood glucose levels, which are called low-glycemic-index (GI) foods and result in better blood glucose control.
Psychological capability		
Know healthy food.	Information about health consequences	• The amount of carbohydrates in your meal has the greatest effect on blood glucose levels. Avoid big servings of carbohydrates in your meals and ensure most of your energy-giving foods are composed of whole meal or high fiber. Make vegetables and fruits take the larger portion of your plate. • There are 2 main types of fat: saturated and unsaturated. Excessive saturated fat in foods, such as fatty meat, sausages, and butter, can increase the amount of cholesterol in the blood, which increases your risk of developing heart disease.
Use advanced planning skills to ensure the selection of healthy food.	Information about health consequences	• Select whole or minimally processed foods, which help control your blood glucose. • Make an eating plan each week: this is the key to fast and easy meal preparation. This will also ensure that you plan for healthy diets and better-controlled blood glucose.
Know the composition of the plate model.	Information about health consequences	• Start with a 9-inch dinner plate. Fill half with nonstarchy vegetables, such as managu, Sukuma wiki, green beans, broccoli, cauliflower, cabbage, and carrots. Fill one-quarter with a lean protein, such as chicken, fish, legumes, beans, or eggs. Fill one quarter with whole-meal carbohydrate foods: grains, starchy vegetables (eg, potatoes and peas), rice, pasta, beans, fruit, and yoghurt. A cup of milk also counts as a carbohydrate food.
Social opportunity		
Change cultural habits on the portion size.	Restructuring the physical environment	• Controlled portion sizes of food are important to reduce calorific intake. To control your portion sizes, plan to use a smaller plate size when serving meals. • Your health is a personal responsibility. When eating, try to avoid places that may entice you to eat excessive food. Eat most of your meals at home for better control of healthy food and your blood sugar.
Reflective motivation		
Intend to select a healthy diet.	Information about health consequences, prompts/cues	• Make your shopping list ahead of time and do not go shopping while hungry. This helps you buy healthier items but also saves money and helps you select healthier foods. • Instead of purchasing processed grade 1 maize flour or Unga that is processed, use posho-milled Unga or whole-meal flour. Posho-milled flour contains fiber and other plant extracts that help in blood sugar control.
Intend to prioritize eating a healthy diet.	Information about health consequences, prompts/cues	• Small changes to more nutrient-dense, single food and beverage choices combine to make a nutrient-dense meal and can lead to a whole day of nutrient-dense meals and snacks, increasing your blood sugar control. • Place fresh and locally available low-carbohydrate fruits on the table or a place that is easy to reach to increase intake of fruits. This will enable you to eat healthy and avoid unhealthy snacking.
Automatic motivation		

XSL•FO
RenderX

COM-B[b] components and what needs to happen for the target behavior to occur	BCT[c]	Mobile text messages
Establish routines and habits to select a healthy diet.	Instructions on how to perform a behavior	• Keep a food diary for a few days to evaluate what you eat every day. Note how you were feeling when you ate: hungry, not hungry, tired, or stressed? Create a list of cues by reviewing your food diary to become more aware of when you're triggered to eat for reasons other than hunger. Is there anything else you can do to avoid the cue or situation? If you cannot avoid it, do something different that would be healthier. Replace unhealthy habits with new, healthy ones.
Establish routines and habits to select a healthy diet.	Prompts/cues	• Replace white rice with whole-grain foods or brown rice. This ensures better blood sugar control.
Establish routines and habits to serve and eat a healthy diet.	Instructions on how to perform behavior	• Eat smaller meals more often. Eat at least 3 meals a day, with snacks in between. When you wait too long to eat, you are more likely to make unhealthy food choices.

[a]mHealth: mobile health.

[b]COM-B: capabilities, opportunities, and motivation for behavior.

[c]BCT: behavior change technique.

Testing the Feasibility of the Developed Intervention

According to the Medical Research Council (MRC) guidance on developing and evaluating complex interventions, the development of an intervention in this study is the first of 4 steps [31]. The other subsequent and iterative steps include feasibility, evaluation, and implementation. Based on this guidance, the intervention has been tested for feasibility through an exploratory trial in the target population, and the findings will be reported elsewhere.

Discussion

Principal Findings

This paper described the systematic development of an mHealth intervention using mobile text messages to optimize glycemic control in adults with T2D in Kenya following the BCW framework. Preparatory analysis preceding this study revealed that adults with T2D in Kenya have unhealthy dietary patterns and lack reliable sources of information to enhance food literacy [28]. The diagnosis also revealed that there are barriers to the target population's capability, opportunity, and motivation relating to food literacy. Based on the diagnosis, 4 intervention functions and 9 BCTs were selected to promote food literacy. Specific BCTs were selected to be integrated into this intervention: for example, adding objects to the environment (eg, using a smaller plate to serve food for portion control) and prompts or cues (eg, replacing white rice with whole-meal foods). The identified mHealth mode of delivery was mobile text messaging based on the practical applicability in the older population of adults with T2D.

When designing this study, we identified food literacy as a channel to address the problem of poor glycemic control. Food literacy has the potential to facilitate dietary behavior change through the connection of food and nutrition-related knowledge, and cooking skills [47]. Considering that food literacy explicitly focuses on health literacy skills in a food context [48], a positive correlation between health literacy and diabetes knowledge has been reported in patients with T2D [49]. Overall, the appropriate application of food literacy is associated with positive health outcomes in adults with T2D.

In this study, we used the BCW framework and contextual evidence to develop text messages for adults with T2D. The approach of basing the development on theory and the content of the text messages on the needs of the target population has been used variedly in recent studies [50-53]. In a recent 2-country African study [50], the BCW framework was used to develop text messages in 4 phases that included exploration of primary and secondary data and focus group discussions (FGDs), which were followed by pretesting through telephone interviews. Bartlett et al [51] developed text messages for patients with diabetes in the United Kingdom based on BCTs in a process that included health care specialist workshops, FGDs, and acceptability and fidelity surveys. MacPherson et al [53] developed text messages guided by BCTs, the motivational interviewing counselling style, and the Small Steps for Big Changes approach [54]. However, unlike our study in which we specifically developed text messages to facilitate food literacy, these studies [50,51,53] have focused on the wider multicomponent approach to diabetes management and prevention. The focused approach in our study was based on evidence showing that food literacy is an important problem in the target population [28], while a multicomponent approach to diabetes care is effective in optimizing glycemic control [55,56].

Strengths and Limitations

We acknowledge some strengths and weaknesses in using the BCW framework in this study. First, this study used contextual data to conduct behavioral diagnosis, which included our qualitative study of facilitators of and barriers to healthy dietary behavior in the target population, as recommended by Buchanan et al [57]. Second, the BCW framework provides a systematic method for designing a theory-based intervention, starting from a behavioral diagnosis of what needs to change, followed by linking the diagnosis to intervention functions, policy categories, and BCTs to change the target behavior. This approach enables the intervention to be contextualized to the needs of the target

XSL•FO
RenderX

population, which increases its chances for success [58]. Third, the BCW framework uses a harmonized language of theoretical constructs and BCTs, which are important for the replication and synthesis of research and evidence [59,60].

However, this study was limited by the BCW framework's lack of a structured framework for operationalizing BCTs into mHealth methods of delivery [61], leaving it open to the creativity of the intervention developers and the context of the target population. However, to address this limitation, we modified previous guidance on the development of text messages [39] and developed messages based on target behaviors following guidelines on healthy diets that are linked to BCTs.

Conclusion

This study reported the systematic use of the BCW framework, the COM-B model, the TDF, and BCTs based on the contextual needs of the target population to develop text messages to influence food literacy in adults with T2D. The efficacy of the text messages will be evaluated through an exploratory trial in adults with T2D in the target population.

Acknowledgments

MM was funded for a PhD scholarship from the Vlaamse Interuniversitaire Raad Universitaire Ontwikkelingssamenwerking (VLIR-UOS; Flemish Interuniversities Council–University Development Co-operation) through an Institutional University Cooperation to the Legume Centre of Excellence in Food and Nutrition Security at the Jomo Kenyatta University of Agriculture and Technology, Kenya (grant number KE2017IUC037A101). The VLIR-UOS was not involved in the conceptualization and interpretation of this manuscript.

Data Availability

The data generated during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

MM and CM selected the approach and designed the intervention. MM, CM, FK, PY, and RV were part of the research team that contributed to the development of the intervention. MM wrote the first draft of the manuscript, while CM, FK, TB, PY, and RV reviewed, revised, and approved the final manuscript. Chatbots and generative artificial intelligence were not used in the conceptualization or any other part of this manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Postoperative complications and readmissions to hospital are factors known to negatively influence the short- and long-term quality of life of patients with gastrointestinal cancer. Active family involvement in activities, such as fundamental care activities, has the potential to improve the quality of health care. However, there is a lack of evidence regarding the relationship between active family involvement and outcomes in patients with gastrointestinal cancer after surgery.

Objective: This protocol aims to evaluate the effect of a family involvement program (FIP) on unplanned readmissions of adult patients undergoing surgery for malignant gastrointestinal tumors. Furthermore, the study aims to evaluate the effect of the FIP on family caregiver (FC) burden and their well-being and the fidelity of the FIP.

Methods: This cohort study will be conducted in 2 academic hospitals in the Netherlands. The FIP will be offered to adult patients and their FCs. Patients are scheduled for oncological gastrointestinal surgery and have an expected hospital stay of at least 5 days after surgery. FCs must be willing to participate in fundamental care activities during hospitalization and after discharge. Consenting patients and their families will choose to either participate in the FIP or be included in the usual care group. According to the power calculation, we will recruit 150 patients and families in the FIP group and 150 in the usual care group. The intervention group will receive the FIP that consists of information, shared goal setting, task-oriented training, participation in fundamental care, presence of FCs during ward rounds, and rooming-in for at least 8 hours a day. Patients in the comparison group will receive usual postoperative care. The primary outcome measure is the number of unplanned readmissions up to 30 days after surgery. Several secondary outcomes will be collected, that is, total number of complications (sensitive to fundamental care activities) at 30 and 90 days after surgery, emergency department visits, intensive care unit admissions up to 30 and 90 days after surgery, hospital length of stay, patients' quality of life, and the amount of home care needed after discharge. FC outcomes are caregiver burden and well-being up to 90 days after participating in the FIP. To evaluate fidelity, we will check whether the FIP is executed as intended. Univariable regression and multivariable regression analyses will be conducted.

Results: The first participant was enrolled in April 2019. The follow-up period of the last participant ended in May 2022. The study was funded by an unrestricted grant of the University hospital in 2018. We aim to publish the results in 2023.

XSL•FO
RenderX

Conclusions: This study will provide evidence on outcomes from a FIP and will provide health care professionals practical tools for family involvement in the oncological surgical care setting.

Introduction

Background

Postoperative complications and hospital readmissions are known to negatively influence the short- and long-term quality of life (QoL) of patients [1]. In addition, complications and readmissions also increase health care demands and costs [2,3]. Readmission rates after gastrointestinal surgery increase up to 30% [4] and are higher compared with general surgery in that these rates range from approximately 4% to 11% [5,6]. In addition, complication rates after gastrointestinal surgery are 34% [7], which is approximately 3 to 8 times higher compared with general surgery [8,9]. Frequent complications in this patient population include delirium, pneumonia, and wound infections [7]. Reducing these readmissions and postoperative complications in patients undergoing oncological gastrointestinal surgery is a priority.

Some postoperative complications are potentially preventable [10]. Several studies have shown that optimizing basic care by executing fundamental care activities prevents postoperative complications, such as pneumonia, urinary tract infections, and delirium [10-12]. Fundamental care activities include early mobilization, breathing exercises, dental hygiene, orientation in time and place, and eating together [13]. Although fundamental care seems simple, it is prone to be missed care [13,14].

The authors of a systematic review of 18 studies concluded that up to 75% of nurses omitted some kind of fundamental care tasks [15]. In a recently published meta-review of 7 systematic reviews, the following categories of missed nursing care were identified: (1) fundamental physical care; (2) communication and information sharing with patients and families; (3) self-management, autonomy, and education of patients and families, including care planning, discharge planning, and decisions; and (4) emotional and psychological care, including spiritual support [14]. Poorly executed or missing aspects of this care threaten patients' QoL and satisfaction, resulting in higher numbers of adverse outcomes and poor care experiences [13,14].

After hospital discharge, family caregivers often play an important role in the delivery of fundamental care activities to patients with cancer [16]. However, family caregivers often feel unprepared to deliver proper care of their loved ones after discharge, and they also feel that they lack the necessary skills and knowledge [17]. This might be because family caregivers are often considered visitors during patients' hospital stay and are sidetracked [18]. Thus, family caregivers are not normally actively involved in postoperative care during hospitalization.

Despite the uncertainty that family caregivers experience, in the past few decades, family-centered care (FCC) has been shown to potentially improve the quality of health care [13,19-21]. Family caregivers have become important care partners who are able to participate in all aspects of care delivery [22,23]. For instance, studies in which family caregivers were actively involved in performing fundamental care activities during hospital admission have shown a reduction in postoperative complications such as delirium and pneumonia [12,24]. The authors of a review of systematic reviews concluded that FCC could be an effective approach for improving the quality of health care, but there was a lack of high-quality studies investigating the effectiveness of FCC [25].

Family caregivers might be better prepared to deliver adequate care to their loved ones after discharge if they are involved in fundamental care during hospitalization, which could also lead to improved adherence to these care activities. Therefore, the incidence of complications and related readmissions might decrease. To promote active family involvement, we developed a multicomponent family involvement program (FIP) in which family caregivers could be actively involved in caring for their loved ones during hospitalization after oncological gastrointestinal surgery [26]. In a pilot study, our FIP was shown to be feasible for patients, family caregivers, and health care professionals [16,27]. In addition, family caregivers had a better understanding and knowledge of their loved one's recovery process [27].

Objectives

Although the results of our pilot study on the FIP were promising, the lack of evidence on the relationship between family involvement and outcomes in patients with gastrointestinal cancer after surgery points to the need for a prospective cohort study. Therefore, the main objective of this study is to evaluate whether FIP for adult patients undergoing oncological gastrointestinal surgery reduces the number of unplanned readmissions compared with usual care. The secondary aims are to evaluate the effect of the FIP on family caregivers by assessing caregiver burden and family caregivers' well-being and to assess the fidelity of the FIP. Here, we describe the study design and summarize the study protocol, which may also provide practical tools for health care professionals to adopt a more family-centered approach.

Methods

Study Design

This study is known by the acronym "ARTIS," which stands for Activating Relatives to Get Involved in Care After Surgery.

XSL•FO
RenderX

The ARTIS study is a patient preference multicenter prospective cohort study. The study protocol described here is reported according to the applicable criteria of the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) [28] and the Template for Intervention Description and Replication (TIDieR) [29]. The results of this study will be reported according to the Strengthening the Reporting of Observational Studies (STROBE) [30].

Study Setting

The study will be conducted at 5 surgical wards that provide care to patients after oncological gastrointestinal surgery in two Dutch tertiary university hospitals in the Netherlands: (1) Amsterdam University Medical Center (UMC), location Academic Medical Center (AMC) and Vrije Universiteit Medical Center, Amsterdam, and (2) University Medical Center Groningen (UMCG), Groningen. The average number of patients undergoing oncological gastrointestinal surgery as treatment for malignant pancreatic, gastric, esophageal, liver, colorectal, or peritoneal tumors in Amsterdam UMC is 415 per year and in UMCG 330 per year. Each participating surgical ward has 25 to 30 beds with a nursing:patient ratio of either 1:4 or 1:5. The participating wards were chosen because health care professionals expressed a willingness to adopt a more family-centered approach to their care.

Eligibility Criteria

Patients

In this study, we will include adult patients (≥18 years) scheduled for gastrointestinal surgery as treatment for malignant pancreatic, stomach, esophageal, liver, colorectal, or peritoneal tumors. The expected hospital stay must be at least 5 days after the operation, which makes adequate training and coaching of family caregivers under the supervision of nurses possible. Furthermore, patients will have to be able to read and write the Dutch language and will be included after providing written consent. Patients will be excluded if they remain in the intensive care unit (ICU) for >72 hours directly after surgery, as family caregivers do not have the opportunity to be involved in care in the first 5 days after the operation. In addition, patients will be excluded if the tumor is considered unresectable during surgery, as these patients do not receive the intended surgery and are discharged after one day.

Family Caregivers

The eligibility criteria for adult family caregivers are that they are willing and able to deliver fundamental care during hospitalization (for a minimum of 8 hours per day) and after discharge (if needed). Furthermore, they should be nominated as the appointed family caregiver by the patient and should not require support from health care professionals to carry out their own self-care activities. Furthermore, family caregivers will have to be able to read and write the Dutch language and will be included after providing written consent. In this study, family caregivers could be relatives or close friends who know the patient and either live with or are involved in the care of the patient. They are individuals who provide support and with whom the patients have a significant relationship.

Intervention

Overview

The FIP is a multicomponent intervention developed using a multiphase quality improvement design [26]. The main components of the program are as follows: (1) active involvement of family caregivers and (2) training and coaching of health care professionals in the FCC. The development process and rationale of this program have been described in further detail by Eskes et al [26]. The FIP is performed in addition to the usual postoperative care.

Component 1: Active Involvement of Family Caregivers

For the first component, multiple tasks involving families in fundamental care activities are described.

Invite Family Caregivers to Participate in Fundamental Care Activities

To standardize FIP delivery, family caregivers will be asked to participate in evidence-based fundamental care activities (Textbox 1). In addition, family caregivers can participate in optional care activities (Textbox 2).

Textbox 1. Fundamental care activities executed by family caregivers.

- Three times a day
  - Mobilization defined as getting a patient out of bed (ie, sitting out of bed and ambulation) [12,31-33]
  - Encouraging oral intake and companionship during meals (ie, breakfast, lunch, and dinner) and ensuring that patients are seated at the table when meals are served [11,32]
  - Supporting patients in doing breathing exercises (ie, coughing and deep breathing) [12,34,35]
  - Supporting active orientation; specific time-, place-, and person-related information in the context of the present day; and daily discussions on actual items (eg, news) [31,32]
- Two times a day
  - Supporting in carrying out oral care (brushing teeth and using mouthwash) [12,34,35]

XSL•FO
RenderX

Textbox 2. Optional care activities executed by family caregivers.

- General care
  - Washing and dressing of the patient
  - Assistance with the use of the toilet
- Wound-related care
  - Wound dressing
- Administering medication
  - Injecting anticoagulation
- Drain-related care
  - Taking care of abdominal drains
  - Taking care of nasogastric tubes

Information About Fundamental Care Activities

Family caregivers who participate in the FIP will gain access to a mobile app (so-called "Mantelzorgapp") before patients' hospital admission. The app has detailed descriptions of the following: (1) the rationale for performing the fundamental care activity, (2) preparation for the activity, (3) the needed material for the activity, (4) a step-by-step description on how to perform the activity, and (5) time and frequency of performing the activity. The app also includes a daily diary in which the family caregivers tick boxes if they have performed a fundamental care activity (yes or no) with writing space for comments. Furthermore, the app includes discharge information, such as whom to contact if they have concerns about patients' health condition. The app can be downloaded without any cost from the Apple Store (Apple Inc) and Google Play Store (Google LLC) and is suitable for several mobile devices (ie, phones and tablets). If family caregivers are unable to use the app, they will receive paper-based information.

Shared Goal Setting With the Patient, Family Caregiver, and Nurse

On the basis of mutual agreement among the patient, the family caregiver, and the nurse, a personalized plan for the patient and family caregiver will be made within 24 hours after the surgery. This plan includes the patient's care needs and personal goals of the family caregiver. This plan will be documented in the electronic patient record. Active participation will start on the first day after surgery in the ward (or within 72 hours in case of ICU admission) and will be continued for at least 5 days after surgery. After this period, the family caregivers choose whether or not to continue the program. We plan to work with the same family caregiver throughout the study period. However, if there are multiple family caregivers, we will recruit a maximum of 3 family caregivers who are available and interested. These family caregivers need to alternate during admission, and each family caregiver needs to be involved in the FIP for a minimum of one day.

Task-Oriented Training of Family Caregivers to Deliver Fundamental Care Activities

During the FIP, the family caregiver will receive training from a registered nurse. All the activities will be supervised by the nurse until the family caregiver is competent, as determined by the nurse, to carry out the activities on their own. To facilitate adequate care delivery, the objective of each activity, including instructions on how to deliver the activity, is described in full detail and accessible in the app. If the activity is carried out, the family caregiver registers it on the registration form in the app. Additional activities will also be recorded in the app.

Physical Proximity (Rooming-in)

Family caregivers are asked to stay with the patient for at least 8 hours per day during the first 5 postoperative days, which offers the opportunity to learn and become competent in new fundamental care activities under supervision. As most of these activities should be undertaken 3 times a day, presence of at least 8 hours provides them with the opportunity to complete these activities.

Presence of Family Caregivers During Medical Ward Rounds

Family caregivers are encouraged to be present and to be actively involved during medical rounds. Health care professionals (eg, doctors and nurses) will support the family caregivers throughout the hospital stay, answer questions related to the FIP, and identify unmet needs.

Component 2: Training and Coaching of Health Care Professionals

To support the delivery of the FIP, structured training sessions will be given to doctors and nurses. The training will mainly focus on the four core concepts of FCC: (1) dignity and respect, (2) information sharing, (3) participation, and (4) collaboration [26]. In the session, the rationale, goals, and benefits of the FIP and the concept of passive and active family involvement will also be explained. In addition, quality- and safety-related topics will be discussed. The training session will be delivered by one of the members of the research team.

XSL•FO
RenderX

Usual Postoperative Care

Patients in the usual care group will receive care based on the Enhanced Recovery After Surgery principles, which include early mobilization, early postoperative feeding, goal-directed fluid therapy, and nonnarcotic analgesia [36]. In addition, patient engagement and a multidisciplinary team approach to the usual postoperative care will be used [36]. Patients will receive care pathways for their specific type of surgery in which day-to-day targets are provided, which promotes autonomy and cooperation from the patients. Patients are encouraged to actively mobilize from the day of surgery until hospital discharge (ie, stay out of bed for 2 hours on the day of surgery and at least 6 hours per day from the first postoperative day until hospital discharge). The patients will not receive detailed information about the content of the FIP. No rooming-in opportunities will be offered to the usual care group, except for family visits (ie, a maximum of 2 visitors at the patient's bedside between 11 AM and 8 PM will be permitted).

Outcomes

The primary patient outcome is the number of unplanned readmissions up to 30 days after surgery (Table 1). Secondary outcomes include the total number of complications at 30 and 90 days after surgery and the number of complications sensitive to fundamental care activities (eg, pneumonia, urinary tract infection, wound infection, deep vein thrombosis, malnutrition, and delirium) at 30 and 90 days after surgery. These data will be collected from patient records, and complications will be classified according to the revised version of the Clavien-Dindo classification system [37]. Secondary outcomes also include emergency department visits, ICU admissions up to 30 and 90 days after surgery, and hospital length of stay. Furthermore, patients' QoL will be measured using the EQ-5D-5L [38], and the level of anxiety and depression in patients will be measured using the Hospital Anxiety and Depression Scale (HADS; Table 1) [39,40]. Patient satisfaction with care and sleep quality will be measured using the numeric rating scale (NRS) ranging from 0 to 10, with higher scores indicating higher satisfaction or sleep quality (Table 1). Sleep quality will be assessed once a day, from the first day after surgery until 5 days after the operation. In addition, the amount of home care (in hours per week) after discharge will be measured (Table 1). The risk screening scores routinely measured during hospital admission will be collected, ie, the Short Nutritional Assessment Questionnaire score (SNAQ) [41], the Delirium Observation Scale score (DOS) [42], the Braden scale [43], the Amsterdam UMC Extension of the John Hopkins Highest Level of Mobility scale score (AMEXO) [44] and the John Hopkins Fall Risk Assessment (JHFRAT; Table 1) [45].

In addition to the effect of the FIP on patient outcomes, we measured the effect of the FIP on family caregiver outcomes, including caregiver burden and well-being up to 90 days after participating in the FIP (Table 1). The Valuation of Informal Care Questionnaire (iVICQ) measures objective burden using the following items: duration and intensity of informal care, patient health, need for permanent surveillance, patients' living situations, and use of professional care [46]. Subjective burden will be measured using the Caregiver Strain Index plus (CSI+) [47], self-rated burden scale [48], and perseverance time [49]. The well-being of family caregivers will be measured using the Care-related Quality of Life instrument (CarerQoL-7D) and Care-related Quality of Life–Visual Analog Scale (CarerQoL-VAS; Table 1) [50]. Finally, the costs of the FIP will also be measured using the iVICQ [46].

To measure adherence, which is considered a bottom-line measurement of intervention fidelity [51], we will record how many patients are offered the FIP and how many patients decline, including the reasons if they want to disclose. We will use the data recorded by family caregivers to assess the fidelity of the intervention. Up to 5 days after surgery, family caregivers will be asked to record the fundamental and optional care activities they have carried out in the app, and if not completed, to add a reason. The family caregiver registers the activity on the registration form of the app. If multiple family caregivers participate in the FIP, they will all be asked to record the executed activities. Rooming-in of the family caregivers during admission will be checked by ward nurses and researchers (SM, SK, and HWH).

[n]CarerQoL-VAS: Care-related Quality of Life–Visual Analog Scale.

Study Procedure

During the preoperative outpatient clinic visit, the patients and their family caregivers will be screened for eligibility and informed about the study (Table 2). If they are interested, a researcher (SM, SK, or HWH) will contact the patients after the visit to determine their preference for the study arm. If patients prefer the intervention arm, at least 2 days before hospital admission, the researcher will confirm the patients' participation depending on the ward capacity. The FIP starts <72 hours after surgery when patients are transferred from the postanesthesia care unit to the participating surgical wards. Depending on the ward capacity and patient preferences, the program can be continued until discharge. During the follow-up period (ie, 30 and 90 days after surgery), the patient and family caregiver will be contacted by telephone by SM, SK, or HWH and asked to complete the questionnaires.

Table 2. Study procedure.

Timing	Activity
Prehospital admission[a]	
Outpatient clinic visit	• Recruitment of patients and family caregivers, screening for eligibility, and informed consent procedure • Group allocation based on patient and family preferences
1 week before hospital admission	• Patients and family caregivers from the intervention group will get access to the mobile app (so-called Mantelzorgapp)
2 days before admission	• The researcher will confirm the patients' participation in the intervention group depending on the ward capacity
Clinical phase[b]	
Within 24 hours after surgery	• Family caregivers will receive a personalized plan based on the identified patients' care needs, and the plan includes the personal goals of the family caregiver • Goals will be documented in the electronic patient record • Patients and family caregivers will complete questionnaires about their baseline characteristics
Day of surgery until 5 days after operation	• Family caregivers start by participating in the fundamental care activities (and optional care activities) • Family caregivers will register all activities in the app. • Depending on the ward's capacity and patients' preferences, the program could be continued until discharge
At discharge	• Patients and family caregivers will complete discharge questionnaires
After discharge	
Follow-up 30 days and 90 days after discharge	• The researcher will send questionnaires to patients and family caregivers for measuring outcomes • The researcher will contact the patient and family caregiver by telephone for outcome measures not mentioned in the questionnaires • The researcher will collect data on the number of readmissions and complications as registered in the electronic patient record

[a]Information about the FIP.

[b]The required clinical data regarding baseline characteristics and outcomes will be collected during hospitalization using standardized case report forms.

Allocation

Participation in the FIP is based on the preferences of patients and, if available, their family caregivers. This means that when the patients and their relatives want to participate in the program, they will be allocated to the intervention group and when the patients or their relatives do not want to participate in the program (but give consent for observation in the usual care group), they will be allocated to the usual care group. By using this patient preference study design, we might introduce

XSL•FO
RenderX

contamination between the intervention and comparison groups, as patients in the comparison group might learn about fundamental care activities and adopt them themselves or receive informal care without the program. Nevertheless, this study design was selected deliberately because no clear signs of contamination were observed between the study groups in the pilot study [16]. To minimize the risk of between-group contamination, the information for patients and their families before inclusion will not include detailed information about the fundamental care activities that comprise the program.

Sample Size

The sample size is based on the primary objective of evaluating the effects of the FIP on unplanned readmissions. In our pilot study, we found an absolute reduction of unplanned readmission rates of 15% [16] and considered this 15% reduction of unplanned readmissions as clinically relevant, representing a readmission rate of 20% in the intervention group and 35% in the usual care group. To detect a 15% reduction in readmission rates at a 5% significance level (α) and a power of 80% ($1 - \beta$), a sample size of 136 patients per group is necessary, using a continuity-corrected chi-square test. We assume a 10% to 20% loss to follow-up (ie, not completing the questionnaires), and to compensate for this, the total sample size per group will be at least 150. Loss to follow-up is expected owing to the use of repeated questionnaires, which may burden patients. Recruitment ends as soon as both the groups have included 150 patients. To minimize attrition, we will collect detailed contact information and offer patients alternative data collection methods such as paper-based questionnaires if patients do not have an email address [52].

Data Collection Methods

Patients

At baseline, the following patient characteristics will be collected from the patient records: sex [53], age [53], length in cm, weight at admission in kg [54], BMI in kg/m^2 [54], WHO performance status [55], American Society of Anesthesiologists Physical Status Classification (ASA PS Classification) [55], use of ≥5 medicaments [56], preoperative diagnosis, tumor type, type of surgery (ie, open, minimally invasive, or robot-assisted), and type of resection. In addition, the risk screening scores (ie, SNAQ, DOS scale, Braden scale, AMEXO, and JHFRAT) will be collected on the day of hospital admission. The number of days spent in the postanesthesia care unit will be collected from the patient records.

Furthermore, socioeconomic data will be collected via a patient questionnaire on the day of admission, including the highest level of formal education, marital status, number of children (≤18 years), and number of live-in children, hours per week of unpaid work and paid work [53]. The degree of social isolation before admission could be a potential confounder, as it is known that socially isolated patients have worse outcomes [57] and will therefore be measured using the Friendship scale [58].

Family Caregivers

On the day of admission, baseline characteristics of the family caregivers will be collected using the iVICQ [46]. Background characteristics include sex, age, educational level, relationship between family caregiver and patient, household composition, unpaid and paid work, monthly net household income, and health status.

Data Management

Patient data will be entered into a web-based data management system (Castor Electronic Data Capture, version 2022.4.1.3), which complies with all applicable laws and regulations. Family caregivers' data will be entered into an online protected database connected to the app. If family caregivers are unable to enter their data into the app, we will provide written case report forms. Participants are assigned a study number but can be identified in the database by their ID number. The participation identification log will be kept separate from the patient data and will be safeguarded by the principal investigator. For the participating centers, a separate site-specific subject identification log will be kept at each study site.

The integrity of both patients' and family caregivers' data will be protected through a variety of mechanisms. Valid rules, range checks, and consistency checks against stored data will be supported. Access to the study data will be restricted, and a password will be used to control access. For the online database, 2-faced authentication is needed for access. Access to the app for family caregivers is password protected, which prevents the user data from being revealed if the device is stolen. Castor data will be stored on certified servers (ISO 27001, ISO 9001, and NEN 7510) as well as app data (ISO 27001 and NEN 7510). Data will also be stored locally in the department's computer system drive. All hard-copy original study forms will be stored in a secure and accessible place. Files will be stored for 15 years after completion of the study. This study will not be monitored because the potential risk to patients participating in the study is negligible.

Statistical Methods

Overview

Statistical analyses will be performed using the R statistical software package (version 3.6.2; R Foundation for Statistical Computing). Descriptive statistics will be used to summarize the baseline characteristics and process outcomes of the patients and family caregivers. Continuous variables will be presented as means and SDs or medians and IQRs according to the distribution of the variables. Categorical variables will be presented as counts and percentages (%), and numbers and frequencies will be presented for dichotomous data. The distribution of variables will be determined by inspecting histograms and box plots.

The patients' baseline characteristics of the study arms will be tested for statistically significant differences using the chi-square statistics, Mann-Whitney *U* test, independent samples 2-tailed *t* test, or Fisher exact test. If there are differences between the FIP and treatment groups, we will adjust for confounding variables using multivariate regression analyses.

Outcomes

Univariable regression and multivariable regression analyses will be conducted using stepwise backward selection. For the

XSL•FO
RenderX

primary outcome (ie, unplanned readmissions up to 30 days after surgery), we will conduct logistic regression analyses. For continuous secondary outcomes, we will use linear regression analyses; for dichotomous outcomes, we will use logistic regression analysis. We will use a general linear mixed model to analyze differences in sleep quality, DOS scores, and AMEXO scores over 5 days after the operation (Table 1). If a difference is observed, a post hoc power analysis will be used to examine which time point differs significantly. A 2-sided *P* value ≤.05 will be considered statistically significant. A 95% CI for the beta coefficient (β) will be calculated.

Additional Analyses

In this study, some additional analyses will be performed. We will analyze whether performing one or more optional care activities (Textbox 2) and the involvement of multiple family caregivers per patient can modify patient outcomes. Furthermore, in a sensitivity analysis, we will compare outcomes from patients in the FIP study arm to those from the comparison group whose family caregivers decline to participate in the FIP. The analysis will be based on intention-to-treat principles, meaning that every patient and family caregiver will be analyzed in the group that they chose before surgery.

Handling of Missing Data

If >40% of the missing data in the data set occur, multiple imputation by the chained equations method in R will be used [59,60]. Overall, 5 independent copies of the data will be analyzed. The estimates of the variables will be pooled according to Rubin rules. The pooled analysis will be presented. A complete case analysis will be performed as sensitivity analyses [60]. If >40% of the data are missing, we will use the observed data and report the extent of the missing data [59].

Ethics Approval

The Medical Ethics Review Committee (METC) of the Amsterdam UMC (location AMC), Amsterdam, the Netherlands, approved the study. The METC reviewed the study protocol and concluded that the Medical Research Involving Human Subject Act did not apply to this study (reference number METC: W19_497#20.015). Written informed consent will be obtained from all the participants.

Results

The first participant in this study was enrolled in April 2019 at the Amsterdam UMC, AMC. The follow-up period of the last participant ended in May 2022. The study was funded by an unrestricted grant of the University hospital in 2018. We aim to publish the results at the end of 2023.

Discussion

Principal Findings

Currently, FCC is becoming more widespread in hospital environments [25]. However, there is still a lack of rigorous evidence regarding the effects of FCC interventions and programs [19]. This multicenter cohort study allows us to evaluate the effect and process of an evidence-based multicomponent FIP in comparison with the usual postoperative care in patients undergoing oncological gastrointestinal surgery. We hypothesize that the number of unplanned readmissions and complications could be reduced by the FIP without increasing caregiver burden.

Before we planned this substantial evaluation of the FIP, we followed a stepwise approach guided by the Medical Research Council framework, as the FIP can be considered a complex intervention [61]. The development phase of the FIP began in 2015. First, we developed an evidence-based and theoretically grounded program [26]. This phase was followed by testing program feasibility in a pilot study, which gave us input about the required sample size [16]. In addition, we evaluated the experiences of family caregivers who participated in the FIP in a qualitative study [27]. The results of the second phase were used to develop the intervention study in which we aimed to assess the effectiveness of the FIP. We initiated a randomized controlled trial (RCT; Dutch Trial Register: NL66712.018.18). However, after consenting, many patients and families mentioned a strong preference and withdrew from both groups directly after randomization, stating in their reasoning that they either be involved as participating family caregiver or not. Continuing the trial would have probably led to high dropout rates and, therefore, decreased the generalizability of results to clinical practice [62].

To deal with the strong preferences of patients and their families, we considered changing the design to a patient preference trial. These trials have been introduced to give patients the opportunity to participate in the study arm they prefer [63,64] and have the main advantage of a lower risk of bias, especially in subjective outcome measures, and a decrease in dropout rates [64]. A consequence of choosing this study design is that it requires a very large sample size when a considerable number of patients have a preference for one particular study arm [64] and that it still needs a group of patients (and families) without preferences who want to be randomized, which appeared not to be the case in our study. Therefore, the best available option was to change the design to a patient preference observational cohort study, which is considered a valuable alternative when an RCT does not meet patients' preferences [65].

Nevertheless, we realize that this patient preference study design still influences the external validity. Eligible patients without an available family caregiver cannot participate in the FIP, and most probably, a substantial number of patients need to decline this opportunity. On the basis of our previous work, we expect that this will be the case in approximately 20% of the patients and another 15% of the family caregivers are expected to decline participation [16]. Therefore, it is essential to compare as many prognostic variables as possible between the 2 groups to assess baseline comparability, including patients' perceived social isolation and living status [66].

Implementation of FIP

By conducting this study, we will gain a better understanding of the behaviors of patients, families, and health care professionals that need to be changed and which implementation strategies are valuable to achieve this change. This input is needed to implement the results after finishing our cohort study

XSL•FO
RenderX

and to guide other organizations also in implementing the FIP. In the pilot study, we developed an implementation plan using Grol and Wensing model [67] that facilitates changes in health care using a stepwise approach. On the basis of the implementation recommendations derived from our pilot study, we implemented our FIP in this cohort study. A summary of our implementation recommendations and lessons learned were published in the article by Schreuder et al [16]. An understanding of how the FIP was implemented by assessing the adherence to the FIP, the bottom-line measurement of intervention fidelity [51], will provide valuable insights when interpreting the effects of the FIP [51].

A potential challenge for implementing the FIP is that it requires health care professionals to accept an FCC approach [21]. This is considered a challenge because some health care professionals may not yet regularly engage patients' family caregivers in their daily practice [21]. Therefore, training and coaching health care professionals in the FCC is an essential component of FIP. Based on our pilot study, acceptable levels of time investment by doctors and nurses were found, and for most nurses, the workload was reduced to some extent [16]. Furthermore, most doctors value the presence of family caregivers during medical ward rounds [16]. Because of the positive experiences of health care professionals during the pilot phase of the study, we did not investigate their experiences again in this study. Nevertheless, one should be aware that work role conflicts because of having family caregivers involved in care are associated with nurses' distress and impaired quality of care [68]. In addition, one should be aware that some patients and health care professionals might view the FIP as an economical solution, replacing nurses with family caregivers rather than trying to improve health care [69,70].

Conclusions

In conclusion, this study will provide health care professionals important information about the relationship between a multicomponent FIP and outcomes in a broad group of patients with cancer undergoing surgery and their family caregivers. The FIP, which consists of evidence-based fundamental care activities for family caregivers, will provide practical tools for health care professionals to adopt a more family-centered approach. Future research should focus on the implementation strategies of FCC, choosing study designs that deal with patient preferences in complex interventions and involving patients when designing studies.

Acknowledgments

The members of the ARTIS Consortium are as follows: Marc M.G. Besselink MD PhD, Chris A. Bakker RN, Rosanna van Langen MSc, Marjan Ouwens RN, Joyce Janssen RN, Barbara L. van Leeuwen MD PhD, Maarten de Jong RN, Rommy Hoekstra RN, and Reggie Smith RN.

The study has received internal funding from the Amsterdam University Medical Center (UMC). The authors would like to thank the nursing and medical staff from the participating wards for their willingness to support the family caregivers in postsurgical care. The authors would also like to thank the following people: Eveline Beem (research assistant, Amsterdam UMC, Academic Medical Center), Michiel Pardieck (registered nurse, Amsterdam UMC, location Vrije Universiteit Medical Center), and Eline Blaauw (medical student, University Medical Center Groningen) for their contribution to data collection and processing in this study; Mariken Horst, RN MSc, and Charlotte Heidsma, MD PhD, for temporarily coordinating this study during the start-up phase; Mariëlla Hoogendoorn, head nurse orthopedic ward Amsterdam UMC, AMC, for her support and flexibility in the PhD trajectory of Selma Musters.

Data Availability

The data sets generated and analyzed during this study are not publicly available because they involve sensitive human research participant data but are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Heart disease and stroke are major and often unheralded causes of serious morbidity and premature death in middle age. Early detection of those most at risk is an urgent unmet need for instituting preventative measures. In an earlier community study (Canterbury Health, Ageing and Life Course [CHALICE]) of healthy people aged 50 years, contrary to previous reports, low levels of the heart hormone B-type natriuretic peptide (BNP) were associated with reduced measures of heart function and higher markers of vascular risk. A specific gene variant (rs198358) was found to be an independent contributor to higher BNP levels. A closely related vascular hormone (C-type natriuretic peptide [CNP]) showed opposite associations—higher levels were correlated with higher vascular risk and reduced cardiac function. To determine whether these novel findings predict serious heart or vascular disease in later life, this proposal re-examines the same CHALICE participants 15 years later.

Objective: The primary objective is to determine the predictive value of (1) low plasma concentrations of the circulating cardiac hormones (atrial natriuretic peptide [ANP] and BNP) and (2) high levels of the vascular hormone CNP at age 50 years in detecting impaired cardiac and vascular function 15 years later. Secondary objectives are to determine specific associations of individual analytes (ANP, BNP, CNP, cyclic guanosine monophosphate [cGMP]) with echo-derived changes in cardiac performance at ages 50 years and 65 years.

Methods: All of the 348 participants (205/348, 58.9% female; 53/348, 15.2% Māori or Pacifica ethnicity) participating in the original CHALICE study—free of history of heart or renal disease at age 50 years and who consented to further study—will be contacted, recruited, and restudied as previously described. Data will include intervening health history, physical examination, heart function (speckle-tracking echocardiography), vascular status (carotid intimal thickness), and genetic status (genome-wide genotyping). Laboratory measures will include fasting blood sampling and routine biochemistry, ANP, BNP, CNP, their downstream effector (cGMP), and their bio-inactive products. Humoral metabolic-cardiovascular risk factors will be measured after an overnight fast. Primary outcomes will be analyzed using multiple linear regression.

Results: The study will commence in 2022 and be completed in 2024.

Conclusions: Proving our hypothesis—that low BNP and high CNP at any age in healthy people predict premature aging of heart and blood vessels, respectively—opens the way to early detection and improved outcomes for those most at risk. Confirmation of our hypotheses would improve current methods of screening and, in appropriate cases, enable interventions aimed at increasing natriuretic hormones and reducing risk of serious cardiovascular complications using drugs already available. Such advances in

XSL•FO
RenderX

detection, and from interventional corrections, have the potential to not only improve health in the community but also reduce the high costs inevitably associated with heart failure.

Introduction

Atrial natriuretic peptide (ANP) and B-type natriuretic peptide (BNP) are cardiac peptides secreted by atrial and ventricular myocytes, respectively [1]. Both hormones circulate in plasma and, acting via a common guanylate receptor (NPR 1), serve to regulate the renal excretion of salt, lower systemic arterial pressure, and reduce intracardiac pressure [2]. A third member of the family (C-type natriuretic peptide [CNP]) acts in cardiac [3] and vascular intimal tissues [4] via a different guanylate cyclase receptor (NPR 2) to reduce inflammation and cell proliferation [4,5] and increase flow and pressure in the microcirculation [6]. In contrast to the endocrine and paracrine actions of ANP and BNP, actions of CNP are largely paracrine and, at levels found in healthy adults, are barely detectable in plasma. The bioactive forms (ANP, BNP, and CNP) of all 3 peptides have strong affinity for a third (non-guanylate cyclase) receptor (NPR 3) that internalizes and degrades these peptides. However, aminoterminal bio-inactive products of the prohormones synthetized in tissues (ie, aminoterminal ANP [NTproANP], aminoterminal BNP [NTproBNP], and aminoterminal CNP [NTproCNP]) are not NPR 3 ligands, have longer half lives in plasma, and serve as surrogates for the respective prohormone production in tissues [7-9]. Increase in intracardiac pressure is a strong stimulus to the secretion of the cardiac hormones, ANP and BNP, which are raised in patients with overt heart failure [2]. Factors regulating CNP are less clear but include cytokines [10] and shear stress [11] in vascular tissues. Numerous studies of community dwellers have shown that higher plasma concentrations of BNP products (BNP or NTproBNP) not only detect cardiac impairment but also predict adverse outcomes [12-14] in participants without evidence of heart disease. However, we found that, in participants without history of heart disease and with plasma concentrations of ANP and BNP within the normal range, higher values associate with lower markers of vascular and metabolic risk and with improved cardiac performance [15,16] (Figure 1). A specific gene variant (rs198358)—previously reported in a genome-wide association study (GWAS) to associate with lower blood pressure [17]—was found to be an independent contributor to BNP levels in 2 quite separate populations: one 28 years old [16] and another 50 years old [15]. Together with recent reports of other closely related gene variants in the community positively affecting BNP levels and reducing adverse cardiac outcome [18], we suggest that genetic factors drive the ANP and BNP links we identified with markers of cardiometabolic health. Acquired factors such as increased adiposity is associated with lower plasma concentrations of BNP [19]—possibly related to an effect of glycosylation on the assay of BNP in plasma [20]. Others have therefore suggested the recognized increase in adverse events such as the metabolic syndrome in obesity are consequent on a BNP-deficient state. Importantly, in our 2 previous community studies, lower BNP levels (which associate with markers of impaired metabolic health) were independent of adiposity.

Few, if any, studies have examined plasma concentrations of CNP products (CNP or NTproCNP) in this context. However, in both community studies [15,16], we found plasma CNP products—opposite to ANP and BNP—are higher in those with impaired cardiometabolic health. We suggest that these associations with CNP likely reflect an adaptive compensatory response to inflammation in vascular [21,22] and myocardial tissues [2,23,24]. Notably, in both age groups, plasma CNP was positively associated with markers of arterial and left ventricular stiffness in both sexes, whereas these associations with BNP were inverse except in older women (Figure 2).

The key question regarding the significance of these findings in predicting adverse cardiac or vascular outcome can only be answered by appropriate re-examination of the same participants at a later date.

Accordingly, here, we outline a proposal to comprehensively restudy participants aged 49 years to 51 years in the Canterbury Health, Ageing and Life Course study (CHALICE) study [15] undertaken 15 years previously. We postulate that (1) participants with lower levels of ANP or BNP at age 50 years will exhibit more advanced cardiac and metabolic impairment 15 years later and (2) higher levels of CNP products at age 50 years will associate with more advanced vascular and myocardial degenerative disease at age 65 years. Although protocols for the study of the predictive value of data on cardiovascular outcomes have been reported in specific disease states such as heart failure [25] or psoriasis [26], no previous study examining the predictive value of natriuretic peptides on cardiovascular outcomes in participants without evidence of heart disease has been reported to date.

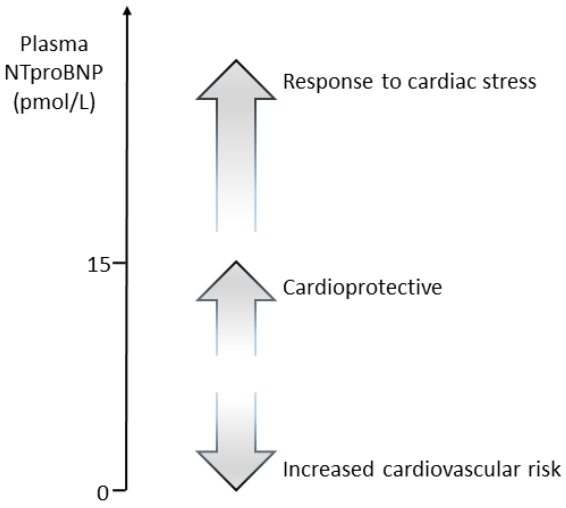
Figure 1. Beneficial and pathological circulating levels of aminoterminal B-type natriuretic peptide (NTproBNP) reflecting expression of the cardioprotective hormone BNP.



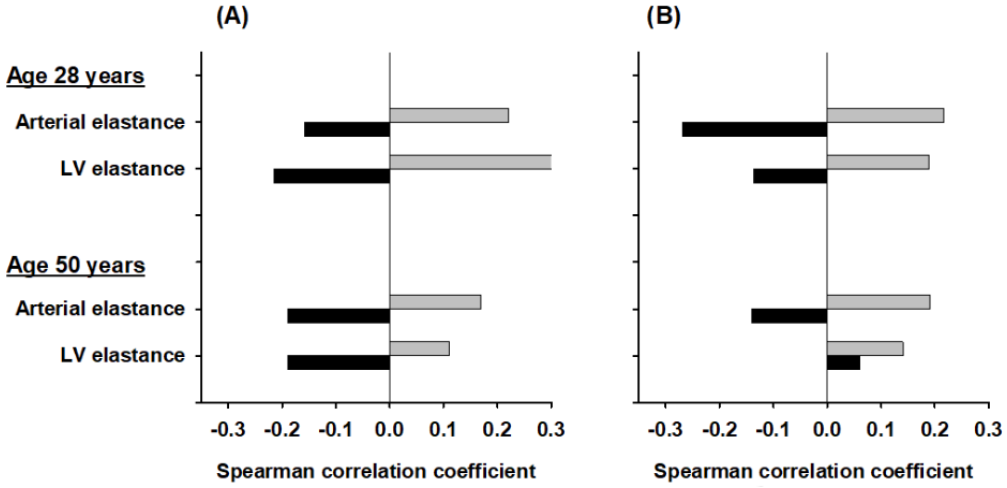


Figure 2. Comparison of Spearman correlation coefficients of aminoterminal B-type natriuretic peptide (NTproBNP; black bars) and aminoterminal C-type natriuretic peptide (NTproCNP; grey bars) with left ventricle (LV) and arterial elastance in healthy (A) men and (B) women aged 28 years and 50 years without a history of heart disease. Stiffer tissues equate with higher elastance. Coefficients >0.18 were significant.

Methods

Participants

All of the surviving 348 participants (205/348, 58.9% female; 53/348, 15.2% Māori or Pasifika ethnicity) participating in the CHALICE study [27] (free of history of heart or renal disease at age 50 years and who consented to further study) will be contacted, recruited, and restudied exactly as previously described [15]. Every effort will be made to re-establish contact with the CHALICE participants, including email, phone, surface mail, and cross checking with the electoral role, when necessary. Participants with cardiovascular events (ischemic heart disease, stroke, heart failure, atrial fibrillation) or renal disease developing since the previous study will be separately studied with respect to natriuretic peptide measurements at age 50 years but excluded in the main analysis of results at age 65 years. Records of hospital visits and admissions or death of participants since the previous review will be obtained from routine national data sets.

Ethics and Governance

All current participants gave written consent, and ethical approval was given by the Southern Health and Disability Ethics Committee (reference URA/10/03/021). Written informed consent will be sought from all participants agreeing to participate in further study. Relationships with Māori will be strengthened, and the studies' governance and policies will be updated to better align with Māori tikanga (customs) and to enhance Māori health outcomes [28].

Data Collection

After obtaining informed written consent, the following data will be obtained: health history (chronic morbidities and medications, tobacco consumption); physical examination (including blood pressure, height, weight, BMI); heart function as measured using echocardiography including speckle-tracking strain [29]; carotid artery intimal thickness as measured during echo examinations; laboratory measures (including fasting urine and blood sampling for routine biochemistry and plasma storage for measurements of natriuretic peptides, cyclic guanosine monophosphate [cGMP], and other analytes). Previously

XSL•FO
RenderX

established metabolic-cardiovascular risk factors will be measured after an overnight fast [15]. Plasma ANP, BNP, CNP (measured after extraction by radioimmunoassay), NTproANP, NTproBNP, NTproCNP, and cGMP will be assayed as previously described [16,30,31]. Because of links between CNP and bone turnover markers [32], plasma type 1 collagen C-telopeptide (CTx) will be measured in these older participants.

In order to generate data for genetic studies, including calculation of polygenic risk scores, DNA extracted from peripheral blood of all consenting participants will be genotyped on an appropriate platform such as the Infinium Global Screening Array (Illumina, San Diego, CA), and imputation will be carried out using standard approaches [33]. Polygenic risk scores will be generated based on existing data for large GWAS of relevant cardiac phenotypes [34].

The predictive value of natriuretic peptides at age 50 years for impaired atrial and ventricular function and for carotid intimal thickness at age 65 years will be determined using multiple variable analysis. In participants excluded from the main analysis because of interval cardiac or vascular disorder after the original study, natriuretic peptides at baseline and at 65 years will be studied in relation to cardiac and metabolic indices documented in the unaffected population and to type of event.

Specific Objectives and Hypotheses Affecting ANP and BNP

Here, we hypothesize that (1) low BNP at 50 years old will be associated with impaired atrial and ventricular structure (volumes and mass) and function (atrial strain and ventricular ejection fraction) at 65 years compared with those with high BNP at baseline; (2) at age 65 years, the percentage increase of BNP in participants with low BNP at 50 years old will be significantly greater than in those with higher BNP at baseline; and (3) in women, for whom the inverse association of ANP/BNP with left ventricle (LV) elastance is lost at age 50 years (Figure 2), decline in cardiac performance at age 65 years will be greater than in men.

Objectives and Hypotheses Affecting CNP

For the first time in humans, CNP has been linked to measures of arterial and LV stiffening at both ages and in both sexes (Figure 2). Here, we hypothesize that (1) plasma NTproCNP at age 50 years will predict decline in atrial and ventricular function as measured by speckle echocardiography at age 65 years, (2) plasma CNP products at age 50 years will predict increased atrial and ventricular stiffness and carotid intimal thickening at age 65 years, and (3) change in plasma concentration of CNP products 15 years later will be linked to markers of impaired cardiac performance and metabolic health at 65 years of age. Again, the contribution of a longitudinal study, undertaken at a period of increasing incidence of heart disease, will be crucial to providing proof of the independent association of CNP's role in maintaining cardiovascular and metabolic health. Showing that CNP levels at 50 years of age heralds later risk of stroke or heart failure identifies likely preventive measures, including treatments augmenting CNP and BNP levels in blood.

Other Objectives

Associations of polygenic risk scores with phenotype (measures of cardiac, metabolic, and vascular status) and associations with plasma natriuretic peptides will be studied. On the basis of previous findings from a single variant, we hypothesize positive links will be strengthened using polygenic risk scores.

Relevance of cGMP in the assessment of cardiac and vascular risk is an important new objective considering its role in mediating actions of all 3 natriuretic peptides. Based on prior work [35-37], we postulate that ANP will be independently associated with cGMP at age 50 years and age 65 years. Increasing recognition of CNP's role in combatting myocardial stiffening and the higher sensitivity of the cGMP response to stimulation of the CNP receptor (natriuretic peptide receptor 2 [NPR2]) in cardiac tissues, compared with that of natriuretic peptide receptor 1 (NPR1), suggests that CNP will independently predict cGMP in women and strengthen further at 65 years of age.

Statistics

The primary outcomes (hypotheses 1, 2, and 3) will be analyzed using multiple linear regression. Allowing for 30% nonresponse (n=244) and 10 covariates, this will be able to detect an f^2 of 0.083 (small-to-medium Cohen effect size) with 80% power and α=.01, which includes a multiple testing correction equivalent to a Bonferroni correction for 5 independent predictors. Nonlinear relationships will be examined with generalized additive models, and all models will be graphically assessed for goodness of fit. Indices will be analyzed as continuous variables or categorized as appropriate. Additionally, mediation analysis [38] will be used to quantify the role of cGMP in the relationship between natriuretic peptides and cardiac structure and performance in the primary outcomes.

Results

In the 10-year follow-up period after the initial study visit, 6 participants have died (none from cardiovascular causes), and 36 (10% of the cohort) were hospitalized for cardiovascular events. Ischemic heart disease (10 participants) was the most common reason for cardiovascular admission. Baseline NTproBNP or NTproCNP concentrations for men or women subsequently hospitalized for cardiovascular events were not significantly different from values of study participants remaining free from cardiovascular events.

The project and protocol have been approved by the National Ethics Committee. Having received funding from the New Zealand Lottery Board (Health), re-enrolment of CHALICE participants commenced in October 2022. At the date of this manuscript submission, 21 participants had successfully completed the protocol without incident.

Discussion

Two separate community studies of participants free of heart disease showed that lower plasma concentrations of the cardiac hormones, ANP and BNP, are associated with increase in vascular stiffness and reduced metabolic health, whereas the

XSL•FO
RenderX

opposite is true of CNP concentrations—lower levels associate with improved cardiometabolic health. These reproducible findings are independent of age and obesity. Restudy 15 years later of those aged 50 years will establish the value of natriuretic peptide levels in predicting adverse cardiac and vascular outcomes using clearly defined hypotheses based on data measured by the same laboratory using best practice quality control.

ANP and BNP as Paracrine and Endocrine Regulators of Cardiovascular Status

In light of strong evidence in experimental animals of protean beneficial actions of ANP/BNP across many tissues affecting the integrity of the cardiovascular system [2,39] and the deleterious impact of ablating ANP/BNP pathway activity [40,41], it is unsurprising that circulating concentrations of ANP/BNP products within the normal range have beneficial effects in maintaining cardiovascular and metabolic health in healthy people [42,43]. Whether these subtle differences in plasma concentrations predict subsequent cardiovascular health is the crucial question addressed in this prospective study. That genetic factors contribute is evident from several studies identifying a single [15,16,44] or more variants [39,45-47] in *NPPA* or *NPPB*. Plausibly, the accumulative impact of these explain, in part, the significant impact of subtle increases in circulating levels on "ideal cardiovascular health" [48] in either sex if maintained from early life. Obtaining array-based genotypes in CHALICE participants, as now proposed, will allow us to more closely examine impacts of additional natriuretic peptide and receptor genetic variants over and above that (rs198358) identified previously. The array data will also enable calculation of polygenic risk scores for various cardiac phenotypes and disease states and allow evaluation of the predictive or prognostic value of these in relation to existing clinical measures and risk factors. The value of this approach to identifying participants most at risk has been emphasized in a recent review of atherosclerosis [49]. Acquired factors such as obesity—lowering BNP [19]—also need consideration and will be assessed by changes in BMI. Although both ANP and BNP activate the same receptor (NPR1), their variable expression, location, and metabolism highlight the need to measure both bioactive forms in plasma [41] in associative studies linking levels with changing indicators of vascular, metabolic, and cardiac function in the 15 years after middle age when the incidence of heart disease increases greatly. No other study has examined these relationships in healthy participants. The conditions and blood sampling for measurements proposed in the re-examination will be undertaken exactly as they were previously (overnight morning fasting in the rested seated position) at one central location (University of Otago Nicholls Clinical Research Centre) utilizing standardized assays of natriuretic peptides developed by research staff of the Christchurch Heart Institute. Importantly, CNP concentrations in plasma will be measured using a validated and sensitive radioimmunoassay that, after extraction, has a plasma limit of detection of 0.2 pmol/L.

Strong evidence suggests that both ANP and BNP regulate energy balance by increasing mitochondrial efficiency and reducing lipogenesis in vitro and in experimental animals in vivo [2]. Our finding that both ANP and BNP in healthy participants at middle age are negatively related to lipid levels and other markers of the metabolic syndrome are consistent with these and other reports [50,51]. This inverse relationship is expected to strengthen over time. Conceivably, by reducing atherosclerotic changes and reducing arterial stiffness, these cardiac hormones ameliorate declines in LV strain and help to maintain high myocardial performance throughout life. Re-examination of cardiac performance after 15 years using speckle echocardiography is expected to reveal differential impacts of ANP and BNP on age-related changes in cardiac contractile function [29]. In this context, it needs to be emphasized that, in health, there is a progressive age-dependent decrease in LV stroke volume and LV volumes and an increase in LV mass along with an increase in LV and arterial elastance in both sexes [52,53]. Aligning with these age-related changes are increases in plasma ANP and BNP. Factors driving this progression are not known, but it is likely that increasing intramural pressure and myocardial inflammation and fibrosis play a major role (reviewed in Sayed et al [54]). Our findings of inverse associations of BNP with LV stiffening at age 28 years and at age 50 years in both sexes (except in older women) are consistent with these changes in chamber structure and function. Plausibly, waning estrogen production in older menopausal women may aggravate myocardial stress [55,56] and initiate an adaptive (compensatory) BNP response in those most at risk by lacking protective gene variants. Notably, a recent cross-sectional study using speckle-tracking echocardiography [29] found that left atrial dysfunction is the earliest sign of age-related cardiac pathology in a population of well people, mean age 65 (range 24-86) years, in which mean BNP level was 2-fold higher than we found in CHALICE. ANP values were not reported. These findings suggest that BNP increases as an adaptive compensatory response to atrial dysfunction [29]—analogous to the loss of the negative association of ANP/BNP with LV elastance we observed in older women (Figure 2). Understanding the impact of the much lower BNP values we identified at 50 years of age with adverse changes in cardiac function 15 years later therefore becomes a pressing need. Based on our findings at age 50 years, we anticipate that the increase in atrial strain will be greater in those with lower ANP and BNP and the percentage change in both peptides at age 65 years will be greater in those with lower levels at baseline (age 50 years). A similar pattern of change in the relationship of LV volumes with ANP and BNP is anticipated. However, it is interesting to note that, in a recent report [18] of the association of a gene variant—rs198389 (increasing BNP)—in preventing LV dysfunction [18] in participants known to be at high risk of developing heart disease, the percentage change in BNP was independent of levels at baseline. Clearly, further studies in healthy participants are needed, preferably when the strong impact of variable age is reduced. As mentioned earlier in this paragraph, a sex difference was noted for older women in whom the negative association of ANP and BNP with LV stiffening is lost. This will be an important finding to re-examine in postmenopausal years, particularly in light of the high incidence of diastolic dysfunction and emergence of heart failure with preserved ejection fraction (HFpEF) in older women [55]. The loss of arterial-LV coupling

XSL•FO
RenderX

[57] implied by our findings at 50 years of age in older women—with an associated (adaptive) increase in BNP—suggests that this may portend more severe dysfunction in later years and can be expected to be clarified in this proposal.

Role of Paracrine CNP

The significance of circulating products of paracrine CNP for cardiometabolic health is less clear than for endocrine-paracrine/BNP [58] largely due to its unique specific (paracrine) actions, rapid degradation at source, and barely detectable levels of bioactive forms (CNP 22 and CNP 53) in adult plasma once growth plates have closed [7]. Nevertheless, there is evidence in experimental animals of important actions in maintaining flow and pressure in the microcirculation [6], counteracting myocardial inflammation and fibrosis [2,23,24], and preserving diastolic function [59,60]. Several studies have suggested these actions come into play after injury (that is, are adaptive) rather than conferring benefit pre-ictus [2,23]. It remains to be seen whether genetic variants increasing CNP/NPR2/cGMP signaling—including loss of function mutations in the natriuretic peptide clearance receptor gene [*NPR3*] [61]—could reduce the incidence of cardiometabolic disease. Other studies of genetic variants—reducing CNP/*NPR3*/Gi P/cAMP activity—reported increased incidence of circulatory disorders and high blood pressure [62]. Links of plasma CNP or NTproCNP with impaired cardiac function or with vascular degenerative disease have been reviewed previously [7] and support the view that the positive association is likely to reflect a compensatory response to loss of structural integrity. Very few, if any, other studies have examined the association of CNP products with measures of cardiac function in community dwellers. However, one large study of 1841 participants reported plasma CNP (using a direct less specific assay without extraction) identified a high-risk cardiovascular phenotype and future risk of myocardial infarction [63]. Consistent with adaptive and protective actions of CNP in humans are our previous findings in healthy volunteers without history of heart disease [64] in whom plasma values of the inactive product of proCNP 1-103 (NTproCNP) and bioactive CNP increased progressively at midlife in both sexes and showed univariate associations with renal function, high blood pressure, and markers of the metabolic syndrome. A key question arising is the likely source(s) of these products in view of the diverse range of tissues expressing *NPPC* [7]. In mature rodents, the vascular endothelium likely makes the major contribution (some 60%) to circulating levels of CNP [23,65]. Positive veno-arterial gradients of CNP across the heart in humans presenting with acute coronary syndrome [66] support contributions from the myocardial, endocardium, or coronary intimal tissues, as does the sustained increase in plasma CNP postictus in participants with acute coronary syndrome [67]. More focused associative studies have shown significant links of CNP products with recognized vascular and metabolic risk factors in both sexes in 2 separate community studies—one at age 28 years and the other at midlife (CHALICE) [15,16]. Importantly in both studies, significant positive associations of CNP products were found with higher arterial and higher LV elastance in both sexes and with lower LV stroke volume and lower LV end diastolic volumes. Likely sources of this increase in CNP are (1) increased vascular endothelial *NPPC* expression in response to shear stress [11] or inflammation [68] and (2) increased *NPPC* expression in LV myocardial tissue inflammation [3,24]. Increase in bioactive CNP rather than both products after cardiac injury [67] likely results from reduced clearance at the source [69,70]. Restudy of CHALICE participants 15 years later, we predict, will show more severe diastolic dysfunction in those with higher CNP levels at age 50 years—and will be greater in women 15 years after menopause [55]. Such findings could establish CNP as an endogenous marker for HFpEF, for which no suitable biomarker is currently available [56]. In this context, it is relevant to note that an increase in plasma NTproCNP was independently linked to adverse outcome in patients with HFpEF [71]. Aligning with CNP's adaptive role in combatting arteriosclerosis [21,22], we also anticipate carotid artery intimal thickening will correlate with CNP values at 50 years of age and with the proportional increase of CNP above values at baseline.

Taken together, this study has the potential to advance understanding of paracrine CNP's role in combatting not only disorders of cardiac function but also arterial degenerative changes not otherwise easily addressed in healthy aging humans. Supportive findings of CNP's independent association can be expected to identify therapeutic targets—for example, novel therapies using CNP agonists (now already approved for use in humans) or new drugs that increase CNP secretion [72] or raise natriuretic peptide levels by extending the half-life in tissues at risk [73].

Relevance of cGMP

An important additional analyte (cGMP)—not previously measured in CHALICE—could illuminate distinct tissue actions mediated by the membrane-bound guanylyl cyclase receptors NPR1 (activated by ANP and BNP) or NPR2 (activated by CNP). Both particulate receptors are widely expressed within the heart, vasculature, kidney, and brain [2], releasing cGMP into the cell and extracellular fluid after ligand binding [74]. We found that contrived increases in plasma ANP and BNP elicit consistent and proportionate changes in cGMP in plasma or urine, which, importantly, also link with respective changes in organ function [35]. ANP is 3-fold more effective in raising plasma cGMP when compared with BNP [75]. Previous studies have examined associations of plasma cGMP with vascular risk markers, plasma BNP, and cardiac function in community dwellers without heart disease [36,37] and concluded that the positive association of plasma BNP with plasma cGMP resulted from compensatory responses in cardiac secretion to increased myocardial wall stress. Importantly, ANP was not measured. To our knowledge, no study has examined links of each of the natriuretic peptides with cGMP and cardiac function in participants without a history of heart disease. Although contrived increases in circulating CNP levels are much less effective than ANP or BNP in increasing cGMP [75], the importance of cardiac *NPR2* signaling [76] and its diffuse distribution across cardiomyocytes, in contrast to the highly compartmentalized location of *NPR1* in tubular niches in myocardiocytes [59], may facilitate cGMP access to extracellular fluid and plasma. Further, in rodent adult cardiac fibroblasts, cGMP response to CNP far exceeds that from ANP

XSL•FO
RenderX

or BNP [77]. Collectively, these findings indicate the need to study putative links of plasma CNP products and cGMP with changes in cardiac structure and function in the course of aging.

Strengths and Limitations

Compared with other community studies, the number of participants in CHALICE is small. However, the detailed and comprehensive assessment of genetic, metabolic, cardiac, and vascular status together with the complete suite of natriuretic peptide measurements—all undertaken at one site and using in-house validated assays—contribute to the unique features of this longitudinal study. The narrow age band (49 years to 51 years at baseline) eliminates variables related to age, which is a major confounder in most community studies. Although only a single sample for assay of natriuretic peptides is drawn at baseline and follow-up, we found excellent agreement between test and retest on different days in well participants when studied seated, after resting for 15 minutes. Whether associations reflect beneficial genetic effects versus organ adaptive compensatory responses can only be determined by longitudinal studies as planned here. The time span between data collection (around 15 years) encompasses the period after middle age when cardiovascular disorders become overt. For these reasons, our hypothesis—that higher concentrations of ANP/BNP at age 50 years reduces the incidence of impaired cardiovascular health—will be fully tested. Notwithstanding the importance if proven—enabling currently available clinical interventions—the opportunity to link change in function with *NPR1*/cGMP and *NPR2*/cGMP activity can be expected to clarify interactions of endocrine and paracrine components of these important hormones in maintaining cardiovascular health in humans for the first time.

Conclusions

In view of the high prevalence of cardiovascular disease and its high morbidity and mortality, there is an urgent unmet need for preventative measures including biomarkers of susceptibility that may allow early intervention in those most at risk. The discovery of the role of natriuretic peptides in maintaining a healthy circulation and metabolism opens up new ways of predicting those most at risk. Previous work in community participants free of heart disease showed that low plasma concentrations of ANP and BNP and higher levels of CNP at midlife associate with increases in pathological measures of cardiac and vascular stiffness and impaired metabolic health. This suggests that natriuretic peptide biomarkers will predict adverse outcomes in later years. Proving this, as described here, will lead to earlier detection of those most at risk and may enable novel preventive strategies augmenting natriuretic peptide levels or activity.

Abstract

Background: Measuring vital signs (VS) is an important aspect of clinical care but is time-consuming and requires multiple pieces of equipment and trained staff. Interest in the contactless measurement of VS has grown since the COVID-19 pandemic, including in nonclinical situations. Lifelight is an app being developed as a medical device for the contactless measurement of VS using remote photoplethysmography (rPPG) via the camera on smart devices. The VISION-D (Measurement of Vital Signs by Lifelight Software in Comparison to the Standard of Care—Development) and VISION-V (Validation) studies demonstrated the accuracy of Lifelight compared with standard-of-care measurement of blood pressure, pulse rate, and respiratory rate, supporting the certification of Lifelight as a class I Conformité Européenne (CE) medical device.

Objective: To support further development of the Lifelight app, the observational VISION Multisite Development (VISION-MD) study is collecting high-quality data from a broad range of patients, including those with VS measurements outside the normal healthy range and patients who are critically ill.

Methods: The study is recruiting adults (aged ≥16 years) who are inpatients (some critically ill), outpatients, and healthy volunteers, aiming to cover a broad range of normal and clinically relevant VS values; there are no exclusion criteria. High-resolution 60-second videos of the face are recorded by the Lifelight app while simultaneously measuring VS using standard-of-care methods (automated sphygmomanometer for blood pressure; finger clip sensor for pulse rate and oxygen saturation; manual counting of respiratory rate). Feedback from patients and nurses who use Lifelight is collected via a questionnaire. Data to estimate the cost-effectiveness of Lifelight compared with standard-of-care VS measurement are also being collected. A new method for rPPG signal processing is currently being developed, based on the identification of small areas of high-quality signals in each individual. Anticipated recruitment is 1950 participants, with the expectation that data from approximately 1700 will be used for software development. Data from 250 participants will be retained to test the performance of Lifelight against predefined performance targets.

Results: Recruitment began in May 2021 but was hindered by the restrictions instigated during the COVID-19 pandemic. The development of data processing methodology is in progress. The data for analysis will become available from September 2022,

XSL•FO
RenderX

and the algorithms will be refined continuously to improve clinical accuracy. The performance of Lifelight compared with that of the standard-of-care measurement of VS will then be tested. Recruitment will resume if further data are required. The analyses are expected to be completed in early 2023.

Conclusions: This study will support the refinement of data collection and processing toward the development of a robust app that is suitable for routine clinical use.

Introduction

The measurement of vital signs (VS) provides important information about a patient's health and, importantly, a change in VS may herald a deterioration in health [1]. Despite the importance of VS to inform clinical decision-making, the accuracy and timeliness of measurement are in need of improvement [2-4]. However, the measurement of VS requires using multiple pieces of equipment that need to be calibrated regularly and is time-consuming. It may also be uncomfortable and stressful for patients, potentially compromising the utility of the information obtained. Standard-of-care medical equipment is not suitable for patients who require regular measurement of VS in the home or community setting to monitor long-term health conditions because of cost, the complexity of the measuring processes, and the need for calibration of equipment. A study of 725 patients reported that while 53% followed at least 10 of the recommended steps necessary for accurate blood pressure (BP) measurement at home, only 1% followed all 15 recommendations [5]. Thus, home measurement of VS is important—and respiratory rate and pulse rate in particular—but requires several pieces of equipment (BP monitor and pulse oximeter) and for patients to be educated in best practices. The COVID-19 pandemic highlighted the need for remote or contactless VS measurement to reduce the risk of infection, which can be operated by people without specific medical training. The shift away from face-to-face to digital consultations during the pandemic also points to the need for easy but accurate measurement of VS.

Photoplethysmography (PPG) is an optical technique based on the measurement of the light reflected from the skin surface, which changes due to volumetric changes in the facial blood vessels; small variations in perfusion provide valuable information about the cardiovascular system [6]. PPG has been used to measure pulse rate [7,8], oxygen saturation [9], BP [10,11], and respiratory rate [7,12] and to detect atrial fibrillation [13].

Lifelight (Xim Ltd) is an app being developed for the contactless measurement of VS using remote PPG (rPPG) via the camera on smart devices such as phones and tablets. The app captures the average color of the region of interest 30 times every second for 60 seconds and sends this as red, green, and blue values to the server for further processing. VS values are obtained from the green channel.

The VISION-D (Measurement of Vital Signs by Lifelight Software in Comparison to the Standard of Care-Development) study measured VS in 8585 patients and healthy volunteers simultaneously using Lifelight and standard-of-care methods. The data were used for machine learning to improve the accuracy of the Lifelight algorithms used to calculate VS. The smaller VISION-V (Measurement of Vital Signs by Lifelight Software in Comparison to the Standard of Care–Validation) study demonstrated the accuracy of the Lifelight app compared with standard-of-care methods for measuring pulse rate, respiratory rate, and diastolic BP [14], providing the basis for the current class I Conformité Européenne (CE) registration [15]. However, some of the methods used in the VISION-V study differed from the procedures described in the standard for BP measurement (ISO81060-2) because of the novel nature of the Lifelight technology. Furthermore, these early studies did not include participants with BP values across the full range likely to be encountered in clinical practice.

To further improve the accuracy of Lifelight, the Measurement of Vital Signs by Lifelight Software in Comparison to the Standard of Care–Multisite Development (VISION-MD) study is collecting data from a wide range of outpatients, inpatients, and patients who are critically ill, and across the full range of skin tones, for use in machine learning. In VISION-D and VISION-V, full-face videos were recorded, but a high proportion of data were not usable. Thus, high-resolution full-face videos are being recorded to maximize the opportunity for machine learning. These data will also be used to evaluate alternative methods of defining the region of interest, as the full face includes areas that are not relevant (eg, areas covered by facial hair and areas that illicit a poor signal).

Given that only a small proportion of the raw video signal is relevant for rPPG measurement of VS (1%-2%), we are developing ways to enhance data collection and signal processing. Video recordings will be of higher resolution than those in the VISION-V and VISION-D studies, and data processing is focusing on the midface region (cheeks, nose, and top of the lip), rather than the whole face; these areas are computationally efficient for rPPG because of their large area and good-quality signal [16] but are not likely to be affected by autoregulation of cerebral blood flow (which discounts the

XSL•FO
RenderX

forehead) [17]. We are also developing a method to identify small regions of interest in the midface in each participant where signal quality is the highest. This approach is expected to overcome some of the challenges of rPPG for routine clinical use, such as positioning of the participant relative to the light source.

VISION-MD (Clinicaltrials.gov NCT04763746) aims to advance the development and accuracy of the Lifelight app as a noninvasive and easy-to-use device to measure VS in hospitals and the community. The study will collect data from a broad range of patients to further develop the accuracy of Lifelight to a level sufficient for clinical applications, including screening and monitoring of cardiovascular disease. The initial data collected are being used for machine learning; later data will be used to test the accuracy of Lifelight compared with standard-of-care measurement of VS.

Thus, the primary objective of VISION-MD is to further develop the Lifelight algorithms across extensive clinical ranges, including critically ill patients and in patients with different skin tones. Secondary objectives are: (1) to improve and test the efficacy of Lifelight estimates for BP, pulse rate, respiratory rate, and oxygen saturation in multiple clinical settings (eg, critical care, outpatient clinics, and general hospital wards); (2) to evaluate the impact of variables on the accuracy of Lifelight VS measurements (eg, age, sex, temperature, health condition, medication, skin tone, and ambient lighting); (3) to understand the health economic potential of Lifelight; and (4) to compare the patients' experience of current contact-based methods for measuring VS and Lifelight and to evaluate the patients' acceptance and appetite for Lifelight.

Methods

Ethics Approval

The VISION-MD protocol was approved by the South Berkshire Research Ethics Committee on November 24, 2020 (20/SC/0432). Before the study started, the initial study protocol was approved by Health Research Authority (HRA) Wales on January 18, 2021 (IRAS 289242). HRA Wales has also approved subsequent protocol amendments.

Participants and Recruitment

Participants are being recruited from multiple venues across Portsmouth Hospitals University NHS Trust, Barts Health NHS Trust, London, and from the community in London and Portsmouth (eg, religious places, community centers, offices, patient events, waiting areas in general practices, academic institutions, sports facilities, and care homes). The participants are inpatients, outpatients, friends and family of patients, visitors, hospital staff members, and the general public. The study staff approach inpatients during their hospital stay and outpatients while waiting for appointments. For adults lacking capacity (eg, critically ill patients), the next of kin are contacted by telephone. In addition, ethics-approved advertising materials are disseminated to Trust staff by email and in meetings, and posters are displayed in staff, patient, and public areas.

Inclusion criteria include individuals aged 16 years and older, sufficiently conversant in the English language, and able and willing to comply with all study requirements and to provide informed consent (either themselves or empowered by law to provide it). There are no exclusion criteria. Eligible potential participants are provided with an ethics-approved participant information sheet explaining the study aims, what is involved, and the requirements for participation; members of the team are available to discuss the study with interested individuals. Informed consent is obtained electronically using Research Electronic Data Capture (REDCap), a secure National Health Service (NHS)–compliant web-based platform for survey and database management (project-redcap-org). For adults lacking capacity, informed consent is obtained from a nominated consultee (next of kin or a doctor not involved in the study). Participation in the study is entirely voluntary, refusal to participate does not incur a penalty or loss of medical benefits, and participants may withdraw from the study at any time.

Recruitment started in May 2021 but was compromised by restrictions implemented during the COVID-19 pandemic to limit access to hospitals by the general public. Protocol amendments were made to increase community recruitment in light of these issues. Target recruitment is approximately 1950 participants to generate measurements for use in the initial training data set and for performance testing. However, the final sample size will depend on the incremental improvement in accuracy of the Lifelight algorithm and therefore cannot be predicted (see Sample Size section). The study will continue until the accuracy of Lifelight for measuring VS is sufficient for various clinical use cases.

Study Procedures

Premeasurement observations

A brief set of demographic and medical history questions are asked, limited to the presence or absence of conditions that might affect skin perfusion and pigmentation and cardiovascular processes and any prescription medicines for these conditions. The study staff record a set of premeasurement observations and the presence or absence of sweat on the participant's face; any facial hair on the cheeks; tattoos, jewelry, birthmarks, scars, or other features on the face; the use of foundation or concealer; and the position of the participant (seated, prone, supine, or lying on one side).

Subprotocol assignment

Patients with capacity are recruited into 1 of 3 subprotocols depending on premeasurement observations (Table 1). Participants may also be recruited to a subprotocol based on their skin tone (Fitzpatrick Skin Type scale [18]) to meet prespecified targets. Adults who lack capacity are recruited into subprotocol 4. Participants may be involved in up to 10 study sessions, allowing the collection of longitudinal data. The subprotocol approach allows the study personnel to focus on fewer tasks. It also enables high-quality data collection while avoiding the collection of data that would not be used to meet study objectives, consistent with the General Data Protection Regulation for data minimization.

XSL•FO
RenderX

Table 1. Recruitment criteria and vital sign measurement in subprotocols 1-4.

Subprotocol	Recruitment criteria	Measurements				Measurements, n
		PR[a]	BP[b]	RR[c]	SpO_2[d]	
1	Abnormal BP[e]	✓	✓		✓	3
2	Any participant			✓	✓	2
3	Expected to have low SpO_2[f]				✓	2
4	Adults lacking capacity	✓	✓	✓	✓	3

[a]PR: pulse rate.

[b]BP: blood pressure.

[c]RR: respiratory rate.

[d]SpO_2: oxygen saturation.

[e]Abnormal defined as systolic blood pressure <100 mm Hg or >140 mm Hg.

[f]Low SpO_2 (anticipated to be ≤95%).

VS measurement

The study staff ensure that participants have been at rest for at least 10 minutes before VS measurement starts and that they have not consumed any food or drink in the previous 30 minutes (other than intravenous fluids or nasogastric feeding). In each study session, VS is measured as per the subprotocol using the standard-of-care equipment while simultaneously capturing a video of the participant's face using the Data Collect app running on a tablet (standard iPad 9.7, 2018) positioned approximately 1 m away and angled toward the participant's face. Controls and instructions on the device start and stop the 60-second video recording. Background luminosity is measured using a handheld lux meter. The study staff have been briefed on the optimum Lifelight measurement conditions. Recordings are repeated once or twice, as set out in Table 1. The app does not return any measurements to the user or participant.

VS measurements are taken and coordinated by 2 nurses, one of whom announces the start and finish of the recording period on the Data Collect app. BP is measured using a standard clinical automatic sphygmomanometer with an appropriately sized cuff (width at least two-thirds of upper arm length) on the participant's nondominant upper arm (unless contraindicated) or via an arterial line if fitted. BP is recorded at the start of the recording period. A standard clinical finger clip sensor for the measurement of oxygen saturation and pulse rate is placed on a finger on the opposite side of the body to the sphygmomanometer. Oxygen saturation and pulse rate are measured at 0, 30, and 60 seconds of the recording period and averaged. Respiratory rate is determined manually by counting chest rises throughout the 60-second period. The nurse may place their hand on the participant's chest to increase the accuracy of manual counting but being mindful not to obscure the camera's line of sight.

Each study session takes approximately 30 minutes. Once the measurements are completed, the study staff complete the postmeasurement observation questions relating to how much the participant moved, their position, whether they were wearing glasses, any hairstyle or other item (eg, face covering) that obscured any part of their face during the recording, and whether the software reported "face not found" at any point during the recording.

Patient Feedback

Equal proportions of participants in subprotocols 1-3 are being asked to complete a questionnaire related to VS measurement and their preferences. The data are fully anonymized and recorded without any identifiable information (including participant ID code).

Clinical Feedback

A questionnaire is available to garner feedback on the technology from the clinical user's point of view (ie, the nurses who take the VS measurements). Questionnaire and interview data are fully anonymized and recorded without any identifiable information.

Health Economics Data Collection

The study also includes activities to obtain information and data to assess the cost-saving potential of Lifelight in different clinical settings, including as a tool to detect undiagnosed cardiovascular disease and to monitor symptoms. The cost of BP monitoring equipment and its maintenance and calibration will also be determined.

Stopwatch observational studies are run to determine how long it takes to measure VS using standard-of-care equipment and Lifelight, starting from the time when the clinician decides to conduct a VS check and incorporating the time it takes to find the measuring equipment, roll up the patient's sleeve, put on the devices, wait for the result, and put the equipment away. This part of the study will involve approximately 20 participants.

Privacy and Data Collection

Each study participant is assigned a unique sequential ID; no identifiable data are stored. All documents are stored securely and are only accessible by the study staff and authorized personnel. The code linking the ID to the participant's personal information is kept within the hospital study site and can only be accessed by the research team.

Full-resolution video data are uploaded during the study. The consent form allows the participants to decide whether data can

XSL•FO
RenderX

be shared as full-face video or with identifying features obscured.

Videos collected in the study constitute personal data, as it may be possible to identify participants, but are collected for research purposes only (not clinical care) and are processed within the legitimate interests of Xim Ltd. These data will be protected according to the General Data Protection Regulation.

Data Handling

For each reading, a high-quality video of the whole face is saved to the internal storage of the iPad in encrypted form. Anonymized rPPG data (the average color of areas of the face) are saved directly and immediately sent to an NHS-compliant cloud server.

Subsequent analysis will be performed using the encrypted files, which are downloaded to a processing site, decrypted, and processed automatically (ie, without any person viewing the videos). This procedure will result in anonymized aggregate data sets. Decrypted files will subsequently be deleted from the processing site.

All protocol-required information besides video data is collected in an electronic case report form. The REDCap electronic cloud is used to store and manage all consent and study data. All data collected about study participants are kept strictly confidential.

Performance Targets

The accuracy of Lifelight using the training data generated in VISION-D was sufficient to support the certification of Lifelight as a class I CE medical device [15]. However, the accuracy needs to be improved further for use in routine clinical practice. Table 2 lists the performance targets for Lifelight; training data collected during VISION-MD will support the progress toward these targets.

Table 2. Performance (accuracy) targets for Lifelight.

Vital signs	Accuracy target	Basis for target
Blood pressure	• SBP[a] can be measured with standard deviation ≤8 mm Hg • British Hypertension Society Grade C for SBP measurement	ISO81060-2[b] for blood pressure cuffs [19]
Pulse rate	• Root mean square error of ≤3 beats per minute	Most common accuracy of CE[c]-marked commercially available devices
Respiratory rate	• Maximum error tolerance of 5 breaths per minute	Accuracy of Philips Health watch, a CE-marked contact-based photoplethysmography device
Oxygen saturation	• Maximum error tolerance of 4%	ISO80601-2-61 standard for pulse oximeters [20]

[a]SBP: systolic blood pressure.

[b]ISO: International Organization for Standardization.

[c]CE: Conformité Européenne.

Sample Size

The sample size cannot be formally calculated because it depends on the incremental improvement in the accuracy of Lifelight achieved through machine learning using the training data generated in the study. However, indicative sample sizes for the 4 subprotocols have been calculated by assessing the optimal data requirements to enable algorithm training toward the standards defined in Table 3, balanced against the practicality of achieving the targets. The split between training and testing data will be determined during the study according to the quality of the data collected.

The initial protocol anticipated data collection from about 8400 participants for training and a further 1000 for independent testing of accuracy, but the recruitment has been compromised by restrictions implemented during the COVID-19 pandemic. However, the high-quality video recording (compared with VISION-D and VISION-V) supported a protocol amendment to reduce the recruitment to 1950 participants (see Results section), with the expectation that data from about 1700 will be used for training the algorithms and data from 250 used for testing. The study management team is monitoring the progress of data collection and accuracy, and updates the study teams monthly. The study will continue until the accuracy of Lifelight for measuring VS is sufficient for various clinical use cases.

As skin tone is expected to affect the accuracy of Lifelight, the aim is to recruit participants across the full Fitzpatrick skin tone scale (1-6). To allow the impact of skin tone measurement accuracy to be determined with statistical robustness, the full data set will be sampled to create a subset for skin tone analyses in which the prevalence of the usually less prevalent skin tones is amplified. This subset will contain 750-1000 measurements, with 15%-20% each from categories 1, 2 and 3, 4, and 5 and 6. These measurements should be spread across the subprotocols as indicated in Table 3.

XSL•FO
RenderX

Table 3. Indicative sample size targets.

Subprotocol	Indicative sample size, n[a]	Characteristics	Participants with skin tone categories 1, 4, 5, and 6
1	1500	Roughly 100 participants will be recruited with SOC[b]-determined SBP[c] in each 10 mm Hg increment from <90 mm Hg to >200 mm Hg (ie, <90 mm Hg; 90-99 mm Hg; 100-109 mm Hg, etc)[d]	Ideally ≥4 in each SBP band
2	375	N/A[e]	Ideally ≥10 in each SBP band
3	35	Approximately 33% with SOC-measured oxygen saturation <88%, 88%-92%, and 93%-95%	Ideally, each band will include participants with each skin tone
4	No specific target; likely to be a small proportion	N/A	N/A

[a]Participants in subprotocol 4 (ie, those without the capacity to provide informed consent) are likely to have vital sign values outside of the normal range and will contribute to all subprotocol targets. Only the first study session per participant contributes to the sample size.

[b]SOC: standard of care.

[c]SBP: systolic blood pressure.

[d]Can include participants with SBP measured from an arterial line.

[e]N/A: not applicable.

Data Analysis

The training data will be used to further develop the signal extraction and processing methodology. The test data will subsequently be used to determine the performance of Lifelight against the targets set out in Table 2.

All statistical analyses will be performed using Microsoft Excel. All analyses will be completed per protocol since there is no intention to treat.

There will be no imputation of missing or implausible data, and any missing, implausible, or problematic readings will be excluded from the analysis. If the Lifelight software is unable to detect the participant's face during the measurement period, this will be recorded in the electronic case report form, and the measurements will be deleted from the data set.

Results

The prototype Lifelight technology has been in development since 2016. The recruitment of participants for VISION-MD started in May 2021 but was compromised by the restrictions implemented to manage the COVID-19 pandemic, including restricting hospital access to the general public. Protocol amendments were thus made to enhance community recruitment, including the use of incentives such as chocolates or gift cards. In addition, the higher-resolution video recording (compared with the earlier VISION studies) supported reduction of the recruitment target to 1950, which is expected to yield sufficient high-quality measurements for machine learning and subsequent testing (reflected in a further protocol amendment). An additional amendment allowed the measurement of BP and pulse rate using devices other than the standard-of-care Welch Allyn devices (and indicated in the electronic case report form), as not all participating centers had the originally specified equipment.

Data for analysis will become available from September 2022, and the algorithms will be continuously refined to improve clinical accuracy. We anticipate that the final analyses to determine the performance of Lifelight against the targets set out in Table 2 will be complete in early 2023.

Discussion

The VISION-MD study is expected to provide sufficient high-quality data from a wide range of healthy volunteers and patients (including critically ill patients) to further develop the accuracy of the software for estimating VS in clinical and community settings. While the VISION-V and -D studies demonstrated the potential value of Lifelight in the contactless measurement of VS and supported class I CE certification [15], further refinement of data collection and analysis methods is needed—particularly VS measurements outside the normal healthy range—to develop the algorithms for clinical use.

The high-quality videos collected in the VISION-MD studies will be instrumental in training the algorithms being developed for data processing. A proportion of the data collected will be retained for testing the performance of Lifelight in estimating VS compared with the standard of care.

The study findings will be published in high-impact peer-reviewed scientific journals and presented at international cardiology, respiratory, and medical device conferences.

Acknowledgments

Abstract

Background: Mental and neurological disorders cause a large proportion of morbidity burden and require adequate health care structures. However, deficits in the German health care system like long waiting times for access to specialized care and a lack of coordination between health care providers lead to suboptimal quality of care and elevated health care costs.

Objective: To overcome these deficits, we implement and evaluate a unique stepped and coordinated model of care (the Neurologisch-psychiatrische und psychotherapeutische Versorgung [NPPV] program) for patients with mental and neurological diseases.

Methods: Patients included in the program receive an appropriate treatment according to medical needs in a multiprofessional network of ambulatory health care providers. The therapy is coordinated by a managing physician and complemented by additional therapy modules, such as group therapy, internet-based cognitive behavioral therapy, and a case management. Statutory health insurance (SHI) routine data and data from a longitudinal patient survey will be used to compare the program with regular care and evaluate SHI expenditures and patient-related outcomes. A health care provider survey will evaluate the quality of structure and processes and provider satisfaction. Finally, an analysis of ambulatory claims data and drug prescription data will be used to evaluate if health care providers follow a needs-led approach in therapy. Ethics approval for this trial was obtained from the ethics committee of the chamber of physicians in North Rhine (September 13, 2017, reference No. 2017287).

Results: Patient enrollment of NPPV ended in September 2021. Data analysis has been completed in 2022. The results of this study will be disseminated through scientific publications, academic conferences, and a publicly available report to the German Federal Joint Committee, which is expected to be available in the first half of 2023.

Conclusions: The NPPV program is the first intervention to implement a stepped model of care for both mental and neurological diseases in Germany. The analysis of several data sources and a large sample size (more than 14,000 patients) enable a comprehensive evaluation of the NPPV program.

Introduction

Mental and neurological diseases continue to be a challenge for health systems worldwide. When measuring disability-adjusted life years, these diseases make up the largest share of all cause morbidity burden in the European Union [1]. Chronic mental and neurological diseases often lead to a loss of quality of life, disability, and even premature death and go along with significant direct and indirect costs of illness [2-4].

From 1990 to 2017, the 27 countries of the European Union and the United Kingdom showed an increase in prevalence of stroke (+25%), dementia (+62%), Parkinson disease (+72%), and multiple sclerosis (+41%), mainly due to demographic changes in an aging population [2]. According to the models by Brinks and Landwehr [5], the number of persons with dementia might increase 2-3 times by the year 2050. For Germany, Steffen et al [6] found an increase of 26% for depression between 2009 and 2017, especially for men and younger patients. Disease prevalence for depression with mild symptoms is on average higher in Germany as compared to other European countries [7].

The increasing burden of mental and neurological diseases will require robust health care structures in the near future to secure adequate treatment for these patients. However, several deficits in the German health care system prevent patients from getting the best possible care. First, timely access to specialized neuropsychiatric care is challenging for patients with mental and neurological diseases, mostly due to a lack of sufficient outpatient care facilities for neurology, psychiatry, and psychotherapy. Almost 3 quarters of patients with a mental disease in outpatient care are treated exclusively by their general practitioners and not by psychiatrists [8], and around 8.5% of patients fail to get an initial examination from a psychotherapist within 3 months [9]. Less than 55% of all patients with newly diagnosed multiple sclerosis receive specialized care by a neurologist within 6 weeks (dementia: less than 26%) [10]. Second, allocation of care occurs without adequate prioritization. According to Walendzik et al [11], half of the psychotherapists offer an appointment to the next inquiring patient without considering clinical needs. Third, treatments do not always follow medical guidelines. Even when excluding mild cases, about 50% of patients with depression do not receive the recommended standard of care at all or an adequate treatment with antidepressants or psychotherapy [12]. Fourth, the Advisory Council on the Assessment of Developments in the Health Care System in Germany criticized a lack of coordination and cooperation between health care sectors and professionals in the treatment of mental diseases and pointed out the need for a primary professional who coordinates the treatment of patients along clinical pathways [13].

To overcome these deficits and improve treatment of people with mental and neurological diseases, we developed a stepped and coordinated care program called “neurological-psychiatric and psychotherapeutic care” (Neurologisch-psychiatrische und psychotherapeutische Versorgung [NPPV]) for patients in the region of North Rhine, Germany. We hypothesize that our model of care will reduce direct and indirect costs of illness, improve quality of care and adherence with medical guidelines, enable a low-threshold access to care and increase health-related quality of life in patients as well as satisfaction with health care situation of patients and health care providers.

Methods

Intervention: The NPPV Program

The NPPV program is a stepped and coordinated model of care for mental and neurological diseases. The program aims at increasing efficiency of care, improve patients’ health outcomes, and reduce direct and indirect health costs. Each patient in the program receives an early evaluation of the patients’ needs for care followed by a timely and appropriate treatment in a multiprofessional network of outpatient health care providers. The network includes specialists from neurology and psychiatry as well as psychotherapists. To plan, coordinate, and ensure an individual treatment according to medical guidelines, every patient is assigned to a managing physician or therapist. These physicians/therapists are the primary contacts for the patients and guide the patient within the network and health care system in general. They also provide special consultation hours, cooperate with other health care professionals in the network and self-help organizations, and may choose from a wide range of additional therapy modules in the program. These modules include group therapy, internet-based cognitive behavioral therapy (ICBT), and an outpatient case management for patients carried out by the NPPV coordination office.

Group therapies are of particular importance for the treatment of mental and neurological diseases and are part of national medical guidelines for depression, posttraumatic stress disorder, or other severe mental diseases [14-16]. In the NPPV program, group therapies may be offered by all qualified health care providers in the network. Possible types of group therapy include (but are not limited to) psychoeducation, neuroeducation and training, strengthening of personal resources, and family counseling. These therapies are supported by the NPPV coordination office, for example, with regard to making appointments.

ICBT may be applied as an alternative or in addition to psychotherapeutic and psychiatric care. These therapies are low-threshold psychosocial interventions and are effective in reducing symptoms, especially for depression, anxiety disorders, panic disorders, and social phobia, and are highly accepted by patients [17-19]. In NPPV, we integrated the digital mental health program called Novego, which has been found to be effective in the reduction of anxiety and depressive symptoms in general and in patients with schizophrenia [20-22]. Novego offers 3 different courses with a focus on depression, burnout, or anxiety. The managing physician or psychotherapist can generate an access code to these courses for a patient. With these codes, patients are able to follow the courses on the internet in their own pace. The administrative tasks related to the courses are carried out by the NPPV coordination office.

Beside the central coordination office, health care providers in the NPPV network are supported by regional network managers. Tasks of the network managers are recruitment of new network

XSL•FO
RenderX

members, implementation of trainings for the professionals, organization of regular quality circles, administrative support for professionals, and quality management. Additionally, physicians and psychotherapists are connected with a common web-based infrastructure ("IVPnet") for patient administration, treatment management, and communication.

The program is funded by the Innovation Fund ("Innovationsfonds"), which was established to support innovative health care projects in Germany in 2015, and financed by the statutory health insurance (SHI) system.

Study Design and Research Questions

The NPPV study is a prospective cohort study with a pragmatic design [23]. Beside the intervention group (participating patients), 2 control groups are drawn by matching techniques. Patients in the intervention group have immediate access to a stepped, coordinated, and comprehensive care program according to medical needs, whereas patients in the control groups receive regular care. In addition, health care providers are participating in a longitudinal survey.

We aim to answer the following research questions: first, does the intervention reduce SHI expenditures per patient? Second, are patients in the intervention group more satisfied with their treatment and do they show a higher quality of life than patients in the control group? Third, can the NPPV structures and processes be established as intended and do they lead to a higher satisfaction among health care providers? Fourth, can the NPPV program induce a more unmet-needs–based approach in the treatment of mental and neurological diseases (eg, do physicians and therapists focus on patient with a higher demand for care and do they follow medical guidelines more closely)?

Study Population and Recruitment

We plan to recruit up to 14,000 patients for the intervention group in the region of North Rhine, Germany. The enrollment period begins in December 2017 and ends in June 2021. Patients eligible for participation in the NPPV program will be identified by their regular outpatient or inpatient health care providers or by their nursing home. They will be referred to a physician or therapist within the NPPV network, who does an entry examination to check eligibility. Inclusion criteria are as follows: age≥18 years, insurance in one of the participating health insurance companies ("AOK Rheinland/Hamburg," "Continentale BKK," and "BKK Deutsche Bank"), and 1 or more medical condition of 7 indication groups as outlined in Table 1. Participation in the NPPV program is voluntary. All patients need to give written informed consent to participate in the program and accompanied study.

Table 1. Medical inclusion and exclusion criteria for indication groups.

Indication group	ICD-10-GM-Codes[a]	Additional criteria
Affective disorders (including anxiety and depression, excluding mania and bipolar disorder)	F30-F39, F41.2	Inclusion when more than 3 weeks unable to work OR at least 2 hospitalizations in 2 years OR minimum score in Mini-ICF Rating for mental disorders
Psychosis (including mania and bipolar disorder)	F20- F31	Inclusion of all patients
Posttraumatic stress or adjustment disorder	F43	Inclusion of all patients
Dementia	F00, F01, G30	Inclusion of all patients
Multiple sclerosis	G35	Inclusion of all patients
Parkinson disease	G20-G22	Inclusion of all patients except vascular parkinsonism (G21.4)
Stroke	I63-I64	Inclusion of all patients with dysfunctions or disabilities, for example, spasticity or cognitive impairment

[a]ICD-10-GM: International Statistical Classification of Diseases and Related Health Problems.

Study Outcomes and Data Sources

Overview

The primary study outcome is the overall SHI expenditures per patient in 12 months after inclusion. Secondary outcomes include SHI expenditures for psychiatric and neurological treatments, hospitalizations (frequency and length of stay), patient-related outcomes (ie, health-related quality of life, satisfaction with health care, and use of intervention modules), and provider-related outcomes (ie, satisfaction, structure and process quality, and needs-led approach).

Data to evaluate the outcomes stem from SHI routine data, outpatient claims data, drug prescription data, a patient survey, and a provider survey. All outcomes and the corresponding data sources are summarized in Table 2.

XSL•FO
RenderX

Table 2. Study outcomes and data sources.

Outcomes	Data source
Primary outcome	
SHI[a] expenditures per patient over 12 months	SHI routine data
Secondary outcomes	
1. SHI expenditures for psychiatric and neurological treatments per patient over 12 months	SHI routine data
2. Frequency of hospitalizations and length of stay over 12 months	SHI routine data
3. Frequency of hospitalizations with ICD[b] codes from inclusion criteria and length of stay over 12 months	SHI routine data
4. Discontinuation of medical treatment over 12 months	SHI routine data
5. Number of days with incapacity for work over 12 months	SHI routine data
6. Health-related quality of life	Patient survey
7. Satisfaction with provided health care	Patient survey
8. Utilization of intervention modules	Patient survey
9. Health care provider satisfaction	Provider survey
10. Structure and process quality	Provider survey
11. Needs-led approach at health care provider level	Ambulatory claims data and drug prescription data

[a]SHI: statutory health insurance.

[b]ICD: International Statistical Classification of Diseases and Related Health Problems.

SHI Routine Data

The participating health insurance companies ("AOK Rheinland/Hamburg," "Continentale BKK," and "BKK Deutsche Bank") provide claims data on inpatient treatment, outpatient treatment, rehabilitation, drug prescriptions, and incapacity to work as well as basic personal information (eg, age, gender, and insurance periods) for participants as well as for 2 pools of control patients. Selection criteria for the first pool of control patients are ICD code of inclusion diagnosis (see Table 2; secured diagnosis of an outpatient health care provider that participates in the NPPV program), age≥18 years at time of diagnosis, and no participation in other special treatment contracts regarding the inclusion diagnoses (this is a pool to generate propensity scores for matching). The second pool consists of patients with the same selection criteria as the first pool, except that these patients should not be treated by a health care provider that is participating in the NPPV program (this is the pool to draw the control group via propensity score matching).

Data are provided at the end of the study and will include data from 4 quarters before inclusion date until March 2021 on each participant that started participation at least in March 2020 and control patients. Inclusion dates for potential control patients are determined by date of inclusion diagnosis. The permission to use the routine data of the participating insurance companies was granted by the State Ministry of Employment, Health and Social Affairs in North Rhine Westphalia.

Patient Survey

Patient-related outcomes are assessed in a longitudinal web-based patient survey. A control group is drawn by direct matching according to specific patient characteristics by the health insurance companies. Patients in the intervention group and the matched control group receive a link to a web-based survey from their respective health insurance company at 4 time points: immediately after inclusion in the intervention group (control group: after matching) and 3, 6, and 12 months after inclusion.

The questionnaire for the intervention and control group consists of several items on health care usage, satisfaction with health care (eg, waiting times and coordination of care), and health-related quality of life (see Multimedia Appendix 1). The latter is assessed using the WHOQOL BREF [24] in all indication groups complemented by indication-specific instruments on quality of life (Q-LES-Q 18 for affective disorders, psychosis and posttraumatic stress, or adjustment disorder [25]; DEMQoL for dementia [26]; MSIS for multiple sclerosis [27], PDQ-39 for Parkinson disease [28]; SA-SIP30 for stroke [29]). In addition, sociodemographic information (eg, age and gender) and data on general health status (eg, hospitalizations and comorbidities) are assessed.

Provider Survey

The quality of structure and processes and provider satisfaction is evaluated with a health care provider survey. All physicians, therapists, and case managers in the NPPV network are invited to participate in a survey carried out by the Central Research Institute of Ambulatory Health Care in Germany (Zi). The Zi developed a 2-part paper questionnaire (see Multimedia Appendix 2). Part A of the baseline survey contains 72 items and asks for an evaluation of structures and processes (eg, coordination and networking in NPPV and IT structures), provider satisfaction, and finally for an assessment of health care quality and workload. Part B of the baseline survey uses 10 questions to gather information about personal data such as

XSL•FO
RenderX

age, gender, and details of health profession and health services. The anonymized questionnaire collects data every year to assess changes over time (4 times during the study period). In order to make comparisons, the structure of the surveys that followed the baseline survey remains the same. There were only additions that reflect current developments, for example, information on health care services during the COVID-19 pandemic.

Ambulatory Claims Data and Drug Prescription Data

An analysis of ambulatory claims data and drug prescription data from the Association of Statutory Health Insurance Physicians in North Rhine aims at evaluating if physicians and therapist focus on patients with high needs. As first source, the claims data contain, among others, outpatient diagnoses coded according to the German modification of the International Classification of Diseases (ICD-10-GM) from the first quarter of 2016 to the third quarter of 2020 for statutory healthinsured individuals in North Rhine. The second data source includes pharmacologic treatments information on the prescribed medication. The 2 data sources were linked together for the analysis. No data were available for residents with private health insurance.

Sample Size Calculation

We calculated minimum sample size for the primary outcome (overall SHI expenditures per patient in 12 months) for which we expect a reduction by 10% in the intervention group as compared to the control group (assuming a coefficient of variation of 0.96). To identify this effect with a statistical power of 80% (α=.05), a minimum sample size of 1456 patients is required in the intervention group and the control group, respectively.

For analyses of secondary outcomes, an effect size of Cohen *d*=0.3 is expected for patient's quality of life (mean difference of 5.38 points on the WHOQOL BREF scale between the intervention group and the control group with SD=17.92 [24]). The sample size required to identify this mean difference with a power of 80% (α=.05) is 175 patients per group.

Data Analyses

Overview

Patient data (SHI routine data and patient survey) are analyzed for the total sample and for different subgroups based on indication groups. There are 2 main subgroups: mental diseases (affective disorders, psychosis and posttraumatic stress, or adjustment disorder) and neurological diseases (dementia, multiple sclerosis, Parkinson disease, and stroke). If sample size is sufficient, single indications groups will be analyzed separately. There will be no linkage between the SHI routine data and patient survey. For all analyses, significance level is set to 5%.

Analyses in SHI Routine Data

SHI routine data are used to evaluate the primary outcome and the secondary outcomes 1-5 (see Table 2). For all outcomes, NPPV participants are compared to a control group that is matched by propensity score matching [30]. Propensity scores are calculated using the data of the first pool of control patients and the participants in a multiple regression model estimating probability of participation in the NPPV program by personal (eg, age and gender) and health characteristics in the 12 months before inclusion date (eg, hospitalizations and frequency of out-patient treatments). The control group consists of matched persons of the second pool of control patients using the estimated propensity scores. To evaluate the outcomes, multiple regression models are estimated, controlling for relevant confounders. If necessary (high intraclass correlation coefficient), multilevel models are used to account for the hierarchical data structure (patients nested in outpatient health care providers that participate in NPPV).

Patient Survey Data

For the analyses of the secondary outcomes 6-8, the data of the longitudinal survey of participants and a control group are used. The control group is drawn by direct matching with the following matching variables: inclusion diagnosis from a health care provider that is not participating in the NPPV program, 10 years age groups, gender, no resident in a care facility, no legal guardian, and grouped number of inhabitants of place of residence. To evaluate the outcomes, descriptive statistics and regression analyses are conducted using longitudinal multilevel modeling techniques.

Provider Survey Data

The evaluation of the developed structures and processes of the project and the health care provider's satisfaction (secondary outcomes 9 and 10 in Table 2) is based on provider survey data. These data were collected by interviewing all participants with a paper questionnaire. The aim is to evaluate if the processes and structures have been established as planned from the point of view of the participating providers. In this context, factors that promote or hinder the implementation of the project should be identified. All data will be collected completely anonymously, so that no conclusions can be drawn about the results of individual providers. Only an overall picture can be collected and compared. This analysis is part of the quality assurance and further development of the project.

Ambulatory Claims Data and Drug Prescription Data

To analyze secondary outcome 11, we use ambulatory claims data and drug prescription data. Ambulatory claims data are used to analyze the frequency of contact to ambulatory health providers. Therefore, the number of treatment cases will be compared to the need of a treatment. The question is if patients with more need of a treatment have higher numbers of treatment cases. A treatment case is defined as the sum of all medical services delivered by 1 physician during 1 quarter. Important diagnostic and therapeutic services for the NPPV patients will be defined and analyzed by checking if the patients receive these selected services and by computing the costs of ambulatory care. In addition, the analysis proves if the patients receive pharmacological care. It is analyzed whether they are under- or oversupplied. Within these analyses, patients who are part of the NPPV program are compared with patients who are not part of the NPPV program. The identification of patients who are part of the NPPV program is done by searching providers in the data who have billed NPPV services. When patients visit these providers, they are classified as an NPPV patient. The

XSL•FO
RenderX

control group will be determined by using propensity score matching. The goal is to determine whether the treatment of the 2 patient groups differs and whether the program can improve the care of certain patient groups.

Ethics Approval

Ethics approval for this trial was obtained from the ethics committee of the chamber of physicians in North Rhine (September 13, 2017, reference No 2017287).

Results

Enrollment of physicians, therapists, and patients is completed. Data analysis was completed in the first half of 2022, and the results will be disseminated through scientific publications, academic conferences, and particularly a publicly available report to the German Federal Joint Committee. This report consists of a comprehensive summary over the study and a detailed description of all evaluation methods and corresponding results. The report is expected to be available after review by the German Federal Joint Committee in the first half of 2023 and can be found on the internet [31].

Discussion

Overview and Perspectives

This paper describes the protocol for a prospective cohort trial to evaluate the effects of the NPPV program. This program is unique and the first intervention to offer a low-threshold access for both mental and neurological diseases, implement a stepped model of care organized according to patients' medical needs, and it builds up on a strong network of multiprofessional health care providers in Germany. We expect that NPPV will in particular reduce costs of illness, improve quality of care, and increase patient and provider satisfaction.

The Act to strengthen care in SHI ("GKV-Versorgungsstärkungsgesetz") from 2015 included a structural reform of outpatient psychotherapy, which came into effect in 2017 [32]. While this reform improved the access to outpatient psychotherapeutic care [9], several evidence-practice gaps in the treatment of mental and neurological diseases prevail. We expect the consequences of the COVID-19 pandemic to further increase the medical and socioeconomic burden of both mental and neurological diseases and enhance the pressure on health care systems [33]. The NPPV program is designed to face these challenges and improve access to and quality of care. While there are several projects funded by Innovation Fund, which focus on mental or neurological diseases, most of them focus on selected settings, specific diseases, health care sectors, or treatment methods [13]. Section 92 of Book V of the German Code of Social Law (§92 SGB V) specifies that regulations on a multiprofessional, coordinated, and structured care for patients with severe mental diseases are to be established in order to advance the German health care system. Several elements of the NPPV program are part of this advancement.

Strengths and Limitations

Our study has some strengths. We include 14,000 patients over 7 indication groups and analyze several different data sources (both primary and routine data). We also consider perspectives of patients, providers, and SHI in our analysis. Taken together, this enables a comprehensive evaluation of the NPPV program for patients with a wide range of mental and neurological diseases. However, our study also has some limitations. First, although we use matched control groups for the patient survey and analysis of routine data, our evaluation has a nonrandomized design. Second, we cannot completely rule out differences in disease severity between intervention and control groups. While an acutely higher disease severity increases the likelihood of being included in the program, this characteristic is not reflected in routine data used for our matching procedure. Third, we may face a selection bias in the patient survey as patients who are younger, healthier, and more educated are more likely to be willing to participate in our study. Finally, long-term effects (>24 months) on costs and patient outcomes cannot be evaluated in our analyses.

Acknowledgments

The authors thank all the following members of the NPPV care group for their work: Sylvia Beckmann, Annegret Boeckenholt, Guido Breuer, Thomas Czihal, René Engelmann, Silke Hochheim, Thorsten Janssen, Barbara Lubisch, Uwe Meier, Gilbert Mohr, Hans-Dieter Nolting, Norbert Paas, Sebastian Rienas, Miguel Tamayo Korte, Stephanie Theiß, Egbert Wienforth, and Anika Zembok. Abstract

Background: Foot baths are used in complementary and alternative therapy to improve the duration and quality of sleep and reduce tension, anxiety, fatigue, and confusion. They are also known to improve the frequency of labor contractions and to increase their duration in women; thus, they are commonly used by midwives in clinical settings in Japan. However, the physical and mental effects of foot baths during labor are unknown.

Objective: This study aims to assess the physical and mental effects of foot baths based on biomarker levels and self-administered questionnaires.

Methods: A single-arm pre-post test trial design is being used in this study, and the study is being conducted at a general hospital in Tochigi Prefecture, Japan. The target study population is women in the first stage of labor, the phase when the uterus starts to contract and when the cervix dilates to 10 cm, or those undergoing labor induction. Participants who meet the eligibility criteria are recruited, and written informed consent is obtained from them. They are asked to answer the questionnaire and to collect 1.5 mL of saliva in 2 microtubes each, before and after the intervention. The intervention is foot baths for 15-20 minutes using a foot bath device. Data on delivery, such as gestational age, gravidity, parity, diagnosis following the last vaginal examination, and presence or absence of membrane rupture, are retrieved from the medical records. The primary outcomes are salivary cortisol levels before and after the foot baths. The secondary outcomes are levels of relaxation and comfort, labor pain, body warmth, vital signs, and interval of labor pain before and after the foot baths, which are assessed using a numerical rating scale. A paired *t* test or Wilcoxon signed-rank test will be performed to compare the data for salivary cortisol levels and numerical rating scale scores.

Results: Data collection started on April 1, 2022. As of October 2022, we had enrolled 10 participants. Because of the COVID-19 pandemic in Japan, it is difficult for medical personnel to freely interact with women in labor until the results of the COVID-19 polymerase chain reaction test are available in the research facility, complicating the recruitment process.

Conclusions: This is the first prospective study to assess the effects of foot baths using a biomarker during the first stage of labor. The findings on the effects of foot baths on women in labor will provide novel insights that may improve the outcomes of delivery. A randomized controlled trial to investigate the effects of foot baths to obtain robust evidence should be conducted in the future.

KEYWORDS

foot bath; women in labor; salivary cortisol; pregnant; pregnancy; alternative medicine; complementary medicine

Introduction

Background

Foot baths are used for cleaning the feet and are useful in complementary and alternative therapy. Foot baths improve the duration and quality of sleep among postmenopausal and older adults [1-4], decrease low back pain in pregnant women [5], and have psychological effects, such as reduced tension, anxiety, fatigue, and confusion in women [6,7]. They are also known to be effective in decreasing edema of the lower limbs by improving blood circulation due to blood vessel dilation [8].

Studies evaluating the effect of foot baths in the first stage of labor reported that they improve the frequency of labor contractions in women with slow labor [9] and increase the duration of labor contractions in primiparous women [10]. Thus, foot baths may show effects on labor induction.

The epidural labor rate has been increasing in Japan (4.6% in 2014, 5.5% in 2015, and 6.1% in 2016) [11], although it remains lower than that in European or American countries [11-15]. One reason for the low rate of epidural labor in Japan is the low number of anesthetists and obstetricians in the country, affecting their availability for all cases. Therefore, several nonmedical methods are used for labor pain relief in clinical settings, including hot bath therapy, reflexology, aroma therapy, breathing, and massage [15-17]. Although previous studies have reported the psychological and labor-inducing effects of foot baths [6,7,9,10], the sample size of some of these studies was small, and others did not include women in labor. Furthermore, the physical and mental effects of foot baths during labor, such as the effects on relieving labor pain, improving relaxation, or decreasing stress, remain unknown, and no study has investigated the effect of foot baths on women in labor using biomarkers. Cortisol is a hormone secreted by the suprarenal cortex and is widely used as a biomarker to measure stress levels. If foot baths are shown to reduce stress in women in labor, they can be recommended for the nonmedical care of women in labor. Therefore, investigating the physical and mental effects of foot baths on women in labor, especially their pain-relieving effects, can facilitate mental relief and a satisfactory childbirth experience for women in labor. Foot baths are commonly used by midwives in clinical settings in Japan and are expected to have psychological and labor-inducing effects.

Study Aims

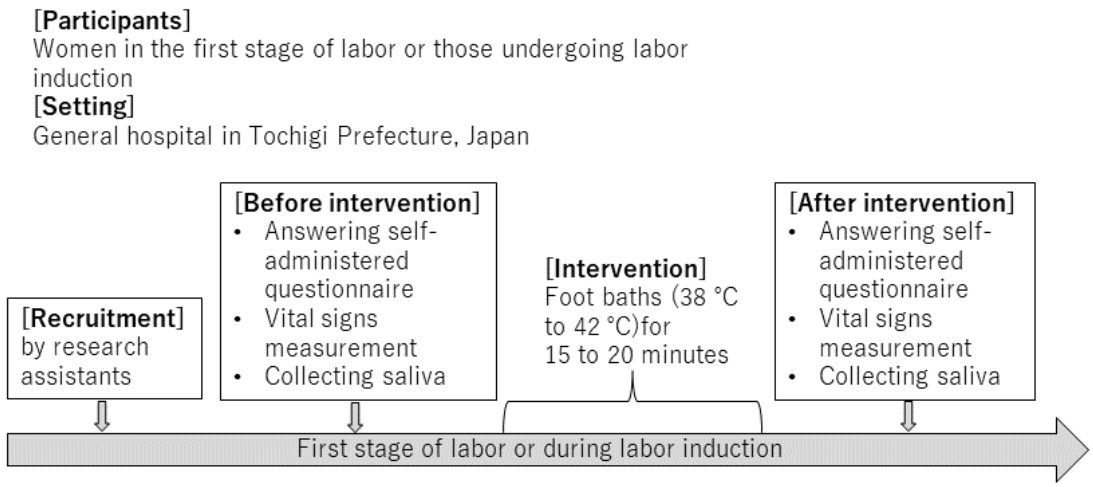
This study aims to investigate the physical and mental effects of foot baths using a biomarker and self-administered questionnaire.

Methods

Study Design

We are conducting a single-arm, pre-post test trial to evaluate the effectiveness of foot baths.

Study Setting and Population



The study is being conducted at a general hospital in Tochigi Prefecture, Japan. The inclusion criteria are women in the first stage of labor or those undergoing labor induction. The first stage of labor is the phase when a pregnant woman's uterus starts to contract and they feel persistent contractions and relaxation, and the cervix dilates to 10 cm. Women who cannot complete the questionnaire or cannot participate in the study because of labor pain or those who are judged to have difficulty participating in the study by midwives because of low literacy of Japanese or due to mental illnesses are excluded from recruitment.

Intervention Description

This is a pre-post test trial; therefore, all participants are to receive the intervention. In this study, a foot bath is defined as the immersion of feet up to the ankle in hot water, set to a temperature that feels comfortable to the participants (38 °C to 42 °C) for 15-20 minutes (Figure 1). During the foot bath, other stimuli, such as pushing acupoints or massage, are avoided, because a meta-analysis has shown the effects of acupressure on labor duration [18]; this point was explained to all research assistants before starting this study. Participants receive the foot bath intervention only once, because midwives usually provide foot baths for women in labor only once in clinical settings; therefore, we aim to evaluate the effects of a single foot bath intervention. The intervention is discontinued if delivery progresses rapidly and if the midwives consider it difficult to continue.

XSL•FO
RenderX

Figure 1. Protocol of the study.

Data Collection

Variables

Data collection is being undertaken by research assistants, who are midwives working in the hospital and on duty, as assigned by the midwife in charge.

Data are collected using a self-administered questionnaire, laboratory assay for the biomarker, anthropometric measurements, and medical records. The self-administered questionnaire was adapted from those developed in previous studies that assessed the effects of foot baths [7,19-23]. Participants are asked to answer a questionnaire evaluating sociodemographic data, such as age, marital status (married, single, divorced, or widowed), education level (junior high or high school; vocational school, junior college, or technical college; and university or graduate school), and occupation (employee, public servant, self-employed, part-time worker, unemployed or housewife, and others). Previous studies used a 10 cm ruler to assess the comfort or feeling of body warmth [19,24], with 0 cm meaning “not at all” and 10 cm meaning “extremely so”; thus, in this study, a numerical rating scale (NRS), ranging from 0 to 10, is being used to collect data on the levels of labor pain and comfort, relaxation, and degree of warmth of the legs and entire body. Participants are asked to provide 1.5 mL of saliva in 2 microtubes before and after the foot bath. Vital signs, such as blood pressure, body temperature, pulse rate, and respiratory rate, are measured by research assistants before and after the foot bath. Data on delivery (gestational age, gravidity, parity, diagnosis following the last vaginal examination [such as dilation, station, effacement, consistency, and position], presence or absence of membrane rupture, use of uterine contraction agents, and estimated fetal body weight) are retrieved from the medical records by the research assistants and entered in the questionnaire.

The primary outcome of this study is salivary cortisol levels before and after the foot bath. The secondary outcomes are levels of labor pain, comfort and relaxation, and leg and body warmth, assessed using NRS scores, vital signs, and intervals of labor pain before and after the foot bath.

Data Collection Methods

We asked some experienced midwives working at the hospital to assist in this study as research assistants. Before study initiation, instructions on data collection and intervention were provided and explained to the research assistants.

The research assistants recruit participants for the study and explain the purpose and contents of the study using an instruction sheet. After obtaining oral consent, written informed consent is obtained.

The research assistants provide the participants with the self-administered questionnaire along with a clipboard and pen. Participants are asked to complete the self-administered questionnaire. After completion, the midwives measure the participants’ vital signs (blood pressure, body temperature, pulse rate, and respiratory rate) and the interval and duration of labor pain.

They also request participants to provide 1.5 mL of saliva in 2 microtubes each. After saliva collection, the specimens are stored at −20 °C until analysis.

The research assistants provide foot baths to participants using a foot bath device (Hietori-kun Micon Premium, FB-C80, Koyo Co, Ltd, Gifu, Japan). The temperature of the water is set to 38 °C to 42 °C, as desired by the participants. AS mentioned, during the foot bath, the research assistants avoid applying pressure on acupoints. The participants are allowed to soak their feet in the bath quietly for 15-20 minutes.

After the foot bath, the research assistants provide the participants with a self-administered questionnaire with a clipboard and pen. After completing the questionnaire, they measure the vital signs (blood pressure, body temperature, pulse rate, and respiratory rate) and the interval and duration of labor pain.

After saliva collection, the specimens are stored at −20 °C until analysis. If the participants have difficulty providing saliva because of severe labor pain, only responding to the self-administered questionnaire and the measurement of the vital signs is allowed.

XSL•FO
RenderX

After recruitment, all salivary cortisol level measurements are conducted at Yanaihara Institute Inc, Shizuoka, Japan.

We will continue to recruit participants until the target sample size is attained, and we may consider adding another hospital as a study setting in case the recruitment does not progress favorably because of the COVID-19 pandemic. It is difficult for medical personnel to freely interact with women in labor until the results of the COVID-19 polymerase chain reaction test are available, complicating the recruitment process.

Data are double-checked during entry, and the data ranges are checked to ensure data quality. The collected data and questionnaires are stored in a locked cupboard.

Sample Size Calculation

According to a previous study that investigated differences in salivary cortisol levels before and after foot baths [20], the sample size was calculated based on the following considerations: effect size (Cohen *d*)=0.4, α (2-tailed)=.05, and β=.80. We estimated the sample size using a two-tailed *t* test to be equal to 100.

Patient and Public Involvement

Neither patients nor the public are involved in the design, conduct, reporting, or dissemination of the study.

Data Analysis

Categorical variables, such as marital status, education level, and occupation, will be presented as n (%), and continuous variables (salivary cortisol levels; NRS scores for labor pain, comfort, and relaxation; and vital signs, such as blood pressure, body temperature, pulse rate, and respiratory rate) will be presented as mean (SD) if normally distributed or as medians and interquartile ranges if nonnormally distributed. We will perform paired *t* tests for continuous variables if the observations are normally distributed, and if they are not, we will perform the Wilcoxon signed-rank test to compare data before and after foot baths. Furthermore, we will divide the participants into 2 groups, nullipara and multipara, for sensitivity analysis. All missing pretest or posttest data for the main outcome will be excluded from the analysis.

All data will be analyzed using SPSS Statistics for Windows (version 28.0; IBM Corp). Two-tailed *P* values of <.05 will be considered statistically significant.

Harms

In this study, foot bath devices with a constant temperature of hot water are used. When preparing hot water, the midwives check the temperature using a thermometer; however, the possibility of burns to the feet cannot be ruled out. Moreover, water spills on the floor may cause falls. In case of accidents, the midwives report to the obstetrician of the maternity ward and arrange for a doctor's visit. The cost of medical treatment is to be covered by the participant's health insurance coverage.

Ethics Approval and Consent to Participate

This study was approved by the Research Ethics Committee of the School of Nursing, Dokkyo Medical University, Japan (No. Nursing 03019) and the Research Ethics Committee of Kamitsuga General Hospital (No. 2021-008). The research assistants explain the purpose and contents of the study using an instruction sheet. Participation is voluntary. The possibility of harm and financial burden in case of accidents is explained to the participants. Written informed consent is obtained from all participants. Participants' identifying information, such as their name, home address, and date of birth, is handled only by the hospital staff, and the information is never taken out of the research facility. All data will be analyzed anonymously, and participants' other identifying information will be removed before analysis. The results of this study will be disseminated to scientific meetings and journals.

Trial Registration

This study was registered in the University Hospital Medical Information Network-Clinical Trial Registry system (UMIN000046539) on January 17, 2022.

Results

Data collection started on April 1, 2022. As of October 2022, we had enrolled 10 participants. Because of the COVID-19 pandemic in Japan, it is difficult for medical personnel to freely interact with women in labor until the results of the COVID-19 polymerase chain reaction test are available in the research facility, complicating the recruitment process. Moreover, the number of medical personnel who can engage in the research decreased in the research facility because some staff were infected by COVID-19; thus, recruitment is currently not progressing.

Discussion

Principal Findings

This is the first prospective study that will assess the effects of foot baths using a biomarker (salivary cortisol) in the first stage of labor. Though foot baths are commonly used by midwives in clinical settings in Japan and are expected to have psychological and labor-inducing effects, psychological effects using biomarkers have not been shown. Participant recruitment started on April 2022, but because of the COVID-19 pandemic in Japan, recruitment is currently not progressing.

Though several studies have reported the physical and mental effects of foot baths, they did not include women in labor as participants [1-8]. Previous studies that targeted women in labor [9,10,25] had several limitations, which are as follows: had a small sample size [9], focused only on the progress of labor effects of foot baths [9,10], and used the visual analog scale to assess anxiety [25]. In clinical settings, midwives sometimes apply pressure to acupoints during foot baths, and they use aroma as part of a midwife's care during the first stage of labor. A meta-analysis has shown the effects of acupressure on labor duration [18], and aroma increased the effects of foot baths [25,26]. Therefore, in this study, we are implementing a simple foot bath without any acupressure or aroma, and the research assistants follow the study protocols because the effects of acupressure and aroma are widely known to midwives in Japan.

XSL•FO
RenderX

In Japan, the rate of epidural labor has been increasing recently [11]. Midwives traditionally implement nonpharmacological care in Japan, and foot baths are a form of such care. However, the physical and mental effects of foot baths have not been fully investigated, especially using biomarkers. Therefore, the findings for the effects of foot baths on women in labor will provide a novel perspective that will be useful worldwide, especially in developing countries where pharmacological care is difficult to access.

The appropriateness of the methodology of this study should be discussed. In this study, the outcomes are measured using salivary cortisol and an NRS for the levels of labor pain and comfort, relaxation, and the degree of warmth of the legs and the entire body. Samples are collected during labor, and therefore, collecting saliva or answering the questionnaire may trigger pain or stress for some participants. However, scoring NRS is not time-consuming, and several studies have used visual analog scales to assess comfort or warmth [19,20,24]; thus, it may be better than using a mental scale. The information about the participants' characteristics, such as marital status, is obtained in this study because participants' characteristics may affect their mental condition under the stress of labor. Moreover, this study is conducted in only 1 prefecture in Japan; thus, participants' characteristics may be biased, and the results should be interpreted with caution.

Furthermore, we need to mention the potential physical harm from foot baths. Foot baths are one of the popular midwifery interventions in Japan due to their psychological and labor-inducing effects. Therefore, most midwives understand the necessary precautions, such as controlling the temperature of hot water and avoiding water spills on the floor. Nevertheless, in this study, we use foot bath devices to maintain the correct temperature of the hot water, although we cannot fully rule out the possibility of burns to the feet.

Moreover, this study uses a single-arm, pre-post test trial design; thus, the interpretation of the study findings requires some attention. With such a design, the results will only show within-individual differences. To obtain robust evidence on the effects of foot baths during labor, a randomized controlled trial should be conducted in the future.

Strengths and Limitations

The strength of this study is that this is the first study that assesses the effects of foot baths during the first stage of labor using a biomarker (salivary cortisol). Though several previous studies have reported the effects of foot baths, few have evaluated them using biomarkers; moreover, there are no studies using biomarkers among women in childbirth.

Nevertheless, this study has some limitations. First, the design of this study is a single-arm pre-post test trial; thus, it is difficult to judge the effects of foot baths. To obtain robust evidence of the effects of foot baths, randomized controlled trials should be conducted in the future. Second, because of the COVID-19 pandemic, participant recruitment has not progressed favorably. Therefore, adding another hospital as a study setting has to be considered.

Conclusion

This is the first prospective study that will assess the effects of foot baths using a biomarker (salivary cortisol) in the first stage of labor. Though participant recruitment has not progressed favorably because of the COVID-19 pandemic, if foot baths are shown to reduce stress in women in labor, they can be recommended for the nonmedical care of women in labor. A randomized controlled trial to investigate the effects of foot baths to obtain robust evidence should be conducted in the future.

Acknowledgments

This study has been funded by the School of Nursing, Dokkyo Medical University, Tochigi, Japan. The funding body did not have any role in the study design, data analysis, manuscript preparation, and submission.

Availability of Data and Materials

Data sharing is not applicable to this article as no data sets have yet been generated or analyzed for the study.

Authors' Contributions

NH, RI, KM, and AI were involved in the conception, design, and drafting of this manuscript. NH was involved in the writing and revision of the manuscript. All authors have read and approved the final version of the manuscript.

Abstract

Background: Home-based (unsupervised) buprenorphine initiation is considered safe and effective, yet many patients report barriers to successful treatment initiation. Prescription digital therapeutics (PDTs) are software-based disease treatments regulated by the US Food and Drug Administration (FDA). The reSET-O PDT was authorized by the FDA in 2018 and delivers behavioral treatment for individuals receiving buprenorphine for opioid use disorder (OUD). A prototype PDT (PEAR-002b) designed for use with reSET-O was developed to assist in unsupervised buprenorphine initiation.

Objective: The primary objective of this pilot study is to evaluate the acceptability of PEAR-002b in individuals with OUD who use it to support buprenorphine initiation, their unsupervised buprenorphine initiation success rate, and their medication adherence.

Methods: Ten adults with OUD will be recruited for acceptability and feasibility testing. Outcomes will be assessed using week-1 visit attendance, participant interviews and satisfaction surveys, and urine drug screening (UDS). Three tools will be used in the study: PEAR-002b, reSET-O, and EmbracePlus. PEAR-002b includes a new set of features designed for use with reSET-O. The mechanism of action for the combined PEAR-002b and reSET-O treatment is a program of medication dosing support during week 1 of the initiation phase, cognitive behavioral therapy, and contingency management. During the medication initiation phase, participants are guided through a process to support proper medication use. PEAR-002b advises them when to take their buprenorphine based on provider inputs (eg, starting dose), self-reported substance use, and self-reported withdrawal symptoms. This study also administers the EmbracePlus device, a medical-grade smartwatch, to pilot methods for collecting physiologic data (eg, heart rate and skin conductance) and evaluate the device's potential for use along with PDTs that are designed to improve OUD treatment initiation. Home buprenorphine initiation success will be summarized as the proportion of participants attending the post–buprenorphine initiation visit (week 1) and the proportion of participants who experience buprenorphine initiation–related adverse events (eg, precipitated withdrawal). Acceptability of PEAR-002b will be evaluated based on individual participants' ratings of ease of use, satisfaction, perceived helpfulness, and likelihood of recommending PEAR-002b. Medication adherence will be evaluated by participant self-report data and confirmed by UDS. UDS data will be summarized as the mean of individual participants' proportion of total urine samples testing positive for buprenorphine or norbuprenorphine over the 4-week study.

Results: This project was funded in September 2019. As of September 2022, participant enrollment is ongoing.

Conclusions: This is the first study to our knowledge to develop a PDT that assists with unsupervised buprenorphine initiation with the intent to better support patients and prescribers during this early phase of treatment. This pilot study will assess the acceptability and utility of a digital therapeutic to assist individuals with OUD with unsupervised buprenorphine initiation.

KEYWORDS

buprenorphine; digital therapeutics; opioid use disorder; OUD; prescription digital therapeutic; PDT; reSET-O; unsupervised buprenorphine initiation; medication adherence; digital health intervention

Introduction

Unprecedented rates of opioid misuse and mortality have led to the current opioid epidemic in the United States [1], with approximately 2.5 million people in the United States meeting the criteria for opioid use disorder (OUD) in 2020 [2]. OUD is a chronic condition with numerous physical, psychological, and personal consequences, including a high risk of death, which has risen in recent years due to the increasing prevalence of potent synthetic opioids (predominantly fentanyl) [3]. According to the latest reports, 74,754 adults died from opioid-related overdoses in the 12 months ending September 2021, representing a daily average of 205 deaths [1], a 55% increase since September 2019 [4]. Opioid-related overdoses now account for 75% of fatal overdoses of all substances, up from 70.6% in 2019, with synthetic opioids accounting for 86.6% of opioid-related deaths [4].

Initiation of evidence-based medications for opioid use disorder (MOUD), such as buprenorphine, methadone, or naltrexone, remains limited; in 2020, only 11.2% of those with OUD received MOUD treatment [2]. One of the key barriers is limited access to MOUD treatment [2], which is amplified by health care provider reservations about prescribing buprenorphine for OUD. Key reasons for this hesitancy include logistical barriers, perceptions that people with addiction are difficult to treat, insufficient time and staff support, limited provider and staff knowledge and training, and lack of a support network of experienced prescribers [5-8]. Despite the recent removal of the "X waiver" training requirement, prescribers may still feel they are not adequately equipped to begin prescribing for the above reasons [9].

For individuals who do access MOUD, medication adherence is unsatisfactory, and medication discontinuation rates are high [10,11]. Buprenorphine discontinuation rates at 6 months range from 50% to 65%, with most discontinuations occurring within the first 3 months of treatment, particularly within the first 30 days, which is a crucial phase that includes initiation and titration of buprenorphine to achieve dose stabilization [10-14]. Evidence from different real-world settings suggests that MOUD discontinuation is estimated to increase the likelihood of relapse by roughly 10 times, with relapse being strongly associated with overdose and death [15-17].

The medication initiation phase for buprenorphine, in particular, is critical. Patients who have negative experiences initiating buprenorphine may not continue treatment beyond the first day of dosing [18]. Successful initiation of buprenorphine requires the patient to be in mild to moderate withdrawal before they begin the medication [19]. People's desire to avoid experiencing withdrawal symptoms is a primary reason they continue to use and can be a major barrier to beginning treatment [20]. Buprenorphine initiation is a high-touch process for clinicians that requires educating the patient on not only the risks and benefits of buprenorphine, but how the medication works, when to start treatment, and how to manage emotions like fear and anxiety that can complicate the process.

Providing an accessible tool that supports both the patient and clinician by offering education as well as motivational and skills-based support during this important phase of treatment could enhance the patient experience and help improve clinician willingness to prescribe. Unsupervised buprenorphine initiation, whether supported via telemedicine or traditional in-person provider interactions, is considered safe and effective and may be an equitable and accessible way to increase the rate of successful MOUD initiation [19]. One potential limitation of unsupervised MOUD initiation is the inability of physicians to monitor patient biometrics (eg, pulse, blood pressure, and oxygen saturation levels), which can inform treatment and dosing decisions. New devices exist to monitor biometrics, but whether unsupervised buprenorphine initiation protocols could benefit from data collected by passive biometric monitoring is unknown.

Another technology that may potentially be leveraged to improve the MOUD initiation process is prescription digital therapeutics (PDTs), which are software-based disease treatments evaluated for safety and effectiveness in randomized controlled trials and authorized by the US Food and Drug Administration (FDA). Prescribed by treating physicians and delivered on mobile devices, PDTs can expand access to evidence-based behavioral therapies across a variety of disease states, including OUD.

The reSET-O PDT was authorized by the FDA in 2018 for patients with OUD being treated with buprenorphine. The PDT delivers two evidence-based mechanisms of action: (1) an OUD-specific form of cognitive behavioral therapy (CBT) based on the community reinforcement approach, delivered as on-demand lessons and interactive text, video, and audio exercises and (2) reinforcement and motivation for lesson completion and abstinence via contingency management (CM), which involves eligibility for positive reinforcement messages or monetary digital gift cards. Moreover, there is currently no FDA-authorized PDT that provides assistance with home initiation of MOUD. Opportunities thus exist to better support patients with OUD in the medication initiation phase and to provide strategies to lower potential barriers to the implementation of buprenorphine MOUD treatment in clinical practice.

XSL•FO
RenderX

Given the importance of buprenorphine adherence and the need to better support both patients and providers during the initiation process, we are conducting a pilot study to evaluate PEAR-002b, an investigational digital therapeutic intended to be used with reSET-O and designed to support patients during unsupervised initiation of buprenorphine. The study also includes a wearable device capable of capturing and transmitting biometric data to evaluate the feasibility of biomarker development.

Methods

Study Objectives

The objective of this pilot study is to evaluate device acceptability, home buprenorphine initiation success rate, and medication adherence rate among participants with OUD who use the PEAR-002b investigational tool.

Study Design

This will be a qualitative observational cohort study with a recruitment goal of 10 adults with OUD (inclusion and exclusion criteria are listed below).

Study Population and Sample Size

The trial will recruit 10 adults diagnosed with OUD. The investigator will ensure that participants being considered for the study meet all eligibility criteria (details are provided in the Study Procedures and Assessments section). No additional criteria will be applied by the investigator to ensure the study population will be representative of all eligible participants. Participants may undergo rescreening with approval of the medical monitor. Due to the exploratory nature of the study, no formal sample size calculations are required.

Inclusion Criteria

Study inclusion criteria are as follows: written informed consent provided prior to the performance of any study-specific assessments; age ≥18 years; English proficiency sufficient to meaningfully participate in the consent process, assessment, and intervention; a *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) diagnosis of OUD made by a treating clinician; desire to start buprenorphine treatment; capability of using common software applications on an internet-enabled mobile device (smartphone or tablet); interest in testing or using PEAR-002b; no prior history of reSET-O use; no participation in investigational drug trials within the past 30 days (or within 5 half-lives of any study drug, whichever is longer) of enrollment; and a judgment that the subject is appropriate for participation by the treating clinician.

Exclusion Criteria

Study exclusion criteria are as follows: currently on methadone or naltrexone pharmacotherapy; currently on buprenorphine MOUD treatment; planning to move out of the geographic area within 2 months; insufficient English fluency to participate in the consent process, intervention, or assessment; inability to comply with study procedures due to physical or mental condition; currently receiving inpatient treatment for OUD; and pregnancy.

Study Setting and Recruitment

The study will be conducted at a single site in the United States. Participants will be recruited verbally by participating clinicians and via community advertising.

Study Tools

Overview

Three tools will be used in the study: PEAR-002b, reSET-O, and EmbracePlus. PEAR-002b is a standalone software app that includes a new set of features designed for use with the reSET-O PDT. The mechanism of action for the combined PEAR-002b and reSET-O treatment is a program of medication dosing support during week 1 of the buprenorphine initiation phase, including psychoeducation, CBT, and CM. During the first week of treatment (ie, the buprenorphine initiation phase) participants are guided through the medication initiation process with psychoeducation to support proper medication use and a self-report withdrawal scale to advise the participant on when to take their buprenorphine. During the use of reSET-O, which occurs in weeks 2 to 4, participants are instructed to complete 4 lessons per week. The EmbracePlus device is a medical-grade smartwatch that will be used to collect physiologic data (eg, heart rate and skin conductance) from participants who agree to use the device.

The smartphones loaned to participants in this study include an installed security feature that blocks downloads of other apps, potentially limiting their market value and thus reducing the risk that the phones will not be returned at the conclusion of the study.

PEAR-002b Summary Description

PEAR-002b includes an algorithm designed to support buprenorphine dosing and provide associated therapeutic content related to medication and recovery. Medication dosing recommendations are based on provider input (eg, starting dose) and reported recent substance use. A withdrawal symptom scale based on the Subjective Opiate Withdrawal Scale helps participants identify when to take their medication and how to titrate their medication dose to manage withdrawal symptoms. Development of all features and content was informed by feedback generated through participant interviews and prototype testing sessions.

The PEAR-002b content was designed to maximize the efficacy of buprenorphine treatment by educating participants on the importance of proper buprenorphine use and adherence in recovery. Videos and text-based modules address the following topics: preparing for buprenorphine initiation; recognizing, coping with, and managing common opioid withdrawal symptoms prior to buprenorphine initiation; proper initiation of buprenorphine; techniques for sublingual or buccal dosing of buprenorphine to maximize absorption and therapeutic drug levels; how medication adherence supports treatment goals; misconceptions and stigma pertaining to buprenorphine treatment; proper storage and security of buprenorphine to minimize the risk of diversion; and the mechanism of action of buprenorphine treatment.

XSL•FO
RenderX

reSET-O Summary Description

PEAR-002b is designed as an optional feature of the reSET-O PDT, which provides an 84-day course of behavioral treatment for OUD as an adjunct to standard buprenorphine MOUD treatment. The reSET-O PDT delivers behavioral therapy modeled on the Community Reinforcement Approach [21], which is a specific form of CBT designed for patients with OUD [22-24]. The PDT provides therapy through a series of 67 interactive lessons delivered via a patient-facing smartphone app. It also has a web-based dashboard for use by clinicians. A typical therapy lesson consists of a CBT component and skill-building exercises. Therapy lesson content is delivered primarily via written text but may also include videos, animations, and graphics. It also has an optional function that patients can use to set medication reminders. The first time a patient opens the app each day, they are asked to report whether they have taken their buprenorphine. Patients who report not taking it are asked to indicate the reasons for nonuse.

Therapy lessons are divided into "core" and "keep learning" lessons. Core lessons cover key CBT concepts, whereas "keep learning" lessons include more in-depth information on key CBT topics covered in the core lessons, as well as additional topics that may be of interest to patients. Once a core lesson is completed, patients can unlock the next lesson. "Keep learning" lessons can be completed in any order and are accessible once the core lessons are completed.

EmbracePlus Summary Description

EmbracePlus is a device worn on the wrist that collects, processes, stores, and wirelessly transmits physiologic parameters to a companion app and monitoring platform. The device consists of an electronic display, display case, wristband, and sensors. The device produces 2 types of data: raw data (high-frequency data recorded by EmbracePlus sensors) and digital biomarkers (computed from raw data using algorithms). Biomarkers aggregated by EmbracePlus (1 value per minute) include pulse rate, pulse rate variability, respiratory rate, blood oxygen saturation, sleep periods, movement, skin conductance, temperature, and wearing time. In addition to collecting physiologic data via its sensors, EmbracePlus enables the user to tag specific events by pressing a button on the side of the device. Data collected via EmbracePlus flow through the Empatica Care app (a participant-facing app that notifies the participant if action is required and provides a real-time display of digital biomarkers) to Empatica Cloud (for data storage) and the Empatica Care Portal (a web app to manage study participants and monitor digital biomarkers computed by EmbracePlus).

Ethical Considerations

Conduct of the Study

This study will be conducted in full accordance with all applicable policies and procedures and all applicable US federal and state laws and regulations, including the 45 Code of Federal Regulations 46, and the Health Insurance Portability and Accountability (HIPAA) Privacy Rule. Any episode of noncompliance will be documented. The investigator will perform the study in accordance with this protocol and will report unexpected problems in accordance with institutional review board (Advarra IRB Services; approval number Pro00037072) procedures and all federal requirements. Collection, recording, and reporting of data will be accurate and will ensure the privacy, health, and welfare of research participants during and after the study. All participants will be required to sign an informed consent document at the screening visit, prior to the start of any study-specific procedures. The informed consent document will include an overview of the study, including a clear description of all study procedures, potential risks and benefits of participating in the study, and alternatives to participating in the study. Participants have the right to withdraw from the study at any time and for any reason, and all participants are made aware that withdrawal will not affect their routine care.

Confidentiality

The anonymity of participants will be maintained. Participants will be identified by their initials and an assigned study number on electronic case report forms (e-CRFs) and other documents submitted to the study monitor. No protected health information will be stored outside of the study clinic, PEAR-002b system, reSET-O, or the encrypted HIPAA-compliant electronic data capture platform. Data collected by the PEAR-002b system will be securely transferred using industry standard encryption to the PEAR-002b backend services, which use a cloud-based infrastructure that serves and communicates with the patient-facing mobile app.

The backend services contain all data and analytics for reSET-O, PEAR-002b, and its clients (participants and clinicians). All data stored by the study devices are hosted and stored by Amazon Web Services (AWS). AWS follows a variety of internationally recognized security standards, such as the National Institute of Standards and Technology SP800-53 and HIPAA. All participant information is automatically encrypted by AWS when it is entered into the system, allowing for secure data transfer (from participant device to clinician device) and storage.

The EmbracePlus and Care apps are compliant with federal regulations, directives, and international standards for medical devices. Empatica Cloud is the infrastructure where the data recorded from EmbracePlus is collected and made accessible via web interfaces and data repositories. Empatica Cloud is HIPAA compliant. Participant data collected via EmbracePlus is securely stored and encrypted within the AWS cloud service.

Participants will be compensated for attending study visits and completing study assessments as follows (all values in US $): baseline clinic visit, $50; weekly study visit (n=4), $20; urine sample (n=5), $10; qualitative interview (n=2), $50; wearable use, $10 per study visit (n=4). Participants also have the chance to receive monetary rewards in the form of digital gift cards, ranging in value from $5 to $100, earned via the use of the CM functionality of the reSET-O study device.

Study Procedures and Assessments

Prospective participants referred to the study will be screened for eligibility criteria by a research assistant based on the study inclusion and exclusion criteria and clinical documentation of

XSL•FO
RenderX

assessments as needed. Diagnoses of OUD will be made by treating clinicians following standard clinical protocols at the study site, based on *DSM-5* criteria. Recruited participants will be given standard screenings in accordance with the assessment schedule. For the convenience of participants, screening and baseline visits may be combined. All participants will be required to sign an informed consent form at the screening visit, prior to the start of any study procedures. Participants meeting eligibility criteria will be assigned a subject identification number during the baseline visit. Study participants will continue to receive standard treatment for OUD following prescriber-recommended instructions for medication formulation and starting dose, as well as clinic visits unrelated to the study (eg, for medication management or counseling). Standard treatment will be supplemented with the therapeutic tools (PEAR-002b and reSET-O).

Participants will be enrolled for 4 weeks to assess the acceptability and ease of use of the PDT. At baseline, if participants still meet all inclusion and exclusion criteria, study staff will provide them with a phone preloaded with the study apps. Participants will be asked if they also agree to wear the EmbracePlus smartwatch for the duration of the study, and those who agree will be provided the device. Study staff will train willing participants in use of the study apps and the EmbracePlus device. Additionally, a UDS will be performed, and the Clinical Opiate Withdrawal Scale (COWS) will be used. One week later, the participant will return to the clinic and complete a survey and an interview. Study staff will conduct another UDS, administer the COWS, and ask about any adverse events (AEs) or side effects. Following this visit, the participant will return weekly for a UDS and AE assessment. At week 4, the participant will return for a UDS and complete a final survey and exit interview. Primary, secondary, and exploratory objectives and end points are outlined in Textbox 1.

Textbox 1. Study objectives and end points.

Primary objectives

- To assess the effect of PEAR-002b on home buprenorphine initiation success rates (ie, the proportion of participants attending the post–buprenorphine initiation visit)
- To evaluate the acceptability of PEAR-002b
- To assess the effect of PEAR-002b on medication adherence rates

Primary end points

- Proportion of participants attending the post–buprenorphine initiation visit and the proportion of participants who experience buprenorphine initiation–related adverse events (eg, precipitated withdrawal)
- Participants' ratings of PEAR-002b for ease of use, satisfaction, perceived helpfulness, and the likelihood they would recommend it
- Participant self-report data and confirmation by urine drug screens

Secondary objectives

- To assess dosing and engagement of participants with PEAR-002b
- To evaluate the contingency management reward structure

Secondary end points

- Participants' use patterns of PEAR-002b, including lesson completion, self-report assessment completion, voluntary use of self-report features, and response to notifications
- Participant interviews and user satisfaction surveys

Exploratory objectives

- To evaluate the preliminary efficacy of PEAR-002b
- To evaluate compliance with wearing the EmbracePlus device
- To evaluate the feasibility of using digital biomarkers to predict withdrawal, craving, and opioid use

Exploratory end points

- Abstinence from illicit opioids and medication adherence, measured by urine drug screens, and retention in treatment, measured by time to dropout (if applicable)
- Device wearing time (eg, total hours worn and average percentage of time worn per day) measured by the device
- Prediction power based on physiologic data (eg, heart rate and skin conductance) collected via the device

XSL•FO
RenderX

Demographics

Demographic information to be collected includes age at time of consent, sex, gender, race and predominant ethnicity, level of education, marital status, employment status, income, number of children, health insurance status, involvement in the criminal justice system, distance of residence from treatment site (in miles), and usual method of transportation.

Medical and Medication History

Relevant medical history and current medical conditions will be collected, including current or prior treatments received for mental health disorders, hepatitis C, HIV, and chronic pain syndromes. History of substance use will be collected for the following categories: opioids, cocaine, stimulants other than cocaine, alcohol, marijuana, benzodiazepines, and other substances. Data to be collected regarding each substance include onset of use, number of years used regularly, amount used, type used (eg, pill vs powder), route of use, history of overdose, and longest period of abstinence. History of substance use treatment will also be collected, including present and prior treatment, type of treatment facility, number of treatment episodes, and current recovery activities. Nicotine use history will also be collected, including type, route, quantity, duration of use, and prior use. Medication history will include the name, dose, frequency, start and stop dates of the medication, and the indication for use. Prior experience with medication for substance use disorder/OUD will also be recorded.

Evaluation of Phone Use

Study staff will evaluate participants' comfort level with using smartphones and navigating through common apps.

Interviews and Surveys

Interviews with participants will be conducted by study staff to evaluate their experiences with the PDT, particularly its ease of use and acceptability. Interviews may be performed in person or remotely via video or phone. These sessions may be recorded for transcript generation if informed consent is obtained from the participant, investigator, or both. Participant surveys will be completed by participants per the assessment schedule. Table 1 shows a schedule of study assessments.

Table 1. Schedule of study assessments.

Data Management, Study Oversight, and Monitoring

Designated staff from the study sponsor (the study monitor) will review the e-CRFs entered by study staff for completeness and accuracy. Authorized study staff will respond to queries and make any necessary changes to the data. Oversight of data management, including data collection, storage, and export; security; tracking; data analysis; and quality assurance will be the responsibility of the sponsor. The study investigator will ensure the accuracy, completeness, and timeliness of the data reported to the sponsor and be responsible for ensuring that all study staff adhere to human subjects/IRB guidelines related to data management. Data files will be backed up at regular intervals and will be accessible only by trained study staff members.

The study monitor will ensure that the research is conducted and documented according to the protocol and in accordance with the guidelines for Good Clinical Practice. Virtual study monitoring visits will be conducted at appropriate times during the study per the monitoring plan.

XSL•FO
RenderX

AE Reporting

The investigator or designee and research site staff are responsible for the detection, documentation, classification, reporting, and follow-up of events meeting the definition of an AE or serious AE (SAE). Spontaneously reported or observed AEs will be recorded throughout the study beginning at the time the participant gives informed consent. AEs will be elicited using a nonleading question at designated time points. Regardless of seriousness, intensity, or presumed relationship to PEAR-002b, all AEs will be recorded in the source documentation from the time of consent until the end of the last study visit. AEs that occur after screening and prior to implementation of PEAR-002b will be recorded in the source documentation under medical history. AEs occurring after baseline and until the last study visit, known as treatment-emergent adverse events (TEAEs), will be recorded in the AE page of the e-CRFs. All measures required for management of TEAEs will be recorded in the source documentation. The investigator will be responsible for informing the IRB and regulatory authorities of SAEs, as required by local and regional regulations.

Statistical Analysis Methods

This feasibility study is largely exploratory, with several end points focused on measuring participant satisfaction, attitudes, and use of the mobile app component of reSET-O and PEAR-002b. Therefore, many of the statistical analyses will be descriptive and will involve computing and reporting measures of central tendency (ie, mean and median) and variability (ie, variance and standard deviation) for the variables of interest. These statistics will highlight which aspects of the therapeutic and the experience are helpful and engaging to participants, and which aspects are less engaging.

Primary End Points

Home buprenorphine initiation success will be summarized as the proportion of participants attending the post–buprenorphine initiation visit (week 1) and the proportion of participants who experience buprenorphine initiation–related AEs (eg, precipitated withdrawal). Acceptability of PEAR-002b will be evaluated based on individual participants' ratings of ease of use, satisfaction, perceived helpfulness, and likelihood of recommending PEAR-002b. Descriptive statistics will be performed on Likert-scale and multiple-choice items that assess user satisfaction and attitudes about the app. Analyses will be conducted on data collected at each assessment point throughout the study, ratings over the course of the study, and for overall user satisfaction as measured at the end of the study. Medication adherence will be evaluated by participant self-report data and confirmed by UDS (ie, a positive result for buprenorphine and norbuprenorphine). UDS data will be summarized as means of individual participants' proportion of total urine samples testing positive for buprenorphine or norbuprenorphine over the 4-week study.

Secondary End Points

For dosing and engagement, descriptive statistics will be calculated for PEAR-002b module completion, assessment completion (both in the app and clinician delivered), voluntary use of in-app self-report features, and response to notifications. For CM rewards, descriptive statistics will be calculated on Likert-scale and multiple-choice items that assess participant satisfaction with and ease of use of the CM system and rewards. Descriptive analyses will examine the frequency of rewards earned throughout the study. Text analysis of qualitative responses and transcripts from interviews and focus groups will be used to identify themes in participant feedback.

Exploratory End Points

Abstinence will be defined by participant self-reports and confirmed by the absence of opioids (other than buprenorphine) in the UDS. UDS data will be summarized as means of individual participants' proportion of total urine samples testing negative for opioids other than buprenorphine over the 4-week study. Treatment retention will be measured as time to drop-out (defined as the last face-to-face contact with a participant) and analyzed using the Kaplan–Meier method.

Feasibility and acceptability of EmbracePlus will be assessed by measuring the total hours and percentage of weeks wearing the device. Week-by-week averages and the total number of hours across all weeks will be assessed. Acceptability will be evaluated based on participants' ratings of ease of use and satisfaction with EmbracePlus. Descriptive statistics will be calculated for Likert-scale and multiple-choice items that assess user satisfaction and attitudes about EmbracePlus. If physiologic data are sufficient, multiple statistical learning models will be used to evaluate if these models have sufficient power to predict withdrawal or opioid use events in advance, levels of cravings, or both.

Results

Recruitment for this study is currently open and will continue until the projected sample size is met. A sample size of 10 participants is standard for a feasibility study.

Discussion

PEAR-002b is being evaluated for its potential to support participants during unsupervised buprenorphine initiation. A comprehensive analysis of data collected in the first week will be used to evaluate feasibility and acceptability. Success will be demonstrated not only by attendance at the week-1 visit, but by evidence that participants engaged with PEAR-002b during the medication initiation process and found it acceptable (ie, helpful and easy to use). If the study is successful, future efforts may focus on refinement of PEAR-002b and its integration with reSET-O, in addition to the development of tools to support provider monitoring of the patient during home medication initiation. These future efforts may help mitigate inequities that impact how individuals access and engage with treatment. These tools may offer standardization and ease of implementation, ensuring proper clinical-care delivery while lightening the burden on health care workers. Future directions could also include providing patients preparing or planning unsupervised buprenorphine initiation with a list of provider-recommended over-the-counter medications to mitigate some of the withdrawal side effects, thereby encouraging patient buy-in and ownership

XSL•FO
RenderX

of their health care during a process that is often perceived as uncontrollable.

Data acquired in this pilot study may also inform larger studies to evaluate the safety and effectiveness of PEAR-002b plus reSET-O. Together, PEAR-002b and reSET-O may improve the success rate of unsupervised buprenorphine initiation and medication adherence rates, which are crucial to an individual's success in OUD treatment.

The study may also guide efforts to refine the use of biometric outputs, such as heart rate and skin conductance, to monitor physiological symptoms of withdrawal and to provide objective data that could be incorporated into the dosing algorithm of the digital therapeutic to more accurately support dose titration. Biometric data could also be included in a dashboard, which would enable clinicians to better monitor their patients. Biometrics may help alert clinicians to patients at risk of precipitated withdrawal.

This is an early feasibility study, and as such, findings may not be generalizable due to the small sample size and the lack of a comparator arm; both of these limitations will be addressed in a full-scale study, should that be pursued. The simplicity of PEAR-002b is also a limitation of the study; for instance, it does not support all sublingual buprenorphine formulations (eg, Zubsolv), nor does it support all buprenorphine initiation protocols, as the current version of PEAR-002b is based on conventional buprenorphine initiation protocols. Due to the prevalence of potent synthetic opioids such as fentanyl in the illicit drug supply, conventional buprenorphine initiation protocols have become less predictable, with an increased risk of precipitated withdrawal, necessitating the development of alternative methods, such as low-dose buprenorphine initiation [25]. In order to create a more flexible and potentially scalable digital therapeutic, future development efforts may focus on incorporating a broader range of buprenorphine initiation protocols, including low-dose initiation, along with a dashboard that enables the prescriber to select the type of protocol, buprenorphine formulation, and starting dose.

Acknowledgments

Editorial assistance on the writing of this paper was provided by Stephen Braun, medical editor at Pear Therapeutics (US), Inc. The authors would like to thank Carol Achtmeyer for informing the development of PEAR-002b, advising on the study design, and providing editorial assistance with this manuscript. This study was funded by Pear Therapeutics (US), Inc. and the National Institute on Drug Abuse of the National Institutes of Health (award number R44DA049493). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

Requests for data required to support the protocol will be evaluated by the sponsor and provided if deemed appropriate. All study-related information will be regarded as confidential.

Authors' Contributions

HL and NE conceived the study concept and design. HL, NE, RG, SM, XX, CK, CC, YM, and JG contributed to the study design. RG and XX are the biostatisticians for the study. All authors reviewed drafts of the manuscript and contributed comments based on their review.

Conflicts of Interest

HL, RG, SM, XX, YM, and SB are consultants or employees of Pear Therapeutics (US), Inc. NE was an employee of Pear Therapeutics (US), Inc at the time this manuscript was written. Pear Therapeutics Inc provided digital therapeutic prescriptions at no cost to Kaiser Permanente Washington during a quality improvement pilot study that was led by JG. JG is a coinvestigator on a grant proposal awarded to Pear Therapeutics Inc by the National Institute on Drug Abuse, which evaluates potential improvements to reSET-O (R44DA042652). Pear Therapeutics does not provide funding to JG.

Abstract

Background: Malaria and HIV, 2 of the world's deadliest diseases, share a lot of territory in sub-Saharan Africa.

Objective: This study seeks to investigate the effect of HIV on the immune response to malaria infection among pregnant women in Kumba in the southwest region (SWR) of Cameroon. The study aims to determine the prevalence of malaria infection, assess the occurrence of Plasmodium falciparum genetic diversity, and evaluate the antibody (immunoglobulin [Ig]G and IgM: apical membrane antigen-1 [AMA1], merozoite surface protein [MSP]1, MSP2, MSP3, and erythrocyte-binding antigen [EBA]175) and cytokine (interleukin [IL]-10, tumor necrosis factor alpha [TNF-α], and interferon gamma [IFNγ]) response to malaria infection among pregnant women with and without HIV in Kumba.

Methods: The study will be a hospital-based cross-sectional design that will run from March 2022 to February 2023. It will recruit pregnant women with and without HIV who are in their third trimester of pregnancy. The study will be carried out in 5 health institutions in Kumba: General Hospital Kumba, Presbyterian Hospital Kumba, District Hospital Kumba-town, Kossala Integrated Health Center Kumba, and Catholic Hospital Kumba. About 3 mL of the mother's venous blood, placental blood, and baby cord blood will be collected from each pregnant women at the point of delivery. Microscopy, rapid diagnostic tests (RDTs), and nested polymerase chain reaction (PCR) will be performed to identify the malaria parasite in all the samples, and nested PCR targeting the different genetic diversity markers for *P. falciparum* will also be performed. Furthermore, sequencing will be performed to study the nucleotide sequence of different alleles, and the genetic diversity of the alleles responsible for malaria infection among pregnant women will be assessed. A multiplex assay will be conducted to analyze the peripheral blood plasma and cord blood plasma for the cytokine and total antibody response to malaria infection among pregnant women with and without HIV. The questionnaire for data collection will be pretested at the Kumba District Hospital, and ethical clearance will be obtained from the University of Buea and the Regional Delegation of Public Health for the SWR. Data will be analyzed using SPSS Statistics and STATA. All *P* values <.05 will be considered statistically significant. BioEdit 7.0.0 software will be used to align the nucleotide sequences of different genes after sequencing. Phylogenetic tree searching will be conducted using the maximum-likelihood (ML) method in MEGA V6.0.

XSL•FO
RenderX

Results: The project started in March 2022 and will end in February 2023. Presently, three-fourth of the project funding has been disbursed to date. A total of 218 participants have been enrolled: 193 (88.5%) women without HIV and 25 (11.5%) women with HIV. Between February 2023 and March 2024, the following results will be ready for publication: maternal-neonatal malaria prevalence among pregnant women and babies in Kumba, the effect of HIV on (1) *P. falciparum* genetic diversity among pregnant women in Kumba, (2) the maternal and neonatal immune response to MSP1, MSP2, and EBA175 IgG antibody response to *P. falciparum*–caused malaria infection among pregnant women, and (3) the maternal and neonatal pro-inflammatory and anti-inflammatory cytokine response to malaria infection.

Conclusions: HIV infection increases the prevalence of malaria infection among pregnant women and also influences the genetic diversity of *P. falciparum*, with MSP1 alleles being the most prevalent. HIV infection also reduces the antibody response to malaria infection, as well as altering the level of pro-inflammatory and anti-inflammatory responses to malaria infection.

Introduction

Malaria and HIV, 2 of the world's deadliest diseases, share a lot of territory in sub-Saharan Africa. As a result, malaria and HIV coinfection is common in the region [1]. In 2019, malaria alone affected over 229 million people worldwide, with the majority (95%) of the cases occurring in 29 countries in sub-Saharan Africa: Nigeria (27%), Democratic Republic of Congo (12%), Uganda (5%), Mozambique (4%), and Niger (3%) [2]. Infection with malaria in humans is caused by 6 species, with *Plasmodium falciparum* being the most virulent of them all [3]. In Cameroon, malaria is a significant public health issue, with the whole nation in danger of transmission [4,5]. Despite considerable progress in recent years to reduce the burden of this infection due to the implementation of several malaria control strategic programs, the disease remains widely spread, with an estimated 3.3-3.7 million probable cases in health care facilities each year [4,6].

Infection with HIV or malaria during pregnancy is often harmful to both mother and child [7]. Coinfection raises the chances of adverse outcomes, which include maternal anemia, increased parasite sequestration at the placenta, low-birth-weight babies, and immune dysregulation to malaria [7]. The immunological reasons behind the increased malaria sensitivity of women with HIV, as well as the effect of coinfection on HIV transmission from mother to child, are major public health problems. Once again, these increased risks are greatest in multigravidae [8]. Epidemiological studies suggest that pregnant women with HIV have a considerable decrease in the acquired immunity to malaria, resulting in a diminished ability to limit *P. falciparum* infection. This finding is corroborated by the fact that sulfadoxine-pyrimethamine–intermittent preventive treatment's (SP-IPT) effectiveness in pregnant women with HIV reduces [7,8].

Prior studies have shown that HIV infection interferes with the breadth of the antibody response to merozoite surface protein (MSP) antigens. According to Daniel et al [9], the antibody response to MSP1, MSP2, and apical membrane antigen-1 (AMA1) reduced in children with HIV, and only AMA1 was statistically significant [9]. HIV was associated with a restricted spectrum of responses to certain merozoite antigens. HIV changed the pace of age-related antibody acquisition against schizont extract but not the rate of age-related response formation to particular merozoite antigens [9]. Another research in Kenya found that serum antibody levels to AMA1 and (MSP1 block 2, MSP2, and MSP3) are negatively associated with the likelihood of acquiring malaria, whereas levels of MSP1 and erythrocyte-binding antigen (EBA)175 are not [10]. Although the findings of this research are interesting, they are inconsistent. As a result, additional research is necessary.

Among pregnant women, studies have shown that HIV dysregulates the immune response to malaria infection, making them more vulnerable to malaria [11]. HIV decreases immunoglobulin (Ig)G levels to circumsporozoite protein (CSP) and terminal complement complex (TCC) in women with infection, while cord IgG to CSP, MSP1, and TCC is considerably lower in neonates delivered to mothers with HIV [12]. This study found that HIV infection is related to decreased levels of cord antibodies to malarial antigens and that hypergammaglobulinemia may contribute to impaired antibody transmission [12]. Another study found that interferon gamma (IFNγ) and tumor necrotic factor alpha (TNF-α) levels are lower in pregnant women who have both malaria and HIV infections. Nonetheless, pregnant women with coinfection had higher mean plasma TNF-α concentrations. It was also shown that interleukin-2 (IL-2) levels decreased in mothers with HIV and with coinfection before increasing in mothers with malaria. IL-10 levels among women with coinfection also decreased when compared to women without infection. There were strong significant associations between plasma IL-2 levels and infection status [13].

Djontu et al [14] revealed that placental malaria reduces maternal plasma levels of cytokines IL-17E, IL-27, and IL-28A, as well as neonatal plasma levels of cytokines IL-17E and IL-28A, which may aid in parasite clearance and enhance infant birth weight. IL-27 and IL-6 are 2 cytokines that can have both pro-inflammatory and anti-inflammatory actions. Indeed, IL-27 has been shown to activate the T-bet transcription factor, which promotes helper T (Th)1 cell differentiation [15,16]. Other investigations have shown that it suppresses the growth of IL-17–producing Th17 cells [17] and decreases the Th2 response

XSL•FO
RenderX

[17]. IL-6 suppresses transforming growth factor (TGF)–induced IL-10–producing regulatory T-cell (Treg) development [18], but when combined with TGF-α, it preferentially promotes IL-17–producing Th17 cell differentiation [19]. Mucosal epithelial cells, as well as several immune cell types, such as mast cells, macrophages, eosinophils, Th2 cells, and NKT cells, can generate IL-17E (IL-25) [20,21]. It promotes Th2 cell responses, while suppressing Th17 cell responses [22]. Previous research identified IL-28A as a newly defined type III IFN, with antiviral properties [22,23] and generated primarily by antigen-presenting cells (APCs) [23]. This cytokine can enhance Th17-induced inflammation, offer Th1 polarization, and suppress Th2 responses [24]. As a result, IL-6, IL-27, IL-17E, and IL-28A are key cytokines that may be implicated in the control of human immunological disorders caused by Th1, Th2, Treg, and Th-17 response imbalance [25].

Cameroon approved the option B+ treatment strategy 2014 to prevent mother-to-child transmission (MTCT) of HIV in 2014 [24,26]. However, effevirenz has lately been replaced with dolutegravir. According to data of a trial study conducted in Cameroon, a dolutegravir-based regimen, which is a low-cost, generic, fixed-dose antiretroviral therapy (ART) combination containing tenofovir, lamivudine, and dolutegravir (TLD), is the preferred first-line treatment for patients with HIV-1 infection [25]. Nevertheless, there are concerns about the overall risks and benefits of use in women of childbearing potential [27]. That is why this study aims to determine the prevalence of malaria infection, assess the occurrence of *P. falciparum* genetic diversity, and evaluate the antibody (IgG and IgM: AMA1, MSP1, MSP2, MSP3, and EBA175) and cytokine (IL-10, TNF-α, and IFNγ) response to malaria infection among pregnant women with and without HIV in Kumba.

Methods

Study Design and Population

This will be a hospital-based cross-sectional study that will run from March 2022 to February 2023. It will enroll pregnant women with and without HIV who are in the third trimester of pregnancy (26-32 weeks) and have willingly accepted to participate in the study by signing a consent form. During delivery, samples will be collected and questionnaires will be appropriately filled.

Study Site

The study will be conducted in Kumba, which is a metropolitan city in Meme Division of the southwest region (SWR) of Western Cameroon. Meme Division is 1 of the 6 divisions of the SWR of Cameroon. It is made up of 5 subdivisions: Kumba I, II, and III (largely urban) and Mbonge and Konye (dominantly rural) [28].

Ethical Considerations

Ethical clearance for this study has been obtained from the Institute for Advanced Medical Research and Training (IAMRAT), College of Medicine, University of Ibadan, Nigeria (ID NHREC/05/01/2008a). However, ethical clearance from Cameroon has been obtained from the Institutional Review Board of the Faculty of Health Sciences at the University of Buea (ID 2022/1655-02/UB/SG/IRB/FHS). Administrative clearance has been obtained from the Ministry of Public Health, Regional Delegation of Public Health for the SWR (ID R11 /MINSANTE/SWR/RDPH/PS/276/281). Further authorization has been obtained from the Meme Health District Health service (ID 12/022/MINSANTE/RDPHSW/KHD/DMO/048). Directors of the health facilities involved have also provided an authorization letter for the study to take place in their various facilities. Participants who wish to participate in the study will first sign an informed consent form. For participants who are unable to read or write, the information will be read out and explained to them and their thumbprints will be taken. The study will consider pregnant women with and without HIV who are in the third trimester of pregnancy and are fully aware of their viral load counts.

Sample Size Determination

The estimated sample size for the study was calculated using the Cochrane formula [29]. The estimated prevalence of malaria among pregnant women with HIV is 81%, as obtained from a study looking at malaria prevalence in pregnant women with and without HIV in neighboring Nigeria [30]. The critical value and standard value for the corresponding level of confidence were 1.96, and the margin of error was 0.05. The estimated sample size is 236. The ratio of pregnant women with to those without HIV will be 1:1, which therefore implies that the total estimated sample size is 472. That is, 236 (50%) pregnant women with and 236 (50%) pregnant women without HIV will be enrolled in the study.

Inclusion and Exclusion Criteria

Inclusion Criteria

The study will enroll only pregnant women who are in their third trimester of pregnancy—that is, within 26-32 weeks of pregnancy—and who willingly provide their consent to participate in the study. The study will also consider only pregnant women who are aware of their HIV status as well as viral load. In addition, the study will accept only those attending antenatal care (ANC) visits at the selected health facilities and who are willing to deliver in the facility of enrolment.

Exclusion Criteria

The study will not consider pregnant women who are not in their third trimester of pregnancy and have not signed the informed consent form to participate in the study. All those who will be attending ANC visits at the selected health facilities but are not willing to deliver in those health facilities will not be considered.

Sampling Technique

A probability proportionate to size sampling will be used to determine the number of participants to be recruited in each health institution (Table 1). A simple random sampling method will be used each day to recruit participants as they come for their ANC visits to the selected health facilities.

XSL•FO
RenderX

[a]Stat: statistics.

[b]PSS: probability sample size.

Sociodemographic and Clinical Baseline of Study Participants

A well-structured semiquestionnaire will be used to collect demographic and clinical parameters from study participants. The questionnaire will be pretested at District Hospital Kumba-town before being issued to participants for data collection.

The result of the rapid diagnostic test and microscopy for each participant will be made available to them. This is to ensure that those positive for malaria should be placed immediately on treatment.

Sample Collection

Briefly, 3 mL of the mother's peripheral (venous) blood, placental blood, and baby cord blood will be collected into EDTA, heparinized, and sodium-citrated tubes, respectively. A capillary puncture will be made to collect the sample, and a thick-film smear will be prepared for microscopy. Smears will be allowed to air-dry and then carefully placed in well-cleaned slide boxes to be stored for further analysis.

Laboratory Analyses

Thick-Film Microscopy

The thick-film smears will be stained with 10% Giemsa for 15 minutes, and the slides will be rinsed and allowed to air-dry. After that, the smears will be examined for the presence of *P. falciparum* under the 100X oil emission objective of the microscope. The parasite density will be calculated using the formula [31]:

> Parasite density = (Number of parasites counted per 200 white blood cells [WBCs]/200) × 8000.

Rapid Diagnostic Test for Malaria

A drop of about 50 µL will be used to determine malaria infection in all the enrolled participants using an SD-Bioline RDT kit, which detects histidine-rich protein II and lactate dehydrogenase. After the application of the sample and buffer, the kit will be allowed to stand for 15 minutes according to the manufacturer's instructions, and results will be interpreted qualitatively and recorded.

DNA Extraction

Drops of venous, placental, and cord blood will be blotted on filter paper and allowed to air-dry. The blotted filter paper will be used to extract the DNA of malaria parasites using the hot chelex extraction method, as described by Musapa et al [32].

Nested Polymerase Chain Reaction

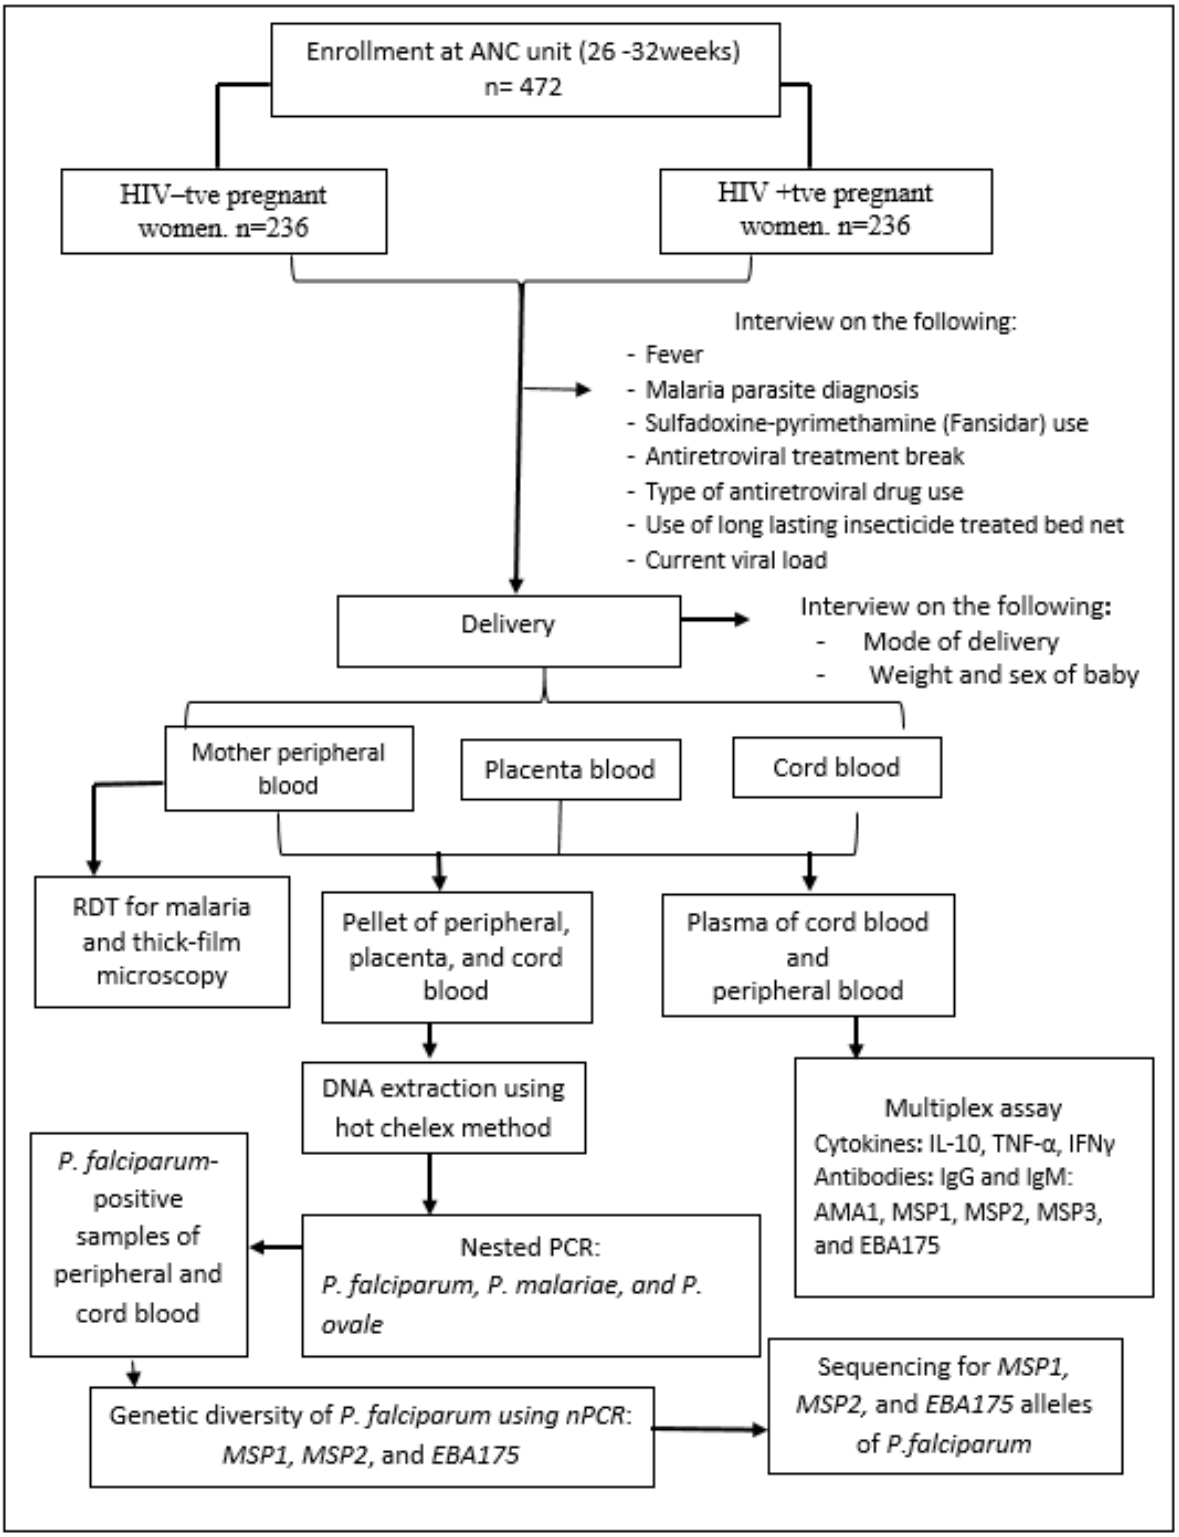
The DNA extract will be used to perform nested PCR using the mitochondria (cytochrome C oxidase 3 [Cox-3]) primers for the detection of *P. falciparum*, as described by Lloyd et al [33].

Genetic Diversity of MSP1, MSP2, and EBA175 Using Nested PCR

A portion of the DNA extract from placental and cord blood will be used to determine the genetic diversity for samples that test positive for *P. falciparum* at the level of placental and cord blood. The 3 polymorphism loci MSP1, MSP2, and EBA175 will be amplified using specific primers targeting the alleles of *P. falciparum* in nested PCR. Primary amplification followed by secondary PCR using specific primers for K1, Mad20, and RO33 (for *MSP1*) and 3D7 and FC27 (for *MSP2*) allelic families will be performed [34]. Primer sequences have been previously described [35]. For the EBA175 loci, specific primers targeting the F1 loop, F2 loop, and C loop will be used to determine the different alleles responsible for infection, as described previously [36].

Sequencing Analysis

A total of 10 samples positive for *MSP1*, *MSP2*, *MSP3*, and *EBA175* at the level of placental and cord blood will be randomly selected and sent for analysis to the Inqaba Biotechnical Industry in Nigeria for sequencing to identify and study the DNA sequences of the alleles responsible for placental and transplacental infection.



Cytokine and Antibody Analysis Using the Luminex Technique

The stored plasma will be used to determine levels of cytokines IL-10, TNF-α, and IFNγ using a magnetic multiplex screening assay (Luminex) with the help of a Human Multi-Analyte Premixed Kit (R&D Systems Inc, Minneapolis, MN, USA) [14]. A portion of the plasma will be used to evaluate the IgG

XSL•FO
RenderX

antibody response level to MSP1, MSP2, and EBA175 using the multiplex assay, as described in previous studies for the detection of IgG antibodies to malaria [12,37]. A summary flowchart of the entire study can be seen in Figure 1.

Figure 1. Summary flowchart for the recruitment of participants into the study. AMA1: apical membrane antigen-1; ANC: antenatal care; EBA: erythrocyte-binding antigen; IFNγ: interferon gamma; IgG: immunoglobulin; IgM: apical membrane antigen-1; IL: interleukin; MSP: merozoite surface protein; nPCR: nested polymerase chain reaction; PCR: polymerase chain reaction; *P. falciparum*: *Plasmodium falciparum*; *P. malariae: Plasmodium malariae*; *P. ovale: Plasmodium ovale*; RDT: rapid diagnostic test; TNF-α: tumor necrosis factor alpha.

Data Management and Analyses

Data will be entered into Microsoft Excel, cleaned, and transformed for the different analyses to be performed. SPSS Statistics (IBM Corp) and STATA will be used for statistical analysis. A normality test will be performed to determine the different parametric and nonparametric tests to be used for the different analyses.

XSL•FO
RenderX

Descriptive analysis of the general study population will be conducted, and both the mean and median of each parameter will be considered. The chi-square test will be performed to analyze categorical variables, and the Student *t*-test/Mann-Whitney *U* test will be performed to analyze continuous and categorical variables. The Kruskal-Wallis test/ANOVA will be conducted to analyze continuous and more than 2 categorical variables, while linear regression/Spearman correlation will be performed for multivariate analysis to determine the strength of association between different factors of the study and our dependent variables. All *P* values <.05 will be considered statistically significant. BioEdit 7.0.0 software will be used to align the nucleotide sequences of different genes after sequencing. Phylogenetic tree searching will be performed using the maximum-likelihood (ML) method in MEGA V6.0.

Results

The prevalence of malaria infection; the occurrence of *P. falciparum* genetic diversity of MSP1, MSP2, MSP3, and EBA175; and the total antibody (IgG and IgM: AMA1, MSP1, MSP2, MSP3, and EBA175) and cytokine (IL-10, TNF-α, and IFNγ) response to malaria among pregnant women with and without HIV will be evaluated.

The first part of the project funding was in December 2021, the second part was in May 2022, and the third part was in December 2022. Currently, three-fourth of the project funds have been released. Data and sample collection started in March 2022 and will end in February 2023. A total of 218 participants have been enrolled: 193 (88.5%) pregnant women without HIV and 25 (11.5%) pregnant women with HIV (see Table 2).

Table 2. Current level of enrollment of participants into the study (N=218).

Sample	General Hospital Kumba, n (%)	District Hospital Kumba-town, n (%)	Presbyterian Hospital Kumba, n (%)	Kossala Integrated Health Center Kumba, n (%)	Catholic Hospital Kumba, n (%)	Total, n (%)
Pregnant women with HIV (n=25)	7 (28)	6 (24)	6 (24)	0	6 (24)	25 (100)
Pregnant women without HIV (n=193)	25 (13.0)	40 (20.7)	10 (5.2)	33 (17.1)	85 (44.0)	193 (100)

Discussion

Main Findings

Immune development during pregnancy is important as it determines the resistance of pregnant women to malaria transmission. Few studies have shown that women develop protective immunity against pregnancy-associated malaria (PAM), which is thought to be due to the acquisition of antibodies to the parasite variant surface antigen 2 chondroitin sulphate A (VAR2CSA) [38]. This immunity becomes stronger, especially in multigravidae [38]. However, this does not appear to be the case with pregnant women with HIV, as studies have shown that HIV alters the immunity against malaria, making both primigravidae and multigravidae vulnerable to PAM [11]. Although studies looking at malaria prevalence have been carried out in Kumba, studies evaluating the immune response of pregnant women with and without HIV to malaria have not been conducted. This study will attempt to determine the prevalence of malaria infection, assess the occurrence of *P. falciparum* genetic diversity, and evaluate the antibody (IgG and IgM: AMA1, MSP1, MSP2, MSP3, and EBA175) and cytokine (IL-10, TNF-α, and IFNγ) response to malaria infection among pregnant women with and without HIV in Kumba.

In Nigeria, the prevalence of malaria infection among pregnant mothers with HIV was 81% compared to 75% among pregnant women without HIV [30]. When compared to mothers without HIV, mothers with HIV have more moderate parasitemia [30]. This finding is in line with a similar study from Kumba, Cameroon, which reported a 61.5% prevalence of malaria among pregnant women with HIV [39]. Even though the prevalence of malaria in Kumba is high, it would have been much higher if more sensitive diagnostic techniques, such as PCR, had been used for diagnosis in this study rather than traditional microscopy, whose sensitivity is dependent on technician expertise [40], and RDTs, which lack specificity due to the high possibility of cross-reaction of antibodies [39]. Kenji et al [40] discovered that PCR could diagnose 64 misdiagnosed cases that were missed by RDTs and microscopy. In addition, in the Republic of Congo, it was discovered that the prevalence of malaria infection is high in pregnant women attending antenatal facilities or hospitalized and that it increases when HIV infection is present [41]. However, in Jos, Nigeria, the prevalence of malaria infection reduced from 34.1% to 7.2% among women administered cotrimoxazole and from 25% to 10% among women administered SP-IPT for malaria prophylaxis [42]. According to some studies, HIV and AIDS cause immunosuppression, which reduces the overall immune response to malaria parasitemia, increasing the frequency of clinical malaria attacks [43,44]. Effective implementation of IPT strategies among pregnant women reduces their likelihood of malaria infection [42]. Nevertheless, studies in Ghana have also shown that HIV infection increases the rate of vertical transmission of malaria to children born to a mother with HIV [45]. This study was able to show that HIV-malaria coinfection is a significant predictor of adverse perinatal outcomes and neonatal morbidity [45]. However, although national guidelines in Cameroon recommend the use of cotrimoxazole for pregnant women with HIV and SP for pregnant women without HIV at all ANC visits [46], most health facilities suffer from drug

XSL•FO
RenderX

shortages, forcing women to attend some ANC visits without medication. The effect can be seen in a study carried out in Cameroon, where not taking Fansidar for IPT was found to be associated with the development of malaria among pregnant women [1].

Studies have shown that *P. falciparum*, the most virulent species, has a wide genetic variety at all degrees of endemicity, which is not surprising, given that genetic diversity has been shown to be a function of transmission in specific regions [47,48]. Oboh et al [49] discovered that the prevalence of the *FC27* allele type in pregnant women isolates is higher (33.3%) than that in nonpregnant women (29.2%) when looking at the genetic diversity of *P. falciparum* (*MSP1* and *MSP2*) infection among pregnant women in Lagos, Southwest Nigeria [49]. This finding is in line with a similar study carried out in Yaoundé, Cameroon [50]. Although no study has been conducted to assess the diversity of *P. falciparum* among pregnant women with and without HIV as 2 distinct entities, a couple of studies have evaluated the diversity of *P. falciparum* among individuals with HIV. In Mutengene, Cameroon, it was reported that the MSP1 allelic variants detected among patients with HIV were KI (65.22%), MAD20 (27.54%), and RO33 (27.54%), while the MSP2 allelic variants were FC27 (30.43%) and 3D7/IC (31.88%), which was high and associated with anemia [51]. A study in Senegal reported no difference in genetic diversity between *P. falciparum* isolates from patients with malaria and concurrent malaria-arbovirus in Kedougou [52]. However, the increased number of genotypes observed in the malaria group was attributed to the larger number of samples rather than the extensive genetic diversity of *P. falciparum* isolates from patients with malaria [52]. The frequency of all MSP1 allelic families (K1, MAD20, and RO33) and the IC/3D7 allelic family of MSP2 was high (>70%) and comparable between the 2 study groups in this study [52]. Nevertheless, clonal *P. falciparum* population dominance is expected to be observed in regions with declining endemicity as a result of genetic drift caused by scale-up interventions [53]. In other words, in parasite populations where control efforts have left behind lineages that create clusters of highly related parasites, the persistence of a specific haplotype throughout the year is expected [53,54]. As a result, unrelated parasites are unlikely to coexist in the same mosquito blood meal [53].

In addition, the protective role of antibodies to malaria cannot be overemphasized, as studies have shown that the antibody response plays a vital role in the protection of pregnant women against PAM infection [55,56]. A sero-surveillance study in Thai-Myanmar at the Shoklo Malaria Research Centre reported a significant variation in the antibody profiles of *Pf*AMA$_1$, *Pf*EBA175, *Pf*MSP$_2$, and *Pf*VAR$_2$CSA. Most controls' antibody profiles for *Pf*MSP$_3$ and *Pv*AMA$_1$ remained low throughout gestation regardless of malaria exposure, whereas the antibody response varied more among the cases and the control group of pregnant women with and without infection [57]. This study is in line with a study in Yaoundé that instead looked at the antibody response of malaria vaccine candidates among children [58]. This confirms that during a malaria infection, antibody levels should rise as an indication of immune protection. Alistair et al [59] even demonstrated that babies born to women with PAM with high levels of VAR2CSA antibodies are protected against the vertical transmission of malaria and have a higher mean birth weight than those with low VAR2CSA antibody levels [59].

In contrast, studies have shown that HIV infection amplifies the effect of malaria, especially among pregnant women [39,43,44]. One of these effects is the dysregulation of immunity to malaria in mothers and even their children exposed in utero [12,60]. In Yaoundé, it was reported that IgG levels to CSP and TCC were lower in mothers with HIV, as were cord IgG levels to CSP, MSP1, and TCC in neonates born to mothers with HIV [12]. This was in line with a study in Kenya that reported that HIV infection is associated with a decrease in the magnitude and breadth of IgG responses to merozoite antigens, as well as a delay in the age-related acquisition of the IgG antibody response to schizont extract [9]. The study also revealed that children with HIV are less likely to be high responders to AMA1 [9]. This effect can be seen in children, as studies have reported that children exposed to HIV are more susceptible to infections than children not exposed to HIV [60]. However, there is still a lack of understanding of why children born to these women are more susceptible to infections [60]. To better understand why children exposed to HIV are more susceptibility to infections, such as malaria, studies evaluating the effect of HIV infection on the vertical transfer of mononuclear WBCs, as well as a longitudinal study monitoring the immune response of these children exposed over time, are needed.

Cytokines and chemokines are elevated in peripheral blood during an acute malaria infection and contribute to parasite clearance, but they are also likely to be responsible for many of the symptoms and pathological changes seen during malaria [61,62]. The balance of pro- and anti-inflammatory signals appears to play a significant role in determining the outcome of an infection (ie, whether it leads to protection or immunopathology) [62]. Eduard et al [63] reported that an imbalanced pro-inflammatory cytokine response may exacerbate infection severity. Among pregnant women in Cameroon, it was realized that placental malaria reduces maternal plasma levels of IL-17E, IL-27, and IL-28A, as well as neonatal plasma levels of IL-17E and IL-28A, which may aid in parasite clearance and increase child birth weight [14]. This is in line with a similar study carried out by Megnekou et al [64]. Nonetheless, Djontu an coworkers [65] showed that IL-28A, IL-27, and IL-17E levels are higher in cord plasma than in maternal peripheral plasma and that they correlate positively with increasing baby birth weight. This positive relationship between birth weight and both Th1- and Th2-promoting cytokines (IL-27, IL-28A) is consistent with the findings of Chêne et al [65], who found a link between low birth weight and lower levels of IFNγ and IL-5 in intervellous plasma samples from Beninese women. A study carried out in Abia State, Nigeria, showed that cytokine levels in the same woman's peripheral and placental blood may differ [66]. It was realized that IFNγ is significantly higher in peripheral blood than in placental blood. IL-4 and IL-10 levels were significantly lower in peripheral blood than in placental blood [66].

Among pregnant women with HIV, it was discovered that cytokine activity during pregnancy, as measured by plasma

XSL•FO
RenderX

cytokine concentrations, varies with antiretroviral therapy and *P. falciparum* coinfection [67]. In Mozambique, it was reported that among adults with HIV, IL-8 and IFNγ-induced protein 10 (IP-10) play a complex role in inflammation during *P. falciparum* infection and a potential pathogenic role [67]. Another study reported that patients with HIV and cerebral malaria have lower median plasma levels of TNF-α and IL-10 than patients without HIV [68]. This goes to confirm that HIV affects the cytokine response to malaria infection. Nevertheless, information about the cytokine response to malaria among pregnant women with HIV is scanty. However, studies comparing the levels of cytokine response in pregnant women with HIV and with and without malaria, as well as pregnant women without HIV and with and without malaria, are required to better understand the role of cytokines in the pathogenesis of malaria.

Future Directions

There is a need for research into the prevalence of malaria among pregnant women in Kumba, considering all trimesters. It is also necessary to conduct a study on *P. falciparum* resistance to SP-IPT as well as a longitudinal study on children born to mothers with HIV in order to understand why these children are more vulnerable to infections.

Conclusion

The results of previous studies depict that HIV affects the prevalence of malaria among pregnant women irrespective of gravidity; malaria prevalence turns out to be much higher among pregnant women with than pregnant women without HIV. It was also revealed that more *P. falciparum MSP1* alleles are associated with malaria infection among individuals with HIV and that genetic diversity is a function of malaria transmission in specific regions. In addition, HIV infection lowers the level of IgG response of antibodies to malaria infection for both mother and newborn babies. The likelihood of children with HIV to develop an immune response to AMA1 is low. HIV infection also alters the levels of the pro- and anti-inflammatory cytokine response, contributing to the lack of immune parasite clearance and parasite pathogenicity.

The findings of this work will be published in peer review journals and will be presented in seminars as well as conferences. Copies of the work will be submitted at the Pan-African University of Life and Earth Sciences Institute, University of Ibadan, Nigeria; the University of Buea; and the hospitals where the samples were collected. A copy will also be sent to the Union for African Population Studies.

Acknowledgments

This paper is part of the partial fulfillment of a PhD in reproductive biology from the Department of Obstetrics and Gynecology, Pan-African University of Life and Earth Science Institute (PAULESI), University of Ibadan, Nigeria. The main author is grateful to the African Union for finding him worthy to be sponsored for the program. In addition, he wishes to extend their profound gratitude to the coauthor team for their time and effort in making this piece of work a reality. This research will be supported by PAULESI and the Union for African population studies.

Data Availability

The terms and conditions established by the local ethical committee will govern whether the data sets generated/analyzed during this study will be made public. However, upon reasonable request, they will be made available to the corresponding authors.

Authors' Contributions

BNO conceived the project and designed the study protocol. JDB and DSN contributed ideas and supervised the project, while ZF and ELF contributed ideas and reviewed the protocol. AH and BNO in the laboratory team were in charge of sample analyses.
