All exercise sessions will be supervised by an instructor at the participant's local gym. The instructors make sure that the planned exercise sessions are performed and adjust the sessions if necessary. They will also register any deviation from the exercise prescription and report the reason for any adjustment following metrics suggested by Nilsen et al [55]. Adverse events will be reported to the study staff. To increase exercise adherence and educate the instructors, the instructors will be encouraged to undergo a series of web-based seminars. They will be introduced to the rationale for the study, behavior change principles, and how to identify facilitators and barriers to exercise.

BCS randomized to the control group will be encouraged to maintain their current activity level at the time of randomization.

Statistical Analysis

The sample size calculation was based on the primary outcome VO_{2peak}, using a mean change of 3.6 (SD 7.2) mL/kg/minute, from a comparable intervention by Adams et al [23]. With a significance level of 5% and a power of 90% (to compensate for using published results from a single study in our sample size calculation), 63 BCS are needed in each group. To allow for a dropout rate of 7 participants (10%), a total of 70 BCS are included in each group. The same number of participants are included in the reference group. The primary and secondary outcomes are analyzed by generalized linear mixed models. Baseline outcomes in women with and without previous cancer are compared by a 2-sample *t* test.

Results

The inclusion started in October 2020 and was completed in August 2022. A total of 209 participants were included and postintervention assessments (T_2) were completed in January 2023. The 24-month follow-up (T_4) will be completed in February 2025.

Discussion

Exercise training has previously been shown to improve CRF [20], but there is a paucity of studies investigating the effects of exercise training on other CVD risk factors following cancer treatment [22]. The CAUSE-trial will provide a novel understanding of the potential of exercise training to improve CRF, CV risk profile, and self-reported health-related outcomes in long-term BCS. Since impaired CRF has been reported in cancer survivors [9,10], it is pivotal to understand how previous exposure to cancer treatment modulates the effects of exercise. We hypothesize that previous exposure to cancer treatment, even 10 years ago, would have an impact on the expected results from exercise training. This study will expand on the current literature by thoroughly evaluating exercise effects across the entire cardiopulmonary-muscle axis, and by including an exercise group without a history of cancer. This allows us to directly compare baseline levels and intervention effects between women previously exposed to cancer therapy and unexposed women, and to identify potential bottlenecks to physiological adaptation to exercise training.

XSL•FO
RenderX

As with CRF, the positive effects of exercise training on several PROMs have been reported previously, but the existing literature is mainly limited to effects of exercise training during or shortly after cancer treatment. This is concerning, since approximately 30% of BCS still report chronic fatigue up to 10 years after completing treatment. Results from exercise training performed during or immediately after cancer treatment cannot necessarily be extrapolated to long-term survivors as the mechanisms behind chronic fatigue might differ from the more acute complaints. Although positive effects of exercise training on quality of life already have been demonstrated, less is known about the impact of exercise on other late effects in long-term BCS, such as mental distress, disturbed body image, pain, and sexual health challenges.

One of the major strengths of this study is the solid multidisciplinary constellation of the research group. Our group includes sports physiologists, cardiologists, oncologists, and behavioral scientists. This is also reflected by the list of study outcomes (Table 1) ranging from cardiopulmonary function to skeletal muscle cell function and morphology, and quality of life. Combined with a well-monitored, individually tailored exercise intervention, inclusion of a noncancer reference group, large study cohorts, and longtime follow-up, this will allow for exploring interactions across disciplines.

Our study design has some potential limitations. As with any lifestyle intervention study, we risk recruiting the most motivated and physically active participants, which may compromise the external validity of our results. We aim to reduce this risk of selection bias by recruiting BCS through the Cancer Registry of Norway rather than through media advertisements. Importantly, we use similar exclusion criteria for physical activity levels between cancer survivors and the reference groups, which enable us to identify any modifying effects of previous cancer treatment. Unfortunately, this study lacks completely blinded assessors. As an effort to reduce the influence of known group allocation, assessors will not know the baseline values of participants prior to the postintervention CPET. Furthermore, study staff will use similar feedback and encouragement during all tests. As in all clinical trials, poor intervention adherence and dropouts are major concerns. We attempt to counteract this by using instructors trained in motivational feedback. The knowledge acquired from this study will help to inform future cancer care guidelines.

Acknowledgments

The study is funded by the Norwegian Cancer Society and Aktiv mot kreft (Active Against Cancer). All authors were actively involved in the drafting and critical revision of the manuscript.

Data Availability

The data sets generated during and analyzed during the current study are available from the corresponding author on reasonable request.

Abstract

Background: Anxiety disorders are the most common mental disorders worldwide. In Hong Kong, 7% of adolescents are diagnosed with anxiety disorders, and 1 in every 4 secondary school students reports clinical-level anxiety symptoms. However, 65% of them do not access services. Long waitlists in public services, the high cost of private services, or the fear of being stigmatized can hinder service access. The high prevalence of anxiety and low intervention uptake indicate a pressing need to develop timely, scalable, and potent interventions suitable for adolescents. Single-session interventions (SSIs) have the potential to be scalable interventions for diagnosable or subclinical psychopathology in adolescents. Providing precise and context-adapted intervention is the key to achieving intervention efficacy.

Objective: This study aims to compare the effectiveness of three SSIs: single-session intervention of growth mindset on negative emotions (SIGMA), SSI of growth mindset of personality (SSI-GP), and active control, in reducing adolescent anxiety.

Methods: Adolescents (N=549, ages 12-16 years) from secondary schools will be randomized to 1 of 3 intervention conditions: the SIGMA, SSI-GP, or active control. The implementation of each intervention is approximately 45 minutes in length. Adolescent participants will report anxiety symptoms (primary outcome), perceived control, hopelessness, attitude toward help-seeking, and psychological well-being at preintervention, the 2-week follow-up, and the 8-week follow-up. A pilot test has confirmed the feasibility and acceptability of SIGMA among adolescents. We hypothesized that SIGMA and SSI-GP will result in a larger reduction in anxiety symptoms than the control intervention during the posttest and 8-week follow-up period. We also predict that SIGMA will have a more significant effect than SSI-GP. We will use the intention-to-treat principle and linear regression-based maximum likelihood multilevel models for data analysis.

Results: This study will be conducted from December 2022 to December 2023, with results expected to be available in January 2024.

Conclusions: This protocol introduces the implementation content and strategies of growth mindset SSIs (consists of 2 forms: SIGMA and SSI-GP) among school students. The study will provide evidence on the efficacy of different growth mindset SSIs for adolescent anxiety. It will also establish implementation strategies for self-administrative SSIs among school students, which can serve as a pioneer implementation of a scalable and self-accessible brief intervention to improve the well-being of young people.

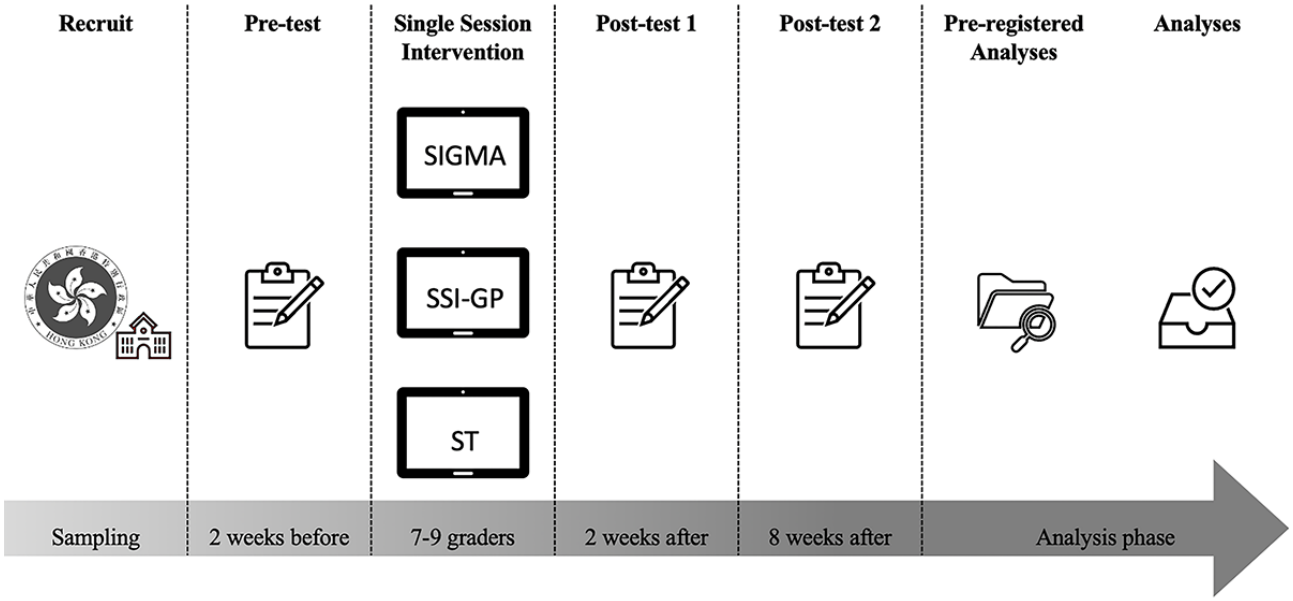
Introduction

Background

Anxiety is one of the leading causes of illness and disability among adolescents aged 10-19 years [1]. In the past decade, Hong Kong recorded a 6.9% prevalence rate of anxiety disorders with severe impairment [2], and 25% of youths were experiencing high subclinical anxiety symptoms in a 3-month period and required a clinical intervention [3]. Based on the prevalence and local youth population data [4], it can be roughly estimated that in Hong Kong there are 85,000 secondary students requiring help and intervention for their anxiety symptoms.

However, an estimated 65% of individuals with general anxiety disorders in Hong Kong do not access mental health services [5]. The median waiting time between the onset of symptoms and receiving public child and adolescent psychiatric service is 58 weeks, and the cost of seeking private treatment is reported HK$3000 (US $385) per monthly consultation, which means that many families have no choice but to wait for public services [6]. Lengthy waitlists or costly clinic-based treatments provided by highly trained mental health professionals may be difficult to disseminate on a broad scale. This traditional setting makes access to service more difficult in special circumstances, such as during the COVID-19 pandemic [7]. Moreover, adolescents with mental health symptoms are particularly vulnerable to stigma and discrimination and may not actively seek school-based interventions [8]. Even among youth who do access care, most drop out prematurely, completing just over 3 therapy sessions on average [9]. There is clearly a need to develop briefer, scalable, nonstigmatizing, and youth-friendly interventions for adolescents with general anxiety symptoms.

Single-session interventions (SSIs) are promising to be scalable, accessible, and cost-effective for youth's mental health needs. SSIs refer to structured programs that intentionally involve only 1 visit or encounter with a clinic, provider, or program [10]. SSIs may serve as stand-alone or adjunctive clinical services. Emerging evidence supports the efficacy of SSIs in reducing and preventing youth's mental health symptoms. For example, Schleider and Weisz [11] found that growth mindset SSIs led to more significant improvement in youth depression and perceived behavioral control in a 9-month follow-up than in active control. They also found that enhancing belief-in-change of personality-enhanced treatment access for adolescent depression [12], but recorded nonsignificant changes in general anxiety, social anxiety, and conduct problems [13].



A brief intervention can be effective if the intervention precisely addresses the underlying psychological process that contributes to the social or psychological problems [14]. Walton [14] and Wilson [15] underscore the importance of precise intervention and adaptive context to secure the potency of brief interventions. Brief interventions targeted to remove specific psychological barriers and produce recursive dynamics will affect long-term outcomes. Thus, the effectiveness of SSI is highly related to the implementation content (what to intervene) and strategies (how to implement). However, the existing SSIs vary in the effect size of effectiveness. Examining psychological mechanisms that address mental health more precisely and designing and implementing the intervention carefully will improve the efficacy of growth mindset SSIs.

This proposal aims to develop and examine the efficacy and effectiveness of growth mindset SSIs for adolescent anxiety in the Chinese context. It will advance the extant literature by implementing and comparing different domains of growth mindset and developing implementation strategies for SSI among Chinese adolescents. The existing growth mindset SSIs teach adolescents the growth mindset of personality (SSI-GP), which means the person can change. However, the effectiveness of SSIs for reducing anxiety was not as significant as reducing depression. Recently, Zhu et al [16,17] found the fixed mindset of negative emotions closely associated with adolescent depression and anxiety. Therefore, an intervention promoting growth mindsets of negative emotions may be a more precise factor in alleviating the worry and anxiety of adolescents, but it is not examined yet. Thus, this protocol presents our newly developed intervention: the single-session intervention for growth mindset on negative emotions (SIGMA) and compares its effectiveness with the SSI-GP and an active control.

The SIGMA, which aims to instill the belief that negative emotions can change, may address the need for a scalable intervention for reducing anxiety. It has 3 unique features. First, it is a mechanism-targeted intervention with a carefully constructed and theoretically precise program that directly addresses the belief of suffering symptoms. Therefore, it may also advance the existing growth mindset SSI in reducing worry about symptoms and increasing perceived control and hope. Second, SIGMA can be developmentally adapted and culturally adapted for adolescents. It will be particularly suitable for secondary school students with general anxiety due to the engaging nature of web-based interventions, videos, peer sharing, and nonstigmatizing feature. Third, the brevity and flexible format could make it attractive to those who might not otherwise access care, and for whom a targeted, "light touch" intervention might be just enough. Given the large need-to-access gap among youths, we propose this 3-arm randomized controlled trial to provide evidence on the effectiveness of SIMGA and compare it against the existing growth mindset intervention (SSI-GP) and support theory as an active control. See Figure 1 for the research design.

RenderX

Figure 1. Design of the 3-arm randomized controlled trial. SIGMA: single-session intervention of growth mindset for anxiety; SSI-GP: single-session intervention of growth mindset of personality; ST: support therapy.

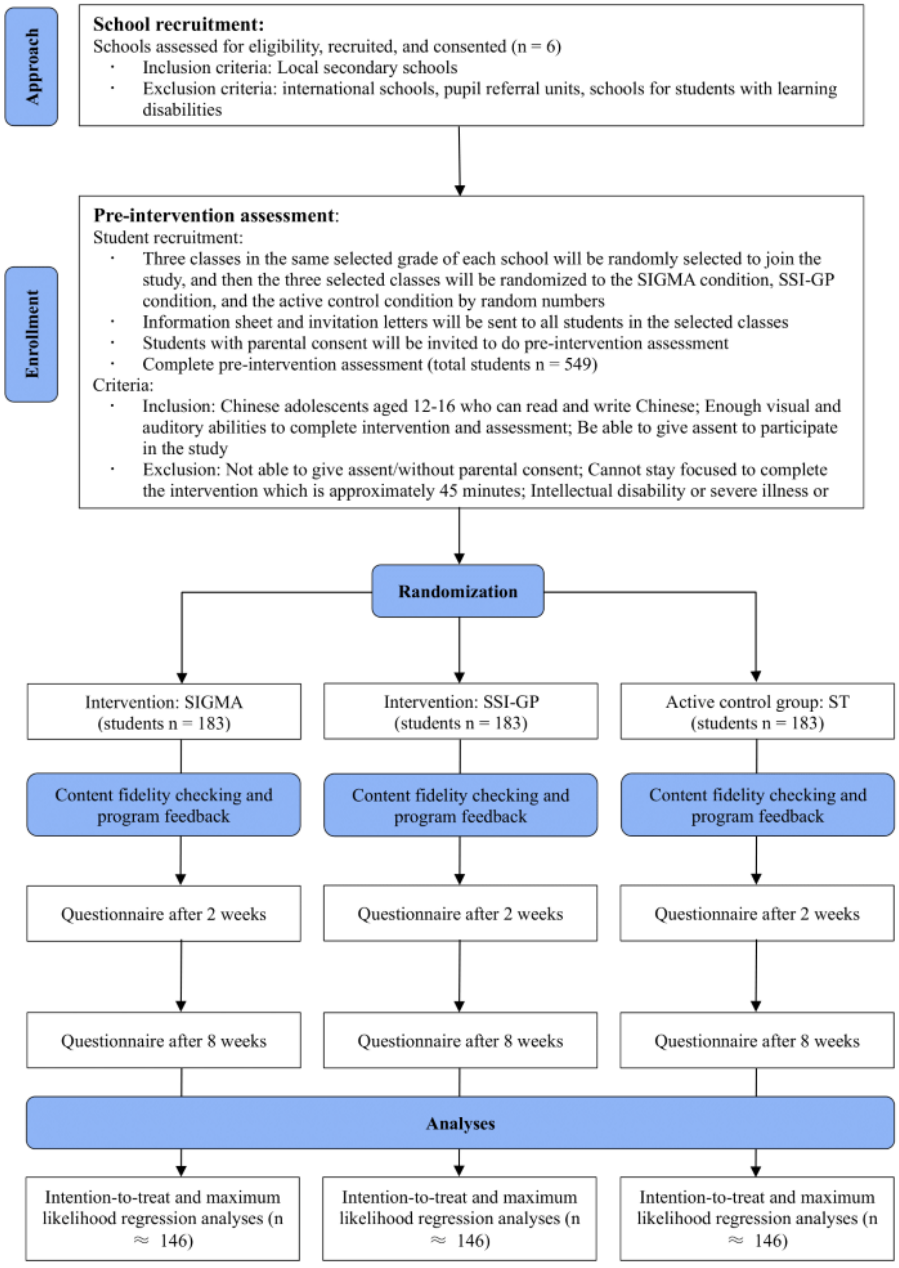
Aims and Objectives

The overarching goal of this study is to build the most effective implementation strategy of web-based growth mindset SSIs for reducing adolescent anxiety.

The primary objective of the proposed study is to evaluate the effectiveness of a SIGMA on reducing general anxiety symptoms in secondary school students. By using a 3-arm randomized control trial, we will compare the effectiveness of SIGMA to the SSI using growth mindset of personality (SSI-GP) and an active control condition using support therapy (ST).

The secondary objective is to compare the effectiveness of the aforementioned programs on secondary outcomes, including reducing hopelessness and increasing perceived control over emotions, attitude toward help-seeking, and psychological well-being.

There are 3 study hypotheses: (1) SIGMA and SSI-GP are more effective than the active control using ST in the primary outcomes, reducing general anxiety symptoms, and secondary outcomes, reducing hopelessness, enhancing perceived control, increasing positive attitude to help-seeking, and enhancing psychological well-being; (2) SIGMA is more effective than SSI-GP in the above primary and seconday outcomes; and (3) the effectiveness of SIGMA is greater in participants with higher motivation for change than in those with low to no motivation.



Methods

Research Design

This study will use a cluster-randomized control trial design. A conceptual model is provided in Figure 1. The intervention protocol will be pre-registered before data collection in ClinicalTrials.gov (ref: NCT05027880), and strictly follow the CONSORT (Consolidated Standards of Reporting Trials) guidelines [18,19]. At least 3 classes in the same grade of the participating school will be randomized (using computer-generated random numbers) into the (1) SIGMA group, (2) SSI-GP group, and (3) ST group (active control condition group), which will provide ST intervention at the same time. All participants will receive regular interventions in school. Three repeated assessments of the measures will be conducted for the 3 groups simultaneously at (1) baseline, (2) 2-week postintervention, and (3) 8-week postintervention (Figure 2). The cluster randomization at the classroom level can balance the risk of contamination between the intervention and active control groups and the school heterogeneity due to the school culture, schedule, and management.

XSL•FO
RenderX

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram reflecting the flow of participants through this study. SIGMA: single-session intervention of growth mindset for anxiety; SSI-GP: single-session intervention of growth mindset of personality; ST: support therapy.

Sample Size Determination

To make sure the sample size is big enough to test the hypotheses, a small to medium effect size (Cohen *d*=0.33) is used based on prior research [11], power set at 0.80, and α set at .05. A final sample size of 438 (146 per arm) is required. With reference to the attrition rate of our previous studies in a school setting, which is less than 20%, there is a requirement to recruit 549 participants at the baseline (183 per arm).

Participant Eligibility and Randomized Control Process

Eligible participants (aged 12-16 years) in grades 7-9 will be recruited from 6 secondary schools through cluster randomized sampling. The inclusion criteria will include (1) ages between 12 and 16 years, (2) Chinese youth who can read and write Chinese, (3) enough visual and auditory abilities to complete the intervention and assessment, and (4) ability to give assent to participate in the study.

Exclusion criteria will include (1) no parental consent; (2) inability to stay focused to complete the intervention, which is approximately 45 minutes; and (3) intellectual disability or severe illness or pain that would lead to significant bias in students' health and mental health situation. Eligible participants will not be screened for their anxiety symptoms; thus, this study will comprehensively examine the efficacy of the interventions for students with mild, moderate, and severe levels of anxiety.

The school and student recruitment process will include the following steps. First, we will send research invitations to schools chosen randomly from the school list. Invitations will stop when 6 schools agree to participate. At least 3 classes in the same selected grade of each school will be randomly selected

XSL•FO
RenderX

to join the study, and then the 3 selected classes will be randomized to the SIGMA condition, SSI-GP condition, and the active control condition by random numbers. All students in those classes will be invited to participate and the final participation depends on parental consent and students' assent. Based on prior trials in local schools, about 60% of students are likely to agree to participate with parental consent. Thus, approximately 90 students will be recruited from each school.

After consenting, students will be asked to complete a battery of questionnaires (detailed below) via the Qualtrics survey system. The students in 1 class will be in the same intervention conditions. The interventions will be conducted separately for each group in the school activity rooms with sufficient computers or tablets and headphones. All intervention activities are self-administered and delivered in a web-based format. The principal investigator and well-trained research assistants will stay in the intervention rooms to provide guidance and help if needed. All groups in 1 school will be conducted concurrently or within 2 weeks to reduce the influence of the time factor.

Implementation Content

SIGMA

The SIGMA intervention group will adapt the SSI-GP protocol in two ways: (1) by introducing the growth mindset of emotions rather than personality and (2) by providing an experiential process of negative emotion change. SIGMA also consists of five components: (1) an introduction to emotions and the brain for conveying a scientific understanding of emotion and growth mindset of negative emotions; (2) stories and testimonials from high school–aged youths who described their beliefs that people's negative emotion states (eg, anxiety, depression, and stress) are malleable, and how these mindsets influence their coping with anxiety; (3) emotion changing experience induced by short videos; (4) common questions and misconceptions about growth mindset; and (5) self-persuasion writing exercises in which the participants write notes to younger students about the growth mindset of emotion. Table 1 presents the key elements of the interventions. For participants at each school who belong to the SIGMA group, we will randomly select half of them to give them booster messages with core intervention content every 2 weeks between the 2-week posttest and the 2-month follow-up survey, that is, a total of 5 weekly booster messages will be sent to half of the participants of the intervention group, which will help us determine the most effective way of implementing the intervention.

Table 1. Intervention elements.

Intervention elements	SIGMA[a] (45 minutes)	SSI-GP[b] (45 minutes)	ST[c] (45 minutes)
Science knowledge about neural plasticity of the brain	✓ Growth mindset of negative emotions	✓ Growth mindset of personality	Nil Science videos about emotions
Stories and testimonials from high school-aged youths	✓ Focused on emotion changing experience	✓ Focused on personality change	✓ Focused on emotion sharing
Experiential exercises	✓ Emotion coping strategies	Nil	Nil
Self-persuasion writing exercises	✓ Focused on the malleability of negative emotion	✓ Focused on the malleability of personality	✓ Focused on sharing emotion to close others

[a]SIGMA: single-session intervention of growth mindset on negative emotions.

[b]SSI-GP: single-session intervention growth mindset of personality.

[c]ST: support therapy.

A pilot test among 13 secondary students (ages from 15 to 17 years) was conducted to confirm the feasibility and acceptability of the intervention in a small sample of the targeted population. The intervention lasted around 45 minutes and could be finished in one school class session.

SSI-GP

SSI-GP intervention group will use the intervention protocol of project personality [20]. We will translate it into Chinese by 2 bilingual native English and Chinese speakers and make adaptations to the local education context. The key potent elements of SSI-GP consist of five components [15,21,22]: (1) an introduction to the brain about the potential of neuroplasticity and behavioral change; (2) written testimonials from older, high school–aged youths of their belief in change of personality; (3) additional vignettes written by older youths about how growth mindset of personality helped them succeed following setbacks; (4) overview of common questions and misconceptions about growth mindset; and (5) an exercise of writing notes to younger students about the malleability of people's personality traits.

Active Control Group: ST

The control condition will be a structurally similar web-based session of supportive therapy. The goals of supportive therapy are to encourage the client to identify and express feelings and to share their emotions—both positive and negative—with close others. The ST group does not teach or emphasize specific skills or beliefs. The active control group includes the same number

XSL•FO
RenderX

of activities as the SIGMA and SSI-GP interventions. Also, to mirror the intervention groups as closely as possible, supportive therapy will include vignettes written by similar school-aged youths, who describe times when they benefited from sharing their feelings with friends or family members.

Implementation Strategies

As the SSIs in this study are all self-administer web-based interventions, we adopt 5 strategies to ensure the interventions are understandable, relevant, acceptable, engaging, and effective. These strategies will also help promote context sensitivity among school students in the Chinese context.

First, we form a youth advisory group to make sure the intervention content is understandable and relevant to students' life. The group includes 2 secondary school students of the targeted age group, 2 school social workers, and 2 university students. For example, the testimonials of anxiety situations and coping should be context-adaptive, and the introduction of scientific knowledge should be in plain language and easy to understand. The youth advisory group includes students from the target population, school social workers and counselors, and local university students. We seek their feedback and suggestions during the development and the pilot test of the study to further improve the intervention.

Second, we adopt the philosophy of solution-focused brief therapy. We do not focus on the problem but seek future-oriented solutions relevant to daily living. These techniques can help engage the participants to make the intervention relevant and can ensure the intervention is solution-focused rather than problem-focused.

Third, we integrate "design art and computing science" to make the intervention engaging; for example, we design animation icons and design videos, and use clickers in the self-administrative intervention to maintain the focus of the participants.

Fourth, we empower student participants to act as "helpers" or "experts" by framing the participants as active contributors in the improvement of the intervention and by asking them to provide support to peers [10,11]. This design aligns with adolescents' desire for respect [22].

Fifth, to ensure the intervention will be conducted in a standardized surrounding, the intervention will be conducted in activity rooms in each school. Around 12 to 20 student participants with parental consent will be invited to participate in the intervention as a group under the support and administration of well-trained research assistants. We also monitor the time spent on each part of the presentation with computing programming techniques. Participants with too long and too short duration time (usually above 2 SDs) in 1 section will be double-checked on their participation effectiveness, and biased data will be eliminated.

Data Collection and Management

Assessments will be conducted by a blinded researcher trained in using the instruments. Self-rated scales will be completed by the participants under guidance. All the measures have been pilot-tested, and the questionnaires take about 20 minutes to be completed. Two attention-checking items will be included in the surveys of each time point for careless responding screening (eg, "Please choose *Strongly Agree* for this item"). Only those who answer both attention-checking items correctly each time will be included in the final data analysis [23]. As the literature has shown motivation playing pivotal roles in people's behavioral change, we will also add 2 items at the beginning of the survey at baseline to assess participation motivation of our participants with a 6-point Likert scale, asking about their motivation to participate in this program and improve their emotion regulation ability, respectively.

Content Fidelity Checking

Mindsets of Negative Emotions

The validated Chinese version 12-item Mindset of Depression, Anxiety and Stress Scale will be used to assess participants' belief in change of negative emotion states, that is, depression, anxiety, and stress [16]. The sample items are "When you have a certain level of depression, you really cannot do much to change it"; "To be honest, people cannot really change how anxious they are"; and "No matter how hard people try, they cannot really change the level of stress that they have."

Each item scores on a 6-point Likert scale; a higher score means a more fixed mindset of negative emotions (Cronbach α=.94). There are 3 subscales: depression mindset, anxiety mindset, and stress mindset, containing 4 items in each subscale. The Cronbach α of 3 subscales are .91, .89, and .90, respectively [16].

Mindset of Personality

Three items of implicit theory of personality [24,25] will be used to measure the belief in change of personality on a 6-point Likert scale from 1 (*strongly disagree*) to 6 (*strongly agree*). A higher score means a more fixed mindset. The sample item is "People can do things differently, but the important parts of who they are can't really be changed." The Cronbach $\alpha$was .85.

Intervention Feedback Scale

It is developed based on the theoretical framework of acceptability (TFA), which consists of 7 component constructs including affective attitude, burden, intervention coherence, perceived effectiveness, opportunity costs, self-efficacy, and ethicality [26]. Except for a general acceptability item, 6 items for the 6 components of TFA except for ethicality and 4 items including 2 open-ended written feedback items in regards to the impression of the intervention from the well-validated Program Feedback Scale [27] will also be integrated to assess the acceptability of the intervention. Among the final scale, except the open-ended item, the other 10 items will be assessed on a 5-point scale, such as "How acceptable was the intervention to you?" ("1=Completely unacceptable" to "5=Completely unacceptable").

Motivation to Apply Things Learnt From the Program

Right after the intervention, we will ask participants after this program the extent to which they would like to apply the intervention content and the extent to which they would like to improve their emotion regulation on a 6-point Likert scale.

XSL•FO
RenderX

Primary Outcome

Anxiety symptoms measured by the Generalized Anxiety Disorder-7 (GAD-7) [28,29] are the primary outcome. The GAD-7 scale includes 7 items that assess whether anxiety symptoms have bothered the individual in the previous 2 weeks, ranging the frequency from 0 (*not at all*) to 3 (*nearly every day*). Example items were "Feeling nervous, anxious, or on edge" and "Not being able to stop or control worrying." GAD-7 is the self-rating scale and effectively reflects symptom severity in adolescents; it is highly correlated with clinician-administered ratings of anxiety symptoms. It is brief and suitable for self-report study [30]. The Cronbach α was .93 [31].

Secondary Outcomes

Perceived Control

The Anxiety Control Questionnaire-Emotion Control [32] is a 15-item questionnaire that measures how much perceived control participants have over their anxiety. It is 1 of the 3 validated subscales of the anxiety control questionnaire and contains 4 items (eg, *I am able to control my level of anxiety*) rated from 0 to 5. The scale has a well-validated factor structure in a nonclinically selected sample, is strongly associated with anxiety and depression symptoms, and has demonstrated good internal consistency in previous investigations. The Cronbach α was .73.

Hopelessness

The 4-item helplessness subscale of the Demoralization Scale [33] will be used to measure the participants' faith in the future. Each item scores on a 5-point Likert scale, and the mean of all 4 items is taken to measure the hopelessness, with a higher score meaning a correspondingly higher level of hopelessness. An example item is "I feel hopeless." The Cronbach α of the Chinese version of this helplessness subscale was .72 [34].

Attitude Toward Seeking Help

We use 2 items from the Attitude toward Seeking Counselling Help Assessment [32,33], participants' understanding of counseling and attitudes toward seeking counseling help. An example item is "If I believed I was having a mental breakdown, my first inclination would be to get professional attention." The Cronbach α was .72 [34]. We develop a brief scale including 2 items to assess participants' help-seeking behavior. The 2 items are "when I encounter difficulties, I will not ask help from teachers" and "when I encounter difficulties, I will not ask help from social workers/counsellors." This scale will be rated on a 6-point Likert scale from 1 (very untrue of me) to 6 (*very true of me*).

Psychological Well-being

The short version Warwick-Edinburgh Mental Well-being Scale (WEMWBS-14) [35,36] will be used to measure the extent to which participants generally experience well-being states. The WEMWBS includes 14 items, scoring on 5-point Likert scale, the average of all 14 items indicates the well-being of the participants. The sample item is "I have been feeling optimistic about the future," and the Cronbach α was .93.

Covariates

Sociodemographic information consists of a range of participant characteristics and is measured at the baseline to examine variability between the groups such as gender, age, grade, ethnicity, and socioeconomic status.

Data Analysis

An intention-to-treat analysis will be conducted for any missing data. Two-level analyses will be used to account for cluster randomization [37]. To examine the effects of the interventions, multilevel regression will be used to test the group effect, time effect, and their interaction effect on outcome measures. Additionally, we will calculate effect sizes using estimated marginal means; these effect sizes compare mean gain scores (Cohen *d*), reflecting changes in each outcome from baseline to 2 follow-ups for youths receiving the mindset versus active control interventions. The effect sizes will also be compared between participants in the intervention group who receive booster messages and those who do not. A *P* value of <.05 will be considered statistically significant, and SPSS version 26 (IBM Corp) will be used for all statistical analyses.

Ethics Approval

The study has obtained research ethics approval from the institutional review board of the principal investigator's university (HSEARS20201004001-01). This trial was preregistered at ClinicalTrials.gov (NCT05027880). Participation will be voluntary. Informed written consent or digital consent will be obtained from parents and participants. We will remind the participants that they have the right to terminate the intervention or omit any questionnaire questions and assure the confidentiality of their answers. We will also provide additional information for referral services to the student participants. Students are also invited to indicate if they need further support from school social workers or counselors in the postintervention questionnaire. With the participant's assent, we will refer the participant to the school caring professionals. All identifiable information will be removed, and codes will replace names to ensure privacy. All personally identifiable data will be locked up and destroyed 3 years after the study ends. Participants' data will not be identifiable in any publication or reporting.

Results

Recruitment will start in December 2022, and data collection is expected to end in 2023. Results are expected to be available in January 2024. We also intend to make the publications available in 2024. The findings of this trial will be presented as well at conferences. We will only report aggregated group data, and no personal information will be leaked.

Discussion

Overview

We anticipate that SIGMA, which highlights that emotion states are changeable, will significantly enhance the growth mindset of emotion and reduce general anxiety symptoms and secondary outcomes compared to SSI-GP and the active control. However,

XSL•FO
RenderX

the effect size will be small because single-session self-help interventions are low-dosage interventions. SSI-GP is hypothesized to have better outcomes than the active control group. The half with booster messages in the SIGMA group will have better outcomes than the half without boosters, especially in the 8-week follow-up.

To date, this will be one of the few randomized controlled trials to apply a single-session growth mindset intervention to reduce anxiety. As focusing on the key aspects and using effective ways to make changes are the key mechanism of effective SSI, addressing the key aspects that can secure changes is essential for designing SSIs. This 3-arm randomized controlled trial will help elucidate the mechanisms of change in adolescent anxiety symptoms: believing that negative emotion can change (SIGMA), believing that personality can change (SSI-GP), or receiving support (active control). This proposed study will find the potent core element of brief intervention in helping youth with anxiety.

This study will also be a pioneer study examining the self-administered web-based intervention among Chinese adolescents. There is a paucity of research in the Chinese context on effective implementation strategies for self-administrative SSI. As the effect size of SSI varies from small to medium in extant interventions, the dedicated design and careful implementation matter in the efficacy of the study. This study will provide a clear protocol of implementation content and strategies, which will be helpful for the future use and development of SSIs.

This project has theoretical, practical, and clinical contributions. Examining the efficacy of the notion of malleability of negative emotion on youth anxiety will advance the understanding of the impact of implicit theory and mental health symptoms. The easy-access self-help program will enable adolescents with anxiety symptoms to access timely help, and reduce the risk of deterioration of anxiety symptoms and development of comorbid mental health problems before adolescents can access therapy provided by a trained therapist or psychiatrist. If proven effective, SIGMA will benefit a proportion of youths who would otherwise go without service entirely. It can also benefit youth on the waitlist for psychiatric services by invoking intrinsic motivation and avoiding hesitance to get treatment. It can also serve as a complement to multisession psychosocial treatments. This project may provide a generalizable model for the development and implementation of SSI among youth people in the Chinese context.

Limitations

There are limitations that need to be considered. First, as this study does not exclude individuals based on the severity of their anxiety symptoms, the efficacy of the interventions to reduce anxiety symptoms of students without anxiety or with low levels of anxiety may not be significant and thus affects the statistical significance on the whole. However, the proposed intervention can be inclusive to youths with a diverse range of anxiety problems and offers a unique opportunity to study the differentiated impacts with subgroup analyses. We expect the secondary outcomes will have significant changes after the intervention, even for those with low-level anxiety symptoms. Second, there is no waitlist control group as all 3 groups are implemented with specific interventions, with even the control group receiving ST (active control). In this study, we aim to compare the effects of different interventions with specific strategies. However, the setting of a waitlist control group will help in better understanding the effect of interventions overall.

Conclusions

This study presents the evidence-based implementation of web-based single-session growth mindset interventions for student anxiety and compares the efficacy of SSIs using growth mindsets on negative emotions and growth mindsets on personality. Our study will provide an example of the implementation of SSIs among the Chinese adolescents and will help to develop easy-access, low-cost, and scalable interventions for mental health promotion among young people.

Acknowledgments

This study was supported by a grant funded by the Hong Kong Research Grants Council (reference number 15601621) that was awarded to SZ. The funding body played no role in the study design, data collection, or manuscript writing. We would like to recognize the contributions of the principals, school counselors, and social workers who share their insights into students' mental health care needs.

Data Availability

Data are not publicly available but can be obtained via contacting the corresponding author.

Authors' Contributions

SZ conceived this evaluation study initially and drafted the first draft of the grant proposal. ST and KLC provided comments for the randomized control trial design and the grant proposal. PL contributed to the data analysis plan. QC provided comments for web-based intervention implementation. JS provided comments from psychiatric profession. SZ developed all aspects of the proposal and manuscript related to the implementation of intervention and data collection. All authors edited and approved the final manuscript.

Abstract

Background: Death of a child in the pediatric intensive care unit is a rare event that can occur after failed cardiopulmonary resuscitation efforts, after a brain death diagnosis, or after a decision to limit therapeutic efforts. Nevertheless, even in the case of children with terminal and progressive illnesses, death is a crisis that comes as a surprise to parents and is perceived as unexpected. In the final stage of a child's life, health care staff play a key role in sharing feelings and experiences with the family and in supporting them throughout the process in order to facilitate the grieving process.

Objective: The aim of this study is to explore the experiences of parents whose children have died in a pediatric intensive care unit.

Methods: To address the study aims, a qualitative phenomenological study based on the van Manen proposal will be carried out. The study will be conducted in the pediatric intensive care unit of a tertiary care hospital. The study population will be parents or guardians (older than 18 years) of children who have died in the unit at least 6 months prior to potential participation in the study. Purposive sampling will be used to ensure sample diversity in relation to experiential variables. Families will be initially contacted by letter sent alongside the standard letter of condolences from the hospital, and then recruited in a subsequent telephone call. The sample size will be determined by data saturation. In-depth interviews will be conducted individually or in pairs. Parents will decide when, how, and where to conduct the interviews, which will be transcribed verbatim and examined using thematic discourse analysis.

Results: This study was awarded a grant in December 2020 and was approved by the Medical and Health Research Ethics Committee on December 21, 2020. Data collection started in April 2021, and the results are expected to be published in 2023.

Conclusions: This project is intended to maintain, strengthen, and build on a particular line of research on end-of-life care with a focus on effective coping, spiritual well-being, and the adaptive grieving process. The results will contribute to establishing action guidelines that are both based on the discourses of parents who have experienced the death of a child and geared toward high-quality end-of-life care through dignified death and adaptive grief management.

hospice and palliative care nursing; intensive care units; pediatric; patient-centered care; family nursing; death; qualitative research

Introduction

Child and adolescent death caused by noncurable diseases is still a present reality despite developments in pediatric medicine [1]. According to the World Health Organization data [2], 6,073,010 children under the age of 14 years died in 2019 around the world, leaving an intense, lasting impact on their families.

Death produces anxiety, distress, depression, and fear, especially when the deceased is a child. As children exhibit different characteristics from adults, the approach to palliative and

XSL•FO
RenderX

end-of-life care for these patients and their families should also be different. The primary objective is to ease suffering through proper symptom control, psychological, social, and spiritual support, and preparation for death and grieving. The maladjustment process that occurs within the family is particularly relevant, as it complicates the acceptance of their loss. The sorrow arising from this loss, coupled with the ongoing decline in the structure and function of the family unit, makes it difficult to develop coping strategies and worsens the experience of grief. Even in the case of children with terminal and progressive illnesses who experience life-threatening events, death is a crisis that comes as a surprise to parents and is perceived as unexpected [3].

In pediatric end-of-life care [4], it is widely accepted that the family's experiences in the hospital can have a significant long-term impact on memories and the grieving process [5]. There is therefore an important incentive to improve the quality of care provided in these circumstances, both to improve patient experience as well as to support the impending grief of families. Meert et al [6] identified a high incidence of complicated grief symptoms in parents whose children had died in the pediatric intensive care unit (PICU). In their study, they note that these symptoms lessen between 6 and 18 months after the child's death, although not for all parents. In light of the above, we believe it is relevant to investigate the experiences of the families of children who have died in the PICU to better discern the actions of health care workers; how to provide the family with the most appropriate resources needed to ease their grieving process; how to foster a supportive atmosphere and a dignified death; and to assess whether the care provided by health care workers is satisfactory.

Over the last decade, pediatric care has seen improvements in the care of critically ill children, most notably, the adoption of the family-centered care (FCC) model. This model is based on the premise that parents are the people who know their children best [7] and should therefore be included in the caring relationship, as their involvement improves patient outcomes. The definition of FCC encompasses 4 fundamental concepts: respect and dignity; information sharing; participation in care and decision-making; and collaboration between patients, families, and the health care team. In addition to the physical benefits for patients, when parents are involved in their children's daily care by playing an active role in the care team, emotional and psychological aspects improve through effective coping.

Death of a child in the PICU is a rare event that can occur after failed cardiopulmonary resuscitation (CPR) efforts, after a brain death diagnosis, or after a decision to limit therapeutic efforts (LTE). According to data provided by the MOMUCIP study [8], which explores the causes of death in PICUs, the most frequent cause of death was after a decision to LTE (n=151, 50.7% of all cases, widely ranging between 19.2% and 64.6% depending on the hospital), followed by indicated but failed CPR (n=114, 33.8%), and brain death (n=52, 15.4%). The main reason for LTE was failure to provide CPR for cardiac arrest (n=45%), followed by withdrawal of mechanical ventilation (n=48, 31.5%), and administration of vasoactive drugs (n=33, 21.6%).

Technological advances have increased the ability to provide support in very critical situations. However, life does eventually come to a natural end, and the continuation of therapeutic interventions is not always suitable, sometimes raising the question of whether continuing treatment is in the child's best interest. If the decision is made to withdraw life-support therapy, the main focus then shifts from an interventionist approach (aimed at sustaining life) to an approach aimed more at providing as much comfort and emotional support as possible to the child and their family. In the final stage of a child's life in PICUs, health care staff play a key role in sharing feelings and experiences with the family and in supporting them throughout the process. Providing high-quality end-of-life care for patients and their families eases suffering through appropriate decision-making and symptom management, which helps to facilitate the grieving process.

In relation to the available evidence, Mitchell and Dale [9] highlight the importance of providing anticipatory care for patients with life-limiting illnesses by planning care in advance together with the family to let them make decisions based on clear information and to avoid unnecessary interventions. Regarding the planning and implementation of palliative care in intensive care units, it is neonatal units that have made the most progress in this area and where the vast majority of scientific evidence is available. As early as 2002, Catlin and Carter [10] established the key elements necessary for an effective approach to palliative care, forming the basis for numerous subsequent studies and protocols, serving as an example of a high-quality practical guide [11].

Recent studies address a range of issues, including evaluating the implementation of a care program in neonatal intensive care units (NICUs) [12]; the benefits of implementing interventions that focus on early symptom management; the possibility of planning interdisciplinary meetings to discuss issues such as end-of-life care (ie, anticipating complications and treatment options or not starting treatment or resuscitative measures); and the promotion of joint decision-making for neonates with severe and incurable illnesses (ie, morbidity and mortality associated with the condition). These studies also emphasize the need to train nurses in palliative and end-of-life care, as lack of training is one of the barriers that may be encountered [13] when preempting symptom recognition in the child and their family and when attempting to improve nursing care and support. The literature also stresses the need to continue new lines of research involving health care workers who care for children with conditions requiring palliative and end-of-life care and for their families [14]. The creation of clinical practice guidelines where palliative and curative approaches coexist and where the timing of their transition is established is also of vital importance, as there is ample evidence of the benefits of palliative care in PICUs and NICUs. However, the number of publications successfully reporting such benefits through protocols and care programs is scarce [11].

All of the above brings to the forefront the fundamental roles that nurses play in end-of-life care [15]. This is further accentuated in intensive care environments and even more so in the pediatrics branch, in the case of FCC. The role of the nursing professional takes on greater importance when it comes

XSL•FO
RenderX

to supporting the patient and their family at the end of the patient's life. This is due to the therapeutic relationship based on trust and support that is established between them, which improves the family's ability to cope. Similarly, several nursing theories and models throughout history have considered palliative care as a significant part of nursing functions [16], creating a framework for action of its own. According to Wu and Volker, the Humanistic Nursing Theory approaches the field of palliative care through the lens of the bond created between the nurse and the patient, seeking to provide patient comfort, encourage decision-making, and maintain dignity [15].

There is also a major pillar of nursing that illustrates the importance of nurses in end-of-life care—the nursing care process (NCP). This, together with the North American Nursing Diagnosis Association taxonomy, allows specific nursing diagnoses directly related to palliative care to be identified, for example, risk for maladaptive grieving (00302), maladaptive grieving (00301), and readiness for enhanced grieving (00285) [17,18]. Through the NCP, and based on standardized language, nurses carry out interventions specific to their discipline (Nursing Interventions Classification) such as active listening, anxiety reduction, coping enhancement, and dying care, which give them a sufficient degree of autonomy when it comes to achieving measurable outcomes (Nursing Outcomes Classification) [19], which in turn contribute to the resolution of patient problems.

For these reasons, the general aim of this study was to explore the experiences of parents of children who have died in the PICU. In addition, the specific aims of this study were the following: to explore parents' perceptions of their capacity for self-determination and active participation in the process of caring for their child at the end of their life; to identify needs perceived by parents when saying goodbye to their deceased child; and to identify limitations regarding family support as perceived by parents and strategies for improvement.

Methods

Design

The project will be based on the constructivist paradigm, and a qualitative phenomenological study will be carried out according to the van Manen methodological proposal. According to this author, phenomenological research is the study of life experiences, of the lifeworld and everyday life (which constitutes the prereflective experience), the nonconceptualized or noncategorized experience [20]. In keeping with the above, an interpretative phenomenological or hermeneutic approach will be taken, as it provides an understanding that there is no single reality but multiple realities [21], which depend on the subjective interpretations of the individuals who experience a given phenomenon, the life stage that they are at when that phenomenon occurs, the place they are in, and their interactions with the people around them) [22].

We propose an intersubjective approach to the study phenomenon, which means seeking to gain access to the multiple interpretations of reality through the subjectivities of the families who have experienced first-hand the loss of a child in the PICU while at the same time recognizing the active participation of researchers themselves in the research process [21,22].

Study Setting

The study will be conducted in the PICU at the Gregorio Marañón General University Hospital in Madrid, Spain. This is a multipurpose unit that provides clinical care for critically ill children and coordinates and supports other hospital services in the prevention and treatment of life-threatening situations, as well as in the care of complex technology–dependent patients. It has an intensive care and an intermediate care hospitalization area with a total of 17 beds and an occupancy rate of 70%-80%.

The reasons for admission of PICU users, according to their clinical records, were as follows: heart conditions or postoperative cardiac surgery (23%); respiratory (30.4%), hemodynamic (14.2%), hemato-oncological (3.5%), neurological, gastrointestinal (2.9%), or renal problems (2.7%); multitrauma (5.9%); and infection or acute sepsis (6.5%), transplant (3.9%), and so forth. During the last 3 years (2018-2020), an average of 385 children were admitted to the PICU per year, with a mortality rate of 4.6%, 1.9%, and 2.9%, respectively. The most frequent causes of death were limitation of therapeutic efforts, multiorgan failure, and brain death [23].

Participants

The study population will include parents or guardians, older than 18 years, of children who have died in the PICU at least 6 months prior to their potential participation in the study [9], who are able to communicate verbally or in writing, and who voluntarily agree to participate in the study. Participants will be assured that their participation and the subsequent interview will not put them at any emotional or psychological risk.

In relation to the grieving process, the literature consulted recommends different time periods for inviting families to participate, ranging from 4 [24] to 12 months [25] after the death of their child. However, each family's circumstances will be assessed during the phone interview, ensuring that all stages of grief have been overcome successfully, and avoiding significant dates such as birthdays and anniversaries.

All persons whose participation in the study may put them at risk of emotional instability, such as parents who are going through pathological or complicated grief, will be excluded [26].

Purposive sampling [27] will be used to ensure sample diversity regarding experiential variables. These variables will be determined by the research team's consultation of available evidence and prior experiential knowledge (Multimedia Appendix 1) and attempts will be made to ensure access to varied, meaningful, and competing narratives. In more advanced stages of the research process, a decision will be made to follow either a theoretical sampling method that includes new variables or experiential criteria, which emerge from the analysis.

For the recruitment of families, together with the institutional letter of condolences sent by the unit, they will be asked in writing about the possibility of participating in the study. In a later telephone call, the project will be explained to them in

XSL•FO
RenderX

greater depth, any doubts or questions will be addressed and compliance with the inclusion criteria will be assessed.

The final sample size will be driven by data saturation, that is, the occurrence of redundant and repeated information [27]. This stage of the research will end when a solid set of primary protocol materials (interviews, observations, and notes) has been collected and described and there are enough data to perform a comprehensive categorization or classification which, in turn, can inform sound analysis, interpretation, and theorization, leading to valuable results [28].

However, after consulting the available literature, it is estimated, in terms of time and budget planning, that data saturation can be achieved after a total of between 10 [9,25] and 25 parent interviews. These sample sizes are taken as a reference, but results will depend on the interviewer's expertise, the richness of participant discourse, and the analyst's ability to see beyond the data (or the analyst's theoretical sensitivity), among other aspects [29].

Data Collection

In-depth individual or paired interviews will be conducted according to each family's preferences (paired interviews allow family practices to be analyzed and shared family realities to be co-constructed) [30]. The interview is a technical instrument that is very much in tune with theoretical hermeneutic phenomenology, as it is intended to explore and collect experiential narrative material and to be the vehicle for investigating the meaning of that experience. Given the sensitive nature of the topic, a script for the semistructured interviews will help the interviewer to focus on the most relevant aspects of the experience while ensuring that emotional vulnerability is carefully managed [20]. Although the interview script is not meant to be a closed framework, it does allow for some control over the most emotionally sensitive areas and the routes to reach them if the participant is not prepared.

Based on the general and specific study objectives and taking the researchers' experiences into consideration, carefully worded dynamic interview questions have been drafted in order of the most general to the most specific, and from the least sensitive to the most sensitive (Multimedia Appendix 2). The script will be flexible in nature and will evolve according to the fieldwork and the needs arising from it. The information gathered and topics emerging from this information will refocus the approach and the collection of additional new data [28].

The families who agree to participate will decide when, how, and where they want to be interviewed: in person, with different locations available (travel expenses will be covered), or remotely, by videoconference or telephone. These will be audio-recorded. The recordings will be kept for up to 1 year after the publication of the study results in case further analysis is required. They will then be deleted.

While the interviews are being conducted, through close observation [29], the data obtained from nonverbal communication will be recorded in a field notebook. This is how, according to van Manen [32], we come as close as possible to the participant's lifeworld, so that we can grasp the meaning of that person's particular experience. This register can help to contextualize the families' discourses and to understand how the death of a child in the PICU impacts their parents in greater depth. Participant files will also be created where sociodemographic, clinical (reason for admission, time spent in the PICU, date, and cause of death), and relational data will be collected to help understand and contextualize their discourses. Some data will be retrievable from their clinical records, while others will have to be completed during the interviews.

Data Analysis

The van Manen hermeneutic approach [32] will be used for the qualitative analysis of the data. The interviews will be transcribed verbatim, and a thematic discourse analysis will be performed by identifying the themes that give meaning to the text and the experience. The themes are interpreted as the significance of the experience itself—attributing meaning and significance to the phenomenon at hand in an attempt to understand it, in such a way that each theme describes a different facet of the experience being faced. As themes emerge, an attempt will be made to capture the thematic status networks in more phenomenologically sensitive paragraphs by making reflective-theoretical notes (memoing) that will result in a creative hermeneutic process [20].

Subsequently, the themes that will inform the phenomenological description will be established: since not all the meanings that we find when reflecting on a phenomenon or lived experience are unique to that phenomenon or experience, this means that the key themes will be identified. To this end, we will identify the main qualities of each of the themes that are quintessential to that phenomenon.

For coding, the support software ATLAS-ti (Estudiantes; L-BFB-FEC, individual license) will be used for structuring the analysis and storage of data. This program will facilitate the identification of codes, the creation of the first themes for analysis, and the initial exploration of all written documents arising from the interviews for the study of qualitative data [33].

During the analysis process, the results will be cross-checked and compared with those of similar studies to verify how they emerge from different perspectives or broader theoretical frameworks and to better explain what the study really means. Comparing and contrasting emerging theoretical proposals with those of other researchers will lead to greater integration and enrichment of the study area's body of knowledge [28]. This comparison will lead to the reformulation, restructuring, extension, or refinement of previous theoretical constructs. The constant comparative method is a way of generating theory from the comparative and systematic analysis of data [34]. In order to synthesize the final findings, efforts will be made to integrate all the themes into a coherent and logical whole, with evocative meaning.

Ethical Considerations

Parents' principle of autonomy [35] will be preserved by signing the informed consent form after reading an information sheet that will be provided to them, containing the rationale for the project, a brief explanation of the study, who is involved, and the risks and benefits associated with their participation.

XSL•FO
RenderX

Permission will be requested from participants to be audio-recorded. All participant questions will be answered before signing the informed consent form. They will choose to participate without any pressure or coercion. Informed consent will be written using the informed consent form designed for this purpose and approved by both ethics committees.

All interviews will be attributed codes, eliminating any personal details of the informants. Confidentiality will be preserved throughout the study, and the safety of participants will be ensured at all times, bearing in mind that the study is sensitive in nature [36]. The project was approved by the Clinical Research Ethics Committee at the Gregorio Marañón Hospital (CuidFin_Enf1; January 12, 2021), as well as by the Research Ethics Committee at the Autonomous University of Madrid, Spain (CEI-121-2451; February 11, 2022).

Rigor

To ensure the internal validity of the project (credibility and accuracy), the following will be used: several forms of triangulation [22] of data collection techniques from interviewers and analysts; audit strategies, for example, member checking [37] or feedback from participants and the "critical friend" strategy [38] or feedback from critical experts); and thorough descriptions of the research process and methodological decision-making.

With regard to external validity (transferability), a detailed description of the characteristics of the participants and the study setting will be provided in order to contextualize the findings and assess the relevance of the gathered evidence for application in other clinical settings.

In addition, auditability will be ensured so that other researchers wishing to conduct the same research based on the data from this study will reach the same or similar conclusions. To this end, all documents and a complete record of all decisions made and ideas put forward shall be made available.

Results

The project was funded in December 2020 and started in April 2021. By December 2022, a total of 19 participants had registered, and the first themes of the analysis were beginning to emerge. These emerging themes are informing further rounds of interviews. Recruitment is expected to be completed in February 2023, reaching thematic saturation, with results to be published in mid-2023.

Discussion

The future results will provide a basis for establishing action guidelines based on the experiences of parents who have suffered the death of a child in the PICU. This is intended to ensure the provision of high-quality end-of-life care that helps patients to die a dignified death and parents to better manage their grief. A review of the literature found numerous studies conducted in NICUs, but only few studies involving PICUs may serve as a reference for future lines of research.

Due to the COVID-19 pandemic, the number of children admitted to the unit has been lower (with a consequent decrease in deaths). This raises the need to recruit participants retrospectively by including parents with children who have died since 2019 in the study population. Initially, a pilot study will be conducted with particularly approachable and cooperative families to decide on the questions that will make up the interview script, as well as the most appropriate time and channel for contacting families.

A potential limitation in the execution of the study is the language barrier, as the PICU at the Gregorio Marañón University Hospital is a leading cardiology unit where admitted patients (and their families) are not fluent in Spanish. Another limitation may be linked to the impact that their child's death may have on parent participation in the study.

End-of-life care is one of the main objectives of health care. Taking an in-depth look at this issue is an opportunity to improve health care delivery and the humanization of care, to help families to manage their grief and to foster a climate conducive to a dignified death. This project is intended to maintain, strengthen, and build on a particular line of research on end-of-life care in order to contribute to care excellence in the psychosocial and spiritual dimensions by focusing on effective coping, spiritual well-being, and the adaptive grieving process.

Acknowledgments

We would like to express our heartfelt gratitude to all the parents who have shared their experiences with us in the hope that families going through a similar experience in the future will receive the excellent care they need. We would also like to thank Elena Peña, Alberto Sánchez, Rosa Blanca Ortiz, and Dr Jesús López-Herce (working in the PICU at the Gregorio Marañón Hospital) for their collaboration in data collection and future participation in subsequent analyses.

Data Availability

The data sets used and analyzed during this study are available from the corresponding author on reasonable request.

Conflicts of Interest

The researchers declare that they have no conflict of interest that could affect their proposed ideas or the undertaking of the present research study. The research protocol has been funded by the Intramural Nursing Programme of the Biomedical Research Foundation at the Gregorio Marañón Hospital in Madrid, with a contribution of €5000 (US $5465.85; document attached). The

XSL•FO

Abstract

Background: Adolescent idiopathic scoliosis is a 3D spine distortion with an unidentified etiology. It results in noticeable trunk deformity, decreased muscle strength and endurance at the trunk, changes in chest volume, breathing issues, and ultimately a decline in the quality of life. Trunk bracing and corrective exercises make up most of the treatment of patients with scoliosis when their deformity is between 20° and 45°, and they have not yet attained skeletal maturity. Evidence suggests that spinal deformity in people with scoliosis may result from improper motor control. Automatic response training is an exercise therapy technique that can modify the pattern of trunk muscle control for supporting the spinal column in normal alignment. An apparatus called a cantilever device is required for this type of exercise, which facilitates training at home. In spite of research showing the benefit of braces and therapeutic exercise in adolescents with scoliosis, less emphasis has been given to the impact of home-based training, especially when this intervention is paired with braces.

Objective: We aim to compare the efficacy of bracing and a conventional exercise program to a combination treatment that includes trunk bracing and exercises with a cantilever device performed at home on the degree of spine curvature, pulmonary function, trunk muscular endurance, and quality of life.

Methods: This study was a 2-arms parallel-group clinical study. A total of 16 adolescents with idiopathic scoliosis and single lumbar and thoracolumbar curves of 20°-45° were recruited and randomly assigned into 2 groups. Group A received a combination of trunk bracing and exercise using an instrument known as a “cantilever.” Group B (controls) received trunk bracing and a conventional exercise program (without a tool). The study outcomes were the Cobb angle of the scoliotic curve, pulmonary function, the endurance of the trunk muscles, and quality of life. The study outcomes were measured at 2 time points: before the intervention (T1) and 12 weeks following the start of the intervention (T2; at this time, the intervention period has been completed). Multivariate analysis of variance was used to test between- and within-group differences.

Results: Recruitment for this study began in fall 2022 and is expected to be completed by the end of summer 2023.

XSL•FO
RenderX

Conclusions: We studied the efficacy of a combined trunk bracing program and postural response exercises using a cantilever device in treating adolescent idiopathic scoliosis and compared it with trunk bracing and conventional home exercises. Exercises performed at home using a cantilever device are anticipated to raise the endurance of trunk muscles, which will help reduce trunk deformity, enhance pulmonary function, and improve the quality of life of participants.

KEYWORDS

home exercise; orthotic device; quality of life; scoliosis

Introduction

Adolescent idiopathic scoliosis (AIS) is a 3D spine deformity with an unknown etiology [1]. It is stated that 0.47%-5.2% of people aged between 11 and 18 years have an AIS [2]. Typical side effects of scoliosis include apparent trunk deformities, pulmonary restriction, muscular weakness, activity limitations, and a decline in health-related quality of life [3,4]. The current treatment goals for AIS include preventing the progression of the deformity, resolving the scoliosis curve, and improving quality of life [5]. Treatment options for AIS vary depending on the degree of spinal curvature and skeletal growth [1]. Physiotherapy, exercise, and monitoring techniques are often used with patients with curves less than 20°, especially those with substantial remaining skeletal growth [6]. Trunk bracing and exercises are prescribed for curves between 20° and 45° to promote soft tissue flexibility and enhance the functions of muscles that support the trunk [6,7]. Surgical correction is a typical treatment for curves greater than 45° [6].

A major concern with AIS is the loss of motor control, which can manifest as asymmetrical or weak muscles [8]. Also, abnormal breathing patterns are observed in those with AIS, which can exacerbate the scoliosis deformity [7,9]. People with scoliosis frequently have less strength and endurance in their trunk muscles than people without the condition [10]. Therefore, exercise therapy is often regarded as the cornerstone of recommended treatment for AIS [11].

Trunk bracing is the most prevalent nonoperative method for preventing curve progression in mild to moderate AIS (ranging from 20° to 45° Cobb angles) [12]. Evidence suggests that the effectiveness varies with different brace types [13]. Rigid braces have shown superior effects in preventing curve progression than nonrigid braces [13,14]. The external corrective forces delivered via a rigid brace reduce asymmetric spine loading and thereby prevent asymmetric growth [15]. The rigid bracing can limit the user's physical activity, resulting in a loss of muscular strength and endurance over time [16,17]. The long-term use of a stiff brace may impede rib cage expansion and decrease lung capacity [18,19]. The study agrees that using selective exercise can compensate for the adverse effects of rigid trunk bracing on muscular and respiratory functions [16,20-22]. Activation of the muscles involved in spinal stabilization can be beneficial in reducing the risk of treatment failure in AIS [23]. Providing expanding chambers in conjunction with pressure zones is a feature of innovative brace designs like the Cheneau that help to activate muscles inside the brace [24].

Scoliosis treatment guidelines recommend home exercise as an adjunct to brace therapy [22]. Physical training enhances the effects of the brace by increasing muscular strength and endurance and removing the drawbacks of trunk bracing as a single treatment [21,25]. Moreover, exercise reduces the curve's progression and improves pulmonary function and the quality of life of people with AIS [21]. Recent ideas on conservative scoliosis therapy suggest that therapeutic exercise should be specifically tailored to modify the motor control of the spine [21]. It has been substantiated that the brain and spine do not communicate effectively in AIS [21,26]. The incorrect perception of gravity could affect muscle tone and cause spinal curvatures [26]. Postural response training is thought to improve the activation of spinal muscles and balance the body against external forces [5,21,26]. An apparatus known as a "cantilever" is typically needed for postural response training to apply external forces to the body during repeated exercise [26]. According to prior research, there is little study on the efficiency of combination brace and exercise therapy in AIS [13,22]. Furthermore, a thorough search of the literature by the authors also discovered that no prior research has yet evaluated the effectiveness of postural response training paired with trunk bracing. This study compares the efficacy of combination bracing and conventional exercise with combined bracing and postural response training. It has been hypothesized that postural control training will improve the functioning of the spine's muscles, which will help to straighten the spine, increase chest space, enhance respiratory function, and eventually enhance an individual's quality of life.

Methods

Study Design

This prospective study was a 2-armed, participant-blinded, randomized controlled trial (intervention vs control group) performed to investigate the objectives. The study procedure was reported using the TIDieR (Template for Intervention Description and Replication) checklist and associated guidelines. The Intervention Description and Replication checklist outlines a consistent method for meticulously recording information and enables authors to define treatments precisely in their research [27]. The CONSORT (Consolidated Standards of Reporting Trials) checklist was used to report data effectively in a clinical trial [28].

XSL•FO
RenderX

Setting

Participants were consecutively recruited from individuals with AIS, Risser sign 0-2, and Cobb curvature 20°-45°, and were referred to a spine specialist (author AA) for their first evaluation in the Orthopedic Clinic at Al-Zahra Hospital in Isfahan, Iran.

Sample Size

A total of 16 adolescents with single lumbar and thoracolumbar curves of 20°-45° and idiopathic scoliosis were recruited for the study. Based on the findings of an earlier study, the ideal sample size was calculated [29]. The Cobb angle was reported as 24.26° (SD 1.96°) for the intervention group and 26.59° (SD 3.57°) for the control group, respectively [29]. We calculated the sample size using G*power software (version 3.1.9.4, Universität Düsseldorf) and determined that 7 subjects in each trial arm would provide 60% power once α was set at .1. We also considered a 10% overall dropout rate (eg, lost to follow-up). Consequently, we aimed to recruit 16 individuals (8 in each study arm).

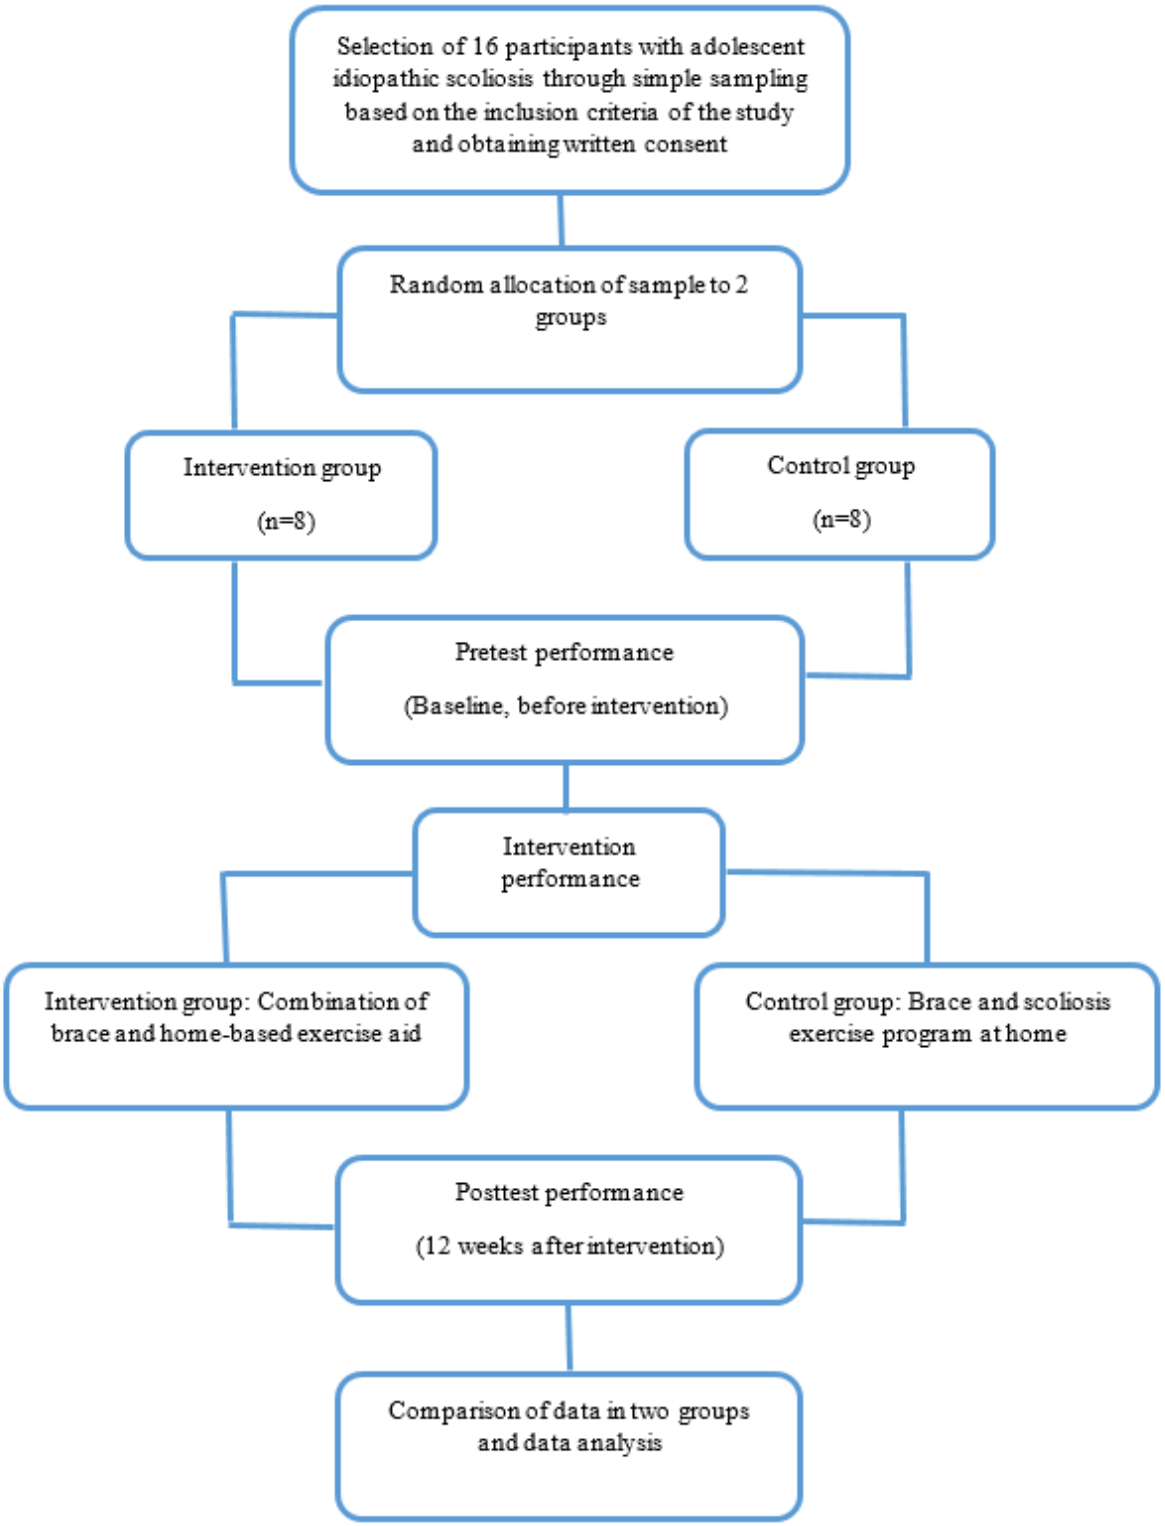
Participants

A simple (convenient) sampling method was used to recruit the AIS individuals with single lumbar and thoracolumbar curves of 20°-45° at the orthopedic clinic. Physical assessments and spine x-rays taken by an orthopedic specialist were used to confirm the diagnosis of AIS [30]. The following are the inclusion requirements of the study: Risser sign (0-2) [31], a single moderate scoliosis curve (20°-45°) in the lumbar or thoracolumbar regions [32], physical and mental capacity to use braces and exercise equipment [33], the absence of AIS treatment in the preceding year [34], and physician approval to take part in the study. The exclusion criteria are as follows: deformities in the lower extremities [35]; having neuromuscular conditions like cerebral palsy, spina bifida, muscular dystrophy, congenital myopathy, and any other illness that prevents them from exercising [33]; and people with any history of surgery, trauma, fractures, or other spine injuries [33,35]. The parent of each eligible participant signed an informed consent form before the study. Participants were allowed to withdraw from the study at any time.

Assignment, Randomization, and Blinding (Masking) Procedures

After verification of eligibility, participants were randomly assigned to one of 2 groups: (1) the intervention group (combined brace and home-based exercise aid; n=8) or (2) the control group (brace and scoliosis exercise program at home; n=8). Block randomization was used, 4 blocks with a block size of 4, to achieve balance in allocating participants to study arms [36]. The assessor uses Random Allocation Software for the randomization process (version 1.0) [37]. This study is single-blinded, so the measurement of the curve angle was undertaken by blinded assessors. The assessors measured the curve angle without being aware of the group assignment or individual information.

Adverse Events and Dropouts



Adverse events were acknowledged and documented throughout the study to ensure participant safety. The final report summarized adverse event information, including the date and the participant's experience. The details of research participants who dropped out were recorded. Furthermore, the causes of dropout, including COVID-19 symptoms, loss of follow-up, and illness, were disclosed.

Study Arms and Content

There were 2 study arms. For the intervention group, the first arm received a combination of brace and home-based postural response training. For the control group, the second arm received a brace and a traditional scoliosis exercise program at home. The outcomes include Cobb's angle of curvature, pulmonary function, the endurance of the trunk muscles, and quality of life index. The study outcomes were measured at 2 time points: baseline, before the intervention (pretest), and 12 weeks after the intervention began [38] (posttest; at this time, the intervention period has been completed). Figure 1 presents the study process.

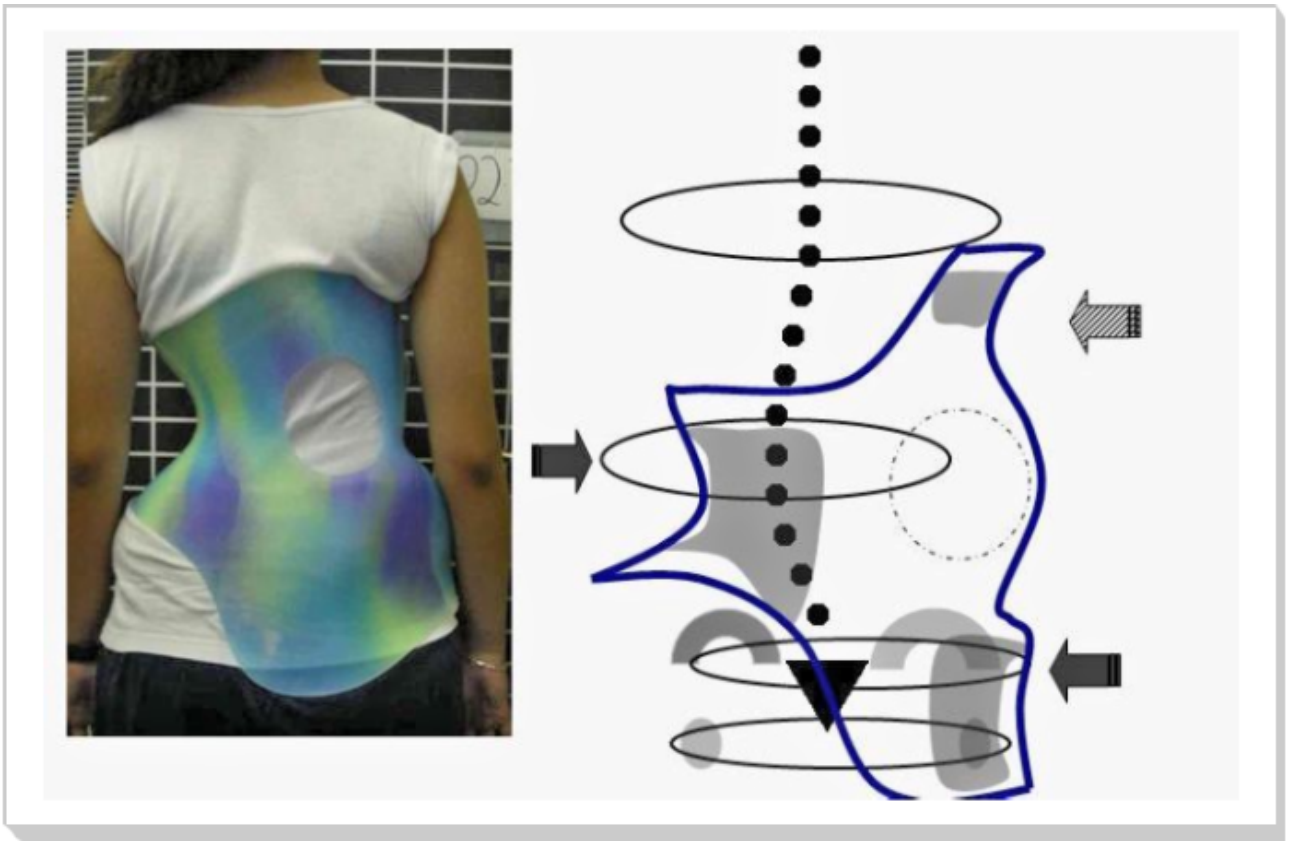
Figure 1. The study flowchart for the randomized controlled trial.



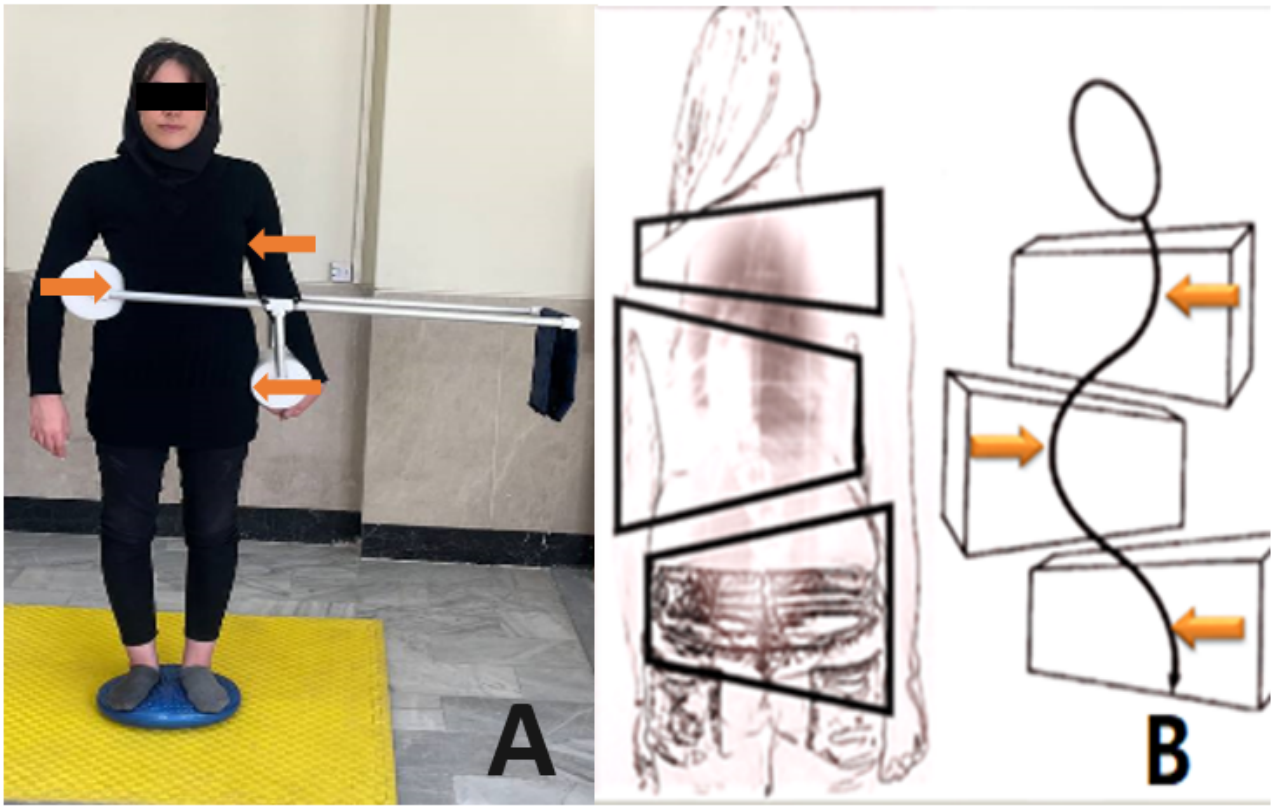
Intervention

Cheneau Brace

Cheneau is a rigid trunk brace used to treat AIS [24]. This thoracolumbosacral brace is made of polypropylene with an anterior opening (Figure 2). The Cheneau brace applies pressure on the convexity of the curve and shifts the spine to the normal alignment. The brace walls allow the overcorrection of the curvature; thereby, the user can perform in-brace muscle contraction and therapeutic exercise [24,39]. In this study, all braces are single lumbar and thoracolumbar, also called E1 and E2, respectively [40]. The E-type Cheneau braces for single lumbar or thoracolumbar curves (Figure 2) are custom-molded orthoses that were fabricated by a qualified orthotist. The brace users were instructed how to wear it and asked to wear it full-time during the trial course.

XSL•FO
RenderX

Figure 2. The E-type Cheneau brace for a single lumbar-thoracolumbar curve pattern [40].



Cantilever Device

In this study, postural response training for individuals with AIS was carried out using a torso trainer device known as the "cantilever" (Figure 3). The cantilever device increases the mechanical advantage of the corrective forces applied to the trunk for curve correction [26]. The 3 pressure points that make up the system's correcting mechanism (Figure 3A) provide transverse force to the spine in order to reduce deformity [26]. Each cantilever device was customized by an orthotist to fit the size of each unique user and has a robust tubular structure (as shown in Figure 3A). Low-density polyurethane was used for the device's pads. The thoracic pad of the device was fitted on the convex side of the deformity, while the lumbar pad is located between the lower ribs and the iliac crest. To enhance the resistance during an incremental training program, up to 4-pound weights can be applied at the end of the lever.

XSL•FO
RenderX

Figure 3. (A) The cantilever device and (B) the 3-point system for correction of deformity [41].

Postural Response Training

This exercise is to modify the activity pattern of the muscles to stabilize the spine. It has been reported that response training could enhance the role of proprioceptive feedback in detecting spinal misalignment [26]. Therefore, postural response training is expected to help regulate the appropriate muscle activity in people with AIS [26,42]. There are 3 phases in each session for postural response [42] as outlined in Textbox 1.

Textbox 1. Three phases of postural response training.

- Participants will first attempt to slide their hand down their outside leg, on the convex side of the curvature while standing. After holding this flexed position for 15 seconds, they will return to the starting position. Participants will complete this workout 20 times with a 15-second break between each repetition.
- Participants will carefully put on the cantilever device during the second phase, placing the pressure pads where the therapist had instructed them and adjusting the length of the levers and the weight distribution. Then participants will stand on a vestibular disk and attempt to adjust their spine toward the convexity of the curve by using a cantilever device so that the weight hanging on the device is at the horizontal level. After holding this level position for 15 seconds, they will return to the starting position and rest for 15 seconds. Participants will perform this workout 10 times, followed by a 5-minute break. This process will be repeated 4 times so that the total training time of the second phase lasts 40 minutes.
- In the last stage, the participants kneel on the floor with their buttocks resting on the heels and stretch their arms as far forward as they can. They hold this posture for 15 seconds.

Conventional Scoliosis Exercise

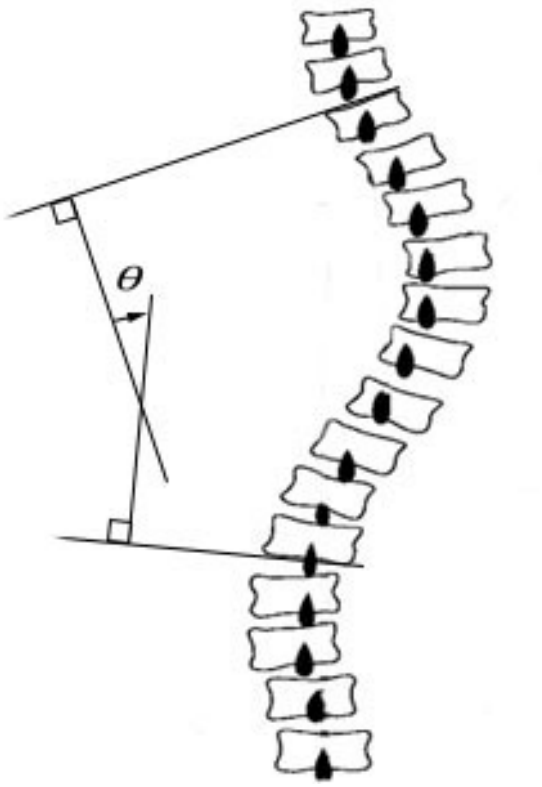
The exercise outlined in Textbox 2 was instructed to each participant and carried out under a physiotherapist's supervision. These exercises are designed based on the literature on exercise for AIS [43,44].

XSL•FO
RenderX

Textbox 2. Steps of conventional scoliosis exercise.

- The participant will face backward on a chair. Sitting far back, they hold hands on the back of the chair, elbows sideways and upwards. The knee on the convex side will be held further back for pelvic derotation. The head and trunk will lean to the convex side.
- The participant is in side-lying on the concave side with the arm stretched underneath the head.
- The participant kneels on the floor with thighs vertical and arms extended forward in a V-position, then brings the upper chest toward the floor.
- The participant will place on all 4 limbs. The participant performs a breathing exercise and simultaneously rotates the trunk to correct the scoliotic curve.
- The participant will be placed in the lateral side-lying position so that the concave side faces the floor. The elbow will be bent, and the arm will support body's weight. The participant then tries to lift the pelvis and correct the spinal curve.
- Participants will sit on a chair with their backs on the wall. Participants will keep their feet together, arms stretched, elbows straight, and hands touching the wall from behind. They lean forward with their trunk as far as possible, without losing the contact between their hands and the wall.

Outcome Measures



The study outcome measures were calculated throughout the course of 2 sessions. All tests were conducted with a certified orthotic practitioner before intervention (baseline) and after 12 weeks of follow-up required to complete the intervention (posttest).

Primary Outcome Measures

Spinal Deformity

The lateral deviation of the spine in the frontal plane was measured using the Cobb angle. This method is the gold standard for correctly identifying, assessing, and predicting the progression of the scoliosis curve [30,45]. An orthopedic specialist manually measured the Cobb angle using an anteroposterior spine x-ray. The Cobb angle was measured by drawing an end-point line at the upper and lower end of the scoliosis vertebrae. The Cobb angle (Figure 4) is the intersection of the 2 vertical lines drawn on each end-point line [30].

Figure 4. Measurement of the Cobb angle (ϕ).

Secondary Outcome Measures

Pulmonary Function

A digital spirometer (HI-301, Chestgraph, Japan) was used to evaluate pulmonary function. The spirometer was used to measure the following parameters: forced vital capacity, peak expiratory flow, forced expiratory volume in 1 second, vital capacity expiratory, vital capacity inspiratory, total lung capacity, and vital capacity. The participants were instructed to take off the brace at least 2 hours before the test. Spirometry is conducted while the patient is seated in a chair [46]. Each

XSL•FO
RenderX

participant was asked to do a regular inspiration first. The participants took a deep exhalation after the mouthpiece of the gadget was put in his mouth. The experiment ended once the participant has had a deep inspiration, a deep expiration, and a deep inspiration. Care was taken during the test to keep the mouth and the device's input together. The time between her inspiration and exhalation should not be broken, and a thorough exhalation should continue for at least 6 seconds [46]. This test was measured 3 times, and the average values were reported for data analysis. Each participant was given 2 minutes of resting time between trials. All tests were administered at the same time during the day in a quiet location, and participants were asked to refrain from engaging in strenuous exercise prior to testing.

The Trunk Muscles' Endurance

The lumbar trunk muscle endurance test was used to measure trunk flexor and extensor endurance, while the side-bridge test measured lateral trunk flexor endurance.

The next assessment was carried out to evaluate the patient's flexor muscle endurance [47]. Each participant was instructed to lie on a flat surface in the supine position and elevate their lower limbs off the ground while maintaining a 90° flexion angle in both the hip and knee joints. Then participant strives to remove both scapulae from the flat surface by maintaining maximal neck flexion as their arms are positioned crosswise on their chest (Figure 5). The patient was instructed to lie prone on a flat surface, elevate the sternum from the surface, and maintain maximal neck flexion to test the patient's trunk extensor muscle endurance [47]. To lessen lumbar lordosis, a cushion was positioned beneath the lower abdomen (Figure 6).

Next, the participants were requested to lie on their lateral side to assess the strength of the lateral muscles in the trunk. The individual rises the upper body and pelvis straight from the surface, while the forearm and leg bear the body's weight (Figure 7). The participant keeps this position as long as possible, and the examiner records the time before the pelvic drops [48]. This test was repeated for the opposite side, and a 5-minute rest was given between 2 trials [48].

Figure 5. Endurance test of trunk flexor muscles.

Figure 6. Endurance test of trunk extensor muscles.

XSL•FO
RenderX

Figure 7. Endurance test of trunk lateral flexor muscles.

Quality of Life

Quality of life was measured using the Persian version of the Italian Spine Youth Quality of life [49]. This questionnaire has good validity and reliability (intraclass correlation coefficient ≥0.7) to use for people with AIS [49]. This questionnaire includes 13 spinal health–related questions and was filled out by each participant. The responses to each question were quantified based on a 3-point rating scale (0-2) with 3 possible replies (never, sometimes, often). The quality of life ranged from 0 to 26, with 0 being the best quality of life [50].

Demographic and Clinical Data

Age; weight; height; BMI; and the type, location, degree, and magnitude of the scoliosis curve as well as the Risser sign, were prospectively gathered and noted on report forms.

Data Analysis

Analysis of covariance was used to compare how well each treatment influenced the outcomes of the study. Trunk bracing with postural response training versus bracing with regular exercise is the independent variable, and the dependent variables are study outcomes recorded after the exercise protocols were completed. In these statistical analyses, the covariant is the baseline measurement of the research results among the individuals. The preliminary statistics were carried out to ensure that the assumptions of normality, linearity, homogeneity of variances, homogeneity of regression slopes, and accurate measurement of covariates are not violated. Statistical analyses were conducted using the SPSS (version 19; IBM Corp). The level of significance was set at .05 for all tests.

Ethics Approval

The Isfahan University of Medical Sciences Regional Ethics Committee approved the study protocol (IR.MUI.NUREMA.REC.1401.025). Then, the research protocol was registered in the Iranian Registry of Clinical Trials on May 9, 2022 (IRCT20220330054371N1).

Results

Recruitment for this study began in fall 2022 and is expected to be completed by the end of summer 2023.

Discussion

Overview

It is well acknowledged that expected scoliosis consequences include dysfunction of motor control, which could demonstrate asymmetrical or weak muscles [8], less muscular strength and endurance [10], and abnormal breathing patterns [7,9]. Consequently, exercise therapy and conditioning are consistently indicated as a necessary element of AIS treatments [11].

Trunk bracing is the most popular nonoperative technique to prevent curve progression in mild to moderate AIS (from 20° to 45° Cobb angle) [12]. Evidence, however, indicates that rigid bracing might restrict a user's physical activity, which can lead to a loss of muscle strength and endurance [17]. Besides, rigid trunk bracing could impede rib cage expansion and reduce lung capacity [19]. Exercise can mitigate the negative impact of rigid trunk bracing on muscular and respiratory functions [20-22]. The study agrees that specific exercise can counteract the adverse effects of rigid trunk bracing on the respiratory and muscular functioning of people with AIS [20,21].

Therapeutic exercise appears necessary as part of conservative scoliosis treatment focusing on changing the spine's alignment control [21]. An incorrect perception of gravity can affect muscle tone and cause spinal curvatures [26]. Postural response training aims to change how one feels gravity and how active one's trunk muscles are. Future research is necessary because there is little research that supports the effectiveness of this approach.

Strengths and Limitations

The study's most noteworthy strength is the combination of trunk bracing and exercise in the treatment of AIS. There is limited research on the benefits of trunk bracing with exercise therapy [13,22]. The Cheneau brace and postural response

XSL•FO
RenderX

training were developed using an active strategy for curvature correction [26]. According to this strategy, individuals with AIS should practice aggressively using their trunk muscles to keep their spine in a normal alignment [44]. Compliance with the intervention may be one of the most significant difficulties in the present study. Through phone calls or SMS text messages, authors strived to keep track of each participant's commitment to brace wearing and exercise and record that information in the logbook.

Abstract

Background: The prescription of prosthetic ankle-foot devices is often based on the professional judgment of the limb loss care team or limited evidentiary research. Current prosthetic research efforts have focused on the design and development of prosthetic devices rather than on understanding which devices are the most appropriate to prescribe. This investigation will evaluate biomechanical, functional, and subjective outcome measures to help determine the optimal prescription parameters of prosthetic ankle-foot devices.

Objective: This study aims to develop evidence-based guidelines for limb loss care teams for the appropriate prescription of commercially available prosthetic ankle-foot devices to improve function and satisfaction.

Methods: This investigation will be a multisite, randomized, crossover clinical trial targeting the enrollment of 100 participants. Participants will use 3 different types of prosthetic devices (energy storing and returning, articulating, and powered) in random order. Participants will be fitted and trained with each device and then separately use each device for a 1-week acclimation period. Following each 1-week acclimation period, participants will be evaluated using several functional measures and subjective surveys. A random subset of participants (30/100, 30%) will also undergo full-body gait analysis, following each 1-week acclimation period, to collect biomechanical data during level ground and incline and decline walking. After all individual device evaluations, participants will be given all 3 prostheses concurrently for 4 weeks of home and community use to capture user preference. Activity monitoring and a guided interview will be used to determine overall user preference.

Results: The study was funded in August 2017, and data collection began in 2018. Data collection is expected to be completed before July 2023. Initial dissemination of results is expected to occur in the winter of 2023.

Conclusions: By identifying biomechanical, functional, and subjective outcomes that are sensitive to differences in prosthetic ankle-foot devices, a benchmark of evidence can be developed to guide effective prosthetic prescription.

Introduction

Background

More than 1700 service members have experienced combat-related limb loss since the beginning of Operation Iraqi Freedom, Operation Enduring Freedom, and Operation New Dawn [1,2]. Most of these service members are now veterans, and 95% of veterans with limb loss from these conflicts use the Veterans Affairs (VA) Healthcare System within 5 years of separation from active duty [3]. VA has a responsibility to serve this unique population for their lifetime and provide care to an additional 41,000 veterans who have lower limb loss at levels proximal to the ankle [3]. At VA, most major limb amputations have resulted from the increase in aging veterans with dysvascular disease and diabetes mellitus [4]. For those receiving prosthetic ankle-foot devices, providers within the limb loss care teams have >100 commercial devices available for prescription [5]. Unfortunately, there are limited evidence-based guidelines available to aid clinicians in prescribing appropriate componentry. As such, prescription tends to be governed largely by professional judgment of the limb loss care team or available research, which tends to be noncommittal or lacks the guidance required for clinical practice [6].

Clinical Consensus for Prosthetic Prescription

As prosthetic ankle-foot devices have evolved over the last 2 decades, clinical prescription has remained a complex and challenging process. Comparative studies have been contradictory or noncommittal, which makes evidence-based prescription difficult for clinicians. In 2004, a Cochrane review was conducted to determine whether a clear clinical consensus on prescription criteria could be determined for various prosthetic ankle-foot devices for individuals with lower limb loss [7]. Review of 23 trials concluded that there was insufficient evidence from high-quality comparative studies to develop or establish criteria for the prescription of prosthetic ankle-foot devices. In 2005, Hafner [8] evaluated clinical prescription and the use of prosthetic ankle-foot mechanisms in the literature, again concluding that the available studies had limited applicability for clinical decision-making. The author suggested that future studies that aim to develop guidelines to prescribe prosthetic devices should include a large sample size and standardize the devices based on shared characteristics or mechanical behaviors. In 2012, Schaffalitzky et al [9] gathered expert opinions on the most important outcomes, predictors, and facilitators of lower limb prosthetic prescription and use. The investigators and an expert panel of 21 service providers and users identified 13 outcomes, 19 predictors, and 34 facilitator factors that can contribute to an evidence base for optimal prosthetic prescription. While highlighting the importance of a comprehensive evaluation, including physical, psychosocial, and environmental outcomes, a universal solution was not identified for optimal prosthetic prescription; however, it is unclear whether all users would benefit from a universal prescriptive solution [9]. Finally, a Cochrane review in 2018, which aimed to investigate the evidence from randomized controlled trials of individuals with lower limb loss, found that the scientific literature did not provide sufficient high-quality evidence to allow strong conclusions about the effectiveness of prosthetic intervention [10]; however, many nonrandomized controlled studies were excluded from the analysis.

Prosthetic Ankle-Foot Device Categories

Despite the lack of scientific guidelines for appropriate prosthetic prescription, energy storing and returning (ESR) ankle-foot devices are the current gold standard for prescription within VA and the Department of Defense (DoD). Individuals with transtibial limb loss using ESR devices have demonstrated faster walking speeds and reduced cost of energy during ambulation compared with those using traditional prosthetic device options, such as the solid ankle cushion heel and stationary attachment flexible endoskeletal feet [11]. Similarly, the use of ESR devices has been shown to improve elastic response [12], reduce the requisite activation for propulsory muscles [13], and improve stair ascent initiation by reducing the time of initial double-limb support [14]. Although there are various types of ESR devices with distinct mechanical features, there remains insufficient evidence to support the prescription of specific prosthetic ankle-foot devices within this overarching classification [15-17]. Moreover, discrete parameters derived from common kinetic and kinematic biomechanical analyses often lack statistically significant differences between these ESR devices [8].

More advanced ESR devices are also commercially available, including passive hydraulic or microprocessor-controlled articulating ESR (ART) ankle-foot devices. Although ART ankle-foot devices have been typically reported to decrease energy return in individuals with transtibial limb loss, there is recent evidence suggesting that current devices can improve ambulation on level ground and on inclines and stairs [15]. For example, De Asha et al [18,19] described improved progression of the center of pressure in a prosthetic ankle-foot device with a hydraulic ankle compared with devices with a fixed attachment in a population of individuals with lower limb loss. Portnoy et al [20] found decreased load at heel strike when using an ESR hydraulic ankle-foot device compared with a conventional ESR device. Fradet et al [21] reported that a microprocessor-controlled ankle-foot device set to adaptive ankle mode improved kinematics during ramp ascent compared with the same device when set in neutral angle mode. This evidence suggests that individuals with lower limb loss who negotiate specific environments may benefit from an ART device.

Commercially available ESR ankle-foot devices with active (ie, powered) plantarflexion have potential biomechanical benefits for the user beyond that of the ESR or ART ankle-foot options.

XSL•FO
RenderX

Empower (Ottobock Inc), the only commercially available powered ESR ankle-foot device, functions to replicate the dynamic contractile tissues of the gastrocnemius-soleus complex in individuals with lower limb loss [22,23]. This powered prosthetic ankle-foot device has the ability to normalize ankle power, which can potentially reduce kinetic asymmetries that lead to musculoskeletal imbalances, thus improving physical function [22,24]. Grabowski and D'Andrea [25] noted that individuals with transtibial limb loss had a reduction in peak resultant forces and knee adduction moments in the unaffected limb during level ground walking when using a powered ESR device (iWalk BiOM) versus a passive ESR device. These reductions could potentially limit the risk of secondary musculoskeletal comorbidities, which are common in this population [26].

Despite the noted advances in prosthetic technology, research efforts so far have largely focused on the design and development of prosthetic technology, rather than on understanding which devices are most optimal to be prescribed for individuals with lower limb loss. Moreover, many studies are limited by small sample sizes, the nonstandardization of device characteristics, and the use of outdated components, which collectively reduce the direct applicability of scientific evidence to clinical decision-making [8]. Through a multicentered clinical trial with a large sample size (N=100), standardized categories of prosthetic ankle-foot characteristics, and the evaluation of outcomes both within laboratory and community-based settings, this research investigation will comprehensively evaluate biomechanical, functional, and subjective outcome measures to help aid in determining optimal prescription parameters of prosthetic ankle-foot devices. Health care, according to comparative effectiveness research, is under constant pressure to become more efficient and effective, while reducing overall cost. The lack of evidence-based scientific guidelines to support lower extremity prosthetic prescription is a critical inefficiency. By identifying biomechanical, functional, and subjective outcomes that are sensitive to differences in prosthetic ankle-foot devices, a benchmark of evidence can be developed to guide effective prosthetic prescription.

Study Objectives

The overarching goal of this investigation is to generate data that offer new knowledge that can be used to improve current clinical practice guidelines and develop new prescription algorithms for prosthetic ankle-foot devices. This information will lead to clinical prescriptions that facilitate the achievement of maximal functional ability and user satisfaction. Criteria will be developed to assist the limb loss care teams in prescribing appropriate, advanced prosthetic ankle-foot devices based on patient-specific needs and goals, in addition to the individual's current physical abilities. Therefore, the purpose of this investigation is to develop the criteria for prosthetic ankle-foot prescription for veterans and service members with transtibial limb loss. The objectives of this investigation are as follows:

1. To determine the appropriate functional and biomechanical outcome measures to support the prescription of a type or category of prosthetic ankle-foot device for veterans or service members with transtibial limb loss
2. To correlate patient goals and subjective measures with objective data to determine the appropriate prosthetic ankle-foot category that will facilitate the greatest overall function for the user
3. To develop criteria for the appropriate prescription of nonarticulating ESR, ART, and powered plantarflexion ESR ankle-foot devices

Methods

Study Overview

This investigation will be a prospective, multicenter study, including 4 sites: Veterans Affairs New York Harbor Healthcare System (VANYHHS), Veterans Affairs Puget Sound Healthcare System, James A Haley Veterans' Hospital (JAHVH), and Walter Reed National Military Medical Center (WRNMMC). Enrollment began in 2018, and data collection is expected to be completed in 2023. A total of 100 participants will be enrolled from the 4 sites. Briefly, participants will use 3 different types of prosthetic ankle-foot devices (refer to device categorization in the following sections) with duplicate sockets. Participants will be fitted and trained with each device and then separately use each ankle-foot device for a 1-week acclimation period. Participants will only use the assigned study device for each acclimation period. Although previously reported acclimation periods for lower extremity prosthetic device studies have ranged from minutes to months depending on componentry [27-30], this study will use a 1-week acclimation period to balance the time that participants need to adjust to the features of each ankle-foot device with the overall duration of their participation. To augment the acclimation period, device-specific training will be provided to ensure that participants meet a minimum standard of performance. Following each 1-week acclimation period, participants will be evaluated in the laboratory using several functional and subjective measures. Furthermore, a subset of participants (30/100, 30%) will be randomly chosen to undergo a full gait analysis to collect biomechanical data during level ground and incline and decline walking using each ankle-foot device. Following the 3-week data collection period, participants will be given all 3 prostheses at the same time for 30 days to use at home and in their community. Step activity monitoring during home-based and community-based use and a final guided interview will be used to determine overall user preference.

Participants

In total, 100 individuals with unilateral transtibial limb loss will be recruited for this investigation. Inclusion and exclusion criteria are presented in Textbox 1. All participants will consent to participate before any study activity.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Veteran, service member, or civilian with unilateral transtibial limb loss
- Uses a prosthesis with a well-fitting socket for a minimum of 1 month
- Must achieve at least modified independence score on the Functional Independence Measure for the 2 mobility items (locomotion and stairs)
- Aged >18 years
- Current use of an energy storing and returning device
- Has a minimum clearance to accommodate all devices

Exclusion criteria

- Active wounds, ulcers, or substantial musculoskeletal comorbidities on the intact limb that would impair the ability to participate in all functional outcome measures
- Any comorbidity that results in rapid limb volume changes (eg, end-stage renal disease with dialysis)
- A poorly fitting socket
- Cognitive deficits or mental health pathology limiting an individual's ability to fully participate in the investigation
- Unable or unwilling to comply with all study visits
- Women who are pregnant or who plan to become pregnant during study activities, determined via self-report
- Body mass greater than product capacity

Ethics Approval and Informed Consent

This study was approved by the following institutional review boards (IRBs): Veterans Affairs New York Harbor Healthcare System IRB (protocol ID 1603); University of South Florida IRB (IRB study Pro00030555), which is the IRB of record for James A Haley Veterans' Hospital; Walter Reed National Military Medical Center IRB (protocol ID WRNMMC-2017-0103); and Veterans Affairs Puget Sound Healthcare System IRB (protocol ID 01587). The oversight and protection of human participants was also approved by the US Army Medical Research and Development Command Office of Human Research Oversight (E04076). All participants will provide informed consent before participating in any study activity.

Ankle-Foot Categorization

In accordance with recommendations from previous literature to standardize the categorization of devices according to specific features [8], the prosthetic ankle-foot devices included in this investigation were systematically selected and categorized at the time of study initiation by a diverse panel of experts in the limb loss field, including prosthetists, physiatrists, biomechanists, physical therapists, and limb loss researchers. The panel considered device structure, componentry, function, and biomechanical properties to create ankle-foot device categories. On the basis of the criteria developed by the expert panel for each group, all ankle-foot devices included in this investigation were placed into one of the following three categories:

1. ESR (nonarticulating)—This group includes any qualifying nonarticulating ESR ankle-foot device that is commercially available. As per the inclusion criteria, participants will use their current device for this category. There are >100 commercially available devices that fit the criteria for this category [5].
2. Active plantarflexion ESR (PWR)—This group will include all commercially available ESR ankle-foot devices with active plantarflexion. Currently, Empower (Ottobock Inc) is the only device classified into the PWR group. No new devices that meet the criteria for the PWR group will be included in this investigation after the commencement of active enrollment. However, it is not anticipated that any future powered device will come to the market during active enrollment.
3. ART—This group includes all current, commercially available options in the K3 Medicare Functional Classification System category that have an articulating ankle and ESR properties. Overall, 14 devices that met the criteria were identified at the time of study initiation (Table 1). No new devices that meet the criteria for the ART group will be included in this investigation after the commencement of active enrollment. If any ART device is replaced by the manufacturer with a new generation during active enrollment, the study expert panel will determine whether the new generation can be considered as a replacement device (if not fundamentally distinct). If the new generation of ART device is considered to be fundamentally different from the study ART device by the expert panel, it will not be included as a study device, to reduce confounding variables during analysis. However, the current generation of ART device used in the investigation will be configured to match patient specifications for any future participant who is assigned that ART device.

Justification for Inclusion of Commercially Available ESR Ankle-Foot Devices

ESR Group

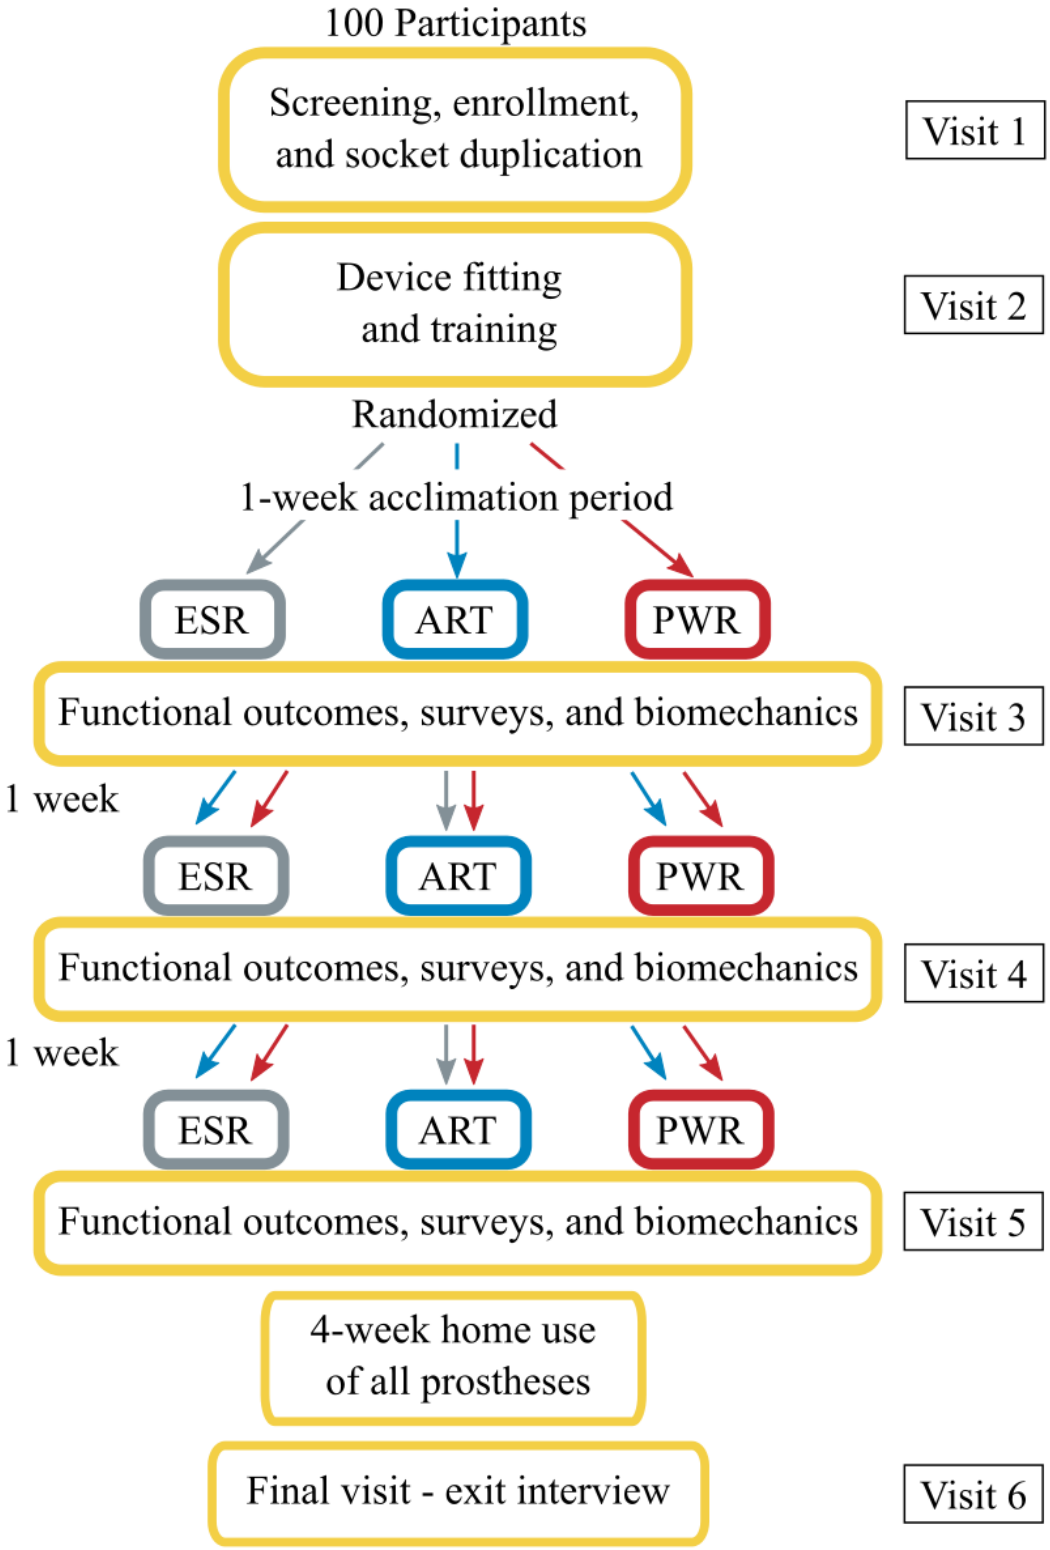
Many nonarticulating ESR prosthetic ankle-foot devices have different mechanical features (eg, torsion and vertical shock) that provide for specific Healthcare Common Procedure Coding System classifications, as descried in the *Prosthetic Foot Project* conducted by the American Orthotic and Prosthetic Association [31]. Although subtle mechanical differences may exist between these ankle-foot devices, studies so far have not shown any significant differences in functional outcomes between different nonarticulating ESR ankle-foot devices [32]. More specifically, published literature often reports contradictory results regarding biomechanics and function during level ground ambulation, stair negotiation, and incline and decline ambulation using these ESR ankle-foot devices [15]. Clinical consensus has also shown that patients may have individual preferences for specific nonarticulating ESR ankle-foot devices, but there is no current metric to predict this. Limiting the investigation to one or just a few nonarticulating ESR ankle-foot devices would limit the generalizability of the findings to the overall group of ESR ankle-foot devices. In addition, most patients who ultimately enroll in this investigation often have the opportunity to trial many different ankle-foot devices as part of their standard clinical care, given that prescription is not driven by reimbursement rates within VA and the DoD. For example, the limb loss care teams at VA and the DoD are not required to abide by the Medicare Functional Classification System for prosthetic prescription and can prescribe any device deemed clinically beneficial for veterans and service members. Therefore, the ESR ankle-foot device the participant enrolls with may be their foot of preference within the overall nonarticulating ESR category. Furthermore, prosthetic devices frequently change, update, or can even be taken off the market for another generation of device. Limiting the ESR ankle-foot devices may also risk not investigating the current or future prescription trends in the limb loss care clinics at all 4 study sites.

ART Group

The ART group includes mechanical and microprocessor-controlled prosthetic ankle-foot devices with ESR properties. These ART devices have different ankle ranges of motion, which vary from 9° to 50°. It has been reported that the average range of motion for a healthy individual with an intact lower limb is 20° to 40° of ankle plantarflexion and dorsiflexion [33]. As such, there is no published research so far regarding the ideal ankle range of motion for individuals with transtibial limb loss; thus, all commercially available ART devices that meet the study specifications will be included (Table 1). Although there are studies comparing these ART devices with solid ankle cushion heel and nonarticulating ESR ankle-foot devices, there are no current studies suggesting any differences among the devices within this group and their effect on functional performance.

PWR Group

Criteria for this group include the following: commercially available, articulating, and provides plantarflexion energy during terminal stance at a rate that is greater than the total energy absorbed (ie, >100%). These criteria are currently only satisfied by Empower (Ottobock Inc).



Internal analysis within all groups will be conducted at the completion of this investigation to substantiate or rebut these groupings and to determine whether there are outliers that should be classified differently for future studies.

Research Protocol

The flowchart in Figure 1 outlines the protocol procedures for each participant in this investigation. The following sections describe each participant visit.

XSL•FO
RenderX

Figure 1. Flowchart of participant protocol visits. ART: articulating energy storing and returning; ESR: energy storing and returning; PWR: active plantarflexion energy storing and returning.

Visit 1—Screening, Consent, Enrollment, and Prosthetic Socket Assessment

Participants (N=100) will be recruited from the rehabilitation and prosthetics clinics at each site. The principal investigator, site–principal investigator, research assistant, research physical therapist, or study prosthetist will meet with interested patients to discuss the investigation and obtain informed consent. Once informed consent has been obtained, participants will be screened according to the inclusion and exclusion criteria and enrolled. Demographic information will be collected, including age, sex, race, ethnicity, height, weight, limb loss etiology, employment, marital status, living situation, and time since transtibial limb loss. A baseline pain measurement using a visual analog scale (VAS) of 0 (no pain) to 100 (worst possible pain) will be performed at the first visit. Fit and comfort of each

XSL•FO
RenderX

participant's existing socket will be evaluated by the study prosthetist using standardized prosthetic guidelines. Once fit and comfort are confirmed, the study prosthetist will create a mold using plaster of Paris or alginate to fabricate 2 additional, identical prosthetic sockets. All sockets will be centrally fabricated at VANYHHS. Identical materials and prosthetic componentry used in the participant's current socket will be used to create each additional socket to eliminate any variance in perceived weight or socket flexibility. Each additional socket will be aligned with a designated ankle-foot device according to the manufacturer's specifications by the study prosthetist.

Randomization of Ankle-Foot Device Selection and Order of Evaluation

The ankle-foot devices for each participant and the order in which they will be evaluated will be block randomized using a computer-generated algorithm that randomly selects from all available devices and then assigns the order. The randomization will be performed before study enrollment, so that each combination of device order is used an equal number of times. Investigators who process and evaluate the data will be blinded to the data. Owing to the distinct differences between prosthetic ankle-foot devices, the participants and study prosthetists cannot be blinded to which foot is assigned.

Visit 2—Static Fitting, Dynamic Fitting, and Prosthetic Alignment

Participants will return to the prosthetic clinic for fitting of the definitive sockets and prostheses by the study prosthetist. Another subjective pain VAS measurement will be performed at the beginning of the fitting visit, before the participant returns home with an ankle-foot device. All prostheses will initially be bench aligned based on the manufacturer's specifications for a static fitting. After successful static fitting is achieved, the dynamic alignment of each prosthesis will occur. The participant will separately ambulate with each of the prostheses, and adjustments will be made to the alignment, as needed, to achieve an optimal gait pattern, as determined by the study prosthetist and physical therapist. Dynamic fitting may require multiple visits, and participants will progress to the next part of the study protocol after an appropriate dynamic alignment has been established.

Device-Specific Training to Meet a Minimum Standard of Performance

After appropriate fit and alignment of each prosthesis has been established using each ankle-foot device, all participants (100/100, 100%) will undergo device-specific training by a qualified clinician to meet a minimum standard of functional performance. Overall, 2 aspects of the Functional Independence Measure will be evaluated: the ability to walk over level ground and the ability to ascend and descend stairs. To advance in the study, the participant must score 6 (modified independence) or 7 (complete independence) on the Functional Independence Measure. If the participant fails to achieve this outcome, guided rehabilitation to enhance the participant's use of their ankle-foot device will be provided until they are able to meet the minimum standard of performance. The process of device-specific training may require multiple visits. When the minimum standard of performance is met, participants will return home with the first randomized ankle-foot device for a 1-week acclimation period.

Description of the Physical Therapy Plan If the Minimum Standard of Performance Is Not Met

Participants who do not meet the minimum standard of performance using a study ankle-foot device will complete a series of physical therapy training sessions lasting 30 to 45 minutes each during the training period, completing 2 sessions per week, on average. Sessions 1 and 2 will specifically focus on education, strengthening through therapeutic exercises, and early neuromuscular re-education. A home exercise program will be initiated with the participant during the initial sessions and progressed along with the program. Sessions 3 and 4 will include gait training on level surfaces. Sessions 5 and 6 will include continued progression in all areas, including multidirectional training for both neuromuscular re-education and gait. Training will conclude with sessions 7 and 8, during which the previously taught skills will be further challenged and mastered. In addition, advanced gait skills, such as ambulation on stairs and ramps, will be covered. If a participant is unable to meet the minimum standard of performance after receiving physical therapy, they will be unenrolled from the study, as determined by the study physical therapist.

Visits 3 to 5—Functional Assessment of ESR, ART, and PWR Ankle-Foot Devices

Visit 3 will begin after the 1-week acclimation period while using the first assigned ankle-foot device. Participants will complete the VAS pain scale and then a battery of outcome measures and surveys (outlined in the following sections). In addition, during visit 3, a subset of participants will also be randomized to undergo biomechanical gait analysis while using the first prosthesis (described in the following sections). Once visit 3 is completed, the participant will receive the second prosthesis according to the established randomization schedule, and the initial prosthesis will be returned to the study prosthetist. The participant will again complete a 1-week acclimation period. During visit 4, the participant will undergo the same pain scale and battery of outcome measures and surveys. The same subset of participants will also undergo biomechanical gait analysis using the second prosthesis. The third prosthesis will be issued at the end of visit 4, and the second prosthesis will be returned to the study prosthetist. Participants will receive the same 1-week acclimation and will complete the same pain scale and battery of outcome measures and surveys during visit 5. In addition, the same subset of participants will undergo biomechanical gait analysis while using the third prosthesis. For visits 3 to 5, a visit window of –2 to +2 days will be implemented.

Functional and Subjective Outcome Measures

The functional and subjective outcome measures were selected to optimize relevance to the participant population, providers, and health care systems. These measures are commonly used in prosthetic clinics and represent critical information in the functional and subjective domains needed to develop guidelines for prescription. Following the completion of the investigation, the selected outcome measures will be statistically analyzed to

XSL•FO
RenderX

determine which measures are the most sensitive to changes in device type. The battery of functional outcome measures and subjective surveys collected after each acclimation period will be administered by a local research team member. Functional outcome measures include the 6-Minute Walk Test, Timed-Up-and-Go, Four Square Step Test, Amputee Mobility Predictor, Stair Assessment Index, and Hill Assessment Index. Surveys include the Prosthesis Evaluation Questionnaire, Short Form-12, and Orthotics and Prosthetics Users Survey. These measures are described in Textbox 2.

Textbox 2. Measures included in the study.

6-Minute Walk Test (6MWT)

- 6MWT measures the distance an individual can walk in 6 minutes without help or encouragement. The 6MWT is a valid and reliable metric that correlates with physical function and functional capacity [34] and has good interrater and intrarater reliability in individuals with lower limb loss [34].

Timed-Up-and-Go (TUG)

- TUG measures the time taken by an individual to stand up from a standard armchair, walk 10 feet, turn, walk back to the chair, and sit down. The TUG is both reliable and valid in individuals with lower limb loss [35]. In addition, the TUG has also been used as a measure to determine risk of falling [36] and correlates well with other measures of physical functioning [37].

Four Square Step Test

- Four Square Step Test is a high-order, complex task assessing dynamic balance and has been validated for use in individuals with lower limb loss [38,39].

Amputee Mobility Predictor

- Amputee Mobility Predictor is a 21-item instrument designed to measure basic prosthetic mobility of individuals with lower limb loss [40].

Hill Assessment Index

- Hill Assessment Index is a rated, qualitative scale on how an individual with lower limb loss negotiates up and down an incline [41]. This will be performed on a standardized ramp (rise-to-run ratio of 1:6) with a minimum length of 4.9 m to allow for sufficient number of steps to be taken by the participant.

Stair Assessment Index

- Stair Assessment Index is a rated, qualitative scale for stair negotiation for individuals with lower limb loss [41]. This assessment will be performed while participants ambulate on at least 4 steps that are compliant with the Americans with Disabilities Act (17 cm high, 28 cm long, and 91 cm wide).

Prosthesis Evaluation Questionnaire (PEQ)

- PEQ is self-report, visual analog scale–style questionnaire for individuals with lower limb loss who use a prosthesis. It is used to evaluate the prosthesis and life with the prosthesis. It consists of 82 items with 9 functional domain scales, including ambulation, residual limb health, utility, appearance, sounds, frustration, perceived response, social burden, and well-being. The PEQ also contains items beyond the subscales, including satisfaction, pain, transfers, prosthetic care, self-efficacy, and importance [42].

Short Form-12

- Short Form-12 is a non–disease-specific survey that can be used to measure the relationship between physical and mental health functioning and the social determinants of health [43].

Orthotics and Prosthetics Users Survey

- Orthotics and Prosthetics Users Survey is a set of self-report instruments that assess functional status, quality of life, and satisfaction with prosthetic devices and services that can be used in prosthetic clinics [44].

Visit 6—Home-Based and Community-Based Assessment

After the completion of visits 1 to 5, participants will return home with all 3 prostheses for a period of 30 days, to assess performance and preference during home-based and community-based conditions. All 3 prostheses will be fitted with a Modus Health StepWatch 3 (Modus Health LLC), which is a research-grade instrument for long-term assessment of ambulatory activity during day-to-day life [45,46]. Capturing prosthetic performance while navigating home-based and community-based environments is a key piece of information that is yet to be effectively used in the prescription process [47]. Activity monitoring devices, such as the Modus Health StepWatch 3 used in this investigation, offer the potential to capture this critical information owing to their accuracy for those ambulating with a prosthesis [48]. Participants will also complete an activity log to document their daily activities to allow for correlation between the prosthesis used and activity. Participants are free to use each prosthesis as they choose. Ankle-foot device preference will be based upon total activity time for each prosthesis. Following 30 days of home-based and

XSL•FO
RenderX

community-based use, participants will return to the prosthetic clinic to complete a closeout, guided interview to assess subjective preferences. A visit window of –5 to +5 days will be implemented for the final visit.

Biomechanical Analysis

In addition to completing the functional and subjective outcome measures during visits 3 to 5, a subset of 30% (30/100) of the participants will also undergo gait analysis during these visits. Biomechanical gait analysis will include kinetic and kinematic evaluation of level ground walking at 3 speeds and kinematic evaluation of incline and decline ambulation at a self-selected speed. The purpose of these sessions is to collect joint angles, forces, torques, and powers while participants use each ankle-foot device.

Gait Laboratory Instrumentation

Gait analysis will be performed at the Veterans Integrated Service Network 2 Biomechanics Research for the Advancement of Veteran Outcomes Laboratory at VANYHHS, the Biomechanics Laboratory at WRNMMC, and the Rehabilitation and Biomechanics Laboratory at JAHVH. The Veterans Integrated Service Network 2 Biomechanics Research for the Advancement of Veteran Outcomes Laboratory is a 1440-square foot space comprising an 11-camera motion capture system (Qualisys Inc) with 4 multiaxis force platforms (AMTI Inc). At WRNMMC, the Biomechanics Laboratory is an 1800-square foot space comprising an 18-camera motion capture system (Qualisys Inc) and 6 multiaxis force platforms (AMTI Inc). At JAHVH, the Rehabilitation and Biomechanics Laboratory is equipped with a 12-camera motion capture system (Vicon Inc) and 4 multiaxis force platforms (AMTI Inc). The systems track the positions of passive reflective markers at a rate of 120 Hz, and force platforms sample ground reaction forces at a rate of 1200 Hz. Visual3D software (C-Motion Inc) will be used for analysis of 3D motion capture data.

Collection of Reliable Gait Data Among Laboratories

A previous interlab reliability study was conducted among gait laboratories at the 3 military treatment facilities, which demonstrated that despite differences in marker configurations, camera systems, and examiners among the sites, reliable gait data were collected across the 3 gait laboratories [49]. A key to similarity among sites was the use of identical anatomical segment definitions for the respective gait models. To reduce variability during data collection, the 3 laboratories in this investigation will implement the key recommendations of the interlab reliability study, including the use of identical anatomical segment definitions. In addition, all 3 sites will use identical marker sets, and a single examiner at each site will conduct postprocessing of the respective data.

Kinematic and Kinetic Data Capture

Gait analysis will be performed after each acclimation period during visits 3 to 5. Each participant will be provided biomechanically neutral shoes that offer neither supinatory nor pronatory control. A custom, full-body passive reflective marker set will be placed on each participant, which tracks each segment independently, allowing for the accurate measurement of movements. A total of 78 markers will be placed or digitized on the head, trunk, pelvis, and extremities in the following locations: bilaterally over the positions of the medial and lateral ankle malleoli; lateral and medial condyles of the femur; tibial tuberosity; fibula head; first, third, and fifth metatarsals; anterior superior iliac spine; posterior superior iliac spine; calcaneus; lateral of the calcaneus; jugular notch; xiphoid process; spinous process of the seventh cervical vertebrae and tenth thoracic vertebrae; acromioclavicular joints; right and left scapulae; medial and lateral epicondyles of the humerus; styloid process of the radius and ulna; forearm; third metacarpal; and 4 markers on the head. Marker placements for the prosthetic limb will be matched to those of the intact leg or on centers of rotation. The cluster technique will be used to minimize the surface-to-bone displacements for the thigh-mounted, shank-mounted, and upper arm–mounted markers [50]. As such, tracking clusters will be placed bilaterally on the thigh, shank (tibial crest), and upper arm. Functional joints will also be calculated for the intact ankle and bilaterally for the knees and hips [51].

Data Collection Procedure

During each experimental session, participants will walk at 3 speeds across a 4-m instrumented walkway until 5 acceptable trials for each foot are completed. Trials will be considered acceptable when a foot makes full contact with a force platform. As kinetic outcome measures are speed dependent, participants will ambulate at 3 separate, controlled speeds: 1, 1.3, and 1.5 m/s. These speeds were selected to represent slow, moderate, and fast walking speeds for individuals with lower limb loss. The order of speeds will be randomized for each participant for each data collection visit. Auditory feedback will be provided to the participant by the study team to ensure that all participants walk at the targeted speed (–5% to +5%). Participants will be asked to repeat the walking trials until 5 acceptable trials for each foot at each speed are collected.

Incline and Decline Ambulation

Participants in this subset will also perform ramp ascent and descent to collect kinematic data during ramp ambulation. This will be performed on a standardized ramp (rise-to-run ratio of 1:6) with a minimum length of 4.9 m to allow for sufficient number of steps to be taken by the participant. Participants will be instructed to ambulate at a comfortable, self-selected walking speed. This will include 5 trials ascending and 5 trials descending the ramp.

Data Analysis

The reflective marker positions will be digitized using motion tracking software. A 15-segment (head, trunk, pelvis, bilateral upper and lower arms, hands, thighs, shanks, and feet) rigid body model will be created based on the skin-mounted markers and functional joints. Local coordinate systems for each segment will be defined using the International Society of Biomechanics recommendations [52,53]. The data of acceptable walking trials of each participant at each speed will be processed using Visual3D. Marker data will be filtered with a 6-Hz Butterworth low-pass filter. Raw analog data will be filtered using a second-order low-pass Butterworth filter with a 25-Hz cutoff frequency. Visual3D will be used to calculate temporal-spatial values, walking speed, and lower extremity kinematics and

XSL•FO
RenderX

kinetics. Inverse dynamic analysis will be applied to the kinematics of the biomechanical model and to the location, magnitude, and direction of ground reaction forces acting on the foot to calculate lower extremity joint torques and powers, including ankle, knee, and hip power of the biological and prosthetic limbs during stance and the frontal plane knee moments for the unaffected limb of participants (30/100, 30%). The resultant ground reaction force will be calculated as the magnitude of the ground reaction force vector. Several parameters, including temporal-spatial variables (eg, step lengths, stance and swing times, cadence, and stride length); peak angles; segment ranges of motion, moments, and powers for the ankles, knees, and hips during each phase of gait; and other biomechanical parameters (eg, external adduction moment rate, impulse external knee adduction moment, peak vertical ground reaction force, and peak resultant ground reaction force) will be measured and statistically compared across all conditions. Means, maximum and minimum values, ranges of motion, SEs, and coefficients of variation will be computed for the values attained per gait cycle over each trial and for each set of trials.

Statistical Analysis

Across the study population, outcomes will be assessed using descriptive statistics (ie, means and SEs) and compared between each ankle-foot device category. Inferential statistics for ordinal data will be conducted with a repeated-measures Friedman test (α=.05) and a Dunn post hoc test at 95% CI. To identify which measures are the most sensitive to changes in ankle-foot device type, a linear mixed effects model will be used. Separate models will be run for each type of measure (ie, subjective, functional, and biomechanical), and measures that have a significant association with device type in the presence of adjusting or control variables will be determined. In the case of significance, pair-wise comparisons will be tested for significance using linear contrasts with Tukey Honestly Significant Difference or by applying Bonferroni correction. The performance of each device in each test will be ranked, and the arithmetic mode will be used to determine which device is the most suitable for each participant. Adjusting or control variables in the model will include weight, height, etiology, time since limb loss, sex, race, functional level, and current ankle-foot device.

Development of Prediction Model

To develop evidence-based guidelines for the prescription of prosthetic ankle-foot devices, the goal of this investigation is to determine which factors and outcomes are the most predictive of optimal performance to meet patient goals. To do this, initial analyses will consist of bivariate cross-tabulations, performed using chi-square analyses. Variable selection for the multivariate model will be informed by these bivariate findings. Logistic regression will then be performed with participants' preference of prosthesis regressed on each of several domains (eg, functional levels and outcomes, activity levels, and biomechanical parameters). The models will simultaneously control for multiple variables, and overall model predictive value will be assessed using the C-statistic. Domain-specific models (based on bivariate findings) and 1 parsimonious stepwise logistic regression model combining the domains will be created to determine whether each distinct component predicts optimal prescription outcome. Each domain-specific model will control for the identified confounding factors. The individual variables of each domain will be used as fixed predictors. Finally, stepwise multiple regression will be used to determine the factors and outcomes that represent the best predictors, which will be conducted through a series of domain-specific, forward regression models. The significant variables in the forward selection models will then be placed in a backward regression model. Significant variables from the backward regression will be considered as the strongest predictive factors and used to develop prosthetic prescription guidelines.

Sample Size Determination and Power Analysis

Sample size determination was based on power analysis of several biomechanical, subjective, and functional measures collected during pilot investigations (Table 2). Assuming an α error rate of 5% and using within-group SDs determined from the pilot investigations, power is provided for selected parameters for a sample size of 100 participants for functional and subjective outcomes and a sample size of 30 for biomechanical parameters.

XSL•FO

Table 2. Sample size determination and power analysis of selected parameters.

Parameters	Difference, mean (SD)	Power (N=100; subset of 30/100, 30%, where appropriate), %
Biomechanical parameters		
Ankle range of motion (°)	2.9 (3)	95.3
Ankle peak plantarflexion (°)	3.2 (3.6)	91.1
Peak ankle power (W/kg)	1.7 (0.7)	99.9
Effective foot length ratio	0.9 (0.06)	99.2
Instantaneous radius of curvature (cm)	7.3 (9.2)	81.7
Subjective outcome measures		
PEQ[a]—satisfaction	13.6 (12.4)	98.7
PEQ—frustration	15.9 (24.7)	68.6
PEQ—utility	8.4 (8.8)	95.5
Functional outcome measures		
Steps at high activity (%)	9 (13.1)	74.4
6-minute walk distance (m)	60 (61)	96.3

[a]PEQ: Prosthesis Evaluation Questionnaire.

Results

The study was funded in August 2017, and data collection began in 2018. Data collection is expected to be completed before July 2023. Data analysis of the full data set is expected to begin after final data collection. Initial dissemination of results is expected in the winter of 2023, with subsequent publication of secondary analyses in 2024.

Discussion

Expected Outcomes and Anticipated Principal Findings

The expected outcomes of this investigation are to generate data that offer new knowledge that can be used to develop new prescription algorithms for prosthetic ankle-foot devices to improve the current clinical practice guidelines. This information will lead to clinical prescriptions that facilitate the achievement of maximal functional ability and user satisfaction for individuals with lower limb loss. Specifically, this study will help to determine the appropriate functional and biomechanical measures to support the prescription of prosthetic ankle-foot devices; correlate patient goals and subjective measures with objective data to determine the optimal prosthetic ankle-foot category to facilitate the greatest overall function for the user; and finally, develop the criteria for the appropriate prescription of nonarticulating ESR, ART, and powered plantarflexion ESR ankle-foot devices.

VA and the DoD have historically been leaders in the early adoption of advanced prosthetic technology for the clinical care of veterans and service members with limb loss. Despite the recent (and ongoing) evolution of lower limb prosthetic technology and the large number of commercially available devices, there are limited guidelines to aid the limb loss care team in prescribing appropriate prosthetic technology to achieve optimal functional ability. With the expectation of continued active lifestyles for veterans and service members with limb loss, the absence of effective, evidence-based interventions not only limits near-term outcomes but likely also increases the susceptibility for secondary physical conditions and degenerative changes over the long term. Furthermore, projected trends indicate that the overall number of amputations will increase dramatically, largely attributable to the aging population and the number of people living with dysvascular disease and diabetes [4]. As the aging veteran population advances in these diseases, this will become a major quality-of-life concern for VA, and effective outcome-based clinical practice will be necessary to decrease long-term disability and provide high quality of life. Therefore, it is the goal of this proposal to develop evidence-based lower limb prosthetic prescription guidelines for the achievement of maximal functional ability and patient satisfaction. Following the completion of this research project, the biomechanical, functional, and subjective parameters that are the most indicative in yielding the most successful and appropriate ankle-foot device prescription will have been determined. Thus, the evidence-based outcomes obtained from this research investigation can be appropriately translated into clinical practice and drive the future of clinical care and research. As future technology develops and becomes available, this protocol will help to establish the methodological framework necessary to aid in the appropriate clinical prescription of prosthetic ankle-foot devices.

Dissemination Plan

It is expected that the outcomes and results of this investigation can become an influential source of evidence-based health care practice for prosthetic prescription that can also be incorporated in lower extremity clinical practice guidelines. Disseminating the results of this study within the DoD, VA, and civilian health care systems will be critical in changing clinical practice to affect the quality of life of individuals with transtibial limb loss. First, both VA and the DoD are integrated networks that leverage various modalities to enable the dissemination and adoption of best practices among different disciplines.

XSL•FO
RenderX

Specifically for limb loss care teams, the DoD and VA Extremity Trauma and Amputation Center of Excellence leads efforts to enhance the health care of veterans and service members. Participation in the Extremity Trauma and Amputation Center of Excellence webinar series will be an excellent opportunity to present the results of this study. The webinars reach a multidisciplinary group of clinicians, scientists, researchers, and other members of the limb loss care team. This webinar series contains presentations that are broadcast and available across the entire DoD and VA health care network and occurs every other month. This forum provides an excellent platform to present the results of this study to a large, diverse audience of researchers and health care professionals in the field of limb loss care. By disseminating our results to leaders and clinicians in the field of limb loss care, we can directly influence the care provided to veterans and service members with limb loss.

To reach stakeholders in the civilian health care systems, we aim to communicate the importance of the results of this study through leading peer-reviewed publications in scientific journals and presentations at professional conferences that target clinical providers (eg, Gait and Clinical Movement Analysis Society conference, American Society of Biomechanics conference, and Military Health System Research Symposium) and by sharing our data through large data repositories.

Finally, in addition to providing a wide distribution of results through peer-reviewed publications, outcomes will be disseminated to industry leaders for improvement of their products. The DoD and VA have supported similar efforts across the prosthetics industry. Specific, relevant results provided to industry leaders can help in the evolution of lower extremity prosthetic components, which will then lead to improved devices for veterans and service members.

Acknowledgments

At the Department of Veterans Affairs New York Harbor Healthcare System, the authors would like to acknowledge Mr David Herlihy and Mr Michael Poppo for their assistance during data collection and processing, Mr Eric Baksh for fabricating the duplicate prosthetic sockets for all sites, Mr Kenneth Breuer and Mr Eric Hubbs for their assistance in prosthesis fitting and alignment, and Dr Jonathan Glasberg and Dr Cristina Roy for training participants to use each ankle-foot device. At Walter Reed National Military Medical Center, the authors would like to acknowledge Mr Jonathan Gladish for his assistance during data collection and processing, Ms Louise Hassinger and Mr Peter Anderson for prosthesis fitting and alignment, Dr Leigh Anne Lechanski for training participants to use each ankle-foot device, and Dr Ashley Knight for her assistance in project administration. At James A Haley Veterans' Hospital, the authors would like to acknowledge Dr Meghan Kern and Dr Lisa Ballestrea for their assistance during data collection and participant training and Ms Anh Du for her assistance in prosthesis fitting and alignment. At Veterans Affairs Puget Sound Healthcare System, the authors would like to acknowledge Mr Wayne Biggs for his assistance in prosthesis fitting and alignment, Mr Mathew Jerrell for his assistance in project administration, and Ms Ellen Ferris for her assistance in data collection and participant training. Finally, the authors would like to acknowledge the Narrows Institute for Biomedical Research and Education for their assistance in grant management. Support was provided by the Congressionally Directed Medical Research Programs–Orthotics and Prosthetics Outcomes Research Program (grant W81XWH-17-2-0014). This funding source had no role in the design of this study and will not have any role during its execution, analyses, and interpretation of the data or decision to submit results.

Abstract

Background: Individuals released from carceral facilities have high rates of hospitalization and death, especially in the weeks immediately after their return to community settings. During this transitional process, individuals leaving incarceration are expected to engage with multiple providers working in separate, complex systems, including health care clinics, social service agencies, community-based organizations, and probation and parole services. This navigation is often complicated by individuals' physical and mental health, literacy and fluency, and socioeconomic status. Personal health information technology, which can help people access and organize their health information, could improve the transition from carceral systems to the community and mitigate health risks upon release. Yet, personal health information technologies have not been designed to meet the needs and preferences of this population nor tested for acceptability or use.

Objective: The objective of our study is to develop a mobile app to create personal health libraries for individuals returning from incarceration to help bridge the transition from carceral settings to community living.

Methods: Participants were recruited through Transitions Clinic Network clinic encounters and professional networking with justice-involved organizations. We used qualitative research methods to assess the facilitators and barriers to developing and using personal health information technology for individuals returning from incarceration. We conducted individual interviews with people just released from carceral facilities (n=~20) and providers (n=~10) from the local community and carceral facilities involved with the transition for returning community members. We used rigorous rapid qualitative analysis to generate thematic output characterizing the unique circumstances impacting the development and use of personal health information technology for individuals returning from incarceration and to identify content and features for the mobile app based on the preferences and needs of our participants.

XSL•FO
RenderX

Results: As of February 2023, we have completed 27 qualitative interviews with individuals recently released from carceral systems (n=20) and stakeholders (n=7) who support justice-involved individuals from various organizations in the community.

Conclusions: We anticipate that the study will characterize the experiences of people transitioning from prison and jails to community settings; describe the information, technology resources, and needs upon reentry to the community; and create potential pathways for fostering engagement with personal health information technology.

KEYWORDS

carceral settings; personal health information technology; qualitative research; systemic oppression; transition from incarceration

Introduction

In a typical year, more than 10 million people cycle in and out of prisons and jails. Incarcerated individuals predominantly come from racial and ethnic minority groups and are of low-income status [1]. Those with a history of incarceration have chronic medical conditions—such as diabetes, hypertension, hepatitis C, depression, and substance use disorders—higher than the general population [2-6]. Upon release, these individuals bear high risks of death and hospitalization from preventable conditions [2,7-9]. Medicare beneficiaries recently released from correctional facilities have higher hospitalization rates and an increased risk of mortality compared with the general population [10,11]. A Washington state study found that individuals recently released from prison had a 2-fold increase in the risk of mortality in the year after release compared to the general population [7].

During incarceration, people reside in a highly controlled environment with constitutionally guaranteed access to health care services and little or no autonomy or opportunity to gain skills in self-management of medications, exercise, or diet [12,13]. This lack of autonomy may adversely affect an individual's ability to manage their health upon release [12-14]. In total, 40% of individuals are diagnosed with a new chronic condition while incarcerated and do not have any experience managing that illness in a community setting [15]. Many individuals are released from carceral settings without any discharge planning and have no information on their health records, their medications, or their recent lab results [16]. Improving health outcomes in this population is further complicated given the immediacy of people's social needs and legal obligations, including securing housing, food, and employment, as well as meeting the mandates of community supervision. After incarceration, people have an increased rate of homelessness, and incarceration leads to increased housing vulnerability due to loss of housing during incarceration, decreased eligibility for employment and public housing, and disrupted community ties [17]. In addition, more than 90% of formerly incarcerated persons meet the United States Department of Agriculture criteria for food insecurity [18]. Although many individuals have at least 1 chronic medical condition on release, 80% are released without health insurance or having a primary care provider [19,20]. Meeting these needs requires individuals just released from incarceration to engage with many different health, social, and legal entities to organize and manage their information.

Personal health information technologies are untapped resources that could facilitate improved access and organization of information, especially in the period after release. In addition, personal health information technologies increase patient engagement in health and self-efficacy efforts by organizing health information, improving communication with providers, and coordinating care. Research on personal health information technologies has mostly focused on patient portals (electronic personal health records tethered to institutional electronic health records), which has helped improve adherence to medications and quality measures for chronic conditions [21-25]. Yet, research has demonstrated this one-size-fits-all approach to designing personal health information technologies has resulted in low utilization of patient portals and barriers to use among racial and ethnic minority groups, people with low socioeconomic status, and people with limited health literacy [22,26,27]. In addition to low utilization and the challenges with use, patient portals do not have the desired functionality to aggregate information between different health systems and other organizations, like community-based social service organizations and carceral health facilities. Furthermore, the existing personal health information technologies that are not tied to an electronic health record aggregate information across multiple different sources but do not have features that address health literacy, concerns of privacy and security, and other barriers to technology use [28-30]. Existing personal health information technology, such as personal health libraries, has not been designed to meet the needs and preferences of people recently released from incarceration, which is critical for its acceptance and use [11,31]. Incorporating input from intended users and knowledge of their technology use and behaviors can help diminish potential intervention-generated inequalities [32,33]. The objective of this study is to explore the facilitators and barriers to using personal health information technology with formerly incarcerated persons and other community stakeholders. This study will inform the design, development, and usability testing of personal health libraries created for people with histories of incarceration to facilitate their transition from carceral to community settings.

Methods

Study Design, Study Setting, and Participants

We will use qualitative methods and conduct semistructured interviews with people just released from jails or prisons (anticipated n=20) and community and correctional stakeholders (anticipated n=10) to understand the individual, organization,

XSL•FO
RenderX

and systemic factors that shape people's access to health and technology supports after release from incarceration. The following study protocol was reviewed and approved by the Yale University Human Subjects Research Committee Institutional Review Board (200028862). The research will be conducted in partnership with a primary-care clinic that cares for people who have chronic health conditions and histories of incarceration. The clinic, located in the northeastern United States, is part of the Transitions Clinic Network (TCN), a national network of primary-care clinics that integrates community health workers (CHWs) who have lived experience of incarceration into clinical teams [3,15]. Additionally, the TCN clinic has collaborations with local organizations that support individuals released from correctional settings. We will create an advisory board for this project that includes clinicians and service providers who care for people with a history of incarceration, CHWs with a history of incarceration, and correctional system administrators. The advisory board will provide overarching feedback on study design, data collection, and data analysis.

Recruitment and Interviewing of Formerly Incarcerated Individuals

One team member (MS), who is a CHW in the clinic, will recruit potential participants through TCN clinic encounters and professional networking with justice-involved organizations. To be eligible for this interview, patients need to be at least 18 years old, carry a diagnosis of at least 1 chronic disease (eg, diabetes, heart disease, kidney disease, arthritis), be English-speaking, and have been released from jail or prison within the past year.

Recruitment and Interviewing of Stakeholders

Team members (MF, MCB, MS, KW) will use professional networks and snowball sampling to recruit stakeholder participants from social service agencies, community organizations, and carceral facilities. To be eligible for this portion, participants need to have direct experience working with people who have recently been released from incarceration.

All interested and eligible people will be given study-informed consent forms with detailed information about the purpose of the study, their rights as research participants, and contact information for further questions. A team member will schedule in-person interviews in physical or web-based spaces that are convenient for participants. All participants, both formerly incarcerated individuals and community stakeholders, will receive a US $50 gift card at the end of the interview in appreciation for their time.

Data Collection

The team developed 2 interview guides using the constructs of the technology acceptance model and input from stakeholders who are part of the TCN professional network (see Multimedia Appendices 1 and 2 for interview guides) [34,35]. The interview guide for people just released from incarceration includes questions about participants' experiences with technology, information-seeking behavior, and needs during their transition from incarceration to the community. Questions include:

- What experiences did you have with technology before incarceration? During incarceration?
- Describe some of the initial things you needed to figure out when you were released.
- How do you figure out what to do next?
- How do you organize your information?

Participants will also be asked to give feedback on wireframe models of a personal health library and share examples of information they would like to track or manage within a digital app, such as their identification card or address of residency prescription medications, or applications for education, employment, or financial assistance.

The stakeholder interview guide seeks to obtain information about technology access and information-seeking behaviors from a service provider perspective. Questions include:

- What kind of information do you collect and store on individuals who are in or just released from correctional settings?
- What type of information do you want to help you with your ability to promote health for the individuals you work with?
- What are your concerns about clients using technology to access their health information?

The team will iteratively refine both interview guides throughout data collection to incorporate emergent ideas into future interviews.

Three researchers will serve as interviewers for the study: 2 are experienced qualitative researchers (MF, MCB) while the third will be trained as part of the larger grant aims (MS). All interviews will be audio-recorded and professionally transcribed. Identifying information will be removed from the transcript to preserve participant confidentiality.

Data Analysis

Four team members (MF, MCB, MS, KW), including the 3 interviewers, will serve on the analytic team. This structure will support a closeness with the data and a collaborative analytic process [36]. The team members' experiences are professionally and personally diverse and span more than 10 years in the care of structurally marginalized populations, including expertise in justice research (MF), social work research (MCB), community health work and community advocacy (MS), medicine and community-engaged informatics (KW). They will use a rapid qualitative analysis to efficiently process and distribute data to the larger study team [37,38], so that the findings are incorporated into the user-centered design and software development process. The analytic team will develop a template to organize the salient findings from each individual interview [38]. The template contains sections describing each participant's experiences with preparation for release from incarceration, perspectives on priorities for people after they are released from incarceration, and the type of information sought, shared, and used during the transition process from carceral settings to the community.

The analysts will complete summaries for each interview independently, with at least 2 analysts assigned to each

XSL•FO
RenderX

transcript. They will then convene as a group to discuss their work and further explore the data through questions and comparisons with other study interviews, field experiences, and research findings. The team will record their progress, including ongoing thematic analysis through memoing and visualizations [39,40]. All written (transcripts, summaries, memos) and graphic (visualizations) data will be uploaded to Dedoose (version 9.0.17; Socio-cultural Research Consultants, LLC) for data storage, sharing, and retrieval. The summaries and visualizations will be sent to the larger research team to inform the ongoing design and development of a personal health library for individuals transitioning from carceral settings. The summary template includes a section that will be used to develop a qualitative codebook that can be applied to all transcripts for further analysis. This coding process will also facilitate the retrieval of aggregated, deidentified data for future study needs [41,42].

Following rapid qualitative analysis, the team will conduct interpretation sessions (led by TM) and develop an affinity diagram [43]. By creating an affinity diagram, the team can take the large amounts of data gathered during the interviews and organize them into groups or themes based on their relationships. The benefit of creating the affinity diagram is that it can reveal common issues and themes across all users and help to identify key requirements for developing the personal health library app. The purpose of the interpretation session is to turn the data gathered from the interviews into draft models for design. The study results will be disseminated to study participants and the advisory board for reflection and feedback.

Ethics Approval

The institutional review board at Yale School of Medicine approved the study and all participants gave informed consent (2000028862).

Results

As of February 2023, we have completed 27 interviews with people just released from carceral systems (n=20) and stakeholders (n=7). The data analysis derived from the interviews will inform the development of user requirements, identify facilitators and barriers to personal health library use with our population of interest, capture emergent needs and priorities during the transition process from correctional to community settings, and build a comprehensive codebook for further analysis. The interviews with people with a recent history of incarceration have elucidated a wide range of social and health services that they interact with upon release, such as identity verification and obtainment of identity documentation, 211 services (information and referral service organization in Connecticut servicing individuals with utility assistance, food, housing, child care, after school programs, elder care, and crisis intervention), the Department of Social Services that delivers and funds a wide range of programs and services as Connecticut's multifaceted health and human services agency, and the Department of Mental Health and Addiction Services, whose purpose is to promote and administer comprehensive, recovery-oriented services in the areas of mental health treatment and substance abuse prevention and treatment throughout Connecticut [44-46]. We are purposively sampling to recruit more female participants with recent histories of incarceration, as well as stakeholders affiliated with specific areas of need.

Discussion

Anticipated Findings

People recently released from carceral settings face a unique set of challenges when they return to the community [47]. They may face challenges with meeting their basic needs, such as being unhoused, unemployed, and food insecure, in addition to challenges maintaining their health and well-being when entering back into the community from prison or jail. In this transition back to the community, personal health libraries may be the bridge that facilitates access to information about community resources as well as facilitate the organization and preparation of personal health information, emergency contacts, community providers, and employment opportunities. From our qualitative analysis, we will have a rich understanding of the experiences of those previously imprisoned and their perspectives on the use of technology, their concern for security and safety use with technology, how they organize information that is important to them, and specifically how technology may or may not be leveraged for their personal health needs. In addition, by leveraging a participatory design process, the findings produced by this study will result in a nuanced understanding of the facilitators and barriers to the design, development, and utilization of personal health information technologies among people returning to the community from carceral settings. These findings from the interviews and the participatory design process may lead to increased personal health engagement through technology use.

Conclusion

Millions of individuals leave jails and prisons each year, and in this transition, many experience poor health outcomes. Personal health information technologies, which are currently underutilized, may positively impact their health by improving individual self-efficacy and by facilitating communication between the health system and social service providers, and control of information by patients themselves. To improve transitions of care from carceral to the community health system, we need to have targeted and feasible solutions to capitalize on the benefits of personal health information technologies.

Acknowledgments

The authors would like to thank the study participants for generously sharing their experiences with our team. The authors would like to acknowledge the staff at the TCN-CT (Transitions Clinic Network, Connecticut) for supporting participant recruitment, members of the Consumer Health Informatics Lab at Yale University, including Mary Peng, Amanda Levi, Meera Swaminath,

Abstract

Background: Innovative care models are needed to address gaps in kidney care follow-up among acute kidney injury (AKI) survivors. We developed the multidisciplinary AKI in Care Transitions (ACT) program, which embeds post-AKI care in patients' primary care clinic.

Objective: The objective of this randomized pilot trial is to test the feasibility and acceptability of the ACT program and study protocol, including recruitment and retention, procedures, and outcome measures.

Methods: The study will be conducted at Mayo Clinic in Rochester, Minnesota, a tertiary care center with a local primary care practice. Individuals who are included have stage 3 AKI during their hospitalization, do not require dialysis at discharge, have a local primary care provider, and are discharged to their home. Patients unable or unwilling to provide informed consent and recipients of any transplant within 100 days of enrollment are excluded. Consented patients are randomized to receive the intervention (ie, ACT program) or usual care. The ACT program intervention includes predischarge kidney health education from nurses and coordinated postdischarge laboratory monitoring (serum creatinine and urine protein assessment) and follow-up with a primary care provider and pharmacist within 14 days. The usual care group receives no specific study-related intervention, and any aspects of AKI care are at the direction of the treating team. This study will examine the feasibility of the ACT program, including recruitment, randomization and retention in a trial setting, and intervention fidelity. The feasibility and acceptability of participating in the ACT program will also be examined in qualitative interviews with patients and staff and through surveys. Qualitative interviews will be deductively and inductively coded and themes compared across data types. Observations of clinical encounters will be examined for discussion and care plans related to kidney health. Descriptive analyses will summarize quantitative measures of the feasibility and acceptability of ACT. Participants' knowledge about kidney health, quality of life, and process outcomes (eg, type and timing of laboratory assessments) will be described for both groups. Clinical outcomes (eg, unplanned rehospitalization) up to 12 months will be compared with Cox proportional hazards models.

Results: This study received funding from the Agency for Health Care Research and Quality on April 21, 2021, and was approved by the Institutional Review Board on December 14, 2021. As of March 14, 2023, seventeen participants each have been enrolled in the intervention and usual care groups.

Conclusions: Feasible and generalizable AKI survivor care delivery models are needed to improve care processes and health outcomes. This pilot trial will test the ACT program, which uses a multidisciplinary model focused on primary care to address this gap.

KEYWORDS

acute kidney injury; acute renal failure; care transitions; chronic kidney disease; nephrologists; randomized controlled trials

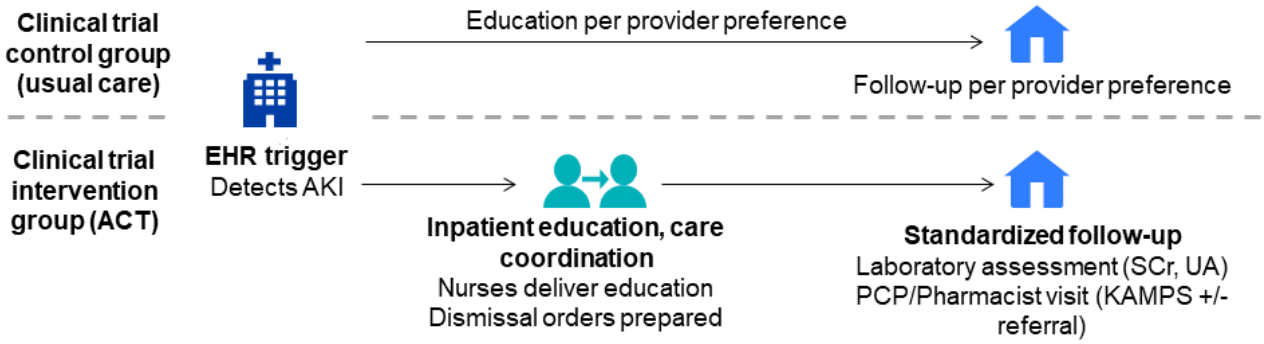
Introduction

Acute kidney injury (AKI) affects nearly 20% of hospitalized patients. It is associated with a 6.5-fold higher mortality, a 3.5-day longer length of stay, and US $5 billion in annual hospital costs in the United States. Chronic kidney disease (CKD) develops in 15%-30% of AKI survivors and 49% are readmitted to the hospital within 1 year. These complications decrease patients' quality of life and strain health care resources. This significant risk of poor outcomes can be partially attributed to gaps in kidney-focused care and education during transitions. One study found that 30% of AKI survivors failed to receive basic laboratory and clinical follow-up of kidney health after discharge and that avoidable nephrotoxin exposure during this period independently increased the risk for chronic kidney disease [1,2]. Another study showed that laboratory monitoring of serum creatinine and urine protein, which is recommended as best practice, was only done in 54% and 14%, respectively, of AKI survivors at 6 months [3]. These care gaps place patients at risk for exposure to potentially modifiable determinants of long-term complications, such as nephrotoxins. A large population-based cohort study showed that 74% of AKI survivors received 1 or more nephrotoxins at hospital discharge. This was associated with a 1.4-fold increase in risk for new or worsening CKD and compounded 1.13-fold with each additional nephrotoxin [2].

Survivorship programs facilitating the transition from inpatient to outpatient care have improved clinical and patient-centered outcomes in patients with complex care needs, such as cancer and critical illness survivors [4-7]. Though experience with AKI survivor care transition programs is limited, the most frequently proposed model is a dedicated nephrologist-led clinic to deliver core components of best practices for post-AKI care. These have been associated with improved patient kidney health knowledge and process outcomes, such as timely serum creatinine monitoring after discharge [8,9]. Despite promising results in initial reports, concerns exist about scalability, acceptability of patients, and generalizability to rural and low-income populations where specialty nephrology care is often unavailable [10,11]. Patients are typically seen more than 1 month after discharge, increasing the risk for nephrotoxin exposure and loss of follow-up. Additionally, specialty consultation may not be needed for all patients and may introduce additional fragmentation of care, costs, and treatment burden. Nephrologists have called for the integration of other disciplines to enhance AKI survivor care delivery capacity [12], including primary care providers (PCP) to evaluate laboratory tests and perform a kidney function assessment early in the postdischarge period [13].

To address these concerns, we developed the multidisciplinary AKI in Care Transitions (ACT) program, which embeds post-AKI care in the patient's medical home, primary care. The bundled intervention includes (1) the use of an electronic health record (EHR) alert to identify high-risk AKI survivors, (2) education and care coordination from nurses in nephrology before discharge, and (3) a posthospital visit with a PCP and a pharmacist within 14 days after discharge. Nephrology referral is coordinated based on the needs and preferences of the patient, inpatient care providers, and the patient's PCP. Pilot testing revealed higher 14- and 30-day cumulative incidence of laboratory and provider follow-up in ACT program participants compared to those receiving usual care. In addition, participants who received kidney health education improved their understanding of AKI and its consequences.

This pilot trial aims to test the feasibility of study procedures for a future hybrid effectiveness and implementation trial, including patients' willingness to be enrolled and randomized, participant retention, and chosen outcome measures. We will also assess the feasibility and acceptability of participation in the ACT program and identify determinants of successful implementation into routine clinical care.



Methods

Overview

In preparation for a future large-scale clinical trial to test the effectiveness and implementation of the ACT program for improving care quality and outcomes, this study will evaluate the feasibility and acceptability for patients and staff (aim 1) and gather preliminary effectiveness data (aim 2). To accomplish these aims, we will conduct a pilot randomized trial using a convergent mixed methods approach (Figure 1). We will use the Consolidated Framework for Implementation Research (CFIR) [14] to systematically assess potential barriers and facilitators (ie, determinants) that influence implementation outcomes.

Ethics Approval

The study was reviewed and approved by the Mayo Clinic Institutional Review Board (21-011055) on December 14, 2021, and was registered at ClinicalTrials.gov (NCT05184894). This study will employ a Data Safety and Monitoring Plan to monitor participant safety, data completeness and adherence to study protocol, data integrity, participant privacy, data confidentiality, and study documentation.

Setting and Participants

This pilot trial was conducted at Mayo Clinic, an academic medical center in Rochester, Minnesota. Mayo Clinic is an integrated health care delivery system delivering primary and specialty care to local, regional, national, and international patients. Mayo Clinic primary care practices provide comprehensive primary care to approximately 150,000 empaneled patients —local area residents, Mayo Clinic employees and their dependents—cared for at 7 full-service clinical sites and 2 express care sites in Rochester and surrounding counties. It employs a team-based care model that includes physicians, advanced practice providers (nurse practitioners and physician assistants), nurses, and embedded clinical pharmacists who consult with patients independently or in collaboration with the PCP. At Mayo Clinic, no formal dedicated AKI-survivor clinic exists.

Mayo Clinic Rochester Hospital has 5 inpatient nephrology consultation services that include nurse educators whose primary role is educating hospitalized patients discharged on dialysis. Patients can be referred for nephrologist follow-up in a Rochester clinic by inpatient care teams, including the nephrology consult services, or any other inpatient or outpatient provider.

Patient participants for the ACT trial are identified using an EHR screening alert, a validated electronic AKI surveillance tool that uses serum creatinine and urine output to detect AKI [15]. Eligible individuals have stage 3 AKI (severe) based on consensus criteria [16] during their hospitalization, a PCP at Mayo Clinic in Rochester, do not need dialysis at discharge, and are not discharged to hospice. Patients who are unable to participate (eg, clinician-documented dementia in the EHR or with limited English proficiency) or who do not provide informed consent are excluded. Recipients of any transplant or acute cellular therapy within 100 days of enrollment are also excluded. Eligibility is determined using the EHR screening alert and through manual chart review by a study team member. Individuals may only be enrolled in the trial one time. Remuneration is not provided to any participant.

Patient participants in the intervention group and staff involved in delivering components of the ACT program are invited to participate in semistructured interviews or observations of ACT program interactions (eg, patient education, provider visit) to explore the feasibility and acceptability of the ACT program. Participants are sampled on key factors (eg, age, urban or rural geographic location, and ACT program role) to facilitate the selection of information-rich cases while capturing major variations based on patient factors or staff background or experience.

Patients provide written informed consent for trial enrollment and indicate whether they consent to be contacted for an interview and/or have their visit observed. Oral consent is obtained from clinicians before participating in interviews or observations. Clinicians are approached for oral consent at the first study encounter they are involved in. This consent carries forward for all subsequent encounters (eg, with other patients). Observations are performed using video and audio recordings. At any time once enrolled, including during the visit, a patient or clinician may withdraw their consent for participation in the trial, observations, or an interview. Declining participation in 1 aspect of the trial does not preclude ongoing participation in others.

Study Groups

Participant Identification

A study team member contacts potential patient participants before discharge to obtain written informed consent for the trial. Patients are approached approximately 48-72 hours before the estimated discharge date. Participants are randomized 1:1 to either the control or intervention group. Individuals are randomly allocated equally to the intervention or control groups using a permuted block design with varying block sizes between 2 and 4. The study statistician set up the randomization scheme and provided numbered envelopes to the study coordinator with the randomly assigned group enclosed. After completing the

XSL•FO
RenderX

informed consent, the study coordinator opens the envelope and discloses the group allocation to participants.

Intervention Group

Participants in the intervention group receive a care bundle inclusive of education, care coordination, and postdischarge follow-up. Before discharge, participants receive a consultation from nephrology nurse educators. These nurses provide kidney health education, as previously described [17], which is tailored to the patient's needs. To ensure consistency, nurses aim to achieve understanding using teach-back questions. Scheduling coordinators place orders for postdischarge laboratory tests (serum creatinine and urine study for protein assessment) and outpatient visits with a PCP and a pharmacist for signature by the primary inpatient service before discharge. Laboratory and provider visits are ideally scheduled within 14 days of discharge [4]. PCP and pharmacist encounters can occur in person or through video (PCP or pharmacist visits) or telephone (pharmacist visits only). Structured around the KAMPS framework (Textbox 1 [18, 19]), the PCP and pharmacist provide patient education, medication reconciliation, and disease state management with specialist referral as needed.

Textbox 1. KAMPS framework for components of kidney follow-up care [18,19].

Framework

- K: Kidney function assessment with laboratory testing
- A: Awareness and education
- M: Medication reconciliation and review
- P: Individualized blood pressure monitoring
- S: Sick day education

It is expected as part of standard care that the PCP and pharmacist review the range of care needs for the patient in the transitional period, including, but not limited to AKI. Pharmacists discuss recommendations with the provider in person, if possible, or through secure message. Clinical decision support tools have been developed and embedded in the EHR [17], including descriptions of the KAMPS framework domains and links to additional kidney care resources through a proprietary medical knowledge system [20]. Orders for outpatient nephrology follow-up, if indicated, may be placed by the inpatient care teams or the PCP. Participants in this group are also invited to participate in semistructured interviews.

Control Group

Participants receive no specific study-related intervention. AKI identification, patient education, and follow-up care are at the discretion of the primary treating team. It is customary for these patients to receive some degree of laboratory monitoring and clinical follow-up in the postdischarge period, but for this group, timing and components are not standardized. Care providers have access to the same educational materials for providers and patients as in the intervention group.

Data Collection

Overview

Individuals that consent to participate will be captured in the REDCap system. Those found to be ineligible or eligible but declining participation will be captured in a recruitment tracking log. If spontaneously offered, reasons for declining participation will be recorded, but these will not be deliberately probed due to regulatory limitations. The Mayo Clinic Unified Data Platform will be used to abstract electronically available data. The Unified Data Platform is an aggregated data resource inclusive of current and legacy EHR and administrative billing data across the Mayo Clinic enterprise. Other sources of data include interviews and direct observations of clinical encounters. An overview of the data collection plan is outlined in Table 1.

[a]ACT: AKI in Care Transitions.

[b]UDP: Unified Data Platform, source for quantitative data collection unless otherwise specified.

[c]AKI: acute kidney injury.

[d]mKiKS: modified Kidney Knowledge Survey.

[e]Intervention patients or clinicians only.

[f]Staff participating in interviews will complete the Feasibility of Intervention Measure and Acceptability of Intervention Measure surveys [21].

[g]MAKE: major adverse kidney event.

[h]ED: emergency department.

[i]CKD: chronic kidney disease.

Quantitative Data

Data will be abstracted from the Mayo Clinic UDP on patient demographics, comorbidities, attributes of the hospitalization, details about the episode of AKI and the degree of kidney function recovery by discharge, follow-up processes of care (laboratory assessments and visits), and clinical outcomes. Health literacy is evaluated in all participants at baseline using the Brief Health Literacy Screen (Multimedia Appendix 1) [22]. Select medication data will be collected at baseline (preadmission based on the documented medication list in the EHR), discharge, and 30-day follow-up. This will include the use of angiotensin-converting enzyme inhibitors and angiotensin receptor blockers, sodium-glucose cotransporter 2 inhibitors, metformin, glucagon-like peptide 1 receptor antagonists, sulfonylureas, insulin, loop diuretics, thiazide diuretics, statins, aspirin, and nonsteroidal anti-inflammatory drugs. The total number of medications at discharge will be evaluated. Using previously described methods, we will review pharmacist documentation of medication discrepancies and drug therapy problems for any patient completing a pharmacist visit [4]. Drug therapy problems will be categorized as pertaining to effectiveness, indication, safety, or adherence and relationship to renoprotective or nephrotoxic medications (Textbox 2). Drug therapy problems will be assessed and categorized by a single pharmacist with 11 years of experience and advanced credentialing as a medication management services pharmacist specializing in primary care.

XSL•FO
RenderX

Textbox 2. Medications classified as nephrotoxic or renoprotective. Medication data will be collected at baseline (ie, preadmission medications), hospital discharge, and 30-day outpatient follow-up.

Nephrotoxic medications

- Antivirals: Acyclovir, ganciclovir, tenofovir, valacyclovir, foscarnet
- Antibiotics: Aminoglycosides, ciprofloxacin, colistimethate, nafcillin, oxacillin, penicillin, polymyxin, rifampin, trimethoprim/sulfamethoxazole, vancomycin (intravenous product only), piperacillin/tazobactam, ticarcillin or clavulanate
- Immunosuppressants: tacrolimus, sirolimus, cyclosporine
- Chemotherapeutics: Carboplatin, cisplatin, cyclophosphamide, ifosfamide, imatinib, irinotecan, gemcitabine, ibrutinib, oxaliplatin, lenalidomide, melphalan, sorafenib, temozolomide, topotecan, methotrexate (>20 mg/week)
- Other: Amphotericin B, lithium, mesalamine, pamidronate, sulfasalazine, topiramate, zonisamide, zoledronic acid, proton pump inhibitors, nonsteroidal anti-inflammatory drugs (includes aspirin doses >325 mg/day)

Renoprotective medications

- Angiotensin-converting enzyme inhibitors
- Angiotensin receptor blockers
- Sodium-glucose cotransporter 2 inhibitors
- GLP-1 receptor agonists

Qualitative Data

Interviews will be conducted by a female study team member with expertise in qualitative methods (DMF) who has no prior relationship with participants. Interviews begin with a brief description of the ACT program, the study's goals, and information about informed consent, which is documented. CFIR domains informed the creation of 1 semistructured interview guide for patients and 1 for staff (Multimedia Appendix 1), where questions are tailored to each role (eg, PCP, pharmacist, and scheduling coordinator). Interviewees will be asked to describe their experiences with the ACT program and their sense of the outcomes. Interviews will be conducted over the phone and recorded and transcribed with permission. Transcripts will be reviewed by 2 additional study team members and content experts (HPM and EFB), with the refinement of the interview guide as needed.

Two study team members, including 1 with training in qualitative methods (HPM), will review observations to assess the impact of the ACT interventions on the clinical encounter. Reviewers will watch the video (when available) or read the transcripts of the encounter. Using an observation template for field notes, encounters will be primarily evaluated for the 5 elements of KAMPS framework (Textbox 1) [19,23]. The duration spent on each KAMPS framework element and discussion about kidney health (relative to other conditions) will be cataloged. Reviewers will record whether they observed the clinician using the ACT clinical decision support tools or any print or electronic materials about AKI or kidney health. Occasions where kidney health is discussed will be cataloged as clinician-initiated or patient-initiated.

Study team members will use freeform field notes throughout the study to document notable observations during interactions with patient and staff participants (eg, participating patients failing to recall study enrollment or their episode of AKI).

Outcomes

Feasibility, Fidelity, and Acceptability

To assess the feasibility of patients' willingness to be enrolled and randomized, we will evaluate the number of patients screened, approached for consent, and randomized during the study time frame (intention-to-treat group). Intervention fidelity will be measured by the proportion of participants in the intervention group who complete the nurse education, laboratory testing, pharmacist visit, and PCP visit (per-protocol group). For those who do not complete the full ACT intervention, we will characterize the attrition (eg, inability to deliver education during hospitalization, inability to schedule postdismissal visits, and patient did not complete the postdismissal visits), which reflects the feasibility of incorporating the ACT program into routine transitional care. We will also evaluate the proportion of participants in the ACT group where clinicians interfaced with clinical decision support alerts using electronic audit trails. Staff participating in interviews will complete the Feasibility of Intervention Measure and Acceptability of Intervention Measure surveys, validated tools to measure implementation outcomes [21]. Acceptability of the ACT program will also be determined through patient completion of the "Was it worth it?" survey at follow-up (Multimedia Appendix 1) [24], qualitative interviews with consenting staff and patients, and observations of the clinical encounter.

Patient Knowledge and Quality of Life

We will evaluate patient knowledge about AKI measured with an adaptation of the Kidney Knowledge Survey (modified KiKS; mKiKS). mKIKS assesses participants' objective knowledge about AKI causes, risk factors, and management [25]. Unanswered questions (missing data) on the mKiKS are assigned a score of 0, and the total score is used for comparisons (Multimedia Appendix 1). Quality of life will be assessed using the PROMIS Global 10 tool v1.2 (Multimedia Appendix 1). Patient-reported outcomes will be collected in person or over the phone by a study team member.

XSL•FO
RenderX

Process and Clinical Outcomes

Participants will be followed for 1 year post discharge or until death or loss of follow-up within that time frame. Process outcomes include kidney laboratory assessments and their timing, clinician visits (eg, with the PCP, pharmacist, and nephrologist), visit type, and timing (in-person vs telemedicine or web-based). At 90 days, clinical outcomes for assessment include major adverse kidney event, emergency department visits, or unplanned rehospitalization. Incidence of de novo or progressive chronic kidney disease or death up to 12 months after discharge will be documented. The number of identified nephrotoxic or renoprotective medications, medication discrepancies, and drug therapy problems will be described.

Data Analysis

Quantitative Data

To describe the feasibility of ACT and generate preliminary estimates of the effect on patient-reported and clinical outcomes, descriptive analyses will be conducted in three groups: (1) the intention-to-treat population (anyone randomized), (2) the per-protocol population (randomized patients who receive all components of the study intervention), and (3) the complete follow-up population (the per-protocol population with follow-up patient-reported outcomes at 30±7 days). Baseline characteristics will be described with means (SDs) and counts and percentages. Comparisons will use the *t* test for continuous data and the chi-square test for categorical data. Any baseline imbalances ($P<.05$) will be explored as a possible factor to adjust for when the outcome measures are analyzed. Clinical outcomes up to 12 months will be compared with Cox proportional hazards models.

AKI knowledge will be described between groups with the mean mKiKS score. Model imputation will be used for patients with incomplete follow-up. Mean between-group differences in the total baseline and follow-up scores will be compared using the *t* test or nonparametric Mann-Whitney *U* test. An exploratory multivariable linear regression model will be fit with group assignment as the independent predictor of interest, mean follow-up knowledge scores as the dependent variable, and baseline scores as a covariate. Other variables to be considered will include age, sex, baseline health literacy, and baseline comorbidities, specifically CKD.

Qualitative Data

Interview transcripts will be uploaded to NVivo, software that assists in qualitative data organization and analysis. Five interview transcripts will be reviewed by 2 qualitative methods experts (DMF and JMG) and 2 content experts (HPM and EFB) to develop an initial codebook, which will be iteratively refined as it is applied to all interview data by 2 independent coders (DMF and HPM). Codes will be deductive (informed by CFIR domains) and inductive (identification of emerging concepts) and used in a framework analysis conducted by experts in qualitative methods (DMF and JMG) and post-AKI care (HPM and EFB). Themes will be developed through discussion and consensus and compared to ensure they capture the full range and depth of interview data. Themes will be compared between data types (eg, staff roles) and assessed for areas of complementarity (eg, domains describing interrelated factors), concordance, and discordance.

Twenty percent of the recorded encounters will be reviewed independently and in duplicate by 2 study team members. Concordance between individuals in assigned ratings of the 5 elements of the KAMPS framework will be evaluated. If greater than 0.8, reviewers will be considered concordant, and 1 study team member will evaluate the remaining encounters. If concordance is not met, an additional 20% of the included encounters will be evaluated in duplicate.

Data Integration

Quantitative data on feasibility and acceptability will be supported by qualitative data and integrated using an embedding approach. Herein, findings from qualitative interviews will supplement results by providing rich data on patient and staff experiences and perspectives on participating in the ACT program. Data will be integrated at the conclusion of the trial. Divergence (ie, inconsistent or conflicting findings) will be examined through refined data analysis and reconciliation, where results are reviewed with a deliberate focus on understanding inconsistencies. Results will be reported using a weaving narrative and joint display tables.

Sample Size

Pilot data estimates that approximately 1-2 patients per week will be identified with the EHR trigger, of which 70% will be eligible, agree to participate in the trial, and have evaluable outcomes data. We will assess the feasibility of study recruitment and randomization and the chosen outcome measures through comparison with these estimates. We project that a sample size of 25 patients per group is needed to assess the feasibility and acceptability of participating in the ACT intervention. Thus, we aim to enroll 50 total patients during an 18-month study time frame.

Results

This study received funding from the Agency for Healthcare Research and Quality on April 21, 2021. Institutional Review Board approval and study commencement were delayed due to unavoidable challenges associated with the COVID-19 pandemic. Following Institutional Review Board approval on December 14, 2021, the first participant was enrolled on January 24, 2022. As of March 14, 2023, seventeen participants each have been enrolled in the intervention and usual care group (total 34).

Discussion

Overview

Nephrologists have called for integrating other disciplines to enhance AKI survivor care delivery capacity [12]. Nephrologists and PCPs support early laboratory monitoring and kidney function assessment in primary care, and PCP follow-up is considered a cornerstone of care continuity [13]. PCPs have a preexisting rapport with patients and caregivers, familiarity with all the patient's medical conditions, and insights into both clinical and nonclinical factors affecting a patient's health and

XSL•FO
RenderX

health care. They may also provide less expensive and more accessible care for the health system [5]. As part of comprehensive primary care, the contribution of other allied health team members to care delivery is a recognized facilitator of high-quality, patient-centered care [19,26]. Nurses delivering kidney health education and coordinating post-AKI care have improved patient participation [9] and kidney health knowledge [27]. Likewise, pharmacists are uniquely qualified to complete a detailed medication reconciliation and identify medication therapy problems during the dynamic arc of kidney function recovery [28]. Pharmacist-PCP collaboration can reduce hospital readmission and the potential for medication harm compared to care with a PCP alone [4,29]. Despite widespread support for a multidisciplinary approach to post-AKI care, there is a paucity of data describing the incorporation of nonnephrologists into health care delivery models. The ACT program is poised to address common barriers faced by AKI survivors transitioning from the hospital to home through a patient-centered approach integrated in primary care.

Limitations of the proposed study must be acknowledged. The primary outcome of the trial is feasibility and acceptability, thus the sample size is modest. The data will be collected to gather preliminary estimates on clinical outcomes to inform a future trial, but this study is not expected to provide definitive insight into clinical outcomes. All participants will receive primary care in the same region as the tertiary care center where they are hospitalized for AKI, and all sites use a shared EHR. Although this minimizes the likelihood of missing follow-up data, it is unknown how these findings may translate to patients receiving primary care at a greater distance or in practices that do not share an EHR with the discharging hospital.

Conclusion

The ACT program uses a multidisciplinary, coordinated care transition model to enhance kidney health, knowledge, and safety in high-risk patients with existing gaps in care quality. Results from this trial will indicate the feasibility of recruitment and retention, study procedures, chosen outcomes, and the acceptability of the ACT program to patients and staff participants. In addition, this will determine the suitability of the ACT program for further large-scale testing, with the ultimate goal of improving patient and provider experience and outcomes.

Acknowledgments

The authors would like to acknowledge the valuable contributions of Brenda Anderson, Dawn Finnie, Gregory Hanson, Laurie Meade, Shelley Preble, AJ Maxson, Kate Mayhew, and Sophea Seng to the Acute Kidney Injury in Care Transitions (ACT) project. This work is supported in part by the National Institute of Allergy and Infectious Diseases of under award number K23AI143882 (PI; EFB), and the Agency for Healthcare Research and Quality HS028060-01 (PI; EFB). The funding sources had no role in study design; data collection, analysis, or interpretation; writing the report; or the decision to submit the report for publication. Its contents are solely the authors' responsibility and do not necessarily represent the official views of the National Institutes of Health.

Data Availability

Source data may be made available upon reasonable request.

Authors' Contributions

All authors take responsibility for the trial protocol and provided critical manuscript revision.

Conflicts of Interest

None declared.

Abstract

Background: Systematic reviews and meta-analyses based on observational studies have shown voluntary medical male circumcision (VMMC) may reduce HIV risk among men who have sex with men (MSM). There is a lack of randomized controlled trial (RCT) data assessing the efficacy of VMMC.

Objective: The primary objective of this study is to assess the efficacy of VMMC for preventing HIV acquisition among MSM who primarily engage in insertive anal sex.

Methods: A multicenter RCT will be conducted among MSM in 8 cities in China. Eligible participants are men aged 18-49 years who self-report ≥2 male sex partners in the past 6 months, predominantly practice insertive anal sex, and are willing to undergo circumcision. Interested men who satisfy inclusion criteria will be tested for HIV 1 month before enrollment and at enrollment, and only those who are HIV negative will be enrolled. At baseline, all enrolled participants will be asked to report sociodemographic characteristics and sexual behaviors; provide a blood sample for HIV, syphilis, and herpes simplex virus type 2 testing; and provide a penile swab for human papillomavirus testing. Participants will be randomly assigned to the intervention or control group. Those in the intervention group will receive VMMC and undergo a web-based weekly follow-up assessment of postsurgery healing for 6 consecutive weeks. All participants will be tested for HIV at 3-, 6-, 9-, and 12-month follow-ups. All participants will also be asked to report sexual behaviors and undergo repeat herpes simplex virus type 2 and human papillomavirus testing at 6- and 12-month follow-ups. The primary end point is HIV seroconversion. Secondary end points are

XSL•FO
RenderX

the safety and satisfaction with VMMC and the changes in sexual behaviors after VMMC. The grouped censored data will be analyzed by intention-to-treat approach.

Results: Recruitment for the RCT began in August 2020 and continued through July 2022. Data collection is expected to be completed by July 2023, and full data analysis is going to be completed by September 2023.

Conclusions: This study will be the first RCT to assess the efficacy of VMMC in preventing HIV infection among MSM. Results from this trial will provide preliminary evidence for the potential efficacy of VMMC to reduce incident HIV infection among MSM.

KEYWORDS

voluntary medical male circumcision; HIV; men who have sex with men; randomized controlled trial; China

Introduction

Overview

Men who have sex with men (MSM) are at high risk for HIV infection. Evidence-based HIV preventive measures for MSM include behavioral interventions (eg, condom use) and biomedical interventions (eg, preexposure prophylaxis [PrEP] and postexposure prophylaxis [PEP]). Condoms are highly effective in preventing HIV transmission, but the prevalence of condomless sex remains high among MSM [1,2]. HIV PrEP reduces risk of HIV infection, but uptake among MSM is limited [3]. The effectiveness of HIV PEP is constrained by lack of awareness, limited availability of PEP services, and poor adherence to medications and clinic follow-ups, particularly in resource-limited settings [4-6]. Innovative, effective, and acceptable HIV prevention measures are needed to complement and expand existing prevention strategies among MSM.

Voluntary medical male circumcision (VMMC) may protect men from HIV infection by reducing mucosal surface area and the concentration of HIV target cells in the penis [7,8]. Three large randomized controlled trials (RCTs) in Africa found that VMMC reduced the risk of HIV infection by 50%-60% among heterosexual men [9-11]. Debate remains on whether VMMC can effectively prevent HIV acquisition among MSM. Two systematic reviews and meta-analyses in 2008 and 2011 [12,13] showed that there was no statistically significant association between VMMC and HIV acquisition among MSM. However, new evidence has emerged over the past 10 years. A 2018 meta-analysis found that VMMC may reduce risk of HIV infection by 20% among MSM [14]. Similarly, a 2019 systematic review and meta-analysis of 67 observational studies [15] reported that VMMC was associated with a 23% lower odds of HIV infection among MSM overall and 42% lower odds of HIV among MSM in low- and middle-income countries. Furthermore, VMMC was associated with a 16% lower odds of herpes simplex virus and a 29% lower odds of penile human papillomavirus (HPV) infection among MSM living with HIV [15]. Another systematic review in 2019 [16] found VMMC was associated with 7% and 38% lower odds of HIV infection among MSM overall and MSM in Asia and Africa, respectively. These systematic reviews found that no previous RCTs have evaluated the impact of circumcision on HIV acquisition among MSM. Interventional trials are needed to confirm the findings of previous observational studies.

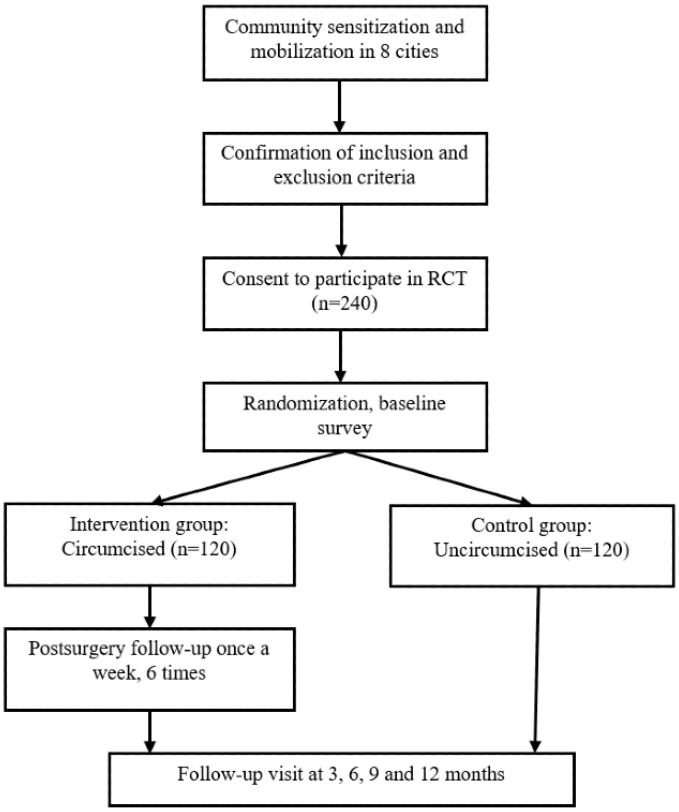
Sexual position preference may have a significant impact on the efficacy of VMMC to reduce HIV infection among MSM. Men who practice insertive anal sex may benefit more from VMMC than those who practice receptive anal sex. Subanalysis in a 2019 systematic review and meta-analysis [15] found that MSM who primarily engage in insertive anal sex had a 56% lower odds of HIV infection, a stronger association compared to what was found among MSM overall. In China, 70% of MSM practice either exclusively insertive anal sex or both insertive and receptive anal sex [17,18]. Thus, VMMC has the potential to become an important HIV prevention option for most MSM in China.

Only 15.3% of MSM in China have undergone circumcision [19]. This proportion is lower than the global average of 37%-39% [20]. Mainstream social conventions and religious practice in China are neutral on circumcision, neither promoting nor forbidding the procedure. Implementing a VMMC intervention in China should not be significantly hindered by Chinese traditions or cultural values. Other potentially effective interventions, such as PrEP, are still in promotion phase in China, which is impeded by high cost, low accessibility, and stigma among MSM [21,22]. As for consistent condom use, the rate of its use among MSM remains relatively low, approximately 50% [23,24]. Hence, it is essential to determine an alternative HIV prevention strategy in China. Given the high proportion of Chinese MSM who are uncircumcised and the need for alternative HIV prevention strategies in China, it is theoretically feasible to conduct an RCT to evaluate the efficacy of VMMC to reduce incident HIV infection among MSM in China. This RCT could provide valuable information to inform HIV prevention policy as well as future mathematical models and additional clinical trials of VMMC.

Objectives

The primary objective of this study is to assess the efficacy of VMMC for preventing HIV acquisition among MSM who primarily engage in insertive anal sex. The secondary objectives are to assess (1) the safety of and satisfaction with surgical VMMC among MSM; (2) changes in reported sexual risk behaviors after circumcision among MSM; and (3) the efficacy

XSL•FO
RenderX



of VMMC for preventing sexually transmitted infections (STIs), including herpes simplex virus type 2 (HSV-2), syphilis, and penile HPV among MSM. Our hypothesis is that VMMC could reduce the risk of HIV infection among MSM.

Methods

Study Design

This is a multicenter RCT to evaluate the efficacy of VMMC on incident HIV infection among MSM in China over a 12-month follow-up period (Figure 1).

Figure 1. The flow chat of the CoM (circumcision of men who have sex with men) Study. RCT: randomized controlled trial.

Study Setting

The VMMC and incident HIV infection among MSM in China (circumcision of men who have sex with men [CoM] Study) will be conducted in 8 cities in Mainland China: Beijing, Tianjin, Qingdao, Chongqing, Shenzhen, Guangzhou, Foshan, and Luzhou (Table 1).

This study began on August 1, 2020, and is scheduled to be completed by September 31, 2023. The study has 3 phases: eligibility screening, enrollment, and follow-up (Table 2).

[a]For participants in the intervention group, they will be formally enrolled after completing the circumcision. There is a maximum waiting period of 3 months for surgery and a 6-week postoperative recovery period before formal follow-up phase. For participants in the control group, they will remain uncircumcised at enrollment and follow-up, and they will enter the formal follow-up phase after completing the enrollment and baseline questionnaire.

[b]STIs include herpes simplex virus type 2, syphilis, and penile human papillomavirus.

Interventions

VMMC is the intervention to be evaluated in this study. Men in the intervention group will undergo VMMC within 3 months of randomization, and they could choose one of 2 types of circumcision (disposable circumcision stapler surgery and conventional surgical procedure), while those in the control group will remain uncircumcised during the follow-up. All men will be followed for 12 months.

Study Outcomes

The primary outcome is HIV incidence, comparing the intervention and control groups. Secondary outcomes are the safety and satisfaction with VMMC; changes in sexual behaviors after VMMC will also be evaluated. The penile HPV incidence, clearance, and persistent infection; HSV-2 incidence; and syphilis incidence are compared in both groups.

Eligibility Criteria

Individuals who meet all of the following criteria are eligible for enrolment in the CoM Study: (1) aged 18-49 years; (2) assigned male sex at birth; (3) ≥2 male sex partners and ≥10 episodes of anal sex in the past 6 months; (4) practiced insertive role in ≥7 of the last 10 episodes of anal sex with male sex partners; (5) HIV negative; (6) has foreskin that covers over half the glans when the penis is not erectile; (7) is willing to undergo VMMC; (8) resides in the city where a study site is located and has no plan to relocate in the next 12 months; (9) is willing to provide a blood sample and exfoliated penile swabs to test for HIV, HSV-2, syphilis, and HPV; and (10) is able to provide informed consent. Men who are already circumcised or enrolled in other biomedical HIV intervention studies will be excluded. Men who have been diagnosed with a bleeding disorder or have other medical contraindications to VMMC will also be excluded.

Patient and Public Involvement

There was collaboration with MSM community–based organizations staff who were not involved in the study, to ensure study processes were well integrated into these settings. Patients were not involved in the design of the study.

Participant Recruitment and Enrollment

As the distribution of our target population unknown and MSM in China are a hard-to-reach population, we will use convenience sampling and snowball sampling to recruit participants. A public account on WeChat (a multi-purpose instant messaging app developed by Tencent, with over 1 billion active monthly users) will be used to communicate with participants. Recruitment, enrollment, provision of health education, and participant follow-up will be accomplished through WeChat. This RCT will also recruit and enroll potential participants in collaboration with local MSM community–based organizations by using their organizational WeChat accounts and in-person outreach activities. An offline survey will be carried out at MSM community–based organizations and the department of dermatology at participating hospitals.

A QR code which links to an online screening questionnaire will be included in recruitment materials. Recruitment materials will include paper materials (eg, posters, folding pages, table tent cards, and business cards) and video materials (ie, a 2-minute enrollment video with a brief introduction and a 15-minute enrollment video with detailed information). Paper and video materials will include summaries of the following: (1) current state of research on efficacy of VMMC to prevent HIV infection; (2) potential benefits of VMMC; and (3) potential

XSL•FO
RenderX

risks of VMMC. Potential participants will be invited to scan the QR code included in these paper or video materials and then complete a web-based screening questionnaire with preprogramed logic to assess eligibility.

Eligible men will be invited to participate in this study. Men who agree to participate will receive a face-to-face introduction to the CoM Study by a trained investigator at the study site. Questions about the study will be answered by these investigators during these introductions. For men who are willing to undergo VMMC, HIV rapid testing will be conducted 1 month before enrollment and at enrollment.

Randomization and Follow-Up

Eligible men will be randomized using a 1:1 allocation ratio to the intervention and control groups. Randomization lists for each study site have been pregenerated by researchers. Each envelope with a unique number will be assigned for 1 allocation sequence, into which a card with grouping information will be put before sealing. Trained investigators at each study site will assign an envelope to each participant according to the order of the participant's arrival. Participants cannot be blinded due to the nature of the intervention. After randomization, trained researchers will provide HIV prevention counseling to participants in both groups, including promotion of consistent condom use and regular HIV testing.

Participants randomized to the intervention group will be encouraged to complete VMMC within 1 week of enrollment. Time to VMMC can be extended up to 3 months after enrollment on a case-by-case basis. We recommend participants to undergo VMMC at a secondary or higher-level medical center of their own choice. Although the clinical VMMC activities are not part of study procedures, a research assistant would accompany the participants to the hospital to undergo the circumcision. This trial will provide a surgical subsidy of CNY 1000 (US $160). If participants do not complete VMMC within 1 month of enrollment, a text message reminder will be sent. The surgeon will check the condition of the foreskin of participants before the operation to determine if surgery is necessary. Men in the intervention group will be advised to abstain from sex for 6 weeks after undergoing VMMC, and the 12-month follow-up period will begin after this 6-week period of abstinence. If men resume sexual behaviors earlier than 6 weeks after VMMC, then the 12-month follow-up period will begin at the time of their first sexual encounter after VMMC.

Men randomized to the control group will complete the baseline survey after enrollment. The 12-month follow-up period for the control group will begin immediately after completing the baseline survey. At the end of the 12-month follow up period, men in the control group will be offered a CNY 1000 (US $160) subsidy to undergo VMMC.

Study Measures

The baseline and follow-up surveys will collect information on sociodemographic characteristics (including age, ethnic, educational background, marital status, and monthly individual income) and sexual behaviors (including the number of male and female sex partners, frequency of vaginal or anal sex, condom use, and HIV-positive sex partners) for all enrollment participants. Follow-up surveys will be completed at 6- and 12-month follow-ups. Men randomized to receive VMMC will also be asked to complete weekly follow-up surveys for 6 weeks after VMMC to monitor for postsurgical complications, including pain, poor surgical site wound healing or infection, and premature resumption of sexual behaviors. If an adverse event is reported, trained investigators will contact participants and provide advice on whether further clinical evaluation is needed.

Fingertip blood drop samples will be collected at baseline as well as 3-, 6-, 9- and 12-month follow-ups and tested for HIV using an HIV rapid test. Venous blood samples collected at baseline as well as 6- and 12-month follow-ups will be tested for HIV, syphilis, and HSV-2. Penile swab samples will be collected at baseline as well as 6- and 12-month follow-ups and tested for HPV.

HIV rapid testing will detect antibodies against HIV-specific antigens using a solid-phase immunochromatographic assay (SD Bioline HIV/Syphilis Duo test; Standard Diagnostics Inc), and these assays will be performed at study sites. Venous blood samples will be tested for HIV using a chemiluminescent microparticle immunoassay (Anti-HIV CLIA Microparticles; Autobio Diagnostics Co) performed at Guangzhou Hybribio Medical Laboratory Limited. If a participant's sample is found to have a positive result for HIV, we will recollect a venous blood sample from that participant and perform a confirmatory Western blot test at the local Centers for Disease Control and Prevention. Except for HIV, laboratory assays will be applied for syphilis, HSV-2, and HPV test. HPV DNA testing and genotyping was performed using the 37 HPV GenoArray Diagnostic Kit (Hybribio; Chaozhou, China). Syphilis serological tests will be performed using tolulized red unheated serum test and treponema pallidum particle assay. Detection of HSV-2 immunoglobulin G and HSV-2 immunoglobulin M in blood samples are based on a chemiluminescent microparticle immunoassay. Participants who test positive for pathogens or antibodies will be offered STI counseling and referred to a hospital for treatment.

Participation Incentives and Follow-Up Reminders

Web-based educational materials on sexual health will be regularly posted for all participants to read via WeChat by the CoM Study's official WeChat account. Short voluntary quizzes will be included at the end of each posted educational material, and participants who complete these quizzes will receive a CNY 2 or CNY 5 (US $0.3 or US $0.8) reimbursement. Each participant will also receive a CNY 50 (US $8) reimbursement each time they complete a questionnaire and provide a blood sample for HIV and STI testing. Participants who complete the surgery according to the study procedures will receive CNY 1000 (US $160) surgery subsidy. In addition, participants will receive an additional CNY 500 (US $80) subsidy after completing all required follow-up surveys as well as HIV and STI testing.

Reminders to complete follow-up surveys will be sent to all enrolled men via WeChat. If follow-up surveys are not completed on time, investigators will contact enrolled participants with additional reminders each week for up to 5

XSL•FO
RenderX

weeks to encourage participation and minimize loss to follow-up.

Data Collection and Management

All data will be collected using Wenjuanxing (Ranxing Information Technology Co, Ltd [25]), a web-based questionnaire platform. Several quality-control questions will be included in the study questionnaires, and the consistency of answers will be examined by trained investigators. Information concerning identification, eligibility, baseline surveys, intervention, and follow-up surveys will be recorded in case record form. Adverse events will also be recorded. Identity information will be collected for allowance distribution purpose only, which will not be used for statistical analysis or intended for information leakage. Only study staff will be able access the study database, which will be protected with a unique log-in password that will be updated monthly to maximize data safety. The data safety monitoring committee (DSMC) of the CoM Study will be comprised of 2 statisticians, 2 clinicians, and key study investigators. The DSMC will supervise procedures, including data quality control, data integrity, data security, data sharing, and data analysis. All investigators have completed standard operating procedure training and data management training.

Sample Size

The sample size is calculated based on the supposed protective rate of circumcision. Studies have shown that HIV incidence among MSM was 12.5/100 person-years in Chongqing [26], 15.5/100 [27] and 10.3/100 person-years [28] in Shenyang, and 15.6/100 person-years in 8 cities in China [29]. Considering participants in the CoM Study predominantly practiced insertive anal sex, consequently with lower HIV infection risk compared with those who primarily practiced receptive role, and that the effect of VMMC may be higher among men who primarily or exclusively practice the insertive anal intercourse than MSM overall, we suppose HIV incidence among MSM to be 10/100 person-years and protective rate of circumcision to be 80%, and thus, HIV incidence would be 2/100 person-years in the intervention group. A target sample size of 240 (120 in each group) is set to achieve 80% power at 1-sided α=.10, with 10% lost to follow-up.

Statistical Analysis

All data will be analyzed based on the principle of intention to treat. We will assess the type of missing data and assess attrition effects by testing whether there are systematic differences between dropouts and nondropouts. Key baseline characteristics will be examined between the intervention and control groups to ensure they are balanced; if not, subsequent analyses will assess whether these characteristics are confounding factors of the intervention.

For continuous variables, we will calculate means and SDs, and means will be compared with 2-sample *t* tests or Mann-Whitney tests. For categorical variables, proportions will be compared with chi-square tests or Fisher exact tests. In addition, we assume that HIV status at the end of follow-ups is grouped censored data and suitable for exponential, proportional hazards model with constant baseline hazard. Therefore, differences between the intervention and the control groups will be identified with a Poisson regression model, which includes observed covariates (ie, HIV risk behaviors, such as condom use, number of sexual partners, frequency of insertive anal sex, and HIV-positive sexual partners as well as demographic variables, such as age, education level, and income). Incidence rates will be calculated for each outcome in the 2 groups. Moreover, the incidence rate ratios and their 95% CIs will be estimated using the Poisson regression model. For all the outcome variables, including the primary (ie, HIV incidence) and secondary (ie, penile HPV incidence, clearance and persistent infection, HSV-2 incidence, and syphilis incidence) outcomes of interest, the aforementioned analyses will be repeated across all the visits (ie, 6- and 12-months follow-ups).

The changes in sexual behaviors after VMMC over time between the intervention and the control groups will be compared with the generalized estimating equations. For outcomes of VMMC safety and satisfaction among circumcised MSM, we will perform the same statistical description and comparative analyses described as above.

A 2-sided *P* value lower than .05 will be used to infer statistically significant difference. All the statistical analyses will be performed with R software (version 4.2.1; R Core Team).

Ethics Approval

This study has obtained ethics approval from Ethical Review Committee for Biomedical Research of School of Public Health (Shenzhen), Sun Yat-sen University (SYSU-PHS-2020041) and Ethics Committee of Beijing Youan Hospital, Capital Medical University (2020-049). All participants will provide written consent prior to taking part in the study.

Results

Participant recruitment began in August 2020 and continued through July 2022. We expect that follow-up phase and data collection will be completed by July 2023, and primary data analyses will be completed by September 2023. The study findings will be submitted for presentation at relevant international conferences and for publication in a peer-reviewed journal.

Discussion

Principal Findings

The CoM Study is an RCT to evaluate the efficacy of VMMC to prevent incident HIV infection among MSM in China. MSM who primarily practice insertive anal sex and are willing to undergo VMMC will be recruited using promotional materials disseminated through web-based platforms and community-based organizations. Participants will be randomly assigned to receive or not receive VMMC and then will be followed for a 12-month period to assess incident HIV infection. As an RCT with limited observed person-years, priority will be given to MSM with high-risk sexual behaviors. Follow-up for MSM randomized to receive VMMC will start after a 6-week postsurgical follow-up period to ensure men in the intervention and control groups have comparable opportunity to acquire HIV

XSL•FO
RenderX

after enrollment. HIV testing will be conducted every 3 months; it helps to detect acute HIV infection. Findings from this trial will provide preliminary RCT evidence on whether VMMC can effectively prevent HIV among MSM.

Limitations

The CoM Study will have several limitations. First, because the 8 study sites are located in different parts of Mainland China, we cannot ensure that VMMC will be performed in a uniform manner for all men randomized to the intervention group. We will provide men in the intervention group with a list of hospitals that provide standard VMMC services. But men will be able to choose a hospital at their own discretion. Second, MSM who undergo VMMC may experience surgical site complications, particularly when they resume insertive anal sex. Men who have recently undergone VMMC may therefore chose to avoid insertive anal sex. This may increase their frequency of receptive anal sex, and thereby, increase their risk of HIV infection. At enrollment, participants will be provided with detailed sexual health consultations to reduce sexual intercourse during abstinence. Third, sexual health behaviors will be assessed by self-report, and therefore, may be affected by recall and social desirability biases.

Conclusions

To achieve the sustainable development goal of ending the AIDS epidemic as a public health threat by 2030, more viable HIV prevention strategies are urgently needed. The CoM Study proposes VMMC as an intervention and assesses its preliminary efficacy to prevent incident HIV among MSM. Results from this study are expected to offer reliable data in supporting the development of mathematical models, which aim to estimate the effect of VMMC on HIV risk reduction among MSM under various conditions and assumptions.

Abstract

Background: Tobacco use continues to be a leading preventable cause of death and disease in the United States, accounting for >480,000 deaths each year. Although treatments for tobacco use are effective for many, there is substantial variability in outcomes, and these approaches are not effective for all individuals seeking to quit smoking cigarettes. New, effective therapeutic approaches are needed to meet the preferences of people who want to stop smoking. Guided imagery (GI) is a mind-body technique that involves the guided visualization of specific mental images, which is enhanced with other sensory modalities and emotions. Preliminary evidence provides initial support for the use of GI as a treatment for cigarette smoking. Meta-analyses have shown that standard treatment for cigarette smoking delivered over the telephone via quitlines is effective. A telephone-based intervention that uses GI might provide another effective treatment option and increase the reach and effectiveness of quitlines.

Objective: This study aims to test the efficacy of *Be Smoke Free*, a telephone-delivered GI treatment for smoking cessation.

Methods: This multisite randomized clinical trial (RCT) will compare a novel telephone-delivered GI tobacco cessation treatment with a standard evidence-based behavioral treatment. The study will be conducted over 5 years. In phase 1, we refined protocols and procedures for the New York State and West Virginia sites for use in the RCT. During phase 2, we will conduct an RCT with 1200 participants: 600 (50%) recruited via quitlines and 600 (50%) recruited via population-based methods. Participants will be randomly assigned to either the GI condition or the behavioral condition; both treatments will be delivered by trained study coaches located at the University of Arizona. Assessments will be conducted at baseline and 3 and 6 months after enrollment by University of Arizona research staff. The primary outcome will be self-reported 30-day point prevalence abstinence 6 months after enrollment. Secondary outcomes include biochemically verified 7-day point prevalence abstinence 6 months after enrollment.

Results: Recruitment in West Virginia and New York began in October 2022. As of March 31, 2023, a total of 242 participants had been enrolled. Follow-up assessments began in November 2022. As of March 31, 2023, of the 118 eligible participants, 97 (82.2%) had completed the 3-month assessment, and 93% (26/28) of eligible participants had completed the 6-month assessment. Biochemical verification and qualitative interviews began in April 2023. Recruitment will continue through 2025 and follow-up assessments through 2026. Primary results are expected to be published in 2027.

Conclusions: The *Be Smoke Free* study is a first-of-its-kind RCT that incorporates GI into telephone-based tobacco cessation treatment. If successful, *Be Smoke Free* will have substantial benefits for the long-term health of people who use tobacco across the United States.

Introduction

Background

Tobacco use continues to be a leading preventable cause of death and disease in the United States, accounting for >480,000 deaths each year, including 41,000 deaths from secondhand smoke exposure [1,2]. The annual economic cost of tobacco use in the United States was US $332 billion in 2014 and increases every year [2,3]. Moreover, tobacco use aligns with other systemic health inequities in the United States [1,4]. The prevalence of tobacco use among Medicaid beneficiaries and individuals of lower socioeconomic status is nearly twice that among the general population [1,4]. Importantly, however, tobacco cessation results in a nearly universal improvement in health.

Although evidence-based treatments for tobacco use are effective for many, there are multiple limitations, including a substantial variability in outcomes and limited reach. Current evidence-based approaches are not effective for every individual seeking to stop smoking [2,5]. Quitlines have made standard cognitive behavioral treatment widely accessible, but they reach fewer than 1% of the individuals who smoke cigarettes annually. In addition, evidence suggests that at least some of the individuals who smoke do not wish to engage in *standard* cognitive behavioral treatment and would prefer a more holistic or integrative approach (ie, combining complementary or alternative and standard treatments) [6-9]. New therapeutic approaches are needed to attract, engage, and retain individual tobacco users in treatment for smoking cessation and ultimately increase the number of individuals who achieve long-term abstinence from tobacco use.

A large proportion of the American population uses integrative health approaches, including mind-body techniques, in addition to, or instead of, conventional treatment [5]. Guided imagery (GI) is a mind-body technique that involves the visualization of mental images. GI is an alternative way to develop effective strategies to quit smoking, such as developing awareness and directing attention to one's thoughts, feelings, situational cues or triggers, and urges. GI can effectively assist individuals to quit or reduce smoking [6-8]. A randomized controlled trial (RCT) with 779 adult smokers compared the use of bupropion versus brief psychotherapy that included GI intended to enhance self-management, decidedness, assertiveness, self-determination, and self-assurance [8]. Intent-to-treat analysis showed 12-month abstinence rates of 39.1% and 12.3% for the psychotherapy and bupropion groups, respectively [8]. In another RCT, 33 adults were taught mindfulness and GI and encouraged to practice at home [9]. The results showed that home practice predicted reduced cigarette use over 4 weeks [9]. In a pilot RCT, a GI program for smoking cessation was found to be feasible and improved intermediate abstinence measures [10]. In a small trial that compared education and counseling with education and counseling plus GI training, abstinence rates were 12% and 26%, respectively [7]. Finally, our teams' preliminary evidence provides strong support for the use of GI for smoking cessation [11,12]. These findings support the potential efficacy of GI for smoking cessation. In addition, we are proposing to deliver a GI intervention in a low-cost highly scalable way (ie, by telephone). To date, no studies have established the efficacy of an integrative GI tobacco cessation treatment delivered by telephone.

Several meta-analytic reviews have shown that proactive telephone-based tobacco cessation services are an effective way to deliver treatment for tobacco dependence [13-15]. Telephone quitlines are efficient, centralized, and a highly scalable way for individuals to access tobacco treatment in all 50 states plus the District of Columbia, Guam, and Puerto Rico. Quitlines are the largest tobacco treatment network in the United States [16,17]. Researchers have demonstrated the cost-effectiveness of telephone quitlines in the United States and Europe over the past 25 years [3,13,15,18]. However, quitlines have limited reach into the population of people who use tobacco in the United States. According to a recent study, most US quitlines reach only 1.1% of this population [19]. This situation has prompted many state sponsors to try to improve their reach by increasing the types of evidence-based treatment offered to tobacco users. Evidence-based integrative treatment approaches that are appealing to those individuals not interested in standard behavioral approaches may increase the reach and effectiveness of quitlines. Using telephone technology enables access to a wide range of people who smoke because it does not rely on having an internet connection or competence in using more advanced technology. According to a 2019 survey [20], about 96% of Americans own a mobile phone of some kind; thus, our intervention is highly accessible and scalable.

Objectives

The objective of this RCT is to test the efficacy of *Be Smoke Free*, a telephone-delivered integrative GI treatment for smoking cessation compared with a standard, evidence-based behavioral treatment. The specific aims and hypotheses of the study are described in the following subsections.

Aim 1

We will test the efficacy of a telephone-delivered integrative GI tobacco cessation treatment versus an evidence-based behavioral treatment on self-reported 30-day abstinence 6 months after enrollment (T2). Secondary outcomes are self-reported and biochemically verified 7-day point prevalence smoking abstinence at T2.

XSL•FO
RenderX

Hypothesis 1

Participants in the GI condition (GIC) will demonstrate 10% higher quit rates than those in the behavioral condition (BC).

Aim 2

We will conduct dose-response analyses on the effect of GIC adherence (measured by self-reported minutes of intervention use per week, the number of times GI skills practiced per week, the number of sessions attended, and coach-rated participant engagement in sessions) on abstinence at 6 months. We will also examine effects of the GIC and BC on tobacco use for those participants who do not report abstinence at 6 months.

Hypothesis 2A

GIC participants who are more adherent to the intervention will have higher rates of abstinence.

Hypothesis 2B

GIC and BC participants who do not report abstinence will report statistically significant reductions in tobacco use.

Aim 3

We will conduct subgroup analyses of moderators (eg, recruitment method, location, sex, race and ethnicity, and the level of tobacco dependence) on tobacco cessation outcomes at 6 months and explore subgroup differences in participants using a mixed methods approach (eg, surveys and in-depth interviews).

Project Impact

The project has the potential for high overall impact. Should this approach become readily available to quitlines as an evidence-based treatment, it will provide a sustainable and powerful alternative to the traditional treatment options available throughout the United States. There have been few innovations in quitline treatment. Thus, increasing the treatment options might also serve to increase the reach of quitlines into the tobacco-using population.

Methods

Overview

This 5-year, 2-group RCT will test the efficacy of the integrative GI treatment versus an evidence-based behavioral treatment. Participants will be recruited from 3 states (Arizona, New York State, and West Virginia). We will randomize 1200 participants to either the GIC or the BC: 600 (50%) participants will be recruited through the quitlines (n=200, 33.3%, per quitline) and 600 (50%) through population-based methods (eg, social media, earned media, local organizations, and health care providers) to ensure that we obtain a representative sample of people who smoke. Assessments will occur at baseline (T0), 3 months after enrollment (T1), and T2. The research team will deliver the GIC and BC protocols, coordinate and conduct all assessments, and perform all data analyses at the University of Arizona. The primary outcome will be self-reported 30-day abstinence at T2. Secondary outcomes will be self-reported and biochemically verified (expired carbon monoxide [CO]) 7-day point prevalence abstinence at 6 months.

This study is being conducted in 2 phases: during phase 1, we refined protocols and procedures for the New York State and West Virginia sites for use in the RCT. During phase 2, we are conducting the RCT.

Phase 1: Revisions to Protocols and Procedures

We worked with our collaborating quitlines to revise procedures for recruitment, screening, data transfer, and reporting for half of our sample. Each of our participating sites provides different services and uses different procedures for screening callers. This required us to tailor our study recruitment, screening protocols, and procedures for each site. We also worked with each quitline to identify existing networks (eg, health departments and community organizations) to add to our population-based recruitment methods for each state. In addition, we tailored the methods for transferring participant data from each quitline to our project staff in a Health Insurance Portability and Accountability Act (HIPAA)–compliant and secure manner. Finally, we worked with each site to determine the process for providing regular reports on client contacts and tracking callers transferred to study staff. Noneligible callers who are transferred by project staff to our study will be transferred back to their respective quitlines so that they may return for quitline services before study completion. We worked with staff at each site to learn about their unique structures and tailor all study processes and materials to fit both the needs of the quitline and our study. Half of our sample will be recruited through the quitlines.

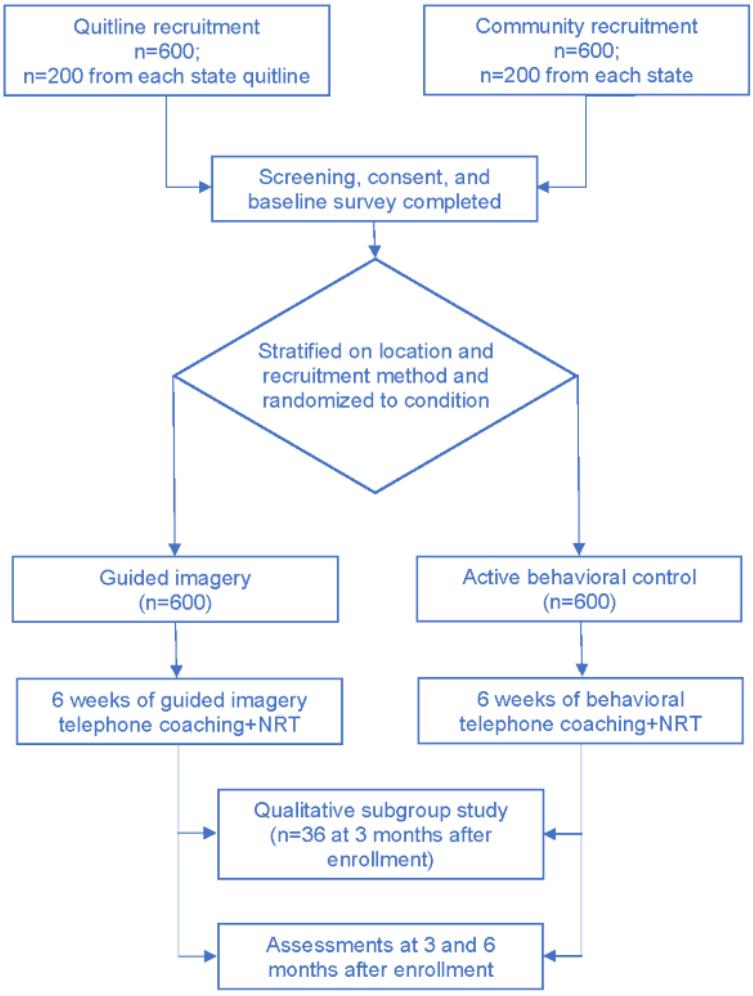
We will use population-based methods (eg, social media paid advertising, earned media, and community contacts) for the other half of the sample. The materials and methods created during the feasibility trial were designed for use in Arizona [21]. Therefore, they were modified for use in the other states participating in this study. These states serve different demographics of tobacco users who may also need to be reached in different ways (eg, rural vs urban and print vs web based). We worked with our collaborators in each state to identify changes that needed to be made to the text and graphics in our recruitment advertisements and materials (eg, wording and images for advertisements placed on social media and different photographs representing tobacco users in each state for use in print materials). We convened a community advisory board (CAB) that included key informants from each state (eg, members of community health organizations identified by our collaborators) to obtain information using semistructured questionnaires. Interviews or group interviews were recorded and transcribed. The study team analyzed the comments and developed a plan for refining the recruitment methods and materials for each state.

In consultation with our collaborating quitlines, we made minor refinements to our study protocols and corresponding participant materials to address the specific needs of people who use tobacco in different states; for example, although all participants will identify their primary tobacco use as cigarette smoking, a proportion will also use other tobacco products (eg, e-cigarettes or vaping products and smokeless tobacco). The use of these other tobacco products varies widely by state. The prevalence of smokeless tobacco use is very low in Arizona but much higher in West Virginia (2.8% vs 8.9%, respectively) [22]. Therefore,

XSL•FO
RenderX

we have included additional information in the protocols to address secondary smokeless tobacco use. On the basis of the information and feedback we received from each participating site, we made final changes to our protocols, which were programmed into REDCap (Research Electronic Data Capture; Vanderbilt University). Using REDCap allows our coaches to consistently deliver the protocol for each condition across participants and collect data on each session. For this RCT, we used the same REDCap system developed under the feasibility trial.

On the basis of changes to the study protocols, we made corresponding refinements to the coach training program and coach materials. Information was added regarding regional differences in smoking and other tobacco use patterns, culturally responsive counseling for specific racial and ethnic groups, issues specific to rural versus urban tobacco users, and other state-specific differences that the coaches may encounter when working with participants across our participating states.



We hired 4 coaches (2 for each condition) to deliver one of the study protocols at the University of Arizona. The training of the intervention coaches included a 2-part workshop, individual and group exercises designed to provide practical experience that resulted in competency to deliver the protocols and achieve a positive therapeutic alliance, and ongoing supervision designed to solve problems and maintain implementation fidelity. The workshops for both conditions involved the cognitive and motivational underpinnings of each program. The BC workshop focused solely on behavioral strategies for motivating and assisting tobacco users to quit and the use of nicotine replacement therapy for minimizing withdrawal symptoms. The GIC workshop included all content in the BC workshop plus the use of GI, including how to create vivid and evocative GI scripts and record them as audio files for participants assigned to this condition.

Phase 2: RCT

Study Design

This 2-group RCT will test the efficacy of the integrative GIC versus the evidence-based BC. Participants will be recruited from 3 states (Arizona, New York State, and West Virginia). We will randomize 1200 participants to either the GIC or the BC. Of these 1200 participants, 600 (50%) will be recruited through the quitlines (n=200, 33.3%, per quitline) and 600 (50%) through population-based methods (eg, social media, earned media, local organizations, and health care providers) to ensure that we obtain a representative sample of smokers (Figure 1). Assessments will occur at T0, T1, and T2. The research team will deliver the intervention and control protocols, coordinate and conduct all assessments, and perform all data analyses at the University of Arizona.

Figure 1. Study design. NRT: nicotine replacement therapy.

XSL•FO
RenderX

RCT Protocol

The study protocol was adapted from our existing protocol [12,23]. Participant recruitment occurs during years 2 to 4 of the project, after coaches are trained and competent in the GIC and BC protocols. All screening, enrollment, and treatment activities are conducted by telephone, email, and SMS text message by research staff at the University of Arizona.

Recruitment occurs through quitlines and population-based activities. Quitline staff prescreen potential participants and describe the study to callers. Quitline staff collect eligible and interested callers' contact information, including their telephone number, and transfer these data to project staff located at the University of Arizona. For population-based activities, potential participants recruited through population-based methods contact project staff.

For both recruitment methods, project staff contact interested callers within 1 business day. Project staff provide a detailed description of the study. Callers who are interested in participating are screened again for eligibility by project staff. Staff then consent eligible callers and administer the T0 survey or send survey links (REDCap) by SMS text message or email to participants who choose to complete the forms themselves. Those participants who complete the T0 survey are randomly assigned to the GIC or the BC via REDCap. Noneligible or noninterested callers are transferred back to their state quitline. Randomized callers are contacted by their study coach within 2 business days. Once callers complete their first session, they are considered enrolled participants in the study. All coaches are located at the University of Arizona. Participants in each condition receive 6 sessions, lasting from 10 to 60 minutes, depending on the condition and session topic.

All session activities and interactions with participants are managed and recorded in REDCap. Coach competencies and protocol fidelity are routinely monitored by the investigators. Process data (ie, coach notes and in-depth interviews) will be collected during the 6-week program and at T1.

Participants are assessed via REDCap or telephone (for nonresponders) at T1 and T2 by project staff. A subsample of participants (36/1200, 3%) will be recruited to participate in surveys and in-depth interviews to explore subgroup differences in intervention use, response, and satisfaction. Participants will receive up to US $100 (in gift cards) for their efforts: US $10 for completing the T0 assessment, US $15 for the 3-month assessment, US $25 for the 6-month assessment, and US $50 for the biochemical verification. Participants chosen for the qualitative interviews will receive a US $25 gift card.

Participant Recruitment, Eligibility, Enrollment, and Randomization

Recruitment Methods

Participants are recruited from two populations: (1) individuals who contact one of our collaborating quitlines; or (2) individuals who smoke in Arizona, New York State, or West Virginia. Different recruitment methods will be used to recruit participants from each population. For the quitline population, we monitor quitline recruitment—an increase or decrease in the number of days per week that we recruit based on the volume of incoming calls. For population-based recruitment, we send out press releases describing the study, post on social media sites, network with our contacts in each state, and place paid advertisements, as needed. We monitor recruitment weekly and make adjustments to recruitment procedures to ensure that we are meeting our recruitment goals. We do not foresee any problems recruiting our sample according to the timeline. However, we have an additional 3 months in which we can extend our recruitment period if needed.

Eligibility Criteria

The inclusion criteria are as follows: primary tobacco use is smoking; smoke daily for the last 30 days; aged at least 18 years; speak English; have a smartphone with SMS text messaging; do not take antipsychotic medications or experience symptoms of psychosis; have not received quitline coaching for the previous 12 months; agree to telephone coaching and SMS text message reminders; can download an mp3 or mp4 file; live in Arizona, New York State, or West Virginia; no current use of any tobacco cessation program or medication; and only 1 participant per household.

Enrollment

Potential participants are screened by trained study staff over the telephone or via REDCap. Eligible participants complete the T0 survey and informed consent over the telephone or on REDCap. Participants download the consent form from REDCap or request that study staff send them a hard copy. Study staff send condition-specific program materials to randomized participants. Ineligible callers are transferred back to the quitline in their state of residence using a *warm handoff* (ie, study staff call the quitline, talk to enrollment staff, and then transfer the caller directly to the quitline enrollment staff) or a HIPAA-compliant electronic process (eg, encrypted email).

Randomization

Participants are stratified by state and method of recruitment (ie, quitline or community) and then randomized automatically in REDCap using a randomization table created by the study biostatistician. Statistical software was used to create a randomized-block allocation to the GIC or the BC, stratified by recruitment method and location.

Measures

Overview

All measures and the time points at which they are administered are displayed in Table 1. All these measures have been used in our previous work [11,12,23-25].

XSL•FO
RenderX

Table 1. Measures by time point for both conditions.

	T0[a]	T1[b]	T2[c]
Demographics	✓		
Tobacco use	✓	✓	✓
Dependence	✓	✓	✓
Cravings	✓	✓	✓
Self-efficacy	✓	✓	✓
Expectancy and credibility	✓	✓	✓
VVIQ[d]	✓	✓	✓
Biochemical verification (expired CO[e])			✓
Consumer satisfaction		✓	
Sociotechnical outcomes		✓	

[a]T0: baseline.

[b]T1: 3 months after enrollment.

[c]T2: 6 months after enrollment.

[d]VVIQ: Vividness of Visual Imagery Questionnaire.

[e]CO: carbon monoxide.

Demographics

At T0, we will collect sex, age, race and ethnicity, level of education, insurance, marital status, smokeless tobacco use, cannabis use, chronic health conditions, and prior use of guided mental imagery.

Tobacco Use

At T0, T1, and T2, we will collect tobacco use status using a series of questions that have been standardized and used in previous studies [25-27] and the level of dependence using the Fagerström Tolerance Nicotine Dependence Scale [28].

Self-Efficacy for Quitting

We will measure self-efficacy for quitting smoking with an abbreviated version of the Condiotte and Lichtenstein Confidence Questionnaire [29].

Cravings

All participants will be asked to rate their experience with withdrawal symptoms and cravings using the Nicotine Dependence Syndrome Scale [30] at each follow-up assessment.

Expectancies and Credibility

We will include items adapted from the Borkovec and Nau Treatment Credibility Scale [31] and used in our completed GI mobile app study to measure expectancies and perceived credibility of GI for smoking cessation [11,23]. We will also adapt this measure to assess for expectancies and perceived credibility of the behavioral program used in the BC.

Consumer Satisfaction Measure

At T1, participants will complete a consumer satisfaction survey that we have used in our previous research [25,32] and consists of up to 11 items (using a 5-point Likert scale), measuring overall satisfaction with the program in each study condition, perceived usefulness and relevance of the information, likeability, the level of interest, and the ease of use, as well as whether they would recommend the program to others.

Intervention Adherence

Adherence will be measured by a composite of self-reported minutes of intervention use per week, the number of times skills practiced per week, the number of sessions attended, and coach-rated participant engagement in sessions.

Imagery Vividness and Sociotechnical and Ethical Outcomes

At T0, T1, and T2, we will assess participants' perceptions about the effectiveness of GI for tobacco cessation and their vividness of visual imagery using the Vividness of Visual Imagery Questionnaire, which we have adapted to include images of smoking [33]. At T1, we will examine participants' use of GI during the RCT and their perception of the GI program's *fit* in their lives through semistructured in-depth interviews [34,35].

Biochemical Verification of Tobacco Abstinence

All participants who self-report 7-day abstinence at the 6-month assessment will be selected for biochemical verification. We will (1) use enhanced collection procedures, including contact with participants via telephone before the assessment and via video call during the assessment if participants request assistance; (2) provide an iCO Smokerlyzer expired CO monitor (Bedfont Scientific Limited) to each participant who reports abstinence, a procedure that has been used successfully in previous remote collection studies and has high accuracy [36-38]; and (3) provide an incentive of US $50 for the completion of the biochemical assessment.

Biomarkers

Expired CO will be measured among smokers using iCO Smokerlyzer personal CO monitors. A monitor will be sent to each participant who reports abstinence at the 6-month follow-up assessment. Each participant will exhale into the monitor

XSL•FO
RenderX

according to instructions. Readings are measured in parts per million. A cutoff of <6 parts per million is recommended [39]. The results will be transmitted electronically to the research team.

Collection Procedures

Project staff will contact participants who report abstinence at the 6-month assessment via SMS text message, telephone, or email to schedule a HIPAA-compliant encrypted video call during which biochemical verification will be completed. On the scheduled day of assessment, project staff will verify the participant's identity through the confirmation of their name and face from a photograph ID. During this session, project staff will provide step-by-step instructions for completing biochemical verification.

Outcomes

Our primary outcome is self-reported 30-day abstinence as measured at the 6-month assessment. Secondary outcomes include self-reported 7-day abstinence as well as biochemically verified 7-day abstinence at the 6-month assessment and, for nonquitters, cigarettes smoked per day.

We will also examine the effect of adherence to the GI on cessation outcomes, conduct subgroup analyses of moderators (eg, recruitment method, location, sex, race and ethnicity, and level of dependence) on tobacco cessation outcomes at 6 months, and use a mixed methods approach (eg, surveys and in-depth interviews) to explore subgroup differences in GI adherence and cessation outcomes.

Qualitative Subgroup Study

Subsample participants (36/1200, 3%) will be recruited after a preliminary analysis of the T1 data and based on the following criteria: recruitment method, location, sex, race and ethnicity, and abstinence status. After a quantitative analysis of the subgroups, the team will identify 36 participants through purposive sampling (eg, identifying participants who were recruited through community methods). Only those participants who indicate an interest in participating in in-depth interviews at T1 will be invited to participate in in-depth interviews via telephone, email, or SMS text message. One-hour telephone interviews will be conducted by a member of the study team, who will use a semistructured interview guide to explore the following aspects: program use during the RCT (eg, how did the technology they used influence completion of coaching calls?), their perceptions of program effectiveness for tobacco cessation (eg, how does GI work to help them stop smoking?), and their perception of the program's *fit* in their lives (eg, how does GI integrate or not integrate with their lifestyle?).

Power and Sample Size

A sample size of 1200 participants would yield 90% power to detect a difference in smoking cessation rates between the arms of 10%, assuming a control arm cessation rate of 0.30, a 20% dropout, and a noncontinuity-corrected chi-square test at a 2-tailed significance level of 5%. We believe that 10% is a clinically significant difference with positive public health implications. Although the control arm had a higher cessation rate in our pilot study (50%) [19], we believe that this rate was unusually high. Furthermore, the rates were self-report, not biochemically verified, which are estimated to be 10% to 50% lower [39]. It was also high compared with quitline cessation rates, which are closer to 30% to 40% [15,40].

This sample size also yields 90% power to detect small-to-medium standardized effect sizes for continuous secondary outcomes of Cohen d=0.28, using a Bonferroni correction to account for multiplicity (20 tests), assuming a 2-sided 2-sample t test. Aim 3 will investigate effect modification, which requires approximately 4 times the sample size (or, equivalently, results in a larger detectable effect size) [41]. Assuming that a subgroup of interest makes up 50% of the sample, we have 90% power to detect a difference in cessation rates of 0.141 and 80% to 90% power to detect standardized effect sizes of 0.26 to 0.30, assuming no multiple testing correction. We recognize that the inputs to these calculations are estimates only.

Table 2 displays a sensitivity analysis, showing power for control arm cessation rates of 0.20 and 0.40, dropout rates of 20% to 40% (typical range for cessation trials), and differences of 0.10 to 0.15, showing ample power for different scenarios. These power calculations are conservative; simulation studies demonstrate that mixed effects models (the proposed analyses [Data Analysis subsection]) yield more power than chi-square and t tests [42,43].

Table 2. Sensitivity analysis (N=1200).

Dropouts, n[a]	Cessation rate: 0.20		Cessation rate: 0.40	
	Detectable difference: 0.10	Detectable difference: 0.15	Detectable difference: 0.10	Detectable difference: 0.15
240	0.95	0.99	0.88	0.99
360	0.92	0.99	0.83	0.99
480	0.87	0.99	0.77	0.98

[a]Dropout rate: 20% (n=240); 30% (n=360); 40% (n=480).

Data Analysis

Overview

This is a 2-arm parallel RCT where the primary outcome is self-reported 30-day abstinence at 6 months. Questionnaires will be scored according to developer instructions. In the case of missing items, where developers do not have explicit instructions, we will use a half-mean imputation rule, as outlined in Bell et al [44]. All analyses will be adjusted for the randomization stratification. The primary analysis will use a

XSL•FO
RenderX

significance level of .05; other tests will use a Bonferroni correction for multiple comparisons to control the overall type I error at 5%. Demographics, including sex, will be described with means, SDs, ranges, and frequencies or proportions and explored as correlates for successful tobacco outcomes using appropriate regression models.

Aim 1

We will test the efficacy of a telephone-delivered GI tobacco cessation treatment versus an evidence-based behavioral treatment on self-reported 30-day abstinence from smoking at T2. Secondary outcomes include self-reported and biochemically verified 7-day point prevalence abstinence at T2.

Hypothesis 1

Participants in the GIC will have 10% higher quit rates than those in the BC.

Generalized linear mixed models with a binomial distribution and a logit link will be used to model smoking outcomes. Time will be used categorically to avoid model misspecification, and the indicators for the stratified variables (ie, location and recruitment method) will be included in the models as covariates to control for the study design variables. Comparisons between the intervention and control groups at 3 and 6 months will be carried out using contrasts within these models. Mixed models are robust to missing outcome data (with respect to bias) and consistent with an intention-to-treat analysis; in addition, they yield more power than chi-square and *t* tests [42,43,45-47]. Secondary outcomes measured over time, including self-reported abstinence, nicotine dependence, self-efficacy, and cravings, will also be analyzed with mixed models (linear for continuous outcomes and generalized linear with a logistic link for binary). Biochemically verified abstinence at 6 months will be analyzed with a logit regression model. Unadjusted and adjusted models will be fitted, with adjusted models including key covariates such as expectancy. Sensitivity analyses with respect to missing data will be undertaken if missing data rates for the primary outcome are >10% at the 6-month follow-up. Multiple imputation by chained equations using data that are associated with missingness, the outcome, or both will be included in the imputation model [16]. We will compare T0 characteristics of participants who drop out with those of participants with complete data.

Aim 2

We will conduct dose-response analyses on the effect of GIC adherence (measured by self-reported minutes of intervention use per week, the number of times GI skills practiced per week, the number of sessions attended, and coach-rated participant engagement in sessions) on abstinence at 6 months. We will also examine effects of the GIC and the BC on tobacco use for those participants who do not report abstinence at 6 months.

Hypothesis 2A

GIC participants who are more adherent will have higher rates of abstinence at 6 months.

Hypothesis 2B

Participants not reporting abstinence will report statistically significant reductions in tobacco use.

We will investigate a dose-response effect of intervention engagement using logistic regression for cessation at 6 months and linear regression for dependence, self-efficacy, and so on, with adherence. Mediation models using a causal framework will also be used [17]. We will compare self-reported tobacco use levels in GI participants who have not quit at 6 months with the control group using regression models and also investigate their changes from T0 use. Consumer satisfaction will be described with summary statistics.

Aim 3

We will conduct subgroup analyses of moderators (eg, recruitment method, location, sex, race and ethnicity, and the level of dependence) on tobacco cessation outcomes at 6 months and assess participants using a mixed methods approach (eg, surveys and in-depth interviews) for exploring subgroup differences.

Logistic regression models will be used to investigate effect modification of the intervention effect on abstinence at 6 months by various moderators. These regression models will include interaction terms, and if statistically significant, a stratified (by moderator) analysis will be performed and reported.

Qualitative interviews will be recorded, transcribed, and consensus coded for themes by 2 coders to guarantee intercoder reliability [48,49]. The team will document variation in the subgroups' reported program use during the RCT, including perceptions of the program's effectiveness and ease of use.

Project Timeline

This project will occur in 2 phases over 5 years. In phase 1 (year 1), we worked with our collaborators in New York State and West Virginia to tailor our protocols and procedures to their quitlines, refine our recruitment methods to each state's smokers, refine all study (participant) materials to ensure that the demographics of each state are represented, and update our training materials to include state-specific data and issues that may be relevant to specific participant populations. We hired and trained all coaches to competency and user-tested all our systems and procedures. In phase 2, we will conduct the RCT. Recruitment, enrollment, T0 assessments, and the delivery of the intervention will occur during years 2 to 4. Follow-up assessments will occur during years 2 to 5, with data analyses and dissemination of the findings in year 5.

Ethics Approval, Informed Consent, Data Protection, and Participation

This study has been reviewed and approved by the University of Arizona institutional review board (2103633455; principal investigator [PI]: JG). All participants complete an informed consent document either through REDCap or on the telephone with trained study staff. Potential participants may ask questions of study staff before signing the consent document. The consent document describes the study, expectations, risks, and benefits of study participation. All study data are housed in REDCap and University of Arizona Box Health. Both systems are encrypted and HIPAA compliant. Only trained study staff have access to participant data, and data are restricted to study staff by role on the project. Participants may receive up to US $125

XSL•FO
RenderX

for participating in all study activities. Participants receive US $10 for completing the T0 survey, US $15 for completing the 3-month survey, and US $25 for completing the 6-month survey. All participants who report 7-day abstinence at the 6-month assessment are asked to complete an expired CO test to biochemically verify abstinence. Participants who complete biochemical verification receive US $50. Some participants will be selected based on their responses to the 3-month survey and invited to participate in a semistructured interview. Participants who complete this interview will receive US $25.

Results

The *Be Smoke Free* study was funded in September 2021 (National Center for Complementary and Integrative Health, R01AT011500; PI: JG). Recruitment started in August 2022, with a staggered start. The West Virginia and New York State quitlines and community recruitment were all active as of October 2022. As of March 31, 2023, a total of 242 participants had been enrolled in the study, surpassing our accrual goal of 240. The Arizona Smokers' Helpline (ASHLine) contract was transferred to another vendor, and we lost this as a recruitment site. The New York State and West Virginia quitlines each agreed to recruit an additional 100 participants to compensate for the loss of 200 Arizona quitline participants.

Follow-up assessments began in November 2022. As of March 31, 2023, of the 118 participants who were eligible for the 3-month assessment, 97 (82.2%) completed the assessment, and 93% (26/28) of participants eligible for the 6-month assessment had completed it. Because of technical difficulties with the hardware and software, biochemical verification began in April 2023. Qualitative interviews began in April 2023. Recruitment will continue through 2025 and follow-up assessments through 2026. Primary results are expected to be published in 2027.

Discussion

Overview

Phase 1 of the study was conducted between October 1, 2021, and July 30, 2022, and completed successfully. The study team met weekly and updated the design, content, and formatting of the intervention quit booklets that were created for the pilot study. We also created recruitment materials, including digital and print media, featuring images representing various communities. We recruited 8 stakeholders from 3 states to form a CAB. We held general and state-specific CAB meetings to obtain feedback on recruitment and intervention materials, as well as recruitment plans and methods. We also updated and refined coach training materials, revised data collection materials from the pilot study, and created new data collection materials. We developed protocols for screening, contact attempts, biochemical verification, and other data collection procedures and programmed and tested them all in the REDCap database. We developed procedures for recording and storing coaching calls using new Zoom (Zoom Video Communications, Inc) technology and hired and trained 4 quit coaches and all research staff. We received institutional review board approval for all human participants study procedures and registered the study with ClinicalTrials.gov.

We began phase 2, conducting the RCT, in July 2022. We have experienced both challenges and successes in the first 6 months of the RCT. To date, we have recruited participants through the West Virginia and New York State quitlines and via study social media posts and posts from community partners in Arizona, New York State, and West Virginia. We designed and sent recruitment postcards to former New York State quitline clients, used display ads on Meta sites, advertised on radio stations in New York State and Arizona, and distributed rack cards and flyers to our CAB members and other contacts in the community (eg, physicians' offices). We recruited our first participant in Arizona in July 2022, then opened recruitment in West Virginia in August 2022, and in New York State in September 2022. In September 2022, the ASHLine contract was transferred from the University of Arizona to National Jewish Health, and the Arizona Department of Health Services declined to collaborate on the rest of the study. The New York State Smokers' Quitline agreed to increase recruitment to compensate for the loss of the ASHLine.

Potential participants who were referred by a quitline or found out about the study from community-based methods were contacted via telephone calls, emails, and SMS text messages and screened by study staff. Potential participants who met the eligibility criteria completed consent and T0 assessments on the web in REDCap and were randomized to 1 of 2 study conditions.

Randomized participants who scheduled and completed the first study visit (session 1) were considered *enrolled participants* in the study.

To ensure that we are meeting our goals and maintaining fidelity of all procedures, we review enrollment and recruitment progress at weekly study team meetings, monitor intervention fidelity in REDCap, and review call recordings on a monthly basis. Any discrepancies in fidelity are immediately corrected, and study personnel receive weekly feedback. Coaches attend individual monthly supervision sessions with the PI.

We are currently retaining >80% of the sample at 3 months and >75% at 6 months. This is similar to our pilot study [12] and compares favorably with other studies that are conducted entirely remotely [50]. If participants miss some data collection visits or drop out from the study after session 1, partial data will be captured for them. As indicated previously, mixed effects models will be used to model smoking outcomes. Mixed effects models have an inherent way to handle ignorable missing data mechanisms (ie, missing completely at random and missing at random), which can be accounted for based on the observed data. In addition, extensive efforts will also be made to maximize retention as well as minimize missing data, and reasons for dropping out and missing data will be recorded. If the missing data mechanism is suspected to be nonignorable (ie, missing not at random), a multiple imputation–based sensitivity analysis approach [51] will be used to evaluate the impact of missing data mechanisms on the intervention effect, where the sensitivity analysis parameter controls the missing mechanism, and the multiply imputed data will be analyzed using standard methods based on the established rules in Rubin [52] that account for uncertainty owing to missingness.

XSL•FO
RenderX

Limitations

We experienced several challenges during the first year of the RCT. First, we lost one of our quitline partners. Despite many attempts to replace the ASHLine, we were unable to do so. Both the New York State and West Virginia quitlines agreed to compensate for our loss of the ASHLine. However, West Virginia experienced a drop-off in call volume and staffing shortages. Therefore, the New York State Smokers' Quitline increased their recruitment to maintain accrual goals. Although the demographics of New York State are different from those of Arizona, we will continue to conduct community recruitment from Arizona so that we can examine treatment outcomes by state.

Second, the social media advertising and earned media (eg, interviews with news outlets) strategies were not as successful as in our pilot study. Therefore, we attempted to recruit using radio advertising. However, radio advertising was not effective either. We have engaged a recruiting firm to assist with community recruitment in Arizona. Despite these setbacks, we have consistently maintained our accrual goals. If needed, we have built in an additional 3 months in year 5 for continued recruitment.

Third, biochemical verification has been difficult for many participants because of inexperience using technology. Although study staff schedule Zoom sessions to *walk participants through* the data collection procedure, many of the participants find it difficult or impossible to complete the expired CO test. Therefore, self-reported 30-day abstinence is our primary outcome, and we will also examine 7-day self-reported and biochemically validated abstinence.

Finally, because the intervention is conducted entirely remotely with no person contact, we experience high attrition between randomization and the first treatment session. Therefore, we classify people as participants only after they have scheduled and completed their first treatment session, and all metrics regarding outcomes are reported for enrolled participants. Participants do not know to which condition they have been randomized until the first session. Therefore, we do not expect differential attrition before session 1 to cause bias while evaluating the intervention effects. Even if the differential attrition rate is not expected to relate to the intervention conditions, an inverse probability of attrition weighting approach [53] will be used to handle differential attrition rates and account for potential bias if attrition is indeed selective.

Conclusions

The *Be Smoke Free* study is a first-of-its-kind RCT that incorporates GI into telephone-based tobacco cessation treatment. This study uses rigorous, transparent, and reproducible methods. The study protocols are based on strong theoretical frameworks and empirical evidence. We use best practices to address challenges in large studies with remote program delivery and data collection, well-established measures to reduce errors associated with self-report, successful recruitment and retention methods to reduce selection and nonresponse biases, and both intent-to-treat analysis and other methods to handle missing data.

Delivering a GI tobacco cessation intervention via telephone is a highly scalable novel integrative approach that may appeal to a broad range of smokers and increase the use of evidence-based tobacco treatment quitlines. This rigorous research has the potential for high overall impact. If successful, the *Be Smoke Free* program will have substantial benefits for the long-term health of people who use tobacco across the United States.

Acknowledgments

The authors wish to thank their partners at First Choice and Roswell Park Cancer Center who operate the West Virginia Tobacco Quitline and New York State Smokers' Quitline, respectively. The authors also wish to thank quit coaches Anjanette Gutierrez, Mindi Horwich, Crista Meinke, and Mary Petersdorf; research assistant Yessenya Barraza; student research assistant Kyiah Moore; and the University of Arizona Cancer Center Behavioral Measurement and Interventions Shared Resource.

Data Availability

Data from this study will be made available after the outcome paper is published or 6 months after the end of the study, whichever comes first.

Conflicts of Interest

None declared.

Abstract

Background: Facial neuromuscular retraining (fNMR) is a noninvasive physical therapy widely used to treat peripheral facial palsies. It consists of different intervention methods that aim to reduce the debilitating sequelae of the disease. Recently, the use of mirror therapy in the acute facial palsy and postsurgical rehabilitation contexts has shown promising results, suggesting its use as an adjunct to fNMR in treating patients with later stages of paralysis, such as the paretic, early, or chronic synkinetic.

Objective: The main aim of this study is to compare the efficacy of an added mirror therapy component with fNMR in patients with peripheral facial palsy (PFP) sequelae in 3 different stages. The specific objectives of this study are to measure the effects of combined therapy compared to fNMR alone on (1) participants' facial symmetry and synkinesis, (2) quality of life and psychological aspects of the participants, (3) motivation and treatment adherence, and (4) different stages of facial palsies.

Methods: This study is a randomized controlled trial that compares the effect of fNMR combined with mirror therapy (experimental group: n=45) with fNMR alone (control group: n=45) in 90 patients with peripheral facial palsy presenting with sequelae 3-12 months after onset. Both groups will receive 6 months of rehabilitation training. Facial symmetry and synkinesis; participants' quality of life; and their psychological factors, motivation, and compliance will be assessed at baseline (T0), 3 months (T1), 6 months (T2), and 12 months (T3) postintervention. Outcome measures are (1) changes in facial symmetry and synkinesis assessed with facial grading tools, (2) quality of life changes with patient questionnaires, and (3) therapy motivation with a standardized scale, as well as adherence to treatment with metadata. Changes in facial symmetry and synkinesis will be judged by 3 assessors blinded to group assignment. Mixed models and Kruskal-Wallis, chi-square, and multilevel analyses will be conducted according to the appropriate variable type.

Results: Inclusion will start in 2024 and is anticipated to be completed in 2027. The 12-month follow-up will be completed with the last patient in 2028. We expect patients included in this study to experience improvement in facial symmetry, synkinesis, and quality of life, regardless of group assignments. A potential benefit of mirror therapy for facial symmetry and synkinesis could be noted for patients in the paretic phase. We hypothesize better motivation and adherence to treatment for the mirror therapy group.

XSL•FO
RenderX

Conclusions: The results of this trial may provide new guidelines for PFP rehabilitation with patients dealing with long-term sequelae. It also fills the need for robust evidence-based data in behavioral facial rehabilitation.

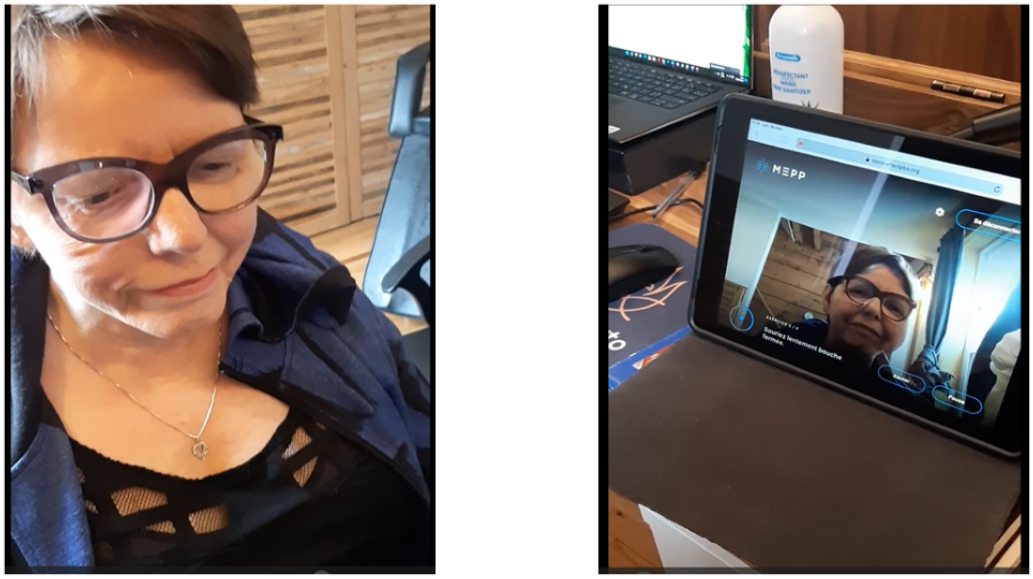
Introduction

Background

Peripheral facial palsy (PFP) with sequelae is a debilitating condition that can significantly impact a patient's quality of life due to functional, social, and psychological factors [1]. Facial asymmetry and the inability to express emotions and smile adequately can make communication challenging, leading to high levels of social problems, frustration, anxiety, and depression [1]. In nonflaccid facial palsy, patients may have hyperkinesis, muscle contracture, and synkinesis, which can affect normal activities such as drinking, eating, and articulating and can cause embarrassment and, in some cases, facial pain [2,3]. Therefore, providing adequate interventions to help patients deal with these issues is essential. Physical therapy is a type of nonsurgical treatment shown to help manage the sequelae previously mentioned in patients with nonflaccid chronic peripheral facial palsy [4]. Optimal facial rehabilitation modalities could also differ depending on the stage of nonflaccid PFP [5]. Although there are no generally accepted guidelines for the different stages, some authors define the paretic phase as recovery from 3 to 6 months after onset, while the early synkinetic phase would be defined as 6 to 9 months after onset [5,6]. The chronic synkinetic phase would begin at 9 months after onset, as defined by Beurskens et al [7].

Facial Neuromuscular Retraining



Mime therapy [8,9] and facial neuromuscular retraining (fNMR) [10] are 2 rehabilitation techniques for managing facial palsy sequelae that stand out in the literature [11]. Mime therapy consists of facial massage and specific facial retraining to coordinate both hemifaces by using emotional cues to express a particular facial movement or by starting to use a specific muscle to create an expression [8]. Similarly, fNMR consists of relearning motor patterns to improve facial movements through conscious, consistent, and slow selective activation of facial muscles using individualized training programs made by qualified facial therapists [12]. This therapy aims to normalize facial muscle functions by inhibiting synkinetic contractions and improving resting tone altered by contractures [13]. In the literature, these 2 therapies have recently merged into one called fNMR, which combines techniques such as soft tissue massage, biofeedback, education, relaxation, and selective movement retraining [14]. fNMR is considered a well-supported approach that has been studied in many cohort studies [14].

Mirror Therapy in Facial Rehabilitation

Mirror therapy is a form of motor therapy that involves placing a mirror in the patient's midsagittal plane, reflecting the unaffected limb or body part onto the affected one, creating the illusion of normal movements on the absent or affected side [15]. It is based on the brain's ability to undergo cortical reorganization [15]. The first clinically reported effects of mirror therapy were pain reduction in arm amputees and alleviation of hemiparesis [16]. Since then, this therapy has been used in other contexts, including facial rehabilitation and uses specific computer software to replicate the unaffected side over the affected side [17] (Figure 1).

XSL•FO
RenderX

Figure 1. Representation of the setting with mirror therapy for facial rehabilitation. (A) Patient sits in front of the computer with a webcam. (B) Visual biofeedback of modified face.

A B

A recent study investigated the effects of mirror therapy over 3 months on 32 patients diagnosed with facial nerve palsy less than 12 months after acoustic neuroma resection surgery [17]. The control group received traditional rehabilitation with mime therapy, while the experimental group had to perform an additional weekly session of mirror therapy using specific software and motor imagery exercises with different emotions or gestures. Both groups were evaluated for facial symmetry using the House-Brackmann Facial Nerve Grading system [18], Sunnybrook [19], and Facial Clinimetric Evaluation (FACE) [20]. Although every subject demonstrated improvement in facial symmetry, the experimental group showed significantly better results than the control group for House-Brackmann scores and quality of life. In a recent case report, mirror therapy and motor imagery were used with a small group of patients (n=5) with chronic facial palsy to reduce synkinesis, which resulted in the reduced muscular activity of synkinetic muscles with mirror therapy [21].

A recent longitudinal study recruited patients with Bell palsy within 14 days of onset and followed them for 1 year [22,23]. The control group received only basic counseling in their rehabilitation, while the experimental group followed a new protocol called the Mirror Effect Plus Protocol (MEPP), which was mainly based on mirror therapy [24] and motor imagery [25]. One year after onset, significant results included less synkinesis development, increased facial symmetry, and improved self-reported quality of life in the experimental group [23]. Although the MEPP shows interesting results in patients with Bell palsy when initiated in the acute phase, to our knowledge, there is very limited evidence for mirror therapy as an effective treatment tool for patients presenting with long-standing peripheral facial paralysis from different etiologies.

Expected Effects of Rehabilitation Techniques

Based on the work of Diels and Beurskens [14], fNMR is expected to improve facial symmetry and reduce synkinesis in long-standing facial palsy. Increased resting tone on the patient's affected side often creates muscle tightness or contractures, leading to decreased range of motion, alteration of facial expressions, and patient discomfort. Therefore, soft tissue mobilization and specific facial manipulations can reduce such tightness and increase facial symmetry at rest [14]. To inhibit synkinesis, the therapy seeks to recognize abnormal movement patterns and uses different strategies to reduce them while activating desired facial muscles [5]. Patients must be instructed to perform slow, small, and controlled facial expressions or movements. As the patient's control improves and the synkinesis movements remain suppressed, the range of motion, facial function, and symmetry are believed to improve [14]. As proprioceptive input is absent in facial muscles, fNMR uses different education and biofeedback strategies, such as surface electromyography and touch, to help patients focus on the right muscle contraction. Although successful results have been demonstrated in the past with patients in the chronic phase, more randomized controlled trials are required to assess its efficacy [4]. It has been noted that when traditional mirrors are used in practice sessions as biofeedback, the mismatch between the motor command and the visual feedback associated with the affected side might result in maladaptive muscle hyperactivity and compensation, which is counterproductive with fNMR [26,27]. In this context, adding mirror therapy during practice is an interesting idea because it might avoid such discrepancies between motor command and sensory input [23]. However, the potential added value of mirror therapy for long-standing facial palsies remains to be proven.

XSL•FO
RenderX

Study Aims

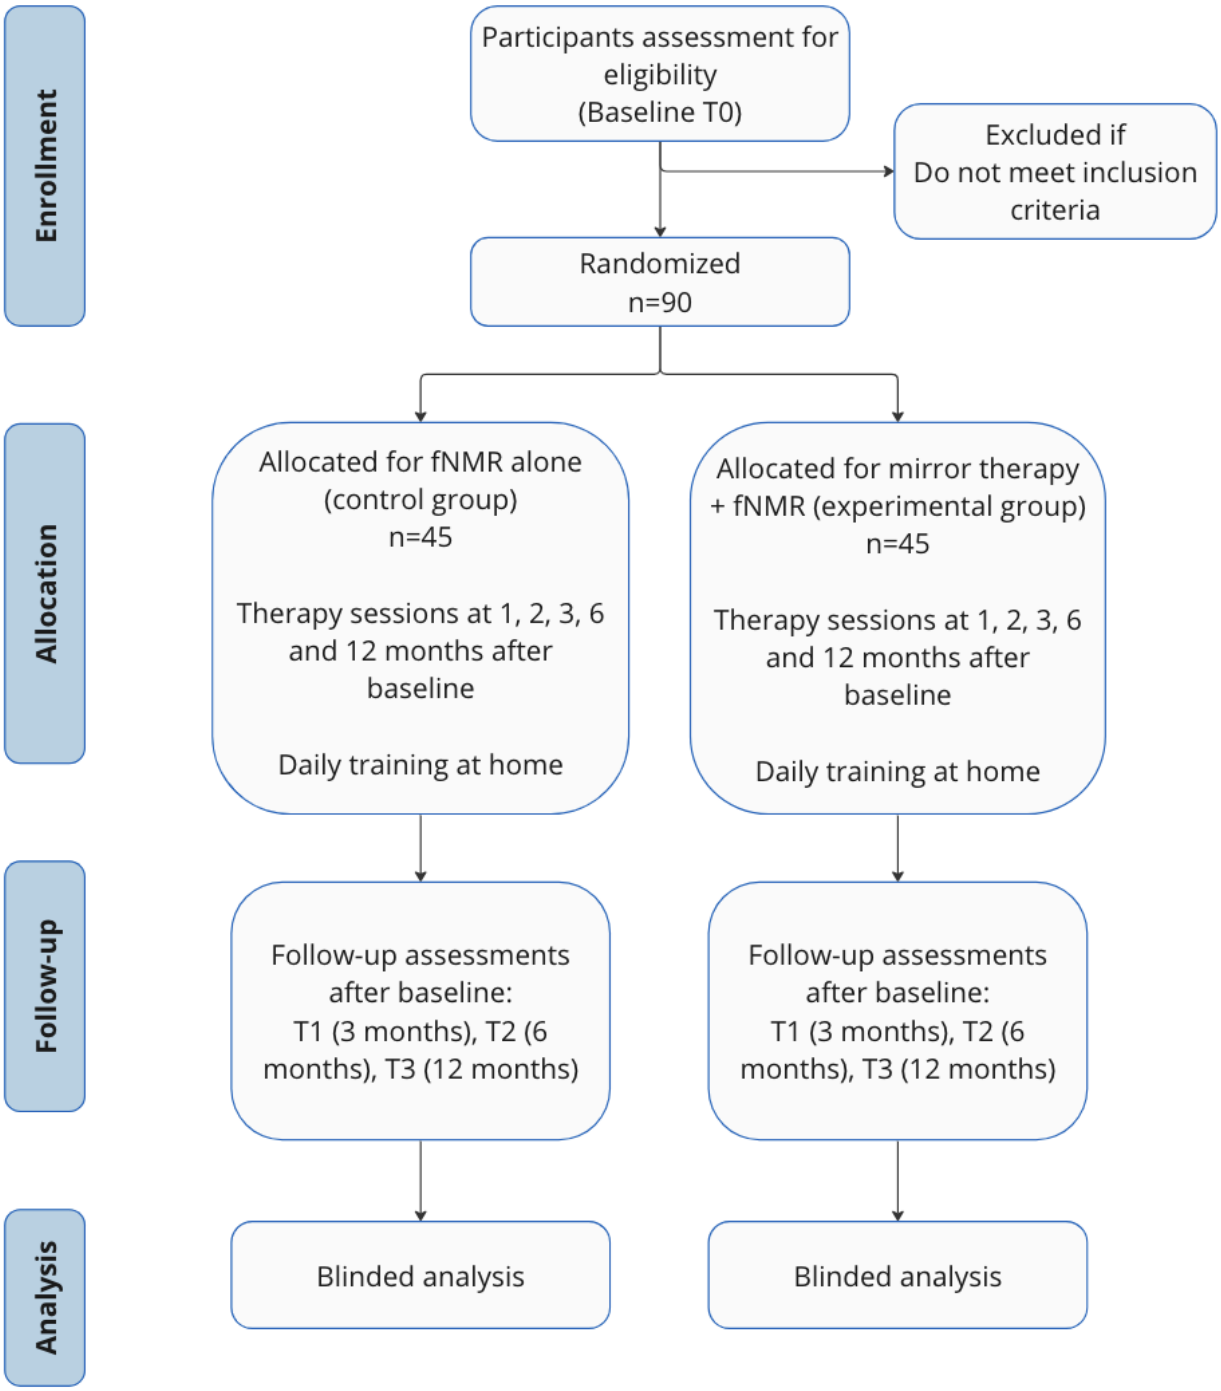
There is a growing interest in exploring the effect of adding mirror therapy as a biofeedback tool in fNMR, particularly in patients with peripheral facial palsy dealing with sequelae 3-12 months after onset. Therefore, the general aim of this protocol is to compare the potential effects of adjunctive mirror therapy with the gold standard fNMR on facial function and rehabilitation in nonflaccid facial paralysis. The specific objectives of this study are (1) to measure the effects of combined therapy compared to fNMR alone on participants' facial symmetry and facial synkinesis, (2) to measure the effects of combined therapy versus fNMR alone on the quality of life and psychological aspects of the participants, and (3) to measure the effects of combined therapy versus fNMR alone on motivation and treatment adherence.

Methods

Eligibility Criteria

To be included in the study, patients must be 18 years or older, experiencing their first PFP, be from 3 months to 12 months after onset, and must have a score 4 or 5 on Facial Nerve Grading System 2.0 (FNGS 2.0) [28]. In addition, they must have sufficient cognitive status, measured by a cutoff score of 23 on the Montreal Cognitive Assessment [29,30], and present with no active mental health diagnosis. They should also not present with a history of neurologic diseases affecting facial function. Patients with concomitant therapies or botulinum toxin type A injections, presenting with bilateral palsies or with medically uncontrolled metabolic diseases, will be excluded from the study. Access to an internet connection and basic computer literacy will also be verified as eligibility criteria.

Recruitment and Compensation



As determined, thanks to a power calculation measure based on Martineau et al [22] to reach a power of 0.8 with a size effect of 0.6 and an α of .005, 90 patients with peripheral facial palsy of diverse etiologies in the paretic (n=30), early synkinetic (n=30), or chronic synkinetic phase (n=30) will be recruited to the study. They will then be randomized into 2 groups, mirror therapy plus fNMR or fNMR alone, by computerized block randomization. No compensation or incentive is planned to be provided at this time. Recruitment is planned to be conducted in 3 tertiary care centers (hospitals) in Canada, England, and Belgium (Hôpital Maisonneuve-Rosemont, Queen Victoria Hospital, and Sint-Augustinus GZA Hospital, respectively). A telehealth option will be available for the participants via institutionally secured platforms.

Study Procedures

This trial will compare the effect of mirror therapy in addition to gold standard fNMR (experimental group) over fNMR alone (control group) in patients with peripheral facial palsy dealing with sequelae 3-12 months after onset. During 6 therapy sessions (Textbox 1), all patients will benefit from standardized education on facial anatomy and physiology, eye care, and management of facial dysfunction (eg, eating, drinking, speaking, and nonverbal communication), as well as from rehabilitation to increase symmetry and decrease synkinesis, specific to their needs. These sessions will be provided by speech-language, physical, or occupational therapists, all certified by their respective professional corporation. In addition, a minimum of 5 years of expertise in facial palsy training is required to be included in the study. These clinicians will also perform the different study measurements, but 3 judges (also experts in facial therapy but blinded to therapy allocation) will then analyze the data. The mirror therapy group will also receive modified visual feedback during facial retraining, along with appropriate instructions about its use. In parallel, patients will be prescribed daily specific at-home rehabilitation depending on the nature of their group. Patients in the combined group (mirror therapy plus fNMR) will do their therapy at home with the MEPP 2.0 app [31], while patients in the fNMR group alone will do their therapy at home with the Physitrack app [32]. Figure 2 presents the overall study design.

Textbox 1. Frequency and length of appointment.

- Sessions
  - Session 1 (1 hour to 1 hour and 30 minutes) for initial assessment and start of management.
  - Session 2 (1 hour) 1 month after session 1.
  - Session 3 (1 hour) 1 month after session 2.
  - Session 4 (1 hour) generally 1-2 months after session 3.
  - Session 5 (1 hour) is generally 3 months after session 4.
  - Session 6 (1 hour) final session generally 6 months after session 5, then discharge to continue independently.
- The total treatment course will last 12 months.
- 2-3 sessions of 10 to 15 minutes of daily home rehabilitation are expected to be done by the patients from baseline until 12 months.

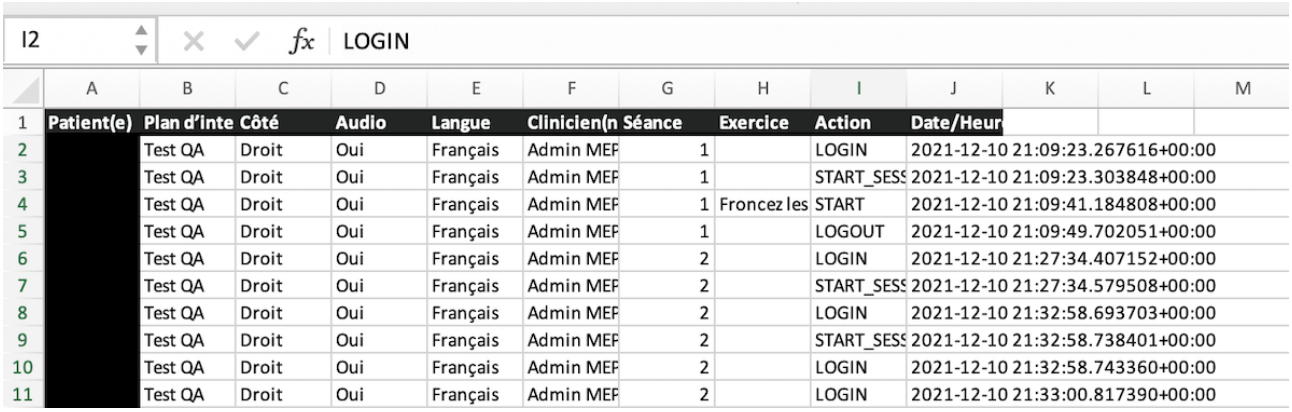
Measures

For data collection, each measure will be taken at baseline, 3 months, 6 months, and 1-year postintervention. Evaluation sessions will be recorded, allowing 3 independent evaluators to blindly assess the objective outcome measures. The final assessment (T3) will measure the training retention of participants following therapy sessions.

Facial Function Assessment Tools: Symmetry and Synkinesis

Different tools will be used to measure the effects of combined therapy compared to fNMR alone on facial symmetry and synkinesis of the participants. First, Emotrics [33], a designed open-source machine learning algorithm, will enable objective facial metrics for patients with facial paralysis. The algorithm uploads a front-view picture of the patient's face into the program. Then, it automatically places 68 facial landmarks and computes a set of facial metrics relevant to facial palsies, such as palpebral fissure width, smile excursion, and smile and brow symmetry. Second, the FNGS 2.0 [28] and Sunnybrook Facial Grading Scale [19] will be used by 3 independent blinded evaluators to assess facial symmetry at rest, voluntary facial movement, and synkinesis. The FNGS 2.0, also called the modified House-Brackmann scale, is a scale where 4 regions of the face are assessed and scored into different categories depending on the degree of movements and synkinesis presence [34]. It generates a final score between 4 and 24 and converts it into one of the original House-Brackmann categories ranging from I (normal function) to VI (total paralysis). In other words, it incorporates synkinesis scoring and regional scoring to the original validated House-Brackmann scale [28]. As described by Vrabec et al [28], this revised scale presents high inter- and intraobserver agreement with the original scale while providing additional information. On the other hand, the Sunnybrook Facial Grading Scale uses a continuous scale of 0% (total facial paralysis) to 100% (normal facial function and symmetry). This scale has been chosen because of its high sensitivity to changes induced by the intervention [34].

Patient-Related Outcome Measures: Quality of Life



To measure the effects of combined therapy compared to fNMR alone on the quality of life and psychological issues of the participants, different patient-related outcome measures will be used including the FACE [20] and the Facial Disability Index (FDI) [6]. The FACE assesses 6 main domains: facial comfort, facial movement, oral function, lacrimal control, eye comfort, and social function through 15 questions. Overall, facial function depends on a score previously calculated that ranges from 0 (worst) to 100 (best) [20]. It has been previously demonstrated that FACE effectively discriminates the normal functional state of a person who does not have facial palsy from the state of a person have the disease [20]. Furthermore, the FACE can be used in different clinical contexts, such as assessing the evolution of patients' facial palsy handicaps from distinct etiologies and reporting changes in patients' perceptions of social and functional plans [20]. Kahn et al [20] performed an exhaustive process to validate the instrument, which is internationally used for its validity, sensitivity, specificity, and reliability [35]. On the other hand, the FDI has 10 questions that assess 2 domains: physical and social function. Social function scores from 0 (worst) to 100 (best), while physical function scores from −25 (worst) to 100 (best) [6]. Its validity and reliability have been demonstrated by VanSwearingen and Brach [6]. While the FACE scale provides more domains, it lacks measures about specific functional information, such as speech, which is why the use of FDI could be complementary [36].

Motivation and Adherence to Treatment

To measure the effects of combined therapy compared to fNMR alone on the rehabilitation process of the participants and motivation to treatment, the intrinsic motivation inventory [37] will be used. This multidimensional tool has been developed to assess participants' intrinsic motivation toward specific activities in laboratory experiments. Interest or enjoyment, perceived competence, effort, pressure or tension, usefulness, perceived choice, and relatedness of a task are all assessed while the participant performs a specific task. The scale has been validated in several contexts [37,38]. Patients' compliance to treatment will be assessed through intrinsic features of both websites that record metadata every time the participant logs in. These features allow therapists to see if the patient completed their rehabilitation program as recommended. Figure 3 shows an example of the metadata that the MEPP website can generate on an Excel (Microsoft Corp) sheet about compliance with treatment.

Statistical Analysis

As mentioned, a power calculation was done based on a previous study [23] for the primary outcome (changes from baseline to 6 months). Every measure of facial symmetry and synkinesis will be judged by 3 assessors, blinded to group assignment. Intraclass correlation coefficients will be calculated to ensure interrater reliability, and the resulting means of the assessors' findings will be used for further statistical analysis. We will first gather descriptive statistics to provide summary data. Then, for continuous variables (Emotrics measurements, Sunnybrook global score, FNGS 2.0 global scores, FACE score, FDI, and intrinsic motivation inventory), a mixed model analysis with patients as random variables and time+group assignment as fixed variables will be considered, with auto-regressive covariance structure, given the structure of the time points for the assessments. Comparison between the timing of recruitment after PFP onset (3-6 months after onset vs 6-9 months vs 9-12 months) and outcomes at T2 and T3 will be specifically measured using multilevel analysis. Kruskal-Wallis analyses will be considered for ordinal variables (synkinesis subscores, symmetry subscores, and motivation subscores). Finally, chi-square analysis will be considered for dichotomous variables (adherence yes or no). Data will be encoded with Excel sheets, and SPSS (IBM Corp) will probably be used for statistical analysis.

Ethical Considerations

Ethics approval will be sought by January 2024 for an international and multicentric randomized control trial involving tertiary care centers in Canada, the United Kingdom, and Belgium. Only participants who are adults and able to consent will be recruited for this study. This study presents minimal risks for participants, as only behavioral therapy will be provided in the study procedures: there will be no use of approved or unapproved drugs, biologics, food, or dietary supplements. This study does not evaluate the safety or effectiveness of a device. No protected health information will be collected or placed into electronic medical records. No compensation or incentive is planned to be provided at this time.

Data Management Plan

All data will be collected in an electronic format. In the unanticipated event that data cannot be collected electronically, the same information will be collected via pen and paper, transferred to Excel, and the paper format will be destroyed at the earliest opportunity. All collected data will be strictly confidential, within the limits established by law, and a numerical code will identify each participant. Data will be recorded in the cloud of the University of Montreal, specially developed for research purposes, and only the team members will have access. Furthermore, all data will be conserved, for a minimum period of 7 years, after which they will be destroyed. None of the potential scientific publications or communications related to the study will contain participant-identifiable information. The researchers and the research assistants will only consult data. No facial recordings or sensitive or medical information will be held on the websites used in the study. Only the name, email address, and information about the affected side of the facial palsy (for duplication of the unaffected side purpose) and preference about sound level (with or without sound) will appear. Moreover, both websites use the latest versions of tools and information components, such as long time support, which offer support and security updates regularly, and a specialized technical team will ensure security updates and support for maximal security.

Results

The inclusion will start in late 2024, and data collection is anticipated to be completed over 3 years by 2027. Therefore, the last patient will have their final follow-up (T3) in 2028. Data analysis will be completed in 2028-2029. The results will be published in 2030.

Discussion

Main Study Findings

The primary objective of this protocol is to compare the potential effects of adjunctive mirror therapy with the gold standard fNMR for facial function and rehabilitation in cases of nonflaccid facial paralysis. In particular, this study aims to evaluate the impact of combined therapy versus fNMR alone on participants' facial symmetry, facial synkinesis, quality of life, motivation, and treatment adherence.

Comparison With Prior Work and Scientific Value of This Work

A recent Delphi study has confirmed the significance of fNMR and mime therapy in treating patients with various types of

XSL•FO
RenderX

peripheral facial paralysis [39]. While mirror therapy was not unanimously agreed upon for inclusion at that time, subsequent data published after the study indicated that mirror therapy, when initiated a few days after the onset (10-14 days) of Bell palsy, had notable benefits. These benefits included a significant improvement in facial symmetry, quality of life, and a reduction in the development of synkinesis [23]. Similar positive outcomes have also been observed in patients with facial palsy after acoustic neuroma resection and in those who underwent lengthening temporalis myoplasty surgery [17,24]. However, despite these findings, there is a dearth of research examining the potential effects of mirror therapy in patients with peripheral facial palsy experiencing delayed recovery and sequelae at least 3 months after the onset, compared to more traditional therapies like fNMR.

Irrespective of the etiology and group allocation (fNMR vs mirror therapy), our hypothesis posits that all patients with peripheral facial palsy enrolled in this study will experience improvements in facial symmetry, synkinesis, and quality of life [11,23,40]. Drawing on previous studies [23,41] and considering that mirror therapy appears most beneficial when initiated early, we anticipate mirror therapy to have greater benefits for patients in the paretic phase (3-6 months after onset), particularly in terms of restoring facial symmetry. Patients presenting with synkinesis at the time of recruitment should experience a decrease in synkinesis in the fNMR group, as indicated by several previous studies [4,5,7,13,14]. Similarly, a decrease in synkinesis is expected in the mirror therapy group, but no significant differences between the 2 groups are anticipated. Moreover, in line with previous findings [5,23], we expect both the fNMR and mirror therapy groups to demonstrate improvements in self-reported quality-of-life measures. Additionally, motivation is crucial in achieving positive therapy outcomes [42] and will be specifically assessed in this study. The hypothesis of greater motivation with mirror therapy is based on a previous study where patients reported that performing facial exercises while viewing a symmetrical face aided them as it represented their desired goal [41]. On the contrary, some patients may experience emotional responses when confronted with a face they perceive as “lost” due to facial paralysis.

Finally, we anticipate that patients in the mirror therapy group will exhibit better treatment adherence compared to those undergoing fNMR alone. Adherence to facial retraining has been shown to be influenced by various factors, including time constraints due to other daily activities and accessibility to the training facilities [43]. Facial therapists often overestimate their patients’ commitment to the facial rehabilitation process, with data indicating that only 30% of patients fully comply [43]. Nonadherence to therapy can impact treatment outcomes, highlighting the importance of measuring adherence in this study. Objective measures of adherence using metadata will be used, providing strength compared to relying solely on subjective measures of compliance. Subjective measures of compliance (such as patient questioning) may be influenced by patients’ memory or perceptions [44]. Furthermore, the postpandemic shift toward telehealth for service delivery may facilitate adherence [44]. In this study, we will document whether participants received care via telehealth and examine whether this factor appears to influence compliance.

Strengths and Limitations

The primary strength of this protocol lies in its international multicentric collaboration, which will facilitate the examination of a substantial number of participants representing diverse etiologies of peripheral facial nerve palsy (n=90, with 45 patients per group). The randomized controlled trial design used in this study allows for assessing the potential additional benefits of incorporating mirror therapy into the rehabilitation of PFP. This investigation has the potential to contribute to an evidence-based approach for clinicians involved in the care of these patients.

However, the study design does have certain limitations. First, it is not feasible to blind both the patients and treating clinicians to the assigned conditions, which could introduce bias in terms of motivation and perception of treatment efficacy. To mitigate these risks, blinded judges will be involved in assessing participants, and therapists will use a standardized feedback approach in both therapy sessions and assessments. Additionally, using Emotrics will allow for more objective facial metrics at each assessment time point [33,45]. Second, the inclusion of paretic patients in the study poses a potential confounding factor due to the occurrence of spontaneous recovery in certain cases of facial palsy [3]. However, the large number of participants and their enrollment at least 3 months after the onset of symptoms should help mitigate potential biases. It is worth noting that in Bell palsy, the most common cause of PFP, approximately 70% of patients experience full recovery within 3 months of onset [3]. The advantage of including patients across such a broad timeframe (3-12 months after onset) is to recruit a cohort that is as representative as possible of the clinical reality of facial rehabilitation in different countries.

Conclusions

By comparing treatment modalities such as fNMR and mirror therapy within the scope of this international study, clinicians can gain valuable insights into effective approaches for addressing specific facial sequelae in patients. Understanding which modalities may be more effective at different stages of PFP is important for the field. Moreover, this study has the potential to shed light on the impact of motivation and treatment adherence on treatment outcomes.

Acknowledgments

This work was supported by a grant for the establishment of a new international research collaboration from Direction des Affaires Internationales de l’Université de Montréal.

Abstract

Background: Black men and their communities are more affected by HIV. Although they constitute less than 5% of the Ontarian population, they accounted for 26% of new HIV diagnoses in 2015, nearly half of which (48.6%) were attributed to heterosexual contact. HIV stigma and discrimination reinforce African, Caribbean, and Black men's HIV vulnerability by creating unsafe environments that deter them from testing and disclosure, resulting in isolation, depression, delayed diagnosis and linkage to treatment and care, and poor health outcomes. In response to these challenges, intergenerational strategies were identified from previous community-based participatory studies as best practices to reduce HIV vulnerabilities and promote resilience among heterosexual Black men and communities. The proposed intervention is premised on this recommendation of intergenerational intervention.

Objective: The overarching objective is to engage heterosexual Black men and communities in cocreating a community centered, culturally safe intergenerational intervention to reduce HIV vulnerabilities and related health disparities.

Methods: We will engage 12 diverse community stakeholders in Ontario, inclusive of heterosexual Black men, in 8 weekly sessions to evaluate existing evidence of effective HIV health literacy interventions, identify essential and relevant aspects, and work collaboratively to co-design the HIV-Response Intergenerational Participation (HIP) intervention for use with Black men and communities. Next, we will recruit 24 self-identified heterosexual Black men aged 18-29, 29-49, and ≥50 years. We will pilot and evaluate the HIP intervention with 24 heterosexual Black men from these 3 age groups (split as 2 events: a total of 12 participants in person in Toronto and 12 participants on the web in Windsor, London, and Ottawa). We will use the data obtained along with questionnaires from validated scales and focus groups to evaluate the effectiveness of HIP. The data will include HIV knowledge, perceived stigma toward people living with HIV, acceptance and uptake of HIV testing, preexposure prophylaxis (PrEP), postexposure prophylaxis (PEP), and condom use. We will also collect data related to perceptions about system-level factors such as discrimination, socially misconstrued masculine identity, etc. Quantitative analysis will essentially be a univariate descriptive analysis. We will use thematic analysis to highlight the results of the focus group discussions. Finally, we will disseminate the evaluation results and engage researchers, leaders, Black men, and communities to expand the project team and scale up the intervention in Ontario and across Canada.

Results: Implementation commences by May 2023, and by September 2023, we should have produced, among others, an evidence-informed HIP intervention that can be adapted for use by heterosexual Black men and communities beyond Ontario.

Conclusions: The pilot intervention will strengthen critical health literacy and build resilience against HIV through intergenerational dialogue among heterosexual Black men of all ages.

community-based participatory project; heterosexual Black men; HIV response; intergenerational participation; intervention

Introduction

Background

Black men and communities are disproportionately affected by HIV through heterosexual exposure than other racialized groups in Canada [1-3]. While Black people make up only 5% of the Ontarian population, they accounted for 26% of new HIV diagnoses in 2015, with nearly half (48.6%) attributed to heterosexual contact [4-6]. Black men remain vulnerable to HIV due to structural inequities, including the lack of access to culturally safe programs that provide them opportunities to dialogue about their vulnerabilities and cocreate solutions [7-9]. Systemic factors such as institutional discrimination, poor representation of Black populations in health care decision-making, a lack of accessible information in relevant languages, and a lack of culturally safe health services constitute barriers to effective HIV responses [10-13]. Furthermore, HIV stigma and discrimination hinder them from testing and disclosure, thereby increasing their vulnerabilities, social isolation, depression, delays in HIV testing, diagnosis, linkage to treatment or care, and poor health outcomes [14,15]. HIV stigma also reinforces community denial, undermines HIV prevention efforts, impedes the provision of accessible community care, and prevents access to HIV information [16,17].

In 2020, the weSpeak team undertook a community consultation on best practices to reduce HIV vulnerabilities among heterosexual Black men and communities. They engaged 60 heterosexual Black men in Ontario through *group concept mapping* [18,19]. Data analysis of the 123 statements generated by the participants showed that the actionable cluster *"individual and family level HIV prevention"* was ranked highest among all the go-zone statements in both the scores of importance (4.06/5.0) and feasibility (3.61/5.0). Furthermore, detailed reviews of the statements within this cluster indicated the need for older generations to meaningfully engage the younger generations within families and in communities to promote cultural pride, collective resilience, and positive action to reduce HIV vulnerabilities. The priority of developing intergenerational programs and safe spaces for heterosexual Black men to engage in culturally safe dialogue and action was also supported by findings from the qualitative phase of weSpeak where over 200 heterosexual Black men and service providers were engaged in focus groups and individuals interviews in 2019 [20-24]. Emerging from these interviews was the call by participants to use an intergenerational approach to engage heterosexual Black men, families, and community stakeholders to raise awareness about HIV prevention and increase connections to HIV care as a community priority.

Evidence from intervention research undertaken in the United States also shows that parent-, family-, and community-engaged HIV prevention programs are effective (eg, the *Collaborative HIV Prevention and Adolescent Mental Health Project*) [25-27]. Intergenerational interventions such as youth-adult partnerships and parent-youth connections have been shown to build connection, improve youth efficacy, increase capacities for engagement, and increase responsibility at individual and systemic levels. They spur social-level benefits such as adult support, encouragement, shared trust, shared experience, and knowledge, and these in turn, further produce individual level outcomes of self-efficacy, self-esteem, and self-confidence. The cycle continues with individual outcomes leading to more social outcomes, such as positive peers, and a system-level outcome, for example, education of others [28-31]. Hence, models that support parent-youth and intergenerational dialogue and connections are promising for HIV-related intervention [32].

Objectives

In this proposed study, we will draw on existing literature and local evidence [17,20-24] to engage heterosexual Black men and communities to co-design the HIV-Response Intergenerational Participation (HIP) intervention. Based on the recommendations from weSpeak concept mapping, intergenerational connection is conceptualized beyond individual families to include social connections across different generations of heterosexual Black men and leaders in Black communities. The overarching goal of the study is to promote literacy on HIV prevention (eg, condom use, preexposure prophylaxis [PrEP], postexposure prophylaxis [PEP], safer sex negotiation, partner communication), testing (eg, access, point-of-care testing, and self-testing), and linkage to care. The specific objectives are to:

1. Advance critical HIV health literacy among heterosexual Black men and communities.
2. Engage heterosexual Black men, community leaders, and stakeholders in co-designing the HIP intervention to reduce HIV vulnerabilities and promote community resilience.
3. Pilot the HIP intervention with heterosexual Black men of diverse ages and assess its acceptability, feasibility, and effectiveness.
4. Apply study results to refine the HIP intervention for potential scale-up in Ontario and Canada.

Theoretical Framework

The project is underpinned by the principles of health equity, community empowerment, and meaningful engagement [33,34]. We will use a community-based participatory research (CBPR) approach to promote *critical health literacy* among heterosexual Black men and communities [35]. Critical health literacy refers to "the degree to which people are able to access, understand, appraise, and communicate information to engage with the demands of different health contexts in order to promote and maintain good health across the course of life" [36]. Early conceptualization of health literacy mainly focused on *functional health literacy skills*, that is, individuals' ability to obtain relevant health information to assess their health risks and engage in relevant health behaviors. Over the years, health

XSL•FO
RenderX

literacy has evolved to include *interactive health literacy skills*, that is, individuals' ability to extract information from different sources to make health decisions and interact with service providers with confidence; and *critical health literacy skills*, that is, individuals' ability to analyze health information to gain a critical understanding of health in the context of social, economic, and environmental determinants and engage in organized efforts to advocate for health equity [37,38]. Critical health literacy has also led to more attention being placed on the roles and responsibilities of health providers and health organizations in providing accessible, culturally safe, and inclusive health information and resources. In using an intergenerational approach to build critical health literacy, heterosexual Black men will be able to tap into community wisdom from key stakeholders (eg, Black men living with HIV, Black knowledge holders, and Black activists for health). A co-designed intervention based on lived experiences and community wisdom will promote collective self-determination among heterosexual Black men and increase community literacy on HIV prevention and care. Guided by *a CBPR approach*, we will apply meaningful engagement strategies throughout the study. We will set up a project advisory committee (PAC) comprising 6-8 Black leaders from the youth, heterosexual Black men living with HIV, LGBTQ+ (lesbian, gay, bisexual, transgender, and queer/questioning), faith, and social justice sectors. The PAC will advise the team on cultural relevance and inclusion, research design and processes, community connections, data interpretation, and knowledge dissemination. Using CBPR, we will build equitable collaborative partnerships that promote meaningful involvement of people, organizations, and communities to increase collective self-determination in Black health, enhance HIV prevention, and improve health outcomes in heterosexual Black men and communities [14-17]. The processes will empower heterosexual Black men and the community to gain a critical understanding of the interpersonal and structural determinants of HIV vulnerabilities and codevelop strategies to address HIV-related health disparities experienced by heterosexual Black men and communities.

Methods

The proposed project consists of 4 interconnected components that work in tandem to engage heterosexual Black men and communities in knowledge uptake and cocreate a culturally safe intergenerational HIV literacy intervention.

Component One: Engaging Heterosexual Black Men in Knowledge Interpretation and Uptake (Objectives 1 and 2)

Overview

The objective of Component One is to apply an integrative approach to engage heterosexual Black men in knowledge interpretation and uptake to inform the development of the HIP intervention. We will recruit 12 self-identified heterosexual Black men with diverse lived experiences. Participation criteria include being aged 18 years or older; being HIV-positive, HIV-negative, or having an unknown HIV status; engagement in faith, arts, media, health or social care, education, or social justice sectors; being interested in codeveloping culturally safe and accessible HIV health literacy intervention for heterosexual Black men and communities; and being available to take part in 2 series of 4 co-design workgroup sessions. To achieve our objective of developing an intergenerational HIP intervention, we will specifically recruit heterosexual Black men from 3 age groups: 18 to 29 years; 30 to 49 years; and 50 years or older. We will engage participants in 4 weekly sessions on critical interpretation of evidence [20-24] to create a shared understanding of HIV vulnerabilities of heterosexual Black men at multiple levels: intrapersonal, interpersonal, organizational, and policy levels. The shared critical understanding gained through the following 4 sessions will be used to inform the co-design of the HIP intervention in Component Two.

Session 1: Social Identities of Heterosexual Black Men and HIV Vulnerabilities

In this session, we will present existing evidence on how heterosexual Black men negotiate their racialized masculine identities and social positions (race or ethnicity, age groups, socioeconomic status, education, employment, relationship status, etc) through practices that may protect them from HIV and put them at increased risk of HIV. We will then engage participants to identify real-world and culturally relevant strategies to address these issues.

Session 2: Structural Determinants of HIV Vulnerabilities of Heterosexual Black Men

In this session, we will present existing evidence on how structural determinants and public policies impact the HIV vulnerabilities of heterosexual Black men through inaccessibility to HIV services and other health and social care resources, socioeconomic resources, and adequate health care access (access to employment, stigma, and discrimination, etc). We will then engage participants to identify real-world and culturally relevant strategies to address these issues.

Session 3: Gaps in HIV Response and Cascade of HIV Care Affecting Heterosexual Black Men and Communities

In this session, we will present local evidence on existing heterosexual Black men's experiences in accessing HIV prevention, testing, and care in Ontario. In addition, we will invite 3 heterosexual Black men panel speakers with lived experiences to share their insights about gaps in HIV response. We will then engage participants to identify strategies to address these issues.

Session 4: Critical HIV-Related Health Literacy for Change

In this session, we will engage participants in learning and critically examining the 3 levels of critical health literacy: (1) functional health literacy skills, that is, heterosexual Black men's ability to obtain relevant and accurate information on HIV prevention (eg, transmission, condom use, PrEP, and PEP; treatment as prevention; undetectable=untransmissible, etc) and connection to care (eg, HIV testing, early diagnosis, and treatment and care) to guide their actions and behaviors; (2) interactive health literacy skills, that is, heterosexual Black men's ability to extract information from different sources (eg,

XSL•FO
RenderX

evidence on social determinants of HIV vulnerabilities, Black pride as a protective factor, social support and resilience, etc) to make HIV related sexual and health decisions, and to interact with service providers with confidence to meet their health needs; and (3) critical health literacy, that is, heterosexual Black men's ability to analyze population health information (eg, proportion of HIV infections among heterosexual Black men compared to other groups; impact of gender discourses on sexual practices) to gain a critical understanding of HIV vulnerabilities in the context of social, economic, and environmental determinants, and to engage in organized efforts to advocate for health equity. We will hire an intervention specialist to work closely with the study team and participants in Component One to ensure that critical information and key elements for co-design are documented and applied in Component Two. Results from Component One will be presented to the PAC for feedback and discussion to inform Component Two.

Component Two: Co-design of HIP Intervention (Objectives 1 and 2)

The aim of this component is to apply the results from Component One to develop the HIP intervention and to seek community feedback on the intervention before pilot testing it in Component Three. We will engage the same 12 participants from Component One in the co-design of the HIP intervention. Participants who are not able to continue due to time constraints or other reasons will be replaced by new participants with detailed preparation based on the results of Component One. There will be *4 sessions* of the HIP intervention co-design:

1. In *session 1*, participants will collaborate to define the intervention objectives and outcome indicators.
2. In *session 2*, participants will identify the contents, learning activities, and required resources.
3. In *session 3*, participants will identify evaluation measurements (tools and indicators). After session 3, the team will work closely with the intervention specialist to construct the HIP intervention based on results and recommendations from participants. This semifinal HIP intervention will be presented to the PAC for feedback.
4. In *session 4*, participants will critically review the HIP intervention and collaborate to finalize HIP. The expected outputs of Component Two include 4-6 intervention modules with a facilitation manual, participant worksheets, experiential learning resources, and community engagement strategies. The HIP intervention modules will be designed based on the 3 levels of critical health literacy, as described above. In addition, we will produce a training toolkit for HIP champions with clear training objectives, theoretical concepts, demonstration videos, and implementation fidelity checklists to ensure that the intervention is implemented consistently.

Component Three: Piloting the HIP Intervention and Evaluation (Objective 3)

Piloting

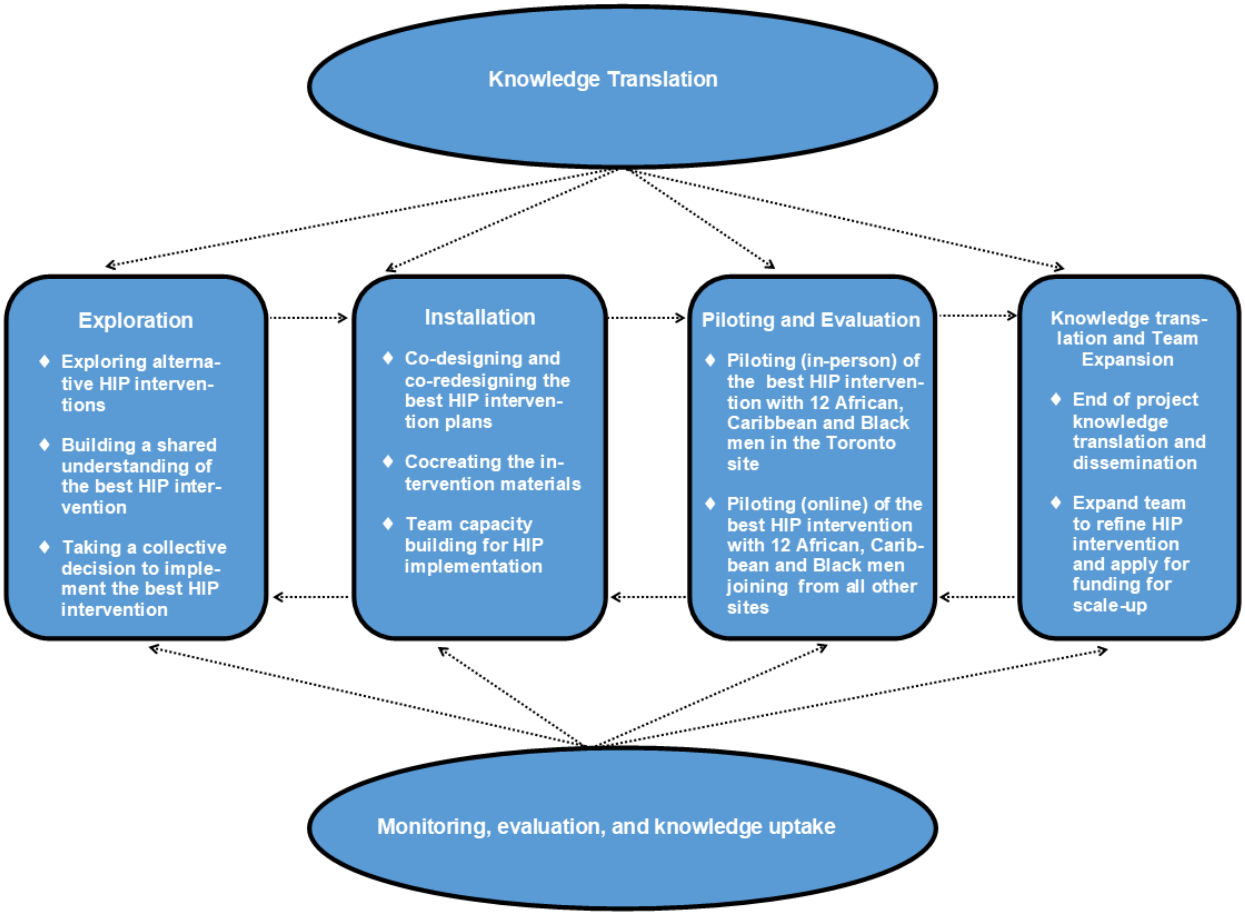
In Component Three, we will pilot the HIP intervention co-designed by participants in Components Two and Three. We will engage 2 groups of 12 heterosexual Black men (N=24): a total of 12 participants for in-person piloting in Toronto and another 12 participants for virtual piloting from all sites (a total of 3 per site). Based on our team's previous experience in intervention research, we anticipate that the HIP intervention will consist of 6 half-day sessions or eight 2-hour sessions (a total of 16-18 hours). Participation criteria include being self-identified as heterosexual Black men; being aged 18 years or older; being interested in HIV literacy and becoming an HIV prevention champion among heterosexual Black men and communities; and being available to take part in 16-18 hours of colearning in group sessions. To achieve our objective of implementing an intergenerational HIP intervention, we will specifically recruit heterosexual Black men from 3 age groups: 18 to 29 years, 30 to 49 years, and 50 years or older to engage in the HIP intervention. The HIP sessions will be cofacilitated by EBE and JPW in person and RA and PNB on the web. Piloting HIP as both an in-person and a web-based intervention will enable us to gain important insights for future scale-up. For example, the web-based format will enable us to engage heterosexual Black men across regions and increase access to participation among heterosexual Black men living in smaller communities.

Evaluation

All participants will be asked to complete a presurvey with sociodemographic information and questions on their knowledge of HIV transmission and prevention, community resources on HIV responses for heterosexual Black men and communities, structural determinants of HIV, stigma attitude, HIV testing behaviors, levels of community engagement, and readiness for HIV championship in Black communities. We will also invite participants to complete a survey at immediate-, post-, and 8-week post-HIP intervention to evaluate the effectiveness of HIP at all 3 levels of critical HIV health literacy. Depending on the final design of HIP, some of the relevant scales may include the HIV Knowledge Questionnaire [39], the adapted Social Capital Scale [40], the Multidimensional Inventory of Black Identity (MIBI) [41], and the Scale of Stigmatizing Attitudes Toward People Living with HIV (SAT-PLWHA-S) [42,43]. In addition, we will collect postsession feedback forms at each training session to assess participants' self-report of satisfaction, knowledge gained, and confidence in specific skills. Insights gained from the postsession feedback will be used to refine and improve HIP for future scale-up.

Data Analysis

Because the survey is for a small-sized sample (N=24), quantitative analysis will essentially be a univariate descriptive analysis with frequencies, percentages, and central tendencies (mean, median, mode, and range). We will use Braun and Clarke's [44] 6-step framework to conduct thematic analysis of the qualitative data from focus groups.



Component Four: End-of-Grant Knowledge Translation and Evidence Uptake (Objectives 1 and 4)

In addition to the knowledge translation activities integrated throughout phases 1-3, we will be engaged in end-of-grant knowledge translation in 2 ways. First, we will expand our

XSL•FO
RenderX

existing research team to engage additional community partners, interdisciplinary researchers, and knowledge users to form a new team to refine and scale up the HIP intervention for use across Ontario and Canada. Second, we will engage community partners and collaborators to coproduce and disseminate culturally inclusive, accessible, and audience-specific knowledge translation products (eg, infographics, e-posters, community reports, conference presentations, peer-reviewed publications, community forums to demonstrate HIP intervention activities, webinars, and social media postings). Figure 1 summarizes the interconnected relationships of all 4 study components [45].

Figure 1. Adapted Fixen's interconnected phases of implementation in HIP Project. HIP: HIV-response intergenerational participation.

Informed Consent

Participants who meet the inclusion criteria and express interest in participating will receive a consent form with detailed information describing the purpose of the study, the data collection process, anticipated risks and benefits, and the process of maintaining confidentiality. The consent will have principal investigator's contact information for participants to reach out to if they have questions or are seeking additional information about the study. Participants will be given a week to review the consent form to enable them to make an informed decision whether they want to participate. As an ongoing process, we will continually seek consent from participants during the implementation of each component of the project.

Team Expertise and Resources

Our interdisciplinary team consists of HIV researchers, service providers, community organizations, faith organizations, and heterosexual Black men. The team consists of researchers of diverse career stages (full professors, associate professors, assistant professors, postdoctoral fellows, research coordinators, and research assistants). The research team brings extensive relevant experience in HIV community-based research, knowledge mobilization, translating research evidence into community-based interventions, intergenerational intervention, heterosexual Black men studies, equity-based health research, etc. The team also includes community collaborators and partners, with capacities to contribute to project advisory, knowledge translation, and the design, delivery, and scaling up of the pilot intervention.

Potential Limitations and Strengths

We recognize 2 potential challenges in carrying out this research. First, as a catalyst project, we are testing out novel ideas over a 12-month period. To ensure that we achieve our objectives, we will establish an implementation plan with clear time lines and deliverables. We will also work closely with our knowledge users and collaborators to ensure successful community engagement. Second, our research activities require participants to engage in a series of 4-6 group sessions. We anticipate that some participants may withdraw due to other competing demands. We will overrecruit, that is, a total of 12 participants per group instead of 8-10 to ensure sustainable participation. In addition, we will design our group activities

XSL•FO
RenderX

in ways that promote enthusiasm and commitment, which our team has achieved in previous studies.

Ethics Approval

This study was reviewed and approved by the University of Toronto HIV Research Ethics Review Board (RIS Protocol #44285), the Toronto Metropolitan University Research Ethics Board (REB 2023-099), and the University of Ottawa Research Ethics Board.

Results

This is a funded 1-year project with a funding start date of September 2022. Due to the time lag for research ethics approval, data collection is proposed to commence in July 2023, with an expected project end date of March 2024. To date, recruitment has been limited to 12 members of the PAC who are providing insights into the project planning activities. Actual recruitment of participants will commence in July 2023 prior to data collection. We expect that our innovative, action-oriented project will produce numerous deliverables, including (1) documentation of effective processes to engage heterosexual Black men and community stakeholders in co-designing the HIP intervention; (2) knowledge and insights gained from piloting and evaluating the HIP intervention; (3) an evidence-informed HIP intervention that can be adapted for use by heterosexual Black men and communities beyond Ontario; (4) accessible knowledge translation products for community members as well as researchers and policy makers; and (5) an expanded team to refine HIP and secure resources to scale-up HIP across Ontario and Canada. We also anticipate many positive outcomes. At the individual level, the expected outcomes include increased capacity among heterosexual Black men to acquire accurate knowledge on HIV prevention and increased understanding of the structural influences on Black masculinities and sexualities; apply knowledge to guide their sexual practices and help-seeking behaviors; and gain increased skills in communicating their needs for HIV resources to service providers. At the collective level, we anticipate increased engagement and collaboration among heterosexual Black men, families, and communities to promote open dialogue about sexualities, HIV prevention and care, cultural pride, and collective resilience. There will also be increased capacity among heterosexual Black men and communities to advocate for a culturally inclusive HIV response and equitable access to related care and resources [46,47].

Discussion

The HIP is an innovative project that recognizes that heterosexual Black men's vulnerability and resilience are not an individualized phenomenon but a function of the social system in which they live. Based on this fact, HIP proposes to apply the collaborative efforts of heterosexual Black men themselves and members of their social system (leaders, service providers, intervention specialists, decision makers, and policy makers, community-based research experts, women, local businesses, the LGBTQ community, people living with HIV, etc) to co-design a culturally safe intervention. The pilot intervention will strengthen critical health literacy and build resilience against HIV vulnerabilities through intergenerational dialogue among heterosexual Black men of all ages without reinforcing any preexisting stereotype and discrimination against any other group in their social system.

Acknowledgments

The study is supported by Canadian Institute of Health Research (CIHR) catalyst grant (CDE-184602) and is being administered by Ontario HIV Treatment Network. The authors acknowledge the contributions of the Project Advisory Committee through their commitment to the planning of meetings at setup.

Data Availability

The anonymized and encrypted data generated by the study will be stored on a secure institutional repository for a period of 5 years for the purpose of conducting secondary analysis by researchers upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Alzheimer disease and related dementias (ADRD) pose significant challenges as chronic health conditions in the United States. Additionally, there are notable disparities in the diagnosis and prevalence of ADRD among diverse populations. Specifically, African American populations have a higher risk of developing late-onset ADRD than White people, and missed diagnoses of ADRD are more common among older African American populations than older White populations. These disparities also impact African American ADRD family caregivers.

Objective: The overall goal of this project is to develop a culturally informed, lay provider psychoeducational intervention named Senior Companion Program Plus (SCP Plus), which is specifically designed for African American ADRD caregivers and is potentially accessible, affordable, and sustainable.

Methods: In the proposed explanatory sequential mixed methods study, a randomized controlled trial will be used that includes 114 African American family caregivers of a relative with ADRD who will participate in the 3-month SCP Plus program.

Results: The study was funded on September 15, 2018, by the National Institutes of Health (1R15AG058182-01A1). Data collection began on May 16, 2019, but due to COVID-19 restrictions, ended 12 months into the planned 27-month recruitment period on March 31, 2023. The study was completed in June 30, 2023, and currently the results are being analyzed.

Conclusions: The SCP Plus offers promise as an intervention that utilizes an existing platform for the delivery of a lay provider intervention and offers a novel approach for addressing gaps in accessible, community-based support for caregivers of people with ADRD.

Trial Registration: ClinicalTrials.gov NCT03602391; https://classic.clinicaltrials.gov/ct2/show/NCT03602391

Introduction

Background

Approximately 6.7 million Americans aged 65 years and older are currently impacted by Alzheimer disease and related dementias (ADRD) [1]. Given that age is a key risk factor for ADRD and the number of older Americans continues to grow, it is expected that cases of ADRD will also increase [1]. ADRD is a disease marked by profound disability and dependence that worsen over time. Informal family caregivers provide most of the care to persons with ADRD, and they are at greater risk for negative physical and psychosocial outcomes when compared to noncaregivers or other types of caregivers [2].

Several intervention strategies have been implemented and evaluated to alleviate stressors and other negative outcomes among dementia family caregivers. In particular, research suggests that psychoeducational interventions may positively impact caregiver well-being, including burden [3], perceived health [4], and mental health [5,6]. While most psychoeducational interventions use trained interventionists, [7,8] peer-led interventions have demonstrated considerable promise. For example, research suggests that peer-led interventions may enhance family caregivers' social support and help with the management of chronic conditions [9-11]. Additionally, the translation potential of peer-led programs is further enhanced because of the use of lay providers rather than trained interventionists.

African American ADRD Caregivers

Based on demographic projections, the African American older population will grow to nearly 11% of the older adult population in the United States by 2050 [12]. Compared to White people, African Americans are about 2 times more likely to develop ADRD [1] and may live longer with ADRD than other races [13]. However, there are disparities in how ADRD is diagnosed and treated among African American older adults. For example, research suggests that missed diagnoses of ADRD occur more often among older African American adults than among Whites [14].

These disparities also affect African American ADRD family caregivers. Among this group, outcomes related to caregiver burden are mixed. For example, as reported by Brewster et al [15], a study presented by McLennon [16] indicated low scores on the Zarit Burden Scale [17] in African American ADRD family caregivers of persons with moderate-to-severe ADRD. However, the qualitative findings suggested that ADRD family caregivers experienced several challenges related to finances, safety concerns such as wandering, and providing physical care. Similarly, Brewster and colleagues [15] reported that in a mixed methods study of African American ADRD family caregivers conducted by Moss et al, participants scored relatively high on measures of quality of life but qualitatively reported stress and negative aspects related to caregiving [18]. Although psychosocial interventions for caregivers of persons with ADRD have shown promise, more research on culturally relevant interventions for African American ADRD caregivers is needed.

The Senior Companion Program

The Senior Companion Program (SCP) is one of 3 core programs funded by AmeriCorps.The SCP focuses on lower-income older adult volunteers providing assistance and friendship to other older adults who need support with daily living tasks [19]. SCP volunteers must be "at least 55 years of age or older and be capable of serving the frail elderly or adults who have one or more physical, emotional, or mental health limitations and are in need of assistance to achieve and maintain their highest level of independent living" [20]. Senior companions (SCs) serve as volunteers for 5 to 40 hours per week and receive modest hourly stipends [20]. Their typical tasks include providing assistance with meal preparation, offering medication reminders, accompanying their care recipient (CR) to social activities and medical appointments, and providing respite to family caregivers [20].

The Senior Companion Program Plus

Despite the benefits of the services provided by the SCP, many ADRD caregivers still report significant stress, as the SCP does not currently include a unique service to address caregiver stress/burden for ADRD caregivers [21]. Augmenting the SCP with ADRD-specific training is ideal as it extends the typical services of the SCP by providing psychoeducation to address the stress and burden that ADRD family caregivers continue to experience.

The Senior Companion Program Plus (SCP Plus) is the proposed intervention adapted from the work of Morano and King [22]. However, the SCP Plus differs from that work by training lay providers (ie, SCs) rather than clinical experts to deliver the intervention to increase its accessibility and translational potential. In the pilot study of the SCP Plus [21,23], the research team held focus groups with African American SCs to refine the work of Morano and King [22] and to adapt their intervention for use with the SCP. The SCP Plus trains SCs as lay provider "interventionists" to deliver a 9-week in-home psychoeducational intervention with African American ADRD caregivers. The SCP Plus includes 9 educational modules that cover topics on education, safety, strategies for challenging behaviors, communication, coping, finding purpose/meaning in caregiving, and community-based services (for an overview of each module, see Fields et al [23]).

The SCP Plus includes 12 hours of training for the SCs over 2 days and reviews the essential components of the intervention. Following this training, SCs deliver 1 module of the SCP Plus to the African American dementia caregivers during a weekly 60-minute meeting in the caregivers' or CRs' homes over a 3-month period (for a total of 9 hours). Based on the success of a pilot study of the SCP Plus [21,23], the proposed project will expand the program to 3 US states to conduct a randomized evaluation of efficacy.

For this proposed study, the revised sociocultural stress and coping model [24,25] provides the conceptual framework to examine caregiver burden, along with how cultural values affect the coping style, social support, and well-being of ADRD caregivers. This study's aims and hypotheses are listed in Textbox 1.

XSL•FO
RenderX

Textbox 1. Study aims and hypotheses.

- Aim 1: We will examine the specific effects of the Senior Companion Program Plus (SCP Plus) to increase knowledge about Alzheimer disease, reduce caregiver burden and stress, and increase caregiver well-being after the SCP Plus intervention.
- Hypothesis 1: Participants will indicate clinically significant and statistically significant (P<.05) reductions in caregiver burden/stress and increased caregiver well-being at 3 months and a 6-month postintervention interval.
- Aim 2: We will examine the specific effects of the SCP Plus to improve caregiver coping skills.
- Hypothesis 2: Participants will indicate statistically significant (P<.05) improvements in coping skills associated with dementia caregiving.
- Aim 3: We will analyze the specific effects of the SCP Plus to increase caregiver satisfaction with social support (eg, received support, satisfaction with support, social support network, and negative interactions).
- Hypothesis 3: Participants will indicate statistically significant (P<.05) increases in social support.
- Aim 4: We will explore and interpret the statistical results obtained in the first quantitative phase to help explain why participants who scored in the lower and upper quartiles on caregiver burden/stress were or were not impacted by the usefulness of the intervention.

Methods

Study Design

The proposed study is a randomized control trial that will assess the effects of SCP Plus on African American dementia caregiver stress and burden, coping skills, and social support. An explanatory sequential mixed methods design [26] will be utilized, involving collecting quantitative data first and then analyzing the data to identify subsamples of participants who reported the greatest and least change in caregiver stress/burden. Among individuals in the SCP group with the highest quartile (n=14, 25%) and lowest quartile (n=14, 25%) of change, we will conduct follow-up qualitative interviews to capture the details of their situation and present a more comprehensive analysis that leverages the strengths of both methods. We propose a 3-year study. The study will take place in collaboration with SCP at sites in Texas, Louisiana, and Arkansas with approximately 114 SC-caregiver dyads. Half of the sample will receive services as usual (SAU) without the SCP Plus intervention. The control group will be randomly selected after baseline screening of all family caregivers, and all measures will be collected blind to the group condition. To further prevent selection bias, statistical techniques such as mixed factorial analysis of covariance (ANCOVA) will be conducted to adjust for covariate imbalance during data analysis.

Participants and Setting

Power analyses performed with G*Power software (version 3.1.9) indicated that a total of 114 participants are required to address our primary research objective using a mixed factorial ANOVA of our primary study outcome—caregiver burden. This sample size estimate was based on a small effect size (f=.12) and a 2-tailed alpha of .05 and a beta of .20. This effect size estimate was generated from our pilot data, which indicated a mean change in caregiver burden of 2.82.

Study participants will be the SC-caregiver dyads that include the SCs (n=114) recruited from the state-wide agencies with SCP as well as the African American caregivers (n=114) of older adults with ADRD who are currently enrolled in a Senior Companion Program in Texas, Arkansas, or Louisiana. Each dyad consists of 1 SC matched with 1 caregiver. To be eligible for this study, SCs must be (1) currently participating in the SCP and (2) currently providing respite services to the caregivers. As per the requirements of the SCP, SCs must be "55 years of age or older, be determined by a physical examination to be capable of serving the frail elderly, and be able to provide such service without detriment to either themselves or the clients served" [20]. For caregivers that receive services from the SCs, they must be (1) self-identified as African American, (2) 21 years of age and older, (3) providing unpaid care for an older adult with ADRD, and (4) cognitively intact as measured by a 6-item screener [27]. CRs with ADRD must have a physician diagnosis of ADRD and live at home in the community. Caregivers who are involved in another caregiver psychosocial intervention study or have an acute illness that would prevent them from participating for at least 6 months will not be eligible.

Study Procedures

Randomization

The SCP directors at each site will first help identify the potential SC-caregiver dyads who meet the inclusion criteria. The identified potential participants will then be randomly selected, and the research team will contact them afterward. Participant dyads who are interested in participating in the study will be guided through the informed consent process, administered a baseline survey via phone, and randomized to one of two groups: (1) the SCP Plus group that will receive the intervention plus SAU and (2) the control group that only receives SAU as part of the SC Program. SAU includes providing respite care for the family caregiver and personal care and light housekeeping/meal preparation for the person with dementia.

Data Collection

Quantitative data will be collected at preintervention, postintervention, and at the 6-month postintervention follow-up. The research team will then analyze the quantitative data at 3 time points to assess the effectiveness of the intervention and identify caregivers who reported the greatest and least change in caregiver stress/burden. Individuals in the highest and lowest quartiles of change in stress/burden will be recruited for follow-up interviews to understand their results in more depth through a qualitative study analysis.

XSL•FO
RenderX

SAU Program

For SAU, SCs volunteer with frail, low-income older adults approximately 20 hours a week. SCs' tasks include helping older adults with ADRD by accompanying them to health care professional appointments, accompanying them to recreation/social activity/senior centers; providing assistance with ambulation and mobility; dressing, grooming, and feeding; reading, writing letters/forms; light cleaning; light meal preparation; monitoring for safety; peer support/companionship; and general caregiver respite. As part of the SCP, all SCs receive 40 hours of training from their agency, which includes topics such as program and agency policies, code of conduct, and a criminal background check.

SCP Plus

SCs randomly assigned to the SCP Plus will receive the 12-hour training. Two members of the research team will conduct all the SCP Plus training in person at each site. The training protocol was developed to affirm and build on the SCs' existing knowledge and skills related to ADRD caregiving [23]. The SCP Plus training will be delivered in person in a group format that includes both didactic approaches and role-play experiences. The SCP Plus training will last 2 days (6 hours per day). To ensure treatment fidelity related to the training, manuals and protocols for the training were created before the onset of this study. The training material will be audio recorded and reviewed by the research team using a checklist to quantify adherence to the training program.

SCP Plus is based on a dementia caregiver program [22] and adapted by Fields and colleagues [21,23]. ADRD caregivers whose SCs are randomly assigned to the intervention group will receive the SCP Plus intervention. The SCP Plus intervention will be delivered face-to-face by the SC who is a part of the SC-caregiver dyad. The intervention involves 9 in-home psychoeducational sessions over a 3-month period with 1 session per week.

Every week for 9 weeks, the SC-caregiver dyad will meet for 1 hour in the home of the CR (ie, the person with dementia). This allows the SC to maintain their duties while still participating in the SCP Plus program. It also allows the ADRD caregiver to receive intervention in the home setting of the person with dementia. Each week, the SC will deliver 1 module from the SCP Plus. "Icebreaker" questions will be included at the beginning of each module to answer any questions that the ADRD may have from the previous module and to facilitate a time for informal, supportive communication between the SC and the ADRD caregiver. At the end of each module, the SC will ask the ADRD caregiver to reflect on the content of the module, which will be written down in the form of brief notes by the SC. The inclusion of incentives (ie, retail gift cards) will be used to reduce caregiver attrition.

Measurements

The outcome evaluation will include measures of caregivers' stress and burden, knowledge of ADRD, coping skills, social support and activity, caregiver appraisal, caregiver physical health, and cultural justifications for caregiving. Standardized measures will be used to assess these outcome variables. The study by Xu and colleagues [28] contains an illustration of how these measures are mapped onto the conceptual model for this study.

The sociodemographic characteristics of the caregivers and their CRs will be collected at baseline, including age, gender, education, length of caregiving relationship, self-rated health [29], and number of hours spent in caregiving. Information about CRs' activities of daily living (ADL) and instrumental activities of daily living (IADL) that require help from caregivers will also be collected [30]. The Global Deterioration Scale [31] will be used to measure the severity of dementia of the person with ADRD. The frequency and duration of weekly contact with the SC will also be collected from the agency timesheets.

Dementia Caregiver burden and stress will be measured by the Zarit Burden Interview (ZBI) [17]. The ZBI was developed to measure the burden experienced by caregivers of persons with dementia living in the community [32]. The ZBI has 22 items measured with a 5-point Likert scale ranging from (never) to 4 (nearly always). Total sum scores range from 0 to 88, with higher scores indicating higher levels of distress. Studies have shown that ZBI has good validity and reliability among various minority dementia caregivers [33], particularly African American caregivers [34].

Knowledge of ADRD will be measured by the Knowledge of Dementia (KAD) scale [35]. KAD consists of 4 subscales concerning the (1) epidemiology and etiology of ADRD, (2) perceived effectiveness of different and currently available treatments, (3) beliefs regarding the perceived threat of ADRD for oneself, and (4) how respondents learned about the disease. KAD has shown good reliability and validity in assessing attitudes and beliefs regarding ADRD among dementia caregivers of different ethnic minorities [36].

Coping skills will be measured by the Brief Coping Orientation to Problems Experienced (COPE) subscales and religiosity coping. The Brief COPE questionnaire consists of 28 items measuring the ways/strategies caregivers have been coping with the stress in their life with a 4-point scale ranging from 1 ("I have not been doing this at all") to 4 ("I have been doing this a lot"). This scale has shown good validity and reliability in caregivers of persons with dementia [37]. Religiosity coping will be examined with the short form of the Brief Religious Coping (RCOPE) scale to measure the positive and negative aspects of religious coping [38]. All items are measured on a 4-point scale ranging from 0 ("a great deal") to 3 ("not at all"). This measure has shown good validity and internal consistency among racially and ethnically diverse populations of ADRD caregivers [33], including African American participants [39].

Social support will be measured with 13 items from four domains: (1) received support [40,41], (2) satisfaction with support [41,42], (3) social support network [43], and (5) negative interactions [41]. Social support networks will be measured by a modified Lubben Social Network Scale [43] that uses 3 items on a 6-point scale (none, 1, 2, 3 or 4, 5 to 8, and 9 or more). All other items have a 4-point scale that ranges from 0 (never) to 3 (very often) [44]. Social support measures have been proven to

XSL•FO
RenderX

be valid and reliable with ethnic minority dementia caregivers [39], including African American dementia caregivers [39].

Caregiver appraisal will be measured with two components: (1) appraisal of problem behaviors and (2) appraisal of benefits. For an appraisal of problem behaviors, a modified version of the Revised Memory and Behavior Problems Checklist (RMBPC) [45] will be used to ask caregivers whether CRs' problems occurred during the past week (yes or no). If the answer is yes, caregivers will then be asked to rate how much the problem "bothered or upset" them on a 5-point Likert scale ranging from 0 (not at all) to 4 (extremely). RMBPC has been shown in the literature to be a valid and reliable measure for different ethnic minority caregivers [46], especially African American caregivers [47]. For appraisals of benefits from caregiving, the Positive Aspects of Caregiving (PAC) scale will be assessed [48]. The PAC has 9 statements about the caregiver's mental affective state regarding their caregiving experience. Each statement begins with "Providing help to the care recipient has…" followed by specific items (eg, made me feel useful, enabled me to appreciate life more). Each statement is rated on a 5-point Likert scale ranging from 1 (disagree a lot) to 5 (agree a lot). Studies show that the PAC is a valid and reliable measure for different ethnic minority dementia caregivers [33] and especially useful for African American dementia caregivers [49].

Caregiver well-being will be measured by the 12-Item Short-Form Health Survey (SF-12) [50] and the 16-item short version of the Caregiver Well-Being Scale (CWBS-ShortVersion). The SF-12 is a frequently used screening scale used to measure physical and mental health outcomes. It asks participants about their health, how they feel, and how well they can complete their usual daily activities. It has been shown to be a valid and reliable measure with African American older adults [51]. The CWBS-ShortVersion was developed to help family caregivers, clinicians, and researchers to identify areas of caregiver strength and areas in which additional support is needed. All 16 items will be measured by a 5-point scale ranging from 1 (rarely) to 5 (usually). The CWBS-ShortVersion has good content and construct validity regardless of the ethnicity of the caregivers [52].

Cultural justifications for caregiving will be measured by the Cultural Justifications for Caregiving Scale (CJCS) [53]. The CJCS consists of 10 items designed to assess caregivers' cultural reasons and expectations in providing care. Each item is measured using a 4-point Likert scale ranging from 1 (strongly disagree) to 4 (strongly agree). Summed scores range from 10 to 40, with higher scores indicating stronger cultural reasons for giving care. Study results have shown this scales' good reliability and validity score with African American caregivers [54].

Qualitative Questions

The second qualitative phase will explore and interpret the statistical results obtained in the first quantitative phase. The interview protocol will include a semistructured interview guide to explore domains of difference (eg, perceptions of treatment, level of engagement, and intervention processes).

Data Analysis

Quantitative Data Analysis

After the data are collected and entered into statistical software, the data quality will be carefully reviewed and then checked both automatically and manually. These review processes include checking the coding of observations, responses, and out-of-range values in SPSS software (IBM Corp), adding variable and value labels where appropriate, checking completeness or any errors of data entry, double-checking any errors in statistical analyses, and correcting errors made during transcriptions. In addition, data will be reviewed for risk of disclosure of research participants' identities, for sensitive data, and for private information to ensure confidentiality. Since all the key concepts in the proposed study are measured with standard scales, reliability tests for each scale and test-retest reliability across the 3 surveys will be conducted. Summed scores will be calculated for each of the standard scales.

Any random missing data, such as those due to random mistakes in data collection and entry, and are not related to research staff or patient noncompliance, will be submitted to maximum likelihood estimation procedures to estimate those missing values. Maximum likelihood estimation for random missing data is a common and accepted procedure for missing data estimation [55,56].

We will apply an intent-to-treat analytic approach to the study data. Fisher exact tests, Pearson chi-square tests, and independent sample *t* tests will be computed to test for group differences that may be attributable to caregiver variables such as gender, age, ethnicity, clinical site, length of caregiving relationship, and number of hours spent in caregiving. If the groups significantly differ on any of these variables, the variable will be incorporated into the following analyses as a covariate, thereby controlling for potential influences that the covariate may have on the dependent variables. As noted in the statistical literature, large power gains can be achieved by including correlated stationary covariates in ANCOVA, ordinary least squares regression, and Cox proportional hazards regression [57]. Moreover, if at the culmination of this study, our sample sizes are unequal in the treatment groups and our outcome data are nonnormal, we will follow through with appropriate statistical corrections where necessary.

Mixed factorial ANCOVAs will be computed to compare the SCP Plus and SAU over time on caregiver burden (ZBI), beliefs about dementia (KAD), coping (Brief COPE), social support, caregiver appraisal, well-being (CWBS-ShortVersion), and cultural expectations (CJCS). The covariates will be any significant variable yielded from the univariate analyses, and the dependent variable will be the scores at the pretest, posttest, and 6-month follow-up periods. Moreover, 95% CIs will be computed for each adjusted mean difference. The study alpha will be set at .05, with no adjustments for multiple comparisons due to the preliminary nature of this study and the increased risk of type 2 errors as a result of alpha adjustment [58]

Qualitative Data Analysis

Qualitative interviews will be recorded digitally, transcribed, and analyzed using conventional content analysis [59]. A

XSL•FO
RenderX

constant comparative approach [60] will be used to explore similarities and differences in participants who did and did not benefit from the SCP Plus. Multiple strategies will be utilized to address rigor and credibility including peer debriefing and an audit trail.

Ethics Approval

The study protocol was approved by the Institutional Review Board of the University of Texas at Arlington (2017-0431 on 9/30/2018). It will be conducted following the Declaration of Helsinki.

Results

This study was funded on September 15, 2018, by the National Institutes of Health (1R15AG058182-01A1). Data collection began on May 16, 2019, and ended on March 31, 2023. The study was completed in June 30, 2023, and currently the results are being analyzed.

The study participants are SC-caregiver dyads. Due to COVID-19 social distancing requirements, data collections were halted in March 2020, 12 months into the planned 27-month recruitment period. The final sample size for the proposed study consisted of 20 dyads at baseline, and only 11 CGs completed the posttest and follow-up test. There were no missing data, so imputation was not necessary.

For the SCs in the 3 sites (N=20), all of them were female with a median age of 71 (range 58-80) years. Over one-third were either widowed or divorced (n=8, 40%). In terms of educational status, half (n=10, 50%) of the SCs were high school graduates or below. All SCs reported attending a religious service at least once per month. The participating SCs had taken care of their current CR with ADRD for a median of 4.5 (range 1-15) years and provided a median of 30 (range 6-40) hours weekly for their CRs. The majority (n=17, 85%) of the SCs felt very confident or confident in providing care to their clients with ADRD. Half (n=10, 50%) of them reported difficulty in paying for their basic needs (ie, financial strain). In general, the SCs had moderate levels of self-rated health (median 3). They helped their CRs with ADL (median 2.5, range 0-6) and IADL (median 7.5, range 4-8).

For the caregiver participants, the 20 CGs were a median age of 60.5 (41-80) years. The majority were female (n=17, 85%), married (n=11, 55%), and lived with their CR (n=16, 80%) for a median of 3 (range 0-48) years. The majority (n=15, 75%) of the CGs worked outside of the home, 45% (n=9) were employed full-time, and 35% (n=7) had to reduce their working hours to take care of the CRs. The CGs reported that spirituality was important (median 3.5, range 1-4). They also regularly attended religious services (median 3, range 1-5) and often prayed or mediated (median 5, range 1-5). The majority (n=13, 65%) of the CGs were children of the CRs. They had been taking care of their CRs for a median of 5 (range 1-26) years and provided a median of 12 (range 2-24) hours of care daily. The majority of CGs used formal services “several times a week” (n=16, 80%) and were “satisfied” or “strongly satisfied” (n=18, 90%) with the services received. The CGs had moderate self-rated health (median 3, range 1-5). They reported their CRs’ general health as low (median 1.5, range 1-4) and their memory issues as a median of 25 (range 10-49).

For other results, please see Xu and colleagues [28].

Discussion

Expected Findings

SCP Plus offers an innovative approach to using a peer-led psychoeducational intervention for caregivers of persons with ADRD. Given that the SCP is a national program, there is potential for sustainability and cost-effectiveness. SCP Plus will advance the scientific knowledge about how African American ADRD caregivers can build coping skills and protective factors through engagement with lay health care providers such as SCs. The implementation of the SCP Plus will increase insight into the sociocultural experiences of dementia caregivers and enhance the ability of community-based providers to meet the unique needs of minority caregiver populations.

Limitations

Due to the risks and feasibility of conducting an in-person intervention with SCs and ADRD caregivers during COVID-19, data collection for the intervention was suspended in March 2020. For a full description of the study limitations, see Xu et al [28].

Comparison With Prior Work

During the past 30 years, the development and evaluation of ADRD caregiver interventions have focused on providing information, skills building and psychoeducation, psychosocial support, and respite to families [61]. Although many ADRD caregiving interventions have demonstrated efficacy, these programs are inaccessible to the majority of family caregivers; for these reasons, current efforts have focused on translating interventions into clinical or community-based settings to evaluate the relevance of study outcomes for key stakeholders [62,63]. However, it remains unknown whether existing dementia caregiver interventions are culturally relevant to African American dementia caregivers [62].

Conclusions

The proposed project is aligned with the National Alzheimer’s Project Act [64] to better address the needs of persons with ADRD and their family caregivers. In particular, SCP Plus is aligned with three NAPA recommendations: (1) ensuring that family and unpaid caregivers have the support that they need; (2) ensuring representation and diversity in ADRD research; and (3) researching evidence-based interventions for ADRD care support. Finally, the implementation of SCP Plus will increase knowledge about how ADRD caregivers from minority populations can build coping skills and protective factors through engagement with lay health care providers such as SCs.

Abstract

Background: Postpartum depression and anxiety are the 2 most common perinatal mental health disorders, with prevalence rates higher among women living in the Middle East than in most Western countries. The negative outcomes associated with postpartum depression and anxiety are profound and include less responsive parenting and compromised infant and young child development. Although interventions exist to prevent postpartum depression and anxiety, to date, there have been no studies that have attempted to prevent postpartum depression or anxiety among Arabic-speaking women in the Middle East, including Qatar.

Objective: The purpose of this study is to conduct a randomized controlled trial (RCT) of an evidence-based postpartum depression preventive intervention—Mothers and Babies (MB)—culturally adapted for use with Arabic-speaking women in Doha, Qatar. MB is guided by a cognitive behavioral therapy framework that focuses on increasing pleasant activities, promoting healthy thought patterns, and increasing the type and frequency of personal contacts. MB is tailored to specific needs and issues related to pregnancy and the postpartum period.

Methods: A multidisciplinary and multiethnic investigator team adapted MB to promote cultural and contextual fit for Arabic-speaking women. Intervention concepts were reviewed to ensure core content would be understood by Arabic-speaking women in Qatar. Subsequently, images, activities, and examples in the intervention manuals were adapted, as needed, to make the content more relevant to Arab culture. To deliver the adapted intervention, 30 Arabic-speaking individuals with mental health backgrounds were trained. The adapted intervention was subsequently pilot-tested with 10 pregnant women receiving prenatal care at Sidra Hospital in Doha. We are now conducting an RCT to examine the effectiveness of the adapted intervention. We plan to enroll 210 pregnant individuals who are Arabic-speaking, with 1:1 randomization to the MB intervention or usual prenatal care. Among the enrolled participants, a stratified subsample of 40 pregnant women with diabetes is being recruited. Data collection will take place at baseline and a 6-month follow-up. The primary outcomes are depressive and anxiety symptoms and perceived stress. Diabetes self-care is the exploratory outcome for the subsample of individuals with diabetes. Intervention implementation will be assessed via client and provider surveys during and after intervention delivery. Power and sample size were calculated using a 2-sided 5% effort rate and assumed analyses on the individual level, accounting for attrition of 20%.

Results: The cultural adaptation and pilot study of the adapted MB intervention are completed. A total of 157 women have been enrolled in the RCT as of March 31, 2023.

XSL•FO
RenderX

Conclusions: This study is highly innovative, as it is the first study to our knowledge to examine the effectiveness of an evidence-based postpartum depression preventive intervention in the Middle East. Limitations include a single follow-up time point and a small subsample of individuals with diabetes.

KEYWORDS

postpartum depression; intervention; prevention; cultural adaptation; Arabic

Introduction

Perinatal mental health (PMH) disorders are common and have significant impacts on women, their infants, families, and communities [1,2]. Postpartum depression and postpartum anxiety are the 2 most common PMH disorders [3,4]. Systematic reviews have found a pooled prevalence of 15.5% across studies conducted in high-income countries [5], while systematic reviews of studies conducted in low- and middle-income countries found a higher pooled prevalence of 24.7% [6]. Among low- and middle-income countries, the highest prevalence rates were found in the Middle East and North Africa. Studies conducted in Qatar have found postpartum depression prevalence rates ranging from 18.6% to 27.3% [7,8].

An array of efficacious interventions exist that prevent postpartum depression [9,10], with several of these interventions demonstrating effectiveness in improving anxiety symptoms given the comorbidity with postpartum depression [11]. One intervention that has demonstrated efficacy in reducing depressive and anxiety symptoms and preventing the onset of new cases of postpartum depression is the Mothers and Babies (MB) course [12-15]. MB is a manualized intervention guided by a cognitive behavioral therapy (CBT) framework. CBT is characterized by a focus on (1) increasing pleasant activities, (2) focusing on one's thoughts, and (3) the type and frequency of personal contacts (ie, social support). MB contains a module in each of these 3 areas. The content of MB is tailored to specific needs and issues related to pregnancy and the postpartum period.

Despite the prevalence rate of postpartum depression exceeding those found in Western countries and the availability of interventions effective in preventing postpartum depression, to date, there have been no intervention studies that have attempted to prevent postpartum depression among Arab women in the Middle East and North Africa region, including Qatar. The overarching goal of this study is to examine the feasibility, acceptability, and outcomes associated with MB delivered to women in Doha, Qatar. However, because MB was developed and previously examined when delivered to Western pregnant women, cultural adaptation was required before rigorous testing of the intervention in Qatar. The specific aims of this study are:

1. To adapt MB for use with Arab Arabic-speaking women in Qatar. Cultural and contextual adaptations were undertaken by a multidisciplinary and multiethnic research team.
2. To conduct a small pilot study (n=10) that examines the acceptability, appropriateness, and feasibility of the adapted MB intervention when delivered to Arab Arabic-speaking women in Qatar. Pilot study findings are used to make final revisions to intervention and research protocols.
3. To conduct a randomized controlled trial (RCT; n=210) to determine the effectiveness of the adapted MB intervention on depressive symptoms, anxiety symptoms, and perceived stress among Arab Arabic-speaking women in Qatar. Our primary hypothesis is that women receiving the adapted MB intervention will exhibit greater reductions in depressive symptoms, anxiety symptoms, and perceived stress compared to women not receiving the intervention.

A subaim is to recruit a stratified random sample of 40 women with diabetes (n=20 control group; n=20 MB intervention) and examine intervention effects on mental health outcomes as well as diabetes self-management.

Methods

Ethics Approval

The study procedures described below have been approved by the institutional review boards of Sidra Medicine (2019-0004) and Northwestern University (STU00211149).

Study Participants, Recruitment or Retention, and Informed Consent

A total of 210 women will be recruited. Women will be recruited from the prenatal care clinic at Sidra Medicine in Doha, Qatar. Women >18 years of age receiving prenatal care at Sidra Medicine—a women's and children's hospital—who are <28 weeks' gestation at the time of study enrollment, are of Arab origin, and speak Arabic fluently will be eligible. Women meeting these criteria will be approached by Arabic-speaking research assistants while they are waiting for their prenatal health care appointment. Research assistants will administer the Edinburgh Postnatal Depression Scale (EPDS) [16] and the Generalized Anxiety Disorder-7 (GAD-7) item version [17]. To be eligible for the study, participants must score between 7 and 12 on the EPDS or 10-15 on the GAD-7, symptom ranges that are both indicative of mild to moderate symptoms of depression and anxiety, respectively. Participants who endorse a past history of major depression will also be eligible, while individuals endorsing current treatment for depression will be excluded given this study's focus on the prevention of postpartum depression and anxiety. Other exclusion criteria have been minimized; however, women who self-reported receiving mental health treatment or having a serious mental health condition will also be excluded, as this may preclude

XSL•FO
RenderX

women from regularly attending intervention sessions. Once eligibility is determined, the Arabic-speaking research assistant will introduce the study, answer any questions, and obtain signed informed consent from the participant.

Recruitment procedures emphasize the importance of participating in all MB sessions (for intervention participants) and remaining in the study through the 6-month follow-up assessment. The research team obtains ample tracking information at baseline, which includes the participant's name, email address, home and cell phone numbers, and mailing address. The research team uploads contact information about each participant's preferred mode of communication (eg, phone and text) at the time of recruitment.

Randomization Procedures and Intervention Conditions

Randomization Procedures

Stratified permuted block randomization with blocks of sizes 2 and 4 will be used to randomize consenting women into the control arm or the intervention arm in a one-to-one fashion. The stratification will be based on the diabetic status of the woman. The randomization will be done by a statistician who is not involved in recruiting patients. A randomized list was created by the biostatistician, which was later uploaded to Research Electronic Data Capture (REDCap; Vanderbilt University) [18,19], a web-based software package for data management. This allows for the lack of human involvement on the part of the research team in the assignment of a participant to a group. It also allows for the on-the-spot assignment of participants into either the control or intervention groups.

Control Arm

Women randomized to the control arm will receive standard prenatal care delivered at Sidra Medicine.

Intervention Arm

Women randomized to the intervention arm will receive the culturally adapted MB intervention. MB consists of 12 sessions, each designed to last 15-20 minutes. The first 2 sessions provide (1) an understanding of the emotional and physical outcomes associated with stress, including concerns related to parent-child interaction, (2) strategies to notice one's mood, and (3) an overview of how the remaining CBT content can help minimize stress levels. Sessions 3-5 focus on the CBT module of Pleasant Activities, while sessions 6-8 focus on Thoughts, and sessions 9-11 focus on Contact with Others. Session 12 is a course wrap-up and graduation. Intervention sessions provide concrete skills participants can use—for example, developing lists of pleasurable activities and strategizing how to overcome obstacles to engage in those activities. At the end of each session, a short personal project is provided to participants to encourage skill practice prior to the next session. Intervention sessions are delivered in-person, by phone, or via telehealth (Zoom and Microsoft Teams) by a mental health professional trained in MB. Sessions are intended to be delivered weekly or every other week, with flexibility given to deliver sessions at the same time to facilitate the timely completion of the intervention. Incentives will be provided to participants after completing each MB module to encourage their continued intervention participation. Additional content was added to selected sessions for the diabetic subgroup. This content was intended to draw links between the core MB cognitive-behavioral skills and diabetes management and self-care. For example, content that indicates how exercise and a healthy diet—aspects that are important for diabetes management—are also related to mental health, as both interventions have a positive effect on mental and emotional well-being, was added.

Interventionist Training

Interventionist training in MB was provided by the senior author (SDT) and first author (SRA). Training was a 1-day in-person training conducted at Sidra Medicine. The first part of the training covered the conceptual underpinnings of MB (eg, its cognitive-behavioral framework), a brief history of previous implementation of MB, instruction on the format of the MB instructor manual, and discussion of implementation logistics. The second part of the training reviewed each of the 12 MB sessions from start to finish. Training was interactive, with opportunities for discussion and modeling the communication of material by the trainers. Training also involved group activities, where training attendees practiced delivering curriculum material and received feedback on strengths and areas needing improvement from the trainer and other training participants. We trained 30 individuals who met the following criteria: (1) employed as a nurse or health care professional or received graduate training in psychology; (2) were aged 18 years or older; and (3) had at least a bachelor's degree in nursing or psychology, or equivalent mental health counseling training, experience, or certification. All trained individuals were fluent in Arabic.

Data Collection Procedures and Study Assessments

The RCT includes 2 data collection time points—baseline and 6-month follow-up. We will attempt to collect 6-month assessments for intervention participants regardless of their engagement with the intervention. Participants will receive a remuneration of US $40 after completing each survey. Baseline and follow-up data will be collected and managed using REDCap. Women who do not choose to complete REDCap assessments will be contacted by phone by the research assistant to complete the assessment by phone or in person.

This study's primary outcomes are a reduction in depressive symptoms, anxiety symptoms, and perceived stress. Secondary outcomes are closely linked with core MB content; secondary outcomes include behavioral activation, social support, mood regulation, decentering of thoughts, and MB skill use. The outcome associated with our exploratory aim is diabetes self-care. All measures have been validated in Arabic.

We will also assess various aspects of intervention implementation. We will conduct client surveys at the end of each MB module to assess clients' perceptions of intervention acceptability and satisfaction. Each survey lasts 2-3 minutes and asks 3 questions pertaining to enjoyment with MB material, understanding of MB material, and anticipated use of MB material. Six months after a facilitator begins MB delivery with a client, the facilitator will receive a REDCap survey to report

XSL•FO
RenderX

on the extent to which they covered all topics within an MB session (on average) and the extent to which clients were engaged in the MB material during intervention sessions.

Safety and Data Monitoring

For any woman who endorses the suicidality question on the EPDS screener with a response that they think about suicide "quite often" or "sometimes," the research assistant conducting the EPDS will escort the client to the outpatient mental health clinic, ensuring that the client is seen by a clinician. The clinicians in the Sidra Medicine outpatient clinic are trained to determine whether the client is in danger of harming herself or others and will determine the necessary steps to ensure the safety of the study participant. Regarding data monitoring, the study team will develop a series of data status and quality reports via an automated task, which study staff will review each week. These reports will focus primarily on reviewing missing data from collected assessments, accrual and retention, adverse events, and the number of women endorsing suicidal ideation.

Statistical Analysis

A flowchart will be constructed based on the CONSORT (Consolidated Standards of Reporting Trials) guidance to show the number of recruited, excluded, lost to follow-up, and analyzed participants. Descriptive statistics will be used to summarize baseline characteristics overall and by study arm. As appropriate, mean (SD) and frequency (proportions) will be used to summarize continuous and categorical variables, respectively. Median (IQR) will be used in cases of skewed or nonnormal distributions. Analyses will use normal theory methodology as appropriate, and in cases of violations of assumptions, transformations or nonparametric analyses may be used. We will use SPSS (version 27; IBM Inc) to perform all analyses.

Analyses will be done using the intent-to-treat principle and will compare the 3 primary outcomes between study arms using the independent 2-tailed *t* test (or the Wilcoxon rank sum test in cases where outcomes were highly skewed). The analyses above will be repeated using univariate linear regression to be able to adjust later for any imbalances in baseline characteristics between the study arms and the baseline values of the primary outcomes. Additional analyses will include fitting multivariate linear regression models for each of the 3 main outcomes to assess the effectiveness of the intervention while adjusting for the baseline value of the outcome and any observed imbalances in participants between the 2 study arms. Unadjusted and adjusted mean differences in the primary outcomes between the 2 study arms will be presented along with their standard deviations and *P* values. For the primary outcomes, missing data at 6 months will be imputed using the average of the patients in that group or other methods such as multiple imputation by chained equations, and the primary analyses will be repeated as a sensitivity analysis. Secondary outcomes will be analyzed by comparing study arms using the chi-squared test (or Fisher exact test if expected cell counts are below 5) for categorical outcomes and the independent 2-tailed *t* test (or Wilcoxon rank sum test for highly skewed data) for numeric outcomes. Compliance with the intervention will be assessed by counting the number of intervention sessions received.

Power and Sample Size Calculations

With 105 participants recruited per study arm and an estimated attrition of 20%, the study will be able to detect an effect size of 0.5 in any of the 3 primary outcomes using the independent 2-tailed *t* test with a power of 80% and a significance level of .017.

Results

This study is in progress. We have completed the cultural adaptation of MB as well as the pilot study of the adapted MB intervention. Recruitment for the RCT began in February 2022.

Cultural Adaptation of MB

A multidisciplinary Arabic-speaking research team comprised of psychologists, psychiatrists, obstetricians, endocrinologists, and nurses led the adaptation process. This research team was of different Arab backgrounds, with ethnic backgrounds represented including Qataris, Egyptians, Sudanese, Omani, and Palestinians. This combination of different ethnic backgrounds helped tailor MB to ensure a diversity of Arab cultures. The research team worked from the MB facilitator and participant manuals and reviewed them to first ensure that core intervention concepts would be understood by Arab-origin, Arabic-speaking women in Qatar. Additionally, images, activities, and examples found in the manuals were reviewed and adapted, as needed, to render the content more relevant and appropriate to Arab culture. For example, mindfulness sessions were adapted to include an Islamic and spiritual perspective to introduce the mindfulness sessions to the client (eg, how to improve the relationship with God, which can help in daily life and how to practice culturally informed mindfulness practices). Examples of pleasant activities that clients could engage in were modified to include culturally appropriate examples (eg, reading from the Quran and visiting family) and address contextual differences in activities (eg, removing examples of window shopping and gardening) that are not typically performed by Arab women in Qatar.

Pilot Study of Adapted MB

A byproduct of this project is deepening the capacity of mental health professionals in Qatar to address mental health with their perinatal clients. As such, 29 individuals fluent in Arabic were trained on the adapted MB manuals. The individuals included graduate students from the Doha Institute for Graduate Studies' new master's in psychology program, medical students from Weill Cornell Medicine in Qatar, PMH nurses from Hamad Medical Corporation and Primary Health Care Cooperation, and nurses from Sidra Medicine. The nomination of these trainees was performed based on their medical backgrounds, prior experience with CBT, and availability to deliver the intervention during the time frame of the research study. Training was led by the 2 multiple principal investigators (SRA and SDT). Training occurred over a full day and introduced trainees to the MB intervention's core concepts and implementation considerations. Subsequently, each intervention session was reviewed with key considerations highlighted by the trainers. Emphasis was placed on highlighting places in the curriculum where adaptations were made to promote cultural

XSL•FO
RenderX

and contextual fit. A second training was held for 14 of the individuals who completed the first training and indicated an interest in facilitating MB intervention sessions. This second training provided these 14 individuals with details on the study's intervention and research procedures (eg, facilitator responsibilities, patient recruitment process). Training was delivered in both Arabic and English.

For the pilot study, 4 of these facilitators delivered the MB intervention to 10 pregnant individuals. The average number of sessions received was 7.0 (out of 12), and 4 individuals completed all 12 sessions. Baseline assessments were conducted to pilot procedures and measures to be used in the RCT. Client and facilitator feedback was used to modify study procedures and slightly adapt the intervention content.

RCT Recruitment

Recruitment for the RCT began in February 2022 and is expected to be completed by December 2023. As of March 31, 2023, a total of 259 pregnant women had been consented and screened for eligibility. Of those screened, 157 were eligible and enrolled in the study.

Discussion

This study has several notable strengths and innovations. It is the first study to our knowledge that examines the effectiveness of a postpartum depression preventive intervention with Arab women in the Middle East, including Qatar. Given the higher prevalence of postpartum depression among women in the Middle East [6], interventions aimed at preventing and treating postpartum depression need to be examined in this context. The intervention tested in this study is an adapted version of an evidence-based postpartum depression preventive intervention—MB. Several RCTs of MB have demonstrated its effectiveness in preventing postpartum depression in diverse perinatal populations in the United States. However, given the significant cultural differences between the United States and Qatar, we engaged in a process of culturally adapting the intervention before testing its effectiveness with Arab-origin, Arabic-speaking women in Qatar. This cultural adaptation is another strength of this study, as a multidisciplinary team of researchers and clinicians from different Arab backgrounds engaged in an intensive process of reviewing and adapting the MB facilitator and participant manuals to ensure their cultural and contextual fit.

Our recruitment of a stratified subsample of diabetic women enhances the potential impact of this project. It is well established that stress during pregnancy has an impact on blood glucose control [20]. Pregnant women with diabetes who receive MB are likely to exhibit reduced stress levels by learning the cognitive, behavioral, and stress management techniques taught through the intervention. As a result, we anticipate that we will observe better diabetes self-management.

Because each MB session lasts only about 20 minutes, sessions can be delivered during an existing health care visit (eg, while waiting for a prenatal care appointment). MB is also highly flexible, allowing for intervention delivery in person, by phone, or via telehealth (eg, Zoom, Microsoft Teams). The use of non-face-to-face interventions may be of particular benefit to women who struggle to attend prenatal appointments—for example, if women do not feel well, have a child who is unwell, or have difficulty accessing transportation or childcare. The use of phone or telehealth approaches allows for the intervention to be more easily delivered during very hot weather or during Ramadan—important contextual considerations for interventions delivered to women in Qatar and the Middle East.

This study is not without limitations. Although the adaptation of MB was conducted to promote cultural and contextual fit, caution will need to be used in generalizing findings beyond the sample recruited from one medical center in Doha. Our 6-month follow-up time point is also limited in its ability to examine sustained intervention effects as well as the impact of the intervention on parenting or parent-child attachment outcomes. Although the diabetic subsample is innovative, our sample size is limited for this exploratory aim.

Pregnancy and the early postpartum period are times of increased risk of mental health disorders—particularly depression and anxiety—that impact not only maternal and fetal well-being and functioning but also mother-infant attachment, parenting practices, and infant development. These time periods are opportune times for mental health interventions given that women access health care more frequently and families are often more motivated to engage in health-promoting activities to promote positive outcomes for their children. This study has the potential to add to the evidence base on postpartum depression preventive interventions broadly and will also be the first of its kind to do so among exclusively Arab women in the Middle East.

Acknowledgments

This publication was made by the National Priorities Research Program–Standard (NPRP-S) Eleventh Cycle (grant NPRP11S-0121-180354) of the Qatar National Research Fund (a member of the Qatar Foundation). The findings herein reflect the work and are solely the responsibility of the authors. We would like to thank the following individuals for their assistance with the project: Molly McGown, Dana Zakieh, Melissa Segovia, Dr Muhammad Azeem (grant development), Raghad Burjaq, and Sajeda Maraqa (participant recruitment and study coordination). We would also like to thank all the facilitators who have been trained on the intervention.

Abstract

Background: Mental health problems are a main contributor to the global burden of disease in children and young people within urban environments. In response, the potential of both school- and sport-based mental health promotion interventions has been advocated. However, there exists limited insights into how sport-based interventions can be integrated within school environment. Moreover, there is a need to consider children and young people's specific needs, challenges, and motivations when designing novel mental health promotion interventions.

Objective: The Strengthening Mental Health and Resilience Through Schools (SMARTS) project aims to co-design an evidence-informed school-sport-based mental health promotion program. Specific objectives include (1) co-designing a multicomponent program, integrating sport sessions with class-based sessions, and complementing with educational modules for teachers and parents; (2) exploring how the mental health program can be implemented most effectively within the Brussels school system; and (3) conducting preliminary process and outcome testing of the program.

Methods: A participatory design framework will be adopted to develop the program. This framework involves end users throughout the entire study process, from problem identification to intervention delivery and evaluation, while at the same time ensuring program development remains directly informed by the available scientific evidence.

Results: Participant recruitment will commence in September 2023. The full project will be completed by March 2027.

Conclusions: With this intervention, we aim to provide a direct contribution to the promotion of children and young people's mental health within the Brussels school context. At a broader level, conducting and documenting this large participatory design project can, hopefully, inspire other researchers to tailor their mental health programs to specific populations.

children; physical activity; psychological symptoms; sport; well-being; youth

Introduction

Overview

Mental health problems form one of the main contributors to the global burden of disease among young people. The first onset of most mental disorders typically occurs in childhood or early adolescence [1], with children and young people between the ages of 13 and 15 years being most at risk for first onset of psychological symptoms and distress. According to the World Health Organization [2], 1 in 7 children and young people is experiencing a mental disorder (eg, depression or anxiety), and suicide forms the fourth leading cause of death among this age group. Moreover, evidence suggests that up to 20% of

XSL•FO
RenderX

school-going youth have engaged in nonsuicidal self-injury (NSSI) at least once [3]. NSSI forms a particularly relevant marker of mental health, as it is one of the strongest predictors of suicide [4] and is associated with a variety of other negative mental health outcomes in children and young people, including anxiety, depression, and personality disorders [5]. The mental health of children and young people also forms a particularly relevant and major social-urban challenge, as evidence suggests that mental health problems are more prevalent within metropolitan contexts compared to rural settings [6,7]. In Belgium, for example, inhabitants from the Brussels capital region tend to report significantly lower perceived well-being and higher prevalence rates of mental disorders, suicide attempts, and use of psychopharmacological medication compared to regional or national averages [8]. Moreover, the mental health of children and young people within urban settings has increasingly come to the forefront during the COVID-19 pandemic. Evidence suggests that the pandemic, as well as isolation and loneliness as a consequence of lockdown measures, have led to a considerable increase in symptoms of depression and anxiety in young people [9,10]. Even post the COVID-19 pandemic, the rates of psychological symptoms seem to remain remarkably high. Overall, the impact of mental health problems on young people is profound, as individuals experiencing psychological distress are particularly vulnerable to social exclusion, discrimination, stigma, educational difficulties, risk-taking behaviors, physical ill-health, and human rights violations [2].

These sobering facts highlight the need for evidence-informed mental health interventions for children and young people within urban settings. The World Health Organization [11] defines good mental health as "a state of well-being that enables people to cope with the stresses of life, to realize their abilities, to learn and work well, and to contribute to their communities. Mental health is an integral component of health and well-being and is more than the absence of mental disorders." This definition supports a 2-factor model of mental health [12], which distinguishes positive subjective well-being and psychopathology as 2 related but essentially distinct dimensions of mental health [11-14].

Concerning psychopathology, there is a clear need for preventive and early intervention programs to complement traditional clinical care. This is particularly important as many children and young people never seek out professional care [15]. In Belgium, for example, data indicate that up to 41% of adolescents who are experiencing severe mental health problems never receive professional treatment [8]. Moreover, even when professional treatment is reached, this typically does not occur until several years after the initial onset of mental disorders [1]. Finally, from a practical perspective, the increased recognition and prevalence of mental health problems in children and young people has severely strained the available health care system, leading to often month-long waiting lists for clinical mental health care. At the same time, the 2-factor model recognizes that mental health reflects more than merely the absence of mental disease or ill-health. Interventions may therefore equally consider a mental health promotion approach [12], focusing on children and young people's ability to achieve developmentally appropriate tasks and enhance their self-esteem, mastery, resilience, social inclusion, and well-being [16,17]. As such, mental health promotion forms an "important component of the mental health intervention spectrum, which can serve as a foundation for the prevention and treatment of mental disorders" [16].

Existing mental health interventions for children and young people have commonly been delivered through school-based programs. School environments offer a unique opportunity to integrate mental health interventions within existing school structures, thereby reaching a far greater group of potentially at-risk children and young people compared to more traditional health care services [18]. In Flanders, for example, the government supports school-based health prevention primarily through activities that are rooted in the strategic plan "De Vlaming Leeft Gezonder in 2025." The idea is to strive for an integrated policy ("Health in all policies") that is reflected in important life domains (so-called "settings," among other educational settings). A growing body of evidence indeed suggests that such school-based programs can be effective in promoting mental health and well-being [19-21], as well as preventing specific psychological symptoms such as NSSI and suicidality [22,23], although a better theoretical understanding of program outcomes and ways of sustaining them remains necessary. This is particularly important given recent suggestions that, in certain cases, universal school-based interventions may not only be ineffective in promoting mental health but even actively cause harm to children and young people [24].

In addition to school-based initiatives, there has been increasing interest in the potential of sport and physical activity to promote mental health in young people. There exists strong evidence indicating the positive effects of physical activity in and of itself on the mental health and well-being of children and young people [25,26]. When used purposefully and deliberately, sport can also form an important vehicle for positive youth development [27]. The notion of positive youth development closely connects with mental health promotion, as it reflects a strength-based approach aimed at providing optimal developmental experiences to enable individuals to lead healthy, satisfying, and productive lives, both as a youth and later in life [28]. Additionally, sport can provide a "hook" to grab children and young people who would otherwise not find their way to traditional help-seeking pathways (eg, men and people of minority ethnic backgrounds) [29]. In particular within major urban areas, sport has the potential to reach and engage underprivileged, difficult-to-reach and at-risk populations, and has been posited as a cornerstone for inclusive and comprehensive social and well-being policies [30].

Despite the potential of sport-based interventions, there still exists a lack of research into the use of sport as a vehicle to promote mental health in young people, and existing initiatives often lack a clear theoretical or evidence base [31]. Moreover, existing programs have mostly been limited to organized sport contexts. To date, only a single study has developed a school-based mental health program that aims to integrate and complement physical activity sessions with traditional classroom-based sessions [32]. Although insightful, this

XSL•FO
RenderX

intervention was developed in the United Kingdom as a response to specific challenges in their local communities. As such, it is unclear to what extent this intervention is transferable to the Brussels context. Moreover, the intervention specifically targeted pupils with a diagnosed mental illness rather than providing a broad mental health promotion intervention targeting the entire pupil population [32].

In sum, there is a timely and important need to develop and test novel evidence-informed mental health promotion programs for children and young people within the Brussels urban setting. The context of Brussels is unique as it is highly polarized geographically, economically, and socially, with a large youth population of minority ethnic background and lower socioeconomic status [33]. These factors have been associated with increased mental health stigma and form crucial barriers toward seeking and accessing traditional forms of mental health care [34]. To address such issues, a mental health promotion program integrating class-based sessions with sport sessions may offer considerable potential. To maximize impact, such a program would be best designed as a multicomponent intervention [18,19], offering multiple intervention components targeting both the promotion of subjective well-being (eg, strengthening resilience and promoting mental health literacy [MHL]) and the prevention of key psychological symptoms (eg, NSSI prevention) [12]. Moreover, interventions may also benefit from adopting a multilevel approach, by engaging multiple stakeholders (eg, parents and teachers) around the individual [2,18]. Such a holistic "whole-school" approach focuses on leveraging social and environmental influences to promote positive mental health in adolescents. At the same time, to be effective and sustainable, interventions need to account for the complexity of each target context and carefully tailor intervention components to the needs, challenges, motivations, and key competencies of the program's end users [18].

Moving Toward a Citizen Science Approach

Although school-based mental health programs have been around for over 3 decades, the majority of these interventions have been developed in the United States. In their review of the literature, Kuosmanen et al [18] noted that interventions tend to show less consistent positive results when they are directly transferred to other countries or contexts. Both cultural and contextual factors play a crucial role in determining a program's impact, and one may, therefore, question to which end existing programs are applicable to handle specific local challenges [18]. Moreover, there seems to exist a "science-to-practice gap" in implementing such preventive mental health interventions [18]. Despite promising results, many large-scale randomized controlled trials of school-based mental health programs have proven difficult to sustain and upscale within "real-world" settings [20] and scholars have noted high levels of attrition within such programs [21]. All in all, these issues highlight the need for interventions to be carefully designed in function of the needs and challenges of the end users within their specific cultural and geographical context and, at the same time, be engaging and motivating to ensure end users are willing to start (and continue participating in) the program. In other words, there is a need to move from discrete intervention packages to creating sustainable implementation structures and climates [18].

Citizen science, or more specifically, a participatory design approach, might, therefore, be particularly suited to tailor a mental health program to the specific needs, challenges, and motivations of children and young people within the Brussels urban context. Participatory design "offers an evolving set of critical, conceptual, and practical tools to support the active participation of users in the design of different systems, services, and products" [35]. As such, interventions are designed from the perspective of the end user and actively involve them as co-designers. Such participatory research, promoting community participation, is particularly important to address "wicked problems," wherein different stakeholders may hold disagreements regarding the interpretation of the problem and the science behind it, as well as conflicting values, goals, and life experiences [36]. As such, addressing these problems cannot be achieved by relying solely on interdisciplinary, expert-driven approaches. Concerning the design of mental health programs, participatory design forms an active affirmation of young people's rights to define their own mental health goals and be involved in their own mental health care [35]. Benefits of adopting a participatory design approach toward developing a mental health program can include addressing stigma in intervention end users, involving populations who are otherwise hard to reach within traditional mental health care (eg, young men with minority ethnic background), creating a "shared language" between researchers and participants, and ultimately improving the likelihood of the program being used in the applied field [35]. Participatory design is also particularly suited to develop an intervention that is evidence-informed and, at the same time, engaging for children and young people. Similar participatory design approaches are currently being implemented to develop evidence-informed mental health interventions in other populations, including sexual and gender minority youth [37] and young people with schizophrenia [38].

Research Objectives

Given the state-of-the-art presented above, the current Strengthening Mental Health and Resilience Through Schools (SMARTS) project aims to co-design a comprehensive, novel, evidence-informed school-sport-based mental health promotion program, developed with, and tailored for children and young people (aged 13-15 years) within the Brussels urban context. The specific objectives set out in this project include (1) co-designing a multicomponent (ie, MHL, strengthening resilience, prevention of NSSI and suicidality, and other psychological symptoms) mental health program for pupils, integrating sport sessions with class-based sessions, and complemented with educational modules for teachers and parents; (2) exploring how the mental health program can be implemented most effectively within the Brussels school system; and (3) conducting preliminary process and outcome testing of the entire mental health program.

To achieve these objectives, a participatory design approach will be central to the project. This participatory design will be informed by the framework set out by Hagen et al [35]. The central principles within this guiding framework are (1) the

XSL•FO
RenderX

involvement of young people as active participants throughout the entire research process; (2) the active contribution of young people in idea generation and program design; and (3) the continuous evaluation of the program from the perspective of young people in terms of relevance, meaningfulness, and engagement.

Underpinning Intervention Principles

The SMARTS intervention components will be informed by several underpinning, evidence-informed principles, and theories. These principles will provide structure and help shape the participatory design process.

MHL Framework

MHL is defined as "understanding how to obtain and maintain positive mental health, understanding mental disorders and their treatments, decreasing stigma related to mental disorders, and enhancing help-seeking efficacy" [39]. It includes knowledge of preventive strategies, the ability to recognize warning signals for mental health problems, awareness of help-seeking options, and first aid skills to help others who are struggling with mental health problems. A lack of MHL has been associated with increased stigma and poor symptom recognition and serves as a barrier toward help-seeking behaviors [15]. As such, developing MHL in young people and their main "helpers" (eg, parents and teachers) has been recognized as a key component for preventive and early intervention programs [40].

Psychological Resilience

Resilience is commonly defined as the capacity to withstand or quickly recover from stressors [41]. It entails a dynamic process of adaptation wherein individuals learn to draw on their personal and environmental resources to maintain mental health under stressful life circumstances. Within the SMARTS project, the focus on resilience reflects a strength-based approach with an emphasis on stress and emotion regulation skills as well as the capacity to build and draw upon social support networks [42].

Onset Prevention of Psychological Symptoms

Promoting MHL and resilience may also be complemented with interventions aimed at preventing the onset of psychological symptoms, such as NSSI. A meta-analysis by Fox et al [43] has demonstrated the insignificant effects of interventions that focus on reducing or preventing NSSI as a stand-alone intervention. However, a recent pilot study investigated the differences between a general in-classroom mental health prevention program called "Happyles" and a school-based prevention program called "HappylesPLUS" which also targeted NSSI by adding a 1-hour NSSI-focused psychoeducation module [23]. The extra module focuses on key variables that impact the onset of mental health problems in general and NSSI specifically, such as the impact of social media on mental health, negative body images, and peer stigmatization. Both groups reported a reduced likelihood of engaging in NSSI in the future 6 weeks after receiving the program in comparison to before receiving the program. Results also indicated increased emotional awareness in both groups. However, analysis of the qualitative data led to the indication that "HappylesPlus" may have direct benefits for some students with lived experience (eg, an increase in help-seeking behavior for NSSI) [23]. Building on this pilot project, the SMARTS project will equally include an NSSI-focused psychoeducational module within the intervention and will broaden its scope to include other prevalent mental health problems in the Brussels region, such as suicidality and addiction.

Sport-for-Development

Sport is often considered a vehicle for the promotion of desirable social and psychological outcomes. For example, with regard to mental health, sport can be a context to promote both MHL and resilience [29,44]. However, sport-for-development scholars have noted that beliefs surrounding the developmental potential of sport in and of itself are often naive, idealistic, and based on limited empirical support [45]. It is crucial to carefully consider the context and conditions under which sport might contribute to such desirable psychological outcomes. Within this project, we therefore focus on a sport plus approach, defined as interventions "in which sports are adapted and often augmented with parallel programs in order to maximize their potential to achieve developmental objectives" [45]. Within such a sport-plus approach, we will critically examine how sports activities can be shaped, adapted, and augmented to maximize the potential to achieve the envisioned outcomes, rather than solely relying on the supposed direct impact of sport and physical activity in and of themselves on children and young people's mental health [25,26].

Methods

Overview

As stated, this study will use the participatory design framework presented by Hagen et al [35], as illustrated in Table 1. This framework identifies 6 research stages that provide a structured approach to involving end users throughout the entire study process, from problem identification to intervention delivery and evaluation, while at the same time ensuring program development remains directly informed by the available scientific evidence.

XSL•FO
RenderX

Table 1. Overview of the study stages.

	WP 1[a]		WP 2[b]		WP 3[c]	WP 4[d]
	IDENTIFY	DEFINE	POSITION	CONCEPT	CREATE	USE
Aim of the study stage	Identify the problem from the perspective of the end users	Define the problem space and objectives within them	Understand how the intervention needs to be positioned in order to have the envisioned impact	Identify, generate, and evaluate concepts that represent what the intervention needs	Evolve, build, and refine an intervention that is useful and usable	Deliver, use, and evaluate the intervention based on the experiences of the end users
Methods to enable active participant involvement	WP 1 focus group interviews with pupils, teachers, and parents	WP 1 focus group interviews with pupils, teachers, and parents	WP 2 co-design workshops with pupils, teachers, and parents	WP 2 co-design workshops with pupils, teachers, and parents	WP 3 pilot study with detailed process evaluation by intervention end users	WP 4 implementation and detailed process and outcome evaluation by intervention end users
Evidence-informed research activities	Consultations with experts and review of epidemiological data	Scoping review of risk factors and resources for adolescent mental health	Consultations with experts and review of behavior change theories underpinning mental health interventions	Consultations with experts to establish relevant process, impact, and outcome indicators	Build and test (qualitative and quantitative) data collection battery	Group-controlled quasi-experimental study

Participants

Pupils

For the first 4 research stages (IDENTIFY, DEFINE, POSITION, and CONCEPT) we will recruit approximately 60 high-school pupils enrolled within the Brussels school context (aged 12-15 years). Within this sample, we will strive for a relatively heterogeneous group, recruiting participants from different schools, different education levels, different ethnic backgrounds, and with a balanced gender distribution. Within the CREATE research stage, we will sample an additional 40 pupils, representing 2 different classes. These classes will be purposefully selected from different schools to complete a pilot study of the proposed intervention. Finally, for the final research stage (USE), 300 participants will be recruited to complete the intervention, with another 300 pupils acting as matched controls. Pupils will be recruited from different schools, different educational levels, and different ethnic and socioeconomic backgrounds. The total number of participants within the USE phase is sufficient to ensure enough power for the planned statistical analyses and takes into account an attrition rate of 30%.

Teachers

For the first 4 research stages (IDENTIFY, DEFINE, POSITION, and CONCEPT), we will recruit approximately 24 high-school teachers. Within this sample, we will purposefully sample those teachers who will be involved in later stages of the delivery of the intervention. Specific attention will also be paid to involve physical education teachers. Within the CREATE research stage, we will sample 15 teachers to participate in the pilot study, representing 2 different schools. Finally, for the final research stage (USE) 50 teachers will be recruited from different schools to participate in the educational module for teachers.

Parents

For the first 4 research stages (IDENTIFY, DEFINE, POSITION, and CONCEPT) we will recruit approximately 24 parents of children enrolled within the Brussels school context. Within this sample, we will strive for a relatively heterogeneous group, recruiting parents of children from different schools, different education levels, different ethnic backgrounds, and with a balanced gender distribution. Within the CREATE research stage, we will sample 15 parents to participate in the pilot study, representing parents of pupils from 2 different schools. Finally, for the final research stage (USE) 50 parents will be recruited from different schools to participate in the educational module for parents.

Experts

For the IDENTIFY, POSITION, and CONCEPT research stages, an interdisciplinary group of applied and academic experts will be involved to help shape the evidence-informed intervention. We expect approximately 16 experts to be involved within the project's life span. These experts will be recruited based on their specific expertise and applied experience within the project topic and setting and through the different project partners. These experts will consist of the following:

1. 4 school directors and 4 "zorgcoördinators" (care coordinators) from different schools within the Brussels region;
2. 2 school counseling consultants from different schools within the Brussels region;
3. 2 government prevention advisors with specific expertise in mental health and well-being;

XSL•FO
RenderX

4. 4 academic experts with specific expertise in mental health and well-being and (clinical) sport psychology.

Procedures

Based on the project design outlined above (see Table 1), 4 main work packages are proposed. Each of the work packages is described separately below.

Work Package 1

The first work package will encompass the IDENTIFY and DEFINE research stages. Key activities and milestones within this work package include the following:

1. Focus group interviews with pupils, teachers, and parents: focus groups will be conducted to (1) understand the problem from the perspective of the end users and (2) help define objectives to address this given problem.
2. Consultations with experts: consultations will be conducted to understand the problem from the perspective of applied and academic experts.
3. Scoping review of the literature: a scoping review will be conducted to (1) evaluate epidemiological evidence and (2) identify risk factors and resources for adolescent mental health.

Work Package 2

The second work package will encompass the POSITION and CONCEPT research stages. Key activities and milestones within this work package include the following:

1. Co-design workshops with pupils, teachers, and parents: co-design workshops will be conducted to understand how the intervention needs to be positioned from the perspective of the end user and generate intervention content.
2. Review of behavior change theories: a brief literature review will be conducted on leading behavior change theories that can aid in the design of engaging, evidence-informed intervention content.
3. Consultations with experts: consultations with experts will be conducted to establish key indicators to evaluate the intervention process, impact, and outcome based on content developed during the co-design workshops.

Work Package 3

The third work package will encompass the CREATE research stage. Key activities and milestones within this work package include the following:

1. Pilot study with detailed process evaluation by intervention end users; a detailed pilot study will be conducted to test the intervention with a small sample of end users.
2. Build, test, and finalize data collection battery (quantitative and qualitative); a battery will be developed and tested during the pilot study based on the established indicators for intervention process, impact, and outcome (see WP 4).

Work Package 4

The fourth work package will encompass the USE research stage. Key activities and milestones within this work package include the following:

1. Implementation of a group-controlled quasi-experimental intervention: a quasi-experimental intervention will be conducted, randomly allocating participants at group level (ie, class) to either experimental or control conditions. The experimental condition will receive the intervention over a 6-month period, whereas the control group will serve as a "usual care" control group. Additionally, a selected sample of teachers and parents of pupils within the experimental group will be provided with the complementary educational modules.
2. Pretest, posttest, and 3-month follow-up (quantitative and qualitative) evaluations; a 3-wave data collection design will be adopted to collect both qualitative and quantitative data on the intervention process, impact, and outcome. These include pretest, posttest, and 3-month follow-up data collection points.

Data Collection

Throughout the project, a mixed methods approach to data collection will be adopted. Qualitative data will be collected primarily through focus group interviews and co-design workshops. Each focus group and co-design workshop will be both audio- and video-recorded. Audio recordings will be transcribed verbatim, and transcriptions will be used for further analysis. Video recordings can be used to clarify the context of certain statements or to ascertain group dynamics within the interviews or workshops that cannot be discerned through audio alone.

Quantitative data will also be collected to evaluate program outcomes during the CREATE and USE research stages. In line with our participatory design approach, the determination of the most relevant project outcomes and the development of a corresponding test battery to assess these outcomes will be based on a co-design process during the project life span. As such, we have purposefully not determined an a priori set of outcome measures. However, an indicative set of outcome measures includes the following:

1. subjective well-being, as measured using the World Health Organization-Five Well-Being Index (WHO-5) [46];
2. psychological distress, as assessed using the Kessler Psychological Distress Scale [47];
3. mental health stigma, as assessed using the Peer Mental Health Stigma Scale [48];
4. help-seeking intentions, as measured by the Attitudes Toward Seeking Professional Psychological Help Scale-Short Form [49]; and
5. emotion regulations, as measured by the Difficulties in Emotion Regulation Scale [50].

Data Analysis

Qualitative data will primarily be analyzed using reflexive thematic analysis. Reflexive thematic analysis is particularly suited to gain sense and meaning from participants' lived experiences while at the same time recognizing the subjectivity of human experience and emphasizing that meaning-making from this experience is the result of a process of cocreation between the participant and the researcher [51]. To support our co-design principles and involve participants as active

XSL•FO
RenderX

contributors throughout all phases of the analysis process, member reflections will also be used. Member reflections are structured opportunities for participants to provide feedback and reflection on tentative qualitative analysis, not as a way to verify the truthfulness of the analysis but rather as a way to generate novel insights and data [52].

Within the USE research stage, analysis of the main outcome measures will be calculated using a mixed-model ANOVA including 2 groups (mental health program vs control group) and measures at 3 time points (pre, post, and 3-month follow-up). Missing data will be dealt with by using appropriate methods.

Ethical Considerations

Institutional ethics approval has been requested and will be obtained for the SMARTS project. All participants will provide active, informed consent before their participation. For the participating children and young people, informed consent will also be obtained from a parent or legal guardian. The informed consent forms and participant information sheets are currently also under review by the institutional ethics board. Given the sensitive nature of the topic, the information sheets will include contact details from the researcher as well as several currently available mental health resources, should the participants feel the need for support following their participation in the study. All data collected throughout the project will be pseudonymized and stored for a duration of 10 years within a secure data repository following the completion of the project.

Results

Funding for the SMARTS project was approved in January 2023. Upon obtaining ethics approval, participant recruitment for the first research phase will commence in September 2023. The full project will be completed by March 2027.

Discussion

Children and young people living within urban environments form a particularly at-risk population for mental health problems [2]. School-based mental health programs have, therefore, often been proposed as key interventions to target this population [19-21]. Additionally, sports have also been proposed as a context for mental health promotion programs, as well as a "hook" to attract children and young people to such programs [32]. Nevertheless, there currently exists a "science-to-practice gap" in the implementation of mental health promotion programs for children and young people [18], with existing interventions often proving difficult to sustain and upscale to broader settings. One potential solution to this issue might lie in the use of participatory design approaches, focusing on the active involvement of intervention end users (ie, children and young people) as co-designers throughout all phases of intervention development. The SMARTS project, thus, aims to develop an intervention that is evidence-informed and, at the same time, engaging for children and young people, through the adoption of a rigorous participatory design approach [35].

To achieve this objective, the SMARTS project will co-design and evaluate a comprehensive evidence-informed school-based mental health promotion program, integrating sport sessions with class-based sessions, complemented with educational modules for teachers and parents. This intervention is targeted at school-going children and young people aged 13-15 years. This particular age range was chosen as it coincides with the typical age during which children and young people are at risk for first onset of psychological symptoms and distress [1]. The mental health promotion program will integrate principles based on MHL [39], psychological resilience [41], existing school-based programs to prevent psychological symptoms [23], and insights from the sport-for-development literature [45]. To develop the program, the rigorous participatory design framework presented by Hagen et al [35] will be adopted. Through several consecutive research stages, the SMARTS project will (1) co-design the multicomponent program, (2) explore how the intervention can be implemented most effectively within the Brussels school system, and (3) conduct preliminary process and outcome testing of the full mental health promotion program. A key challenge when conducting such a participatory design project lies in the recruitment and activation of all relevant stakeholders within the co-design process. However, this can be mitigated as the SMARTS consortium, which includes local school organizations, will play an active role in both participant recruitment and the design and implementation of the eventual organization.

With this intervention, we aim to provide a direct contribution to the promotion of children and young people's mental health within the Brussels school context. This is particularly relevant as children and young people within the Brussels urban context tend to report higher prevalence rates of mental disorders, compared to regional or national averages [8]. In part, this may be attributed to increased mental health stigma, as well as experienced social and economic barriers toward traditional mental health care. At a broader level, we hope that conducting and documenting large participatory design projects like SMARTS can inspire and guide other researchers to tailor mental health interventions to specific at-risk populations.

Acknowledgments

The authors would like to express their gratitude to all partner organizations involved in the SMARTS project, including the GO! Scholengroep Brussel, CLB Brussel, and Gezond Leven. We would also like to explicitly thank Anja De Neve and Elke De Ridder for their contributions to the conceptualization and design of the project. Finally, we would like to thank the Citizen Science Contact Point of the Vrije Universiteit Brussel for their practical support in the organization of the SMARTS project. Funding for the SMARTS project was provided through the "Bijzonder Onderzoeksfonds" (BOF) of the Vrije Universiteit Brussel (grant OZR4051).

Protocol

Improving the Quality of Postpartum Care in Ghana: Protocol for a Parallel Randomized Controlled Trial

Abstract

Background: Although the postpartum period poses substantial risks and can result in significant maternal morbidity and mortality, postpartum care of the mother receives much less attention in transitional countries.

Objective: We describe the protocol for a randomized controlled trial to implement and evaluate a postpartum care delivery model titled Focused-PPC (Focused Postpartum Care).

Methods: Focused-PPC is an integrated group postpartum care model that meets the clinical care, education, and support needs of mothers up to 1 year after birth. The Focused-PPC intervention is a parallel randomized controlled trial with a total of 192 postpartum women at 4 health centers in Tamale, Ghana. Participants will be randomized into 1 of 2 trial arms at a 1:1 allocation ratio: (1) the control arm, which receives the standard postnatal care currently delivered in health facilities, or (2) the intervention arm, which receives the Focused-PPC model of care. Women enrolled in the intervention arm will receive postpartum clinical assessments and education for the first 6 weeks and will continue to receive education, measures of vital signs, and peer support for 12 months post partum during child welfare visits. Led by trained midwives, each postpartum group in the intervention arm will meet at 1-2 weeks, 6 weeks, and monthly thereafter for up to 1 year post partum, following the Ghana Health Service postnatal care schedule.

Results: The Focused-PPC guide, data collection tools, and audiovisual education materials were successfully developed and translated into the local language. We have enrolled and conducted baseline surveys for 192 women (sample size met) in the Focused-PPC trial who have been randomized into intervention and control arms. We have established a total of 12 Focused-PPC groups in the intervention arm, 3 groups from each site, all of which have sessions underway.

Conclusions: Focused-PPC has the potential to change the postpartum care delivery model in Ghana and other countries in sub-Saharan Africa and beyond.

Trial Registration: ClinicalTrials.gov NCT05280951; https://clinicaltrials.gov/study/NCT05280951

Introduction

Maternal mortality is a major global health challenge, defined as the death of a woman while, or up to 42 days after, termination of pregnancy, related to the pregnancy itself and not by accidental causes [1]. Around the world, about 810 women die every day from preventable causes related to pregnancy and childbirth [1]. Most maternal deaths are preventable, yet sub-Saharan Africa continues to be impacted disproportionately compared to the rest of the globe, accounting for two-thirds (66%) of all maternal mortality worldwide [1].

XSL•FO
RenderX

Ghana has a particularly high maternal mortality ratio of 308 deaths per 100,000 live births, compared to a maternal mortality ratio of 211 globally and only 11 in high-income countries [1]. Most of these deaths occur during the postpartum period, the period following birth, as compared to during pregnancy or labor and delivery [2].

In terms of health care provision, the postpartum period receives much less attention than pregnancy or childbirth. However, the period after birth still poses substantial risk to mothers and can result in significant maternal morbidity and mortality [1]. The median national coverage of routine postnatal visits for the mother stands at 71%, which is still significantly behind global targets for 2025, with some nations demonstrating coverage as low as 44% [3]. The World Health Organization (WHO) recommendations for postpartum care include continuous care in a health care facility for up to 24 hours and further postpartum clinical examinations at 48-72 hours, 7-14 days, and 6 weeks after birth [4]. These recommendations also state that postpartum clinical examinations should include assessments of vital signs, vaginal bleeding or discharge, uterine contraction, fundal height, urine void, and breast tenderness [4]. However, within developing countries, recommended postpartum clinical assessments are not consistently provided to women at recommended time points [5,6]. For instance, among women delivering in health facilities in Malawi, over half reported a lack of postpartum clinical assessments, including blood pressure checks, temperature checks, abdominal examinations, vaginal examinations, and breast examinations [5].

Mortality is worsened by a lack of access to appropriate postpartum care. Postpartum complications are frequently unforeseen and necessitate an immediate reaction, making quality care essential for the health and survival of the mother after birth. For instance, postpartum hemorrhage can be fatal within a matter of hours without prompt treatment [7]. Sufficient postpartum care enables medical professionals to quickly recognize and address complications as they arise [8]. Postpartum care also provides the opportunity for health care providers to meet the social and health needs of women and to encourage women to adopt evidence-based postpartum practices at home. As maternal self-care typically occurs at home after birth, it is essential that mothers are empowered with proper knowledge to mitigate their health risks after birth [4].

Within the postpartum period, obstetric complications are the primary cause of direct maternal deaths worldwide [2]. Complications such as hemorrhage, hypertension, and sepsis account for 62.4% of maternal deaths in sub-Saharan Africa [9]. Each of these complications has identifiable warning signs that, if noticed early, are likely to result in improved maternal outcomes. Therefore, ensuring knowledge of warning signs of complications is a key strategy in improving women's complication readiness and reducing deaths resulting from delays in seeking care [10]. If a mother has adequate knowledge of warning signs, she is far more likely to promptly recognize symptoms and seek timely postpartum care. However, several studies have reported that postpartum women in transitional countries experience inadequate knowledge of postpartum warning signs of complications [11-14]. Furthermore, midwives working in Tamale, Ghana, have self-reported inadequate knowledge and skill sets to adequately educate patients about all detrimental postpartum complications and how to manage those complications [15,16].

Comprehensive patient education is a widely established, low-cost intervention effective in improving health outcomes [17-19]. Patient education addressing postpartum recovery and potential complications that may happen after birth has significant potential to improve postpartum health outcomes among women in Ghana. Women are expected to manage their postpartum recovery following discharge from the hospital, meaning that all women are expected to recognize potential complications and seek timely emergency care accordingly from 48 hours after birth and beyond [20]. Therefore, it is crucial to ensure that all women, regardless of their risk factors, are educated regarding the early warning signs of potential complications and when symptoms necessitate care-seeking. Maternal morbidity and mortality can be reduced through the provision of quality education administered by health care providers [21].

From our experience working in the setting, there is a lack of integrated postpartum care that incorporates recommended clinical assessments, education, and support for women after birth. Our intervention, entitled Focused Postpartum Care (Focused-PPC), fills this gap through the provision of comprehensive postpartum clinical care, targeted education, and peer support for women in Ghana. A shift toward standardized care simultaneously addressing the needs of both the mother and the baby has significant potential to reduce maternal morbidity and mortality in this setting. In this paper, we describe the protocol for a randomized controlled trial in Tamale, Ghana. The aim of our study is to implement and evaluate Focused-PPC in a parallel randomized controlled trial with 192 postpartum women at 4 health centers in Tamale, Ghana.

Methods

Study Design

This is a parallel randomized controlled trial with balanced randomization (1:1) conducted in 4 health centers in Sagnarigu municipality, Tamale, Ghana. An overview of the study design can be found in Textbox 1.

RenderX

Setting

The study will be conducted in Sagnarigu municipality, Tamale, which is located in the Northern region of Ghana. The public health sector in this area is run by the Ghana Health Service (GHS) and constitutes the most commonly accessed health facilities. The study will be conducted at 4 GHS health centers. The health centers are: Choggu Health Center, Kanvilli Health Center, Bagabaga Health Center, and Kalpohin Health Center.

Participants and Recruitment

Participants who are 18 years of age or older will be recruited in their third trimester while attending antenatal care visits in the health centers. Project assistants employed in each health center will conduct face-to-face recruitment using a script. The script describes the study, its eligibility criteria, and its voluntary nature. Typically, women arrive at the antenatal care visit and wait until it is their turn to enter the consulting room. Recruitment will occur during this wait time. When eligible patients agree to participate, they will provide their name and contact information for follow-up. Eligible and interested participants will also be provided with the project contact information and project assistant number to call or text at delivery, and project assistants will also follow up with women. Participants will be enrolled in the research study after delivery. Eligibility criteria at enrollment include being currently admitted to the postnatal ward, having had a live birth, having a newborn not in the neonatal intensive care unit, being able to speak and understand English or Dagbani, and having the capacity to provide informed consent. Since the intervention arm requires participants to have given birth within the same week or 2, randomization into the intervention arm (Focused-PPC) and control arm (usual care) will occur after each woman has given birth.

Sample Size

To establish an appropriate sample size, a power analysis was conducted using G*Power (Erdfelder, Faul, and Buchner) [22,23]. The experimental design has 4 total health centers. Individuals at every health center will be randomly assigned to an intervention arm, keeping in mind that the intervention arm needs to be in multiples of 8 at a time and that intervention groups are equal in size. Baseline characteristics are not expected to affect the outcome. In G*Power, the power analysis was run with 2 groups (the control arm and the intervention arm), which were then split up into 8-equal sized subgroups (health center A intervention, health center A control, ..., health center D intervention, health center D control). The model included 3 time points for measurements. The correlation among repeated measures that varied for a range of values from 0.05 (representing nearly uncorrelated measurements) to 0.3 (representing moderately correlated measurements) was considered. The desired power was always set to 0.8, and the nominal type I error was set to .05. A range of Cohen (1988) effect sizes was evaluated, from 0.10 (very small) up to 0.25 (a medium effect size). The outcome, the mean knowledge of postbirth warning signs, is a continuous variable. This was accomplished by varying the intervention arm's mean knowledge level. Based on previous study data, 1.9 was used as the control sample's mean knowledge score, and 1.4 was used as the SD within groups. For the intervention sample, a range of values for the mean knowledge score was tested, from 2.2 (which equates to a 0.1 effect size) to 2.65 (equating to a 0.25 effect size). The control arm and the intervention arm were assumed to have the same SD.

Under optimal conditions, where the correlation among repeated measures is minimal at 0.05 with a medium effect size of 0.25, a total sample size of 64 (16 individuals split into 1 intervention and 1 control group per clinic) is required [24]. Whereas under the worst assumed conditions (a small effect size of 0.10 and any correlation among repeated measures), a total sample size of 512 (128 individuals per clinic split into 16 intervention and 16 control groups) would be necessary. Assuming we want to detect a Cohen f of 0.15 with any size correlation up to 0.3 among repeated measures and no attrition, the recommended sample size is 192 (with 48 individuals split up into 3 intervention and 3 control groups per clinic).

Randomization

Project assistants will meet with eligible participants after birth, at discharge, in a designated private spot at the health facility, where they will obtain consent and complete the baseline survey. After the baseline survey, participant allocation will be 1:1 for equal intervention and control sizes. Allocation will be completed according to a computer-generated list of random numbers, allocating group sizes of 8. The allocation will be generated by a data scientist on the research team. The data scientist will provide participant allocations (intervention arm or control arm) to the project team. Participants in the intervention arm will also receive a group allocation (allocated in groups of 8). Intervention arm group participants will then be contacted to begin their group postpartum care. There will be no blinding, as the study team will know which women are in the intervention arm (receiving Focused-PPC) and the control arm (receiving usual care).

Group Conditions

Control Arm

Women in the control arm will receive standard postnatal care currently practiced in their respective health centers. This involves attending visits at the health center within 14 days after birth, at 6 weeks, and monthly thereafter up to 1 year. Currently, the GHS recommends beginning postnatal care immediately after birth, with the mother and baby receiving care within 14 days and at 6 weeks. After 6 weeks, the mother attends monthly child welfare clinic visits with the baby for up to 12 months.

Intervention Arm

Overview

Each Focused-PPC group in the intervention arm will consist of 8 postpartum women who will meet at 1-2 weeks, 6 weeks, and monthly thereafter for up to 1 year post partum, following the GHS postnatal care schedule. All Focused-PPC group sessions follow a guide developed by the research team with content derived from evidence-based guidelines, reviewed by experts, and approved by the GHS. These group sessions consist of two components: (1) 15-minute individual clinical assessments and counseling for each mother performed by

XSL•FO
RenderX

midwives and (2) a 1-hour-long group education session and peer support led by midwives. Each Focused-PPC session will be led by 2 trained and registered midwives from each health center, who will provide both clinical care and education and support as needed. In addition, each group session will be supported by a project assistant, who will be responsible for collecting research data. Focused-PPC will be implemented in addition to newborn care.

Postpartum Clinical Assessments

The clinical care component of the intervention follows the recommended clinical assessments by the GHS and the WHO and includes assessment of vital signs, fundal assessment, vaginal bleeding or discharge assessment, incision assessment, and a breast examination. After the 6-week postpartum time point, only vital signs are measured at each session. In sub-Saharan Africa, over 60% of maternal deaths occur within the vulnerable first year after birth [2]. Since maternal deaths extend far beyond the traditional 6-week time frame, it is important that quality clinical care extend to 1 after birth. Focused-PPC provides regular contact with and monitoring by a midwife for up to a year following birth.

Postpartum Education

The content of Focused-PPC education will focus on the unique needs of postpartum women based on the time frame after delivery. Educational resources will be developed by the research team and an expert panel to apply to different time points throughout the postpartum period and to address the complex needs of postpartum mothers while conforming to the regulations and practices of the GHS. Educational content will then be converted into audiovisual resources, which will be used by midwives to present information during Focused-PPC sessions. Education content will cover the following topics: what to expect for normal postdelivery recovery, self-care, potential postpartum complications and danger signs, risk factors, food and nutrition, breastfeeding, mental health, social support, family planning, menstrual cycles, and interconception care.

Postpartum Peer Support

Women in Focused-PPC groups will engage in peer support by discussing issues relevant to them. Group prenatal care models have been shown to improve both pregnancy outcomes and maternal satisfaction with care [25-27]. In the postpartum period, group treatment and peer support programs have been shown to improve postpartum depression and prevent postpartum depression [28-31].

Intervention Fidelity

The Focused-PPC intervention will be maintained and monitored through fidelity checklists that are specific to each time point at which a session is held. These checklists will be completed by project assistants and midwives at every session. Additionally, video recordings will be recorded during Focused-PPC sessions at the initial sessions, midpoint sessions, and final sessions. Project assistants will also file session reports that address participant actions and discussions and other session details.

Data Collection or Measures

In addition to the baseline survey, all participants will be given surveys at 1-2 weeks, 6 weeks, 3 months, 6 months, and 12 months from baseline. All surveys will be interviewer-administered by the project assistants and completed electronically via tablets using a secure database system. Strict procedures will be followed to protect participants' confidentiality. We also plan to evaluate the feasibility, acceptability, and satisfaction of Focused-PPC. Focus Group Discussions will be conducted with the midwives who implemented Focused-PPC and with each group of participants enrolled in the Focused-PPC intervention arm after their 12-month sessions.

Independent variables and potential covariates will be measured through demographic and obstetric history questions and the Dagbani Readiness for Hospital Discharge Scale-New Mother Form (RHDS-NM). The RHDS-NM is a 22-item instrument that includes a self-reported rating scale with item scores ranging from 0 to 10 and possible scale scores ranging from 0 to 220 [32]. Higher scores indicate greater readiness for hospital discharge. The RHDS-NM, designed for use within English-speaking populations, was translated into Dagbani and adapted for use in Tamale. The Dagbani version of the RHDS-NM has demonstrated excellent reliability (Cronbach α=.94) and measures postpartum mothers' perceptions of readiness for discharge through examination of their personal status, knowledge, coping ability, and expected support [33].

The primary outcome is knowledge of postbirth warning signs, measured through questions developed based on an evidence-based assessment of the most common postbirth complications. The secondary outcome is postpartum health behaviors, including specific questions assessing health behaviors tailored to the specific time frame postpartum. Other descriptive outcomes include postpartum health status, which will include measures of postpartum depression, stress, complications experienced, vital signs, and other questions on health status as appropriate to the time frame after delivery. Postpartum depression is measured through the Edinburgh Postnatal Depression Scale (EPDS), a self-report screening tool commonly used in perinatal settings [34,35]. The EPDS consists of 10 items assessing women's depressive symptoms over the past week. The EPDS has a maximum score of 30, with higher scores indicating higher frequency and increased severity of depressive symptoms. Stress is measured through the Perceived Stress Scale (PSS), a 10-item scale assessing women's stress levels over the last month [36]. The PSS evaluates a woman's perceptions of unpredictability, lack of control, and overloading in her life, with a higher score indicating higher levels of perceived stress. The feasibility and acceptability of the intervention will be measured using end-project focus group discussion data obtained from midwives and participants in the intervention arm. Outcomes and time points of data collection can be found in Table 1.

Analysis Plan

Differences in outcomes between the intervention and control arms will be assessed. We expect that the intervention arm will have higher knowledge of postbirth warning signs than the

XSL•FO
RenderX

control arm at every time point measured and that the intervention arm will have a larger increase in knowledge of postbirth warning signs between time points. We expect postpartum health behaviors to be different between the intervention and control arms.

All data will be reviewed for completeness and transferred to STATA (StataCorp) statistical software for analyses [37]. The primary variable of interest is knowledge of postbirth warning signs, measured on 4 occasions. The baseline measurement of knowledge of postbirth warning signs will be used in an initial *t* test to confirm that there is no difference in knowledge between the intervention and control arms before the study to validate the randomization procedure. We will model and test the difference between intervention and control arm knowledge of postbirth warning signs at each time point, and knowledge between time points will be assessed using a repeated measures multivariate ANOVA (MANOVA) with a time and treatment interaction as the primary analysis controlling for baseline demographic variables. For the intervention arm, follow-up secondary analyses will measure the change in postpartum health status, postpartum health behaviors, and clinical assessment data over time using repeated measures MANOVA. Ancillary analyses to be run between the intervention and control arms include a proportion test for the patient's readiness for hospital discharge. Additionally, an evaluation of feasibility, acceptability, and satisfaction will be summarized for inclusion when discussing the cost or benefit of the intervention.

Using intent-to-treat, participants providing data at baseline and first check-in will be included. Missing data (eg, due to attrition) will be accounted for using multiple imputations via the mice package in R (R Core Team) [38]. Sensitivity to missing data will be assessed by comparing multiple imputations to complete case analyses.

Ethics Approval

The Informed Consent process and all other study procedures were reviewed and approved by the University of Notre Dame institutional review board (protocol 21-06-6662). Additionally, in-country ethical approval was obtained from the Navrongo Health Research Center institutional review board (App/Focused-PPC/7/2021). Approval to conduct the study has also been obtained from both the regional and district levels of the GHS. All project team members have current human subject training. Informed consent will be obtained from all participants.

Results

In the first 6 months of the project, we will complete start-up activities inclusive of inception meetings with GHS representatives at the district and regional levels, developing training guides and Focused-PPC education content, training project staff, and developing data collection tools. In the next 6 months of the project, we will recruit and enroll participants, begin Focused-PPC intervention sessions, and complete data collection. Focused-PPC intervention sessions and data collection will continue in year 2 of the project. End-line focus group discussions will be conducted with project participants and midwives when groups have completed their final intervention sessions at 12 weeks.

Ethical approval was successfully obtained from the Navrongo Health Research Center, and the appropriate approvals were obtained from the GHS. The Focused-PPC Guide (education and session guide) was successfully developed with input from GHS and evidence-based resources and underwent multiple levels of expert review to produce the final guide. All team members, midwives, and project assistants have been trained in the study protocol. Measures for data collection were successfully translated into Dagbani (the local language), and audiovisual resources for the sessions were developed and translated into Dagbani. Clinical trial registration is completed at ClinicalTrials.gov (NCT05280951).

We have enrolled and conducted baseline surveys for 192 women (sample size met) in the Focused-PPC trial who have been randomized into intervention and control arms. We have established a total of 12 Focused-PPC groups in the intervention arm, 3 groups from each site, all of which have sessions underway. Midwives are successfully conducting Focused-PPC sessions using the study's established guide and protocol. The Focused-PPC intervention is maintained and monitored through fidelity checklists, which are specific to each time point and completed by project assistants and midwives at every session. Project assistants are also documenting sessions through photos, videos, and session reports, addressing participant actions, discussions, and collaboration.

Discussion

Principal Findings

The purpose of this study is to implement and evaluate a postpartum care model entitled Focused-PPC in a parallel randomized controlled trial with 192 postpartum women at 4 health centers in Tamale, Ghana. Focused-PPC sessions are underway in all participating health facilities. The primary outcome is knowledge of post-birth warning signs. We expect that the Focused-PPC group will have higher knowledge of post-birth warning signs than the control group at every time point measured and that the Focused-PPC group will have a larger increase in knowledge of postbirth warning signs between time points. We are also measuring postpartum health behaviors such as eating a healthy diet, uptake of family planning, breastfeeding, and so on. We expect that more participants in the Focused-PPC groups will eat a balanced diet most days of the week and uptake family planning compared to participants in the control groups. Additionally, we also expect mental health outcomes such as positive depression screens to be significantly lower over time in the Focused-PPC group compared to the control group. Other descriptive outcomes include postpartum health status, and we expect to capture and treat blood pressure cases during the course of the study.

Challenges Encountered

A major hurdle the team faced early in the intervention, which impacted the scheduled engagements with the leadership of GHS, was the application and subsequent acquisition of institutional review board clearance from the Navrongo Health

XSL•FO
RenderX

Research Center. The clearance was obtained after about 3 months of waiting time, and implementation could not commence unless proof of clearance was presented to the leadership of GHS in the Northern Region for permission to be given for the team to commence implementation. Delays in reviewing the Focused-PPC guide also contributed to a later than expected start of recruitment. The guide went through multiple levels of review, and reviews took longer at each stage than had been planned. In addition, the project team faced some difficulties finding context-specific audiovisual content to be used as supporting aids during the FPPC sessions. Finding and creating context-specific teaching aids took longer than expected. There have been no protocol modifications to the study so far.

We are consistently monitoring and improving upon data collection as necessary. For instance, following issues with inconsistent participant tracking numbers, our data scientist was able to install a mechanism into our survey software that double-checks each tracking number and will not allow remaining data to be documented until this has been addressed. We have also implemented solutions to address accidental missed data by alerting project assistants in real time if important information is missing, allowing them to review entered surveys before submission, and getting an email confirmation immediately after submitting a survey. Our monitoring efforts on this front have led to more accurate and comprehensive data so far and also improved the process of recording data for our project assistants. Furthermore, we have held monthly meetings with the project team, including all members from both the United States and Ghana. These meetings have helped substantially in prioritizing the goals of the trial and have allowed us to properly deal with obstacles as they arise.

Anticipated Limitations

Due to the nature of the study described in this protocol, the intervention is not blinded. There may be a potential for contamination since the midwives implementing the study are used in the health centers. However, since the study is not blinded, different midwives provide care and education to women during postpartum visits if they are in the control group to minimize contamination. In addition, the study is being conducted in one municipality in Tamale, so generalizability will be limited. We hope to conduct a larger study in the future. Given that the team in Ghana has worked in the setting since 2009 and has an established relationship with the health centers and women in the communities, we do not anticipate major recruitment difficulties. However, retention of participants and some participants missing scheduled sessions may be a challenge. We will engage participants and call them individually to remind them of upcoming sessions. We will ensure that midwives recap sessions are comprehensive enough to ensure knowledge transfer to those who missed previous sessions.

Dissemination Plan

To ensure that the results of this research impact practice and maximize the benefit to women, we will target multiple audiences with our research findings. These include health care providers, community service providers, nonprofit organizations, policy makers, the public, academia, and pregnant and postpartum women. We will prepare, print, and share information notes about the project and its findings and share these among key stakeholders. We will also produce a 5-minute video documentary of the project that demonstrates what was done at each stage of the project and the ultimate outcomes. This project's video documentary would be widely disseminated through various web-based and offline platforms. Our dissemination plan includes (1) peer-reviewed manuscripts, (2) peer-reviewed presentations at prestigious conferences, (3) presentations to stakeholders, (4) media releases, blog or website posts, (5) technical and research reports, and (6) presentations to postpartum women at the study facilities during postnatal care gatherings as well as community dissemination.

Conclusions

This project will be the first of its kind to implement an integrated and comprehensive group postpartum care delivery model in Ghana, focused on the care of the mother in addition to the baby. Focused-PPC has the potential to change the postpartum care delivery model in Ghana and other countries in sub-Saharan Africa and beyond. Results from this implementation will be used to further refine and scale up the Focused-PPC model of postpartum care.

Acknowledgments

This project was funded, in part, with support from the Indiana Clinical and Translational Sciences Institute (funded in part by grant UL1TR002529 from the National Institutes of Health, National Center for Advancing Translational Sciences, Clinical and Translational Sciences Award). Protocol

Reminiscence and Digital Storytelling to Improve the Social and Emotional Well-Being of Older Adults With Alzheimer's Disease and Related Dementias: Protocol for a Mixed Methods Study Design and a Randomized Controlled Trial

Abstract

Background: Increasing attention is being given to the growing concerns about social isolation, loneliness, and compromised emotional well-being experienced by young adults and older individuals affected by Alzheimer disease and related dementias (ADRD). Studies suggest that reminiscence strategies combined with an intergenerational approach may yield significant social and mental health benefits for participants. Experts also recommended the production of a digital life story book as part of reminiscence. Reminiscence is typically implemented by trained professionals (eg, social workers and nurses); however, there has been growing interest in using trained volunteers owing to staffing shortages and the costs associated with reminiscence programs.

Objective: The proposed study will develop and test how reminiscence offered by trained young adult volunteers using a digital storytelling platform may help older adults with ADRD to improve their social and emotional well-being.

Methods: The proposed project will conduct a randomized controlled trial to assess the effects of the intervention. The older and young adult participants will be randomly assigned to the intervention (reminiscence based) or control groups and then be randomly matched within each group. Data will be collected at baseline before the intervention, in the middle of the intervention, at end of the intervention, and at 3 months after the intervention. An explanatory sequential mixed methods design will be used to take advantage of the strengths of both quantitative and qualitative methods. The quantitative data from surveys will be entered into SPSS and analyzed using covariate-adjusted linear mixed models for repeated measures to compare the intervention and control groups over time on the major outcomes of participants. Conventional content analysis of qualitative interviews will be conducted using data analysis software.

Results: The project was modified to a telephone-based intervention owing to the COVID-19 pandemic. Data collection started in 2020 and ended in 2022. In total, 103 dyads were matched at the beginning of the intervention. Of the 103 dyads, 90 (87.4%) dyads completed the midtest survey and 64 (62.1%) dyads completed the whole intervention and the posttest survey. Although we are still cleaning and finalizing data analyses, the preliminary results from both quantitative and qualitative data showed promising results of this intergenerational reminiscence approach that benefits both the older adults who have cognitive impairments and the young adult participants.

Conclusions: Intergenerational reminiscence provided by young adult college student offers promising benefits for both the younger and older generations. Future studies may consider scaling up this pilot into a trackable, replicable model that includes more participants with diverse background (eg, public vs private college students and older adults from other agencies) to test the effectiveness of this intervention for older adults with ADRD.

KEYWORDS

Alzheimer's disease and related dementias; ADRD; digital storytelling; DST; intergenerational reminiscence; older adult; young adult; randomized controlled trial

Introduction

Background

The projected number of individuals aged ≥65 years living with Alzheimer disease and related dementias (ADRD) is expected to reach 7.1 million by 2025, marking a 22% increase from the current figure of 5.8 million older adults affected [1]. Unless significant advancements in medical research lead to preventive measures, treatments, or cures for ADRD, these statistics are projected to escalate to 13.8 million by 2050 [1]. In addition to memory loss, difficulties in daily functioning, and behavioral symptoms, ADRD profoundly affects the social and emotional well-being of those living with the condition.

Most older adults with ADRD live in the community, and many of these individuals live alone [1,2]. There is growing concern about social isolation and loneliness among people with ADRD, particularly as both have been widely linked to poor physical health outcomes and compromised quality of life and well-being [3]. Studies suggest that people with ADRD are at great risk for social withdrawal, social isolation, and loneliness [4]. Individuals with ADRD also tend to have few close friends, which may negatively affect their quality of life [5]. In addition, ADRD is associated with increased risk of depression; anxiety; and other negative emotional well-being outcomes [6], including decreased resiliency, which may prevent individuals from recovering from life's challenges [7,8]. Although there are no interventions to prevent or cure ADRD, there is a pressing need to address and understand the social and emotional well-being of people with the disease.

However, people of all ages may experience social isolation and loneliness. The younger generation has various sources that caused their loneliness. It has been reported that Generation Z (aged 18-22 years) is the loneliest generation and claims to be in worse health than older generations [9]. Overall, 7 out of 10 respondents feel alone (73%), shy (72%), or that no one really understands them well (71%) [9]. In the workplace, they also feel abandoned by their coworkers when under pressure at work (42%), alienated by their coworkers (40%), emotionally distant from the people they work with (54%), and disconnected from others at work (55%) [9]. Moreover, young adults were reported to experience heightened levels of loneliness and mental health challenges during the COVID-19 pandemic [10]. Neglecting the issue of social isolation and loneliness can have detrimental effects on both the mental and physical well-being of individuals, as evidenced by studies such as that by Mushtaq et al [11]. Therefore, it is crucial to develop programs or interventions that aim at preventing or addressing loneliness, so that physical and mental health of young and older adults is maintained.

Reminiscence Approach

Reminiscence has been identified as a potentially effective intervention strategy for alleviating depression [12-14] and in promoting social and emotional well-being for older adults [15]. Reminiscence typically involves a discussion of past activities, events, and experiences aided by the use of familiar items and objects such as photographs and music [16]. Reminiscence work with people with ADRD is viewed as a psychosocial intervention with a credible evidence base [17]. There is also evidence suggesting that individual reminiscence work that involves a life review and subsequent production of a life story book is associated with improvements in the well-being of people with ADRD [18].

Intergenerational Reminiscence Approach

Studies suggest that reminiscence combined with an intergenerational approach may yield significant social and mental health benefits for young and older adults. Through intergenerational reminiscence, older people may pass on their life experiences and life lessons to younger generations [19,20], and the sharing of autobiographical memories has both social and psychological functions [21]. Previous studies also assert that the use of an intergenerational approach is an effective strategy for promoting positive social and mental health in later life, such as reducing social isolation or loneliness [22]. Establishing intergenerational contact and fostering relationships between older individuals and young adults serve as effective measures to prevent the formation of stereotypes or negative attitudes and to challenge and dispel existing ones [23,24]. In addition, intergenerational programming can enable the younger generation to develop meaningful connections with older adults [23].

Reminiscence is typically implemented by trained professionals (eg, social workers and nurses); however, there has been growing interest in using trained volunteers owing to staffing shortages and the costs associated with reminiscence programs [25]. As part of the efforts to use volunteers rather than professionals, the concept of joining young volunteers and older generations together for intergenerational reminiscence has emerged as a promising area of research. So far, the work of Chung [25] and Gaggioli et al [26] are the only peer-reviewed studies implementing intergenerational reminiscence with young volunteers. Although several benefits were reported for both generations in these 2 studies, the small size of the sample and absence of a control condition limited the study results. The findings underscore the need for more studies related to intergenerational reminiscence that include young adult

XSL•FO
RenderX

volunteers, as this approach may potentially offer a more sustainable and cost-effective intervention for implementation in community-based settings. Thus, more studies are needed to better understand and rigorously measure this approach to intergenerational reminiscence interventions, particularly for older adults with ADRD.

Reminiscence and Digital Storytelling

There are previous studies of reminiscence work that endorse the use of a life story book that are pertinent to the proposed study [18,25]. Recent studies recommend the production of a digital life story book [17] as part of reminiscence. Digital storytelling (DST) is a technology that uses a 2- to 5-minute audio-visual clip combining text, images, music, photographs, voice-over narration, and other audio [27]. Psychological well-being benefits of DST for the general population have been reported in a systematic review [28]. Previous studies also demonstrate the benefits of DST for people with ADRD [29,30]. Studies of intergenerational DST, which combines DST and intergenerational programming, reported positive outcomes including reciprocal relationships, empathy, connection, and confronting agism [31]. However, few studies combined a reminiscence approach and DST or intergenerational DST. Thus, this study is the first one to develop and test how intergenerational reminiscence using a DST platform may help older adults with ADRD and young adults to improve their social and emotional well-being.

College Student Involvement

The proposed study will include young adult volunteers recruited from University of Texas at Arlington (UTA), a large and diverse institution of higher education. The rationale for including undergraduate and graduate students in the proposed study is that the positive impact of intergenerational learning experiences on students' academic and personal development is well documented [32]. Previous studies support the value of intergenerational activities in postsecondary education; provide evidence of benefits, reciprocity, and empowerment outcomes [33]; and suggest that these learning experiences may better prepare undergraduate and graduate students for future work with older adults [31]. Studies further suggest that intergenerational learning experiences that involve interactions with people with ADRD also result in positive gains in academic learning and attitude toward older adults among college students [34]. By connecting young adult volunteers with older adults through interactions during the proposed intervention and preintervention training, this proposed study aims to have a positive influence on attitudes toward aging and knowledge about ADRD. Furthermore, with rapidly changing demographics in the United States, there is an urgent need to combat the stereotypes and negative attitudes toward aging and agism and discrimination of older adults that often exists among younger populations [35].

Studies suggest that intergenerational reminiscence is promising for individuals with ADRD; however, these studies are limited by small sample sizes and less rigorous study designs. A recent systematic review of reminiscence therapy provided in the Cochrane Library specifically recommends large-scale, randomized controlled trials that include a life story book component for people with ADRD [17]. Although a few studies have attempted to use young volunteers as part of small-scale intergenerational reminiscence studies [25,26], the use of undergraduate and graduate students is unexamined so far.

Aims and Research Questions

Overview

To fill the abovementioned research gaps, the proposed study aims to develop and evaluate the feasibility and effectiveness of an intergenerational reminiscence approach in improving the social and emotional well-being of older adults with ADRD. The intervention is guided by continuity theory [36], which posits that the reminiscence process guides individuals to adjust and adapt to changes that occur in their lives. Moreover, a continuity theory approach to reminiscence may also facilitate a strong sense of self [37] and has been recently used in other reminiscence interventions [38]. On the basis of literature and the continuity theory, it is hypothesized that the framework of reminiscence combined with an intergenerational approach and DST will help to improve the social and emotional well-being of both generations and help strengthen or build resilience in older adults with ADRD. Specifically, the study addresses 5 goals.

Goal 1—To Quantitatively Test the Effectiveness of This Intervention in Improving the Social Well-Being of Older Adults With ADRD and Young Adults

The objectives are to (1) provide a 10-session intervention with reminiscence and DST to older adults by trained young adult volunteers and (2) test whether older or young adults report significant improvement in quality of life or decline in loneliness after the intervention. Hypotheses include the following: (1) older participants in the intervention group will have high levels of quality of life in the middle of and after the intervention compared with their pretest scores and compared with those in the control group and (2) young and older participants in the intervention group will have low levels of loneliness in the middle of and after the intervention compared with their pretest scores and compared with those in the control group.

Goal 2—To Quantitatively Test the Effectiveness of This Intervention in Improving the Emotional Well-Being of Older Adults With ADRD

The objectives are to (1) provide a 10-session intervention with reminiscence and DST to older adults by trained young adult volunteers and (2) test whether older adults report significant changes in affect or resilience after the intervention. Hypotheses include the following: (1) older participants in the intervention group will have high positive affect (PA) and low negative affect (NA) in the middle of and after the intervention compared with their pretest scores and compared with those in control group and (2) older participants in the intervention group will have high resilience scores in the middle of and after the intervention compared with their pretest scores and compared with those in control group.

XSL•FO
RenderX

Goal 3—To Quantitatively Test Attitudes Toward Aging Among the Young Adult Volunteers

The objectives are to (1) offer opportunities for trained young adult volunteers to engage with older adults in the 10-session intervention and (2) test changes in their attitudes toward aging after the intervention using surveys. Hypotheses include the following: (1) young adult volunteers in the intervention group will have more positive attitudes toward aging after the intervention compared with that before the intervention and (2) young adult volunteers in the intervention group will have more positive attitude toward aging after the intervention compared with those in the control group.

Goal 4—To Quantitatively Test Knowledge and Awareness About ADRD Disease Among the Young Adult Volunteers

The objectives are to (1) offer a 3-hour training to the young adult volunteers before the intervention starts, which covers the biological aspects of ADRD and how to communicate and connect interpersonally to people with ADRD, and (2) test changes in their reported knowledge and awareness about ADRD using surveys. Hypotheses include the following: (1) young adult volunteers in the intervention group will report more knowledge and awareness about ADRD disease after the intervention compared with their pretest scores and (2) young adult volunteers in the intervention group will report more knowledge and awareness about ADRD disease compared with those in the control group after the intervention.

Goal 5—To Qualitatively Evaluate the Usefulness of This Intervention From the Perspectives of the Dyads

The objectives are to (1) explore and interpret the statistical results obtained in goals 1 and 2 through individual interviews with older adults who report the greatest and least changes in well-being; (2) explore and interpret the statistical results obtained in goals 3 and 4 through individual interviews with young adult volunteers who report the greatest and least changes in attitudes toward aging; and (3) examine dyad participants' perceptions about the intervention in terms of its quality, benefits, and usefulness.

Methods

Study Design

The proposed project will conduct a randomized controlled trial to assess the effects of the intergenerational reminiscence approach with DST on the social and emotional well-being of older adults with ADRD. An explanatory sequential mixed methods design [39] will be used, which first involves collecting quantitative data and analyzing the data to identify subsamples of participants who report the greatest and least changes and then conducting qualitative interview with these subsamples. Half (46/92, 50%) of the dyad sample will receive the reminiscence DST intervention, and the other half (46/92, 50%) of the sample will receive a regular social visit from young adult volunteers without the intervention. Dyads will be randomly assigned to either the intervention or control group after baseline screening of all participants and, subsequently, randomly matched within each group. To further prevent selection bias, statistical techniques such as covariate-adjusted linear mixed models will be used to adjust for covariate imbalance during data analysis.

A total of 92 dyads are required to test the effectiveness of the intervention in this proposed study (refer to power analysis in the *Sample and Recruitment Plan* section). We will recruit participants on a rolling basis until we recruit 92 dyads. At least one-fourth (23/92, 25%) of the total sample of older adults and young adult volunteers will be recruited before they are randomly matched. Upon signing the consent form, participants will be given the chance to engage in the study. They will be provided with guidance throughout the informed consent process and will subsequently undergo a baseline survey in which all measures will be collected blind to group conditions.

The first group will receive the intervention (X), which includes reminiscence and DST components provided by the young adult volunteers, whereas the second group will serve as the sham control group, which will include social visits calls by the young adult volunteers and an unstructured, nondigital recording (eg, scrapbook or journal) of the social visits. To account for the potential influence of attention and social interactions stemming from the intervention, the control activity is intentionally designed to offer comparable social contacts. This ensures that any observed improvements in participants cannot solely be attributed to the intervention itself. The features of the intervention and sham protocols are the same, except that participants in the intervention group will participate in structured reminiscence and DST, whereas those assigned to the control group will be facilitated to do otherwise. Similar to the study by Lai et al [40], the sham protocol will include talking about overall issues related to wellness in later life (eg, diet and health, social activities, and family relationships) and creating a wellness scrapbook or journal.

As shown in Figure 1, data will be collected at baseline before the intervention, in the middle of the intervention, at the end of the intervention, and at 3 months after the intervention. The design of this study is depicted in scientific notation.

Figure 1. Data collection overview. G1: first group; G2: second group; O1: before the intervention; O2: middle of the intervention; O3: end of the intervention; O4: 3 months after the intervention; X: intervention.

$$\begin{array}{cccccc} G_1 & O_1 & X & O_2 & O_3 & O_4 \\ G_2 & O_1 & \text{Sham} & O_2 & O_3 & O_4 \end{array}$$

Sampling and Recruitment Plan

Power analyses performed using G*Power 3.1.9 indicated that a total of 92 dyads (or 184 participants) are required to address our study objectives using a linear mixed model. This sample size estimate was based on a small effect size (*f*=0.22), a significance level of α=.05, β of .20, anticipated *r* over time of

XSL•FO
RenderX

0.30, and 5% attrition rate based on the findings of Chung [25], for 2-tailed tests.

Participants in this study will be community-dwelling older adults and undergraduate and graduate students (ie, young adult volunteers) enrolled at UTA. The eligibility criteria of the older adult participants include individuals who (1) are aged ≥65 years; (2) have cognitive impairment measured by the Ascertain Dementia 8 (AD8) [41]; (3) have decisional capacity as measured by the University of California, San Diego Brief Assessment of Capacity to Consent (UBACC) [42]; (4) are not participating in any other research protocol currently; and (5) can speak and understand English. The exclusion criteria for older adults are (1) participating in another trial, (2) having health issues that prevent them from participating in the study for 3 months, and (3) inability to commit to being available for the full 10 weeks of the intervention.

The older adult participants will be recruited through Tarrant County Meals On Wheels (MOW), which is a partner agency of the Area Agency on Aging of Tarrant County. Eligibility criteria to enroll in Tarrant County MOW is that a person must be homebound and have no one to help them on a regular basis. The Area Agency on Aging is very committed to expanding services and supports to people with ADRD, as many MOW clients with ADRD are living alone in Tarrant County. Moreover, studies suggest the need for additional research in the area of loneliness among clients using MOW [43]. Participant recruitment will begin with case managers and other MOW staff using their client database system to search for clients with ADRD who meet the study criteria. Next, case managers will contact potential study participants and then ask for permission to share their telephone number with a member of the UTA research team. The principal investigators (PIs) and graduate research assistants (GRAs) will follow-up with all the potential participants provided by MOW.

The young adult volunteers will include undergraduate or graduate students from UTA. The inclusion criteria for the young adult volunteers are the following: (1) aged 18 to 30 years, (2) currently enrolled as a student at UTA, and (3) can commit to be available for the full 10 weeks of the intervention. Young adult volunteers who have health issues or limited availability that prevent them from participating for the entire 10 weeks of the intervention will be excluded from the study. The study will be widely advertised across the UTA campus through avenues such as different student organizations, departmental social media accounts, departmental websites, and the offices of campus partners (eg, student health services, career services, campus recreation, and undergraduate honor program). Other recruitment efforts will include posting flyers across the campus, emailing student listserves, social media, advertising on television monitors located in buildings across campus, and classroom visits.

Procedure

Before the intervention starts, the young adult volunteers in the intervention group and control group will be offered a mandatory separate group training through Microsoft Teams. Training for young adult volunteers in the intervention group will last 3 hours and be offered by LX, NLF, KMD, and BAT. Students will be provided with hard and electronic copies of the training materials. As part of the training, LX will cover an overview of the study and the intervention protocol, project timelines, responsibilities of the young adult volunteers, roles of the research personnel, and importance of human participants' protection in the research activities. KMD will provide training related to ADRD, communication skills with older adults with ADRD, and how to deal with unexpected behavior or emotional symptoms of older adults during the intervention. NLF will cover how to communicate with older adults with ADRD. BAT will provide an overview of DST and details about DST techniques and demonstrate strategies for successful DST. Similarly, training for the young adult volunteers in the control group will be approximately 1 hour in duration and will cover human participants' protection; study procedure (social visits); and explanation of the unstructured, nondigital record of the social visits. The trainings will be audio recorded and later analyzed for fidelity.

Subsequently, participants will participate in this telephone-based intervention. In this study, the young adult volunteers (in both the intervention and control groups) will talk with older adults through telephone calls each week for 10 weeks with the same process described in the following sections. Older adults in the intervention group will receive 10 sessions of life review with the trained young adult volunteers (1-1.5 hours each week for 10 weeks). During weeks 1 to 6, a life history interview will be conducted with different themes in each week: major turning points in life (W1), family history (W2), life or career accomplishments (W3), history of love and hate (W4), stress experiences (W5), and meaning and purpose of life (W6). Guidelines for conducting a life history interview will be prepared for the young adult volunteers based on the work of Watt and Cappeliez [44]. The implementation outline will encompass integrative and instrumental reminiscence techniques that aim to foster self-acceptance, conflict resolution, reconciliation, sense of purpose and self-value, recollection of effective coping strategies used in the past, and leveraging past experiences to address current challenges. After each session, the young adult volunteer will write a 1-page summary and reflect about the interview to help prepare for the subsequent DST in the later weeks. During weeks 7 to 10, the dyads will develop the DST together using tablets already owned by the UTA School of Social Work. The contents of sessions 7 to 10 will be structured as outline or script; plan and storyboard (W7); film and record (W8); evaluate, integrate, and finalize (W9); and publish or share (W10). It is acceptable if no filming or video aspect of the DST is conducted. Audio-based DST without video recording is still common, as it captures the voices that give life to the photos [27]. Photos obtained from the internet or the participants may be used as part of the DST to accompany the audio. For example, photos of the individual's hometown, familiar places (ie, parks), familiar vacation locations (ie, monuments and historical markers), and so on, will help augment the voice recordings.

Older adults in the control group will have general social visit conversation with the young adult volunteers, and the content of weeks 1 to 6 will be based on general topics related to wellness in later life, instead of structured reminiscence

XSL•FO
RenderX

guidelines. The topics of weekly social conversation are diet and health (W1), exercise or activity and health (W2), emotions and health (W3), religious or spiritual practices and health (W4), family or friend relationships and health (W5), and social activities or engagement and health (W6). For weeks 7 to 10, instead of DST, the young adult volunteer will work with the older adult to create an unstructured, nondigital record of the social visit related to wellness in later life (eg, wellness scrapbook or journal).

Every effort will be made to minimize risks by closely monitoring participants' mood during weekly fidelity treatment checks. Weekly calls with the dyads in both the intervention and control groups will be conducted by the research team to closely monitor the participants' mood and to serve as a fidelity check. These calls will include questions related to the study protocol (eg, topics covered, time spent, and challenges that occurred) and questions related to the well-being of participants (eg, How are you feeling? Do you need anything from the research team? and Are you experiencing any challenges?). If a study participant experiences emotional distress during the study, a clinical social worker and registered nurse practitioner, who are members of the research team, will offer consultation, and if necessary, they may refer study participants to additional services through the local Area Agency on Aging. Finally, individual retraining will be provided to the young adult volunteers in the case of problems with treatment fidelity.

To prevent contamination, the importance of confidentiality will be emphasized to participants in the intervention group at the beginning of the study. Participants (especially the young adult volunteers) in intervention group will be asked not to share the protocol with the participants in the control group for the duration of the study to minimize contamination. To further prevent contamination, the research team will check in with young adult participants in the intervention group 3 times (3 weeks, 6 weeks, and 9 weeks after the intervention starts) via telephone to ensure that no information has been shared with participants in the control group. Furthermore, young adult participants in the control group will also be asked 3 times during the study period whether they received any information related to the reminiscence and DST content, and this will be documented by the research team. In addition, substantial contamination can be tolerated within the usual individual randomized trial [45]. Finally, if contamination occurs, any documentation of hearing about or implementing reminiscence in the control group will be included as a covariate in the study analyses.

After the intervention, qualitative interviews with subsamples in the intervention group will be conducted. For the individuals in the highest 10% and lowest 10% of changes based on survey tests, we will conduct follow-up qualitative interviews to capture the details of their situations and present a more robust analysis, taking advantage of the strengths of both methods. The interview will last for 45 to 60 minutes and will be conducted by research teams through telephone calls.

Measurement

Overview

The primary outcomes of the study will be the social and emotional well-being of older adults, and the secondary outcomes will be the benefits to the young adult volunteers. Social well-being will be measured by quality of life and loneliness, whereas emotional well-being will be measured by affects (positive and negative) and resilience. Regarding social well-being, quality of life is a relatively global and stable phenomenon that comprehensively measures people's psychosocial well-being [46]. Recent studies suggest that loneliness, which represents the negative subjective experience of the inadequacy of social relationships, is a factor in evolutionary fitness across the life span [47] and is a good indicator of social well-being [48]. Regarding emotional well-being, PA and NA have been used as general dimensions to describe affective, emotional components of subjective well-being [49]. Resilience, as an important indicator of emotional well-being, assesses one's ability to bounce back from or adapt to stressful situations or crises, such as having been diagnosed with ADRD [10,11]. Young adult volunteers will be asked about their attitude toward aging and knowledge and awareness about the ADRD disease. Demographic information about each dyad, such as age, sex, education, self-reported health, and so on, will also be collected in the pretest survey. A pilot test will be conducted on 3 volunteer dyads using assessment tools to evaluate participants' possible overload impacts. In accordance with the input provided by pilot participants, the research team will review and make necessary modifications to the measurement selections within the initial 6 months of the project (preparation stage).

Primary Outcome Measurements for Older Adults

Quality of life of older adults in this study will be measured using Quality of Life–Alzheimer's Disease (QoL-AD) [50]. The QoL-AD questionnaire consists of 13 items that cover various aspects including physical health, energy levels, mood, living situation, memory, family relationships, marital status, friendships, self-perception, ability to perform daily chores, engagement in enjoyable activities, financial situation, and overall life satisfaction. The higher the QoL-AD score, the better is the quality of life. Self-rating QoL-AD will be used, which had showed high reliability and validity [51,52].

Loneliness among older participants will be measured using the De Jong Gierveld Loneliness Scale [53]. This 6-item scale measures both emotional and social loneliness. This instrument has undergone validation in numerous countries, with validation studies encompassing various sexes and age groups and specifically including older adults. High scores indicate great loneliness. Reliability coefficients for both subscales were 0.81 to 0.85 [54].

The measurement of PA and NA in older adults will be conducted using the widely used Positive and Negative Affect Schedule (PANAS) [55]. PANAS assesses the respondent's emotional state by inquiring about 10 positive and 10 negative emotions using a 5-point scale ranging from "Very slightly or not at all" to "Extremely." This scale has demonstrated strong

XSL•FO
RenderX

psychometric properties, with Cronbach α of .88 for PA and .87 for NA. Furthermore, PANAS has been validated across various cultures and languages worldwide, consistently exhibiting robust psychometric properties in multiple studies [49,56]. Total scores will be calculated for PA and NA, with high scores indicating more PA and NA, respectively.

The resilience of older adults will be measured using the Brief Resilience Scale [57]. The Brief Resilience Scale is recognized as one of the top and extensively endorsed resilience scales and recommended by Windle et al [58]. Extensive literature supports its high reliability and validity, as demonstrated by studies conducted by Smith et al [57,59]. A total of 6 items will be asked, and responses for each item ranges from 1 (*low resilience*) to 5 (*high resilience*). After reverse coding 3 items, total scores will be calculated for final analysis, with high score indicating more resilience.

Secondary Outcome Measurements for Young Adults

To measure the loneliness among young adult participants, we will use the De Jong Gierveld Loneliness Scale [53], following the same methodology used for measuring loneliness among older adults, as mentioned previously.

The Alzheimer's Disease Knowledge Scale (ADKS) [60] will be used for the young adult volunteers. The ADKS is a comprehensive instrument consisting of a 30-item true or false scale. It can be completed in approximately 5 to 10 minutes and covers a wide range of domains, including risk factors, assessment and diagnosis, symptoms, disease progression, impact on daily life, caregiving, and treatment and management. Initial findings indicate that the ADKS exhibits satisfactory reliability, including test-retest and internal consistency and validity, including content, predictive, concurrent, and convergent validity. These results have been reported in studies conducted by Carpenter et al [60] and Spector et al [61]. Total scores will be calculated for final analysis, with high score indicating more knowledge.

To assess the young adult volunteers' attitudes toward aging, the Fraboni Scale of Agism (FSA) will be used. The FSA, initially developed by Fraboni et al [62] and subsequently revised by Rupp et al [63], consists of 29 statements. Participants will rate their agreement on a 4-point Likert scale, ranging from 1 (*strongly disagree*) to 4 (*strongly agree*). The FSA has been widely used among college students and has demonstrated strong internal consistency and robust validity in previous studies [64,65]. Total scores will be calculated for final analysis, with high scores indicating more agism.

In addition, a 20-item questionnaire [25] will be developed to collect feedback from the young adult volunteers, covering (1) intervention preparation and organization, (2) intervention format and workload, and (3) perceived gains. Each item is rated on a 5-point scale (1=*strongly disagree* to 5=*strongly agree*), and the higher the score, the more positive the perception about the intervention.

Other Outcomes

Follow-up qualitative interviews will be conducted to explore participants' overall experience with and perceptions about the intervention. On the basis of the results from the survey, we will select older and young adult participants who have the highest and lowest levels of changes in the outcomes for further qualitative interviews (10 dyads in total). Each generation's experiences, perspectives, challenges, and suggestions regarding this intervention will be asked during these in-depth interviews.

Data Collection Plan

Data will be collected at baseline, midpoint, end of the intervention, and 3 months after the intervention by telephone. A total of 3 GRAs will be trained to collect the data. Training on the assessment battery and interview techniques will be provided by PIs to GRAs. For the quantitative survey, after training, interrater reliability checks will be performed by 1 PI on pilot interviews of team members and participants (3 older adults and 3 college students not included in the final sample size), based on audiotaped interviews. For the qualitative interviews, training related to conducting interviews will be provided to GRAs, such as talking less and listening more, how to build rapport with the respondents, and how to handle unexpected emotions of participants. The GRAs will also pilot-test their qualitative interviewing skills based on role-plays with the research team. GRAs will have weekly supervision meeting with the PIs regarding participant recruitment and follow-up and survey assessments.

Several strategies will be used to track clients during the study and to minimize attrition. At the baseline and at each subsequent interview, participants will be asked to provide the names of 2 people who may know where they are if the researcher has difficulty in contacting them. We will also have the older participants' MOW case managers as a backup point of contact. We will adopt the strategies of minimizing attrition in longitudinal studies [66], which results in 90% follow-up. These strategies (ie, getting several contacts, getting emails, reminder letters, and thank you letters) have proved to be useful in previous community-based studies conducted by the research team.

For individual missing responses on multiitem scales, we will compute scale scores by summing the available item scores as long as at least 80% of the item responses are available [67]. Missing data at the variable level will be handled through maximum likelihood imputation [67]. A concern with longitudinal research is that data are not missing randomly owing to systematic dropout. We will conduct attrition analyses to identify any factors systematically related to dropout and, if found, control for these effects in subsequent analyses. Any missing data that are random in nature, such as those that occur owing to random mistakes in data collection or entry and are not related to research staff or patient noncompliance, will be submitted to maximum likelihood estimation procedures to estimate those missing values. Maximum likelihood estimation for random missing data is a common and accepted procedure for missing data estimation [68,69]. If specific patterns of missing data are identified, we will further address missing values with multiple imputation. Multiple imputation will maximize accurate statistical inferences and allow for valid statistical inferences by appropriately accounting for the uncertainty caused by missing data [68,69].

XSL•FO
RenderX

Statistical Analysis

After data are collected and entered into the statistical software, data quality will be carefully reviewed and then checked both automatically and manually. The review processes involved in data management encompass several steps. These include cross-checking the coding of observations or responses and identifying out-of-range values; ensuring data completeness; adding variable and value labels as needed; verifying random samples of digital data against the original data; implementing double entry of data; conducting statistical analyses such as determining the frequencies, means, and ranges to identify errors and unusual values; and rectifying any errors made during transcription. In addition, data will be thoroughly reviewed to address concerns related to the protection of human participants and confidentiality. This includes assessing the risk of potential disclosure of research participants' identities, safeguarding sensitive information, and preserving the privacy of the collected data. As all the key concepts in the proposed study are measured using standard scales, reliability tests for each scale and test-retest reliability across the 4 surveys will be conducted.

For quantitative data analyses, descriptive analyses will first be conducted to provide the overall means and frequencies of key outcome variables for both older and young participants in the intervention and control groups. Fisher exact tests, Pearson chi-square tests, and independent samples *t* tests (2-tailed) will be computed to test for group differences that may be attributable to participants, such as age, sex, education level, income, and health conditions. If the groups significantly differ on any of these variables, the variable will be incorporated into the following analyses as a covariate, thereby controlling for potential influences that the covariate may have on the dependent variables. Moreover, in the event that at the culmination of this study, our sample sizes are unequal in the treatment groups or our outcome data are nonnormal, we will follow through with appropriate statistical corrections where necessary. Covariate-adjusted linear mixed models for repeated measures will be performed to compare the intervention and control groups over time for the major outcomes of older adults and young adult volunteers. The covariate will be any significant variable yielded from the univariate analyses, and the dependent variable will be the scores before the intervention, in the middle of the intervention, at the end of the intervention, and at 3-month follow-up. In this study, 95% CIs will be computed for each adjusted mean difference. The study α will be set to .05, with no adjustments for multiple comparisons owing to the preliminary nature of this study and the increased risk of type-2 error as a result of α adjustment [70].

Several different combinations of statistical results are possible. The results may indicate that the intervention and control groups significantly differ in outcomes among the older participants and the young adult volunteers. Another possibility is that differences may be discovered for one age group but not the others. Outcome measures may significantly change over time for none of the groups, some groups, or all groups. Another possibility is that the pattern of change over time for one group may not replicate in another group. This possibility, which would be identified via a significant interaction in linear mixed models, would require post hoc testing to investigate the nature of changes over time. In this case, groups will be isolated, and patterns of change will be identified via linear mixed models for repeated measures (with no between-participants factors). *For the qualitative data analysis*, the process will involve digitally recording and transcribing the qualitative interviews, followed by using conventional content analysis, as outlined by Hsieh and Shannon [71]. The research team, including LX and NLF, along with the research assistants, will independently code the data, forming the foundation for an initial coding framework. Subsequently, the researchers will convene to compare and establish consensus on the coding outcomes. Pertinent excerpts from the transcripts will be extracted and reorganized based on thematic relevance. The constant comparison process, as described by Glaser and Strauss [72], will be used to explore similarities and differences among participants who did and those who did not benefit from the intervention, generating subthemes within the broad topics. This comparative approach will enhance consistency and broaden the dimensions and comprehensiveness of each code. Eventually, the codes will be synthesized or combined into overarching recurrent themes. During the analysis stage, themes, research notes, and field notes will be reviewed using thematic charts. Multiple strategies, including peer debriefing, will be implemented to address potential investigator bias and enhance the study's credibility. Maintaining comprehensive documentation will also ensure that an audit trail is available for future reference.

Data Management and Participants' Safety

The research team will be the sole individuals with knowledge about and access to the names of both the older and young participants. Although certain demographic information, such as age, sex, and racial and ethnic background, may be recorded, the questionnaires will not contain any participant identifiers such as date of birth or address. The preintervention and postintervention questionnaires will also be devoid of participant identifiers. To ensure confidentiality, participant names will be deidentified, with each individual assigned a unique study identifier or number. All data files will be securely stored in encrypted, password-protected folders on laptops provided by UTA. These laptops will also have encryption in accordance with the guidelines set by the UTA Office of Information Technology. Participant privacy will be diligently safeguarded, and records containing names and other identifiable information will be stored separately from the interviews, using password-protected, encrypted files on UTA-issued laptops. The PI (LX) and the UTA institutional review board (IRB) will bear the responsibility of ensuring participant safety and the attainment of the study's scientific objectives. The research team possesses previous experience in organizing and managing clinical trials, including implementing data safety monitoring measures for interventions.

All the older adults and young adult volunteers will provide informed consent before participating in the study. Potential participants will be informed that refusal to consent to the study or withdrawing from the study will have no effect on the services that they currently receive or might receive through UTA (ie, young adult volunteers) or through MOW or the Area Agency on Aging (ie, older adults). Participants who provide informed

XSL•FO
RenderX

consent will be contacted for baseline measurement and then randomized to 1 of the 2 treatment groups. The protocol and consent forms will be approved by the UTA IRB before conducting any study procedures. Student members of the research team will receive training regarding procedures required to obtain informed consent.

Human participants' risk related to the study is minimal. The study carries potential risks related to the identification of depression or anxiety, as participants may become aware of their symptoms during the intervention sessions. This heightened awareness could lead to the recognition of distressing thoughts. In addition, there is a risk associated with the process of recalling past memories, as it may evoke difficult or emotional experiences for participants. Every effort will be made to minimize risks by closely monitoring the participants' mood during weekly fidelity treatment checks. In the event that a study participant experiences emotional distress during the study, KMD, a registered nurse and gerontological nurse practitioner, along with NLF, a licensed clinical social worker, will be responsible for providing the necessary support and counseling to address the participant's emotional well-being. They will also be available as needed for referral to the resources through the local Area Agency on Aging for the older adults and university services for the young adult volunteers, as needed.

Ethics Approval

The study was approved by the UTA IRB on March 25, 2021 (2021-0206).

Results

The study was funded in January 2021. Data collection started in May 2021 and ended in mid-2022. In total, 103 dyads were matched at the beginning of the intervention. Of the 103 dyads, 90 (87.4%) dyads completed the midtest survey and 64 (62.1%) dyads completed the posttest survey. Although a total of 92 dyads were planned to test the effectiveness of the intervention in this proposed study, the post hoc power analyses performed using G*Power 3.1.9 indicated that 64 dyads will yield sufficient power to test the interaction between groups over time (power=0.95), the changes over time (power=0.95), and the differences between the groups (power=0.71). These parameters are based on a small anticipated effect size (f=0.22), α=0.05, two-tailed, with measures correlated at r=0.30.

We also collected qualitative interview data for this study with selected dyads in the intervention group (8/27, 30%). Weekly reflection page from UTA student participants, weekly fidelity check forms, final digital story books, and final scrapbooks were also saved for future data analyses. We are currently engaged in data cleaning and analysis for both quantitative and qualitative data. One manuscript has already been published [73], and we anticipate publishing several more manuscripts reporting the results within the next 1-2 years.

Discussion

Principal Findings

The aim of this study is to develop and implement a 10-session intervention that combines reminiscence and DST techniques and foster connections between young adult college students and older adults with ADRD in a community setting. Through the collection of qualitative and quantitative data, this study seeks to evaluate the intervention's potential efficacy in enhancing the social and emotional well-being of young and older adults and in improving the knowledge about ADRD and attitudes of young adults toward aging. By focusing on reminiscence and life review content, integrating DST technology, and including older adults with cognitive impairment, this study will contribute valuable and current data to address the existing research gaps.

Considering the multitude of psychological and mental health challenges experienced by older adults with ADRD, this study holds academic significance. By focusing on the social and emotional well-being of this population, the aim is to enhance their overall life satisfaction, positive emotions, and sense of purpose, factors that contribute to resilience and quick recovery from adversities linked to dementia diagnosis. Furthermore, this study adopts an innovative approach that combines the beneficial practice of reminiscence or life review facilitated by a DST product, alongside an intergenerational perspective, which also aims to address the social well-being (loneliness) issues of young adults. By engaging young adults as interventionists, this strategy empowers them to gain insights into older adults with ADRD, while reshaping their perspectives about aging. It also taps into their enthusiasm as volunteers, addressing staffing shortages and reducing expenses linked to professional interventionists. Consequently, it establishes a sustainable and economically viable intervention approach that is well suited for community-based environments. In addition, this study aims to address the limitations identified in previous studies, such as small sample sizes and the absence of a control condition.

Limitations

A limitation of this study is its lack of representativeness. The older adult participants in this study only include MOW clients who generally have low income and are homebound. The young adult college students come from 1 public university in Dallas-Fort Worth area. Thus, the study has limited representativeness that cannot extend to other community-dwelling older adults and college students from other universities. Moreover, this study only focuses on the Dallas-Fort Worth area and thus, its results cannot be generalized to other cities, states, or regions. Future studies may consider scaling up this pilot into a trackable, replicable model in multiple sites to test the effectiveness of this intervention for older adults with ADRD. In addition, this protocol is proposed for in-person interactions between young and older generations. Owing to the risks and feasibility of conducting an in-person intervention during the COVID-19 pandemic, this project has to be tailored to telephone-based approach. Future study may

XSL•FO
RenderX

consider comparing the effectiveness of interventions between in-person meeting versus telephone-based approach.

Conclusions

Intergenerational reminiscence program that connects older adults with ADRD with young adult college student volunteers offers promising benefits for both younger and older generations in improving their social and emotional well-being. Future studies may consider scaling up this pilot into a trackable, replicable model that includes more participants with diverse background (eg, public vs private college and older adults from other agencies) to test the effectiveness of this intervention for the benefits of older adults with dementia and young adults.

Acknowledgments

The research team received support from the Retirement Research Foundation for Aging (2020125).

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

LX, NLF, KMD, and BAT were involved in conceptualization; LX, NLF, KMD, and DJC contributed to the methodology; LX and NLF were involved in validation, investigation, resources, supervision, and project administration; LX, NLF, and DJC conducted the formal analysis; and LX was involved in data curation. All authors were involved in preparing, reviewing, and editing the original draft of the manuscript and in funding acquisition. All authors have read and approved the published version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Pes planus is one of the most common foot deformities. Although there are many studies on the effectiveness of various exercise methods in pes planus rehabilitation, the number of studies on video-based game exercise therapy applications is very limited.

Objective: This study aims to evaluate the effectiveness of 2 video-based game exercise therapies and structured exercise practices in pes planus rehabilitation.

Methods: This study is a 3-arm, parallel-group, single-blinded randomized controlled trial. The study will include 69 patients with flexible pes planus aged between 18 and 25 years who attend the orthopedics and traumatology clinic and meet the inclusion criteria. The primary outcomes are measures of navicular drop and pedobarographic analysis before and after the intervention, and the secondary outcomes include balance, femoral anteversion, and lower extremity muscle strength. Participants will be evaluated with a navicular drop test for medial longitudinal arch height, a pedobarographic analysis system for plantar pressure analysis, a Craig test for femoral anteversion, the Becure Balance System for balance measurement, and a myometer device for lower extremity muscle strength measurement. Participants will be randomly assigned to a structured exercise group, an exergame group, or a serious game group according to their order of arrival. The structured exercise group will use a short foot exercise, a towel-picking exercise, and various walking and balance exercises. Patients in the serious play group will play the lower extremity games in the Becure Balance System. Patients in the exergame group will play balance games on the Nintendo Wii game console. All participants will participate in 18 exercise sessions (3 days a week for 6 weeks). After the treatment, the initial measurements will be repeated.

Results: The study started in January 2023. It is expected to be completed in June 2024.

Conclusions: This study will be the first randomized controlled study to evaluate the effectiveness of 2 different video-based game exercise therapy applications in pes planus rehabilitation. Through this study, the use of video-based game exercise therapy in pes planus rehabilitation, together with the developing technology, will be a guide. In addition, a new exercise protocol, including serious game exercises, will be added to the literature. In the future, it is expected that our study on the development of different game systems, especially for the ankle, will provide pioneering feedback.

Introduction

Pes planus, one of the most common foot deformities in all age groups, is defined as the condition where the medial longitudinal arch (MLA) chronically loses its height [1]. The most significant problem with pes planus is excessive pronation during load-bearing activities. Increased pronation of the subtalar joint causes the tibia to remain in internal rotation (IR) longer than usual during walking. For this reason, valgus stress occurs in the knees and IR increases in the hips. Anterior tilt is seen in the pelvis, increasing lumbar lordosis [2-5]. Complaints of pain, fatigue, and weakness while walking and standing may also accompany the symptoms [6]. Previous studies show that pes planus affects the mobility of the MLA, increases stress on the foot, and causes impaired load distribution; it also causes posterior tibial tendon failure, patellofemoral pain syndrome, and compensatory hip internal rotation. These have been reported to negatively affect performance and balance [7-10].

Pes planus deformity can be seen together with pain, instability, and various functional limitations, or it can be mild. However, the biomechanical changes caused by the deformity may increase over the years and cause clinical symptoms and functional problems. Therefore, even if pes planus is asymptomatic in young adults, it should be treated considering the problems it may cause in the future. Treatment can be surgical or conservative, depending on symptoms and clinical assessment. Conservative treatment options include activity modifications, analgesic drugs, physiotherapy, and orthotics. The physiotherapy program includes intrinsic foot exercises, stretching, strengthening and balance exercises for the ankle and lower extremity muscles, and video-based game exercise (VBGE) programs. The literature on rehabilitation of pes planus includes studies on the effects of exercise practices on the MLA, foot biomechanics, and balance [11-18].

Pes planus is a pathology that requires long-term rehabilitation. Considering the secondary pathologies that the deformity may cause, rehabilitation protocols that have high participation from an early period are needed. This makes VBGE treatments, which are becoming increasingly widespread in rehabilitation with the development of technology, come to mind. The literature describes VBGE treatments as exergames, serious games, and rehabilitative games.

Exergames are the therapeutic application of commercially developed video games in an exercise form. Exergame applications use game systems such as the Wii (Nintendo Inc), Xbox Kinect (Microsoft Corp), and PlayStation Move (Sony Inc), which were produced for entertainment purposes and are frequently used in rehabilitation. [19,20]. It has been reported that lower extremity games for the Xbox applied for 12 sessions in patients with flexible pes planus improved balance and navicular drop [12]. Serious games are games developed for rehabilitation rather than entertainment purposes. These games are developed specifically for a certain disease group or disease symptoms. Thus, they aim to provide rehabilitation by increasing active participation in therapy with higher motivation. One of the systems developed for this purpose is the Becure system, formerly known as Fizyosoft. The Becure system has software that can integrate with the Wii Balance Board. Studies in the literature show that Becure games lead to positive results in different disease groups [21-25]. However, there has been no study conducted with serious games for pes planus.

Today, the rapid development of technology and patients' search for new treatments have made it necessary to add these technologies to the rehabilitation process. There are many studies in the literature on VBGE therapy in different patient groups. However, there is a lack of literature regarding VBGE therapy in individuals with flexible pes planus. There is only one study, which used the Xbox Kinect [12]. Thus, we aim to compare the effects of different exercise protocols on functional parameters in pes planus rehabilitation. Also, our study will contribute to the literature by being the first study to compare Wii-based exergame protocols and Wii-based serious game exercise protocols.

Methods

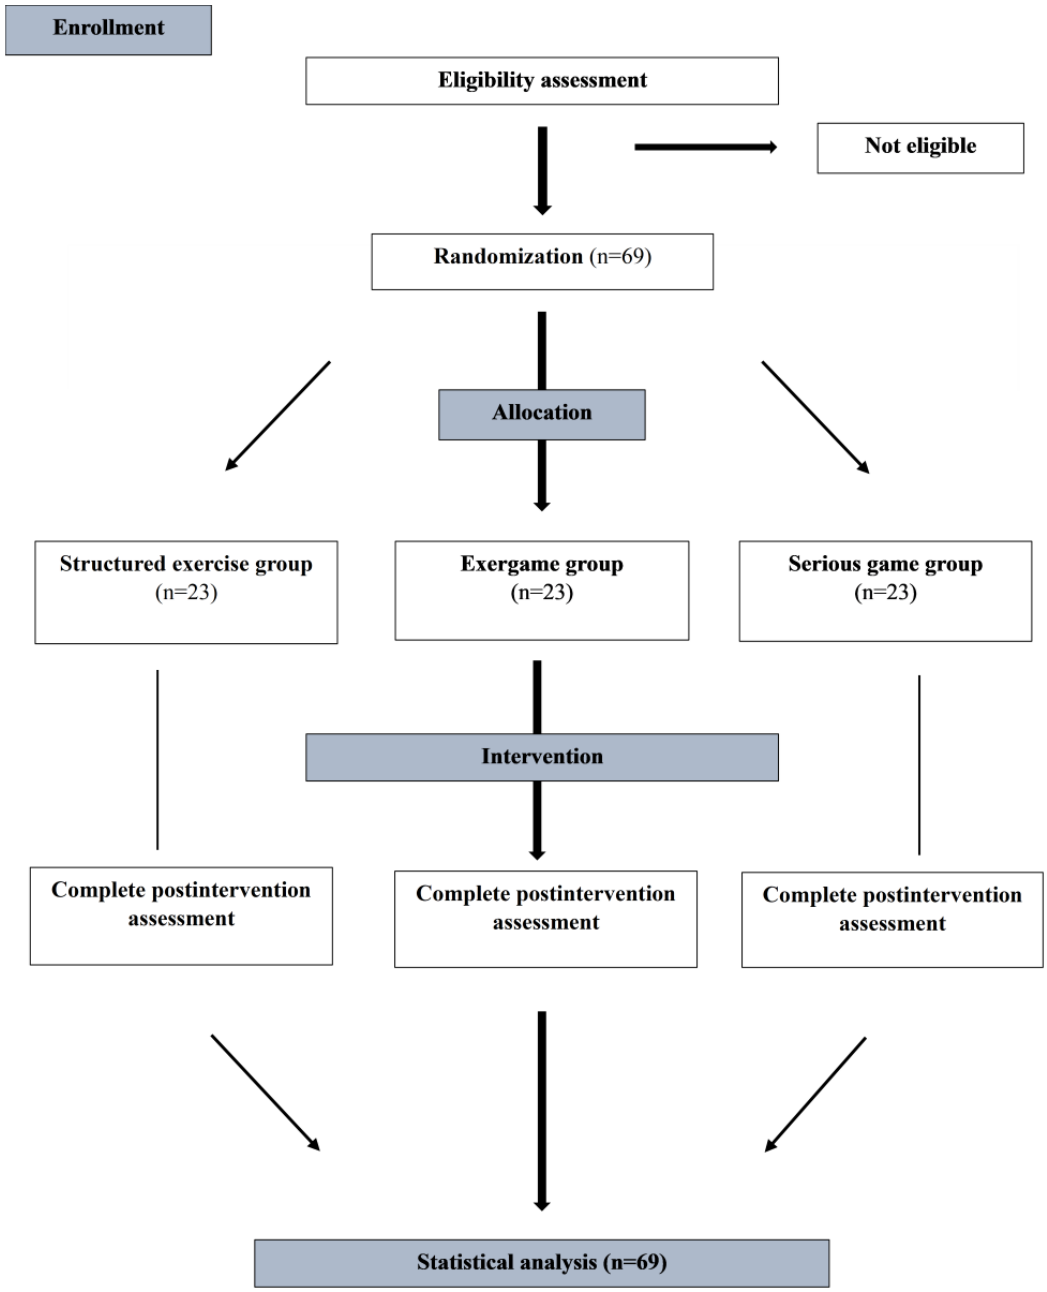
Participants

The number of cases to be included in the study was determined by G*Power (version 3.0.10; Universitat Düsseldorf). Navicular drop test results from the study by Yıldırım Şahan et al [12] were taken as a reference. For α=.05 (error), 1–β=95% (power), and f=0.49 (effect size), we determined that it would be necessary to include a total of 69 people, with 23 in each group.

Participants will be recruited among individuals aged 18 to 25 years who attend the Medipol Mega University Hospital Orthopedics and Traumatology Department. The study will include 69 individuals who volunteer to participate and meet the inclusion criteria. The inclusion criteria were a navicular drop of more than 10 mm, flexible pes planus, and no previous use of insoles or exercise therapy. At the same time, since excess weight can affect pes planus, only individuals with a BMI within the range of 18 to 24.9 kg/m^2 will be included. Individuals with orthopedic or neurological problem affecting the lower extremities and balance, a history of surgery or trauma in the last 6 months, diabetes, pregnancy, or visual or auditory problems will also be excluded from the study.

Ethical Considerations

The study was approved by the Istanbul Medipol University Non-Interventional Clinical Research Ethics Committee (E-10840098-772.02-7170; November 28, 2022). The Declaration of Helsinki will guide the study. After eligibility is confirmed, written and verbal information about the study will be provided to all participants. Then, participants will sign a written informed consent form stating that they agree to



XSL•FO
RenderX

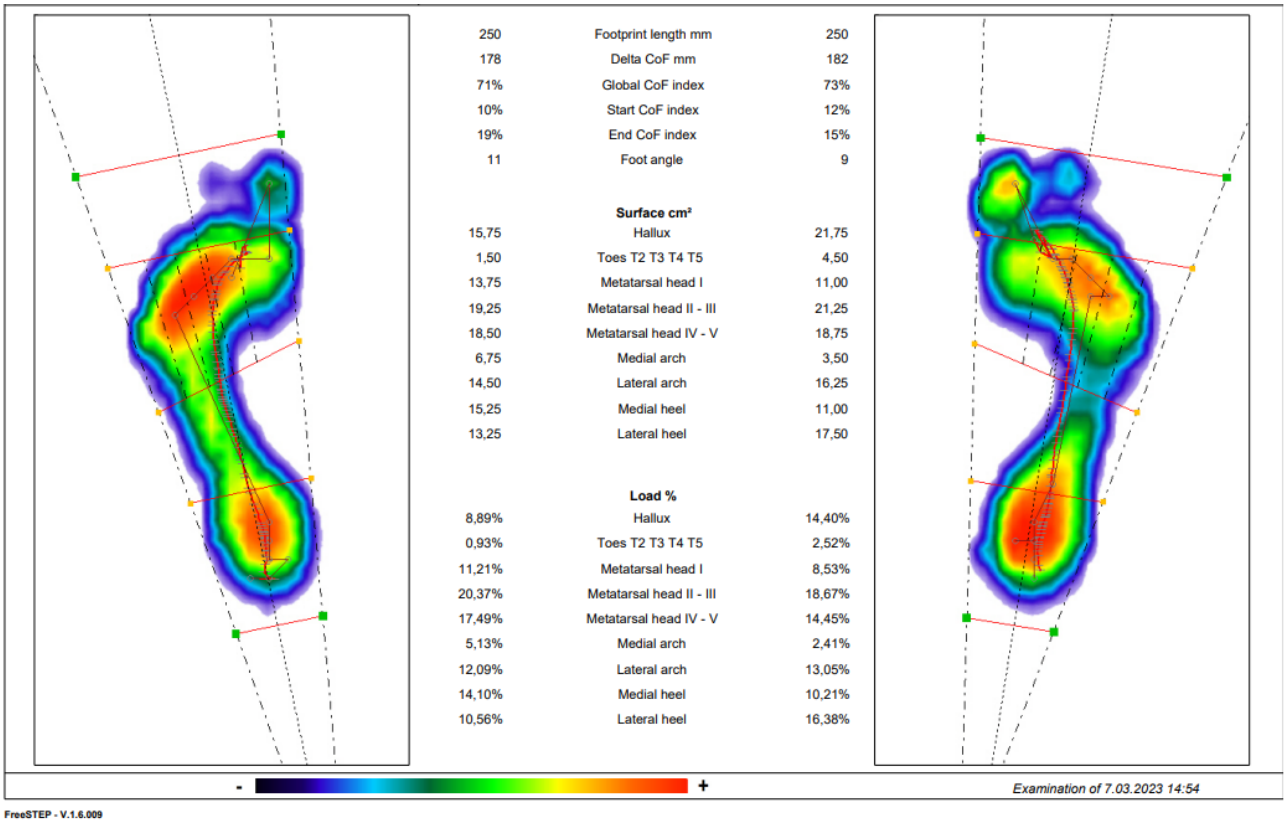
participate in the research. The informed consent form also states that participation in the study is free and voluntary. No additional fees will be charged to the participants, and no payment will be made. The personal data and identity information of the participants will be kept confidential. Participants have the right to withdraw from the study at any time. The data will be used purely to contribute to science without any profit motive. At the same time, the data can be statistically analyzed without secondary approval when necessary. The trial intervention is similar to other clinical practices, so we consider that risks from the trial are minimal.

Study Design

This study has been registered with ClinicalTrials.gov (NCT05679219). It is a 3-arm, parallel-group, single-blinded randomized controlled trial. The study will be carried out in Istanbul Medipol University Physiotherapy Laboratory. A permit has been obtained from the institution. The demographic characteristics of the participants (eg, age, height, weight, diseases) will be recorded. Participants will be divided into 3 groups using a simple randomization method according to the order of arrival (1:1:1) with a web-based randomizer [26]. Participants do not know which exercise group they will be included in, nor will they know the differences between the exercises. The participants and the therapist who made the assessments were blinded. The flow chart of the study is shown in Figure 1.

Figure 1. Study flow diagram.

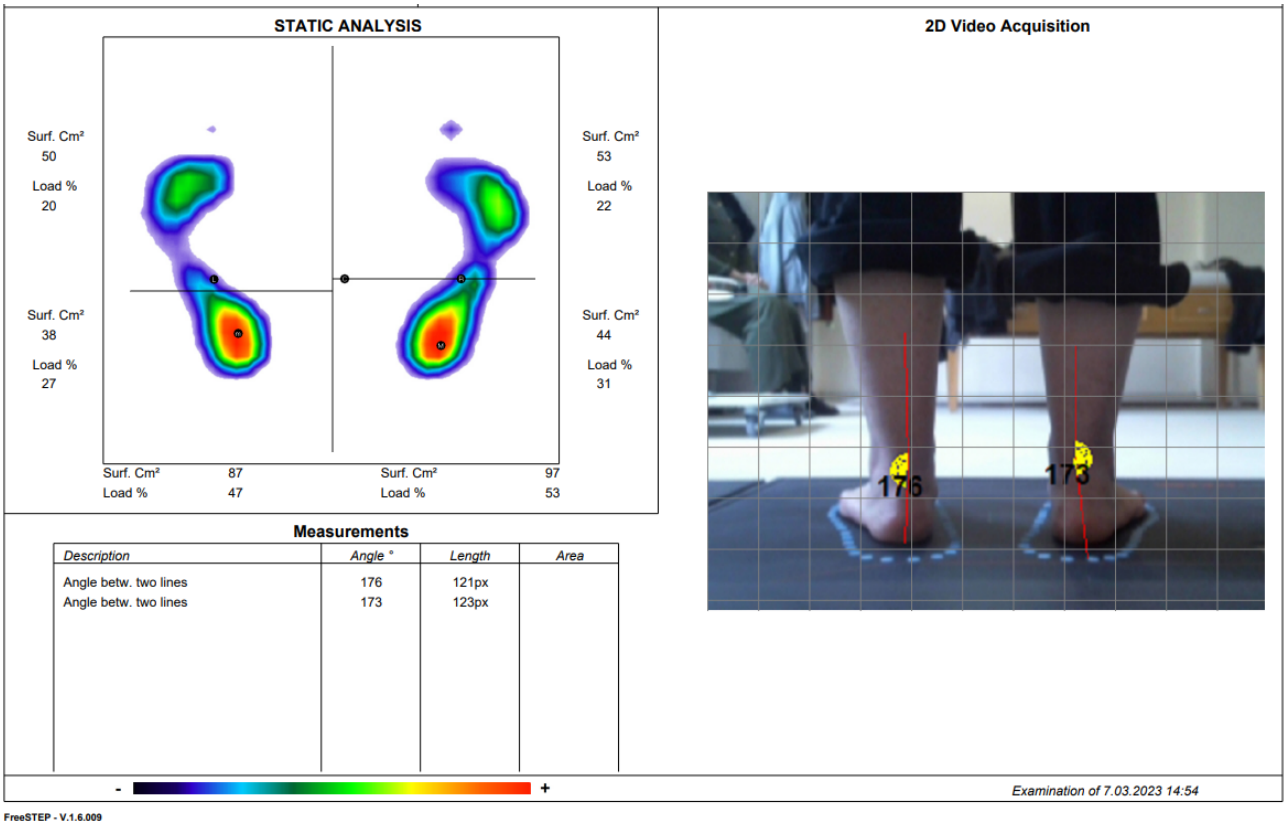
XSL•FO
RenderX



Outcome Measures

The primary outcome measures are navicular drop and the results of a pedobarographic analysis, and the secondary outcomes include balance, femoral anteversion, and lower extremity muscle strength. Participants will be evaluated before and after treatment. Measurements will be taken by an experienced therapist, who will not be the same therapist as the one who performs the exercises. The therapist performing the measurements will create the random allocation order, enroll the participants, and assign the participants to the interventions.

Pedobarographic Analysis



The pedobarographic analysis will be done in 2 steps, statically and dynamically, with the Sensor Medica Maxi brand device (Sensormedica). Static analysis data will be recorded while standing upright. Dynamic analysis data will be recorded while walking on the platform 6 times. Data such as ankle valgus angle, medial arch, lateral arch, medial heel, lateral heel surface area (cm²), and load (%) will be recorded. Plantar pressure analyses will be determined through FreeStep (version 1.6.009; Sensormedica), which is compatible with the device (Figures 2 and 3) [27].

Figure 2. Screenshot of pedobarographic analysis (dynamic analysis). CoF: center of foot.

XSL•FO
RenderX

Figure 3. Screenshot of pedobarographic analysis (static analysis). Betw: between; px: pixel; Surf: surface.

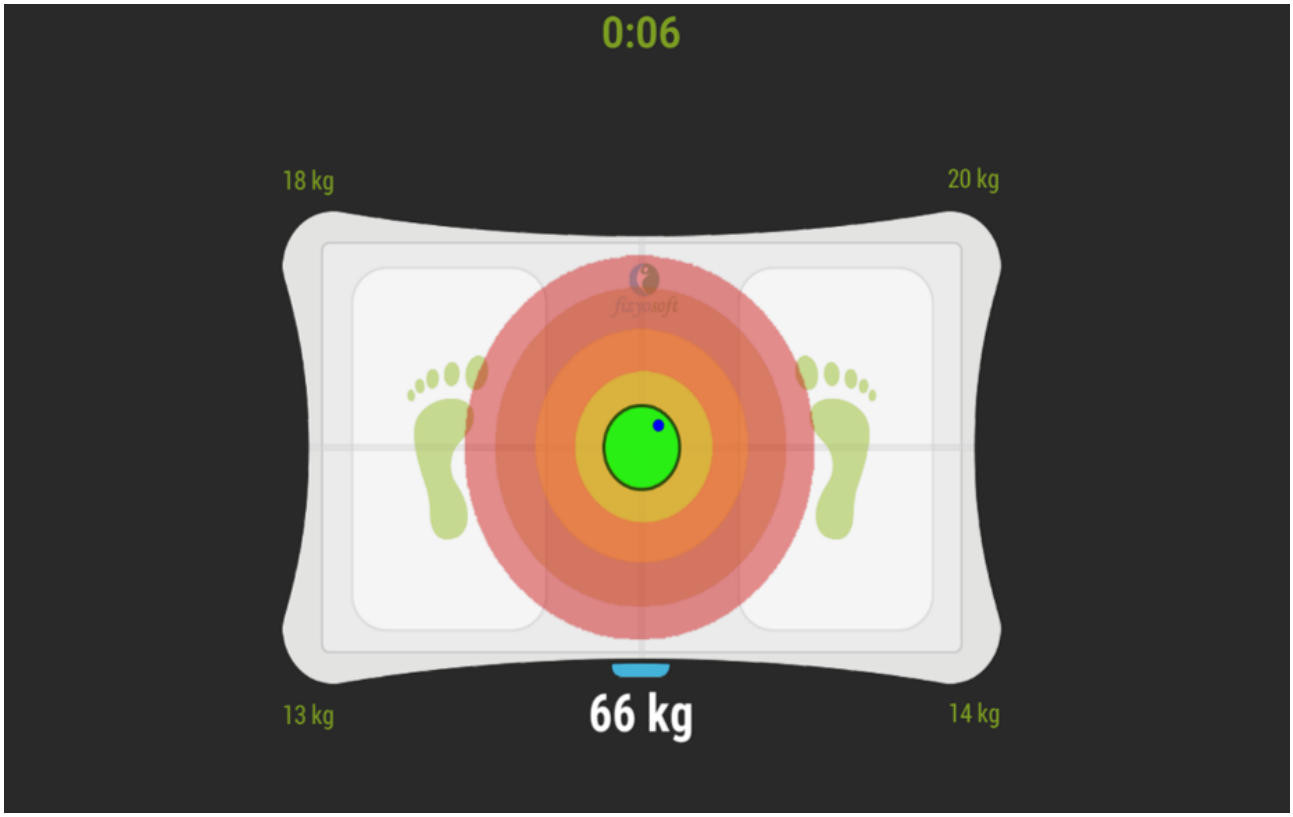
Navicular Drop

The navicular drop test will determine the severity of pes planus. A navicular drop greater than 10 mm is an inclusion criterion. To determine the result of the exercises, the measurements will be repeated and compared to determine whether they have decreased [28].

Femoral Anteversion

The femoral anteversion angle will be evaluated with the Craig test. The participant will lie prone with the knees flexed to 90 degrees. In this position, the participant will be asked to rotate their lower extremities internally. The resulting angle will be measured with a goniometer [29].

Flexibility



Flexibility will be evaluated with the Jack test [30]. The test is positive if MLA is formed by passive extension of the first toe. This test is one of the most important indicators that the pes planus deformity is flexible and that the foot shape can be altered with exercise.

Balance

Balance measurements will be evaluated with the Becure Balance System (Becureglobal). A validity and reliability study of the Balance Board balance device, which is integrated with Becure, was conducted by Tarakcı et al [24]. In this context, measurements of individuals with their eyes open or closed on both feet or a single foot will be taken (Figure 4). The system reports the oscillation in centimeters to stay balanced during the measurements [24]. A decrease in oscillation after treatment is interpreted as improvement.

XSL•FO
RenderX

Figure 4. Example of balance measurement.

Muscle Strength

Participants' muscle strength in the lower extremity dorsiflexor, plantar flexor, inverter, evertor, knee flexor, knee extensor, and hip flexor muscle groups will be measured with a Lafayette myometer device (Pelican 1150 Case; Pelican Products). Results will be recorded in newtons [31].

Intervention

Participants will be treated by a specialist physiotherapist 3 days a week for 6 weeks for a total of 18 sessions of 40 minutes each. The same therapist will follow the exercises of all 3 groups.

Structured Pes Planus Exercise Group

In this group, exercises will include a short foot exercise, towel curl, walking (toe, heel, tandem), eccentric gastro soleus stretching, object picking with toes, and balancing on 1 leg (Figure 5). The primary purpose of the exercises is to increase the MLA, especially by contracting the foot intrinsic muscles, and simultaneously to improve balance. Walking exercises will be performed for 10 meters over 10 rounds, while other exercises will be performed with 30 repetitions for both feet; the entire session will be 40 minutes. The first 2 sessions with the participants will be face-to-face with the therapist. Then, an email with photos and videos of the exercises will be sent. The remaining sessions will be performed online (mobile-based) and supervised by the therapist every 3 sessions.

XSL•FO
RenderX

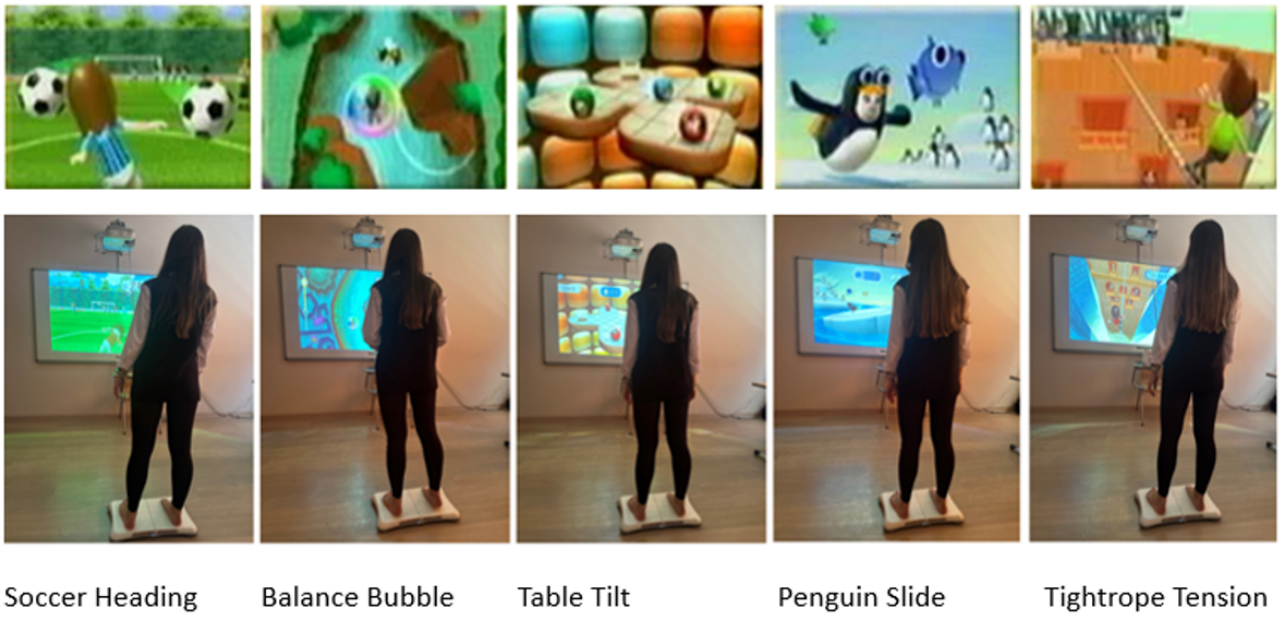


Figure 5. Structured pes planus exercises.

Wii-Based Exergame Group

Balance games for the Wii game console, which is frequently used for different disease groups in the literature, will be played by this group. In this context, 5 games will be played for a total of 40 minutes (8 minutes playtime each) under the supervision of a specialist physiotherapist (Figure 6). It will be noted that the person should not transfer weight to the medial part of the foot.

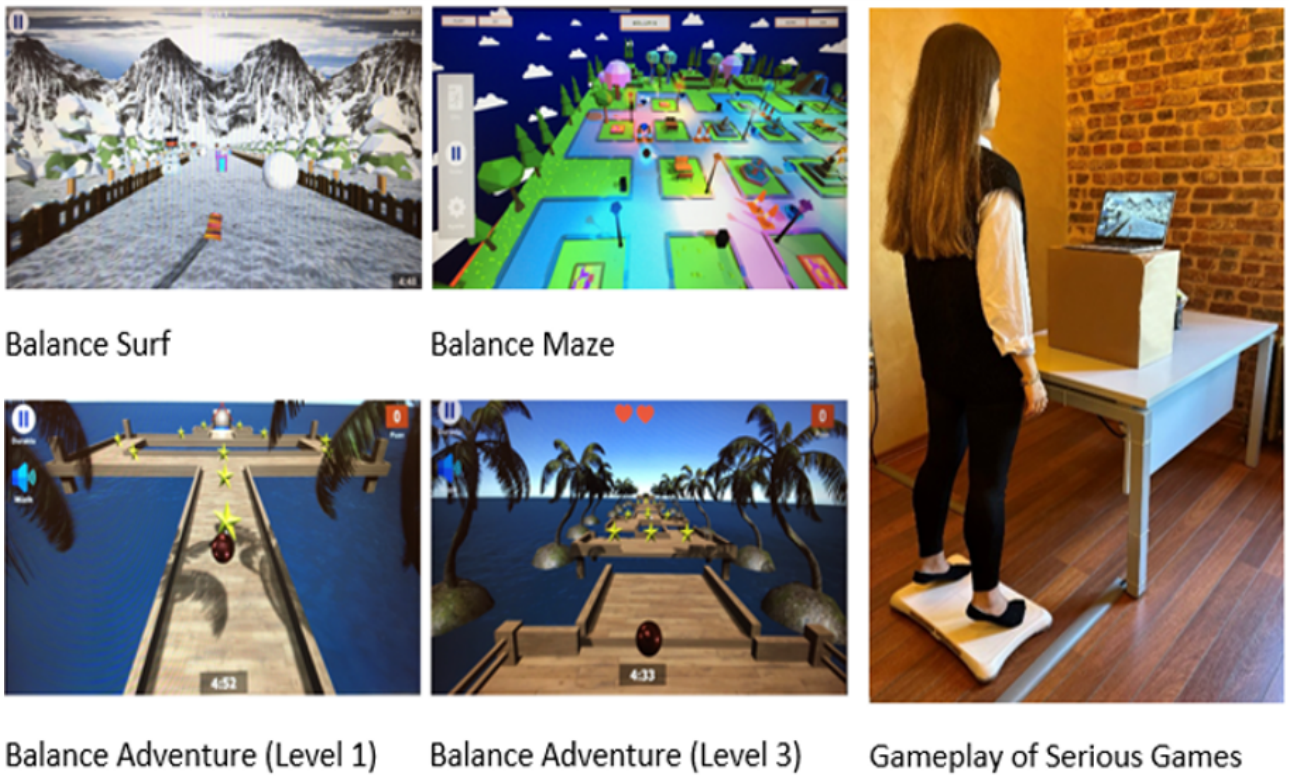
Figure 6. Wii-based exergame game screens and gameplay.

In the Soccer Heading game, weight transfer to the right and left is required to catch balls coming out of the goal. The more balls caught, the higher the score. It is necessary to avoid objects other than the ball in order not to lose points.

In the Balance Bubble game, it is necessary to transfer weight to the forward, right, and left in order to move forward without hitting the surface of a river. In order to advance quickly, it is necessary to put weight on the tips of the toes. This position is essential in increasing the MLA by causing the contraction of the foot's intrinsic muscles. The aim is to complete the stage as quickly as possible.

In the Table Tilt game, it is necessary to transfer weight in 4 directions to hit balls into gaps in a target. After all the balls pass through the gap, the level is passed. There are 9 levels in total. As the levels progress, the game becomes more complex, and the number of balls that need to be passed through the gaps increases. It is necessary to put weight on the tip of the toe during anterior weight transfer.

XSL•FO
RenderX



In the Penguin Slide game, the aim is to catch a fish without falling into the water over a glacier and collect points. The game includes transferring weight from right to left. The aim is to complete the game by catching all the fish as soon as possible.

In the Tightrope Tension game, weight transfer must be done rhythmically to the right and left to complete the game. The aim is to reach the goal by walking along the rope as quickly as possible.

Wii-Based Serious Game Group

This group will play the games in the Becure Balance System. Three games considered suitable for the participants will be played under the supervision of an expert physiotherapist for 40 minutes in each session (Figure 7). It will be noted if a participant should not transfer weight to the medial part of the foot.

Figure 7. Wii-based serious game screens and gameplay.

Balance Adventure is a game that involves transferring weight in 4 directions. There are 3 different levels, from easy to complex. At level 1, the aim is to reach the exit by collecting all the stars. In level 3, the aim is to collect the stars on a moving surface and advance the ball without dropping it. Each participant will play level 1 of the game for 5 minutes for warm-up and level 3 for 10 minutes; they will play for the highest target score and use the most-forward weight transfer mode. Selecting the forward weight transfer mode requires placing more weight on the front of the foot in order to advance the target. It is necessary to put weight on the tip of the toe. Thus, the foot's intrinsic muscles are more active.

The Balance Surf game is played with right to left and forward weight transfer. The aim of the game is to gain points by directing the surfboard on the screen, collecting stars and gift package objects. Speed parameters can be determined automatically and manually. Each participant will play the game for 15 minutes at level 8, the balanced weight transfer mode, with manual speed adjustment. In automatic mode, transferring weight toward the tips of the toes does not affect the progression speed. However, in manual-speed mode, the more weight the participant moves forward, the faster they move. Progress stops if the participant stands straight without moving weight to the front. This position requires the person to play the game by rising more on their toes. This is designed to make the foot's intrinsic muscles more active and increase the MLA.

Balance Maze is played with anterior to posterior and lateral balance movements. There are 5 levels. As the levels progress, the maze floor that is moved becomes larger, and the number of stars to collect increases. At the same time, the number of obstacles on the playing field increases. The game must be finished by collecting all the stars. Level 4 and level 5 will be played for 5 minutes each for all participants.

Statistics

Data will be statically analyzed using SPSS (version 25.0; IBM Corp). Normality tests (visual and analytical) will be applied. Descriptive statistics will be expressed as arithmetic means with SDs. After obtaining the results of the normality evaluation, analyses will be carried out with tests suitable for the distribution of the groups. Statistical analyses will be interpreted according to the significance level of $P<.05$.

Results

The study was approved by the ethics committee on November 28, 2022. The study was funded by Tübitak on April 19, 2023.

XSL•FO
RenderX

From this date, cases started to be included in the study. So far, the treatment has been completed for an average of 7 patients per group. Data will be analyzed when all subjects scheduled to participate have completed treatment. The study is expected to be completed in June 2024.

Discussion

This study evaluates the effectiveness of 2 VBGE applications (an exergame and a serious game) and structured exercise applications on functional parameters in pes planus rehabilitation. In this context, the effects of exercise protocols on functional parameters such as navicular drop, muscle strength, balance, and plantar pressure will be evaluated. All 3 exercise protocols are expected to yield positive results on functional parameters. It has been reported in the literature that exercises for lower extremity muscle groups provide improvement in functional parameters.

Lynn et al [8] compared the short foot exercise and towel curl exercise, which were repeated 100 times per day for 4 weeks; they determined that the short foot exercise led to greater improvement in dynamic balance. Kim and Kim [14] compared the effects of the short foot exercise and insoles applied 3 days a week for 5 weeks in individuals with flexible pes planus. They reported that short foot exercises led to greater improvement in navicular drop and dynamic balance.

Ravichandran et al [16] compared the effects of concentric and eccentric tibialis posterior strengthening exercises in individuals aged 18 to 25 years with flexible pes planus. Like our study, the participants used exercises such as resistant dorsiflexion, plantar flexion and inversion, towel curls, and toe-tip elevation. They determined that both concentric and eccentric exercises improved navicular drop equally. Goo et al [11] evaluated the relationship between navicular drop and muscle activation during walking with 2 exercise protocols assigned to individuals with pes planus. They assigned abductor hallucis strengthening exercises combined with gluteus maximus strengthening exercises to one group and abductor hallucis strengthening exercises to the other. They reported that gluteus maximus strengthening exercises were important in recovering navicular drop and providing a typical gait pattern. Engkananuwat et al [32] evaluated the effects of performing gluteus medius strengthening exercises in addition to foot exercises in individuals with flexible pes planus. For 4 weeks, one group performed the short foot exercise and the other group performed a hip-strengthening exercise in addition to the foot exercise. The authors found that hip exercises added to the foot exercise; they determined that it was more effective in reducing medial plantar pressure, static balance, and navicular drop data. The exercise protocols in our study are similar to the studies in the literature.

The biomechanics of the foot directly affect the whole body's posture and gait. Considering the studies in the literature, it is not sufficient to only strengthen the intrinsic foot muscles in pes planus rehabilitation. Strengthening the other lower extremity muscles is also very important. In parallel with the literature, we will assign strengthening exercises for all lower extremity muscles in all 3 groups in our study.

In recent years, VBGE therapy applications have been used frequently in orthopedic rehabilitation, in accord with patients' search for new treatments and the development of technology. There are studies showing that video-based exercise applications lead to positive results in different patient groups [19-25]. However, there are insufficient studies on these applications for pes planus rehabilitation. There is only one study in cases with pes planus. Yıldırım Şahan et al [12] divided 40 patients with flexible pes planus into 2 groups and compared the effects of Microsoft Xbox Kinect lower extremity games and short foot exercises performed 3 days a week for 4 weeks. They found a significant improvement in both groups' navicular drop and balance data after treatment. They reported that VBGE was an effective exercise method in patients with pes planus. However, the study's limitations were a limited number of participants, a short duration of treatment (12 sessions), and a lack of objective evaluation methods.

Compared to the study by Yıldırım Şahan et al [12], we used a relatively longer session duration (18 sessions), included a large number of cases, and used only objective evaluation methods, thereby increasing the importance of our study. However, it is known that games for the Nintendo Wii game console (exergames) and the Becure Balance system (serious games) are designed to improve the overall body balance. Therefore, it is unclear to what extent exercises for the intrinsic and extrinsic muscles of the feet are included in the content of both video-based games. They are likely to have similar potential effects. This situation can be considered as a limitation of our study. But at the same time, thanks to our study, the effectiveness of these games in the rehabilitation of pes planus will be determined, and the ground will be prepared for the development of specific games for the treatment of foot and ankle pathologies in the future.

Our study will contribute to the literature, as it is the first to compare Nintendo Wii games and Wii-based serious game protocols for pes planus rehabilitation. At the same time, it will determine whether video-based game exercise applications are superior to structured exercise applications. We aim to determine which exercises are superior with the most objective methods. The use of VBGE therapy for the rehabilitation of pes planus will be a guiding principle. Also, this study will introduce a new exercise protocol that includes serious game exercises to the literature. In the future, we expect that our study on the development of different game systems, especially for the ankle, will be a pioneer in providing feedback.

Acknowledgments

This study is entitled to be supported for 12 months with a project decision letter dated January 19, 2023 (222S879), within the scope of the Tübitak 1002-A Rapid Support Module.

Abstract

Background: Normal saline (NS) and Ringer's lactate (RL) are the most common crystalloids given to hospitalized patients. Despite concern about possible harm associated with NS (eg, hyperchloremic metabolic acidosis, impaired kidney function, and death), few large multicenter randomized trials focused on critically ill patients have compared these fluids. Uncertainty exists about the effects of these fluids on clinically important outcomes across all hospitalized patients.

Objective: The FLUID trial is a pragmatic, multicenter, 2×2 cluster crossover comparative effectiveness randomized trial that aims to evaluate the effectiveness of a hospital-wide policy that stocks either NS or RL as the main crystalloid fluid in 16 hospitals across Ontario, Canada.

Methods: All hospitalized adult and pediatric patients (anticipated sample size 144,000 patients) with an incident admission to the hospital over the course of each study period will be included. Either NS or RL will be preferentially stocked throughout the hospital for 12 weeks before crossing to the alternate fluid for the subsequent 12 weeks. The primary outcome is a composite of death and hospital readmission within 90 days of hospitalization. Secondary outcomes include death, hospital readmission, dialysis, reoperation, postoperative reintubation, length of hospital stay, emergency department visits, and discharge to a facility

XSL•FO
RenderX

other than home. All outcomes will be obtained from health administrative data, eliminating the need for individual case reports. The primary analysis will use cluster-level summaries to estimate cluster-average treatment effects.

Results: The statistical analysis plan has been prepared "a priori" in advance of receipt of the trial data set from ICES and any analyses.

Conclusions: We describe the protocol and statistical analysis plan for the evaluation of primary and secondary outcomes for the FLUID trial.

Introduction

Crystalloid resuscitation fluids, including normal saline (NS) and Ringer's lactate (RL), are among the most common interventions administered in hospitalized patients [1,2]. These fluids may be used as a life-saving measure to re-establish hemodynamic stability, replace fluid losses, and maintain intravascular volume.

In observational studies, NS has been associated with acute renal injury as compared to RL and other balanced crystalloid fluids, hypothesized to be due to higher chloride concentration and resultant metabolic acidosis that can occur with NS administration [3-5]. However, RL and other balanced crystalloid fluids with buffers have the potential to cause metabolic alkalosis [6,7] and theoretically, cause arrhythmias, tetany, coma, and seizures [8-10]. The lactate in RL may accumulate in the setting of liver failure and may influence clinical diagnoses and clinical decision-making [11-13]. Moreover, RL has a lower osmolarity in comparison to NS; when administered rapidly in large volumes, RL theoretically reduces plasma osmolarity and increases the risk of edema formation [14], which raises potential concern for patients with cerebral edema.

In total, 2 large single-center multiple crossover trials conducted in the intensive care unit (ICU) and the emergency department (ED) among patients who did not require admission to the ICU, found that balanced crystalloid fluids as compared to NS were associated with lower major adverse kidney events at 30 days, which is a composite outcome of mortality, new renal replacement therapy, or persistent renal dysfunction [2,15]. In contrast, 2 large multicenter randomized trials (Balanced Solution versus Saline in Intensive Care Study [BASICS]; Plasma-Lyte 148 versus Saline [PLUS]) [16,17] examined the efficacy of NS as compared to a balanced crystalloid (RL and Plasma-Lyte 148 respectively) on the primary outcome 90-day mortality. Neither of these trials detected differences in 90-day mortality. In BASICS, the mortality rate was 22% versus 21.8%; and in PLUS, mortality was 27.2% versus 26.4% in patients receiving NS and RL, respectively. Renal function did not differ between the fluid groups in either trial, although the PLUS trial was stopped early due to recruitment challenges and insufficient funding during the pandemic. In a systematic review of 35,884 participants in 13 critical care trials published before January 2022, there were no detectable differences in renal function. In low-risk-of-bias trials, there was no significant difference in mortality for the NS as compared to the balanced crystalloid group (28.2% and 27.9% respectively; Relative Risk 0.96, 95% CI 0.91-1.01), nor renal function [15-28]. However, the authors concluded that there is a high probability that balanced crystalloids reduce death since the CIs ranged from a 9% relative reduction to a 1% relative increase in death.

Crystalloid fluids are administered to the majority of patients admitted to the hospital and continued throughout their hospital stay. To address ongoing uncertainty on this topic, and address this evidence gap about fluid administered outside the ED and ICU, we designed a cluster randomized crossover trial. Our objective was to compare a hospital-wide strategy to preferentially stock NS or RL as the main crystalloid resuscitation fluid, aiming to have all admitted patients receive the allocated crystalloid from the time they enter hospital to hospital discharge, evaluating the primary composite outcome of death or readmission to hospital in the first 90 days. The design of the FLUID trial is novel because it involves a pragmatic cluster randomized crossover design, a waiver of patient informed consent to include all hospitalized patients, hospital-based randomization, and the use of routinely collected electronic health administrative data for the description of baseline characteristics and all study outcomes. FLUID will generate data at low risk of bias, providing key evidence about the consequences of crystalloid fluid on clinically important outcomes, and informing patient care and health care policy. It will also provide insight into a novel approach to the conduct of large pragmatic clinical trials.

This manuscript describes the protocol and statistical analysis plan for the evaluation of primary and secondary outcomes for the FLUID trial.

Methods

Overview

The protocol and feasibility results for the FLUID pilot trial have been published [29,30]. The 4 pilot sites will be included in the analysis of the large trial as only feasibility outcomes have been previously reported and no major protocol changes were necessary following the pilot trial. The structure of this protocol and statistical analysis plan (version 1.0; March 29,

XSL•FO
RenderX

2023) follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) Guidelines [31] (see Multimedia Appendix 1 and Table 1) and Guidelines for the Content of Statistical Analysis Plans in Clinical Trials (see Multimedia Appendix 2) [32]. The reporting of the trial results will follow the CONSORT (Consolidated Standards of Reporting Trials) Statement's extension for Cluster Trials [33] and Randomized Crossover Trials [34], as applicable.

Trial Design

The study is a pragmatic, multicenter, 2×2 cluster crossover comparative effectiveness randomized trial. A completed PRECIS-2 table and wheel have been attached as Table S1 and Figure S1 in Multimedia Appendix 3. We defined clusters as hospital sites, allocated to one of two sequences in a 1:1 ratio. The interventions are a hospital-wide strategy of stocking predominantly NS (control) or RL (treatment) throughout the hospital. FLUID is an open-label trial as the cost of blinding the fluids is infeasible and prohibitively costly; this design is in keeping with a real-world evaluation of NS and RL whereby research is integrated into clinical care.

FLUID has two 15-week study periods. For each study period, week 1 will serve as a run-in, weeks 2-13 (12 weeks) as the study period during which all patients with index admissions to the study hospital will be included for analysis. Weeks 14 and 15 are the run-out period during which time the study fluid remains stocked in the hospital for use by patients admitted during weeks 2-13; however, new patients admitted during weeks 14 and 15 will not contribute to the analysis. After the 2-week run-out period, sites will have 1 week to switch out the study fluid and cross over to the period 2 study fluid. See Figure 1.

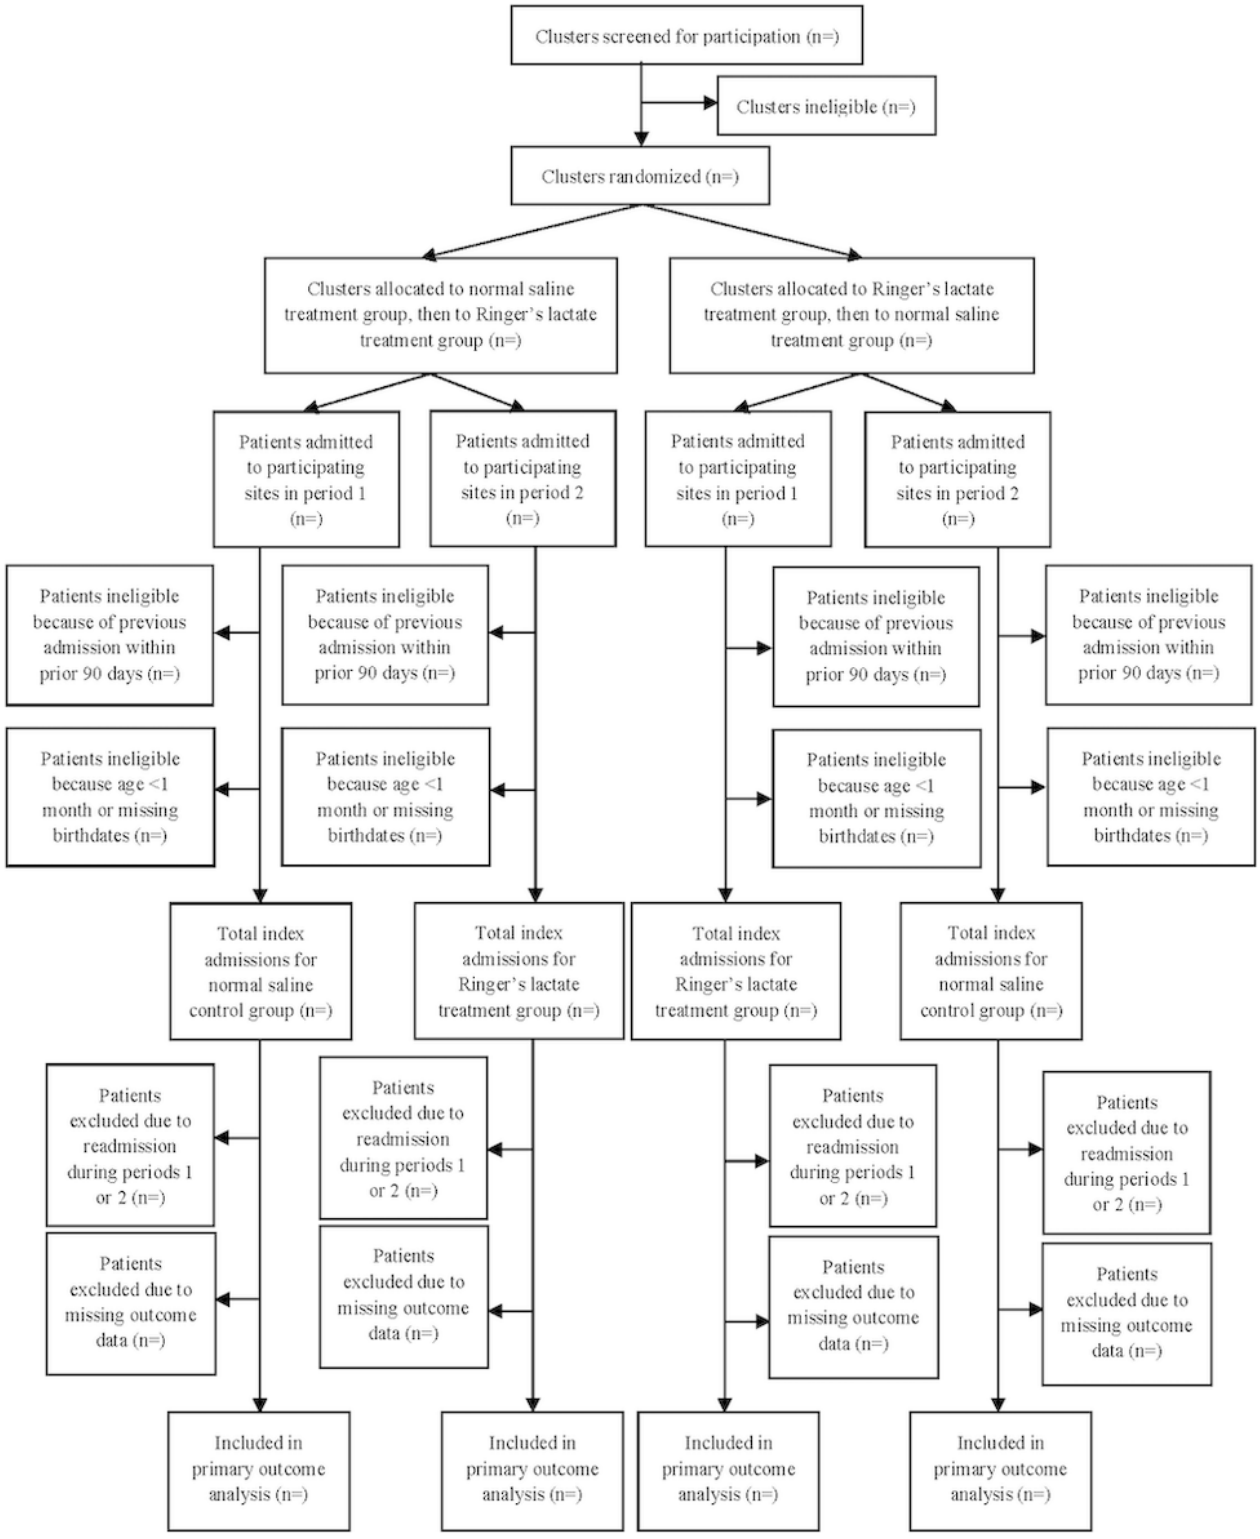
RenderX

Figure 1. FLUID trial study design.

Trial Population

Cluster Screening and Eligibility



Inclusion criteria for participating clusters include (1) level II or III ICU capacity [35] and (2) the admission of at least 6000 patients per year to hospital. A list of included study sites will be included in the main trial report.

Patient Screening and Eligibility

All admitted patients to participating study sites for the first time (index hospital admission) over the duration of the study period will be included under a waiver of informed consent obtained from the research ethics committee; only neonatal patients (age <1 month) will be excluded as RL is not recommended for use in this population [36]. Patients readmitted to the hospital during study periods 1 or 2 and patients admitted during the run-in or run-out study periods will also be excluded. An index admission is defined as a patient admission with no prior hospital admission in the previous 90 days. CONSORT flow diagram of participant recruitment is presented in Figure 2.

XSL•FO
RenderX

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram for participants.

Randomization

The order of treatment allocation for each hospital site (cluster) will be randomly assigned using computer-generated random numbers, using a permuted block design of length 2, at the coordinating center. The allocation sequence will be prepared by a statistician not familiar with the participating sites, which will be randomized in a 1:1 ratio. Half of the sites will be allocated to sequence 1 and begin the trial with NS as the control, while the other half will be allocated to sequence 2 and begin the trial with RL as the treatment. Each site will cross over to the other fluid after the 12-week study period. To control for period effects, while balancing logistical considerations, randomization will proceed in batches of 4 sites. The allocation sequence will be maintained on a password-protected computer and concealed from investigators until the next batch of sites have been enrolled and are ready to receive their allocation.

XSL•FO
RenderX

Approach to Safety

No serious adverse events were reported to the coordinating center during the 4-center pilot trial. A Data and Safety Monitoring Committee conducted a review of the data from the 4-center pilot trial, reporting no reason to suspect harm resulting from either fluid. For the main trial, participating hospitals monitor serious adverse events via routinely scheduled meetings of safety committees or morbidity and mortality rounds. Site Principal Investigators report to the coordinating center any serious adverse event occurrence related to study fluid administration.

Sample Size

A total of 16 hospital sites (including the 4 pilot sites) will yield data on approximately 144,000 hospital admissions. It required 12 sites in a 2-period cluster crossover trial over 6 months to achieve 80% power with a 2-sided α of 0.05 to detect a minimum clinically important absolute difference of 1% in the primary outcome in favor of RL, assuming a proportion of 0.16 in the NS condition, a within-period intracluster correlation coefficient of 0.006, a cluster autocorrelation coefficient of 0.95, and an average of 1500 patients per hospital per month [37]. These estimates were calculated from available routinely collected data for January 1 to December 31, 2013, for all eligible hospitals across the province of Ontario, Canada. Our calculations account for nonadherence based on pilot data (94% adherence NS, 80% RL). We added 2 clusters as an approximate small sample correction [38] and a further 2 to account for cluster size variation [38], for a final sample size of 16 sites.

Interim Analysis and Stopping Guidance

As a risk to participants in FLUID is minimal, and given the delayed availability of data from the Ontario provincial health administrative databases needed for outcome assessment, no interim analyses are planned in the FLUID trial.

Adherence and Protocol Deviations

Protocol adherence will not be measured at the individual patient level. Adherence will be measured according to the aggregate use of the study fluid throughout the hospitals using the hospital inventory system. Adherence will be monitored at 2-week intervals over the study period and reported according to each study group across all participating hospitals, combined and according to major fluid user groups in specific settings (ED, surgery, medicine, operating room, ICU, postoperative assessment unit, and obstetrics). Overall adherence will be defined as the total use of the allocated study fluid divided by the total combined use of NS and RL.

Participant Withdrawal

We will not be collecting individual patient-level data, as all data will be collected through the ICES provincial database. As informed consent is not being sought, only clinically available data are being analyzed, and no unique research data are being collected, participants cannot withdraw from the study.

Participant Follow-Up

We anticipate near 100% follow-up since all clinical data and outcome measures from participating sites in Ontario will be available at ICES, except for a very small number of patients who leave the province of Ontario within 90 days after enrollment.

Data Sources

Data will be obtained and housed using Ontario's population-based health administrative databases at ICES. ICES is an independent, nonprofit research institute whose legal status under Ontario's health information privacy laws allows the collection and analysis of health care and demographic data. The data sets identified in Table 2 were linked using unique identifiers and analyzed at ICES.

Timing of Final Analysis

All follow-up and data collection for patients at the participating sites will be captured by ICES. The approach to analysis will be supervised by the study statistician and principal investigator; however, the final analysis will be conducted by an independent statistician not involved as a coinvestigator in the FLUID trial.

Statistical Principles

Analytical Framework

All study outcomes will be tested for superiority.

CIs and P Values

All statistical tests will be 2-sided and performed using a 5% significance level. We will report all CIs as 95% and 2-sided. Results will be expressed as absolute differences produced by analyses described below.

Analysis Populations

Our primary analysis will use the intention-to-treat approach and will include all enrolled patients in the treatment groups to which their cluster was randomized at the time of the index hospitalization. Because true fluid exposure status is not recorded in administrative databases, all admitted patients will be included in the analysis, regardless of actual fluid administration.

Outcome Definitions

Primary Outcome

The primary outcome is a composite of death or readmission to the hospital within 90 days of the index hospitalization. All-cause death will be obtained at a patient level using the Registered Persons Database, while hospital readmission will be measured from Discharge Abstract Database (DAD). Cluster randomized trials can address 2 types of estimands: the participant-average or the cluster-average treatment effect [39]. The former estimates the effect of an intervention for an average participant, whereas the latter estimates the effect for an average cluster. In the FLUID trial, intervention exposure will be unknown at the individual patient-level and the primary study objective is to inform a decision by the health system stakeholder; thus, the primary estimand in the FLUID trial is the cluster-average treatment effect. It is known that cluster-average and participant-average treatment effects will differ when cluster sizes are informative, meaning that either the outcomes or treatment effects vary with cluster size. In the FLUID trial, it is possible that treatment effects will vary between larger or smaller hospitals, and thus, informative cluster sizes cannot be ruled out. The statistical analysis plan was therefore formulated to yield an unbiased estimate for the cluster-average treatment effect in the presence of informative cluster sizes.

XSL•FO
RenderX

Secondary Outcomes

The secondary outcomes are 90-day death, hospital readmission within 90 days of the index hospitalization, and requirement for new dialysis within 90 days; and for surgical patients, requirement for reoperation, postoperative reintubation in the postoperative assessment unit, ED visits within 90 days, hospital length of stay, and discharge to facility other than home. All secondary outcomes will be obtained at the patient level from DAD and National Ambulatory Care Reporting System.

Tertiary Outcomes

The tertiary outcomes relate to the health economic analyses and include the incremental cost per one death averted and incremental cost per one quality-adjusted life year (QALY) gained.

Analysis Methods

Descriptive Analyses

Baseline data will be collected and summarized as means and SDs for continuous variables or counts and percentages for categorical variables as shown in Table 3. We will summarize outcome data as cluster-period frequencies and proportions for dichotomous primary and secondary outcomes and medians with IQRs for the length of stay. Outcome data will be reported by the treatment group.

Primary Analyses of the Primary and Secondary Outcomes

All analyses will be conducted according to recommendations for cluster randomized crossover trials, accounting for clustering to ensure correct type I error rates and CIs [38,40]. In the case of a small number of clusters, mixed-effects regression and generalized estimating equation approaches are known to not perform well; analysis for FLUID will, therefore, be performed using cluster-level summaries. This method is known to perform well even with a very small number of clusters. Equal weight will be given to each cluster to obtain unbiased estimates for the cluster-average treatment effect. To implement the cluster-level method, binary outcomes will be expressed as proportions in each cluster-period and the differences (proportion under RL minus proportion under NS will be calculated for each cluster. These differences will then be analyzed using an unweighted linear regression model as described by Turner et al [41]. The t-distribution with degrees of freedom equal to the number of clusters minus 2 will be used. The intervention effect will be expressed as an absolute difference with 95% CI. To improve precision, the primary analysis will account for the following patient risk factors as fixed effect covariates: age, sex, comorbidity index, type of hospital admission (medicine, surgery, pregnancy and childbirth, and mental health), and admissions to ICU, using the 2-stage method recommended by Hayes and Moulton [42]. Patient age will be modeled using a restricted cubic spline to allow for the possibility of a nonlinear association. Mean imputation within

XSL•FO
RenderX

hospitals will be used for missing baseline covariates. The same approach and covariates will be used for primary and secondary outcomes. The 2-stage method will be implemented as follows: (1) a multivariable regression model (logistic regression for binary outcomes and linear regression for length of stay) with the baseline characteristics as covariates but excluding the treatment and cluster indicators will be fit to the individual patient data in period 1 and period 2. Length of stay will be log-transformed prior to analysis. We will use each regression model to obtain predicted probabilities for each binary outcome and predicted length of stay for each patient. (2) For binary outcomes, we will calculate the expected number of events by summing the predicted probabilities across all patients in that cluster period; for length of stay, we will obtain the expected mean length of stay by averaging across all patients in that cluster period. (3) We will obtain residuals for binary outcomes by calculating the observed number of events minus the expected number of events divided by the number of patients in the cluster, and for length of stay by calculating the observed mean minus the expected mean. To estimate the treatment effect, the cluster-level method described above will then be applied to the residuals. Estimated intracluster correlation coefficients will also be reported [33]. The data presentation is indicated in Table 4.

Table 4. Study outcomes.

	Normal saline (control; n=XXX)	Ringer's lactate (treatment; n=XXX)	Absolute difference (95% CI)	*P* value
Primary outcome, n (%)

ED[a] visit within 90 days within 90 days of index admission				
Hospital length of stay, median (IQR)				
Discharge to a facility other than home				

[a]ED: emergency department.

Subgroup Analyses

The primary outcome will be analyzed within the following subgroups of patients who are at a higher risk for exposure to fluids and with greater risk profiles and or severity of illness than other patients. These include age (<18, 18 to ≤65, 66 to ≤80, and >80 years); sex; type of hospital admission (medical, surgical, pregnancy and childbirth, mental health); elective and urgent or emergent surgical admissions, surgical admissions <24 hours, surgical subgroups (as described in Table 3); admission to ICU, infection alone and infection and organ dysfunction, infection alone and infection and organ dysfunction and ICU admission, trauma with injury severity score (ISS) ≥12, trauma with ISS=12 and ICU admission, traumatic brain injury, traumatic brain injury and ICU admission, and comorbidity index (Elixhauser) [43]. These subgroup analyses will be implemented without covariate adjustment and using the cluster-level summary method as described for the primary and secondary outcomes but applied to subgroup differences within each cluster. Results will be presented using forest plots.

Sensitivity Analyses

Testing for carryover effects will not be carried out as the risks of carryover were minimized in the design by allowing for a wash-out period to allow most patients admitted in the first period to complete their hospitalization before the hospital crosses over and by only considering index hospitalizations.

Sensitivity analyses for primary and secondary outcomes will exclude patients who are extremely unlikely to receive the study fluids (direct hospital admissions to psychiatry), those who are otherwise healthy (patients who have vaginal and cesarean births and elective surgical admissions <24 hours), and those who may have been exposed to both types of study fluids (lengths of stay spanning both FLUID study periods).

Cost-Effectiveness Analyses

We will conduct a cost-effectiveness analysis of RL and NS from the perspective of the Canadian public health care payer using a hybrid decision tree and Markov models. A decision tree with a 90-day time horizon will be used to determine the effects of each fluid on mortality, requirement for dialysis, and health system costs. Baseline characteristics will be based on

XSL•FO
RenderX

the concurrent trial. Surviving patients will enter a Markov component of the model [44] in which outcomes and costs will be modeled in annual cycles for the remainder of the patient's lifespan. Based on close consultations with coinvestigators, the model structure will incorporate the long-term consequences of fluid therapy; potential health stats may include dialysis-free, dialysis, and death. In each Markov cycle patients could remain in their existing health state, progress to the more severe state, or die. Transition probabilities between health states will be obtained from the concurrent trial and utility values will be derived from the published literature. Direct health care costs, such as physician costs and dialysis costs, will be derived from provincial health administrative data available at ICES and from publicly available sources in Canada.

The model outcomes will include incremental cost per one death averted and incremental cost per one QALY gained. An annual discount rate of 1.5% will be applied to both costs and health outcomes, as recommended by Canada's economic evaluation guideline [45]. Scenario analyses will be conducted to assess the impact of structural uncertainty and the uncertainty associated with model assumptions on cost-effectiveness results. The model will be fully probabilistic and address parameter uncertainty.

Missing Data

The prevalence of missing data is expected to be minimal as outcomes will be obtained from ICES. Nevertheless, missing data for each outcome will be summarized by the treatment group. If substantial missingness is observed (>10%), sensitivity to missing data will be examined under a range of missing-not-at-random scenarios by assuming first that all patients with missing outcomes had the event of interest and then that all patients with missing outcomes did not have the event of interest.

Statistical Software

The statistical analyses will be performed with SAS (version 9.4; SAS Institute) and R (R Foundation for Statistical Computing).

Dissemination of Findings

Guided by a theory and evidence-informed dissemination planning guide [46], the plan will be guided by the dissemination objective, knowledge of user audiences, dissemination strategies targeted to the audience, and the expertise required to deliver the strategies and required resources. Knowledge user audiences will certainly include health policy leads, health system managers, clinicians, patients and caregivers, and researchers. Depending on the magnitude, strength, and nature of the findings, the dissemination goals could range from increasing awareness of the findings by interested parties to influencing hospital policy and physician prescribing practices at the provincial, national, and international levels. To reach researchers and clinicians, we plan rapid open access publication of our study results in a high-impact journal. We will hold webinars to present and discuss our study results with hospital administrators and clinicians in Ontario. We will reach out to local and provincial social media and traditional media to inform the public, patients, and caregivers about our study findings. If RL is found to be superior to NS, then we will have a particular dissemination focus on health policy and decision-makers to encourage the switch to use these fluids in Ontario hospitals. Finally, we will communicate and present our study findings to the Council of Academic Hospitals of Ontario and plan to host meetings targeted toward health policy decision-makers and high-level hospital administrators (chief executive officers) around the province of Ontario.

Ethical Considerations

The FLUID Trial was approved at all participating sites through Clinical Trials Ontario (#0778) and the Queensway Carleton Hospital Research Ethics Board (#16-05). Waivers of patient consent were obtained to receive the study intervention and for data collection from ICES, as the risks of study participation are minimal, and requiring informed consent would render the study infeasible.

Results

At the time of this submission, a total of 7 centers have completed recruitment into FLUID. The statistical analysis plan has been prepared "a priori" in advance of receipt of the trial data set from ICES and any analyses.

Discussion

The results of this trial will determine whether a hospital-wide policy of stocking predominantly NS versus RL reduces the composite of death and readmission to hospital, as well as other adverse secondary outcomes. We provide a detailed statistical analysis plan which will reduce the risk of data-driven approaches and biased interpretation and increase the transparency of our analyses and results.

There are several challenges related to the design and conduct of the large FLUID trial. These include a risk of study fluid contamination due to a lack of awareness of FLUID, noncompliance to the study protocol, and carryover due to the crossover design. Hence, our team first conducted the FLUID pilot trial in advance of the large trial with the aim of evaluating strategies to address these challenges [29]. In the pilot study, we developed extensive center-specific communication plans for multiple stakeholder groups (eg, chief executive officers, hospital administrators, clinical managers, physicians, nurses, trainees, and logistical services) for implementation in the large trial. To maximize compliance with the study fluid, we implemented (1) an automatic substitution order during the trial study periods for both paper and electronic orders with an override if the treating physician indicates "no substitution" in the physicians' orders, (2) the hospital ward shelves were stocked with at least 80% study fluid for the duration of the study periods, (3) bright signage prominently placed where NS and RL are stored to help remind nurses about the automatic substitution, and (4) to have the other resuscitation crystalloid fluid available only in small quantities on the clinical shelves. The risk of carryover (effect of study fluid on patients included in study period 1 carrying over to study period 2) is minimized as the vast majority of patients will be different in each study period. The median length of hospital stay is 2 days (10th and

XSL•FO
RenderX

90th percentile 1 and 5.2 days; data derived from FLUID-eligible sites using ICES data); the majority of administered crystalloid resuscitation fluids occur during the first few days of hospital admission; and only index admissions will be included. Furthermore, a 2-week run-out between study period 1 and the end of study period 2 will minimize the occurrence of patients being exposed to 2 different kinds of fluids during the same hospitalization.

Conclusions

We describe the protocol and statistical analysis plan for the evaluation of primary and secondary outcomes for the FLUID trial. FLUID will determine whether RL as compared with NS reduces death or requirement for hospital readmission by an absolute difference of 1%. In contrast to trials that have generated evidence in specific populations with fluid interventions limited to geographic locations in the hospital (ICU, ED), the results of FLUID will apply broadly to patients who are admitted throughout the hospital. As such, FLUID will provide important evidence-based guidance at the hospital and system level as to what fluids could be predominantly stocked for use throughout the hospital and the associated health care resources required for such supply.

The results of FLUID will help define clinical practice for physicians who care for patients admitted to the hospital regardless of whether differences between the 2 fluid groups in the proposed clinical outcomes are found. The question of the selection of optimal crystalloid fluid is, as evidenced by contemporaneous studies on this theme, an international one, and the results of FLUID will impact hospital management practices around the world. Should FLUID reveal a difference in clinical outcomes for patients, reflected in lives saved and hospital admissions avoided, then one fluid will become the dominant fluid stocked in centers; it may also result in significant savings to the health care system through bulk purchasing of one type of fluid. If no differences are found, then the less expensive crystalloid fluid may become the dominant fluid stocked in centers.

Data Availability

The data sets generated or analyzed during this study will not be publicly available as this trial used exclusively health administrative data provided by ICES in the province of Ontario, Canada. The data sets generated and analyzed during the study are not publicly available to protect study participant privacy.

Authors' Contributions

JFS drafted the manuscript for this paper in close collaboration with LAM, MT, TM, and YO. All authors made substantial contributions to the development of the manuscript and approved the final version of the manuscript. LAM, MT, and DAF are the principal coinvestigators. MT is the senior statistician. YO is the trial statistician.

Abstract

Background: COVID-19 is a recent major public health concern caused by the SARS-CoV-2 virus, with approximately 44.6 million COVID-19–positive cases and 530,000 deaths in India (as of February 1, 2023). The COVID-19 vaccination drive in India was initiated in January 2021; however, an effective preventive strategy with high efficacy and immunological safety remains elusive.

Objective: The aim of this study is to assess the immunogenic responses of *Arsenicum album* 30CH (AA30CH) as COVID-19 prophylaxis, including assessment of immunological markers, innate and acquired immune responses, COVID-19 symptoms, and its associated antibody responses.

Methods: This randomized controlled clinical trial (RCT) will include two parallel comparator groups of AA30CH and placebo with an allocation ratio of 1:1 conducted in the Pathanamthitta district of Kerala, India. The placebo or AA30CH will be administered in three intervention schedules and blood samples will be collected before and after each of the intervention schedules. Based on the inclusion and exclusion criteria, 112 participants per arm (with an expected dropout of 20%) will be screened. Immunogenic responses will be evaluated by determining the antigen density and modulation in immunological markers and lymphocyte subsets CD3, CD4, CD8, CD24, CD27, CD38, CD4 interferon-γ, CD4 CD17, CD4 CD25 (activated T lymphocytes), T cells, B cells, dendritic cells (mature and immature), and natural killer cells on days 1, 5, 23,27, 45, 49, and 66. The innate and acquired immune responses will also be evaluated by a real-time reverse-transcriptase polymerase chain reaction (RT-PCR) array profiler (84-gene set) before and after the study interventions. The toxicity status of AA30CH in study participants will be evaluated through hepatic, renal, and hematological parameters and peripheral smears on days 1, 5, 23, 27, 45, 49, and 66. The number of participants developing COVID-19–like symptoms per National Centre for Disease Control guidelines and the number of participants testing positive for COVID-19 in RT-PCR during follow-ups in any of the three intervention schedules will be identified. Moreover, a subgroup analysis will be used to assess the COVID-19 antibody responses between vaccinated and unvaccinated participants.

Results: This RCT protocol has been approved by various committees and funded by the Central Council for Research in Homoeopathy, Ministry of Ayush, Government of India. The project has been implemented in collaboration with the Department of Homoeopathy, Government of Kerala. The RCT was rolled out on January 25, 2023, and enrollment was completed April 3, 2023. The immunological assays will be conducted at the Department of Biotechnology-Translational Health Science and Technology Institute, Faridabad, India.

XSL•FO
RenderX

Conclusions: This study will represent the first evaluation of the immunological efficacy and safety of AA30CH in an RCT, which may significantly impact the use of homeopathy as an evidence-based medicine approach.

Introduction

COVID-19 infection caused by SARS-CoV-2 is a recent major public health burden leading to clusters of mild to moderate respiratory illnesses. COVID-19 became a pandemic affecting more than 200 countries worldwide owing to its high infectivity [1,2]. COVID-19 infection is accompanied by an aggressive inflammatory response that releases several proinflammatory cytokines [3,4]. The host immune response to the SARS-CoV-2 virus is hyperactive, resulting in an excessive inflammatory reaction [5]. The incubation period of COVID-19 was reported to be 2-14 days [6,7]. It is currently believed that SARS-CoV-2 is most likely of zoonotic origin [8-10] and transmits from person to person by infected droplets, with more severe infections mainly found in older people and those suffering from comorbidities [11,12].

The World Health Organization (WHO) dashboard of COVID-19 reported approximately 753,479,439 confirmed cases of COVID-19, including 6,812,798 confirmed deaths (as of January 31, 2023) globally. The United States has been declared the country with the highest number of cases, followed by China, India, France, Germany, Brazil, Japan, the Republic of Korea, Italy, the United Kingdom, the Russian Federation, Turkey, and Spain, respectively (as of January 31, 2023) [13]. As per official reports of the Government of India, the country reported 44,682,895 COVID-19–positive cases with 530,740 deaths as of February 1, 2023. The Indian states of Maharashtra and Kerala reported the highest number of cases. Maximum deaths were reported in the second wave of COVID-19, which peaked in May 2021 [14]. The Government of India initiated the COVID-19 vaccination drive in January 2021. Nevertheless, an effective preventive measure needs to be identified with evidence of breakthrough infections and reduced protection against the Delta variant of SARS-CoV-2.

Several therapeutic strategies and clinical evaluations are ongoing to combat SARS-CoV-2 infection; however, no effective treatment has been developed with immunological safety. The WHO initiated a large global, randomized clinical study on four therapies (remdesivir, hydroxychloroquine, lopinavir/ritonavir, and interferon [IFN] therapy), showing that all four therapies had little or no influence on overall mortality, ventilation initiation, or hospital stay for hospitalized patients [15]. Furthermore, the usage of antibiotics in patients with COVID-19 raises the risk of harmful consequences such as antibiotic resistance [16,17].

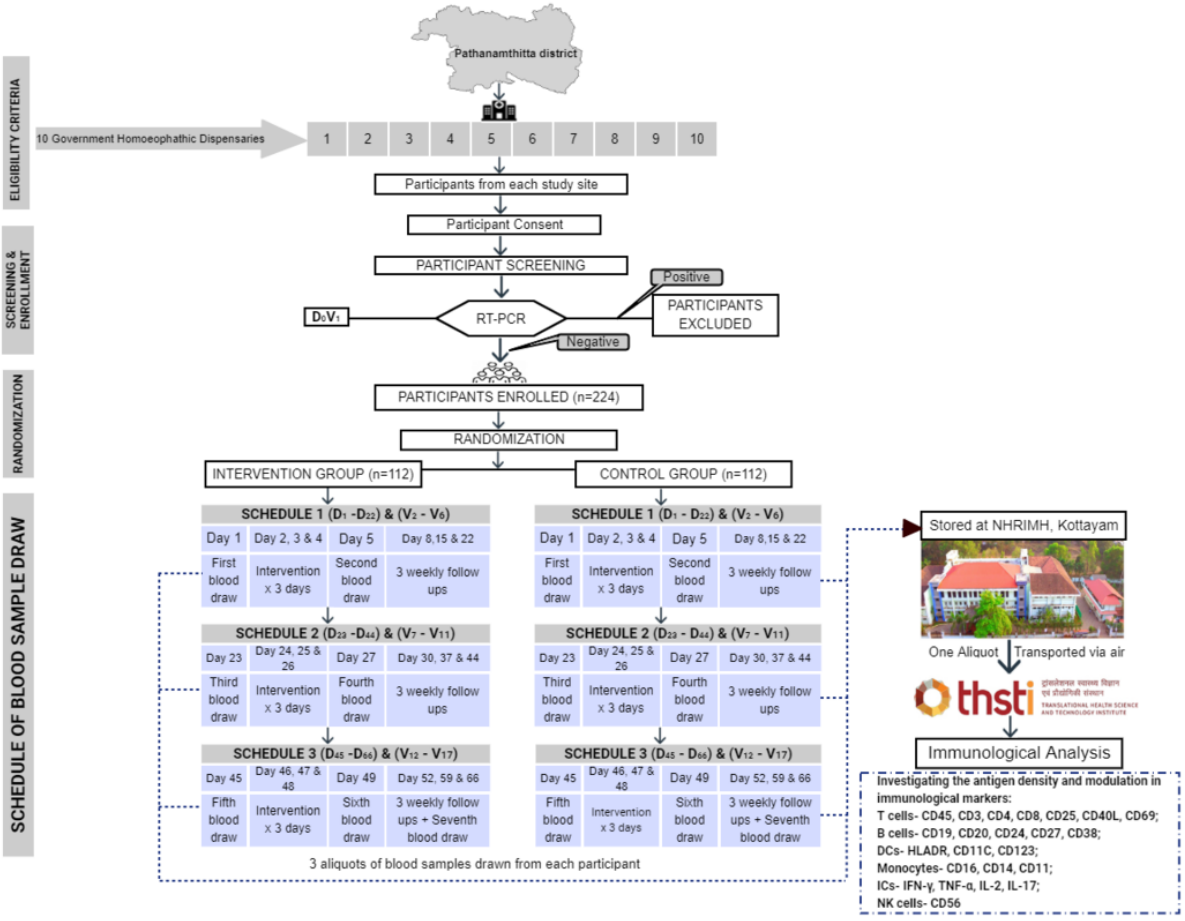
Homeopathy has been vital in preventing epidemics, especially before modern sanitation, antibiotics, and vaccinations [18]. Homeopathy has also displayed effectiveness in combating many outbreaks in its history of 200 years, such as scarlet fever in 1799 [19], leptospirosis in 2007 [20], and dengue fever in 2018 [21,22]. Homeopathy has also been successfully documented in the medical literature for both the treatment and prophylactic use of flu-like epidemics such as the “Spanish” flu of 1918 [23], “Asian” flu of 1951 [24], and H_1N_1 influenza pandemic of 2009-2010 [25]. The homeopathic formulation *Arsenicum album* 30CH (AA30CH) was previously reported to be effective in various respiratory diseases such as swine flu, influenza-like illness, and other respiratory illnesses [25-29]. In one study, *Arsenicum album*, as one of the constituents of 7X-24X complex, exhibited nuclear factor-κB hyperactivity according to reduced expression of the reporter gene in green fluorescent protein-transfected HT29 cells and also reduced the release of tumor necrosis factor-α in macrophages [30]. Due to the looming threat of the COVID-19 pandemic and the lack of effective treatments, alternative preventive strategies need to be established.

During the pandemic, AA30CH was advised as a preventative medicine for COVID-19 by the Ministry of Ayush, Government of India, toward the end of January 2020 [31]. A subsequent advisory issued by the Ministry of Ayush on March 6, 2020, also mentions the immunomodulatory action of AA30CH [32]. However, the exact role of AA30CH in innate immunity against COVID-19 was not fully understood. The observation that individuals with underlying diseases are more susceptible to severe illness than healthy people or young children is mainly attributed to the low efficacy of the innate immune response [33]. Therefore, the aim of this study is to investigate the cellular pathways related to innate and adaptive responses to AA30CH using flow cytometry–based immunological assays and gene expression analysis of 84 vital genes with a real-time reverse transcription-polymerase chain reaction (RT-PCR) array profiler. This PCR array profiler includes genes related to the interleukin-1 receptor (IL-1R) and Toll-like receptor (TLR) signaling pathways, including IL-1R and TLR genes involved in the sensing of pathogens. Genes related to host defense are also represented in this array, including the acute-phase response, complement activation, the inflammatory response, and the antiviral humoral response.

Moreover, gene expression profiling of human natural killer (NK) cell responses will also be investigated. This randomized controlled clinical trial (RCT) is being conducted by the Central Council for Research in Homoeopathy (CCRH), an apex research body under the Ministry of Ayush, Government of India, in the Pathanamthitta district of Kerala state, in close collaboration with the District Medical Office (under the

XSL•FO
RenderX

Department of Homoeopathy, Government of Kerala) after signing an agreement with the Government of Kerala. The CCRH also signed a Memorandum of Understanding with the Department of Biotechnology-Translational Health Science and Technology Institute (DBT-THSTI), Faridabad, a Coalition for Epidemic Preparedness Initiative–approved laboratory facility under the Government of India for conducting the immunological assays as part of the primary objective of the study.



The primary objectives of the study are to elucidate the immunogenic responses of AA30CH in COVID-19 prophylaxis by determining the antigen density and identifying the variation in immunological markers and lymphocyte subsets CD3, CD4, CD8, CD24, CD27, CD-38, CD4 IFN-γ, CD4 CD17, CD4 CD25 (activated T lymphocytes), T cells, B cells, dendritic cells (DCs; mature and immature), and NK cells; and to estimate the innate and acquired immune responses by real-time RT-PCR array analysis (see Multimedia Appendix 1). The secondary objectives of the study are the toxicological evaluation in study participants who took either a placebo or AA30CH, limited to hepatic, renal, and hematological parameters, by conducting liver function tests (LFTs), renal function tests (RFTs), complete blood count (CBC), and peripheral smear; to identify the number of participants developing COVID-19–like symptoms as per National Centre for Disease Control (NCDC) guidelines during follow-ups in any of the three intervention schedules; to identify the number of participants testing positive for COVID-19 in RT-PCR during follow-ups in any of the three intervention schedules; and to determine the COVID-19 antibody responses between vaccinated and unvaccinated participants.

Methods

Study Design

This clinical trial is designed as a randomized, double-blind, placebo-controlled clinical study with two parallel comparator arms of AA30CH and placebo, using an allocation ratio of 1:1. The participants will be enrolled and randomized only after two phases of initial screening (screenings I and II), followed by three schedules of intervention and follow-ups in the intervention phase of 66 days. The flow chart of the study design is represented in Figure 1. The protocol is reported following the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 guidelines.

Figure 1. Flow diagram of the screening and randomization of the participants. D: day; DC: dendritic cell; IFN: interferon; IL: interleukin; NK: natural killer; NHRIMH: National Homoeopathy Research Institute in Mental Health; RT-PCR: reverse transcription-polymerase chain reaction; TNF: tumor necrosis factor; V: visit.

Study Setting

This RCT will be implemented in the 10 government homeopathic dispensaries/hospitals located in 10 different panchayats of the state of Kerala in India, identified by the District Medical Officer (Pathanamthitta District), Department of Homoeopathy, Government of Kerala, based on the higher incidence of COVID-19 and elevated test positivity rate (TPR).

XSL•FO
RenderX

These identified study sites are: (1) Government Homoeopathic Dispensary, Elanthoor panchayat; (2) Government Homoeopathic Dispensary, Naranganam panchayat; (3) Government Homoeopathic Dispensary, Kulanada panchayat; (4) Government Homoeopathic Dispensary, Pandalam panchayat; (5) Government Homoeopathic Dispensary, Ezhamkulam panchayat; (6) Government Homoeopathic Dispensary, Puthusserimala Ranni panchayat; (7) Government Homoeopathic Dispensary, Mezhuveli panchayat; (8) Ayush Primary Health Centre Homoeopathy (under National Health Mission, Government of India), Ranni Angadi panchayat; (9) Government Homoeopathic Dispensary, Ayush Health and Wellness Center, Kuttappuzha panchayat; and (10) Government Homoeopathic Hospital, Kottanad panchayat. The National Homoeopathy Research Institute in Mental Health (NHRIMH), located in the Kottayam district of Kerala state under the CCRH, Government of India, is designated as the facilitating institute of the study with prior approvals, and two nodal site principal investigators (PIs) and supporting team will operate from the NHRIMH during the RCT. The PI will form monitoring teams who will visit the 10 study sites on all blood draws and on intervention days of the trial and report to the competent authorities in real time.

Eligibility Criteria

Inclusion Criteria

Apparently healthy male and female participants, aged 18-60 years, residents of the Pathanamthitta district of Kerala, with negative COVID-19 RT-PCR test reports at least 48 hours before the first day of the intervention, and those who have not taken *Arsenicum album* medicine in any homeopathic potencies in the past 4 months will be included in the study; both COVID-19 vaccinated and unvaccinated participants will be eligible for inclusion.

Exclusion Criteria

Participants with a positive COVID-19 RT-PCR test report at least 48 hours before the first day of the intervention; those with history of severe viral diseases in the past 3 months, such as herpes zoster, dengue, chikungunya, and chicken pox; those having a history of chronic respiratory ailments with shortness of breath as a recurring symptom; and those taking concomitant medications such as immunosuppressants, hormonal therapies, or Ayush therapies for chronic ailments will be excluded from the study.

Sample Size

The study is aimed at evaluating the immunologic responses of AA30CH. The study is based on earlier encouraging leads provided through community studies on the role of AA30CH in preventing COVID-19. Several parameters are in consideration for the evaluation of immunogenic responses. With regard to the computation of sample size, based on the literature and expert opinions, it is proposed to consider some limited immunologic parameters that are more relevant. Owing to the scarce availability of literature, it would be quite challenging to hypothesize the assumption. Assuming a type 1 error of 5% and a power of 80%, it was estimated that there would be 93 participants each in the intervention and control groups, with a total of 186 participants. This could be escalated based on attrition due to loss in follow-up. If this loss to follow-up is considered at 20%, a total of 112 participants have to be enrolled in each group, with a total sample of 224 that would need to be recruited for the study.

Randomization and Blinding

The study participants will be recruited from 10 preidentified study sites in the Pathanamthitta district of Kerala. Recruitment will be achieved according to the study inclusion criteria and based on the initial and final screening. The participants will be allocated to either intervention or placebo groups as per the randomization sequence generated using PASS 2021 (v21.03) software. Prenumbered or coded identical containers will be used for allocation concealment. The PI at CCRH headquarters will be involved in the sequence generation process and allocation concealment procedure. The PI will label the interventions as per the randomization codes, which will be handed over to the site PIs. The site PIs will enroll participants and randomly assign participants to interventions. The trial participants and the site PIs assigning participants to interventions will be blinded. To ensure blinding quality, the packaging for both the intervention and placebo will be identical in shape, color, size, taste, and odor. The unblinding will be done only at the end of the study by the PI at CCRH headquarters. If the participants reported severe adverse events (SAEs) during the trial, unblinding may be performed per Data and Safety Monitoring Board (DSMB) or ethical committee recommendations. The reason for urgent unblinding should be well-documented.

Pretrial Preparation

The selection of 10 homeopathic dispensaries was based on the COVID-19 incidences and TPR in the Pathanamthitta district. The CCRH conducted a preliminary short survey to identify these 10 sites. Following Central Ethics Committee approval, the clinical trial was registered in the Clinical Trials Registry-India (CTRI) under registration number CTRI/2022/08/045089 (August 30, 2022). An Indian Council of Medical Research–approved and National Accreditation Board for Testing and Calibration Laboratories–accredited laboratory was engaged for RT-PCR screening, hematology, clinical biochemistry, and peripheral blood mononuclear cells (PBMCs) isolation. The isolated PBMC samples for conducting immunological assays will be stored in a –80°C freezer located at the central laboratory facility in the facilitating institute of the RCT. The isolated PBMC samples will be transported to the DBT-THSTI in batches for the immunological assays. The blood samples collected from the study participants will also be used to evaluate the safety profile of the drug, mainly in terms of hematology parameters, liver function, and renal function. Training will be administered to the laboratory staff for the procedures of PBMC isolation. A mock drill will also be conducted at one of the study sites to identify the practical difficulties encountered during the screening, participant recruitment, sample collection, and storage procedures (no participant recruitment will be allowed with the mock drill). All site PIs in the 10 sites will be included in the mock drill for the practical demonstration of handling the samples and to

XSL•FO
RenderX

streamline the logistics involved in the sample transportation and PBMC isolation procedures until storage in the –80°C freezer. Detailed standard operating procedures for the procedures and data collection, case record forms (CRFs), and screening forms were designed and printed as individual booklets.

Screening and Enrollment

All the participants will be voluntarily invited to the study and then required to sign an informed consent form containing information on the regulatory authorities and related procedures, including initial RT-PCR screening, laboratory screening, and subsequent randomization after enrollment. The RT-PCR test will screen the participants fulfilling the eligibility criteria for an ongoing COVID-19 infection. If the RT-PCR test result is found to be negative for COVID-19, the participant will be investigated for an initial (baseline) LFT, RFT, CBC, and peripheral blood smear as part of the second screening for any abnormal parameters. Those with borderline elevated or normal values will be enrolled in the trial, followed by randomization. Screened participants with positive RT-PCR reports for COVID-19 will be notified to the local health authorities. Their health status will be telephonically monitored during quarantine or hospital stay by the site PI. Each study site will maintain a log register that records all details of the screened participants and the reason(s) for exclusion. Enrolled participants will then be randomized and allocated to the intervention or the placebo arm as per the generated randomization sequence using PASS software version 21.03.

Assessment, Data Analysis, and Manuscript Preparation

The laboratory parameters recorded during the seven blood draws of each participant will be analyzed for any statistically significant changes using appropriate statistical tests. The PBMCs isolated during the seven blood draws and stored in the –80°C freezer will be transported as air freight in liquid nitrogen tankers to DBT-THSTI, Faridabad, for immunological assays and data analysis. The interim reports will be confidentially submitted to the designated DSMB, internal committees of CCRH, and Ministry of Ayush, Government of India, on availability as per requirements. Manuscripts with the study findings will be prepared and submitted to Scopus-indexed peer-reviewed journals. Patents pertaining to this RCT will be filed as per the directions of the Ministry of Ayush, Government of India.

Dropout, Withdrawal, and Suspension Criteria

Dropout Criteria

Participants who develop SAEs will be withdrawn from the RCT after reporting to the Institutional Ethics Committee. Participants who develop concomitant diseases of viral origin during the trial that would affect the efficacy and safety assessment intervention, participants with poor compliance, those changing the intervention or adding therapy prohibited under the study for any reason, breaking the double-blind setting of the clinical trial, and those found to have any serious violations of the inclusion/exclusion criteria after enrollment will be withdrawn from the study.

Voluntary Withdrawal of Participants

The participant can become unwilling/unable to continue in the RCT and request the site PI to withdraw them from the RCT; other participants who stop visiting even after prompt reminders by the site PI will be withdrawn from the study. Every participant can withdraw from the trial anytime for any reason and without prejudice. Any participant who withdraws from the trial shall undergo a complete final examination, if possible, or at least a last telephonic interview at the time of withdrawal from the study about the state of their health by the investigator, and if necessary, from the point of view of drug safety and the validity of study results. The reason for the withdrawal will be recorded in the Participant Off Study form of the CRF.

Conditions for Trial Suspension

If any SAE occurs during the study, the trial will be terminated immediately as per recommendations of the DSMB and Ethics Committee. If there is a major error in the trial or a serious protocol deviation during implementation, which would make it difficult to evaluate the drug efficacy and safety, the trial will be stopped. The trial will also be terminated if the funding agency or collaborating institution requests to stop the trial or if the regulatory authority cancels the trial. The Council is entitled to terminate the trial prematurely at any time for medical and/or organizational reasons. This decision will generally be made based on the recommendations of the Scientific Advisory Board, CCRH, New Delhi, or the Director of Homoeopathy, Government of Kerala.

Intervention Procedure

Preparation of Study Intervention and Placebo Materials

AA30CH will be prepared at Dr Willmar Schwabe India Pvt Ltd, Noida, Uttar Pradesh, India (a licensed homeopathic drugs manufacturing company complying with Good Manufacturing Practice standards in India) as per the Homoeopathic Pharmacopoeia of India standards, using the active component of *Arsenicum album* in a fine powder mixed with glycerin, purified water, and pharmaceutical-grade ethanol following standard homeopathic drug manufacturing protocols approved by drug licensing authorities in India. The placebo (30CH) will be identically prepared using only glycerin, purified water, and pharmaceutical-grade ethanol, without the medicinal active component (*Arsenicum album*).

Interventions in Each Group

Following the second screening, participants with normal or borderline elevated values will be allocated to intervention and placebo arms as per the randomization sequence generated using the software PASS 2021 (v21.03). The intervention period for both groups consists of three schedules of 21 days each, with a total trial period of 66 days, including intervention, blood sample collection before and after the intervention, and three weekly telephonic follow-ups in each of the schedules. The sealed bottles of AA30CH and placebo 30CH dilutions will be opened at the in-house pharmacy of NHRIMH, Kottayam, under the supervision of the PI and the pharmacy in charge. Following standard pharmacy practice, these dilutions will further be used (approximately nine drops) for medicating one-grain lactose/sucrose (inert nonmedicated) tablets. Participants will

XSL•FO
RenderX

be administered either the homeopathic medicine AA30CH or placebo as per the randomization sequence in three doses of single tablets orally for each of the 3 consecutive days of the 21-day schedule. Each of the three intervention schedules will be preceded and followed by a blood draw of the participants. The administered dose will be recorded in the Drug Dispensation Log of the CRF.

Criteria for Discontinuing or Modifying Allocated Interventions

All participants shall be advised to telephonically inform the site PI if they develop symptoms similar to COVID-19 infection. If any participant reports symptoms, the intervention shall be stopped, and if testing positive for COVID-19 in RT-PCR, the local health authorities will be informed by the site PI. Study participants shall be advised to take the treatment of their choice from the dispensary at the study site through teleconsultation or from other medical facilities nearby. In case of requirement, the study participants will also be provided support through an already allocated medical health insurance policy (valid for 1 year) for their hospitalizations or other related treatments. They shall be under observation in this study until their recovery from the symptoms and may report any events that may be an SAE. The site PI will record the days to recovery, disease stage, and severity of symptoms, among other clinical data. The details of treatment and progress will be acquired from family members or the participants themselves, which may be recorded in the follow-up and participant study forms in the CRF. A COVID-19–positive status with the intervention or placebo will be considered as the study endpoint for participants with a positive test result on RT-PCR.

Strategies to Improve Adherence to Intervention Protocols and Procedures for Monitoring Adherence

The participants must visit the study site for the 3 days of the intervention at each schedule. To ensure compliance, the independent dispenser will only administer the medicine and placebo to the participants at the prescribed dosage. The intervention procedure will be under the supervision of the site PI to ensure adherence. Any deviation in these procedures will be recorded in the Deviation/Unanticipated Problem Tracking Log of the CRF. Participants will be under observation of the site PI at the study site for at least 1 hour to monitor for any immediate drug-related adverse effects, which will be recorded and informed to the PI. If the participant feels any discomfort, they will be medically examined by the site PI. Vital parameters such as heart rate, respiratory rate, and blood pressure will be monitored and recorded. In case of any SAE, the participant will be referred to a tertiary-care facility after receiving appropriate first aid at the site by the site PI. The DSMB and Ethics Committee will be duly informed about these events. Blood samples will be drawn and stored 1 day before and after 3 days of the intervention and on the last day of the study by the designated laboratory involved in sample collection and storage. During each visit, participants will be compensated for travel from their home to the study site and provided with protein-based refreshments to minimize their difficulty at each visit to the study site, thereby improving adherence.

Relevant Concomitant Care and Interventions Permitted or Prohibited During the Trial

Any medical problem a participant faces during the trial period will be informed to and managed by the site PI of the study site appropriately and documented and reported to the PI. The administration of vaccinations is not permitted during the study duration as it would interfere with the study results. If a participant is taking immunosuppressants, hormonal therapies, or any other Ayush therapies for chronic ailments, they will be considered a dropout. If the participant reports the intake of any other concomitant medications not specified in the exclusion criteria, the same may be documented in the Concomitant Medication Log of the CRF.

Outcome Measures

The primary outcome measures of the study are the estimation of antigen density and modulation in immunological markers (CD3, CD4, CD8, CD24, CD27, CD38, CD4 IFN-γ, CD4 CD17, CD4 CD25 [activated T lymphocytes], T cells, B cells, DCs [mature and immature], and NK cells) observed from the blood sample drawn 1 day before and after 3 days of the intervention (ie, on days 1, 5, 23,27, 45, and 49) and at the end of the study (day 66), along with the innate and acquired immune responses from the blood sample drawn on days 1, 23, 45, and 66 of the study interventions.

The secondary outcome measures of the study are to evaluate the toxicity status of study participants who have taken AA30CH or placebo based on hepatic, renal, and hematological parameters and peripheral smears 1 day before and after 3 days of the intervention (ie, on days 1, 5, 23, 27, 45, and 49) and at the end of the study (day 66); the number of participants developing COVID-19–like symptoms as per NCDC guidelines during follow-ups in any of the three intervention schedules; and the number of participants with COVID-19–like symptoms who test positive for RT-PCR during follow-ups in any of the three intervention schedules.

Participant Timeline

The study consists of three schedules of 21 days each. Each participant will have seven blood draw visits (V2, V6, V7, V11, V12, V16, and V17) during the study period. The blood samples will be drawn for conducting LFTs, RFTs, CBC, and peripheral smears 1 day before and after 3 days of the intervention (ie, on days 1, 5, 23, 27, 45, and 49) and at the end of the study (day 66) (Table 1, Figure 2).

Adverse Events

Any SAE that occurs during and after the study period and is possibly considered due to the study intervention or participation will be recorded and reported immediately to the concerned ethical committee and DSMB.

Data Monitoring and Management

The PI will monitor the study regularly, and site visits/online meetings will be held periodically on intervention and blood draw days. The PI will allocate adequate time for such monitoring activities and ensure that the monitor or other compliance or quality assurance reviewer can access all the study-related documents and study-related facilities (eg, pharmacy, diagnostic laboratory). The original records of participants (including CRFs, consent forms, follow-up forms, and laboratory reports) will be maintained at the study site by the site PI. These records will be reviewed during the scheduled monitoring visits by the PI to ensure compliance. The site PI will be responsible for the completeness and accuracy of the study materials and the nodal site PIs will check these during their visits to the study sites. Any observations/corrective

XSL•FO
RenderX

measures required will be duly communicated to the site PIs for compliance. These records will be sent to the PI at CCRH headquarters after the completion of the study or as per the requirement of the study. The data of the laboratory parameters that indicate the safety aspects of the drug will be evaluated at the end of each of the three schedules. They will be presented/submitted to the DSMB for their recommendations. The data will be analyzed after completion of the study.

Statistical Analysis

Data analysis will be performed following the intention-to-treat/per-protocol method. The safety and immunological parameters will be analyzed at each of the seven time points and comparisons will be made between the subjects and groups. Additional analyses (eg, subgroup analyses according to age, sex, and perceived risk categories) will also be performed based on the evolving trends from the analysis. A trial statistician will be engaged for the statistical analysis of the clinical trial.

Ethics Considerations

Research Ethics Approval

The Scientific Advisory Board and the Central Ethics Committee of the CCRH have approved the study protocol and the amendments (6-2/2020-2L/CCRH/Tech./27thEC/4656; August 16, 2022). The study will be conducted in accordance with the Declaration of Helsinki and the standards of Good Clinical Practice in India. CCRH will provide insurance cover in the trial for the said study duration, according to the terms finalized under clinical trial cover with the identified insurance firm.

Protocol Amendments

The investigator has to meet the study requirements as specified in the protocol. Protocol amendments are possible only in exceptional cases (eg, where the health or well-being of the participant is affected) and only after approval by the Ethics Committee. Every amendment must be justified in writing and signed by all those concerned. Every amendment will be notified to the CTRI. Circulating protocols will be numbered and their distribution list will be maintained. The PI will update all circulating protocols by adding the amendment.

Informed Consent

Individuals above the age of 18 years will be considered eligible for consent. The site PI will obtain voluntary consent from the participants before the screening test after explaining the study. The participants will be provided with the Participant Information Sheet describing the study details and will voluntarily sign the consent form if they agree to take the intervention. The site PI must also countersign the consent form at each study site.

Confidentiality

The investigator will inform the participants that all trial results recorded will be treated in strict confidence. During documentation and analysis, the participants will only be identified by their subject code and unique identifier number. In contrast, the name of the participant and any personal data of the participants will be stored as per data protection regulations.

Dissemination Policy

The investigators will communicate trial results to participants, health care professionals, the public, and other relevant groups (via publication, reporting in results databases, or other data-sharing arrangements) after the completion of the study. However, no information based on unjustified claims or the findings of interim analysis would be communicated in any form.

Auditing and Inspecting

The PI will permit study-related monitoring, audits, and inspections by the DSMB constituted for the study, Ethical Committee, or government regulatory bodies and make available all study-related documents (eg, source documents, regulatory documents, data collection instruments, study data). The PI will also ensure the capability to inspect applicable study-related facilities (eg, pharmacy, diagnostic laboratory).

Results

The CCRH, Ministry of Ayush, Government of India, funded the project in September 2022. Further, collaborations with the Department of Homoeopathy, Government of Kerala, were initiated, and the study was rolled out on January 25, 2023. As of April 3, 2023, the enrollment has been completed and the immunological assays will be conducted at DBT-THSTI, Faridabad, India.

Discussion

The COVID-19 pandemic has become widespread worldwide and severely impacted the human population. Vaccination efforts have increased exponentially in the past 2 years to protect the vulnerable population, mainly through emergency clearances. According to the vaccine study literature, adverse effects have always been part of mass vaccination strategies across the globe. According to the WHO, in the case of side effects of inactivated virus–based vaccines, the most common local and systemic adverse reactions are injection site reactions, fatigue, fever, headache, and allergic dermatitis, which are self-limiting [34,35]. With the emerging evidence of breakthrough infections and reduced protection against the Delta variant of SARS-CoV-2, an effective preventive therapeutic strategy still needs to be identified.

During the COVID-19 pandemic, the homeopathic medicine AA30CH was widely distributed to the 10.6 million Indian population as a prophylactic. The data obtained from 580,000 individuals were analyzed to conclude that preventive consumption significantly reduced the risk of contracting COVID-19 in high-risk groups [26]. A prospective parallel cluster cohort study conducted by Nayak et al [28] reported the protective effect of AA30CH against laboratory-confirmed COVID-19 cases of 74.40%. Interestingly, this study also reported AA30CH treatment as an adjunct to standard treatment in COVID-19 patients [28]; however, the current protocol is the first investigation exploring the immunological efficacy and

XSL•FO
RenderX

safety of AA30CH in an RCT. Different aspects in clinical trials with homeopathic drugs were previously explored, where the prominence of placebo-controlled RCTs in homeopathy was critically reviewed [1]. The medications used in those RCTs of homeopathy were mostly prepared as per the guidelines laid out in pharmacopoeia of the respective countries; however, several recommendations in the design and conduct of trials on homeopathic medicinal products were recently discussed [2]. In a previously published RCT in homeopathy conducted in France, the intervention was prepared according to the French National Pharmacopoeia standards, where the placebo was identical pillules containing only unmedicated pharmaceutical-grade ethanol [3]. The preparation for both the intervention and placebo in this study will be similar to that adopted in previous studies; however, we will adhere to the standards mentioned in the Homoeopathic Pharmacopoeia of India.

Several previous studies evaluated the immunological responses to COVID-19 infection and the efficacy of vaccine candidates [36,37]. The strategies toward these immunologic responses to develop candidate vaccines were vastly explained [38,39]. Immunological considerations to develop vaccine candidates were reported [40]; however, no such system was established for any alternative system of medicines, especially for homeopathy. This study intends to explicitly reveal the protective effect of AA30CH against COVID-19 by investigating the possible immune mechanisms that might play a role in its prophylactic action. The current protocol represents the first such evaluation, including immunological phenotyping; determining the antigen density; and identifying the variation in immunological markers and lymphocyte subsets CD3, CD4, CD8, CD24, CD27, CD-38, CD4 IFN-γ, CD4 CD17, CD4 CD25 (activated T lymphocytes), T cells, B cells, DCs (mature and immature), and NK cells.

The current protocol also investigates the expression analysis of 84 vital genes of interest related to the cellular pathways associated with innate and adaptive immune responses. This will be studied in detail using a well-established RT-PCR array profiler previously used for several other viruses [41-45]. The array selected for this study includes genes related to the IL-1R and TLR signaling pathways and genes involved in the sensing of pathogens. Genes related to the host defense response are also represented on this array, including the acute-phase response, complement activation, inflammatory responses, and antiviral humoral response. NK cells are reported to be vital to lyse virus-infected cells, thereby controlling the viral infection and cellular damage [38]. This protocol also aims to investigate the expression profiles of vital genes involved in the human NK cell responses, which may further reveal the possible effect of AA30CH on viral sensing and neutralization.

As mainly overseeing the primary objective of immunological efficacy and safety of AA30CH, this study also aims to assess the safety of AA30CH in terms of the results of LFTs, RFTs, CBCs, and peripheral smears between the intervention and placebo groups. Previously, the acute and subacute toxicity of AA30CH were investigated in an animal model and no adverse events or organ-related toxic effects were reported [46]. This study would also evaluate these findings in an RCT, which may support establishing the safety profile of AA30CH that could further open new vistas of research for an effective prophylactic therapy against SARS-CoV2 infection.

The timely, detailed investigation of the immunopharmacology of drug candidates is challenging [47,48]. In searching for therapeutic strategies against the COVID-19 pandemic, these essential investigations may be limited to a preliminary analysis or primary data obtained due to the pressing priority. Based on the objectives, our study is limited to the immunological responses of AA30CH against COVID-19 in healthy individuals; however, when AA30CH is mass distributed in an ongoing COVID-19 transmissible zone, a detailed investigation on the prevalence of COVID-19 incidence may provide more insights into its prophylactic efficacy.

In conclusion, the current RCT primarily emphasizes the immunological efficacy of AA30CH as a COVID-19 prophylaxis. Secondarily, the hematologic, hepatic, and renal toxicity evaluation of AA30CH would provide a comprehensive understanding of its use in healthy individuals; however, further directions on these parameters in comorbid conditions still need investigation.

Acknowledgments

The authors sincerely acknowledge the help and support of Dr Xinix Xavier, Scientist-I, National Homoeopathy Research Institute in Mental Health (NHRIMH), Kottayam; Dr Kaushal Kumar Savera, Scientist-II, NHRIMH, Kottayam; Dr Anjali PR, Senior Research Fellow (H), NHRIMH, Kottayam; Mr Amit Pachauri, Office Assistant, Central Council for Research in Homoeopathy (CCRH), New Delhi; Dr Vijayambika MN, Director (Homoeopathy), Government of Kerala; Dr Jaya Narayanan, State Program Manager, National Ayush Mission (NAM), Kerala; and the 10 site investigators (under the Department of Homoeopathy, Government of Kerala) of the proposed project. The authors also acknowledge the members of the Scientific Advisory Board, Special Committee for Clinical Research and Central Ethics Committee of CCRH, and the Data and Safety Monitoring Board (DSMB) of this randomized controlled trial for their valuable comments/suggestions to improve the protocol design. This protocol was fully funded by the CCRH, New Delhi (620/2022-23).

Abstract

Background: Pre-exposure prophylaxis (PrEP) is recommended by the US Centers for Disease Control and Prevention, but behavioral factors limit uptake, especially among men who have sex with men. A better understanding of how humans cognitively process information may inform health message development to promote PrEP uptake.

Objective: This paper is informed by the neuroscience of persuasion and influence and describes the protocol of a neuro-influence experiment using functional near-infrared spectroscopy (fNIRS) to evaluate the persuasiveness of PrEP promotion messages among men who have sex with men in Baltimore, Maryland.

Methods: We will conduct a randomized controlled trial using fNIRS to measure brain activation among 60 participants viewing PrEP promotion messages either developed through a crowdsourcing open contest implemented by the study team or developed with a traditional social marketing approach. We will evaluate the effectiveness of PrEP promotion messages by assessing brain activation in the regions associated with persuasion and changes in PrEP willingness, behavioral intention, initiation, and action between the 2 groups.

Results: This study is funded by the National Institutes of Health (National Institute of Mental Health: R34MH116725). Participant recruitment and data collection were completed in October 2023. The first results are expected to be submitted for publication in 2024.

Conclusions: In addition to providing insight into the effectiveness of PrEP promotion messages, this study will examine the feasibility, acceptability, and utility of neuroimaging techniques to evaluate PrEP promotion messages for high-risk men who have sex with men. The findings can also demonstrate the utility of fNIRS as a tool for preproduct testing of health campaigns and enable the public health community to deliver more effective messages to improve health outcomes.

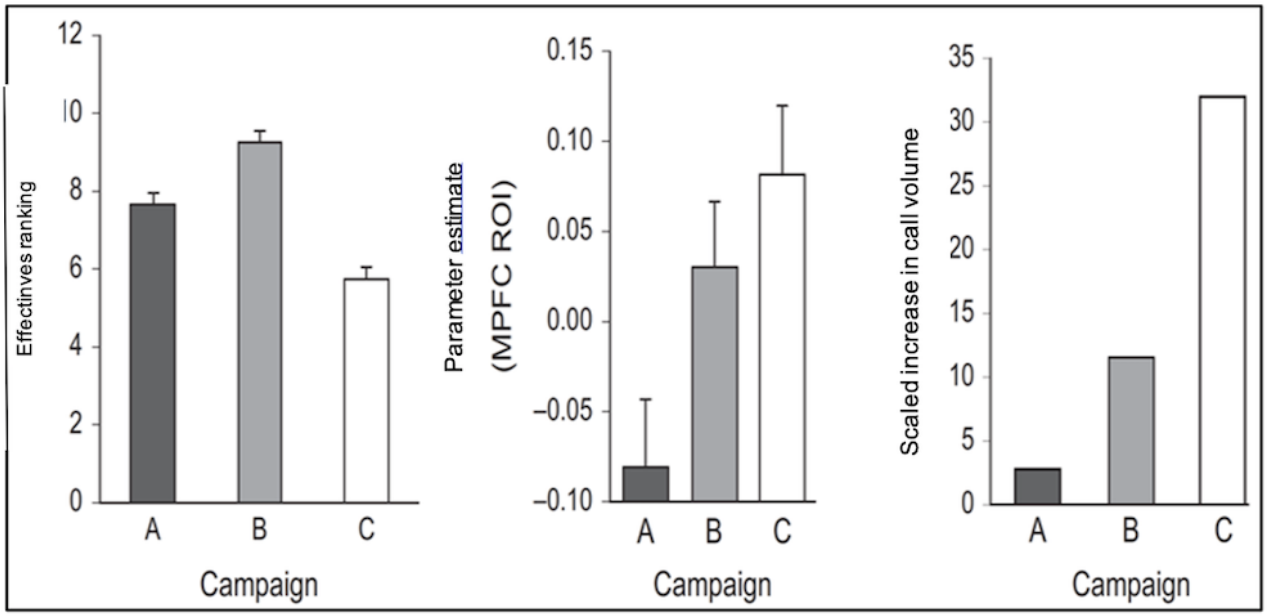
Introduction

Background

Pre-exposure prophylaxis (PrEP) is a highly effective HIV prevention drug for decreasing new infections [1]. There has been an increased effort to identify effective health communication strategies for increasing awareness, acceptability, and uptake of PrEP among those most at risk for HIV transmission as an HIV primary prevention tool [2]. Pretesting the effectiveness of health communication materials before large-scale implementation is highly beneficial given the significant expenditures associated with the implementation of a large-scale campaign [3]. However, some research suggests that using traditional methods to select public health campaign messages, such as self-reports, may not always be the best way to predict population-level behavioral change [4,5].

A better understanding of how humans cognitively process information may inform the selection of persuasive messages that are more likely to change attitudes and behaviors. A core foundation of many persuasion theories is that a message must connect to and resonate with an individual's preexisting beliefs, values, and identity. Social judgment theory [6], for example, posits that all individuals have latitudes of acceptance around different attitudes—that is, alternate points of view they are willing to accept. Messages that fall outside this zone, into an individual's latitude of rejection, will elicit counterarguments and will be rejected. Cognitive dissonance theory [7] offers additional insight into this process: individuals will be more likely to adopt messages that are consonant with, or can be incorporated into, their existing beliefs, values, and identity, and more likely to reject messages that are dissonant. Thus, messages that are too discrepant may result in no effect, at best, and a boomerang effect, at worst.



Empirical data on neural correlates of persuasion suggest that neuroscience may be significantly more reliable than traditional methods for understanding persuasion and behavior change [5,8,9]. A systematic review identified 20 studies that provided evidence of persuasive processing and outcomes of health communication messages using neurocognitive measures across different health behaviors (eg, smoking, sun safety, and narcotic substances), message types (eg, text-based phrases, video, and audio), and cultural groups [10].

The Neurocognitive Persuasion Model [11] identifies key brain regions associated with influence and persuasion. Accordingly, successful persuasion is associated with brain activity in the medial prefrontal cortex (MPFC) [6,12-14], through a process of self-integration, that is, increased brain activity for messages and cues that are successfully integrated with one's self-concept [15]. In a population-level study [5], individuals viewed 3 tobacco cessation advertisements (A, B, and C) and were then asked to rank the effectiveness of the advertisements for helping them quit smoking on a scale of 1 to 10 (the left graph in Figure 1). The center graph in Figure 1 shows the average brain activity within the MPFC for those individuals viewing the advertisements, measured by functional magnetic resonance imaging (fMRI). To measure the population-level effectiveness of each advertisement, a 1-800 quitline call volume was assessed the month after each campaign aired. The right graph in Figure 1 shows the call volume after each advertisement was aired. Results indicated that the MPFC activity provides a stronger correlation to the real-world effectiveness of different advertising campaigns at the population level than self-report in this study, suggesting that neural response is a more reliable correlate of behavior change than self-reported perceived effectiveness.

In recent years, technological advances in the field of neuroscience have allowed us to study the structure of the brain and its functioning from a previously unknown approach. Functional near-infrared spectroscopy (fNIRS) is a noninvasive tool to measure key neural processes associated with influence and persuasion. fNIRS is particularly attractive for studying the neuroscience of persuasion and influence because most regions of the brain associated with this process are in the frontal cortex and accessible through fNIRS. The lower cost and greater portability of fNIRS make it a more cost-effective tool than fMRI, thus allowing scalability. In this study, we will use fNIRS to measure MPFC as the region most commonly predictive of individual- and population-level behavior change in past studies. There have been multiple studies that have used fNIRS measurements of MPFC to predict a person's preferences [16,17]. To the best of our knowledge, there has been no published study using fNIRS in sexual health research or among highly marginalized populations.

Figure 1. Comparison of self-report (left) and neural response (center) to tobacco cessation advertisements against effectiveness measure (right). MPFC: medial prefrontal cortex; ROI: region of interest.

Objectives

Informed by the neuroscience of persuasion and influence, this paper aims to describe the protocol of a neuro-influence experiment using fNIRS to compare the effectiveness of 2 sets of PrEP promotion messages, one developed through a crowdsourcing open contest the study team implemented [18] and another developed through a traditional social marketing approach. Open contests, a form of crowdsourcing, involve a large number of community members in developing, vetting, and implementing solutions to public health problems in the form of a contest [19]. In our study, 79 PrEP promotion messages were submitted by community members, and then the top 4 entries were selected by 155 community votes in Baltimore. We expect the messages developed through open contests to be highly relevant to the community because open contests explicitly incorporate local knowledge, culture, and style by directly involving a large number of community members [20].

We hypothesize that individuals viewing PrEP promotion messages developed through crowdsourcing open contests will show higher brain activation in the MPFC regions than those viewing messages developed by a social marketing approach. We further hypothesize that brain activation in the MPFC regions will be significantly more correlated with PrEP behavioral intention, initiation, and action than self-reported message effectiveness.

Methods

Overview

We will conduct a randomized controlled trial using fNIRS to measure brain activation in MPFC among 60 participants. The key inclusion criteria for the participants are as follows: (1) 18 years or older, (2) biological male sex at birth, (3) never taken PrEP, and (4) being eligible for taking PrEP [21]. Participants will be recruited by community partners in Baltimore, Maryland, from a range of settings, including venue-based outreach (community-based organizations and health clinics) and word-of-mouth referral.

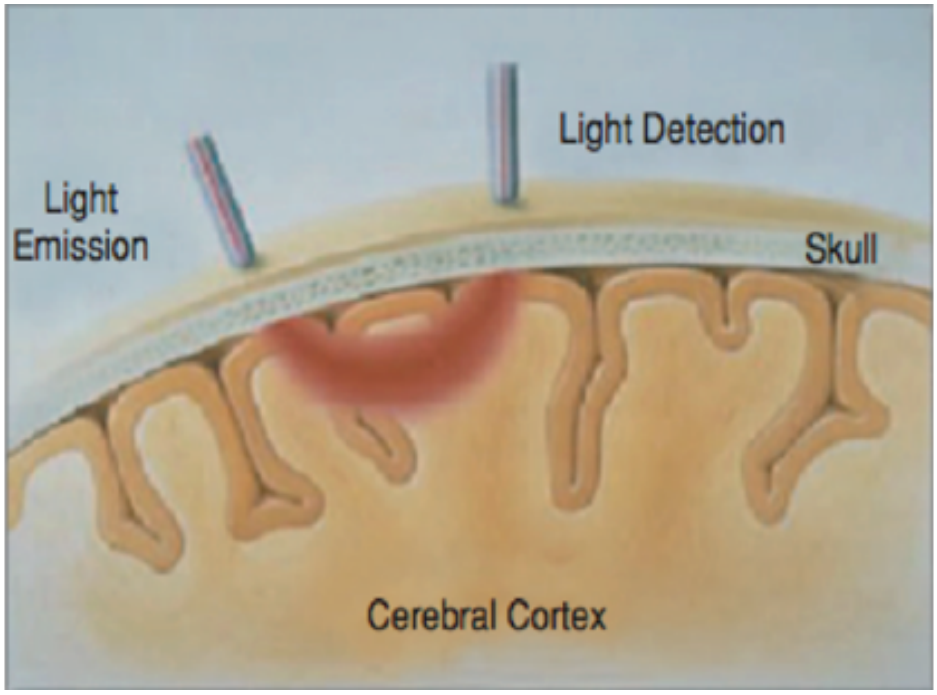
Participants will be randomly assigned to view 4 PrEP promotion messages developed through an open contest the study team implemented [18] or PrEP campaign messages developed with a traditional social marketing approach. We will compare brain activities between the 2 groups and follow up with participants in 30 days to assess any behavioral change.

Study Procedure

After being screened eligible and providing written consent, each participant will be assigned a study ID and complete a baseline survey programmed in Qualtrics. Then we will make an appointment for an in-person experimental visit, roughly a week after completing the baseline survey. During the experimental visit, participants will be randomized to one of two conditions: (1) the top 4 messages developed through an open contest (ie, the intervention group) or (2) a total of 4 PrEP campaign messages developed with a traditional social marketing approach (ie, the control group). The participant's assigned condition will be recorded in a logbook. Block random assignment (in batches of 10) will be used to keep the sizes of the 2 groups similar. The order in which the groups are assigned in each block is randomized and determined by a computer algorithm. This process is repeated for consecutive blocks of study participants until all participants are randomized.

After the randomization, a research assistant will take the participant to a private room. The research assistant will measure and fit the participant's head for the fNIRS headband, which is connected to an NIRSport2 (NIRx) [22]. NIRSport2 is a portable fNIRS device to measure the neural response as participants view 4 messages on a computer screen. Once participants are fitted with the headband, the signal quality will be checked. The

XSL•FO
RenderX



lights in the room will be turned off during testing to limit ambient light. A black shower cap will be placed over the participant's head to further limit any potential ambient light, and the research assistant will verify signal quality again. The LED emitter and detector on the headband will measure brain activity when participants view messages. Participants in each group will view 4 messages programmed in PsychoPy [23] on a computer screen while brain activity will be recorded. Each message appears on the screen for 10 seconds, and there are 10 seconds of resting time between messages. Messages are ordered randomly, and we did not find any ordering effect in our previous study [11]. After reviewing all messages, participants will answer questions on self-efficacy (individual's beliefs about their ability to follow through on a given behavior) and willingness and behavioral intention to use PrEP (see the "Measures" section). Semistructured questions on the acceptability of fNIRS will also be asked. All participants will complete a 2-week follow-up call to assess PrEP behavioral outcomes.

Measures

Brain activity

fNIRS detects the ratio of oxygenated hemoglobin (O2HB) to deoxygenated hemoglobin (HHB) based on its optical properties, with higher ratios indicating greater neural activity. Neural tissues are relatively transparent to light in the near-infrared range between 700 nm and 1000 nm, and O2HB and HHB reflect distinct wavelengths in this range. By modulating light at different wavelengths, emitting the light on the skin-exposed areas of the cranium, and detecting that light, fNIRS measures the blood oxygenation level–dependent signal like fMRI. Because the photons reflected from neural tissue follow a reliable "banana-shaped" path, photodetectors can be used to measure this on the scalp (see Figure 2). By measuring the amount of absorbed light directed at the neural tissue, we can measure the amount of O2HB and HHB present in a region of the brain at a given time and draw inferences about the level of neural activity.

Figure 2. Functional near-infrared spectroscopy measurement of cerebral cortex.

PrEP-Related Beliefs, Willingness, Behavioral Intention, and Behavior

All questions will be asked to participants at baseline (only to individuals aware of PrEP), at the second visit after reviewing all messages, and at the 30-day follow-up, except questions on PrEP action and initiation, which will only be asked at the 30-day follow-up. Self-efficacy [24] is assessed on a 5-point Likert scale ranging from "strongly disagree" to "strongly agree" to rate their agreement with the statement "I feel confident I could take PrEP as prescribed." Willingness is assessed by asking participants, "Suppose that PrEP is at least 90% effective in preventing HIV when taken daily. How likely would you be to take PrEP if it were available for free?" with responses ranging from "I would definitely take it" to "I would definitely not take it" [25]. We will assess behavioral intentions to actually begin PrEP based on a real-world situation [25]. To do this, participants will be asked, "PrEP is currently available with a prescription from your doctor and research has shown that a majority of insurance companies cover most or all of the costs of PrEP. Do you plan to begin PrEP?" Response options range from "yes, I will definitely begin taking PrEP" to "no, I definitely will not begin taking PrEP." Those participants who indicate they intend to take PrEP will also be asked a follow-up question regarding how soon they plan to begin taking PrEP. PrEP action and initiation will be assessed by asking, "Have you spoken with a provider about PrEP during the past 30 days?" and "Have you started taking PrEP during the past 30 days?" [25].

XSL•FO
RenderX

Message-Related Measures

All questions will be asked after participants finish reviewing each message during the second visit. Perceived effectiveness will be measured using a validated scale [26]. Participants will be asked, on a 5-point Likert scale ranging from "strongly disagree" to "strongly agree," to rate their agreement that the message is believable, new, unconvincing, and important to them; helps them feel confident about using PrEP; would help their friends use PrEP; and puts thoughts in their mind about using PrEP and how much they agree or disagree with the message.

Acceptability of fNIRS

Participants will be asked to provide feedback on their experience with fNIRS, including questions: (1) "Do you feel comfortable wearing the cap?" with responses ranging from "extremely comfortable" to "not comfortable at all." (2) "Do you feel the size of the cap is too small, a good size, or too big?" (3) "How do you feel about a machine reading your brain activity?" with responses ranging from "extremely comfortable" to "not comfortable at all." (4) "How likely are you to participate in another study using the same type of machine in the future?" with responses ranging from "I would definitely take it" to "I would definitely not take it."

Baseline Socioeconomic and Behavioral Factors

We will collect baseline data on age, the highest level of education attained, living situation, employment status, relationship status, biological sex at birth, gender, sexual identity, sources and amount of personal and household income, health insurance status, usual health care, and sexual behavior in the past 90 days.

Data Analysis

We will conduct a descriptive analysis of the acceptability of fNIRS. The primary aim of data analyses is to assess the effectiveness of PrEP promotion messages developed through an open contest by assessing brain activation in the MPFC regions and changes in PrEP willingness, behavioral intention, initiation, and action between participants in the intervention group and those in the control group. We will compare (1) the level of neural activity in MPFC, (2) the increase in willingness and behavioral intention to take PrEP between baseline and 30-day follow-up, and (3) PrEP action and initiation at 30-day follow-up between participants in the 2 groups. A secondary aim is to evaluate the neural correlates of behavioral change.

Neural time series data will be captured for 23 brain regions in the prefrontal cortex. The time series signals will be averaged for each stimulus duration and for each 30-second rest period in between stimuli. These block averages will in turn be averaged across participants from the 2 groups. The level of brain activation for the intervention group compared with the control group will be evaluated using a pairwise comparison. For the binary outcome measures, that is, the increase in willingness and behavioral intention to take PrEP and PrEP action and initiation, we will first compare proportions by groups separately for each measurement period using standard bivariate analytic techniques such as Spearman rank-order correlations, odds ratios, and the Fisher exact test. Then we will use generalized linear mixed models (GLMM) to evaluate the effectiveness of messages developed through an open contest. GLMM permits us to measure the fixed effect of the messages developed through an open contest on neural activity, willingness, and behavioral intention to take PrEP, and PrEP action and initiation while allowing a random effect that accounts for within-person correlation. Given the binary nature of 2 primary outcomes, we will specify a logit link function for our GLMM models. Comparisons of the characteristics of participants who are lost to follow-up to those who are evaluated will be conducted to assess for systematic patterns that could influence results.

Self-reported effectiveness for individual messages will be averaged to compute self-reported message effectiveness for each group. We first examine the overall ordering of (1) self-reported message effectiveness by group assessed by mean ratings, (2) neural activity by group assessed by mean MPFC parameter estimate, and (3) PrEP action and initiation by group assessed by proportion of participants reporting taking PrEP action and initiation during 30-day follow-up. We next use a chi-square test to compare the proportion of individuals who produce each possible ranking with what would be expected by chance (1/6). Finally, we will confirm the reliability of the proportion-based predictions using weighted Kendall tau [27].

Ethical Considerations

The study protocol has been approved by an institutional review board (Study ID: Pro2022000225). Screening for participant eligibility will be conducted in person or on the web after verbal consent. Once screened, eligible individuals will review the written consent and consent if they agree to participate in the study. Each participant will be assigned a study ID. Participants will receive US $15 for completing the baseline survey, US $60 for completing the experimental visit, and US $10 for completing the follow-up call.

Results

This study is funded by the National Institutes of Health (National Institute of Mental Health: R34MH116725). Participant recruitment and data collection were completed in October 2023. The first results are expected to be submitted for publication in 2024.

Discussion

Findings from the study will improve the scientific understanding of health communication in HIV prevention and treatment efforts. PrEP promotion messages identified as most persuasive with fNIRS will serve as a template for future contests with a focus on visual images (eg, color photographs, black-and-white photographs, and videos less than 1 minute) and distribution networks (eg, men who have sex with men social media networks, in-person men who have sex with men businesses, and in-person men who have sex with men social networks). The findings can also demonstrate the utility of fNIRS as a tool for preproduct testing of health campaigns and enable the public health community to deliver more effective messages to improve health outcomes.

XSL•FO
RenderX

We are well aware of the limitations of relying exclusively on small-scale pilots to determine whether messages developed through an open contest approach are more persuasive, namely that sizable standard errors are associated with effect sizes due to the small sample size. However, we are primarily interested in exploring the pattern of results for any evidence of support for the effectiveness of PrEP messages developed through the open contest on the primary outcomes. Effect size estimates determined through this study will be essential in the design of a larger and fully powered efficacy study that tests intervention effects on PrEP uptake.

In summary, the findings of this proposed study will transform the design, evaluation, and implementation of HIV campaigns, potentially bringing new ideas for local health departments and community-based organizations to develop more impactful PrEP campaigns.

Abstract

Background: Current guidelines for gender-affirming hormone therapy (GAHT) for transgender women are mostly based on clinical experience from experts in the field and treatments used on postmenopausal women. While care is currently provided with the best available evidence, there is a critical gap in knowledge about the safest and most effective estradiol routes of administration for GAHT in transgender women; this statement is supported by the World Professional Association for Transgender Health on their *Standards of Care for the Health of Transgender and Gender Diverse People, version 8*. Furthermore, the reported rates of cardiometabolic adverse events in transgender women highlight the importance of investigating changes in lipoproteins, glucose, and insulin sensitivity, among other markers while receiving GAHT.

Objective: This study aims to evaluate the degree of testosterone suppression achieved at 1, 6, and 12 months in treatment-naive transgender women when randomized to GAHT with estradiol and spironolactone as antiandrogens. As a secondary aim, this study will assess the treatment effect on metabolic and coagulation factors from baseline to 6 and 12 months after initiating GAHT.

Methods: This is a prospective pilot, open-label, randomized clinical trial conducted at an adult transgender clinic in a tertiary medical center. The 3 treatment arms include once-daily sublingual 17-β estradiol, twice-daily sublingual 17-β estradiol, and transdermal 17-β estradiol. All participants received spironolactone as an antiandrogen. Transgender women aged 18 to 45 years who are being evaluated for the initiation of GAHT with 17-β estradiol and did not have a history of coagulopathy, cigarette smoking, liver disease, dyslipidemia requiring treatment, or use of gonadotropin-releasing hormone agonist were eligible to enroll. The main outcome is the total testosterone suppression at 1 and 6 months after the initiation of GAHT, and the secondary outcome is to assess treatment effect in a lipid panel; homeostatic model assessment for insulin resistance; coagulation factors II, IX, and

XSL•FO
RenderX

XI; Von Willebrand factor; activated protein C resistance; protein C; and protein S at baseline, 6 months, and 12 months after therapy is initiated.

Results: This study was funded in March 2022, and enrollment concluded in August 2022. It was concluded in July 2023, and currently, the results are being analyzed for publication.

Conclusions: The Transgender Estradiol Affirming Therapy (TREAT) study offers a rigorous and reproducible approach to answer important questions regarding GAHT in transgender women, specifically, the most effective 17-β estradiol regimen to suppress testosterone levels to 50 ng/dL, as currently recommended.

KEYWORDS

transgender research; transgender health; clinical trial; estrogen; transwomen

Introduction

Transgender individuals experience discordance between their self-identified gender and biological birth sex [1-3]. Some transgender individuals experience gender dysphoria, which the *Diagnostic and Statistical Manual of Mental Disorders* defines as clinically significant distress or impairment in social, occupational, or other key areas of functioning. Increasing numbers of adolescents seek care at gender identity centers in Western countries [4,5].

Studies using short self-reports of gender identity and its variants suggest that 0.17% to 1.3% of adolescents and young adults identify as transgender [6]. Even using the conservative estimate of 0.3%, the number of people living in the United States who identify as transgender is nearly 1 million [7]. Given the widespread acknowledgment of the health care needs of this population, priority should be given to those actions that will ensure timely access to appropriate care. Such action includes coverage of transition care and a requirement to ensure safe, effective, appropriate, and sensitive care in health centers [8-10].

Transgender women seek gender-affirming hormone therapy (GAHT) to reach physical features consistent with their gender identity [11-13]. The goal of GAHT for transgender women is to achieve feminine features and maintain estradiol levels within the normal woman range while suppressing endogenous testosterone [11]. The current approach to GAHT is not uniform and is used off-label for this indication. It also depends on the cost of the regional health care system and availability of estrogens and antiandrogens.

A typical regimen includes estrogen to provide feminizing effects in conjunction with therapy to block testosterone (antiandrogens or gonadotropin-releasing hormone analogs) [14]. The currently preferred estrogen formulation that can be provided in tablets, patches, and injections is 17-β estradiol, and spironolactone is the most prescribed antiandrogen in the United States.

Studies have demonstrated that transgender individuals on hormone therapy have higher rates of adverse cardiovascular events (myocardial infarction, venous thromboembolism, and ischemic stroke), highlighting the importance of investigating surrogate markers such as changes in lipoproteins, estrone, glucose, and insulin-sensitivity based on the estrogen preparation used during GAHT [8,15-21].

Both the World Professional Association for Transgender Health and the Endocrine Society have created transgender-specific guidelines that serve as a framework for providers caring for gender minority patients [9,22]. These guidelines are primarily based on clinical experience from experts, and guidelines for estrogen therapy in transgender women are loosely based on treatments for postmenopausal women [1]. Therefore, stronger evidence is needed to guide clinicians on best clinical practices for this population, as stated in the *Standards of Care for the Health of Transgender and Gender Diverse People, version 8*: "Determining the safest and most efficacious estrogen compound and route of administration for transgender people is an important topic" [9,22,23].

For this proposed study, we aimed to evaluate the degree of testosterone suppression and treatment-related changes in metabolic and coagulation factors in transgender woman patients undergoing randomized GAHT for a period of 12 months. Participants were randomized to once-daily sublingual 17-β estradiol, twice-daily sublingual 17-β estradiol, or transdermal 17-β estradiol, using spironolactone as an antiandrogen in all 3 treatment arms.

We chose to look at once versus twice-daily sublingual 17-β estradiol to evaluate if there is a difference in the level of suppression of gonadotrophins based on 1 larger peak serum level of estradiol versus 2 peaks. To date, no studies have looked at the effects of estradiol pulses (once vs twice) on suppression of the hypothalamic or pituitary axis.

Methods

Overview

This prospective pilot, open-label, randomized clinical trial compares the testosterone-suppressing effects of 3 commonly used 17-β estradiol regimens in transgender woman adults initiating GAHT. The 17-β estradiol regimens used in this trial include once-daily sublingual 17-β estradiol, twice-daily sublingual 17-β estradiol, and transdermal 17-β estradiol patch.

The primary end point is testosterone suppression from baseline to 1 and 6 months with secondary evaluation of treatment-related

XSL•FO
RenderX

changes in lipid panel; homeostatic model assessment for insulin resistance; coagulation factors II, IX, and XI; Von Willebrand factor; activated protein C resistance; protein C; and protein S at baseline, 6 months, and 12 months after therapy is initiated.

The study took place at the Washington University Transgender Center. Patients aged 18 to 45 years who were being evaluated for the initiation of GAHT with 17-β estradiol and did not have a history of coagulopathy, cigarette smoking, liver disease, dyslipidemia requiring treatment, or use of gonadotropin-releasing hormone agonist were eligible to enroll. Initially, the study was limited to those aged 18-30 years and with BMI <30 kg/m^2, but these were later removed to increase the population available to screen and participate in the study.

Power analyses indicated that 12 participants per group would provide 80% power to detect differences in total testosterone between groups when the true difference between groups is 230 ng/dL. The type I error probability is .05.

We will use a likelihood-based mixed-effects model to separately evaluate the effects of time and treatment assignment on serum testosterone, estradiol, and estrone from baseline to 1 and 6 months after initiation of medications.

We will also use a likelihood-based mixed-effects model to separately evaluate the effects of time and treatment on metabolic and coagulation factors from baseline to 6 and 12 months after the initiation of treatment. We will also determine if there is any correlation between estradiol and estrone levels with coagulation factors as suggested by other studies.

Ethical Considerations

The Washington University in St. Louis Institutional Review Board approved the study protocol (IRB# 202104092) in May 2021, which was executed in accordance with the Declaration of Helsinki. Participants received financial compensation for their time and costs associated with participation in the study ($30 per visit).

Study Procedures

Participants who met eligibility criteria and provided informed consent were randomized 1:1:1 to either once-daily sublingual 17-β estradiol, twice-daily sublingual 17-β estradiol, or a transdermal 17-β estradiol patch. All participants received spironolactone as an antiandrogen. The dosing protocol is shown in Table 1.

Table 1. Dosing regimen per treatment group.

Medication	Once-daily sublingual	Twice-daily sublingual	Transdermal
17-β estradiol	• Starting dose: 2 mg once a day • Increase by 2 mg/day	• Starting dose: 1 mg twice daily • Increase by 2 mg/day	• Starting dose: 100 mcg/24 h • Increase by 100 mcg/24 h
Spironolactone	• Starting dose: 50 mg daily • Increase by 50 mg/day • Maximum dose: 200 mg/day	• Starting dose: 50 mg daily • Increase by 50 mg/day • Maximum dose: 200 mg/day	• Starting dose: 50 mg daily • Increase by 50 mg/day • Maximum dose: 200 mg/day

Initial evaluation included a comprehensive medical history, physical examination, and baseline laboratory testing. During the initial visit, patients were randomized and started on spironolactone and 17-β estradiol based on their treatment group assignment. The initial evaluation was completed in conjunction with the treating endocrinologist with follow-up conducted by the study investigator.

Once participants started their GAHT treatment assignment, they underwent a titration phase in which the hormone profile including estradiol, total testosterone, estrone, and basic metabolic panel was assessed every 4 weeks until total testosterone was less than 50 mg/dL. If the total testosterone is above goal, 17-β estradiol and spironolactone doses were adjusted based on their group dosing regimens as depicted in Table 1.

Anthropometric measurements and metabolic and coagulation factors were obtained at baseline, 24 weeks, and 52 weeks (Table 2). Blood testing was conducted before their morning dose for participants randomized to sublingual 17-β estradiol or the morning when the transdermal 17-β estradiol patch is due for replacement.

Results

This study was funded in March 2022, and enrollment concluded in August 2022. It was concluded in July 2023, and currently, the results are being analyzed for publication.

Discussion

Expected Findings

The Transgender Estradiol Affirming Therapy (TREAT) study offers a rigorous and reproducible approach to answer important questions regarding the GAHT in transgender women. Specifically, the study will determine if significant differences in testosterone suppression between once-daily, twice-daily, or transdermal 17-β estradiol exist.

This study will also provide insights into metabolic and coagulation changes in transgender women on GAHT with sublingual and transdermal 17-β estradiol and spironolactone as antiandrogens. These outcomes, with the GAHT used in this study, have not been explored in prior studies.

In addition, this study will provide insights into the best strategies and most reliable methods to inform the design of future, fully powered randomized clinical trials.

Limitations

Due to a lack of uniformity on the current prescription patterns for GAHT, we decided to conduct this study using the most common regimens prescribed in our clinical setting with no prior studies describing their effects on metabolic and coagulation factors. Hence, it may not be representative of other approaches to GAHT in transgender women, including estradiol valerate or cypionate, which were not included in the study.

Conclusions

The proposed study addresses areas of research that have been determined as important by the most recent World Professional Association for *Standards of Care for the Health of Transgender and Gender Diverse People, version 8*, including the most effective estrogen regimen (route of administration and dosing schedule), while providing insights on metabolic and coagulation factor changes with concurrent use of spironolactone, which has not been explored previously. Furthermore, this study

XSL•FO
RenderX

provides insight into methodology and statistics that will inform larger clinical trials.

Acknowledgments

The Washington University Institute of Clinical and Translational Sciences and the National Institutes of Health (NIH)/National Center for Advancing Translational Sciences grant UL1TR002345 funded this study.

Abstract

Background: Despite improvements in radiation techniques, pelvic radiotherapy is responsible for acute and delayed bladder adverse events, defined as radiation cystitis. The initial symptoms of bladder injury secondary to pelvic irradiation are likely to occur during treatment or within 3 months of radiotherapy in approximately 50% of irradiated patients, and have a significant impact on their quality of life. The pathophysiology of radiation cystitis is not well understood, particularly because of the risk of complications associated with access to bladder tissue after irradiation, which limits our ability to study this process and develop treatments.

Objective: It is an original study combining digital data collection to monitor patients' symptoms and biological markers during irradiation. The main objective of our study is to evaluate the correlation of biological biomarkers with the intensity of acute radiation cystitis and the quality of life of patients, assessed with the digital telemonitoring platform Cureety.

Methods: Patients with intermediate-risk localized prostate cancer who are eligible for localized radiotherapy will be included. Inflammatory biomarkers will be analyzed in urine and blood samples before the start of radiotherapy and at weeks 4, 12, and 48 of irradiation, through quantitative methods such as a multiplex Luminex assay, flow cytometry, and enzyme-linked immunosorbent assay. We will also characterize the patients' gut and urine microbiota composition using 16S ribosomal RNA sequencing technology. Between sample collection visits, patients will complete various questionnaires related to radiation cystitis symptoms (using the International Prostate Symptom Score), adverse events, and quality of life (using the Functional Assessment of Cancer Therapy–Prostate questionnaire), using the Cureety digital remote monitoring platform. Upon receipt of the questionnaires, an algorithm will process the information and classify patients in accordance with the severity of symptoms and adverse events reported on the basis of Common Terminology Criteria for Adverse Events and International Prostate Symptom Score standards. This will allow us to correlate levels of urinary, blood, and fecal biomarkers with the severity of acute radiation cystitis symptoms and patient-reported quality of life.

Results: The study started in March 2022. We estimate a recruitment period of approximately 18 months, and the final results are expected in 2024.

Conclusions: This prospective study is the first to explore the overexpression of inflammatory proteins in fluid biopsies from patients with symptoms of acute radiation cystitis. In addition, the 1-year follow-up after treatment will allow us to predict which

XSL•FO
RenderX

patients are at risk of late radiation cystitis and to refer them for radioprotective treatment. The results of this study will allow us to develop strategies to limit radiation damage to the bladder and improve the quality of life of patients.

Introduction

Background and Rationale

Prostate cancer is the leading cancer diagnosed in men in France, with 50,400 new cases and 8100 deaths in 2018. Improved diagnostic strategies and therapeutic management have led to a 3.7% reduction in mortality between 2010 and 2018, and the survival rate is 93% at 5 years and 80% at 10 years [1], resulting in improved overall survival. However, treatment-related adverse events can be significant and have an impact on adherence to treatment, frequency of hospitalization and associated costs, as well as on the health-related quality of life of patients [2].

Radiation therapy (including conventional radiation therapy, stereotactic body radiation therapy, and brachytherapy) is an important therapeutic technique in the management of pelvic cancers, including prostate cancer [3,4]. Despite improvements in radiation techniques, pelvic radiotherapy remains responsible for a number of acute and late bladder adverse events—these symptoms are grouped under “radiation cystitis.” In France, late radiation cystitis affects 9000 to 18,000 patients per year [5].

Early symptoms of radiation cystitis may occur during treatment and up to 3 months after the end of radiotherapy, with an estimated all grade incidence of nearly 50% after pelvic irradiation [5]. These side effects are characterized by frequent and urgent urination during day- and nighttime, a burning sensation during urination (irritative symptoms), and pain. Difficulty in urinating (obstructive symptoms) or, more rarely, blood in the urine (hematuria) may also be present [6]. More rarely, in 5%-10% of cases, complications appear later (more than 6 months after radiotherapy), whether or not they were preceded by early signs [5,7]. Late lesions involve blood vessel damage and fibrosis of the bladder wall, which may progress chronically and lead to bladder atrophy and even retraction in the most extreme cases [5]. Clinical signs vary depending on the dominant clinical form: cystalgia, pollakiuria, bladder hyperactivity, and isolated mictional disorders. In a classic clinical scenario, recurrent hematuria is a predominant symptom, occurring in abundance and with variable frequency, which can potentially progress to urinary retention with bladder clotting. The chronic and recurrent nature of hemorrhagic cystitis often has a considerable impact on the quality of life of patients. The most severe forms can lead to clot formation and acute urinary retention, which can be life threatening [5,7].

Although some factors have been identified, such as the dose received, fractionation and, comorbidities (eg, diabetes and tobacco smoking), the pathophysiology of radiation cystitis remains poorly studied, particularly because of the risks of complications arising from access to the bladder tissue post irradiation, thus limiting our knowledge of and therapies targeting this process.

The Role of Immunity in the Pathomechanism of Radiation-Induced Injury

Immunity plays an important role in the mechanism of radiation-induced toxicity or inflammation [8,9]. During the repair process of radiation-induced injuries, inflammatory cells (macrophages, neutrophils, and lymphocytes) are recruited to the site of injury, which may contribute to late inflammatory tissue diseases through a continuous mechanism involving inflammation, hypoxia, and fibrosis [10]. The balance between M1 and M2 macrophages plays a central role in the fibrotic process, with a polarization toward M1 macrophages in a fibrotic situation [11,12]. Functional tests measuring the apoptosis of $CD4^+$ and $CD8^+$ T lymphocytes after irradiation found a significant association between these apoptotic lymphocytes and the risk of occurrence of late genitourinary toxicity [13].

The interstitial cystitis model is similar to the radiation cystitis model in terms of not only collagen accumulation but also symptoms. Patients with interstitial cystitis have very severe genitourinary pain, and many are diagnosed with depression and anxiety. A positive correlation between elevated urinary proinflammatory cytokines (interleukin [IL] 4 and macrophage-derived chemokines) and the severity of interstitial cystitis has been reported [14,15].

Role of the Microbiota in the Pathomechanism of Radiation-Induced Lesions

Evidence of the protection of microbial communities, especially in the gastrointestinal tract, has led to investigations of the role of the human microbiota in patient health and well-being [16,17].

Radiation therapy to the prostate causes a disruption in the composition of the microbiota, which may promote gastrointestinal toxicities through altered gut barrier function

XSL•FO
RenderX

and inflammation [18,19]. It has been shown that the gut microbiota of patients with pelvic cancers who have had radiotherapy is less diverse than that of patients who have not been irradiated [18]. Wang et al [19,20] reported that pelvic radiotherapy is associated with dysbiosis characterized by a decrease in α-diversity in favor of β-diversity. In order to reduce the digestive disorders induced by pelvic radiotherapy, an approach based on fiber supplementation in patients (partially hydrolyzed guar gum) has proven to be effective in reducing diarrhea induced by radiotherapy and has allowed the improvement of the bacterial load of the microbiota while improving nutritional status and the quality of life of patients with cancer [21]. However, the numbers considered in Bull et al's [21] study were limited. Another study [22] also considered fecal microbiota transfer as a therapeutic solution to slow the spread of radiation-related symptoms—this approach showed encouraging signals for reducing the symptoms of hematuria and diarrhea.

Biomarkers based on the urinary microbiota may represent new diagnostic, prognostic, and therapeutic tools for functional disorders of the lower urinary tract. It has been shown that the urinary microbiota of patients with interstitial cystitis is less diverse than that of patients without these symptoms [20].

To date, no study has evaluated the modification of the urinary microbiota in patients with radiation cystitis. A better understanding of the impact of the urinary microbiota on the etiopathogenesis of urological disorders may help optimize medical management.

It is also important to note that the microbiota of different organs are linked. It is known that the gut microbiota is capable of changing its microbial composition, and these changes can affect the urinary microbiota [21].

Main Objective

The main objective of this study is to determine inflammatory and remodeling markers involved in the occurrence of early (<3 months) radiation cystitis in patients with localized prostate cancer.

Secondary Objectives

Our secondary objectives are to determine biological markers of the severity of early radiation cystitis and to describe changes in urinary and fecal microbiota in accordance with the severity of early radiation cystitis.

Exploratory Objectives

Our exploratory objectives are to describe the biological markers of severity of late radiation cystitis (>6 months) and to describe the lipidome and metabolome changes in accordance with the precocity of radiation cystitis.

Methods

Study Design

The Radiotoxicity Bladder Biomarkers (RABBIO) study is an interventional, prospective, single-arm, exploratory study aimed to identify factors potentially related to radiation-induced bladder toxicity in patients with localized prostate cancer treated with radiotherapy. This study will be conducted at the Bégin Military Teaching Hospital (Saint-Mandé, France).

Ethical Considerations

The study has been validated by national ethics committees (unique protocol ID number 2021-A03196-35; favorable opinion of the South Mediterranean Committee for the Protection of Persons I 03/02/2022) and the French Data Protection Agency. The study is registered on ClinicalTrials.gov (NCT05246774). The survey complies with the tenets of the Declaration of Helsinki. All patients will be informed that the data collected may be used for research purposes, and will be asked to provide their written consent.

Patient Population

The eligibility criteria for the RABBIO study are listed in Textbox 1.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

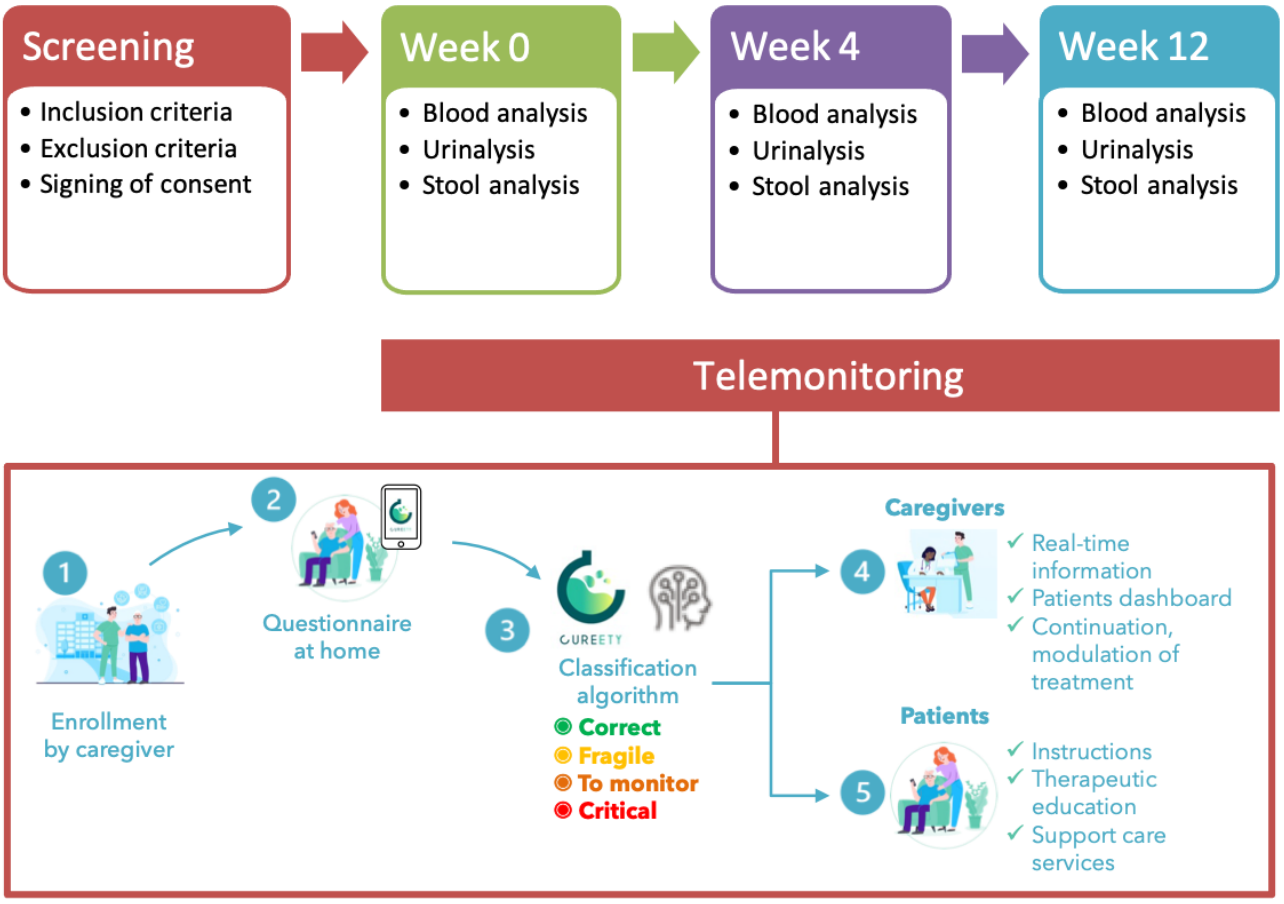
Inclusion criteria:

- Collection of signed informed consent forms prior to participation in the study
- Patients are aged ≥18 years at the time of selection
- Histologically confirmed adenocarcinoma of the prostate is present
- Localized adenocarcinoma of the prostate according to the D'Amico classification is present
- Patients are eligible for external radiotherapy or brachytherapy
- Patients are affiliated to a social security scheme
- Patients are able to communicate well, understand, and comply with the requirements of the study according to the physician investigator
- Patient has a smartphone or computer to use the Cureety platform

Exclusion criteria:

- Patients have advanced or metastatic prostate cancer
- Patients are receiving preirradiation hormone therapy
- Patients have bladder or urethral cancer or a history of cancer
- Previous urinary tract surgery (bladder augmentation or cystectomy)
- Patients are participating in an interventional clinical study
- Patients have a history of pelvic irradiation

Participants' Calendar



Early symptoms of radiation cystitis are likely to occur during treatment or within 3 months of radiotherapy in approximately half of the patients [7]. Therefore, we decided to follow the early manifestations of radiation-induced bladder toxicity for 3 months (weeks 1 to 12) and to attempt to identify biomarkers that are potentially related to acute radiation cystitis symptomatology.

Late manifestations of bladder damage secondary to pelvic irradiation may occur after a minimum of 3 months or even several years after the end of irradiation [4,6]. It has been established that the average delay in the occurrence of these complications is 2 years [6]. However, the pathophysiological changes between the end of radiation and the occurrence of late complications are not known. In this study, we aim to, as an exploratory objective, determine biomarkers that may be predictive of late radiation cystitis by quantifying biomarkers at week 52.

The design of RABBIO study is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Study design.

Data Collection

Clinical Data

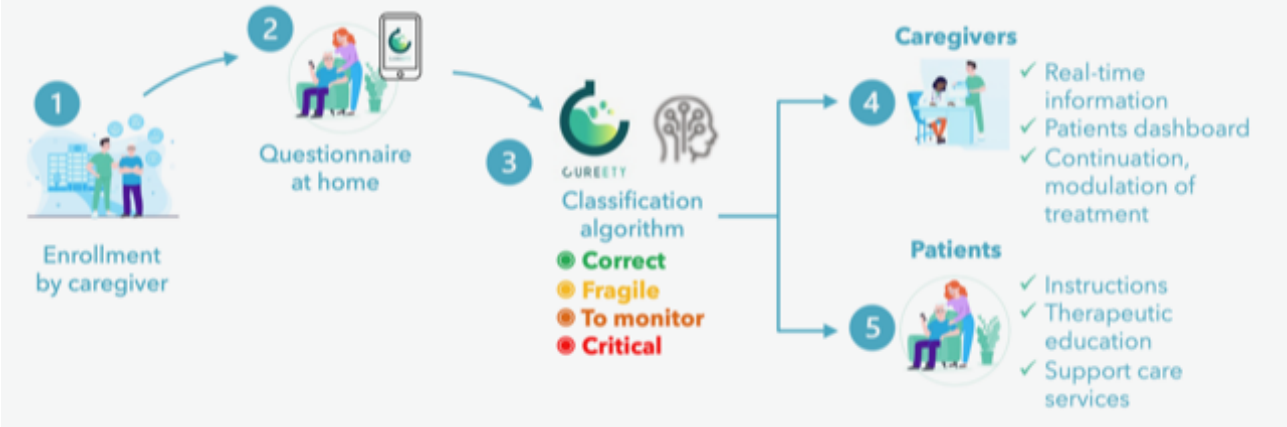
Demographics and Disease Characteristics

Demographic data and cancer characteristics (localized or biologically relapsed prostate cancer, stage of disease, radiation regimen, concomitant treatments, and comorbidities) of the patients will be collected.

Clinical Examination

Clinical examination at each visit will include performance index (performance status), weight, blood pressure, heart rate, and oxygen saturation.

Monitoring of Radiotherapy Adverse Events and Patient-Reported Quality of Life Using the Cureety Platform



The Cureety platform will allow remote monitoring of urinary symptoms reported by patients in accordance with the CTCAE (Common Terminology Criteria for Adverse Events) guidelines [22] (Multimedia Appendix 1).

Patients will complete the Pelvic Radiation Adverse Events Questionnaire at the inclusion visit, then once a week for 3 months (weeks 1 to 12), and then at the end-of-study visit (week 52). The questionnaire includes the following items: fatigue, nausea or vomiting, pain, hematuria, frequency of urination (pollakiuria), urinary burning, diarrhea, fecal incontinence, urinary leakage, blood in the stool (rectorrhagia), constipation, weight loss, and dysuria.

On receipt of the questionnaires on the adverse effects of radiation, an artificial intelligence algorithm will classify patients into 1 of 4 states: correct condition (green), fragile state (yellow), condition to monitor (orange), and critical condition (red; Figure 2). The patient will receive therapeutic advice depending on the severity of the symptoms. If the patient's condition changes to orange (watch) or red (critical), rapid management of the patient will be activated by the health care team (Figure 2).

Figure 2. Monitoring of radiotherapy adverse events and patient-reported quality of life using the Cureety app.

International Prostate Symptom Score

The International Prostate Symptom Score (IPSS) [23] is a structured, validated, self-administered questionnaire that assesses lower urinary tract voiding disorders. The questions cover the following items: incomplete emptying of the bladder, frequency of micturition, intermittent micturition (stopping and restarting the stream), urgent micturition (feeling of "urgency"), weak stream, effort to urinate (forcing or pushing), and nocturia (Multimedia Appendix 1).

The Functional Assessment of Cancer Therapy–Prostate Questionnaire

The Functional Assessment of Cancer Therapy–Prostate (FACT-P) questionnaire [24] is a prostate cancer–specific, self-administered questionnaire that assesses weight loss, appetite, pain, physical comfort, urinary, and sexual and bowel function in 12 items. The score ranges from 0 to 156, with higher scores reflecting a better quality of life.

The International Physical Activity Questionnaire

The International Physical Activity Questionnaire (IPAQ) [25] is a 7-item questionnaire that assesses overall physical activity and sedentary time over the past 7 days. The questionnaire assesses intense or moderate walking activity, as well as time spent sitting (sedentary), whether during leisure activities, at work, in daily life, or during transport. The questionnaire classifies the subject in accordance with 3 levels of activity: inactive, moderate, and high [25].

The IPSS, FACT-P and IPAQ questionnaires will be completed by the patient via the Cureety platform at inclusion and at the visits at weeks 4, 12, and 52.

Biological Data

Overview

Nearly 2 dozen studies have defined urinary biomarkers indicative of visceral disorders. Three main categories of markers have been studied: proteins involved in epithelial cell growth, mediators of inflammation, and neurotrophins. All marker levels were significantly altered in patients with interstitial cystitis, but antiproliferative factor, epidermal growth factor, and heparin-binding epidermal growth factor were the markers with the most promising results [26,27]. For radiation cystitis, the 2 studies by Zwaans et al [9,28] are the only ones to report elevated urinary levels of plasminogen activator inhibitor 1, the matrix metalloproteinases tissue inhibitor of matrix metalloproteinase 1 and 2, hepatocyte growth factor, VEGF-A, and placental growth factor. Based on the biomarkers reported in the literature, we chose to assess variations in the expression of 33 serum and urine biomarkers [9,28].

Biomarkers of urinary and intestinal microbiota may be prognostic of radiation-induced functional disorders [18-20]. Thus, we chose to assess changes in the composition of the urinary and fecal microbiota before, during, and after radiotherapy.

Physical activity, as determined on the basis of muscle contraction and the oxygen consumption it generates, can induce changes in the gut microbiota profile, helping to explain the health benefits of exercise. Researchers have identified differences in the composition of the gut microbiota of elite athletes in comparison with those of sedentary individuals [29]. A recent study has shown that the composition of the microbiota also differs in accordance with the sport practiced [30].

The collected samples will be analyzed for circulating biomarkers and microbiota composition.

Inflammatory and Remodeling Biomarkers

Overall, 6 mL of blood and 5 mL of urine per patient per visit will be used for the analysis of the following 33 biomarkers: inflammatory biomarkers (including macrophage migration inhibitory factor; cytokines IL-1α, IL-1β, IL-4, IL-6, IL-7, IL-8, IL-10, IL-13, and IL-17α; macrophagic inflammatory protein 1α; TNF-α; vascular cell adhesion molecule 1; intercellular adhesion molecule 1; chemotactic cytokines including monocyte chemoattractant protein 1 and 3 and regulated on activation, normal T-expressed, and secreted; the C-X-C motif chemokine ligand 10; the M1:M2 macrophage ratio; $CD4^+$ and $CD8^+$ T cells; and CRP) and biomarkers of remodeling (including plasminogen activator inhibitor 1, metalloproteinases such as matrix metalloproteinase 9, matrix metalloproteinase inhibitors including tissue inhibitor of matrix metalloproteinase 1 and 2, hepatocyte growth factor, placental growth factor, VEGF, epidermal growth factor, heparin-binding epidermal growth factor, nerve tissue growth factor, and glycoprotein GP51).

XSL•FO
RenderX

Urinary and Fecal Microbiota

The advent of molecular biology and high-throughput sequencing has revealed the diversity of urinary and fecal microbiota and led to a better understanding of these ecosystems. Over the past 2 decades, shotgun metagenomic and 16S ribosomal RNA sequencing approaches have been widely used to determine the composition of these microbiota.

Lipidome and Metabolome

This involves the analysis of metabolites (small molecules) and lipids in the blood and urine before, during, and after radiation therapy. The identity and quantity of the different metabolites and lipids depend on several factors such as available nutrients, environmental stimuli, or physiological state. Metabolome and lipidome analyses help elucidate the influence of radiotherapy on the expressed phenotype and metabolism of the patient. A GC 7890B gas chromatography system (Agilent) coupled to a MS 7010 triple quadrupole mass spectrometer will help identify lipid and metabolic proinflammatory mediator profiles in the serum and urine of patients.

Statistical Analysis

As this is a pilot exploratory study, the sample size was not based on a statistical argument. As the variability and evolution of biomarkers over time and the history of the disease are not known, and in order to explore the links between biomarkers and the occurrence of radiation cystitis, based on the hypothesis that half of the patients initially included will develop cystitis, a sample size of 60 individuals—including 30 individuals with cystitis and 30 individuals without cystitis—seems acceptable. Statistical analysis will be carried out using SAS (version 9.4; SAS Institute Inc) and R (The R Foundation) [31].

Basic statistics will be used for continuous variables n, missing n (if applicable), mean, type of deviation, median, first and third quartiles, and minimum and maximum values, and for categorical variables, we will use frequency and percentage values.

The type I error (α, 2-sided) will be 5%. The type II error (β) will be 20%; that is, a power (1-β) of 80% will be considered.

End Points and Evaluation

The primary end point will indicate variations in the expression of the 33 inflammatory and remodeling biomarkers assessed using the MILLIPLEX MAP technique for the analysis of circulating markers and flow cytometry for the analysis of the immune population at the 4th and 12th weeks after the start of irradiation.

The secondary endpoints will indicate symptoms and the severity of early radiation cystitis through electronic reporting of patient-reported outcomes–CTCAE self-assessment questionnaires at inclusion and once a week during weeks 1 to 12. We will also be interested in voiding disorders, quality of life, and physical activity assessed using the IPSS, FACT-P, and IPAQ self-assessment questionnaires at inclusion and at weeks 4 and 12. Furthermore, we will characterize the composition of the urinary and fecal microbiota via 16S ribosomal RNA sequencing at baseline and at weeks 4 and 12. Finally, we shall explore the eligibility criteria, and then at week 52, the symptoms and severity of cystitis will be assessed through electronic reporting of patient-reported outcomes–CTCAE self-assessment questionnaires, and voiding disorders, quality of life, and physical activity will be assessed with the IPSS, FACT-P, and IPAQ self-assessment questionnaires, and then the composition of the urinary and fecal microbiota will be characterized through 16S ribosomal RNA sequencing. We will analyze serum and urine lipidome and metabolomes at weeks 4, 12, and 52.

Results

The RAABIO study started in March 2022. It is an original study combining digital data collection to monitor patients' symptoms and biological markers during irradiation. We estimate a recruitment period of approximately 18 months. The final results are expected in 2024.

Discussion

The quality of life of long-surviving patients is a goal of their care. Minimizing the impact of our treatments remains very challenging. This study is expected to improve our knowledge of the pathophysiology of radiation cystitis and its impact on the quality of life of our patients.

Radiation cystitis—which is characterized by hematuria, inflammation, and partly by fibrosis—has a strong impact on the daily life of our patients. Telemonitoring allows the recording of patients' experiences and the assessment of the impact of side effects on his quality of life. Collecting data from the patient (patient-reported outcomes) help to correct the discrepancy in the severity of the side effects when reported by the clinician or by the patient. Remote monitoring has been shown to provide high-quality care and has the potential to significantly improve patient care.

An increasing number of pathologies or their treatments, including radiation therapy of the prostate, now report alterations of the host-microbiome symbiosis [32,33]. In addition to remote monitoring patients' experiences, disorders involving the gastrointestinal area could be assessed by monitoring host-microbiome interactions using wireless ingestible capsules technologies as described recently by Miley et al [34]. These emerging technologies could be useful in tailoring daily treatments and helping patients reduce the side effects of radiation.

This prospective study is the first to explore the overexpression of inflammatory proteins in fluid biopsies from patients with symptoms of acute radiation cystitis. In addition, the 1-year follow-up after treatment will allow us to predict which patients are at risk of late radiation cystitis and to guide them toward radioprotective treatment. The RABBIO study will provide a better understanding of the pathophysiology of radiation-induced cystitis, along with data on the kinetics of these biomarkers. The results of this study will allow us to develop strategies to limit radiation damage to the bladder and improve the quality of life of patients.

Abstract

Background: Excessive dietary sodium intake is an independent risk factor for hypertension and cardiovascular disease (CVD). Despite the large body of evidence concerning the effects of dietary interventions on blood pressure (BP) and CVD outcomes, trials have often reported low adherence to decreased sodium intake, likely due in part to heterogeneous BP responses. To address the challenges, recent clinical findings suggested a precise and personalized dietary approach that seeks to deliver more preventive and practical dietary advice than the "one-size-fits-all" guidelines and weighs the personal risk of developing specific diseases.

Objective: The purpose of this pilot randomized controlled trial was to test the feasibility and preliminary efficacy of integrating the use of mobile technology and metabolomics with a low-sodium diet intervention in patients with hypertension to develop personalized low-sodium diet programs. Additionally, the study will examine the associations of urine metabolites with urinary sodium levels and BP control based on the hypothesis that targeted urine metabolites. In this report, we describe the design and protocol of the pilot trial.

Methods: A total of 40 patients with hypertension will be randomly assigned to either a 8-week low-sodium diet group (n=20) or a standard care group (n=20). Each week, intervention participants went through individual sessions with an interventionist via videoconferencing to discuss low-sodium diet regimens, patients' food choices, and BP tracks on mobile apps. The control group followed their usual care for hypertension management. All participants in both groups monitored diet and BP using mobile apps for 8 weeks. A 24-hour urinary sodium excretion for the estimation of dietary sodium intake, systolic, and diastolic BPs were measured at the baseline and at 8 weeks. The primary outcomes of this study include the feasibility of conducting a randomized controlled trial (RCT) by reporting recruitment, retention, and completion statistics. The preliminary effects of intervention will be tested by a generalized estimating equation model.

Results: This pilot RCT study was approved by the institutional review board at the University of Texas Health San Antonio in January 2021. The first participant was enrolled in April 2021, and currently, 26 participants were enrolled. All data collection is expected to conclude by March 2023, with data analysis and study results ready for reporting by December 2023. Findings from this pilot RCT will further guide the team in planning a future large-scale study.

Conclusions: The findings of this proposed study will establish a comprehensive knowledge base for future research and development of personalized dietary interventions to promote adherence to dietary strategies and self-management of chronic disease using the Precision Health approach for millions of Americans who are struggling with uncontrolled hypertension.

Introduction

Excessive dietary sodium intake is an independent risk factor for hypertension and cardiovascular disease (CVD). CVD is the leading cause of death in the United States. Risk factors for CVD include obesity, diabetes, and hypertension. Nutritional practices are a critical component in the prevention of CVD [1,2]. It is well documented that excess sodium intake can lead to hypertension, the primary risk factor for CVD [3]. Indeed, among all risk factors for CVD, elevated intake of sodium alone was ranked the 11th most important [4]. The scale of this problem resulted in calls for dietary sodium reduction to be considered a public health priority. Sodium intake is included in the top 5 priority actions for chronic disease control [5]. Despite this effort, daily dietary sodium intake among Americans chronically exceeds recommendations (2300 mg per day).

Numerous clinical trials demonstrated that a low-sodium diet reduces the risk of cardiovascular outcomes, including the incidence of hypertension, stroke, and cardiovascular morbidities [6-8]. Most recently, a systematic review and meta-analyses demonstrated that lowering sodium intake significantly reduced resting systolic blood pressure (BP) by 3.39 mm Hg and resting diastolic BP by 1.54 mm Hg [9]. When sodium intake was < 2 g/day versus ≥ 2 g/day, systolic BP was reduced by 3.47 mm Hg and diastolic BP by 1.81 mm Hg [9]. These changes seem small but are significant.

Prior dietary interventions successfully reduced sodium intake, but adherence to these dietary strategies is difficult to maintain [10,11]. This issue is likely due in part to the heterogeneity of BP responses to alterations in dietary sodium intake. In addition to examining group average BP responses to sodium intake, BPs of some—but not all—individuals fall with reduction in sodium intake, leading to the concept of intraindividual variability in BP response to a low-sodium diet [11-14]. Because there is considerable intraindividual random daily variation in BP without a change in sodium intake, both individual and intraindividual random variations in BP must be considered [15]. This proposed pilot study aims to address these challenges and investigate whether a low-sodium diet would induce changes in metabolic profiling and reflect intraindividual variability in response to a low-sodium diet among patients with hypertension, and also measure the association with reduced BP.

In recent years, precision health is often described in relationship to precision medicine, an emerging approach for disease treatment and prevention that accounts for intraindividual variability in genes, environment, and lifestyle [16]. Precision or personalized nutrition focuses on ways to deliver tailored dietary recommendations to promote and maintain health and prevent disease [17]. However, this field is in its infancy and currently has limited clinical applicability to CVD.

Metabolomics can measure the full profile of small-molecule metabolites in biofluids and provide a comprehensive picture of a person's overall dietary intake [18]. Diet encompasses a complex set of intercorrelated exposures, and self-reported tools are prone to random and systematic errors [18]. Although several biomarkers that measure nutrient intake have been identified, objective measurement of the overall dietary pattern remains elusive. Metabolite profiling accounts for intrinsic variability in metabolism by measuring downstream components or metabolic products of foods and, therefore, may more accurately measure true exposure than the traditional methods that measure individual food intake [18]. Although a few studies [19,20] identified metabolites associated with sodium intake, little research addresses metabolic phenotyping in relation to a low-sodium diet. This project aims to examine the variance in metabolite profiling caused by a low-sodium diet while controlling for covariates such as age and gender and provide the preliminary findings that estimate the variance of a modifiable factor (a low-sodium diet) in BP control.

Salt sensitivity (SS) as a preceding factor for individual BP response to a low-sodium diet can be tested with a genetic approach. SS is influenced by many factors, including genetics, age, gender, race or ethnicity, BMI, and diet [20,21]. The most robust method for assessing SS is through modifying dietary sodium intake using a crossover study design where a 5-7–day intervention period is given for a normal, low, and high dietary sodium intake level [22,23]. When a change in BP is not observed despite changes in sodium chloride intake, the individual is classified as salt resistant. Validated rapid tests or diagnostic markers to identify SS of BP in clinical practice were not available until now. In the most recent published study, which used data from the Genetic Epidemiology Network of Salt Sensitivity, GNAI2 single-nucleotide polymorphisms (SNPs) were positively associated with SS independently of subject sex or age [24]. Examining SS in BP using a genetic approach will enhance the identification of individuals at high risk for developing hypertension and would also benefit from a low-sodium diet.

Mobile apps that monitor food intake have the potential to improve eating habits and promote healthy diets. Although most popular apps are intended to monitor calorie intake to promote weight loss, they could also be used to monitor specific nutrient concerns such as dietary levels of sodium or monitor adherence to therapeutic dietary plans. One pilot study using a smartphone

XSL•FO
RenderX

app showed that the change in the predicted 24-hour sodium excretion significantly differed between groups using an app versus a group recording intake in a journal (mean change −838, SD 1093 and 236, SD 1333 mg, respectively) [25]. Thus, further research is needed to explore whether mobile apps facilitate the real-time assessment of dietary intake as a means to improve self-managing dietary behavior using more precise monitoring [26].In conclusion, despite the benefits of low-sodium diet programs for reducing high BP and improving CVD outcomes in patients with hypertension, much of the existing empirical support for low-sodium diet programs are based on the evidence from a one-size-fits-all approach and has not accounted for individual responses to diet modification. Using a precision nutrition approach, we can address these gaps by providing more personalized interventions that may enhance adherence to a low-sodium diet and improve sustainability for individuals with hypertension. However, research developing and implementing a personalized low-sodium diet for patients with hypertension is limited, and more foundational evidence is needed.

Methods

Study Design and Overview

We are currently conducting a randomized controlled trial to test the feasibility of integrating the use of mobile technology and metabolomics with a low-sodium diet program compared to standard care (control). We will randomly assign 20 participants with hypertension to each group (N=40) to the intervention or the control group. The intervention is 8 weeks long and we will measure adherence and BP outcomes as the primary end points.

Ethical Considerations

This study is approved by the University of Texas (UT) Health Science Center at San Antonio's Institutional Review Board (#HSC20200054H). All databases containing personal data will be encrypted to minimize the risk of a breach. In addition, all the servers where data are stored will be encrypted and require a one-time password to be made available for analysis. Participants who completed the baseline visit and follow-up visit received US $60 of ClinCards per institutional policy as compensation for their time.

Specific Aims and Hypotheses

The aims of this clinical trial are to (1) determine the feasibility and preliminary efficacy of delivering a low-sodium diet intervention focused on changes in metabolomic profiling and reduction of urinary sodium level and BP in patients with hypertension; (2) examine the associations of urine metabolites with urinary sodium levels and BP control based on the hypothesis that targeted urine metabolites will have significant associations with urinary sodium level and differences in systolic BP (SBP) and diastolic BP (DBP).

Study Setting

The UT Health San Antonio School of Nursing will serve as the coordinating center for this study. Eligible participants will be recruited from primary care centers at UT health physicians. Data will be collected in the UT Health San Antonio School of Nursing.

Sample

Sample Size Justification and Power

This is a pilot study and will be inherently underpowered; therefore, quantitative outcomes will be interpreted only as feasibility and pilot data. A sample size of 40 subjects will provide an adequate sample size [27] to calculate meaningful CIs for our estimates of feasibility and preliminary effects. With this sample size, we expect to have sufficient diversity of input on the intervention components to plan refinements for a larger intervention trial.

Inclusion and Exclusion Criteria

To examine the underlying mechanism of intraindividual response to a low-sodium diet, a randomized, controlled study will be conducted in a sample of 40 patients with hypertension aged >40 years. Children are thought to have minimal levels of high BP; therefore, we will only recruit adults. Participants will be asked to own their own smartphone for using mobile apps during the study. Our exclusion criteria are clinic BP of <140 mm Hg; estimated glomerular filtration rate of <15 mL/min/1.73 m^2 or on dialysis; history of organ transplantation; cardiovascular event, procedure or hospitalization for unstable angina/chronic heart failure within last 6 months; life expectancy of <1 year or a cancer diagnosis and treatment within the past 1 year that, in the judgment of clinical study staff, would compromise participant's ability to comply with the protocol and complete the trial; active alcohol or substance abuse within the last 12 months; residence in a nursing home; diagnosis of dementia, treatment with medications for dementia; and unwilling or unable to participate in either of the interventions.

Measures

After obtaining informed consent, we will begin collecting baseline data and schedule the 8-week study visit. The summary of variables, measures, and time of evaluation is presented in Table 1.

XSL•FO
RenderX

Table 1. Factors, variables, measures, and time data collected.

Factors and variables	Measures	Time data collected
Individual characteristics		
Age	Years	Baseline
Sex	Male and female	Baseline
BMI	Weight and height	Baseline and 8 weeks
Physiological factors		
Metabolite profile	24-hour urinary sample	Baseline and 8 weeks
Salt sensitivity gene	Single-nucleotide polymorphism genotyping	Baseline
Feasibility measures		
Retention rate	Number of subjects that came to the follow-up visit	Over 8 weeks
Attendance at education sessions	Number of education sessions attended on the internet	Over 8 weeks
Adherence to dietary sodium intake monitoring	Logging a meal in the app/manual	Over 8 weeks
Adherence to in-home blood pressure monitoring	Logging BP using BP monitor device	Over 8 weeks
Outcomes		
Blood pressure	WelchAllyn Vital Signs Monitor	Baseline and 8 weeks
Sodium intake	24-hour urinary sodium excretion	Baseline and 8 weeks

Individual Characteristics

Age and sex will be self-reported. BMI will be calculated using height and weight measurements and obtained with an Accu-Hite wall mounted stadiometer and a Withings electronic scale, respectively.

Physiological Factors

Metabolite profile will be measured by using targeted capillary electrophoresis/mass spectrometry (CE/MS) for 48 amino metabolites from 24-hour urine samples collected at baseline and at 8 weeks.

The SS gene will be screened using targeted genotyping. The targeted gene under investigation will be GNAI2 SNPs, which are positively associated with SS independently of sex and age. The primary SNPs investigated will be rs10510755, rs9852677, rs2282751, rs4547694, and rs2298952 identified from the HapMap and 1000Genomes projects to capture 100% of the genetic variation in GNAI2 using the Affymetrix Genome Wide-Human SNP Array AFFY_6.0.

Feasibility Measures

Four feasibility measures will be used to help elucidate our understanding of using a low-sodium diet intervention with mobile technology and metabolomics to measure intervention compliance intervention and protocol adherence.

Retention rate is the percentage of subjects who attended the 8 weeks post intervention. Attendance to education sessions will be measured by the number of 8-week education sessions attended within intervention group.

We will measure adherence to dietary sodium intake monitoring with the Fitbit companion mobile dietary app. The Fitbit app is intended as an intervention tool to enhance self-monitoring and promote adherence, not as a reliable assessment tool for dietary sodium intake (the 24-hour urinary samples will be used for this purpose). Each subject will register and assigned a unique ID in the platform developed by the Center on Smart and Connected Health Technologies at UT Health San Antonio. Each Fitbit account will be linked to his or her unique ID through this platform. Subjects will be instructed to record food intake in real time. Adherence to sodium intake monitoring is measured by calculating the percentage of days a participant logs at least 1000 kcal his or her meals in the dietary app.

Adherence to in-home BP monitoring is the percentage of days a subject uses the BP monitoring device (Omron 7 Series Upper Arm BP Monitor) to log BP. It has a range of 0 to 299 mm Hg for BP and 40 to 180 beats per minute for heart rate. The cuff is inflated with an electric pump and deflated with a pressure release valve. SBP, DBP, and heart rate are displayed on the LCD screen after each measurement. The device can also display a symbol on the screen, indicating an irregular heartbeat detected during measurement of SBP and DBP. Each subject will register for an Omron app account, which will be linked to their Connected Health platform unique ID. We will provide instructions on how to measure BP while in a sitting position and transfer the BP data to Omron mobile app using the BP monitoring device.

Outcomes

BP will be measured with the Vital Signs Monitor 300 Series model (WelchAllyn) at baseline and 8-week follow-up appointments. The midsection circumference of the dominant upper arm will be measured with a tape measure [28], and the proper sized cuff will be selected accordingly. SBP and DBP will be measured in the dominant arm twice with a 2-minute rest period between measures [29]; the 2 measures will be averaged. Sodium intake will be measured using a 24-hour urinary sodium excretion (mg excreted/day) test collected at baseline and at 8 weeks post intervention.

XSL•FO
RenderX

Procedures

Recruitment

Recruitment began in April 2021. After obtaining approval from the institutional review board, subjects will be informed about the study via (1) UT Health San Antonio internal IT systems (ie, email and clinical trials website), (2) using Epic system to identify potentially eligible patients and send MyChart invitations, (3) study brochures posted at the primary care centers, and (4) word of mouth. For interested potential subjects, the principal investigator arranged a convenient time for consent process and screening for eligibility.

Informed Consent, Screening, and Randomization

After explaining the study's purpose, procedures, and potential benefits and risks in greater detail, we will obtain informed consent and screen BP (Table 2). For those meeting all criteria, we will arrange a convenient date and time for data collection in the Biobehavioral Research Laboratory. To prevent subject attrition, we will send appointment reminders 1 day prior to the scheduled visit. We will randomly assign the subjects into 1 of 2 groups using block randomization to balance sample sizes across groups [30].

Table 2. Procedures.

Variables	Screening (30 minutes)	Pretest (60 minutes)	Intervention (8 weeks)	Posttest (30 minutes)
Information session	N/A[a]	• A low-sodium diet intervention • Using wireless, wearable, and a mobile app • 24-hour urine collection	N/A	N/A
Self-report	• Age • Informed consent	N/A	• Dietary sodium intake • In-home blood pressure monitoring	N/A
Noninvasive measure	• Blood pressure	• Height and weight • Blood pressure • 24-hour urinary excretion	N/A	• Height and weight • Blood pressure • 24-hour urinary excretion
Blood collection	N/A	• Salt sensitivity gene	N/A	N/A

[a]N/A: not applicable.

Baseline Data Collection

After measuring height and weight, BP will be measured twice with a 2-minute rest period between the measurements. Next, we will draw 4.0 mL of blood by venipuncture. The research team will provide a low-sodium diet intervention tutorial and hold an information session to explain the mobile app, Fitbit wristband, and the in-home BP monitoring system. Subjects will be instructed to create user accounts for each device and receive hands-on training for dietary sodium intake and BP level self-monitoring using the Fitbit and wireless device. We also will provide participants with a designated helpline number for technical support. We will issue a designated container and instructions for 24-hour urinary collection. Subjects will be asked to note the start time in a written log and discard the first urine, then collect all urine over the next 24 hours, noting the time and amount excreted for each collection in the written log. Stored urine will not require refrigeration. In total, 4.0 mL of peripheral blood will be drawn into an anticoagulant tube during baseline visit. The anticoagulant tube will be centrifuged at 4000 rpm at 4 °C for 10 minutes. The Illumina Infinium system will be used for high-throughput genotyping of SNPs using microarrays. The 24-hour urine sample will be analyzed using the targeted capillary electrophoresis/mass spectrometry method for 48 amino metabolites.

Group Conditions

The intervention consists of 8 educational sessions (45 minutes each) delivered via a videoconferencing program and accessed through personal computer or smartphone at participants' preferred time. In the control condition, 20 subjects will receive their routine medical and nursing care for hypertension and take medications as prescribed. In both groups, over the 8-week intervention, participants will be allowed in digital self-monitoring using Fitbit, its companion app, and wireless BP monitor (Table 3).

XSL•FO
RenderX

Table 3. Major content of intervention sessions.

Session	Content
1. Getting started and blood pressure overview	• Introduction to the program • Education about blood pressure and hypertension • Discussion of symptoms and complications for uncontrolled hypertension
2. A low-sodium diet and digital self-monitoring	• Education about a low-sodium diet in hypertension • Discussion of the importance of digital self-monitoring of diet and taking blood pressure at home
3. Gradual dietary sodium reduction	• Education about the rationale for gradual adaptation strategy, physical gradual adaptation process in taste buds, and psychological adaptation process • Setting up weekly goals in gradual adaptation
4. Strategies to overcome barriers to adhere to a low-sodium diet	• Education about individual's barriers to adhere to a low-sodium diet including cooking, eating out at restaurants, grocery shopping, salt substitutes or seasonings, fast food choice, and menu development
5. Food labels and sodium	• Education about reading food labels and nutrition facts • Facts about salt and sodium, and tips for how to lead a low-sodium life • Revisiting the gradual sodium reduction goal
6. Serving sizes and portion control	• Discussion about serving sizes, portion control, and the plate method • Reviewing the gradual sodium reduction goal
7. Meal planning, shopping, and eating out	• Discussion of planning for meals and tips for shopping and eating out • Checking in on goal progress
8. Planning for lasting change	• Review of overall program content • Discussion of what worked with a low-sodium diet adherence • Planning for lasting change activity

Follow-up Data Collection

After completion of the intervention, the PI will ask all participants to measure BMI, BP, and collect a 24-hour urine sample to measure sodium excretion in the same manner as the baseline.

Data Analytic Plan

Data analysis will be performed with SAS (version 9.4; SAS Institute) and R (version 4.1+; RStudio, Inc). Baseline demographic information will be summarized using descriptive statistics. Continuous variables will be summarized with means and SDs. Categorical variables will be summarized with counts, proportions, and medians (IQR). The distribution of all variables will be examined before any analysis, using appropriate statistical tests like the Shapiro test for normality checking. If the assumption of normality is not met, equivalent nonparametric approaches or data transformation will be used; for instance, log transformation can be conducted to the metabolomics profile before standardized to unit variance and zero mean. The multiple testing problem will be accounted for using Bonferroni correction or the Benjamini-Hochberg procedure: for example, the false discovery rate will be controlled when testing multiple urinary metabolites. All testing will be 2-sided, and a P value of .05 will be used as the family-wise significance level. If needed, statistical analysis will also be conducted after controlling for age, sex, and BMI.

Aim 1

Using both pre- and posttest data, we will assess feasibility by measuring (1) the percentage of subjects present at the 8-week follow-up, (2) the number of education sessions attended on the internet (intervention group), (3) the percentage of days subjects logged meals using a mobile dietary app; and (4) the percentage of days subjects logged in-home BP measurements with the BP monitoring device. We will test the preliminary effect of a low-sodium diet on the outcome variables using a generalized estimating equation model to account for the repeated measures over 8 weeks, which includes fixed effects of time (baseline and 8 weeks) and study arm (intervention or control), an interaction term for time by arm, and other covariates such as age. The interaction term will be tested to assess whether the changes from baseline differ by groups.

Aim 2

Using pretest data, a random forest [31] using R (version 4.2.0) will be used to identify associations between 48 amino metabolites, BP phenotypes (including SBP or DBP), and 24-hour urinary excretion to predict the classification of study subjects. For urinary metabolites nominated by the random forest analysis, we will use generalized linear model to generate P values and false discovery rate to correct for testing multiple urinary metabolites using the Benjamini-Hochberg procedure.

Results

To date, interventionist training is completed. The first participant was enrolled in April 2021, and currently, 26 participants were enrolled. All data collection is expected to conclude by March 2023, with data analysis and study results ready for reporting by December 2023. The findings from this

XSL•FO
RenderX

pilot randomized controlled trial (RCT) will further guide the team in planning a future large-scale study.

Discussion

Findings and Implications

This report describes the protocol and design of a pilot RCT of a low-sodium diet intervention leveraging digital self-monitoring of daily diet and BP among patients with hypertension. We hypothesize that excessive sodium intake in individuals with hypertension can be modified with nutritional advice in addition to real-time diet and BP tracking and daily trends. Participants in the intervention group are anticipated to have a greater reduction in dietary sodium intake and BP than those in the control group. This study is the first attempt to develop a rigorously designed, low-sodium diet intervention to enhance metabolite response and dietary adherence for this vulnerable population. In addition, by examining metabolites to BP response and outcomes to a low-sodium diet, the findings of this study may establish a comprehensive knowledge base for future research and the development of precise and personalized nutrition regimens for high-risk individuals who are vulnerable to the negative effects of sodium on BP control based on genetic phenotypes and metabolite profiles. The findings of this proposed study will establish a comprehensive knowledge base for future research and development of personalized dietary interventions to promote adherence to dietary strategies and self-management of chronic disease using the Precision Health approach for millions of Americans who are struggling with uncontrolled hypertension.

Strengths and Limitations

First, this study is a pilot randomized trial, the sample size is relatively small, and we are not adequately powered to detect statistical significances between groups. Second, study recruitment and retention will likely be the most challenging aspect, given the multiple web-based lessons and self-monitoring activities. We will monitor recruitment monthly, and if lagging, will expand recruitment clinics. We will also encourage enrollment by compensating participants with a US $30 gift card for completing each visit. We will use multiple strategies (eg, being flexible for scheduling appointments and sending motivational messages) to address and reduce dropout. By providing flexibility, we are successfully maintaining the enrollment of participants in the current pilot study over 8 weeks without dropout. Finally, potential confounding factors were not analyzed: randomization should address differences in other factors that may affect BP, such as physical activity, sleep, and comorbidity. These factors will be measured in a larger study.

Nonetheless, this study represents an initial step to examine the metabolite responses to integrating the use of mobile technology and metabolomics with a low-sodium diet intervention in patients with hypertension to develop personalized low-sodium diet programs. If the results are promising, this may serve as an important milestone in considering how to develop and implement personalized low-sodium diet interventions in millions of Americans who struggling with uncontrolled hypertension. The findings from this study will also serve as the foundation for a large full-scale RCT to test the program in a broad population.

Acknowledgments

The project described was supported by the National Center for Advancing Translational Sciences, National Institutes of Health, through Grant KL2 TR002646.

Abstract

Background: Extensive research suggests that physical activity (PA) is important for brain and cognitive health and may help to delay or prevent Alzheimer's disease and related dementias. Most PA interventions designed to improve brain health in older adults have been conducted in laboratory, gym, or group settings that require extensive resources and travel to the study site or group sessions. Research is needed to develop novel interventions that leverage mobile health (mHealth) technologies to help older adults increase their engagement in PA in free-living environments, reducing participant burden and increasing generalizability of research findings. Moreover, promoting engagement in moderate-to-vigorous PA (MVPA) may be most beneficial to brain health; thus, using mHealth to help older adults increase time spent in MVPA in free-living environments may help to offset the burden of Alzheimer's disease and related dementias and improve quality of life in older age.

Objective: We developed a novel PA intervention that leverages mHealth to help older adults achieve more minutes of MVPA independently. This pilot study was a 12-week randomized controlled trial to investigate the feasibility of providing just-in-time (JIT) feedback about PA intensity during free-living exercise sessions to help older adults meet current PA recommendations (150 minutes per week of MVPA).

Methods: Participants were eligible if they were cognitively healthy English speakers aged between 65 and 80 years without major cardiovascular, neurologic, or mental health conditions; could ambulate independently; and undergo magnetic resonance imaging. Enrollment occurred from October 2017 to March 2020. Participants randomized to the PA condition received an individualized exercise prescription and an mHealth device that provided heart rate–based JIT feedback on PA intensity, allowing them to adjust their behavior in real time to maintain MVPA during exercise sessions. Participants assigned to the healthy aging education condition received a reading prescription consisting of healthy aging topics and completed weekly quizzes based on the materials.

Results: In total, 44 participants were randomized to the intervention. A follow-up manuscript will describe the results of the intervention as well as discuss screening, recruitment, adverse events, and participants' opinions regarding their participation in the intervention.

Conclusions: The long-term goal of this intervention is to better understand how MVPA affects brain and cognitive health in the real world and extend laboratory findings to everyday life. This pilot randomized controlled trial was conducted to determine

XSL•FO
RenderX

the feasibility of using JIT heart rate zone feedback to help older adults independently increase time spent in MVPA while collecting data on the plausible mechanisms of change (frontal and medial temporal cerebral blood flow and cardiorespiratory fitness) that may affect cognition (memory and executive function) to help refine a planned stage 2 behavioral trial.

Introduction

Background

It is projected that Alzheimer's disease and related dementias (ADRD) diagnoses in people aged ≥65 years will increase by 22% from 2020 to 2025 [1]. Given the lack of effective treatments for ADRD, interventions that focus on healthy lifestyle choices to prevent cognitive decline and bolster brain health are important. In this regard, the evidence suggests that the modifiable lifestyle factors most strongly associated with ADRD risk include midlife obesity, physical inactivity, and low education [2] and that approximately 21% of Alzheimer's disease cases in the United States are thought to be attributable to physical inactivity [3]. Importantly, up to 40% of dementia cases could be prevented by management of modifiable risk factors, including physical inactivity [4]. Moreover, strong evidence links physical activity (PA) with a reduction in age-related cognitive decline and dementia risk [4-6]. For example, higher PA is associated with 14% lower risk of dementia when compared with those with lower levels of PA [7], whereas, compared with sedentary individuals, even low-to-moderate PA has been associated with a 35% reduction of risk for cognitive decline [8]. Despite this, just 46% and 32.3% of individuals aged 65 to 74 years and ≥75 years, respectively, met the 2008 Physical Activity Guidelines for Americans [9], and 29.4% of people aged ≥65 years reported performing no PA other than their job in the past 30 days in 2020 [10]. The 2018 Physical Activity Guidelines for Americans issued by the US Department of Health and Human Services recommend that older adults achieve at least 150-300 minutes per week of moderate-intensity PA or 75-150 minutes per week of vigorous-intensity PA, perform muscle-strengthening activities on ≥2 days per week, do balance training, and “move more and sit less” throughout the day [11,12]. Traditionally, the cognitive and ADRD-preventing benefits of PA have been more strongly linked to changes in moderate-to-vigorous PA (MVPA) [13] that can lead to improvements in cardiorespiratory fitness [14,15]. As such, interventions that target MVPA are needed to help older adults achieve current PA guidelines and prevent ADRD in late life.

It should be noted that most interventions that investigate how changes in MVPA affect cognition and brain health have been conducted in controlled settings or under supervised conditions. These interventions are difficult to implement on a large scale and are less generalizable than those conducted in a person’s natural environment. Research is needed to develop novel interventions to help older adults increase their engagement in MVPA in free-living environments. Notably, mobile health (mHealth) technology (eg, smartwatches and heart rate trackers) can help fill this gap and extend laboratory findings to the real world by helping older adults achieve PA recommendations independently, reaching more individuals, and potentially increasing adoption and adherence [16,17].

To maximize the efficacy of mHealth interventions, there is a need for these technologies to offer adaptive and just-in-time (JIT) feedback to help individuals change their behavior in real time [18,19], as well as provide social support to help promote behavior change [20]. For example, leveraging heart rate tracking to provide JIT support about PA intensity in real time during an exercise session can cue individuals to change their walking pace accordingly and spend more time in MVPA during an exercise bout. This JIT support can also help with self-monitoring, which is an important component of successful mHealth PA interventions [20]. Although mHealth use may at times be challenging for some older adults, there is low-to-moderate evidence that mHealth interventions may help to increase PA in older adults in the short term [20], and research supports the effectiveness of mHealth approaches in those aged ≥50 years [21]. Similarly, tracking with mHealth devices has been shown to enhance the positive effect of PA levels on satisfaction with physical fitness [22], and older adults find that mHealth devices that provide JIT feedback can help them to walk faster during free-living exercise sessions [23]. Overall, research suggests that mHealth can facilitate behavior change in older age [24-26].

Objectives

The Independent Walking for Brain Health study was a 12-week small pilot randomized controlled trial (RCT) conducted to determine the feasibility of using JIT heart rate–based feedback to help older adults independently meet PA recommendations of 150 minutes of MVPA per week [12,27], while collecting data on the plausible mechanisms of change (frontal and medial temporal cerebral blood flow [CBF] and cardiorespiratory fitness) that may affect cognition (memory and executive function) to help refine a planned stage 2 behavioral trial. We hypothesized that the heart rate–based JIT feedback would help older adults to increase the time they spent in MVPA during free-living exercise sessions [23]. The long-term goal of this intervention is to better understand how MVPA affects brain and cognitive health in the real world and extend laboratory findings to everyday life. Participants randomized to the PA

XSL•FO
RenderX

condition (PAC) were provided with personalized walking prescriptions, weekly performance summary emails, goal setting, and regular telephone calls from study staff to review achievements and revise goals if needed. JIT mHealth strategies included immediate haptic and visual alerts when the participants deviated from their individualized heart rate target zone during an exercise session. Participants in the healthy aging education condition (HAEC) received a reading prescription and answered quizzes based on the materials. We collected accelerometer data, cardiorespiratory fitness data, brain imaging data, and cognitive performance data to evaluate the feasibility of the study procedures, as well as daily-level heart rate data from the mHealth device that participants used to record their exercise sessions. This protocol paper describes the Independent Walking for Brain Health pilot RCT.

Methods

Study Procedures

The Independent Walking for Brain Health study was a 12-week free-living pilot RCT to determine the feasibility of using JIT heart rate–based feedback to help older adults independently meet PA recommendations of 150 minutes of MVPA per week. Participants who met the inclusion criteria (described in the next section) were randomly assigned to the PAC or HAEC and were provided with either a walking prescription or a reading prescription, respectively. All aspects of the intervention took place remotely, aside from the measurement visits, which were conducted at the University of California San Diego at baseline, 6 weeks, and 12 weeks. More details about each component of the intervention and the measures collected are described in the sections that follow. Table 1 shows the assessments collected and the time interval in which they were administered. Figure 1 depicts the study flow and procedures.

Participant Recruitment and Inclusion Criteria

Participants were recruited from ongoing studies at the Wellness Initiative for Senior Enrichment laboratory at the University of California San Diego and the Shiley-Marcos Alzheimer's Disease Research Center, as well as from ResearchMatch [28], flyers, community engagement talks (ie, talks at retirement communities, senior centers, libraries, and health fairs) and by word of mouth. All participants were enrolled between October 2017 and March 2020, at which time study recruitment was terminated because of the COVID-19 pandemic.

All potential participants were prescreened via telephone to determine basic eligibility, which included (1) age between 65 and 80 years, (2) able to obtain a signed physician's clearance for participating in PA, (3) English speaking, (4) not meeting the current PA recommendations of 150 minutes of MVPA per week (via self-report), (5) not reporting contraindications for magnetic resonance imaging (MRI), and (6) able to ambulate independently. Participants were excluded if they had (1) objective evidence of cognitive impairment during the telephone screen (scores ≤34 on the modified Telephone Interview for Cognitive Status [29]) or during baseline (first in-person visit) neuropsychological testing (performance >1 SD below demographically adjusted norms on at least 2 measures within the same cognitive domain [30]); (2) history of head injury involving loss of consciousness within the past 6 months; (3) major neurological disorders (eg, dementia, multiple sclerosis, or epilepsy); (4) chronic major psychiatric disorders (eg, schizophrenia or bipolar disorder); (5) history of major vascular events (eg, myocardial infarction or stroke); (6) history of diabetes; (7) history of falls in the last year resulting in hospitalization; and (8) unstable or severe medical problems (eg, uncontrolled heart failure or hypertension, pulmonary disease with hypoxia or hypercapnia, significant liver problems, or renal failure), treatment of cancer (other than nonmelanoma skin cancer) in the past 2 years, or were HIV positive.

Ethics Approval

All study procedures were reviewed and approved by the institutional review board of the University of California, San Diego (IRB #151278), and abided by the declaration of Helsinki. Written informed consent was gathered from all participants after a thorough discussion of the risks and benefits of participating in the program. All data were deidentified and maintained in a Health Insurance Portability and Accountability Act–compliant server (Research Electronic Data Capture [REDCap]; Vanderbilt University). All participants were compensated up to US $200 for participating in the in-person study visits.

Study Design

The Independent Walking for Brain Health pilot study was a 12-week RCT designed to test the feasibility of using an mHealth device to assist older adults independently achieve recommended PA guidelines (≥150 minutes per week of MVPA) in their free-living environments. Only the participants randomized to the PAC received an individualized exercise prescription and a commercially available mHealth device that provided heart rate–based JIT feedback regarding PA intensity during exercise sessions. Those assigned to the HAEC received a reading prescription about healthy aging topics and completed weekly quizzes based on the materials. More details are provided in the following sections.

Randomization Procedures

We planned to recruit 60 older adults to be randomized to the HAEC (n=30, 50%) or PAC (n=30, 50%). Because of the COVID-19 pandemic, only 44 participants were randomized before study termination, with 23 (52%) in the HAEC and 21 (48%) in the PAC. Stratified blocked randomization was used to ensure a similar balance of age (block 0: 65-72 years and block 1: 73-80 years) and sex (block 0: male and block 1: female) between the intervention conditions (block 0: HAEC and block 1: PAC). The randomization table was generated by an independent statistician and uploaded to the REDCap database. Participants were randomized to the PAC or HAEC after completing their first baseline visit to ensure that they met our cognitive testing inclusion criteria and were able to safely perform the cardiorespiratory fitness test. Participants who did not meet our cognitive testing inclusion criteria or did not pass the treadmill test were withdrawn from the study before randomization (Figure 1). Randomization was performed by the REDCap database using the randomization schedule randomly created by the statistician. Given the pilot nature of

XSL•FO
RenderX

the study, the principal investigator (PI) and measurement staff were not blinded to the participants' assigned condition.

Intervention Arms

PAC Description

The main goal of the PAC was to use the mHealth device as a *coach* to provide JIT support to prompt real-time changes in PA intensity to maintain MVPA. Participants received individualized walking prescriptions based on heart rate targets equivalent to MVPA obtained from submaximal graded exercise testing (GXT) at baseline. As such, each participant's heart rate target for the MVPA prescription was different based on their GXT performance (described in the Measures section). The individualized exercise prescriptions were built to gradually increase the intensity of PA and the number of minutes spent in MVPA to 150 per week. Refer to Table 2 for an example of the exercise prescription. Although the prescriptions were based on walking, participants were encouraged to perform any purposeful activity that increased their heart rate above their individualized minimum target equivalent to MVPA. Participants who did not meet the weekly number of MVPA minutes in the prescription during a given week were encouraged to increase MVPA by 10 minutes the following week. The exercise prescription also included prompts for performing strength and flexibility exercises weekly (ankle circles, toe lifts, partial stands, knee flexion and extension, and wrist, shoulder, calf, and shin stretches) accompanied by pictures and descriptions to guide participants on how to perform these exercises safely at home. As our focus was on increasing MVPA, we did not track progress or engagement in the strength and flexibility exercises.

Table 2. Exercise prescription. Prescribed number of minutes per week within each intensity level.

Intervention week	Slow minutes	Moderate minutes	Fast minutes	MVPA[a] (moderate+fast) minutes	All active minutes per week

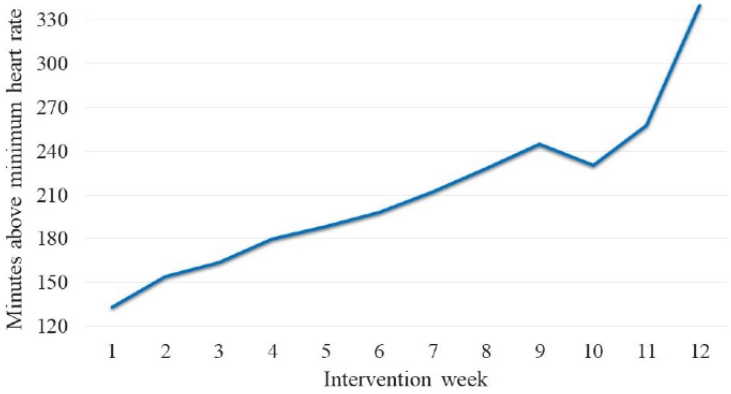
10	0	115	35	150	150
11	0	125	35	160	160
12	0	125	35	160	160



[a]MVPA: moderate-to-vigorous physical activity.

During the randomization visit, participants in the PAC received their individualized walking prescriptions, the mHealth device, and a folder containing readings about PA, safety, and troubleshooting the mHealth device, as well as important contact information and a detailed schedule of upcoming telephone calls and in-person appointments. Participants were also coached on how to use the mHealth device and respond to the JIT feedback during a walking session with study staff. Participants received a weekly personalized email summarizing the number of minutes spent in MVPA for that week (Figure 2), which also delineated their MVPA goal for the following week. Weekly telephone calls from study staff (ZZZ, the PI, who is a licensed clinical neuropsychologist) lasted 10 to 15 minutes and were conducted during the first month, followed by biweekly calls during months 2 and 3. The telephone calls focused on reviewing the minutes of MVPA achieved, identifying challenges to engaging in exercise, revising goals as needed, and checking on each participant's safety.

At home, the mHealth device tracked participant heart rate during each exercise session, providing JIT haptic and visual feedback in real time (blue=below zone, green=in zone, and red=above zone) when they deviated from their prescribed heart rate target zone. This allowed them to correct their walking pace or exercise intensity in real time. Participants were encouraged to exercise above their minimum heart rate equivalent to MVPA, but they were not discouraged from going above their target zone if they felt it was safe to do so. Minute-by-minute heart rate data gathered from the mHealth device was saved to the device and later synced with the corresponding app and emailed to the study team on a regular basis. This helped with accountability and tracking by the study team to provide weekly feedback about progress via emails and telephone calls. Participants' perspectives about using the mHealth device in this study have been described elsewhere [23].

XSL•FO
RenderX

Figure 2. Example progress graph emailed weekly to participants in the physical activity condition to review moderate-to-vigorous physical activity goals and set new goals for the following week. The y-axis shows the number of minutes the participant spent above their minimum moderate-to-vigorous physical activity heart rate target for each week based on tracking from the mobile health device. The x-axis depicts the treatment week.

HAEC Description

Participants assigned to the HAEC received a reading prescription that equated the time spent reading study materials to the time those in the PAC spent engaging in PA (approximately 2.5 hours per week). The reading prescription consisted of 50 short or bulleted chapters to be completed over 12 weeks on topics that included retirement, quality of life, talking to your physician, bladder health, pain, preventing falls, legal and financial planning, heart health, nutrition, stress management, and humor. There were 4 to 5 chapters (the number of chapters varied based on chapter length) emailed to participants every week, which they could read at their own pace. Participants received a weekly quiz via REDCap that required them to answer 3 to 5 questions about each chapter to measure adherence to the reading prescription. Participants received weekly telephone calls from study staff during the first month, followed by biweekly calls during months 2 and 3. The purpose of the telephone calls, which lasted 5 to 10 minutes, was for the participants to receive equal amounts of attention from study staff between the conditions as well as for the study staff to answer any questions related to the materials and check on the participant's health status. All the chapters were prepared by the investigative team using materials freely available from the National Institute on Aging and Alzheimer's Association websites among other reputable sources. Textbox 1 lists the reading prescription topics assigned per month.

Textbox 1. Reading prescription topics assigned to participants in the healthy aging education condition.

Month and topics
1. Retirement, driving, immunizations, health care, prostate and bladder health, pain, memory, eye health, medications, heart health, disability, taste, smell, frontotemporal disorders, quality of life, and talking to your physician
2. Mental health, dementia, preventing falls, antiaging tips, leukemia, disease prevention, hearing loss, arthritis and osteoporosis, legal and financial planning, mild cognitive impairment, Alzheimer's disease, lifestyle and longevity, sexual health, high blood pressure, Alzheimer's disease caregiving, and humor
3. Heart disease, stress management, gum disease, alternative medicine, headaches and migraines, diabetes, myocardial infarction, nutrition, preventive medicine, skin care and aging, sleep and aging, social media, stroke, constipation, hydration, food for thought, and happiness in the home and the community

Measures

Cognitive Testing

In a quiet room with a trained study staff member, participants completed the Mattis Dementia Rating Scale [31]; the National Institutes of Health (NIH) Toolbox Cognition Battery [32] (including the optional Oral Symbol Digit Test); the Rey Auditory Verbal Learning Test (RAVLT) [33]; the Golden version of the Stroop Color Word Interference Test [34]; the Wechsler Memory Scale-revised Logical Memory I and II [35]; Trail-Making Test parts A and B [36]; and verbal fluency tests (FAS Test [assessment of phonemic fluency by requesting an individual to orally produce as many words as possible that begin with the letters F, A, and S within 1 minute] and animal naming) [37]. As executive and memory functions are most responsive to exercise in intervention trials with older adults [14], we created executive and memory composite scores by converting raw scores into *z* scores based on the entire sample, and then averaging across *z* scores for the following tests:

- Executive composite scores: Trail-Making Test part B minus Trail-Making Test part A (scores were reversed before averaging to reflect higher scores=better performance), Stroop Color Word Trial, and verbal fluency FAS Test
- Memory composite scores: Wechsler Memory Scale-revised Logical Memory I and II; RAVLT trials 1 to 5, trial 6 (short-delay free recall), and RAVLT delayed recall

We picked these measures because they have previously been reported in the PA intervention literature and have been shown to change as a function of exercise [14].

XSL•FO
RenderX

PA Measurement

PA was measured using triaxial accelerometers (GT3X; ActiGraph, LLC) for 7 consecutive days [38,39]. Participants were instructed to wear the accelerometer on a belt on their hip during waking hours for a minimum of 12 hours per day. They were also instructed not to change their regular activities. To ensure compliance, all participants received 2 telephone calls from study staff (on days 2 and 5 of the monitoring period). Participant data were considered valid only if they had accumulated a minimum of 600 minutes of accelerometer wear per day and a minimum of 3000 total minutes of wear spread across at least 4 valid days. Data were processed using ActiLife software (version 6.0; ActiGraph, LLC). Using the low-frequency extension option thought to be most appropriate for older adults [40], data were aggregated to 60-second epochs so that published cut points could be applied. Consistent with standard practice, sedentary time was defined as time spent at <100 counts per minute and MVPA as ≥1952 counts per minute [41]. Minutes within each intensity level were then averaged across days worn, reflecting the average time in minutes per day spent at each intensity level.

Cardiorespiratory Fitness Measurement and Heart Rate Target Zones for the Exercise Prescription

Cardiorespiratory fitness was measured via submaximal GXT protocol at baseline and at 12 weeks. During the treadmill test, heart rate was plotted against the workload and its corresponding estimated VO_2 [42], and VO_2 max was estimated plotting the slope of the line to estimated maximal heart rate (calculated using the formula 220–age). A 1-minute warm-up at 2 mph (3.2 km/h) was used to familiarize participants with the treadmill and give them time to adjust to walking without holding the handrails. After the warm-up, the speed was increased to 2.5 mph (4 km/h) at 0% grade, equivalent to 2.9 metabolic equivalents (METs), which is just below the threshold for moderate-intensity exercise. This stage lasted 3 minutes to ensure that steady state was achieved. The speed was then increased to 3 mph (4.8 km/h) at 0% grade, equivalent to 3.3 METs, which is just above moderate-intensity exercise. This stage lasted 5 minutes. One-minute stages with grade increments of 1.5% (0.62 METs) per stage continued until the participant's heart rate reached volitional fatigue. Heart rate was monitored continuously using a Polar heart rate monitor (Polar FT4 or similar; Polar Electro) throughout the test and for at least 5 minutes of recovery. Blood pressure was recorded for the first 3 stages of exercise and every minute during recovery, at which time participants continued walking at a very slow pace (1 mph; 1.6 km/h) for 2 minutes, followed by 3 minutes of sitting recovery with light foot tapping to prevent venous pooling.

The heart rates measured during the final 10 seconds of minutes 7 and 9 of the GXT were used to determine heart rate target zones for the exercise prescription.

These heart rate measurement times occurred during stage 3 (3 mph; 4.8 km/h) at which participants are estimated to be working at a level equivalent to 3.3 METS, a threshold slightly higher than the minimum level to be considered *moderate* activity. Minutes 7 and 9 of the total protocol were chosen because of the likelihood that participants would have reached *steady state* after ≥3 minutes at that workload. Steady state is the point at which the heart's work is equal to the workload and is unlikely to change with increased exercise duration. For exercise prescription purposes, the 2 heart rate values gathered during minutes 7 and 9 of the total protocol were averaged if the difference was ≤3 beats per minute, and the greater of the 2 heart rates was used if the difference was >3 beats per minute. Participants were asked to refrain from consuming caffeine or other stimulants on the day of their test.

For this pilot RCT, we were interested in examining the plausible mechanisms by which changes in MVPA may affect cognition, including changes in cardiorespiratory fitness. We defined changes in cardiorespiratory fitness as the total time to 85% of estimated maximal heart rate (with an exception made for participants taking β-blockers, as described later in this paragraph) and changes in rate-pressure product (RPP), which is the product of heart rate and systolic blood pressure divided by 100 measured toward the end of each of the first 3 stages of exercise. RPP is an indirect assessment of cardiac workload. A decrease in RPP for a given amount of aerobic work often signifies an improvement in cardiac function [43]. Individuals taking β-blockers were asked to exercise to a workload corresponding to 80% of their age-predicted maximal heart rate. This precaution accounts for the approximately 5% reduction in heart rate observed with taking β-blockers and allowed the research team to provide scaled exercise prescriptions.

Brain MRI Measurement and Processing

MRI data were acquired on a GE Discovery MR750 3.0T (General Electric Company) whole body system with a body transmit coil and an 8-channel receive-only head coil at the University of California, San Diego Center for Functional MRI. The structural brain sequence consisted of a high-resolution T1-weighted fast spoiled gradient echo (3DFSPGR) scan for anatomy and registration purposes: 172 1-mm contiguous sagittal slices, field of view=25 cm, repetition time (TR)=8 ms, echo time (TE)=3.1 ms, flip angle=12°, inversion time=600 ms, 256 × 192 matrix, bandwidth=31.25 kHz, frequency direction=S-I, NEX=1, and scan time=8:13 minutes. CBF was quantified with a 2D pseudocontinuous arterial spin labeling (ASL) MRI sequence: TR=4500 ms, TE=3.2 ms, field of view=24 cm, labeling duration=1800 ms, postlabeling delay=2000 ms, with a single-shot spiral acquisition and a total scan time of 4:30 minutes plus a 40.5-second calibration scan. The calibration scan was acquired immediately after the ASL scan using a spiral readout with TR=4.5 seconds and TE=3.2 ms with 8 dummy radiofrequency pulses (amplitude set to 0) to generate a 36-second delay followed by a 90-degree radiofrequency pulse in the last repetition interval to generate proton density–weighted contrast. Field map scans were collected for offline field map correction to minimize signal bunching and dropouts in the frontal or medial temporal lobes.

T1-weighted anatomical images were processed using FreeSurfer software (version 6.0). Briefly, images underwent skull stripping, B1 bias field correction, segmentation of gray matter and white matter, reconstruction of cortical surface models, and parcellation and labeling of regions on the cortical surface, as well as segmentation and labeling of subcortical

XSL•FO
RenderX

structures [44]. FreeSurfer was also used to generate intracranial volume. ASL data were processed using the Cerebral Blood Flow Biomedical Informatics Research Network (CBFBIRN) [45] pipeline established by the University of California, San Diego Center for Functional MRI. CBFBIRN uses a combination of custom MATLAB (The MathWorks, Inc) [46] routines and various Analysis of Functional NeuroImages [47] and FMRIB Software Library [48] functions to quantify CBF and adjust for partial volume effects. MATLAB was used to form a mean ASL image from the average difference of the control and tag images. Voxelwise CBF calibration was performed using the proton-density image to convert the ASL difference signal into physiological units (mL/100 g/min). Slice-timing delays were also accounted for, making the postlabeling delay slice specific. Skull stripping of the high-resolution T1-weighted image was performed using the Analysis of Functional NeuroImages 3dSkullStrip function. Tissue segmentation was performed using the FMRIB Software Library Automated Segmentation Tool algorithm to define cerebrospinal fluid, gray matter, and white matter regions. The high-resolution T1-weighted image and partial volume segmentations were registered to ASL space. A linear regression method was used to correct for partial volume effects and ensure that CBF values were not influenced by decreased perfusion in the white matter or increased volume of cerebrospinal fluid [49], with a 5 × 5 regression kernel to obtain corrected gray matter CBF measurements. Each participant's partial volume–corrected quantified CBF map (in units of mL/100 g tissue/min) was downloaded to a local server. Voxels with negative intensities were replaced with 0. FreeSurfer was used to generate a priori anatomical regions of interest for the CBF data. Briefly, for each participant, the FreeSurfer-formatted T1-weighted brain volume was registered to the ASL CBF-aligned T1-weighted anatomical image (the latter was derived as part of the CBFBIRN pipeline). The resulting coregistration matrix was used to align the FreeSurfer aparc+aseg segmentation volume to the ASL CBF-aligned T1-weighted image. The CBF-aligned FreeSurfer volumes were visually inspected to ensure proper alignment and were then downsampled to the resolution of the CBF ASL image. Mean CBF was then extracted for FreeSurfer regions of interest. For this pilot RCT, we were interested in examining the plausible mechanisms by which changes in MVPA may affect cognition, including changes in total gray matter CBF, frontal lobe CBF (mean of superior frontal, rostral and caudal middle frontal, pars opercularis, pars triangularis, pars orbitalis, lateral and medial orbitofrontal, precentral, paracentral, and frontal pole CBF), and medial temporal lobe CBF (mean of entorhinal, parahippocampal, and hippocampal CBF).

Apolipoprotein E Measurement

Saliva samples were collected using the Isohelix SK-2S DNA buccal swab kit (Cell Projects Ltd) to provide information regarding genetic risk for Alzheimer's disease. Genotype for apolipoprotein E was determined by real-time analysis of single nucleotide polymorphism using TaqMan technology (Life Technologies). The real-time analysis was performed using validated TaqMan assays on a CFX96 Touch Real-Time Polymerase Chain Reaction Detection System (Bio-Rad Laboratories, Inc) according to the manufacturer's instructions. Analysis was performed using Bio-Rad CFX Manager software.

Monitoring Adverse Events and Data Safety and Monitoring Plan

All adverse events were carefully monitored via telephone contact with participants throughout the trial and were reported to the institutional review board of the University of California, San Diego, and the National Institute on Aging program official according to NIH guidelines. A data safety and monitoring plan was developed for this study focusing on close monitoring by the PI (ZZZ) and research staff, in conjunction with oversight from a safety officer (AAM, a practicing geriatrician). A future publication of the pilot trial's results will report all adverse events.

Data Management and Quality Control

All study staff completed NIH-required human research participants training as well as thorough training by the study PI (ZZZ) on how to perform telephone screenings, administer and score the cognitive tests, and interact with participants, as well as on ethical aspects of clinical trials research and safe data monitoring practices. All cognitive testing data were double scored by 2 different staff members and entered into the REDCap database, which was also double-checked for accuracy. Accelerometer and cardiorespiratory fitness data were collected by professionals at the University of California, San Diego Exercise and Physical Activity Resource Center, which specializes in collecting these measurements with highly trained exercise physiologists. All brain imaging data were collected and analyzed by highly trained study personnel, including the PI. Study protocols were strictly followed to ensure scientific rigor and allow for reproducibility.

Results

Enrollment for this study began in October 2017 and was terminated early in March 2020 as a result of the COVID-19 pandemic. In total, 44 participants were randomized to the intervention, with 21 (48%) in the PAC and 23 (52%) in the HAEC. In keeping with the CONSORT (Consolidated Standards of Reporting Trials) guidelines for pilot and feasibility trials [50,51], the results from this pilot intervention will focus on discussing the feasibility of the JIT mHealth alerts to increase MVPA, presenting estimates of variability in response to the outcome and plausible mechanisms, presenting recruitment and retention numbers and challenges, discussing adherence by study condition, discussing adverse events, discussing the ability to implement the intervention or lessons learned, and summarizing the participants' opinions regarding the intervention. The results, which will be reported in a separate manuscript, will inform the optimization of a planned stage 2 behavioral intervention trial to help maintain cognitive function through increases in MVPA using mHealth.

Discussion

Overview

This protocol paper describes the Independent Walking for Brain Health pilot RCT. The study was an innovative mHealth trial to determine the feasibility of using heart rate–based JIT feedback to help older adults maintain MVPA during free-living exercise sessions. This pilot trial also explored the mechanisms, namely changes in CBF and cardiorespiratory fitness, by which increasing MVPA via JIT alerts may influence cognitive function. Between October 2017 and March 2020, a total of 44 participants were randomized to the intervention, with 21 (48%) in the PAC and 23 (52%) in the HAEC. A follow-up manuscript will describe the results of the pilot intervention.

The literature shows that MVPA, performed under supervised conditions (in the laboratory, gym, or supervised by a trainer) is important for maintaining brain health [52-55] and can boost cognitive performance in older age [56-59]. However, there is a lack of interventions that leverage mHealth to help older adults increase their engagement in MVPA independently, which would generalize study findings to the real world and remove some of the barriers to performing PA (eg, travel to the gym and monetary constraints). This pilot RCT is the first step in the refinement of a future stage 2 behavioral trial to help older adults achieve and maintain MVPA independently to help support their cognition and brain health. The findings from this pilot RCT will help inform the larger trial and refine the plausible mechanisms of change, as well as determine whether JIT heart rate–based feedback can help older adults to increase time spent in MVPA independently.

Limitations

The pilot study includes the following limitations:

1. A short intervention time (12 weeks), which is not sufficient to observe changes in cognitive function [60]. Future mHealth interventions should be of longer duration.
2. The mHealth device used in this study was not specifically designed for older adults. Future trials should use devices that have been tested with older adults to increase the likelihood of adherence to, and acceptability of, the intervention.
3. Importantly, this trial focused on promoting only MVPA because evidence suggests that MVPA is needed to maintain brain health and perhaps prevent ADRD [13]. That said, we did encourage participants to perform stretching and toning exercises twice per week (and provided them with related materials) to follow the current PA guidelines.
4. Most recently, dementia prevention interventions have followed a multimodal approach, targeting several lifestyle factors such as diet, sleep, and cognitive training along with PA [61-67]. This study is limited in targeting only MVPA as a tool to promote brain health; however, data gathered from this study will be useful to determine whether using JIT heart rate–based feedback via mHealth successfully increases MVPA in free-living environments, which could be implemented in future multimodal interventions.

Conclusions

In conclusion, the findings from this pilot RCT can inform future mHealth interventions that target MVPA to promote brain and cognitive health in older age and will help us to determine the utility of using JIT heart rate–based feedback to help maintain MVPA in free-living environments. Although more research is needed to determine the efficacy of JIT interventions to improve PA in older age, these interventions have the potential to be a powerful tool to help older adults lead healthier lifestyles [18,19,68]. Healthy lifestyles that include higher levels of MVPA are promising to ameliorate the burden of ADRD on the health care system and patients and their families, as well as improve the quality of life of older adults [4,63,69].

Acknowledgments

The research reported in this publication was supported by grants from the National Institute on Aging of the National Institutes of Health (K23AG049906 and R01AG066657) to ZZZ and a grant from the VA San Diego Healthcare System Center of Excellence for Stress and Mental Health and VA Health Services Research & Development Career Development Award (IK2CX002335) to CCHW. Support was also received from grants P30AG021684 and P30AG059299. The REDCap software system provided by the University of California, San Diego Clinical and Translational Research Center is supported by a grant from the National Center For Research Resources (UL1TR001442). The authors would like to acknowledge their research participants for volunteering their time and effort to advance scientific knowledge. The authors thank the students of the Wellness Initiative for Senior Enrichment laboratory who helped with data collection efforts. The authors also thank Zoe Mestre, Jessica Osuna, and Dr Jacqueline Kerr for their contributions. Finally, the authors thank the University of California, San Diego Shiley-Marcos Alzheimer's Disease Research Center for assisting with participant recruitment.

Abstract

Background: Over 700,000 people die by suicide annually, making it the fourth leading cause of death among those aged 15-29 years globally. Safety planning is recommended best practice when individuals at risk of suicide present to health services. A safety plan, developed in collaboration with a health care practitioner, details the steps to be taken in an emotional crisis. SafePlan, a safety planning mobile app, was designed to support young people experiencing suicidal thoughts and behaviors and to record their plan in a way that is accessible immediately and in situ.

Objective: The aim of this study is to assess the feasibility and acceptability of the SafePlan mobile app for patients experiencing suicidal thoughts and behaviors and their clinicians within Irish community mental health services, examine the feasibility of study procedures for both patients and clinicians, and determine if the SafePlan condition yields superior outcomes when compared with the control condition.

Methods: A total of 80 participants aged 16-35 years accessing Irish mental health services will be randomized (1:1) to receive the SafePlan app plus treatment as usual or treatment as usual plus a paper-based safety plan. The feasibility and acceptability of the SafePlan app and study procedures will be evaluated using both qualitative and quantitative methodologies. The primary outcomes are feasibility outcomes and include the acceptability of the app to participants and clinicians, the feasibility of delivery in this setting, recruitment, retention, and app use. The feasibility and acceptability of the following measures in a full randomized controlled trial will also be assessed: the Beck Scale for Suicide Ideation, Columbia Suicide Severity Rating Scale, Coping Self-Efficacy Scale, Interpersonal Needs Questionnaire, and Client Service Receipt Inventory. A repeated measures design with outcome data collected at baseline, post intervention (8 weeks), and at 6-month follow-up will be used to compare changes in suicidal ideation for the intervention condition relative to the waitlist control condition. A cost-outcome description will also be

XSL•FO
RenderX

undertaken. Thematic analyses will be used to analyze the qualitative data gathered through semistructured interviews with patients and clinicians.

Results: As of January 2023, funding and ethics approval have been acquired, and clinician champions across mental health service sites have been established. Data collection is expected to commence by April 2023. The submission of completed manuscript is expected by April 2025.

Conclusions: The framework for Decision-making after Pilot and feasibility Trials will inform the decision to progress to a full trial. The results will inform patients, researchers, clinicians, and health services of the feasibility and acceptability of the SafePlan app in community mental health services. The findings will have implications for further research and policy regarding the broader integration of safety planning apps.

Introduction

Background

More than 700,000 people die by suicide every year, representing the fourth leading cause of death among 15-29-year-olds globally in 2019 [1]. In Ireland, provisional figures indicate that 340 individuals died by suicide in 2020 [2]. Approximately one-third of people who die by suicide have been in contact with mental health services in the year before their death, and approximately 1 in 5 had contact with a health professional in the month before their death [3]. Suicide prevention guidelines recommend safety planning interventions alongside follow-up treatment by mental health services for those presenting to health services at risk of suicide [4]. However, the decision to implement safety planning in practice can be influenced more by clinicians' beliefs about their efficacy than by empirical research [5]. The transient nature of suicidal ideation [6] may challenge the feasibility of paper-based plans and suggests the need for alternative modalities.

Suicide Risk Factors

Suicidal behavior remains extremely difficult even for experienced clinicians to predict [7], leading researchers to focus their efforts on brief interventions designed for those at immediate risk [8]. A meta-analysis of 50 years of research in the area indicated that our predictive ability has not improved in that time and called for a shift from a focus on risk factors to machine learning–based risk algorithms [9]. The application of machine learning to large data sets may offer a means of better understanding the complex processes proposed by prominent theorists in the area [10,11]. Reflective of these research findings, recent clinical best practice guidelines recommend against the use of suicide risk assessment measures to predict future suicide or repeated self-harm in young people [12] and point to the importance of comprehensive psychosocial assessment and the development of a collaboratively developed and accessible safety plan.

Safety Planning Intervention

The safety planning intervention (SPI) developed by Stanley and Brown [13] is a collaborative safety plan developed with a trained practitioner and recorded using a paper-based document. It is a brief structured intervention widely used in health systems and is often cited as the best practice in the treatment of patients with a high risk of suicide [14]. SPI is a key component across multiple treatment approaches targeting suicidal behavior, such as collaborative assessment and management of suicidality and cognitive behavioral therapy for suicide prevention. A safety plan outlines the steps to take in an emotional crisis and includes the identification of personalized warning signs, internal coping skills, people and places that provide distraction, people to contact for support, and contact details to use in a crisis. A cohort comparison trial of patients in the emergency department in US veteran hospitals presenting with suicidality found that SPI and phone follow-up significantly reduced suicidal behaviors and increased treatment engagement [13]. A recent systematic review of the effectiveness of SPI for adults experiencing suicide-related distress indicated improvements in suicidality (ideation, behaviors, and death), suicide-related outcomes (depression and hopelessness), and treatment outcomes (hospitalization) [15].

Safety Planning Mobile Apps

Recording a safety plan on a mobile app may further enhance accessibility. The use of mobile devices by individuals at risk of suicide has been recommended by the World Health Organization [16]. The delivery of suicide prevention interventions through mobile health (mHealth) apps provides many opportunities when individuals need help the most [17]. SPI has been shown to be adaptable in its modality (digital or paper based) [15]. Further research is needed to better understand the extent to which using apps as an add-on to the treatment of patients with suicidal tendencies is feasible for clinicians and patients themselves. The MYPLAN safety planning app is undergoing clinical trial (ClinicalTrial.gov NCT02877316), and the Continuous Assessment for Suicide Prevention And Research study aims to implement a Dutch translation of the MYPLAN app alongside a self-monitoring app for suicidal patients in the Netherlands [18]. Researchers recently reported on the feasibility of using smartphone apps as treatment components for outpatients with depression and suicidal tendencies and found that mobile safety planning (using

XSL•FO
RenderX

the BackUp app) was acceptable and usable for this group; however, the integration of apps into routine treatment needs to be further explored [19]. Indeed, researchers attest that effective interventions for suicidality do exist, but many patients do not receive them because implementation efforts tend to be time limited and unsystematic [20].

Integrating mHealth in Mental Health Services

This protocol is underpinned by the research team's previous research on the experiences of mental health professionals involved in integrating mHealth technology into existing mental health services [21]. The potential benefits of using mobile apps identified by mental health professionals include increased accessibility, increased engagement with young people, and the convenience and feasibility of a client using a mobile app during a crisis [21]. Many of the benefits identified in previous research are consistent with those asserted by mental health professionals in previous research [22]. A concern identified by professionals included the potential for the technology to be used instead of face-to-face services. Such findings are in line with previous research [23], suggesting that although professionals acknowledge their possible benefits and cost-effectiveness, health care providers are conservative about integrating mHealth technologies into everyday practice.

Mental health professionals identified the following barriers to adoption: lack of trust in the technology (privacy and confidentiality) and in the health care organization, training needs, policy guidance requirements, technical support requirements, and the need for further research. This mirrors the systematic review findings of the app literature, calling for further research before such technology is recommended or prescribed [24]. The benefits identified included the needs addressed by this technology to increase accessibility, enhance engagement, enhance the efficacy and generalization of skills acquired outside of the clinic setting, and the potential for individualized data collection to enhance treatment [24]. Similar enablers have been cited by mental health professionals in previous research [23].

Engaging Young People

The use of mobile apps to record and store one's safety plan may be particularly useful in supporting young people experiencing suicidal thoughts and behaviors, often simultaneously experiencing a transition to adulthood and to adult-focused services. The onset of many psychopathologies has been shown to coincide with the transition age [25,26]. Approximately 75% of all psychiatric disorders in adults start before the age of 24 years, and 50% of all psychiatric disorders start before the age of 14 years. However, there is discord in the pattern of increased risk of psychopathology in young people and mental health service use. Clinicians have previously identified the potential benefits of mobile app use in promoting engagement among young people with mental health services [21]. Approximately 64% of adolescents reported using apps to manage their mental health symptoms [27]. Indeed, 59% of health and fitness app users are aged between 18 and 34 years, indicating a higher level of engagement in health apps within this age group [28].

Methodological Considerations

This trial is informed by a systematic review examining the effectiveness of mHealth technology tools in reducing suicide-specific outcomes, along with the review protocol [29,30]. This systematic review identified 7 studies that met the inclusion criteria. A total of 4 published articles that reported on the effectiveness of the following mobile phone apps were included: iBobbly [31], Virtual Hope Box [32], BlueIce [33], and Therapeutic Evaluative Conditioning [34]. The results demonstrated some positive impacts for individuals at an elevated risk of suicide or nonsuicidal self-injurious behaviors, including reductions in depression, psychological distress, and self-harm and increases in coping self-efficacy. However, none of the evaluated apps demonstrated the ability to significantly decrease suicidal ideation when compared with a control condition.

A significant limitation identified across all studies pertained to the heterogeneity of outcomes. Studies focused on differing suicide outcomes such as suicidal ideation as opposed to suicidal behaviors and often used differing outcome measures (ie, Beck Suicidal Intent Scale, Columbia Suicide Severity Rating Scale [C-SSRS], and Suicidal Ideation Attributes Scale). This hampered the extent to which the data could be compared and generalized. Another methodological issue is the practice of excluding individuals experiencing current suicidal thoughts or behaviors from participation. Importing empirically supported treatments for depression may not be appropriate because the trials in which efficacy was established excluded individuals who engage in suicidal behavior By embedding the trial within secondary-level mental health services, individuals at risk of suicide can participate safely while accessing mental health treatment. This methodological change is designed to reduce sample bias, enhance generalizability, and inform implementation research [20]. The evidence available indicates that suicide prevention mobile apps lead to reductions in depression, psychological distress, and self-harm in those at elevated risk of suicide or self-harm [29]. However, the pace of suicide prevention app development needs to be matched by scientifically rigorous research and the use of clinically valid methodologies that inform broader implementation of existing mental health services.

SafePlan

SafePlan is a safety planning mobile app designed to be used as an adjunct to therapy for individuals experiencing suicidal thoughts and behaviors who access mental health services. The SafePlan app was designed and developed following significant stakeholder engagement and cocreation with young people, clinicians, suicide prevention researchers, suicide prevention policy developers, computer scientists, and human-computer interaction specialists. The SafePlan design process is described in detail elsewhere [35]. In addition to the capacity to develop and record a collaborative safety plan on the app, it also supports the completion of dialectical behavior therapy (DBT) diary cards, which was deemed appropriate. This feature was included on the advice of clinicians who noted that individuals who complete a safety plan as part of their treatment may also engage in DBT. The integration of DBT diary cards [36] can be enabled

XSL•FO
RenderX

in the app's clinical settings, in consultation with a mental health care professional, for patients who are engaged in this form of intervention. Consistent with research evaluating the Virtual Hopebox [32], the app also supports the inclusion and display of personalized Reasons for Living, such as photos, text, and videos, in visibly prominent places within the app.

This study details the first feasibility trial of the SafePlan mobile app within mental health services. Current Medical Research Council (MRC) guidance on complex interventions [37] advocates pilot trials and feasibility studies as part of a phased approach to the development, testing, and evaluation of health care interventions.

Study Objectives

The study objectives are as follows: (1) examine the feasibility and acceptability of the SafePlan app as an adjunct to therapy for patients (aged 16-35 years) accessing secondary-level Irish mental health services and their clinicians; (2) assess the feasibility of the study procedures for both clinicians and patients within secondary-level mental health services; (3) determine the sample size required for a full randomized controlled trial (RCT) by collecting suicide outcome data at baseline, post intervention, and at 6-month follow-up; (4) determine whether the SafePlan app condition yields superior outcomes on the outcomes of suicidal ideation, suicidal behavior, and nonsuicidal self-injurious behavior at 6-month follow-up and post treatment when compared with the control condition; and (5) complete an economic analysis of the intervention.

Research Question

> *Is the SafePlan app, along with the proposed outcome measures, feasible and acceptable to patients aged 16-35 years at risk of suicide and their clinicians, in secondary-level mental health services in Ireland?*

The feasibility and acceptability of using the following outcome measures in a full RCT will be assessed: the Beck Scale for Suicide Ideation (BSSI), C-SSRS, Coping Self-Efficacy Scale (CSES), Interpersonal Needs Questionnaire (INQ), and Client Service Receipt Inventory (CSRI) [38-42].

Data will be collected at baseline, post intervention, and at 6-month follow-up to determine whether the SafePlan app yielded superior outcomes on primary outcomes of suicidal ideation, suicidal behavior, and nonsuicidal self-injurious behavior when compared with the control group.

- Participants: A total of 80 patients aged 16-35 years accessing secondary-level mental health services who present with current suicidal ideation, nonsuicidal self-injurious behavior, or a previous suicide attempt will be randomized to the SafePlan or control condition.
- Intervention: SafePlan is a safety planning mobile app informed by the paper-based SPI by Brown and Stanley [13]. Participants in the SafePlan condition will use the SafePlan app to record their safety plan in consultation with their mental health professional over an 8-week period as an adjunct to usual treatment.
- Comparison: The control group will receive treatment as usual (TAU) supplemented with the paper-based safety plan by Brown and Stanley [13] completed with their mental health professional.
- Outcome: The primary outcomes are feasibility outcomes and include the acceptability of the app to participants and clinicians, feasibility of delivery in this setting, recruitment, retention, and app use. Data collected on measures of suicidal ideation; suicidal behavior; and nonsuicidal self-injurious behavior at baseline, post intervention (8 weeks), and at 6-month follow-up will be used to compare changes in outcomes for the SafePlan condition relative to the control condition. A cost-outcome description will also be undertaken. Thematic analyses will be used to analyze the qualitative data gathered through semistructured interviews with patients and clinicians.

Methods

Design

The SafePlan study is a pilot RCT of SafePlan, a mobile-based safety planning app. A parallel group randomized design will be used with 1:1 patient allocation to the 2 treatment arms. In the control condition, participants will receive TAU supplemented with a paper-based safety plan. In the intervention condition, participants will use the SafePlan app to record their safety plan in consultation with their mental health professional, in addition to routine treatment. In both conditions, participants will receive appropriate care through their mental health team for an elevated risk of suicide throughout the study. Quantitative data will be collected at baseline, post intervention (8 weeks), and at 6-month follow-up (from baseline), with an additional safety check assessment at 4 weeks in both conditions.

Participants

Participants will include patients aged 16-35 years who are currently accessing secondary-level mental health services (child and adolescent mental health services [CAMHS] or adult mental health Services [AMHS]). Participants who present with current suicidal ideation, nonsuicidal self-injurious behavior in the previous 6 months, or a previous self-reported suicide attempt will be recruited across 2 community health care organizations. Participants will be assessed by members of their mental health team, will be accessing treatment with an assigned key therapist for the entire duration of the intervention, and will provide appropriate consent (for participants aged 16-18 years, parental consent is also required). Key workers will inform potential participants who meet the eligibility criteria (Textbox 1) and for whom a SPI is clinically indicated. Participants' psychiatric diagnoses will be recorded, but it will not be a cause for exclusion, as suicidality occurs across diagnostic categories.

XSL•FO
RenderX

Textbox 1. Participant inclusion and exclusion criteria.

Inclusion criteria

- Aged 16-35 years
- Presenting with current suicidal ideation, nonsuicidal self-injurious behavior in the last 6 months, or having a lifetime history of a self-reported suicide attempt
- Currently accessing Health Service Executive community mental health services (child and adolescent mental health services or adult mental health services)
- Have been allocated a key clinician to work with the participant for the duration of the intervention
- The key clinician or treating team identify that a safety plan is clinically indicated
- They were proficient in English to allow the provision of informed consent and the completion of measures in English
- Use a smartphone and can download the SafePlan app

Exclusion criteria

- Indicates no suicidal ideation, nonsuicidal self-injurious behavior, or previous suicide attempts
- Are medically unfit for interview
- Are not actively engaged with mental health services
- Are unable to provide informed consent
- Are outside of the specified age range
- Level of English is not sufficient to complete outcome measures in English
- Do not have access to a smartphone

Clinicians

Clinicians involved in providing the intervention in both arms will be mental health service professionals and members of the patient's multidisciplinary team who have undergone specialist training in addressing suicidality in clinical practice and the implementation of safety planning and who have completed the SafePlan technical orientation and training session. Data regarding the type of treatment received will be collected across both groups from the person's clinical file (number of face-to-face contacts, therapeutic approach used, profession of the key clinician, and prescribed medications) and the CSRI [42].

Sample Size

There is no established gold standard for calculating the sample size for a feasibility study, as the purpose of the study determines the sample size justification. In a systematic assessment of sample sizes in pilot and feasibility trials, Billingham et al [43] reported a median sample size of 36 participants, ranging from 10 to 300 participants. The aim of the SafePlan trial is to evaluate the feasibility of using the app as an adjunct to treatment. According to the clinician's and service manager's advice, a sample of 60 patients would be eligible for recruitment. With an expected 25% (20/80) dropout rate [43], a sample of 80 patients appeared adequate for the purposes of this study. Therefore, we will aim to recruit 80 patients from mental health services in Health Service Executive (HSE) West and Mid-West.

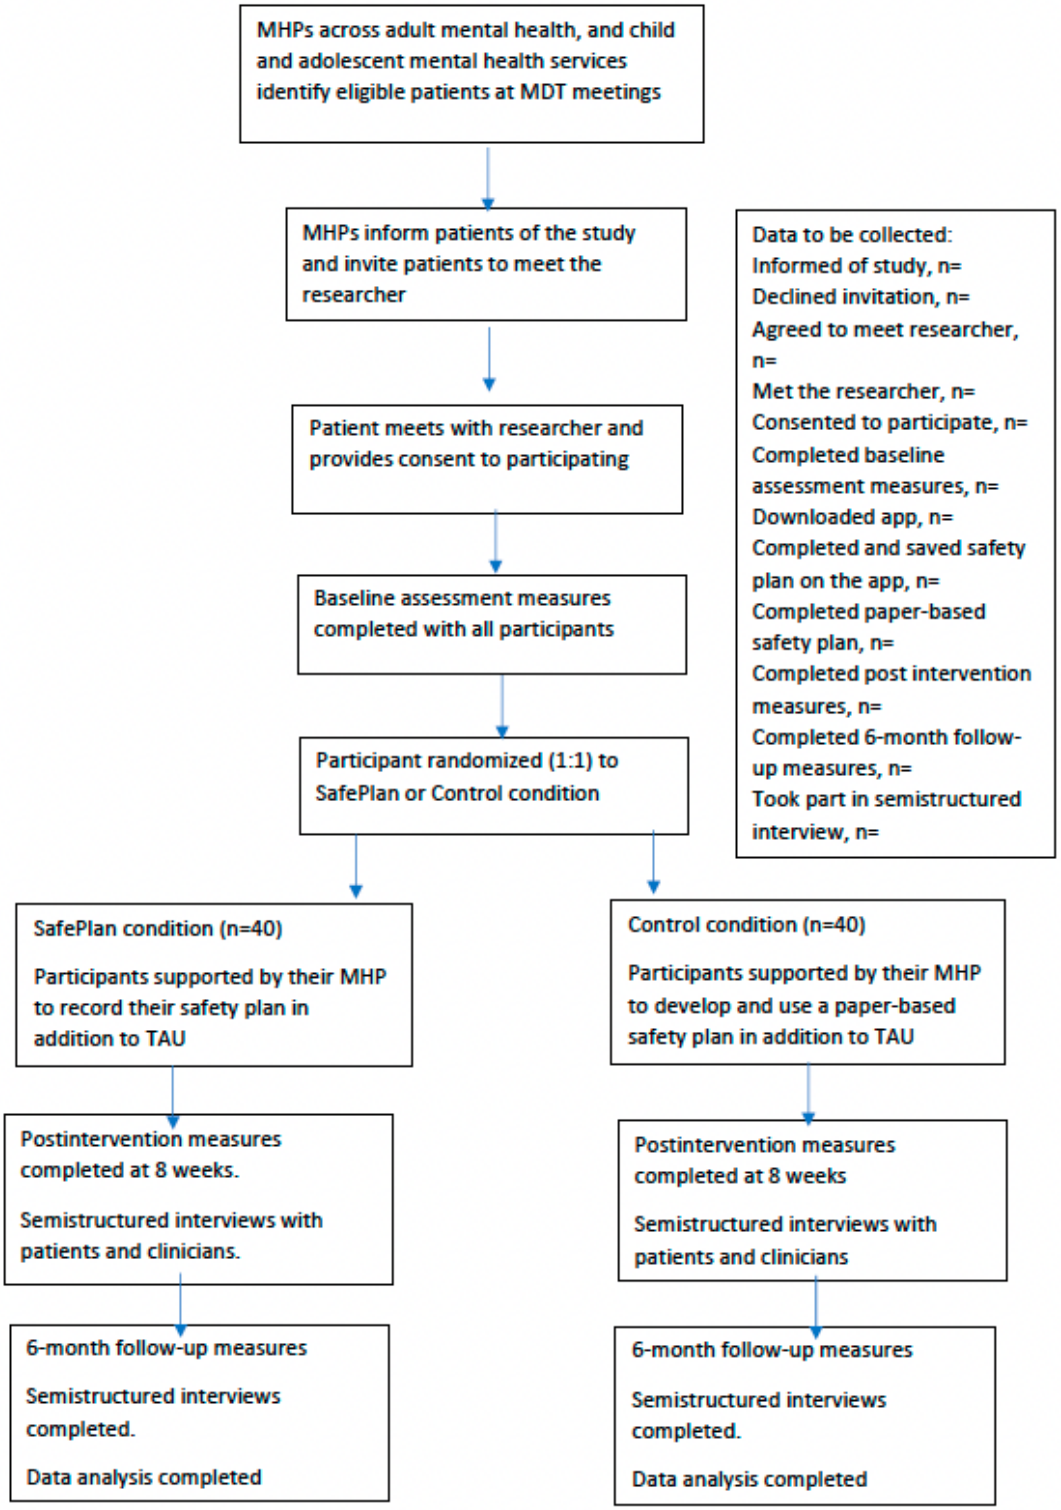
Setting

Participants will be recruited from community mental health services across 2 Irish community health care organizations. Participants will complete the baseline, postintervention, and follow-up measures in their mental health service setting. The orientation to the SafePlan intervention will be conducted face-to-face in the participant's service. The control condition participants will also be introduced to paper-based safety planning face-to-face and in their service. Semistructured interviews will be conducted in the participants' service and in the clinician's workplace. Interviews exploring the intervention process may also be conducted by phone, depending on participant's preferences and other safety considerations. Where face-to-face data collection is not possible owing to health concerns or other unforeseen circumstances, measures may be completed remotely. In such instances, the researcher will communicate with the participant's key worker and members of the treating team, following the call to ensure that any information relevant to the participant's safety is communicated to their treating team.

Procedures

Mental health service multidisciplinary teams across both health care areas will be informed of the study and made aware of the inclusion and exclusion criteria. Team members will be asked to identify patients who are eligible to participate and for whom a safety plan is clinically indicated. Mental health service professionals will inform potential participants about the study and invite them to meet the researcher. If the patient agrees, the researcher will approach the patient, provide them with a participant information sheet, and answer any questions they may have. If the patient agrees, informed consent will be obtained by the researcher. In consenting to participate, participants will also agree to the researcher accessing their medical file notes. Information on the semistructured interviews and fidelity assessment will also be provided, and consent to

XSL•FO
RenderX



future contact for this purpose will be sought. Clinicians across both community health organizations will be invited to participate in semistructured interviews to discuss their experiences of delivering the intervention.

Previously established clinician champions at each site will promote recruitment within their own teams and at weekly team meetings. Doctorate in clinical psychology students, in fulfillment of their clinical research experience and under the supervision of the principal investigator, will also support data collection across sites.

Baseline assessment measures will be administered to eligible participants who have consented to participate. Following the baseline assessment, participants will be randomized (1:1) to either the SafePlan or control condition.

An overview of the study procedures is provided in Figure 1.

Figure 1. Overview of SafePlan protocol. MDT: multidisciplinary team; MHP: mental health professional; TAU: treatment as usual.

XSL•FO
RenderX

Randomization

Randomization of participants will occur with equal probability for both groups. Participants will be stratified based on the suicide outcomes reported using the C-SSRS (Suicidal ideation/Non Suicidal Self Injurious Behavior/Suicide Attempt). Randomization will be carried out by a clinician using the sealed envelope randomization package.

Blinding

Neither the participant nor the researcher will know the treatment arm allocation while the initial study measures are being completed. Participants will receive either the SafePlan as an adjunct to TAU or TAU supplemented with a paper-based safety plan. After randomization, both the participant and researcher will be unblinded to the participant's allocation, which is unavoidable given the nature of the study.

Before starting the SafePlan intervention, all participants will receive a 15-minute training session on how to use the app, including downloading and password protection settings. Measures will be taken face-to-face at baseline, post intervention (8 weeks), and at 6-month follow-up. In addition to accessing TAU, phone-based check-ins will be conducted at week 4 for all participants. Participants will, therefore, have face-to-face or telephone contact with the clinician researcher at baseline assessment, 4 weeks (check-in), 8 weeks (post intervention), and 6-month follow-up. The control group participants will receive the same schedule of contacts and assessment measures.

SafePlan Condition

The SafePlan mobile app is available to download for free and is accessed at no cost to participants. SafePlan enables participants to record their safety plan, developed with a clinician, and store it on the app to facilitate access and use outside of the clinic. Participants assigned to the SafePlan condition will meet the researcher for instructions on downloading and using the app on their personal smartphones and subsequently meet their key clinician to guide individual use of the app for safety planning. Participants will be guided by the researcher and subsequently their clinician to use SafePlan to record their safety plan in the clinic and implement the plan outside the clinic. Both patients and clinicians will be encouraged to refer to the SafePlan app during their appointments over the 8-week course of the intervention period. The SafePlan app will be used as an adjunct to treatment and will be implemented in parallel with routine community mental health care.

Control Condition

Participants assigned to the control condition will similarly meet the researcher following enrollment for orientation to paper-based safety planning and subsequently meet their clinician to guide individualized safety planning using the safety planning template by Brown and Stanley [12]. As with the SafePlan condition, participants in the control group will be guided by the researcher and subsequently by their clinician to develop and record a safety plan using the paper-based safety plan template by Brown and Stanley [12]. Both patients and clinicians will be encouraged to refer to the paper-based safety plan during their appointments over the 8-week course of the intervention period. A paper-based safety plan will be used in addition to routine community mental health care.

Data Collection

Feasibility

Feasibility is defined as the extent to which the app can be successfully used by patients attending community mental health services and by their clinician as components of standard treatment. Feasibility will be assessed in terms of recording a safety plan on the app, in-session app use, and app use over the course of treatment (as reported by patients and clinicians). Quantitative data from patients will be collected at baseline, post intervention (8 weeks), and at 6-month follow-up; qualitative data from patients and clinicians will be collected through semistructured interviews. Table 1 presents the study data collection timelines. Psychometric measures will be administered at multiple time points to identify possible differences in the outcomes over the course of the study.

Feasibility outcomes will include the acceptability of the intervention to participants and clinicians, feasibility of delivery in this setting, recruitment, retention, and app use. Quantitative data on the number of potential patients who were approached and who declined, who were not eligible, and who were retained will be recorded and presented in the Consolidated Standards of Reporting Trials diagram for the study.

This study will be conducted in line with the MRC guidelines on the evaluation of complex interventions [37], with data collected via quantitative and qualitative methods.

Participants who consent to be contacted for the qualitative element of the study will be invited to participate in a one-to-one interview about their experiences of the intervention and of study procedures. The interviews will be conducted face-to-face at the university or health service site, and where necessary, participants will be given the additional option of a telephone interview. In the case of telephone interviews, verbal consent will be audio-recorded at the beginning of the interview.

Mental health professionals (n=12) directly involved in participants' care and in delivering the intervention (eg, CAMHS/AMHS multidisciplinary team members) will be invited to participate in the semistructured interviews. Interviews will focus on the feasibility of the intervention and the acceptability of the study and intervention procedures, including experienced or perceived barriers and facilitators, intervention "fit" within the setting, and suggestions for improvement.

Outcome Measure Feasibility

Participants will be asked to complete several questionnaires with the researcher to assess the feasibility and acceptability of using these questionnaires in a full trial. The questionnaires to be completed during the trial are detailed below (an additional check-in at 4 weeks will include further administration of the C-SSRS [38]).

The BSSI [39], the proposed primary outcome for a full trial, will be administered at baseline, post intervention (8 weeks), and at 6-month follow-up to assess the feasibility of this measure in collecting suicide outcome data at multiple time points. The data collected using the BSSI will be used to calculate the sample size required for a full trial. The scale has been used as a tool for screening for the presence or absence of suicidal ideation and, more recently, as a brief measure of change in suicidal thoughts and ideation over time. This scale has high internal reliability and concurrent validity [39].

The C-SSRS is a 20-item semistructured brief and valid tool used to assess suicide risk including suicidal ideation, suicidal behaviors, previous attempts, and preparatory behaviors [38].

The CSES has shown reliability and validity in a mental health service population and can be used to assess changes in coping ability over time [40]. The Cronbach α coefficients of the factors 1, 2, and 3 and the whole CSES-Vietnamese version were at acceptable levels (.91, .86, .75, and .93, respectively).

The INQ is a 15-item measure of perceived burdensomeness and thwarted belongingness, with items rated on a 7-point Likert-type scale [41].

The CSRI is a measure used in mental health service evaluation to capture information about the use of services. The following domains will be captured within this study: general practitioner (GP) consultations, outpatient visits, use of hospital services for physical or mental health problems, mental health helpline contacts, and psychiatrist or social worker or psychologist contacts [42].

The remaining data to be gathered at 8 weeks will include the self-rated helpfulness, benefit, ease of use, likelihood of continued use, and likelihood of recommending the SafePlan app to others.

Demographic Data

Participants will be asked to provide consent to share clinical data and will have demographic data collected at enrollment. This will include participant age, sex, relationship status, highest level of educational attainment, employment status, type of service (AMHS or CAMHS), and geographic service area (Community Health Organisation 1 & 2). Clinical data collected from the participant's file will include details of current

XSL•FO
RenderX

psychiatric diagnoses, current treatment plan (including medication if relevant), key clinician profession, and information in relation to previous suicidality to supplement participant self-report (suicidal ideation, nonsuicidal self-injurious behavior, and previous suicide attempt). Information regarding previous suicide risk or behavior is necessary to support patient safety and to inform factors that may be considered potential moderators or mediators in a full trial. A description of treatment received in both the TAU and the SafePlan conditions will be captured using the CSRI and clinical file data.

Data Sharing

At baseline, participants will be asked to consent to the researcher accessing their mental health clinical file; the researcher accessing details of the participant's emergency contact or key clinician, consultant psychiatrist, and GP and sharing clinically important information with those individuals to maintain patient safety as necessary during the trial; and the collection of data post intervention and at 6-month follow-up.

Participants in the SafePlan condition will hold their own data on their device until they choose to show it to their mental health professional when they attend the clinic in person. Their data are not automatically shared or monitored, and this is communicated to participants both upon enrollment in the study and through the terms and conditions presented when downloading the app.

A separate participant information and consent form has been developed for use with mental health professionals who will partake in semistructured interviews focusing on the feasibility and acceptability of the intervention and study procedures. All interview data will be anonymized in the final report.

Qualitative Interviews

Qualitative interviews will be conducted with patients (SafePlan group, n=12; control group, n=12) and clinicians (n=12) involved in delivering the intervention to assess the feasibility of the intervention and study procedures. The participants and their clinicians will be informed of the qualitative component of the trial during the consent process. Participants will be invited to attend a semistructured interview following the completion of the 8-week intervention. Semistructured interview topic guides will be used. Interviews will seek to better understand participants' experience of the SafePlan intervention and of the study procedures and to identify barriers to engagement with the intervention. Researchers will also seek to interview participants in the control condition (n=12) to better understand their experiences of TAU, paper-based safety planning, potential contamination, and the acceptability of study procedures.

Ethics Approval

This study was approved by the University Hospital Limerick Research Ethics Board in October 2021 (REC Ref: 055/2021). This study was preregistered through the Open Science Framework.

Consent

The researcher will follow the SafePlan Standard Operating Procedure to take appropriate action to maintain participant safety throughout. In accordance with the HSE CAMHS Operational Guidelines [44] and local HSE policy and as stated in the study information sheet, this may include contacting the participant's key clinician, consultant psychiatrist, GP, and emergency contact or contacting emergency services.

Participants will be identified by members of their mental health team and will be accessing treatment with an assigned key therapist for the entire duration of the intervention. Clinicians will identify potential participants for whom a safety plan is clinically indicated and will provide them with further information about the trial. Participants who wish to participate will be approached by the researcher, and informed consent will be obtained. In the case of those aged <18 years, assent will be required from the young person, and parental or legal guardian signed consent will be obtained before the person can proceed to enrolling in the study. All participants will be informed of their right to refuse to participate and their right to withdraw from the study.

In consenting to participate, the participants will also agree to the researcher accessing their clinical file. Information on the semistructured interviews and the fidelity assessment will also be provided, and consent to future contact for these purposes will be sought.

Data collected during the administration of the outcome measure will be shared with the participant's key clinician to support participant safety. The researcher and any personnel involved in the study will receive standardized training in addressing suicidality in line with the Irish HSE National Office for Suicide Prevention Education and Training Plan 2021-2022 [45]. Baseline, outcome, and follow-up assessments will be conducted (unless otherwise required by the participant) in the participant's mental health clinic and face-to-face to ensure optimum clinical support in situ. It is hoped that the semistructured interviews will provide further information on any potential adverse effects of data collection.

The SafePlan study will be conducted in accordance with the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use Good Clinical Practice standards, which is an international minimum quality standard for the ethical and scientific conduct of clinical research [46]. Safety planning is an established suicide prevention intervention that has been found to reduce the recurrence of suicidal behaviors [15]. Therefore, although the information arising from that intervention will be recorded differently, participants across conditions will receive an evidence-based intervention that is considered good practice alongside TAU. One group will store this information on a paper-based safety plan template, and the other group will store the information on their SafePlan app.

Fidelity Assessment

The MRC guidelines [37] on complex interventions strongly recommend the inclusion of fidelity assessment to explain discrepancies between expected and observed outcomes, to understand how context influences outcomes, to clarify causal mechanisms, and to provide insights to aid implementation.

Treatment fidelity assessment will include the following:

XSL•FO
RenderX

1. Documentation of key clinician's behavior, including attendance at the SafePlan orientation and training session, completion and filing of paper-based safety plan (control condition), and development of an interactive safety plan and recording this plan using the SafePlan app (intervention condition).
2. A checklist based on the 6 core steps outlined in the safety planning template by Brown and Stanley [13] will be used to assess the extent to which key components of safety planning are addressed by clinicians in both conditions.
3. A sample (16/80, 20% approximately) of participant intervention sessions will be attended by the researcher, and the checklist will be completed to further assess the fidelity of the plan by Brown and Stanley [13].

Health Economics

A cost-outcome description will be undertaken. Data on costs will be collected on resource use related to intervention delivery (staff costs, training, and intervention materials) and patient resource use in terms of the broader health service. The CSRI will be used at baseline, 8 weeks, and 6-month follow-up to capture information regarding the use of health and social care services, such as GP consultations, outpatient visits, use of hospital services for physical or mental health problems, and social worker contacts.

The cost of providing the intervention will be calculated based on the average time taken to carry out the intervention and the hourly cost of employing the mental health professional involved. The hourly employment rate of a mental health professional at the midpoint of the salary scale will be calculated based on the available health service salary scale [47]. This will be revised upwards to account for employer-related costs and overheads, based on guidance for conducting an economic analysis within the Irish health care system [48]. Following estimation of the cost of carrying out the intervention, net cost benefit and cost-benefit ratio for providing the service will be calculated.

Data Analysis

Quantitative Data Analysis

Descriptions of recruitment rates, attrition, retention, and reported app use will be summarized. The baseline characteristics of both groups will be summarized (age, diagnosis, and treatment details). Descriptive statistics will be used to examine the uptake of the app (reported in-session app use, reported app use outside the clinic, completion of a safety plan using the app, and use of modified exponential moving average features). Data from all other measures completed at baseline, post intervention, and at 6-month follow-up (C-SSRS, INQ, Emotion Regulation Questionnaire, and Client Receipt Inventory) will be summarized.

The proposed primary outcome measure to be used in a further definitive trial—BSSI—will be summarized by a randomized group. Analyses will be conducted according to the intention-to-treat principle, using available measurements from all participants and according to their allocated groups. Missing data will be accommodated based on all available information using maximum likelihood estimation. We will examine between-group differences in BSSI scores from baseline to post intervention (8 weeks). To further explore preliminary efficacy, we will evaluate within-group changes from baseline to post intervention for each condition separately and then for both groups combined. Finally, within each condition separately, we will explore the potential maintenance of intervention benefits with a repeated measures ANOVA, including the 3 data collection time points (baseline, 8 weeks, and 6 months).

Qualitative Data Analysis

Qualitative data from interviews with study participants and clinicians will be analyzed via thematic analysis using the approach by Braun and Clark [49]. Data collection will continue until data saturation is reached. In total, 25% (9/36) of the interviews will be double coded to ensure reliability. Disagreements will be resolved by discussion.

There are specific ethical challenges when conducting qualitative research. As there may be potential for distress, the team developed a research protocol that provides contact details of appropriate additional support if needed. It is important to maintain confidentiality and pseudoanonymity. Informed consent is an ongoing process that continues after obtaining written consent [50]. The team will be cognizant of this throughout the project.

McGrath and Nilsson [51] outlined the challenges in qualitative data sharing. However, transparency and rigor are critical. We will use some of the strategies outlined by McGrath and Nilsson [51], which include outlining procedures for data sharing when obtaining informed consent, data minimization, and pseudonymization.

Tsai et al [52] advocated that "coding queries may offer greater anonymity compared with full transcripts because statements are grouped by theme rather than by study participant." They further support this process as preferable to sharing full transcripts. In this research, qualitative analysis will be managed using NVivo (version 12; QSR International) qualitative analysis software [53]. This will provide a clear audit trial and permit the execution of coding and matrix queries to ensure transparency.

Progression From Feasibility to Full Trial

Shanyinde et al [54] reported 14 issues that needed to be evaluated in feasibility studies or pilot trials. "A process for Decision-making after Pilot and feasibility Trials" (ADePT) by Bugge and Williams [55] examines the "methodological issues" identified in a feasibility study that may hinder or facilitate progression to a definitive trial. ADePT permits an examination of the evidence from the feasibility study and the degree to which "methodological issues, " such as recruitment, retention, adherence, and acceptability of the intervention, among others, have been successful. From the feasibility study findings, ADePT provides a framework to decide whether there should be an amendment to the intervention, context of its delivery, and confirmed trial design before embarking on a full trial. This study will use the ADePT 14-point reporting framework of methodological issues and decision tools to evaluate whether the feasibility study has achieved its objectives and to identify

XSL•FO
RenderX

the need for intervention, clinical context, and trial design modification.

Results

As of January 2023, funding has been approved, ethics approval has been received, and clinician champions across mental health service sites have been established. Service-wide Suicide Prevention and Self-harm Mitigation Training has been completed with clinicians with the support of the National Office for Suicide Prevention. The process of research personnel recruitment has commenced. Data collection is expected to commence when personnel are in post (estimated April 2023). The projected date of submission of completed manuscript is April 2025.

Discussion

Principal Findings

This study will provide clinically valid data on the feasibility and acceptability of the SafePlan app as an adjunct to therapy for patients (aged 16-35 years) accessing community mental health services and their clinicians. It is hypothesized that patients and clinicians will find the app both feasible and acceptable and that important barriers and enablers to its use within Irish community mental health services will be identified. Data regarding the feasibility of the study procedures for both patients and clinicians will inform the decision to progress to a full trial. This is the first study to examine the feasibility of the SafePlan app and accompanying trial study procedures. Suicide outcome data collected at baseline, post intervention, and at 6-month follow-up will inform the sample size required for a full RCT. These data will also help determine whether the SafePlan app condition yields superior outcomes on standardized measures of suicidal ideation, suicidal behavior, and nonsuicidal self-injurious behavior at 6-month follow-up and post treatment when compared with the control condition. It is hypothesized that the SafePlan app condition will yield superior outcomes when compared with the control condition.

Safety planning interventions offer an evidence-based means of addressing suicidality in at-risk individuals [14]. A meta-analysis of safety planning–type interventions (SPTIs) for suicide prevention found that the relative risk of suicidal behavior among patients who received an SPTI compared with a control condition was 0.570 (95% CI 0.408-0.795; *P*=.001; number needed to treat: 55). The results support the use of SPTIs to help prevent suicidal behavior and the inclusion of SPTIs in clinical guidelines for suicide prevention [14]. SafePlan moves beyond the recording of safety plans using paper-based templates to record and store the plan, developed with a health care professional, on a mobile app. The results of this study will inform further research and the integration of safety planning apps within mental health services.

SafePlan is distinctly different from the mobile apps currently being trialed with this population [19,31,32]. Previous and ongoing trials used a safety planning app and a separate ecological momentary assessment app in parallel. Trial authors note “the next step would be to combine mobile safety-planning and self-monitoring apps” [19]. SafePlan delivers this by providing a means of recording behaviors that patients can discuss with their mental health professional at their next clinic appointment. The findings of this study will, therefore, provide provisional data on the feasibility and acceptability of this next-generation safety planning app in community mental health services.

Previous research has focused on the use of safety planning interventions in hospital settings and as a stand-alone intervention [13]. However, safety planning is also an important treatment component of community mental health services for those presenting with suicidal ideation and behaviors. This study adds to the existing research by focusing on the feasibility of using such technology within such services.

Limitations

A potential limitation of the study procedure is that the participants will be unblinded to the type of intervention once they have been assigned to either condition. This is unavoidable, given the distinct nature of each condition (paper based vs app based). However, both the participants and researchers will be unaware of the treatment condition while the baseline measures are being completed.

As data are not automatically shared by the app with the clinician on an ongoing basis, the researcher will depend on the participant attending follow-up appointments and choosing to share their data at that time. It may be the case that useful data will be lost because of attrition, particularly at 6-month follow-up. This may be particularly relevant to understanding the experiences of participants who discontinued using the app. However, the data-sharing procedures were designed to respect and protect participant data. All participants were informed of the procedures before they consented to participate. It is hoped that the inclusion of semistructured interviews with both patients and their clinicians will help address this potential limitation.

Conclusions

Health care policy nationally and internationally [56,57] proposes the need for integrated care facilitated by innovations in digital health. The use of mobile devices by individuals at risk of suicide has been recommended by the World Health Organization [16]. The SafePlan app was designed to support individuals in completing and recording an evidence-based safety plan with their clinician. This protocol outlines the first feasibility and acceptability trial of the SafePlan App and the related study procedures. The trial adds to the existing research conducted in hospital settings by examining the feasibility of this safety planning mobile app within community mental health services. The findings may have implications for patients, clinicians, health services, and policy makers regarding the integration of safety planning mobile apps more generally and may inform future research in mHealth and suicide prevention.

Abstract

Background: Reducing the rates of sexually transmitted infections (STIs) among young people is a public health priority. The best way to avoid STIs from penetrative sex is to use a condom, but young people report inconsistent use. A missed opportunity to intervene to increase condom use is when young people access self-sampling kits for STIs through the internet. The potential of this opportunity is enhanced by the increasing numbers of young people being tested through this route every year in England. Hence, in a cocreation by young people, stakeholders, and researchers, Wrapped was developed—a fully automated, multicomponent, and interactive digital behavior change intervention developed for users of STI self-sampling websites, who are aged 16-24 years.

Objective: This paper is a protocol for a feasibility randomized controlled trial (fRCT). The fRCT seeks to establish whether it is feasible to run a randomized controlled trial to test the effectiveness and cost-effectiveness of Wrapped. Wrapped aims to reduce the incidence of STIs through increasing correct and consistent use of condoms among users of STI self-sampling websites, who are aged 16-24 years.

Methods: A 2-arm parallel-group randomized fRCT of Wrapped plus usual care, compared to usual care only (basic information on STIs and condom use), with a nested qualitative study. A minimum of 230 participants (aged 16-24 years) are recruited from an existing chlamydia self-sampling website. Participants are randomized into 1 of 2 parallel groups (1:1 allocation). Primary outcomes are the percentage of users recruited to the fRCT and the percentage of randomized participants who return a chlamydia self-sampling kit at month 12. Additionally, besides chlamydia positivity based on biological samples, surveys at baseline, month 3, month 6, and month 12, are used to assess condom use attitude, behavioral capability, self-efficacy, and intention, along with details of any partnered sexual activity and condom use, and health economic data. Nested qualitative interviews with trial participants are used to gain insight into the factors affecting recruitment and attrition.

Results: Recruitment to the fRCT began in March 2021 and was completed in October 2021. Data collection was completed in December 2022.

XSL•FO
RenderX

Conclusions: This feasibility study will provide data to inform the design of a future-definitive trial. This work is timely given a rapid rise in the use of internet testing for STIs and the sustained high levels of STIs among young people.

Introduction

Background and Rationale

Sexually transmitted infection (STI) diagnoses in England have been persistently high over the past decade [1]. Although the most recent annual data show a 32% reduction in STI diagnoses, down from a 10-year high of 467,096 in 2019 to 307,901 in 2020, this likely reflects a temporary shift brought about by the COVID-19 pandemic, which placed restrictions on public behavior and reduced access to STI testing [1,2]. Young people continue to carry a high burden of infection, with 46% of all new diagnoses among 15- to 24-year-olds [1]. Furthermore, women, those of Black ethnicity, those living in the most deprived areas, and men who have sex with men, remain disproportionately affected [1]. Among young people, chlamydia continues to be the most prevalent STI [1]. Rates of chlamydia among 15- to 24-year-olds have been high but stable over recent years, whereas increases have been observed for other STIs, such as gonorrhea and syphilis [2]. The removal of COVID-19 restrictions and an increase in testing availability will likely bring with it a return to prepandemic levels of STI diagnoses and as such, sexual health continues to be a public health concern [1]. Untreated STIs can lead to serious health consequences, such as pelvic inflammatory disease, ectopic pregnancy, and infertility, which have a significant impact on health and quality of life [3]. The estimated annual cost to the National Health Service (NHS) of STI treatment is £620 (US $762.6) million [4]. The best way to avoid STIs from penetrative sex is to use a condom [5], but young people report inconsistent use [6,7].

Although condom use is the cornerstone of STI prevention, STI testing is important for treatment and to prevent onward transmission. There have been notable changes in the landscape of STI testing within England since 2017. In the period between 2017 and 2019, against a backdrop of increasing testing overall, there was a shift toward the use of internet services, and away from other nonspecialist services [8]. Between 2018 and 2019, while the number of tests carried out by specialist sexual health services (eg, genitourinary medicine services) remained relatively stable, those carried out by nonspecialist services (excluding internet testing), such as pharmacies, general practice, and community-based settings, decreased by 9%, and those by internet services increased by 69% [8]. This trend reflects recent year-on-year increases, with internet testing accounting for 4% of all testing in 2017, 13% in 2018, and 19% in 2019 [8]. The global COVID-19 pandemic has further served to accelerate the move in this direction across Europe [9,10]. In England, despite there being a reduction of 30% in expected levels of chlamydia testing in 2020, a 2-fold increase in internet testing was observed, with approximately 40% of all chlamydia testing being processed through the internet in 2020 [1]. Whether internet testing remains at these elevated levels or begins to adjust back toward those observed prepandemic, remains to be seen. Regardless, internet testing is now an established and significant route to STI diagnosis and treatment within England.

Evidence indicates that STI self-sampling websites are effective at reaching higher prevalence groups; chlamydia positivity is comparable to that of other nonspecialist services [8], and they attract equivalent numbers of males and females, and those from across the spectrum of deprivation (E Hollis, unpublished data, 2017). Repeated use of internet testing services is however common, with chlamydia positivity remaining high for those that retest (E Hollis, unpublished data, 2017), suggesting that testing online does not reliably translate into future individual prevention efforts. Furthermore, while information on STIs and contraceptive methods is typically found on self-sampling websites, this is insufficient for behavior change [11], and inconsistent with Public Health England guidance to provide those at elevated risk of STIs with preventative intervention [12]. As such, self-sampling websites provide an important but currently missed opportunity to intervene with a priority group.

In 2016-2017, with the support of Medical Research Council Public Health Intervention Development funding and in line with Medical Research Council guidance on the development of complex interventions [13], Wrapped was cocreated by young people, stakeholders, and researchers [14]. Wrapped is a fully automated, multicomponent, and interactive digital intervention developed for the users of STI self-sampling websites aged 16-24 years. It aims to reduce the incidence of future STIs by increasing correct and consistent use of condoms for penetrative sex. The users of STI self-sampling websites can be signposted to Wrapped upon order of an STI self-sampling kit (through a hyperlink). Content is tailored, with between 1 and 6 different components allocated to users in accordance with their self-identified barriers to condom use. These barriers reflect important behavioral determinants of condom use identified through existing meta-analyses [15-18], namely condom use attitudes (particularly beliefs around pleasure, enjoyment, and spontaneity), condom availability, and behavioral capability and self-efficacy for condom use and communication.

In 2019, funding was awarded by the National Institute for Health and Care Research Public Health Research program to determine whether it is feasible to run a randomized controlled

XSL•FO
RenderX

trial (RCT) to test the effectiveness and cost-effectiveness of Wrapped. This paper presents the protocol for this feasibility randomized controlled trial (fRCT).

Aim and Objectives

The aim of this study is to assess whether and how it is possible to carry out a future definitive RCT to evaluate the effectiveness and cost-effectiveness of Wrapped plus usual care, in comparison to usual care only.

The primary objectives are to estimate the following parameters for planning a definitive RCT:

1. The rate of recruitment of eligible participants.
2. The rate of participant follow-up for the definitive RCT primary outcome measure (chlamydia positivity at 12 months measured using biological samples).

The secondary objectives are as follows:

1. Estimate the rate of participant follow-up for the definitive RCT secondary outcome measure chlamydia cumulative incidence.
2. Identify whether the level of deprivation of the final sample is representative of web-based STI self-sampling users.
3. Identify whether differential retention occurs across groups (gender, ethnicity, sexual identity, deprivation, randomized groups, and chlamydia diagnosis at baseline).
4. Measure chlamydia positivity at 12 months in the intervention and control groups (to support sample size calculation for the definitive RCT).
5. Identify the rate of attrition at 3 months, 6 months, and 12 months, and ways of minimizing this.
6. Determine the feasibility and participant acceptability of all primary and secondary outcome measures (including health economic measures).
7. Identify which recruitment messages result in the highest rate of recruitment.
8. Identify and remove the intervention "friction points" (using web analytics data) to minimize attrition and maximize the future intervention dose.
9. Identify costs and resource use associated with the intervention for health care services and users (to inform the design of the definitive RCT and the future economic evaluation).
10. Measure contamination of intervention effect in the control group.
11. Identify possible adverse effects of the intervention, for example, participants' inadvertent disclosure that they are testing for an STI or increase in consumption of pornography.

Study Design

A 2-arm parallel group fRCT of Wrapped plus usual care compared to usual care alone with a nested qualitative study.

Methods

Please refer to Multimedia Appendix 1 for a visual representation of the study design, recruitment process, and timing of measures based on the Consolidated Standards of Reporting Trials (CONSORT) extension for pilot and feasibility trials [19].

Study Population and Setting

Recruitment, intervention delivery, and data collection are conducted entirely on the internet. Participants will be recruited from an existing chlamydia self-sampling website (freetest.me [20]). Freetest.me provides a web-based chlamydia testing service to local authority areas across England (typically subcontracted to and administered through NHS trusts) and is free at the point of use. For the purposes of this study, users of freetest.me residing in 1 of 4 local authority areas will be invited to participate.

Eligibility Criteria

The inclusion and exclusion criteria are outlined in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Aged 16-24 years.
- Living in a local authority area participating in the study.

Exclusion criteria:

- No internet access.
- Sexual activity does not typically include penetrative sex (penis in vagina or anus).

Participant Timeline

Table 1 gives an overview of participant activities and timing.

To recompense for time spent in completing activities, participants will receive payment in the form of vouchers (see Multimedia Appendix 2 for the schedule of payments).

XSL•FO

[a]M0: month 0.

[b]M3: month 3.

[c]M6: month 6.

[d]M12: month 12.

Recruitment

A study invitation will be placed on the "thank you" page of the freetest.me website displayed to users after they have placed an order for a chlamydia self-sampling kit. Every 2 weeks, the advert will change to emphasize a different value proposition (see Multimedia Appendix 3 for the list of adverts). A hyperlink within the advert will take users to Research Electronic Data Capture (REDCap), a secure data capture and management platform, for participant information and consent (see Multimedia Appendix 4 for a copy of the participant information and consent form). Each individual's freetest.me order number will be appended to the URL. This order number will be captured by REDCap enabling the research team to ensure that each participant is a unique and genuine user of freetest.me.

Survey Completion (Months 0, 3, 6, and 12)

REDCap is being used to monitor and manage all survey data collected as part of this study. Surveys will be conducted at baseline (month 0 [M0]), month 3 (M3), month 6 (M6), and month 12 (M12) and used to collect data on condom use attitude, behavioral capability, self-efficacy, and intention, along with details of any partnered sexual activity and condom use that has occurred in the previous 3-month period. The surveys will also be used to measure the experience of partner resistance to condom use and to collect health economic data. There are between 63 and 76 core items per survey (depending on time point), with data largely being collected using fixed response items and Likert scales (see Multimedia Appendix 5 for survey items). The baseline survey will additionally collect participant's contact details to enable communication with participants regarding the completion of follow-up surveys, and basic demographic data. The M3 survey will also be used to collect self-reported data on participant engagement with the intervention.

Completion of the baseline survey is scheduled immediately after consent is provided. All other survey completion will be triggered by email. Participants who do not complete the survey will be sent up to 3 reminders (delivered by SMS text message). Subsequently, if no response is received, 1 email and 1 telephone call will be made to prompt completion. During the telephone call, participants will be given the option to verbally respond to a reduced set of survey questions. Finally, if there is still no response, a paper-based version of the survey will be posted out with a stamped addressed return envelope. Those who have not provided any data 20 days after the initial survey is sent out will be classed as nonresponder. Surveys will continue to be sent to nonresponders (as well as chlamydia tests—see below) at subsequent time points unless a participant asks to be withdrawn from the study.

Chlamydia Testing (M0, M3, and M12)

Chlamydia tests will be processed by freetest.me at M0, M3, and M12. The chlamydia test at M0 is triggered by participants when they order a self-sampling kit through the freetest.me website immediately before receiving the study invite (see "recruitment" above). Participants will be asked to self-report their result, and any treatment received if applicable, through SMS text message. A single SMS text message reminder will be sent to participants who do not respond. Those who have not provided this data 4 weeks after the SMS text message contact is made will be classed as nonresponders.

The chlamydia tests at M3 and M12 will be processed differently to that at M0. For this purpose, chlamydia self-sampling kits will be sent directly from the study team to participants. One week before posting the kits, participants will be sent an SMS text message asking them to confirm or amend their postal address. The kits that participants receive at M3 and M12 will contain the usual user instructions to collect the sample and return by Freepost to freetest.me for processing. Participants will be sent 3 SMS text message reminders to complete the test kit. If the test kit still has not been returned after this point, 1 phone call will be made to prompt return. Those who have not returned their kit 30 days after it is posted out will be classed as a nonresponder. Participants who have a positive test result at M0, M3, or M12 will receive 1 item within SMS text message survey 2 weeks post results to record whether their infection has been treated or not. If treatment is incomplete, or the participant does not respond, they will be sent 1 reminder SMS text message to obtain this information. Each local NHS trust will be informed of any positive cases (for participants residing in their local authority area) so that they can provide appropriate treatment and follow-up.

Randomization

Randomization of participants to trial groups in a ratio of 1:1, is fully automated, and fully concealed within REDCap software, and will take place following completion of the M0

XSL•FO
RenderX

survey. Before randomization of each participant, the research team will manually check that each individual is unique, by cross-checking their identifying information (name, email address, postal address, mobile phone number, and freetest.me order number) with participants already within the sample. They will also check that the participant has answered the baseline survey with reasonable care (ie, no evidence of random responding or completion under the expected minimum time). Those not meeting these criteria will not be randomized. Participants will be blind to group allocation and the research team will be unable to influence any aspect of this procedure. The randomization list will be generated by the study statistician who will monitor randomization on a weekly basis during active recruitment to ensure that the algorithm is being correctly applied. Randomization will be at the individual level as control group contamination is not anticipated (although this will be monitored to determine the suitability of this approach for the definitive trial). Stratification across groups, using randomly permuted blocks (ethnicity, sexual identity, deprivation) will be performed to balance participants across the trial arms.

Intervention Access, Content, and Tracking

Participants will be individually randomized within the stratifications into 1 of 2 groups: usual care or Wrapped plus usual care (see "Wrapped website" and "comparator website" below for further details on the respective interventions). Participants will be directed to their allocated intervention following randomization through a hyperlink. All participants will be free to interact as much or as little with the respective materials; participants will be emailed the hyperlink to enable repeat visits. An email reminder to visit the intervention will be sent to all participants who have not done so 2 weeks after first access is provided.

Wrapped Website

See Multimedia Appendix 6 for the intervention logic model which presents the theoretical model and an outline of intervention components. Newby et al [14] have provided a detailed description of intervention content reported in line with Template for Intervention Description and Replication guidance and have provided screenshots, images of intervention materials, and example videos.

Comparator Website

Usual care is the comparator. Existing STI self-sampling websites typically provide only basic information on STIs and condom use to their users [21]. To replicate this level of health promotion, and to provide an equivalent "intervention" experience for those in the control group, a stand-alone WordPress website presenting comparable basic information has been created [22]. The same basic information is also provided on the Wrapped website.

Analytics Data

Participant access to and engagement with their allocated website will be tracked. There is no minimum acceptable level of engagement—all participants will be allowed to continue in the trial regardless of their level of interaction with the material. Tracking will occur in the background (with each participant's explicit consent) to ensure that it is unobtrusive. Data will be collected within the Wrapped website itself using an analytics package called Matomo, a secure open-source platform [23] (see Multimedia Appendix 7 for details on what will be measured). Analytics data will be used to calculate intervention dose received and to identify any fixable "friction points" in the user journey that may adversely affect usability.

Primary Outcome Measures

Primary outcome measures are as follows:

1. The percentage of freetest.me users recruited to the feasibility RCT.
   This will be assessed as the number of participants randomized out of those using freetest.me in the 4 local authority areas, that is, all those exposed to the recruitment advert.
2. The percentage of randomized participants with a valid primary outcome measure. This will be assessed as the percentage of randomized participants who provide a chlamydia test result at M12.

Secondary Outcome Measures

Secondary outcome measures are as follows:

1. Percentage of randomized participants with outcome data required to measure cumulative incidence of chlamydia (measured using M3 and M12 chlamydia self-sample, and the relevant item within M3, M6 and M12 surveys).
2. The distribution of Index of Multiple Deprivation quintile among users of freetest.me over the 3-month recruitment period, compared to that of the final sample, within each of the 4 recruitment areas.
3. The number of randomized participants with a valid primary outcome measure at M12 by group (gender, ethnicity, sexual identity, deprivation, randomized groups, and chlamydia diagnosis at baseline).
4. The number of randomized participants testing positive for chlamydia at M12 in the intervention and the control group.
5. Attrition curves comparing the percentage of valid participants in the trial at randomization, M3, M6, and M12 plotted for the intervention and control arms (dropout attrition).
6. Completeness of data from outcome measures that would be needed in a definitive trial (ie, self-report of chlamydia result at baseline, results from biological samples, demographic information, self-report of condom use and chlamydia infection, and data needed for cost-effectiveness and cost-utility analyses).
7. The percentage of freetest.me users randomized following each of the different recruitment messages employed.
8. The percentage of valid participants in the 2 arms that do not achieve predetermined intervention "goals" (ie, do not follow instructions within each component of the Wrapped website to their culmination, for example, ordering a sample pack, or watching a suggested video), and the bounce rate for home and content pages.
9. Completeness of data on costs and resource use that would be needed for the economic evaluation in the definitive RCT.

XSL•FO
RenderX

10. Proportion of participants in the control group who report (at M12) any exposure to Wrapped.
11. The total number of adverse events reported during the course of the study (inadvertent disclosure that sexually active or testing for STI if overseen using Wrapped, initiation or change in the consumption of pornography, or other).

Sample Size

At least 60 participants per arm are recommended to allow proportions to be estimated with good precision [24]. This is inflated to allow for an estimated 25% nonreturn of initial chlamydia self-test sample (based on freetest.me statistics; 60/0.75=80) and a further estimated 30% dropout over the course of the feasibility trial (a conservative estimate based on 19% dropout achieved in Free et al [25] sexual health feasibility RCT (80/0.7=114 per arm). Based on this, the total sample size required for the present fRCT has been calculated as 230 participants.

Progression Criteria

The following criteria will be used to inform progression to a full trial:

1. The proportion of freetest.me users recruited to the feasibility trial is sufficient to obtain the sample size required for the definitive RCT (sample size for the definitive RCT will be determined using data from multiple sources, including chlamydia positivity in the control group of the present fRCT and national level data on chlamydia positivity among young people testing for STIs through the internet (used to estimate the level of chlamydia positivity in the target population), expert opinion on what would be a clinically meaningful reduction in chlamydia positivity for the target population, typical effect sizes achieved in comparable studies, and the size of the available sampling pool for the future RCT).
2. A total of 60% (138/230) of participants (those randomized) followed up for the definitive RCT primary outcome measure at M12
3. Index of Multiple Deprivation quintile distribution for the final sample is comparable to that of individuals in the sampling pool (freetest.me users in the partner local authority areas).
4. Adverse events are judged as sufficiently infrequent and/or serious to cause concern.

The progression decision will be determined by the independent Study Steering Committee (SSC), in conjunction with the Data Monitoring and Ethics Committee, based on achievement of all the above criteria, or convincing evidence that any 1 criterion is amenable for necessary improvement.

Ethical Considerations

Ethical approval was obtained from the NHS East Midlands—Leicester Central Research Ethics Committee (reference 20/EM/0275) and the trial was registered with the ISRCTN (ISRCTN17478654). To participate, all individuals will be required to provide informed consent. All participants will receive a £65 (US $79.95) payment in the form of vouchers to recompense for time spent completing the research activities. All research data will be deidentified before analysis and reporting.

Data Management and Analysis

Data Management

All trial data will be collected in REDCap, a secure data management program hosted on a university server. REDCap will create a unique ID for each participant at the point of consent. All activity will be associated with this unique ID, enabling data across time points to be easily and accurately linked. Analytics data will be stored within Matomo and the Wrapped website, also linked to the unique ID. Only the research team will have access to data stored on REDCap, Matomo, and the Wrapped website. At the end of data collection, all data captured through these platforms will be exported to a password-protected folder for analysis purposes. Only the research team will have access to this folder. Consent data will be separated from all other data (research data) through storage in 2 separate folders. For the research data, at the point of export, all identifying data will be removed and the remaining data linked using the unique participant ID before cleaning. Once the research team agrees that all data is present and complete, all data present in REDCap, Matomo, and the Wrapped website will be permanently deleted. Research data will remain in the password-protected folder until analysis is complete after which it will be deleted. Consent data will be kept for 6 years before deletion. In line with the funder's requirements, a copy of the raw anonymized research data will be deposited within the University of Hertfordshire Research Archive (UHRA [26]) and made available indefinitely on an open-access basis.

Statistical Analysis

Researchers performing the analysis (KN, KB, LJ, and SB) will be blinded to participant allocation. Quantitative data will be analyzed descriptively. Measures of location and dispersion, including means and SDs, medians and IQRs, and number and percent for categorical variables, will be used to describe the data at baseline and at each follow-up time point. CIs will be calculated and presented as appropriate. All analyses will be performed using SPSS (version 28; IBM Corp). As with the raw data, the syntaxes used for analysis and the output generated will also be deposited within the UHRA and made available indefinitely on an open-access basis.

Nested Qualitative Study

A nested qualitative study will be conducted during the fRCT. The aims of this study will be to explore participant's views and experiences of the Wrapped intervention, experience of trial procedures and materials, and perceptions of whether and how the intervention has changed their condom use beliefs or behavior.

Approximately 30 individuals (number to be determined by data saturation) participating in the fRCT will be invited to take part. All participants will receive a £20 (US $24.6) voucher in recognition of their time. Participants will be asked at baseline (single question in survey) whether they are willing to take part

XSL•FO
RenderX

in a semistructured telephone or video call interview and if so, to provide suitable contact details.

Participants will be purposively selected to create a varied sample representing different demographic criteria, completers and noncompleters from both trial arms, those with varying levels of intervention engagement, and those thought to have experienced specific events that could influence dropout. Selected individuals will be contacted and directed to a new project page on REDCap where they will be asked to provide informed consent to take part in this additional aspect of the study.

Interviews will last up to 1 hour and will be fully transcribed before analysis. Framework analysis [27] will be used to analyze the data.

At the end of each interview, a second aspect of the qualitative study will be discussed with the participants. This is interviewing sexual partners to better understand any changes in condom use decision-making in light of the intervention. After the interview, an email invitation will be sent to the participant which they can choose to forward to their partner if they wish. It will then be up to the sexual partner to contact the research team if they want to participate. They will be given the option to email or telephone the research team if they have any questions, or simply to follow a hyperlink straight to the relevant project page on REDCap. Here, they will be required to provide informed consent to take part in the study. All data will be collected, processed, and analyzed as described above for primary interviewees. Each individual who participates will be given a £20 (US $24.6) voucher in recognition of their time.

Patient and Public Involvement

A patient and public involvement (PPI) group will be formed for this study. Members will be existing users of web-based STI self-sampling services. The research team will work with the PPI group to determine the different value propositions included in the study advertisements; determine strategies for effective retention of participants (eg, the level and timing of voucher payments provided, communication methods, and tone of messaging); draft the participant information and consent statements for the fRCT and nested qualitative study to ensure that they are clear and easy to understand; iteratively test the surveys before their use to maximize content validity, readability, clarity, and comprehensiveness; review fRCT findings and reflect on changes that should be made to recruitment and retention strategies before a definitive trial; and two members of the PPI group will also support the monitoring of the fRCT by serving as members of the SSC.

Research Governance Risks, and Dissemination

Monitoring

An independent SSC and Data Monitoring and Ethics Committee will be convened to provide oversight and ensure adherence to standards of best practice. Institutional sponsorship is required. A clinical trial unit will provide trial management and statistical oversight.

Risks, Support, and Safeguarding

Participating in the fRCT has limited risk associated with it for participants. As a result of participation in the fRCT, some people may attempt to use condoms and fail, if for example, their sexual partner responds negatively to their request to use a condom or there are condom-use errors, and this may have some negative psychological impacts in the short-term. Both the Wrapped and the comparator website will contain links to sources to help and support on topics of sex and relationships, including condom use and intimate partner violence. All participants will be provided with a debrief email at the end of their participation in the trial (at M12). Surveys at all time points will include items that measure sexual well-being. Responses may indicate that a participant was or is the victim of sexual coercion or abuse. Participants aged 18 years and over who indicate this will be signposted to appropriate sources of support by email and offered, at their request, to receive support from a university safeguarding officer. Alternatively, if a participant younger than 18 years indicates coercion or abuse, the study safeguarding procedure will be initiated. Under these circumstances, the confidentiality agreement with the participant will end, and the information provided will be passed to their local NHS trust sexual health service so that they can support them in line with existing protocols. Data-sharing agreements will be in place with these trusts to enable this action to be performed. The relevant individual will not be able to refuse this referral process, but they will be informed that this is happening. All participants are informed of this safeguarding procedure within the participant information and are required to agree to this at consent. A reminder of this process is also stated alongside the relevant questions within each survey. Participants will also be asked to disclose their experience of adverse events within M3, M6, and M12 surveys. These events could be as follows: (1) inadvertent disclosure to another person that the participant is sexually active or testing for an STI as a result of them being overseen using Wrapped, (2) initiation or change in the consumption of pornography by the participant, and (3) other. If an event is disclosed, the circumstances will be discussed by the research team who will seek advice from the sponsor, ethics committee, and/or steering committee, if required before determining the most appropriate course of action.

Participation in the nested qualitative study is low risk. Participants will be asked about their experiences of condom use before and after the intervention. It is possible that some participants may find these types of questions uncomfortable. The nature of the study is clearly outlined in the participant information and participants are made aware that they can withdraw at any time, as well as choosing not to answer any question that they are uncomfortable with. Debriefing information will be emailed to all secondary participants (sexual partners of participants in the fRCT) after the interview; primary participants will receive this on completion of the fRCT.

Consent

Informed consent will be taken on the internet through REDCap (separately for the fRCT and the nested qualitative study). Participants must agree to all statements before being allowed

XSL•FO
RenderX

to proceed. Participants who do not agree will be thanked for their interest and routed out of the project; no data will be collected (see Multimedia Appendix 4 for a copy of the consent form).

Confidentiality

Individuals' decision to take part and all their data will be treated as confidential. All data will be stored securely, and access restricted to the research team. At the point of consent, a unique identifier will be assigned, and all data linked using this. At download, personal identifying information will be removed from the data set. The only data preserved after the end of the study will be consent data (kept for 6 years) and the anonymized data set, held in a research archive indefinitely.

Dissemination

During the study, progress will be communicated to stakeholders through a project website and linked Twitter account. At end of the study, findings will be disseminated to the public through a written and video lay summary. Findings will be communicated to the academic community through conference presentations and publications in an open-access journal.

Results

Recruitment to the fRCT began in March 2021 and was completed in October 2021. Approximately half of all participants have reached the M12 time point (study end) to date. Data collection was completed in December 2022.

Discussion

Overview

This fRCT is designed to assess whether and how it is possible to carry out a future definitive RCT to evaluate the effectiveness and cost-effectiveness of an intervention to increase condom use among young people. The rapid increase in use of web-based STI self-sampling services, accelerated by the COVID-19 pandemic, means that young people are increasingly required to self-manage their own sexual health screening. This, along with persistently high rates of STIs among this age group, makes the provision of behavior change support in this web-based context imperative.

Strengths and Limitations

This fRCT employs the proposed design and methods that would be used in a full RCT. This will enable the research team to develop, assess, and optimize all the systems and procedures required to run the full trial before time and resource commitments are allocated. Furthermore, the study has been setup to inform important aspects of this future trial, such as which advertisements results in the highest recruitment rate? Are there any friction points within the intervention content that may contribute to dropout? Could the tone, content, or frequency of communication with participants be improved? Should the progression criteria for this feasibility fRCT be satisfactorily met, the research team will refine intervention content and study procedures in line with this to further enhance participant recruitment and retention, and study efficiency.

As this is an fRCT, the study is being conducted on a much smaller scale than a future trial. Some technical aspects of the study that are manageable at this stage will likely need to be revised. In the present study, for example, the research team are reporting positive chlamydia test results (arising from M3 and M12 testing) to each relevant trust which is time-consuming and represents an avoidable data protection risk. An alternative would be for this information to be passed directly to the trusts by the self-sampling service provider. In the future-full trial, the team would seek to overcome such technical issues.

The unusual context in which this fRCT is being run should be acknowledged. The COVID-19 pandemic has affected sexual health services and sexual behavior in ways that could not have been imagined at the time this study was conceived. When recruitment to the fRCT was initiated, restrictions on public behavior imposed to control the spread of infection were still in place but were lifted approximately 3 months later. The impact of the environment at that time on STI testing and diagnoses will not be known until the release of annual STI data in Autumn 2022. Although an increase in the use of internet testing will serve to increase the size of the sampling pool drawn upon for this study, thus potentially accelerating recruitment, it should not impact upon the recruitment rate, as this is merely a reflection of the rate at which those who see the advert are converted into participants. It should, however, be acknowledged that the pandemic is likely to have both positively and negatively impacted on people's time and/or willingness to engage in research, factors which for some will also have changed with changing restrictions and may serve to influence study recruitment and retention. It is also important to consider whether changes in sexual risk behavior during this time could lead to fewer cases of chlamydia being identified in the present study than anticipated. This concern is, however, not supported by community surveys, which indicate that a substantial proportion of people continued to engage in at-risk behavior during 2020 [28-30], and the most recent STI data which shows that among those seeking internet testing, chlamydia positivity was comparable between 2019 (23,426/284,050, 8.2%) and 2020 (33,294/381,744, 8.7%) [1].

Abstract

Background: Sleep disorders are common among the aging population and people with neurodegenerative diseases. Sleep disorders have a strong bidirectional relationship with neurodegenerative diseases, where they accelerate and worsen one another. Although one-to-one individual cognitive behavioral interventions (conducted in-person or on the internet) have shown promise for significant improvements in sleep efficiency among adults, many may experience difficulties accessing interventions with sleep specialists, psychiatrists, or psychologists. Therefore, delivering sleep intervention through an automated chatbot platform may be an effective strategy to increase the accessibility and reach of sleep disorder intervention among the aging population and people with neurodegenerative diseases.

Objective: This work aims to (1) determine the feasibility and usability of an automated chatbot (named MotivSleep) that conducts sleep interviews to encourage the aging population to report behaviors that may affect their sleep, followed by providing personalized recommendations for better sleep based on participants' self-reported behaviors; (2) assess the self-reported sleep assessment changes before, during, and after using our automated sleep disturbance intervention chatbot; (3) assess the changes in objective sleep assessment recorded by a sleep tracking device before, during, and after using the automated chatbot MotivSleep.

Methods: We will recruit 30 older adult participants from West London for this pilot study. Each participant will have a sleep analyzer installed under their mattress. This contactless sleep monitoring device passively records movements, heart rate, and breathing rate while participants are in bed. In addition, each participant will use our proposed chatbot MotivSleep, accessible on WhatsApp, to describe their sleep and behaviors related to their sleep and receive personalized recommendations for better sleep tailored to their specific reasons for disrupted sleep. We will analyze questionnaire responses before and after the study to assess their perception of our proposed chatbot; questionnaire responses before, during, and after the study to assess their subjective sleep quality changes; and sleep parameters recorded by the sleep analyzer throughout the study to assess their objective sleep quality changes.

Results: Recruitment will begin in May 2023 through UK Dementia Research Institute Care Research and Technology Centre organized community outreach. Data collection will run from May 2023 until December 2023. We hypothesize that participants will perceive our proposed chatbot as intelligent and trustworthy; we also hypothesize that our proposed chatbot can help improve participants' subjective and objective sleep assessment throughout the study.

XSL•FO
RenderX

Conclusions: The MotivSleep automated chatbot has the potential to provide additional care to older adults who wish to improve their sleep in more accessible and less costly ways than conventional face-to-face therapy.

Introduction

Overview

Evidence exists for a bidirectional relationship between sleep disorders in the aging population and people with neurodegenerative disease [1-3]. Specifically, between 40% and 70% of the older population report difficulties in sleep onset or maintenance and insomnia symptoms [4-6], which increase their risk of developing neurodegenerative disorders. Similarly, there is a high prevalence of sleep disorders, such as sleep apnea and circadian rhythm disorders, among people with neurodegenerative disorders [7-10], where sleep disorders can accelerate cognitive decline [11,12]. Moreover, neurodegenerative disorders affect not only patients but their entire households, especially the primary carer. Indeed, studies [13-16] have shown that approximately two-thirds of older adult caregivers have some form of sleep disturbance. Thus, early intervention of sleep disorders among older adults can improve their quality of life, reduce their risk of developing neurodegenerative disorders, and prevent further complications among household members.

Researchers have conducted clinical trials using cognitive behavioral therapy [17-19] and motivational interviews [20-22] to improve sleep quality among older people, people with neurodegenerative disorders, and their carers. However, one-to-one individual therapies (in-person or remote) and face-to-face group therapies may be costly and difficult to access.

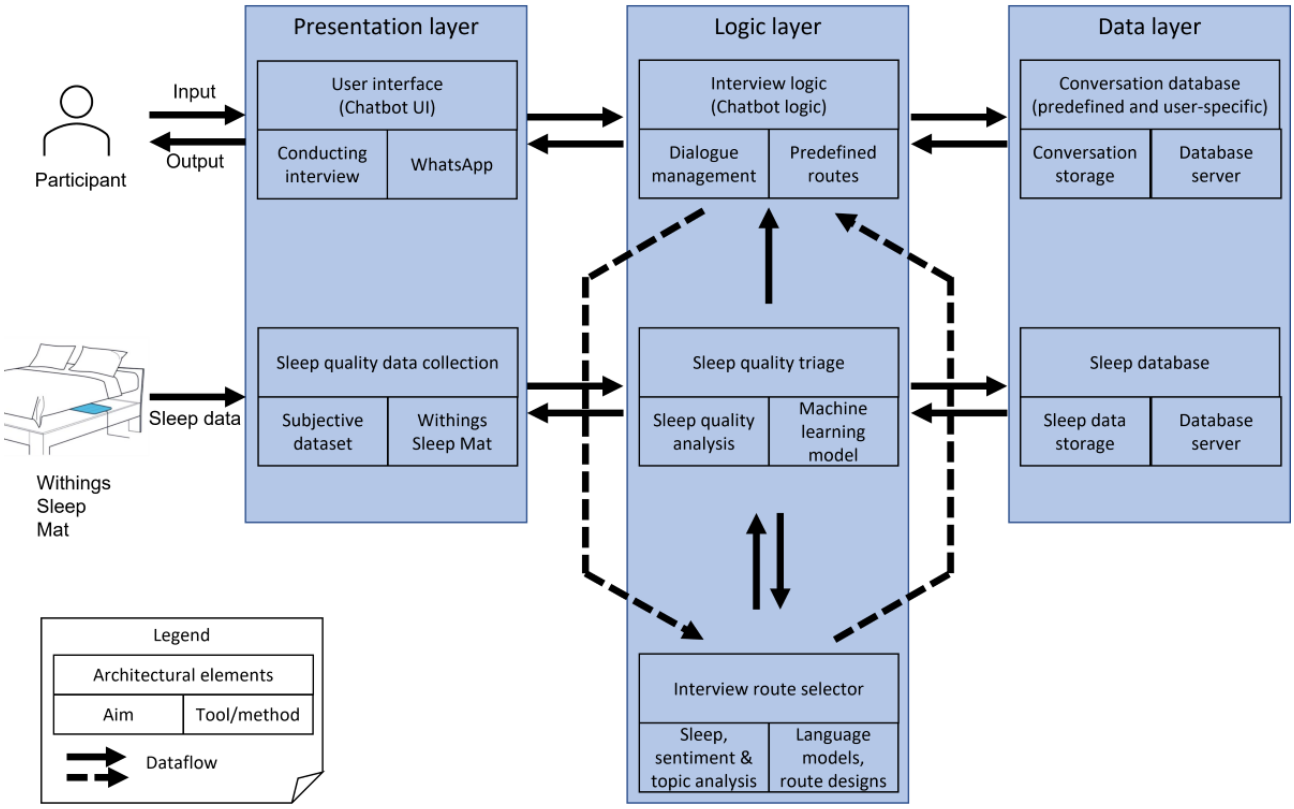
Several digital insomnia tracking and treatment systems [23,24] have been developed and evaluated. For example, Zaslavsky et al [22] developed a mobile health (mHealth) monitoring and self-management app. mHealth monitors sleep quality through the wearable Fitbit Charge 2 and automatically sends text messages that provide weekly information and motivational feedback. Zaslavsky et al [22] showed that their proposed mobile app mHealth, combined with motivational interviews conducted by telephone, can significantly improve participants' self-reported sleep quality after 19 weeks of participation. In addition, Aji et al [23] showed that a self-reporting mobile app (SleepFix), connected to a wearable sleep-tracking device, can encourage users' engagement with the app's self-reporting functionality in a pilot randomized controlled trial.

However, these studies only combine digital sleep quality monitoring with a digital self-reporting mechanism or periodic text messages to encourage users to engage in sleep quality reporting, good sleep habits, and routine. They do not engage in conversations that may further encourage information sharing and behavioral changes. To engage more actively with users, Rick et al [24] proposed a Telegram-based chatbot, SleepBot, that dynamically enquires about users' sleep information based on preprogrammed questions. Aarts et al [25] proposed a chatbot Snoozy for children aged 8-12 years with sleep difficulties, which asks children how their sleep was, the reasons for it if they slept poorly, and what behavioral methods they have tried to help with their sleep. Aarts et al [25] showed that a chatbot could help collect subjective reports from children over sustained period instead of traditional diaries.

In this feasibility study, we propose a sleep intervention chatbot design named MotivSleep. Our proposed MotivSleep first triages participants' sleep based on information gathered from a contactless sleep-tracking analyzer. Then, MotivSleep starts conducting sleep interviews only when the sleep analyzer identifies a bad night's sleep. The automatic sleep interview asks participants about any potential adverse factors that might have affected their sleep the night before, prior to using this information to provide personalized recommendations for better sleep (ie, healthy habits that you can practice during the day to help you get a good night's sleep) [26] and encouraging them to maintain good sleep habits.

Design Engineering Process

This work is built upon automated and manual monitoring and care procedures followed by the Care Research and Technology Center (CRT), part of the UK Dementia Research Institute (UK DRI). The design of our proposed MotivSleep chatbot involved an advisory group with patients and health care professionals from its conception, following the identified key characteristics in developing human-centered care technologies [27]. Specifically, carers, health professionals, occupational therapists, sleep specialists, chatbot researchers, and designers have come together in 2 workshops where the needs and values of the stakeholders were discussed [28]. We also requested input from the advisory board, conducted interviews with people living with dementia and their carers, conducted patient and public involvement and engagement sessions with healthy older adults, and surveyed results to develop initial dialogue plans that can conduct sleep interviews through chatbot.



Based on information and advice from the groups mentioned above, we built a sleep management chatbot integrated with WhatsApp. This internationally available messaging platform provides instant text and voice messaging services through the American company Meta Platforms. To access the proposed MotivSleep chatbot, we will gather the participants' phone numbers and add them to the MotivSleep database, where messages will be sent out automatically at the user's preferred time, potentially daily. Additionally, we will use the Withings sleep analyzer, a commercially available contactless device, to

XSL•FO
RenderX

monitor and track participants' objective sleep parameters. The sleep analyzer can be installed under the participant's mattress, and the information gathered can be accessed through an API. The Withings sleep analyzer is chosen due to its passive recording ability (ie, it does not need recharging or adjustments once installed) and previous collaboration between UK DRI and Withings that provides easy integration. Additionally, the Withings sleep analyzer has been evaluated and showed comparable results to actigraphy and polysomnography based sleep assessment, in older people [29]. In this study, we will analyze participants' sleep data to monitor the participants' objective sleep parameters based on respiration, heart rate, snoring, and apnea episodes. This analysis triggers the conversation stage of our proposed MotivSleep chatbot.

The chatbot component of our proposed MotivSleep chatbot will automatically start a conversation with the user at least twice a week, on Wednesdays and Saturdays, to prevent data scarcity and ensure we collect data from all participants. In addition to the previously mentioned 2 days, the chatbot will start the conversation when the server detects anomalous sleep patterns from the participant's data. Other than on these occasions, MotivSleep will not start the conversation to avoid too many repetitive requests for information from participants. Furthermore, participants can trigger the chatbot at any time by initiating the chat (ie, by sending "Hi MotivSleep" to the chatbot). The architecture of MotivSleep is shown in Figure 1 and is based on the Distinguish Business Logic from ML Model pattern [30].

Figure 1. The architecture of the proposed MotivSleep chatbot. UI: user interface.

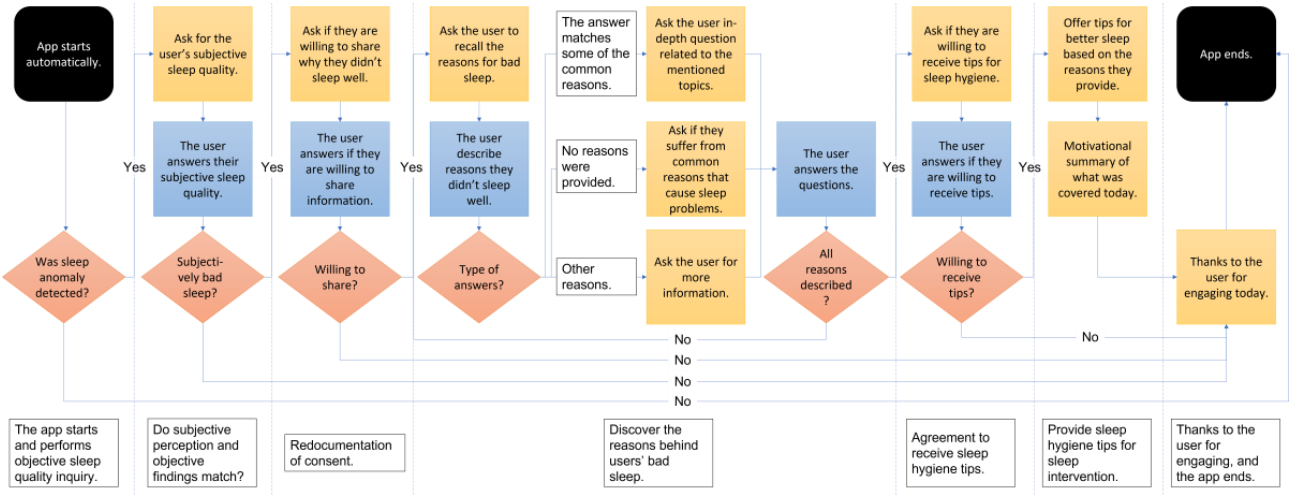
Specifically, MotivSleep consists of 3 layers: a presentation layer, a logic layer, and a data layer, as follows:

1. The presentation layer provides a user interface to conduct interviews where participants interact with MotivSleep delivered through WhatsApp. Backend structures allow MotivSleep to acquire sleep data from the Withings sleep analyzer.
2. The logic layer that provides the chatbot logic to manage the chatbot dialogue based on predefined dialogue routes, a sleep assessments triage module that analyzes participants' sleep assessments using pretrained machine learning models, and an interview route selector that selects conversation paths based on sentiment analysis and topic modeling using machine learning models.
3. The data layer that provides data storage for participants' conversation history and sleep data gathered from the Withings sleep analyzer.

Chatbot Features

The participants will interact with the WhatsApp chatbot and have a Withings sleep analyzer installed to track their sleep. Our system's backend server is connected to the Withings sleep analyzer database. The sleep monitoring data is accessible through the designed triage mode and the chatbot feature, with which the participants can interact. Specifically, MotivSleep accesses participants' sleep-tracking data in the morning and triages their objective parameters. The triage will result in three signals, as follows:

1. Red: an anomalous night with significant differences from the usual (ie, gathered 2 weeks before the start of the chatbot engagement) patterns is detected. Specifically, this relates to participants' bedtime, wake-up time, the number of times they leave the bed during the night, and the duration of snoring time.



XSL•FO
RenderX

2. Yellow: when the model detects ongoing problems in their sleep.
3. Green: when there are no significant differences in sleep patterns or other existing sleep problems.

The MotivSleep chatbot follows a dialogue route with multiple branches, which may end or continue the conversation. Figure 2 shows the dialogue design of our chatbot. Specifically, our chatbot is designed with seven stages, as follows:

1. The objective sleep assessment: sleep quality is highly challenging to assess, with a range of potential models for data fusion from the internet of things devices. In the context of our study, we will initiate analyses of the objective sleep assessment using measures provided by the installed Withings sleep analyzer. Specifically, MotivSleep starts at a predefined time each day and calculates the sleep quality using the sleep tracking device. If the triage result is red or yellow, MotivSleep will continue to the next stage to start the chatbot and engage with the participant; otherwise, MotivSleep will not send the initial text message and will quit automatically. We note that the UK DRI CRT has ongoing work in sleep quality evaluation using the Withings sleep analyzer, which could be incorporated into the study for comparison when available.
2. The subjective sleep assessment: MotivSleep chatbot activates the interview through WhatsApp and asks the participant, "Did you sleep well last night?" This stage helps MotivSleep confirm with the participant if they had a bad night's sleep. If the participant denies having had a bad sleep, our chatbot will go to stage 7, wishing them a good day and quitting. However, if the participant confirms that they have had a bad night, the chatbot will continue to ask the next question.
3. Redocumentation of consent: the chatbot will briefly remind the participant about the study, ask them for their consent to participate in the current interactions, and provide insights into their poor sleep. If they do not consent, the chatbot will go to stage 7, where we thank them for their engagement, and the chat ends; otherwise, the chatbot will continue to the next stage.
4. The information-seeking stage: in this stage, the chatbot will ask the participant for reasons that might explain why they did not sleep well the previous night. This open question seeks insights into participant's behaviors before and during their sleep that may have contributed to a bad night's sleep. Answers to this question are collected and analyzed, and the analysis result will prompt the following three types of further questions:
   i. In-depth questions related to predefined specific reasons that cause their poor sleep. These questions will be triggered if we identify predefined reasons from the participant's answers;
   ii. Multiple-choice questions consist of potential reasons that might cause poor sleep. These questions will be asked if the participant answers that they do not know why they had a poor sleep;
   iii. Similar questions to the previously asked question (ie, why did you sleep poorly?) until they confirm there is no more information to add. These questions will be asked if the reasons the participant provided early are not one of the predefined reasons.
5. Agreement to receive personalized recommendations for better sleep: in this stage, the chatbot will ask the participant whether they want to hear personalized recommendations for better sleep. If they disagree, the chatbot will go to stage 7, where we thank them for their engagement, and the chat ends; otherwise, the chatbot will continue to the next stage.
6. Provide personalized recommendations for better sleep: in this stage, we provide specific recommendations to the participant based on the information gathered during stage 4. Furthermore, we provide a motivational summary of what was covered today, including their reasons for poor sleep and recommendations for better sleep.
7. The end of the conversation: in this stage, we thank the participant for the engagement, wish them a good day, and end the conversation. To further motivate the participants, the chatbot also praises the participant if some of the repeated behaviors negatively affecting their sleep were not mentioned in this interaction.

Figure 2. Chatbot dialogue design. Note that the black ovals denote the start and the end of the skill, the yellow rectangles denote the dialogue by the chatbot, and the blue rectangles and the blue diamond denote the participants' inputs. The orange diamonds denote the diverging options.

XSL•FO
RenderX

This chatbot aims to perform knowledge transfer, that is, using the information gathered from the fourth stage to provide personalized recommendations for better sleep in the sixth stage, thus transferring knowledge on better sleep to the participants.

Research Questions

The MotivSleep chatbot used in this feasibility study has been co-designed with patients, carers, and other health professionals. Together, we identified the following research questions:

1. *RQ1* Is our proposed MotivSleep chatbot accessible to participants, and how feasible is it to engage the participants with interviews using MotivSleep? We focus on assessing the feasibility and usability of our proposed MotivSleep, by measuring the number of turns and time spent chatting with the skill per engagement. Moreover, we assess MotivSleep's accessibility by asking participants to rate their willingness to promote the chatbot using the net promoter score (NPS) [31] question in the exit questionnaire. Finally, we assess the participants' perception of the chatbot by asking participants to complete the Godspeed Perceived Intelligence subscale (GPIS) [32] and Trust Perception Scale-Human Robot Interactions (TPS) [33] questionnaires.
2. *RQ2* Can our proposed MotivSleep chatbot help improve participants' subjective sleep assessment? We aim to evaluate the participants' self-reported sleep assessment to analyze if the proposed MotivSleep helps participants to subjectively sleep better through the completion of the Epworth sleepiness scale (ESS) [34], Insomnia Severity Index (ISI) [35], modified Pittsburgh sleep quality index (PSQI) [36], and the single-item sleep quality scale (SQS) [37], conducted at the beginning, the end, and every 2 weeks throughout the study.
3. *RQ3* Can our proposed MotivSleep chatbot help improve participants' sleep, measured using the Withings sleep analyzer? We aim to analyze participants' objective sleep assessments using sleep recordings gathered by Withing sleep analyzer throughout the study.

Methods

Overview

Once reviewed by the Imperial College Research Ethics Committee, we will recruit 30 healthy older adults (aged 65-90 years) in 3 cohorts through the UK DRI CRT community outreach group community outreach in West London. Participants will have access to the conversational agent through WhatsApp chat. We estimate that the average conversation will take less than 10 minutes. Each participant will also have access to the Withings sleep analyzer provided by the research group.

A poststudy questionnaire consisting of the GPIS, TPS, and NPS will be completed when the participant finishes the study. We analyze participants' answers to assess the participants' opinions on the proposed MotivSleep chatbot's intelligence, trustfulness, and participants' satisfaction with MotivSleep, to answer RQ1. Additionally, all participants will complete the ESS, ISI, modified PSQI, and SQS questionnaires before the start, fortnightly during the study, and at the end of the study. We analyze the answers to these questions to investigate RQ2.

The first cohort of 10 participants will use both the Withings sleep analyzer for 6 weeks (the first 2 weeks aims to establish baseline sleep assessments without the usage of MotivSleep) and the WhatsApp chatbot for 4 weeks, with WhatsApp message reminders to encourage WhatsApp chatbot engagement sent out fortnightly (ie, twice for the first cohort of 10 participants). The first batch of participants' feedback and engagement measures will inform a new iteration of improvements.

The second cohort of 10 participants and the third cohort of 10 participants will use the WhatsApp chatbot for 8 weeks and 12 weeks and the Withings sleep analyzer for 10 weeks and 14 weeks, respectively. Participants will be reminded fortnightly (ie, 4 times for the second cohort participants and 6 times for the third cohort participants) to encourage participation with the WhatsApp chatbot when activated. After each cohort, participants' technical feedback will be addressed by improving the software.

The feasibility study will have a single experiment condition that includes three types of features:

1. A sleep tracking device (ie, Withings sleep analyzer) and sleep analysis model.
2. A chatbot (ie, MotivSleep) hosted on WhatsApp that conducts sleep interviews. The dialogue is designed to understand the reason behind participants' sleep problems, provide personalized recommendations for better sleep, and support behavior changes to improve their sleep assessments.
3. WhatsApp messages that encourage interaction with MotivSleep.

We will measure three classes of outcome variables as follows:

1. Assess the feasibility and usability of our proposed chatbot MotivSleep (RQ1)—the number of interactions in each MotivSleep conversation and time spent chatting with MotivSleep, and the poststudy questionnaire consisting of NPS, GPIS, and TPS.
2. Assess the subjectively perceived sleep assessments (before, during, and after the study) (RQ2)—ESS, ISI, PSQI, and SQS questionnaires.
3. Assess the objectively measured sleep assessments (before, during, and after the study) (RQ3)—obtained from the Withings sleep analyzer and analyze using the Withings provided sleep analysis models.

Recruitment

This study will be conducted in 3 batches. Participants in all 3 batches will be healthy older adults with no neurodegenerative disease. The participants will be recruited through the UK DRI CRT community outreach group in West London. The recruitment process follows the recommendations and requirements laid out in the UK National Institute for Health and Care Research Clinical Research Network policy, based on the inclusion and exclusion criteria. Specifically, Participants should be aged between 65 and 90 years, able to communicate fluently in English, experiencing sleep problems and wanting

XSL•FO
RenderX

to improve their sleep, willing to install a Withings sleep analyzer and use the WhatsApp chatbot and have access to high-speed wireless internet connection at home, and able to provide informed consent. The exclusion criteria include the following: (1) people with unstable mental states, including severe depression, severe psychosis, agitation, and anxiety; (2) people with severe sensory impairment; (3) people who have active suicidal thoughts; (4) people who are receiving treatment for terminal illnesses.

Participants will be compensated for their time and inconvenience with £25 (US $31.15) per 2 weeks for participation, that is, for filling out the prestudy informed consent and questionnaires before, during, and after the study and engaging with the chatbot. The questionnaires will be provided on Qualtrics, separately to the chatbot, and sent to the participants as WhatsApp messages. Additionally, our team will teach the participants to complete the questionnaire using their smartphones before the study on an in-person visit when they sign the consent form. The subsequent questionnaires during the study will be sent to their mobile as WhatsApp messages.

A total of 30 individuals will be recruited in 3 cohorts. In total, we aim to include 18% of individuals who self-identify as members of a minority ethnic group to ensure alignment with the UK population [38] and avoid exclusion. Only approved phone numbers (of people who have consented to the study) can interact with the chatbot.

Data Management

WhatsApp messages are automatically encrypted, so conversations are private and cannot be accessed by Meta (the mother company of WhatsApp).

We will create 2 databases in Microsoft Azure, where both databases are only accessible through designated virtue private network connections, which are available only to the app and the researchers. We will use the Research Data Storage (RDS) managed by the Imperial College London to host the data sets after obtaining them through Azure. RDS is only available to researchers within the project through university-hosted Virtual Private Network connections.

Specifically, we will first pseudoanonymize each user by assigning them an automatically generated user ID and storing this information in a secure Azure database. MotivSleep then automatically stores the transcripts anonymously in a second secure database. Both databases are hosted on Azure before being transferred to RDS. After moving both user information and transcripts to RDS, they will be permanently deleted from the Azure databases. There will be 2 copies of sleep tracking data, that is, Withings will store 1 copy, and the RDS will store another copy. Responses to the questionnaires will be stored in Qualtrics servers.

According to the Imperial College data retention policy, the data will be retained for at least 12 years.

Analysis Plan

We aim to analyze the following four types of data:

1. The dialogue transcripts: dialogue transcripts can help us understand how much time participants spend talking to the chatbot, what sleep behaviors each participant exhibits, and how often these behaviors appear when troublesome sleep patterns are detected.
2. The answers to the GPIS and TPS questionnaires: these answers help us to understand how participants perceive our proposed chatbot MotivSleep, in terms of usability, feasibility, intelligence, and trustfulness.
3. The answers to the ESS, ISI, modified PSQI, and SQS questionnaires before, during, and after the study help us analyze participants' subjective views of their sleep assessments and provide insights into their perceived sleep changes over time.
4. The sleep data tracked by the sleep tracking device Withings sleep analyzer: Sleep tracking helps us monitor participants' objective sleep assessment changes over time, measured by the tracking devices unrelated to participants' subjective feeling of their sleep.

Ethical Considerations

The study will be submitted to the Imperial College Research Ethics Committee at Imperial College London, London, United Kingdom. All participants will be provided with an information sheet detailing the aim and rationale for the research; inclusion and exclusion criteria; what will happen if they agree to take part; any risks of taking part in the study; clarification of the process for ensuring anonymity and confidentiality, including any limits to confidentiality; what information will be held about them and who will have access to it; possible benefits; and plans for project report. All participants will then be required to sign the informed consent form before participating in the study. Additionally, all participants' identifiable data will first be anonymized. The identifiable and anonymized data will be stored in separate secure cloud-based databases (Azure PostgreSQL server) before being transferred to Research Data Store. Finally, each participant will be compensated £25 (US $31.15) per 2 weeks for their participation.

Results

The planning and development of this study started in August 2022. We have since developed the chatbot MotivSleep. The chatbot's design is being evaluated by carers, health care professionals, and occupational therapists and will be updated after their evaluation. The first cohort of participation recruitment will start in May 2023, the second cohort will begin in June 2023, and the third cohort will start in August 2023. The anticipated study completion date is December 2023.

In this study, we aim to test three hypotheses as follows:

1. First, we hypothesize that participants will perceive our chatbot as intelligent and trustworthy and are satisfied with our proposed MotivSleep.
2. We also hypothesize that our proposed chatbot MotivSleep can improve participants' subjective sleep assessment over their usage of the chatbot based on collected using ESS, ISI, PSQI, and SQS questionnaires and their objective sleep quality based on the Withing sleep analyzer.

XSL•FO
RenderX

3. Finally, we hypothesize that participants' objective sleep assessment will improve, measured by the Withings sleep analyzer.

Discussion

Principal Findings

Sleep disturbances are commonly observed among older people, with and without neurodegenerative disorders, and among carers for people with neurodegenerative disorders. This study will provide critical evidence pertaining to the feasibility and acceptability of the proposed chatbot MotivSleep, hosted on WhatsApp, which aims to conduct automatic sleep interviews and provide personalized recommendations for better sleep that may improve their sleep. Specifically, we evaluate the participants' perceived usability and feasibility of the chatbot, changes in participants' subjective sleep assessment before, during, and after the study, and changes in participants' objective sleep assessment measured by the sleep tracking device Withings sleep analyzer.

This paper describes the protocol used in the MotivSleep study. To the best of our knowledge, no other studies have focused on developing an automated chatbot for older people with problematic sleep or conducting automated sleep interviews. The MotivSleep study aims to shed light on the feasibility of using a chatbot to conduct interviews for a prolonged period of time. Furthermore, the intervention and protocol were designed to be more accessible and simpler than frequent in-person assessment or intervention sessions. This allows future deployment to older adults with mobility issues or within hard-to-reach communities.

Limitations

Our study requires participants to use 2 devices (a Withings sleep analyzer and a smartphone to access WhatsApp) and complete web-based questionnaires. As such, older people unfamiliar with or unwilling to use these devices might self-exclude. However, successful findings from this study could be leveraged to revise further to allow for more accessible options on the technological design for a broader audience and users. Additionally, excluding participants with diagnosed life-threatening illnesses and severe mental health problems is a limitation. However, for this preliminary study, such exclusion is warranted to ensure that participants are medically stable and not reporting severe clinical symptoms that would require a higher level of care, which a digital chatbot cannot help treat.

Furthermore, we acknowledge the small number of participants in this feasibility study. Thus, we do not expect to find significant differences with respect to gender or age. However, the proposed sample size aligns with previous research on the number of participants needed to assess usability and feasibility.

Conclusions

To conclude, the MotivSleep study is innovative in using an automated chatbot to conduct sleep interviews for older people who wish to improve their sleep. Evidence of its feasibility and acceptability will facilitate a larger trial. Participants perceived changes and sleep tracking devices' recorded changes will provide early evidence of its effectiveness. Moreover, the MotivSleep chatbot has the potential to be deployed by a large number of people due to its automated nature. This can offer older people access to supportive care that is more easily accessible and more affordable than face-to-face therapy with sleep experts.

Acknowledgments

This work was supported by the UK Dementia Research Institute Care Research & Technology Center (DRI-CR&T).

Data Availability

The sleep anomaly detection model is developed based on sleep records from more than 3.6 million nightly summaries from 13,671 individuals from the general population who use the Withings sleep analyzer, which is unavailable to the community due to the Withings Company's policy. However, based on the ethics approval, dialogue data will be made available upon request to support scientific transparency.

Conflicts of Interest

None declared.

Abstract

Background: Emotion regulation is an ability related to psychological well-being; when dysregulated, individuals may have psychiatric symptoms and maladapted physiological responses. Virtual reality–assisted cognitive behavioral therapy (VR-CBT) is an effective psychotherapy to target and strengthen emotion regulation; however, it currently lacks cultural sensitivity and can be improved by adapting it to the cultural context of service users. During previous participatory research, we co-designed a culturally adapted cognitive behavioral therapy (CBT) manual and 2 virtual reality (VR) environments to function as a complement to therapy (VR-CBT) for Inuit who would like to access psychotherapy. Emotion regulation skill building will occur in virtual environments that have interactive components such as heart rate biofeedback.

Objective: We describe a protocol for a proof-of-concept 2-arm randomized controlled trial (RCT) with Inuit (n=40) in Québec. The primary aims of this research are to investigate the feasibility, benefits, and challenges of the culturally adapted VR-CBT intervention versus an established VR self-management that is available commercially. We will also investigate self-rated mental well-being and objective psychophysiological measures. Finally, we will use proof-of-concept data to identify suitable primary outcome measures, conduct power calculations in a larger trial for efficacy, and collect information about preferences for on-site or at-home treatment.

Methods: Trial participants will be randomly assigned to an active condition or active control condition in a 1:1 ratio. Inuit aged 14 to 60 years will receive a culturally adapted and therapist-guided VR-CBT with biofeedback or a VR relaxation program with nonpersonalized guided components over a 10-week period. We will collect pre- and posttreatment measures of emotion regulation and biweekly assessments over the treatment and at 3-month follow-up. The primary outcome will be measured by the Difficulties in Emotion Regulation Scale (DERS-16) and a novel psychophysiological reactivity paradigm. Secondary measures include psychological symptoms and well-being via rating scales (eg, anxiety or depressive symptoms).

XSL•FO
RenderX

Results: As this is the prospective registration of an RCT protocol, we do not yet report any results from the trial. Funding was confirmed in January 2020, and recruitment is expected to start in March 2023 and is set to finish in August 2025. The expected results are to be published in spring 2026.

Conclusions: The proposed study responds to the community's desire for accessible and appropriate resources for psychological well-being, as it was developed in active collaboration with the Inuit community in Québec. We will test feasibility and acceptance by comparing a culturally adapted, on-site psychotherapy with a commercial self-management program while incorporating novel technology and measurement in the area of Indigenous health. We also aim to fulfill the needs for RCT evidence of culturally adapted psychotherapies that are lacking in Canada.

Introduction

Emotion Regulation and Mental Health

Emotion regulation is a set of skills and competencies that individuals have to a variable extent: strong emotion regulation skills can facilitate mental health. When those skills are dysregulated, the difficulties related to emotion regulation are implicated in various psychological complaints and disorders [1]. Biosignals such as heart rate, skin conductance, and diastolic blood pressure response are also phenotypical in populations with difficulties in emotion regulation, indicating multiple levels of involvement in the health of individuals [2]. Some psychotherapies exert to large effect, decreasing dysregulation and increasing the ability to regulate emotions [3-6]. Improvements in emotion regulation during psychotherapy are associated with decreases in anxiety, depression, substance use, and other psychopathologies [7]. Moreover, emotion regulation is robustly and longitudinally associated with psychological resilience [8] and associated with life satisfaction, positive affect, and other well-being indicators with a small to moderate effect size [9].

Enhancing Emotion Regulation Interventions With Virtual Reality and Biofeedback

Virtual reality (VR)–assisted mental health interventions effectively increase mental well-being, including building the ability to regulate emotions [10-12]. VR is an interactive, computer-generated, 3D world of images, videos, and sounds delivered through a VR headset system. Combined with the efficacy of cognitive behavioral therapy (CBT), v*irtual reality–assisted cognitive behavioral therapy (VR-CBT)* has several therapeutic advantages, including increased interactivity of the therapy and patient participation. Immersive visuals can create a holistic approach to therapy with mind-body exercises (eg, biofeedback integrated with VR). Therapists can present clients with enhanced skill-building scenarios and modulate elements in the environment for the personal needs of the client. For instance, the varying intensity of the exposure can be shown to the client through visual aids that reflect their physiological states [13]. *Biofeedback* is a process of rapidly demonstrating physiological metrics to an individual, sometimes with the goal of changing thoughts, behaviors, or physiology [14].

Integrating Inuit Culture, Community Needs, and Technology

In addition to therapeutic advantages, combining VR and CBT presents a unique opportunity for the advancement of cultural sensitivity in treatment. Up to 60% of Inuit live in urban centers, and many experience adversities in health [15]. Inuit residing in urban centers reported only fair or poor access to health care [16], and in Montreal, Indigenous peoples reported trauma, anxiety, and depression to be some of their primary concerns to be addressed [17]. The increased mental health risks and lack of culturally sensitive resources for First Nations, Métis, and Inuit are part of the complex consequences of ongoing settler colonialism. The mental health impacts of colonialism can be intergenerational, with adverse impacts documented into the second and possibly third generations [18,19]. The Indigenous historical and intergenerational trauma also stresses the importance of development and research with the aim of increasing the knowledge base toward strengthening resilience of the communities and their members.

Because of its relatively low cost, flexibility, and immersion, VR has been used in Indigenous contexts, such as in art, storytelling, culture, language, and transferring cultural heritage [20-23]. There is interest in digital technology solutions for Indigenous health and mental well-being; however, most follow a format of conventional psychotherapy via telemedicine [21,24]. VR could offer opportunities for access to mental health care resources for populations affected by health inequities, delivering specialized content at a low cost and in many locations.

Co-design and Collaboration With Inuit in Québec

VR-CBT

To expand access to mental well-being resources for Inuit in Québec, we will evaluate the efficacy of 2 emotion regulation–based VR interventions in a proof-of-concept randomized controlled trial (RCT). Our team developed the VR-CBT with experts in psychotherapy, VR, and Inuit health

XSL•FO
RenderX

and culture, including an Inuit advisory committee. The advisory committee was composed of Inuit and non-Inuit individuals, health and social services providers, and Inuit representational organizations. The advisory committee included both women and men. We consulted Inuit representational organizations before embarking on this project with the aim of naming research priorities and building a collaboration toward those goals. We then collaborated to culturally adapt the study procedures and materials. The process of culturally adapting the treatment manual and other materials will be described further in Gomez Cardona et al, *in preparation*.

VR for Mental Well-Being: Self-management

Another application that is part of the study is Calm Place—a commercial VR program previously developed by Mimerse that involves guided relaxation and meditation techniques. The application has been used in clinical settings and is rooted in nature's effects on well-being [25]. This intervention was chosen in consultation with the advisory committee based on the unacceptability of the waitlist or nonactive controls and similar therapeutic goals (eg, emotion regulation through guided activities).

Research Aims

The primary aims of this proof-of-concept RCT are to investigate the feasibility, benefits, and challenges of a culturally adapted VR intervention versus an established VR self-management program. We will assess the feasibility and validity of psychophysiological measures as objective outcomes of the interventions. In addition, we estimate the effect size of each treatment through between-group and within-group measures of emotion regulation, mental well-being, and difficulties in mental well-being (anxiety, depression, and posttraumatic stress disorder) with a longitudinal follow-up.

We work in a novel area in the literature, providing a VR intervention for an Indigenous population with a specifically therapeutic aim [24]. In addition, we will use both objective and subjective outcome measures—a novel but robust approach [2]. This novel psychophysiological approach has been validated in healthy individuals in our laboratory (Seon et al, in preparation).

Methods

Design

The study design is a 2-arm proof-of-concept RCT co-designed with an Inuit advisory committee. The first treatment arm (A) is a 10-week VR-CBT. An active control treatment with minimal attention; the second treatment arm (B) will be using Calm Place as a 10-week self-management. There will be no crossover between conditions, and we will use a 1:1 ratio randomization procedure. The protocol is described in accordance with the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines for interventional trials and is detailed in Multimedia Appendix 1. Ultimately, the goal of the study is to establish the initial feasibility of the VR-CBT and the technologies used and to identify the best measures for initial efficacy.

Setting

This trial will take place at an outpatient psychiatric institute in Québec, Canada.

Participants

Sampling

Our primary *inclusion criteria* are that the participants must (1) self-identify as Inuk, (2) live in the city where the study is taking place, (3) be aged between 14 and 60 years of age, and (4) be proficient in English or French.

With exclusion criteria, we confirm safety and best fit with the study necessitating VR and psychophysiological equipment use. We exclude those who do not identify as Inuk, youth aged <14 years, and adults aged >60 years, as well as individuals who do not tolerate VR headset and study sensors. We exclude individuals with a self-reported history of psychosis or schizophrenia, with current substance abuse as measured by screens (score >8 on the Alcohol Use Disorders Identification Test C (AUDIT-C) or >3 on the Drug Abuse Screen Test), or with any change in psychoactive medications 4 weeks before screening. In addition, we exclude individuals with physical conditions that might cause risks during VR use (ie, history of cardiac condition or epilepsy). There are no exclusions based on other concomitant care.

Meeting the diagnostic criteria for any specific disorder, verified history of trauma, or trauma symptoms was not part of our inclusion and exclusion criteria, given our focus on cultural sensitivity, our chosen skills-building approach in the therapy manual, and the shared history of trauma by community members.

Sample Size

There is, to our knowledge, no estimate of the effect size of emotion regulation–based VR interventions among Indigenous populations, and this proof-of-concept study will be necessary for accurate estimation of power in future trials. As described in the previous section, mental health risks among Indigenous and Inuit populations differ from those among the general population, which emphasizes the need for this proof-of-concept study specifically in this population for power calculations in future work. However, a previous VR intervention for anxiety disorders among a general population sample had an estimated effect size of g=0.78 (medium) compared with minimal-attention controls and g=0.90 (large) with no-treatment controls [26,27]. To attain statistical power >90% with an alpha of $P<.5$, the sample size of n=20 in the active treatment group and n=20 in the active control group is sufficient for generalized linear models with a similar effect size (power=0.97; $df=38$; $P=.05$).

Procedure

Recruitment

The research team will recruit participants who are potentially willing to participate in either of the 2 arms of the trial. Recruitment methods will include word of mouth, flyers, and posts on social media, websites, and Montreal neighborhoods. First contacts with potential participants will involve informing them about the study and screening for initial eligibility criteria

XSL•FO
RenderX

(eg, aged 14-60 years, having no acute medical or psychological risks, etc). First contacts will be done to further explain the study protocol and evaluate the eligibility criteria with potential participants. This can occur over the phone, via secure email, or in person. Our eligibility criteria include screening for suicide risk and higher scores on alcohol and drug measures. This screening will occur in person during the first visit to enroll in the study or via telephone. Once eligibility and interest in the study are established either in person or via telephone, the participants can proceed to the informed consent process with our team (in person).

Randomization and Masking

After receiving informed consent for participation, a research assistant will use a computerized randomization generator to randomly assign participants in a simple 1:1 ratio (VR-CBT or Calm Place). Before randomization, we will show participants the treatment rationales, explaining the 2 possible study groups. They will report their preference for either treatment in a forced-choice question, rate their preference for each treatment on a scale from 1 to 10, and provide comments on why they selected this choice. This information is collected to inform future larger trials and clinical services. The treatment cannot be supplied blinded to the content. However, as the measurements are self-reports and objective measurements, we do not use blinded outcome evaluation. Once random assignments are decided, they will be kept hidden from researchers and research assistants until the participants begin the trial.

Ten-week VR Interventions

Culturally Adapted VR-CBT as the Active Condition

The culturally adapted therapy is a manualized CBT with an emotion regulation focus. The VR-CBT therapy will take place in a clinical setting and will consist of traditional therapeutic processing complemented by therapist-guided training in a VR environment. The main therapeutic strategies are stress inoculation and guided mastery with biofeedback components. Our group developed 2 VR environments (SB UQO [Université du Québec en Outaouais] cyberpsychology laboratory)—one for safe practice and the other for challenging emotion regulation skills. The first, called Snowy Place, is a snowy tundra that mimics the arctic life well known to Inuit. In developing Snowy Place, the Inuit advisory committee believed that this would be a comforting environment. The second is a small environment with many people and no children (small stressors), where the environment and elements (eg, social and situational) demand emotion regulation skills. The participant will train learned emotion regulation skills using these environments under the guidance of a psychotherapist. The VR-CBT can have interactive components where partial avatars (eg, hands of the participant) and preprogrammed avatars (eg, static or acting people in the room) are present. Multimedia Appendix 1 provides a detailed overview of the CBT therapist manual, including a session-by-session overview.

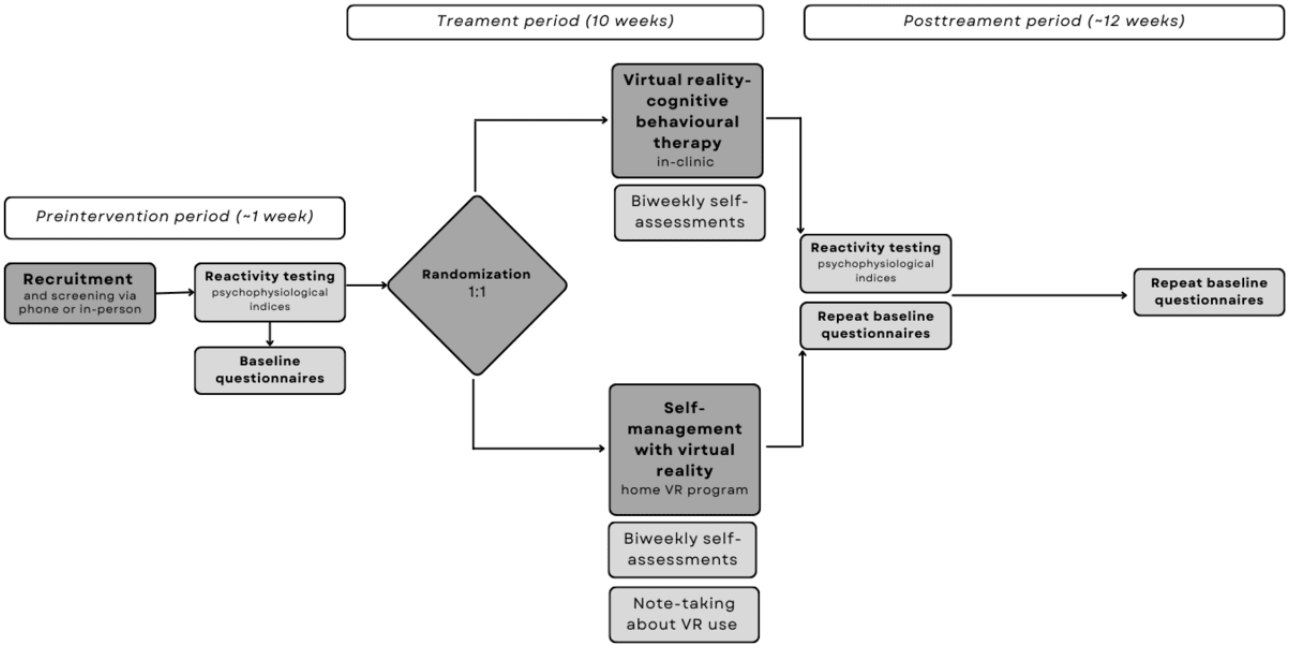
Calm Place as the Active Control

During the use of the VR application, the Calm Place user may see flowing water, mountains, and tree cover; a tropical atoll with sand, palm trees, and the ocean; or an arctic scene with large pines, snow cover, and large stones. In Calm Place, each virtual environment offers applications [25,28], such as visual breathing aids, time and weather cycles, and meditation voice overs, with the guidance of the VR program. Here, the guidance on relaxation is nonpersonalized and is based on the selections of the user within the VR environment. Thus, though participants' weekly choices regarding prevalence and duration of use are self-managed and done from their home, this intervention involves guided programming for guidance. The self-management program—Calm Place—does not have any avatar, social-interactive, or personalized components. The research team will contact these minimal-attention control participants weekly to check whether they use the application and to verify their safety.

Translation

A professional translator translated each of the self-reported measures that did not have the existing French versions. For comparability, given the small sample size, the surveys will be administered in either English or French for data collection, and the language controlled for in statistical analysis. However, each psychometric measure was translated to Inuktitut to complement the understanding of English and French surveys.

Data Collection



Week 0: Screening, Consent, and Randomization

Before their participation, participants will be fully informed by research assistants about their role in the study and treatment options; if willing to participate in either of the treatments, adults or guardians will sign an informed consent form (study procedures in Figure 1). The number of participants rejecting one or another treatment and thus excluded from the actual trial will be registered for evaluation of acceptance. Initial visits will involve checking eligibility and preference for treatment. We then randomly assign participants to one of the 2 VR interventions—Calm Place or VR-CBT—for a maximum of 10 weeks.

The participant study procedures from recruitment until the end of participation include a baseline measurement, a 10-week intervention period, and follow-up.

XSL•FO
RenderX

Figure 1. Flow of proof-of-concept study. VR: virtual reality.

Week 0: Baseline Measurement of Subjective and Objective Outcomes

At the first evaluation done in the days before the intervention, we evaluate the baseline subjective and objective measurements. Data will be collected and stored with REDCap (Research Electronic Data Capture) data collection software (Vanderbilt University), protecting the confidentiality of patients with research IDs. We will collect data on participants' rest and stress psychophysiology during a 1-hour reactivity testing paradigm, where VR exposure will evoke relaxation (forest walk) or moderate stress (height exposure). Baseline measures include the Difficulties in Emotion Regulation Scale (DERS)-16 [29]; Clinical Outcome Routine Evaluation-Outcome Measure (CORE-OM) and Clinical Outcome Routine Evaluation- 10 item (CORE-10) [30,31]; Warwick-Edinburg Mental Well-being Scale (WEMWBS) [32,33]; Generalized Anxiety Disorder 7-item (GAD-7) [34]; Primary Care Screen for Posttraumatic Stress Disorder for Diagnostic and Statistical Manual 5 version (PC-PTSD-5) [35]; Patient Health Questionnaire 9-item (PHQ-9) [36]; visual analog scales for anxiety, emotional arousal, and emotional valence [37-40]; DAST-10 [41]; AUDIT-C [42]; and Severity of Dependence Scale for Cannabis (SDS-C) [43]. We will measure blood pressure using a calibrated, Health Canada–approved device. Figures 1 and 2 show the study flow diagram.

Weeks 1 to 10: Intervention Period and Weekly Questionnaires

During the intervention period, we will send participants biweekly questionnaires. In their final visit, participants will repeat the procedures from the first visits (visits 1 and 2). Participants will receive a small financial compensation (gift card) for each visit.

Week 10 to 11: Repeat Measure of Subjective and Objective Measurements

Once the intervention is complete, participants repeat the questionnaires and the reactivity testing paradigm from week zero to provide a second measurement.

Week 22: Postintervention Follow-up

Twelve weeks after their final visit, we will follow up with the participants on all baseline questionnaires.

Materials

To support the delivery of the interventions and the corresponding collection of data during the trial, a sensor management system and web-based clinician portal were developed in collaboration with the National Research Council Canada (DJ and CP). The sensor management system facilitates the connection and initialization of the biofeedback sensor, eVu TPS (Thought Technology Ltd) as well as the streaming of data to the web portal. The web portal allows the management of participant sessions as well as live and postsession biofeedback data visualization. The raw biofeedback data (in CSV format) are also available through the portal to study coordinators and clinicians for postprocessing and analysis.

XSL•FO
RenderX

Measures

Primary Outcome Measures

DERS-16 Scores

The DERS-16 is a short, valid measure of emotion regulation [29,44]. Participants rate their ability to accept and be aware of their emotions, direct themselves toward their goals, control their impulses, access regulation strategies, and have emotional clarity [45]. The DERS's psychometric properties are favorable, having moderate to very strong internal consistency (α=.69-.97) and strong retest reliability (*r*=0.88; ρI=0.85) [29, 46-49]. Correlating with anxiety, depression, stress, borderline traits, and more, the DERS-16 has good construct validity [29,47,50]. Although consistent across demographics and culturally adapted for some groups, the scale is not yet adapted for any Indigenous groups [48,51]. The full DERS is translated into French and validated [52]. Although there are no formal cutoff scores for the DERS, the English scale achieves moderate diagnostic accuracy (area under the curve [AUC]) among emotional disorders and nonsuicidal self-injury populations [53-55], and it is sensitive to changes following treatment [56-60].

Visual Analog Scales: Anxiety, Emotional Arousal, Emotional Valence

Participants will respond to the Visual Analog Scale (VAS)-Anxiety (VAS-A), Visual Analog Scale-Emotional Arousal (VAS-EA), and Visual Analog Scale-Emotional Valence (VAS-EV) during reactivity testing. These items have favorable properties, including construct validity and sensitivity [37-40].

Objective Measures

The participants will undergo a psychophysiological reactivity testing paradigm. This will be repeated after the end of the VR intervention for those who completed a minimum of 7 and a maximum of 10 sessions of therapy as soon as possible after the final session. We will collect and measure several metrics, including heart rate, blood volume pulse, skin conductance, blood pressure, and accelerometer data. Participants first respond to baseline subjective arousal, emotional arousal, and VAS-EV. We then begin collecting psychophysiological data with a portable finger sensor, covered with a piece of cloth for light sensitivity, by attaching it to the participant's nondominant index finger. They fill out a survey, including several symptom scales as described during this approximately 15-minute period, and have their blood pressure taken with an ambulatory blood pressure machine. We also record a no-task seated baseline recording of sensor data for 3 minutes. Then, participants will familiarize themselves with VR in a forest walk environment with no tasks other than to walk and explore (5.5 minutes), with minimal interaction with the research team. In the next segment, participants walk a VR plank exposing them to the heights below for 5.5 minutes (instructed to walk back and forth, with no interaction). If the exercise is too challenging (eg, participant distress at a tolerable level), participants remain in the environment without walking for 2 minutes or withdraw completely (eg, intolerable distress) from the exercise. Finally, participants re-enter the same VR environment, this time with a floor rather than a plank beneath them and walk (3 minutes). The last segment is a 10-minute seated rest period. After each segment, participants report using the same visual analog scales.

Secondary Outcome Measures

PC-PTSD-5 Scores

On a scale of 5 items, the PC-PTSD-5 first verifies trauma exposure and then evaluates the presence of the 4 symptom clusters of PTSD [35]. The 5 items include symptoms such as arousal, re-experiencing, avoidance, and negative cognitions and mood. The scale has strong test-retest reliability (*r*=0.83) and is associated with important clinical variables such as suicide [35,61]. With a cutoff score of 3, the PC-PTSD-5 has strong diagnostic accuracy (AUC=0.941) [35]. The scale was translated by the Clinical Psychology and Psychotherapy Unit of the Bielefeld University into French [62].

WEMWBS Scores

The WEMWBS with both its 14-and short 7-item versions, measures holistic aspects of well-being. The dimensions include eudemonic aspects, hedonic aspects, psychological functioning, and subjective well-being [32,33]. Positive mental health provides an independent factor for functionality in the presence or absence of a mental illness. This scale has favorable psychometric properties. Using the WEMWBS, we can calculate mental health costs and quality-adjusted life-years [63,64]. In a study of Indigenous Australians, the Short-Form WEMWBS achieved an internal consistency of α=.69 to .88 [65]. The WEMWBS has also been evaluated in various minority and cultural groups [66].

GAD-7 Scores

The GAD-7 [34] is a validated self-report scale that measures anxiety presence and severity [67]. Among outpatients with anxiety and mood disorders, the GAD-7 is a reliable (*P*=.85) and sensitive (79.5%) measure with a cutoff score of 10 [68]. The GAD-7 scores have been categorized into mild, moderate, and severe anxiety, with cutoffs of 5, 10, and 15 [34,68]. Among Indigenous students in Canada, the GAD-7 achieved an internal consistency of α=.86 and correlated strongly with related constructs [69]. The scale was translated and validated in French [70].

PHQ-9 Scores

The PHQ-9 is a depression severity measure based on the Diagnostic and Statistical Manual Version IV [36]. In a meta-analysis of the scale's psychometric properties, the PHQ-9 achieved optimal sensitivity and specificity with a cutoff score of 10 [71]. Among Indigenous North Americans, the scale's psychometric properties were favorable, with an internal consistency of α=.94 [72].

CORE-OM, 10-Item Version

The CORE is widely used as an outcome measure in psychotherapy and has several versions, including the CORE-OM and the 10-item version CORE-10 [30,31]. The CORE-OM and CORE-10 are screening measures for psychological distress, including items for well-being, psychological symptoms, functioning, and risk. The CORE-OM has excellent internal consistency in clinical samples (α=.94) and for each of its subscales (α=.75-.94); it also has good

XSL•FO
RenderX

test-retest reliability (*P*=.83) [73]. The CORE-10 with a cutoff score of 11 differentiated between clinical and nonclinical general samples with a sensitivity of .85. Its internal consistency was α=.90, and it had a reliable change index of 6 points [30]. The widely accepted French translation had validity results forthcoming from the University of Toulouse [74].

Feasibility: Attrition and Adherence

We will collect data about the feasibility of the treatment in the form of weekly use data (Calm Place group) and study attrition and adherence to treatment (VR-CBT group). These metrics will be assessed by the number of treatment sessions attended, completion of treatment, percentage of sessions attended, number of patients who dropped out, and when possible, reasons for dropping out, comments and notes on feasibility in diary responses, the time spent using the program, and consistency in using the program over 10 weeks. Treatment completers for VR-CBT will be defined as individuals who attend 7 out of 10 sessions, and for Calm Place, 7 reported sessions over 10 weeks. Dropouts for VR-CBT are defined as individuals missing 2 consecutive sessions of therapy without rescheduling (no-show). Noncompleters are individuals who complete <7 sessions (but attend at least 1). In the case participants are judged by the research team as *at risk* (eg, psychologically), they may also be withdrawn from the study.

Safety: AUDIT-C, DAST-10, and SDS-C

During the treatment period, we also want to confirm that the VR-CBT is a safe pretreatment and want to observe a potential increase in the use of alcohol and drugs during the therapy. This will be done using presession evaluations with AUDIT-C, DAST, and SDS-C with a 1-week time frame. The AUDIT-C assesses alcohol consumption and drinking behaviors using 3 items [42]. The full AUDIT with 10 items has been translated and validated. Both the English and French versions of AUDIT have favorable psychometric properties, including high sensitivity and specificity (approximately 90%), and this also concerns the AUDIT-C [75-77].

The DAST is a 10-item validated self-report scale that will be used to screen for and assess drug use over the previous 12 months [41,78]. Typically, the DAST-10 achieves a sensitivity of 41% to 95% and a specificity of 68% to 99%, depending on the population and diagnostic information used [78]. No information is yet available about the validity of the French translation of the DAST.

The SDS-C[43] consists of 5 items with good internal reliability and discriminant validity, with a cutoff score of 4 [79]. No information is yet available about the validity of the French translation of the Severity of Dependence Scale [80].

Data Analysis

Analyses for Rating Scales

Expecting nonnormally distributed data in a small human sample, we will conduct nonparametric tests and generate descriptive and comparative statistics to detect between-group differences for the 2 conditions, VR-CBT (A) and Active Control VR program (B), using R Statistical and Computing Software (R Core Team). We will use generalized mixed linear models to compare the 2 conditions using scores on DERS-16 across several time points (pre- and posttreatment as well as biweekly and bimonthly time points). In addition, we will describe changes in mood, anxiety, and trauma symptoms for the 2 conditions (pre- and posttreatment, as well as biweekly and bimonthly time points). The data collection for time points varies based on the administration instructions for each scale (weekly, biweekly, monthly, etc). Cohen *d* or nonparametric tests will calculate the effect size between the 2 conditions.

Objective Psychophysiology Data Analyses

To accurately identify peaks and not simply gradual increases in skin conductance observed over time, we will filter skin conductance data with a threshold value of 0.04 µS and average over 5 seconds [81,82]. As our study involves movement in a VR space in addition to exposure to a potential stress-inducing situation, we will filter the data with a lower limit of 40 bpm and an upper limit of 200 bpm [83]. Heart rate will also be averaged over 5 seconds. Following averaging, we will use open-source filters for preprocessing the data; then, the psychophysiological data will be processed with existing packages in MATLAB and Python. To correlate the DERS-16 and secondary outcome measures (CORE, WEMWBS, GAD-7, PHQ-9, and PC-PTSD-5) with psychophysiological data, we will employ nonparametric regression analyses in R Statistical and Computing Software. In addition, we will explore preliminary cutoff sum scores for therapeutic response by plotting receiver operating characteristic curves and conducting AUC analyses. We will also compare baseline to postintervention (second baseline) changes in psychophysiology using regression models. Cohen *d* or nonparametric tests will calculate the effect size between groups A and B.

Ethical Approval

The protocol was approved by the Research Ethics Board of the Centre Integré de Santé et Services Sociaux de l'Ouest de l'Ile (IUSMD 21-52), and it follows the standards of the World Health Organization's Helsinki Declaration 1975, revised in 2013. Approval for the protocol was granted by the Douglas Mental Health University Institute Ethics Review Board (IUSMD 21-52). In accordance with Tri-Council Policy Statement 2 and guidelines by the Inuit Tapiriit Kanatami and Nunavut Research Institute, the consent process involves both community and individual consent [84,85]. First, we consulted Inuit representational organizations and co-designed with community members. Before participation, we will obtain written, informed consent from all participants, their parent or guardian, or oral consent. Data will be collected and stored with REDCap data collection software, protecting the confidentiality of patients with research IDs. All publications resulting from the research will maintain confidentiality requirements by deidentifying any data. Participants will receive a small financial compensation (gift card) for each hour of in-person participation and surveys (approximately CAD $15 [US $11] per hour).

Data Dissemination Plan

Respect for Inuit Ethical Standards

This research recognizes community protocols and the holistic approach to health and wellness in many Indigenous cultures.

XSL•FO
RenderX

By doing that, we respect the ethics framework in Indigenous contexts, composed of principles of respect for persons and concern for Equity and Reciprocity [84]. We seek to follow and respect the principles outlined by Inuit communities in the Tri-Council Policy Statement 2 and the National Inuit Strategy on Research and the Negotiating Research Relationships with Inuit Communities guide [85,86]. These guidelines can apply to Inuit, First Nations, and Métis communities and provide structure for privacy, intellectual property, data custody, and secondary use of data. In adherence to these values, respect for people is necessary, and this is achieved through free, informed, and continued consent of the Inuit community and individual research participants [87]. We also aim toward, "research that is efficacious, impactful, and meaningful to Inuit" [85] in aligning with Inuit research priorities through consultation with representational organizations and the formation of an advisory committee. We strive to bolster social equity through the creation of materials that will belong to the Inuit community.

Maximized Participation of the Inuit Community

All results of this research will be validated by the community members and representational organizations and returned to them. We will communicate the final results and a report of the study to all those who participated in it and to the community organizations that would be interested. All publications resulting from the research will maintain the requirements of confidentiality and where they approve, will mention the contribution of everyone involved. The rights of coauthors of Indigenous contributors will be recognized. In any publication derived from this project, participants' geographical localization will be mentioned as well as the Indigenous group they belong to (Inuit in Québec). This identification of participants as a group will be disclosed but not their personal information.

Inuit Ownership of VR Manual and Environments

The rights and permissions to use the treatment manual and VR environments belong to the Inuit community, although they are attached and available in this document. As the main intention of all products of this study is to benefit the Inuit community in Québec, the materials will not be commercialized; however, authors should be consulted before use (to be approved by the Inuit community). Any use of study materials should acknowledge the role of the advisory committee (Inuit community) in developing them and should only be used with express permission (contact SB to initiate this process).

Results

As this is the prospective registration of an RCT protocol, we do not yet report any results from the trial. This study has been registered prospectively and is available on the web [88] (registration number ISRCTN21831510). Funding was confirmed in January 2020, recruitment is expected to start in March 2023, and is set to finish in August 2025. Expected results to be published in spring 2026.

Any major changes to the protocol will be submitted and approved by our research ethics board, documented on the trial registration platform, and justified in future publication.

Discussion

Summary of Objectives

This proof-of-concept study is necessary to respond to the following main concerns: (1) the limited availability of culturally acceptable versions of otherwise validated treatments [89], (2) limited number of RCTs on culturally adapted psychotherapies in Canada, and 3) the use of self-management as an active comparator. This protocol, which compares VR-CBT and Calm Place as self-management, responds to the community's desire for culturally safe and efficient therapeutic treatments and scientific needs for further investigation into the need and efficacy of culturally adapted treatments. The Inuit community in Montreal co-designed this project with the research team based on their desire for a resilience-based mental health resource.

Gaps in Research on Culturally Adapted Interventions

Previous evidence of increased acceptability and increased adherence of culturally adapted treatments, with a comparable efficacy to conventional psychotherapy and pharmacological interventions, is promising [90-92]. A recent systematic review of 14 studies conducted in Canada involving culturally adapted mental health treatments concluded that most interventions reduced anxiety, depression, and suicidality among First Nations, Métis, and Inuit [93]. Nevertheless, none of the 14 studies included an RCT, with most RCT evidence for culturally adapted interventions so far being conducted in the United States, low-and middle-income countries, or among refugee populations [90-93]. Furthermore, previous reports have mainly focused on clinic-based treatments or inactive controls. Although our study is randomized, we do ask about preferences between the active treatment and active control treatment and will record the number of participants excluded after accepting only one of the treatments. This will give some indication of the initial perceptions of the acceptability of the treatments.

Implications of VR With Culturally Adapted Therapies

As technology-assisted psychotherapies advance, VR-CBT or self-management with VR may become complementary options for Indigenous health. In addition to the possibilities of remote treatment (or telemedicine), VR-CBT combines a transdiagnostic and effective treatment modality with potentially improved control and immersion into therapy [1,7]. For instance, therapists can track real-time psychophysiological responses to therapeutic challenges through biofeedback [13]. The client can participate in the therapy in any environment judged most appropriate by the therapist and client to enhance access to treatment. Lastly, Inuit in Nunavik—the northern part of Québec—often experience inconvenience and financial and emotional devastation when attempting to seek care for a health concern, as they may have to travel away from their family to the southern part of the province [94]. We explore several health technologies in the RCT, and future work includes continuing remote therapy.

Strengths and Limitations

The process of cultural adaptation of psychotherapy was conducted to increase acceptance. The advisory committee

XSL•FO
RenderX

recommended study inclusion based on sociocultural background, not trauma symptoms, to improve the cultural safety of the trial. Accordingly, inclusion is based on subjective motivation for improved mental health rather than any categorical diagnosis or subjective or objective need for treatment. In addition, the content of the psychotherapy was modified to confirm safety, according to the comments from the advisory committee. These modifications include reducing exposure and distress-producing exercises and removing the homework normally part of the therapy. A limitation is that these changes may challenge the odds of a psychotherapeutic response.

In our study protocol, we included an active control group, noting the vulnerability of the study population; this may lead to reduced between-group effects. However, only the active treatment is culturally adapted and guided by a psychotherapist, which could improve attendance and thus long-term efficacy in the active treatment group. We will observe the impact of the setting as compared with the content on acceptance while asking for the preference for therapist-guided or self-management treatment. This proof-of-concept RCT will inform us about the potential challenges or limitations of the study protocol, and we can characterize the best outcome measures and calculate power for the further efficacy trial. We consider the scientific risks acceptable, given the extreme imbalance between the need and availability for access to valid and safe treatments.

Conclusions

The proposed study responds to the community's desire for accessible and appropriate resources for psychological well-being, as it was developed in active collaboration with the Inuit community in Québec. We will observe preference for therapist-guided, at-clinic treatment, or at-home self-management and compare the acceptance and feasibility of a culturally adapted, VR-assisted psychotherapy with a commercial self-management program in VR. We incorporate novel technology in providing treatment and in objective outcome measurement in the area of Indigenous health. We also aim to fulfill the needs for RCTs to test the efficacy of culturally adapted psychotherapies.

Acknowledgments

This project was funded by Fonds de soutien à l'innovation en santé et en services sociaux grant # 8400958 (OL) and McGill University's Healthy Brains Healthy Lives Fellowship (QS). The funders had no role in study design or in later collection and data analysis. The authors would want to thoroughly thank and acknowledge the advisory committee for their important investment in the project and its co-design; according to their acceptance, some of them are listed as coauthors, but all of them were essential to developing the project. The authors also thank Nunavik Translations for translating the study materials to Inuktitut and would also like to acknowledge the members of our research team, colleagues, and supervisors for the comments on the manuscript as well as personnel at both Douglas Institute and the National Research Council of Canada for their continuous support for the project. They would like to thank Inuit representational organizations and friendship centers such as Ullivik Centre, Makivik Corporation, Ivirtivik, and Southern Québec Inuit Foundation for their investment in boosting community mental health and volunteer contributions to make this project possible. The project would not have proceeded without the essential work by students Katherine Jalbert and Andrew Emard (the coding associated with the portal), Alain Hajjar who worked on the initial version of the manual, and the staff members who worked on the virtual environments (Marie-Christine Rivard and Simon Tremblay).

Data Availability

The final trial data set will be accessible to the researchers of this project. The data generated from this study are not publicly available to respect the privacy and confidentiality of participants (who are a small group that is potentially more identifiable) but are available from the corresponding author on reasonable request. The initial version of the portal (backend) that was provided to Douglas Research Institute at the beginning of the project is owned by NRC, ownership of the developments and integrations for the specific work is determined by the IP policy of Douglas Research Institute. The rights to benefit from and permissions to use the treatment manual and VR environments belong to the Inuit community, although they are attached and available in this document.

Authors' Contributions

OL is the primary investigator who confirmed the funding, conceived the study, and led the project development and planning. LGC coordinated cultural safety and co-design. SP, JO, EPR, CS, and M Lalonde, among others, comprised the advisory group; only consenting AG members were included as co-authors. SP, JO, EPR, CS, M Lalonde, OL, LGC and SB co-designed the content of the Virtual Reality–Assisted Cognitive Behavioral Therapy. SB led the design of the treatment manual and technical design of the VR environment based on the AG comments. DJ and CP (National Research Council of Canada, NRC) were in response of the creation of the therapist portal. SB, DJ, and CP were responsible for the integration of the portal, sensor data, and visual biofeedback in the VR environment. EPR followed cultural safety during the integration phase. NM, MK, MY, M Lashley, LGC, DJ, CP, QS, SB, and OL contributed to the design and development of the trial protocol, with comments from the advisory group. QS and OL authored the first version of the manuscript. All authors read and approved the final manuscript.

XSL•FO
RenderX

Conflicts of Interest

SB is president and a shareholder of Cliniques et Développement In Virtuo, a university spin-off that uses virtual reality as part of its clinical services and distributed virtual environments. The terms of these arrangements have been reviewed and approved by the Université du Québec en Outaouais in accordance with its conflict-of-interest policies. The remaining authors report no financial relationships with commercial interests.

Multimedia Appendix 1
The appendix contains the treatment manual for psychotherapists (for use contact S.B).

Abstract

Background: Osteogenesis imperfecta (OI) is a rare bone fragility disorder associated with muscle weakness. Individuals with OI may therefore benefit from exercise interventions aiming to improve muscle and bone strength. Given the rarity of OI, many patients do not have access to exercise specialists who are familiar with the disorder. As such, telemedicine, the provision of health care through technology to provide care at a distance, may be well suited for this population.

Objective: The main objectives are (1) to investigate the feasibility and cost-effectiveness of 2 telemedicine approaches for the delivery of an exercise intervention for youth with OI and (2) to assess the impact of the exercise intervention on muscle function and cardiopulmonary fitness in youth with OI.

Methods: Patients with OI type I (the mildest form of OI; n=12, aged 12-16 years) from a pediatric orthopedic tertiary hospital will be randomized to receive a 12-week remote exercise intervention in either (1) a supervised group (n=6), monitored every session, or (2) a follow-up group (n=6), receiving monthly progress update appointments. Participants will undergo the following pre- and postintervention evaluations: sit-to-stand test, push-up test, sit-up test, single-legged balance test, and a heel-rise test. Both groups will be given the same 12-week exercise regimen, which includes cardiovascular, resistance, and flexibility training. For each exercise training session involving the supervised group, a kinesiologist will provide instructions to participants through live video sessions using a teleconferencing application. On the other hand, the follow-up group will discuss their progress with the kinesiologist every 4 weeks over a teleconferencing video call. Feasibility will be assessed by recruitment, adherence, and completion rates. A cost-effectiveness analysis of both approaches will be computed. Changes in muscle function and cardiopulmonary fitness will be examined between the 2 groups, pre- and postintervention.

Results: It is anticipated that the supervised group will have higher adherence and completion rates compared to the follow-up group, which may be associated with greater physiological benefits; however, it may not be as cost-effective compared to the follow-up approach.

Conclusions: By determining the most feasible telemedicine approach, this study may serve as a basis for providing increased access to specialized adjunct therapies for individuals with rare disorders.

Introduction

Osteogenesis imperfecta (OI) is a rare congenital disorder characterized by bone fragility occurring in approximately 1 in every 10,000 individuals [1]. OI is typically caused by a dominant mutation in 1 of the 2 genes that code for the alpha chains in collagen type I, *COL1A1* and *COL1A2* [1]. The Sillence clinical classification of OI is divided into 4 phenotypic groups, with type I being the mildest and most frequently diagnosed [1,2]. OI type I comprises individuals with bone fragility and those whose stature falls within or close to normal limits [2,3]. While bone fragility is the leading characteristic of OI, we have shown that children and adolescents with OI type I have lower peak muscle force and muscle size compared to age- and sex-matched controls [4,5]. Given the positive relationship between muscle force and bone strength, muscle function deficits are likely to contribute to bone mass deficits in youth with OI [4-6].

For both healthy children and children with OI type I, exercise has been shown to be an effective method for improving cardiopulmonary fitness, as well as muscle strength [7,8]. Therefore, given the previously mentioned muscle deficits in children and adolescents with OI [4,5], individuals with OI type I may be more likely to benefit to a greater extent from this adjunct therapy, in addition to the typical mainstay of treatment, which includes rehabilitation programs, bisphosphonate therapy, and orthopedic surgery [9]. However, given the rarity of the disorder, many patients have challenges accessing exercise specialists who are familiar with the treatment of OI; thus, patients often seek or receive care from specialized tertiary hospitals. Attending both regular exercise training interventions in addition to frequent therapeutic visits at tertiary care centers may present a barrier for many patients, as specialized hospitals are often located in large urban areas, which can be far from patients' homes.

Telemedicine is a method for the remote delivery of professional health services at a distance by linking clinicians and patients through information technology [10,11]. Lambert et al [12] used a telemedicine approach for the delivery of a 16-week home exercise program for pediatric acute lymphoblastic leukemia survivors. This supervised telemedicine approach was shown to be feasible, as the results demonstrated a mean adherence rate of 89% and a completion rate of 75% [12]. In contrast, Gagnon et al [13] used a follow-up telemedicine approach for the delivery of a 12-week home exercise program for youth with arthrogryposis multiplex congenita, where clinicians conducted follow-ups with study participants every 3 weeks. The results showed a 68% adherence rate and a 64% completion rate, which was sufficient for most study participants to achieve their goals [13]. As the recent literature demonstrates, the follow-up approach may be less effective as it led to a lower completion rate [12,13]. However, additional clinician time cost associated with the supervised approach may exceed the increase in benefits associated with constant supervision.

There remains a gap in the literature with respect to the comparison between supervised and follow-up telemedicine approaches and the associated cost-effectiveness of both approaches. Hence, the aim of this study is to evaluate the feasibility and cost-effectiveness of 2 telemedicine approaches (supervised vs follow-up) for the delivery of a home exercise program. The secondary aim of the study is to investigate the effectiveness of the home-based exercise program on muscle function and cardiopulmonary fitness in youth with OI type I. Given the aims of this study, it is hypothesized that participants in the supervised group will have higher adherence and completion rates compared to the follow-up group, which will be further associated with greater increases in muscle strength and cardiopulmonary fitness from the exercise intervention. However, the additional intervention delivery time required for the supervised group may make it less cost-effective compared to the follow-up approach.

Methods

Study Design

This pilot study examines the feasibility of delivering an exercise intervention to a pediatric and youth population with OI by means of telemedicine. Study participants will be randomized into 1 of 2 telemedicine approach groups: (1) the supervised group and (2) the follow-up group. Given the COVID-19 pandemic, this protocol was designed to be conducted remotely, including the assessments. Therefore, simple clinical tests rather than hospital-based evaluations, which require cutting-edge technology, were favored.

Participant Eligibility

Individuals with a diagnosis of OI type I based on clinical evaluation and genetic mutation who are followed at a tertiary pediatric orthopedic hospital, ranging in age from 12 to 16 years, will be invited to participate in this study. Inclusion criteria encompass (1) confirmed genetic mutation in *COL1A1* or *COL1A2* genes; (2) medical approbation to initiate an exercise program by the patient's treating physician; (3) the ability to communicate in either English or French; and (4) the availability of the internet, a webcam, and a microphone. The exclusion criteria include (1) fractures of long bones in the lower or upper limbs within the past 12 months, (2) fractures of the spine within the past 12 months, (3) lower and upper limb long bone or spinal surgery within the past 12 months, and (4) location outside of the province of Quebec due to professional license restrictions.

Ethical Considerations

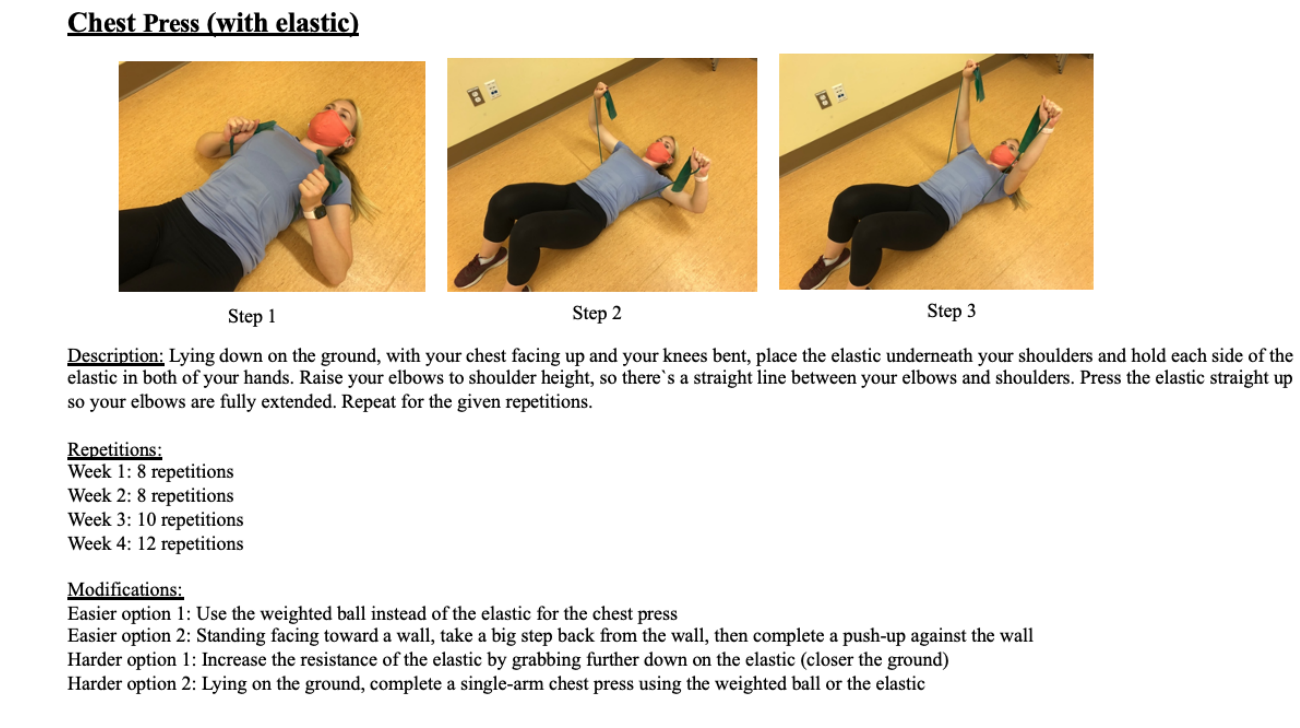
Study approval was granted by McGill University's Faculty of Medicine and Health Sciences Institutional Review Board (A01-M01-17A). Informed consent forms will be provided for participants aged 14 years and older. Any participant younger than 14 years will be asked to sign an assent form. Additionally, for those younger than 14 years, parents or caregivers will be required to sign a parental consent form as per Quebec's provincial regulations. Individuals who meet the study inclusion criteria and agree to participate in the research study will be deidentified and assigned a study ID number. Direct subject identifiers will be stored as key codes and kept separate from the study data set. Patient's medical record number, date of birth, and corresponding study ID number will be saved in a password-protected file that will be stored on a hospital

XSL•FO
RenderX

computer in the office of the principal investigator. The key code will be the only link that reidentifies the study participant to their health information; all other patient data will be deidentified. All study records will be retained and stored in the principal investigator's office for 7 years. Study participants will not receive compensation for their participation.

Recruitment

A total of 12 patients with OI type I will be recruited at a tertiary orthopedic hospital. Given that this study will be conducted remotely, patients who meet the study eligibility criteria will be contacted by the study coordinator over the phone. Those who are interested in participating will receive a follow-up email from the study coordinator with the appropriate consent or assent form, providing them with more information regarding their participation. Based on participant's preference, consent or assent forms will be either emailed or mailed to their place of residence. To ensure privacy, all emails from the study coordinator will be sent encrypted. Study participants will be randomized into either (1) the supervised group or (2) the follow-up group. Study personnel will produce a block randomization list using a random number generating software, which will be sent to the principal investigator. Each randomized number will be written on piece of paper and placed in an envelope. Once a study participant is enrolled, a hospital employee who is not involved in the study will select one of the envelopes and deliver it to the study personnel, who will assign the study participant to the specified group.



Evaluations and Intervention

Overview

The duration of the study is 16 weeks: 12 weeks for the intervention and 2 weeks at the beginning and end for evaluations. All participants will be given an exercise program to be completed at home. Both groups will use the teleconferencing application Microsoft Teams (version 1.3.00.28, Microsoft Corp). The supervised group will be monitored every session, while the follow-up group will receive feedback every 4 weeks.

Previous to the intervention, participants will be provided with initial testing and tutorials on the telemedicine application (Microsoft Teams) and the activity and heart rate monitor (Polar A370 watch; Polar Electro). Participants will be mailed the required equipment, such as the Polar A370 activity monitor (Polar watch), a 5-pound exercise ball, and a resistance band. All attempts possible have been made to ensure this study uses a minimal amount of equipment in order to reach a larger population that may have limited access to resources while also ensuring no sacrifices are made to the overall quality of the study. Both video and written instructions in English and French will be available to participants throughout the study. Instructions for the following will be included: telemedicine connections, completion of questionnaires, and Polar watch details (Bluetooth and USB connections, charging, and data transfer). Additionally, all study participants will have access to the 12-week exercise plan throughout the entire study. The exercise plan includes an illustration, video, and written description of each exercise, as well as 2 easier and 2 more difficult modifications for each movement (Figure 1). The exercise plan comprises 6 warm-up exercises, 7 to 8 exercises that will be repeated 3 times, and 5 cool-down stretches.

Figure 1. Home-exercise program instructions.

RenderX

Evaluations

Overview

To assess the impact of the 12-week exercise program, a comparison of pre- and postintervention evaluations will take place (Table 1). The pre- and postintervention evaluations will be recorded on Microsoft Teams in order to better assess and compare participants' progress before and after the intervention. Throughout the evaluations, study personnel will ask participants to have a parent or caregiver supervising nearby. During the pre- and postintervention evaluations, participants will be asked to complete the following three Patient-Reported Outcomes Measurement Information System (PROMIS) questionnaires: (1) Mobility Short Form, (2) Pain Interference Short Form, and (3) Physical Activity Short Form. Previous research has shown that PROMIS questionnaires have been successfully validated and are clinically feasible for a pediatric population [14]. These questionnaires will establish a baseline indicator for participant's pain, mobility, and physical activity levels previous to the intervention. Participant's pre- and postintervention questionnaires will be compared to determine what changes, if any, were realized by the participant.

Table 1. Pre- and postintervention evaluation tests.

Test	Assessment	Parameter
Sit-to-stand test	Cardiopulmonary fitness and lower body muscular strength	Heart rate (beats per minute) and total number of repetitions performed
Single-legged balance test	Visual and proprioceptive inputs	Time (seconds)
Push-up test	Upper body muscular endurance	Total number of repetitions performed
Sit-up test	Abdominal strength	Total number of repetitions performed
Heel-rise test	Lower body muscular endurance	Time (seconds)

Sit-to-Stand Test

The sit-to-stand test assesses cardiopulmonary fitness and lower body muscle strength [15,16]. The participant will sit down and stand up from a chair with their hands on their hips as many times as possible within 1 minute. The participant's heart rate (in beats per minute) will be taken immediately before, during, and after the test, which will be measured on the Polar A370 heart rate monitor. The number of repetitions completed will be recorded at the end of the test and expressed in absolute value [16]. Additionally, the number of completed repetitions will be expressed as the product of body weight to provide an index of total work (repetitions × weight in kg) [16,17].

Single-Legged Balance Test

Postural control will be assessed with 2 visual conditions: eyes open and eyes closed. The participant will stand on 1 leg with their arms crossed over their chest for up to 45 seconds. The participant will complete both visual conditions on each foot. Throughout the test, study personnel will ask the participant's parents or caregivers to stand close by for support in case the participant loses their balance. The duration of time the participant can maintain their balance under each condition will be collected [7].

Push-Up Test

The push-up test assesses upper-body muscular endurance of the chest, shoulders, and arms. The participant will perform as many consecutive push-ups as they can with no time limit. The test will be stopped if the participant is unable to maintain proper technique over 2 consecutive repetitions. Following the Canadian Society of Exercise Physiology, Physical Activity Training for Health (CSEP-PATH) guidelines, female participants will use their knees as their pivot point, whereas male participants will use their toes as their pivot point [7].

Sit-Up Test

The sit-up test will evaluate abdominal strength. The participant will complete as many sit-ups as they can within 1 minute. The participant will rise to a seated position from lying down with their knees bent and their arms crossed over their chest [7].

Heel-Rise Test

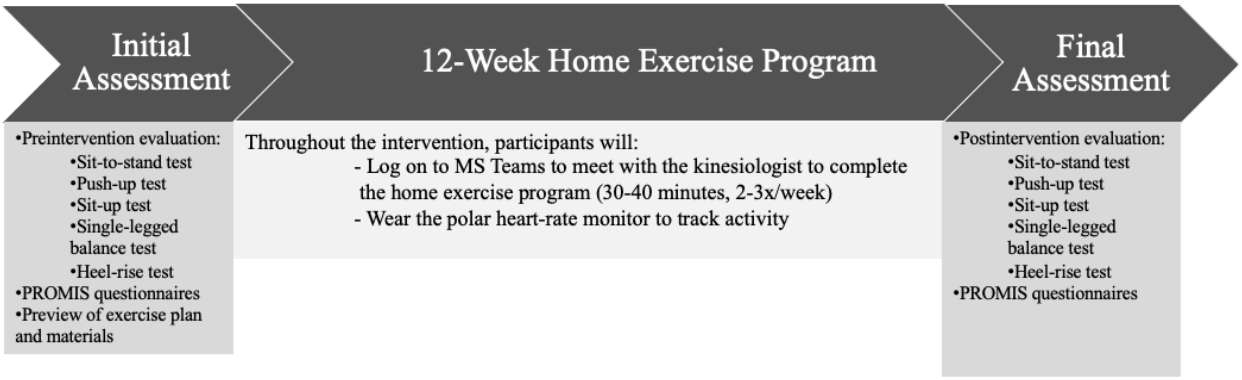
The heel-rise test evaluates muscular endurance of the lower limbs [18]. The participant will complete 2 trials of raising their heels 20 times in a row, as fast as possible, with their arms crossed over their chest. Participants will be given a rest period of 2 minutes between the 2 trials. Ankle plantar flexor strength is scored from 0 to 5, based on the number of heel rises the participant is able to complete [18].

Exercise Intervention

The exercise intervention will begin with 35 minutes twice a week, including a warmup and cooldown, each 5 minutes in duration. Every 4 weeks, the training will intensify in either duration of exercise or number of sessions per week, which is required to stimulate physiological adaptation and enhance improvement [7]. For the duration of the intervention, a kinesiologist (human movement specialist) will provide training and supervision to participants in the supervised group at home through live video sessions. Participants in the supervised group will be separated into 2 groups of 3 participants. For the follow-up group, the kinesiologist will meet with participants individually every 4 weeks to review their progress, preview the next month's exercise plan, and address any concerns or challenges the participants may have. The exercise program timelines for both groups are outlined below (Figures 2 and 3).

XSL•FO
RenderX

Figure 2. Summary of the 12-week home exercise program for the supervised group. PROMIS: Patient-Reported Outcomes Measurement Information System.



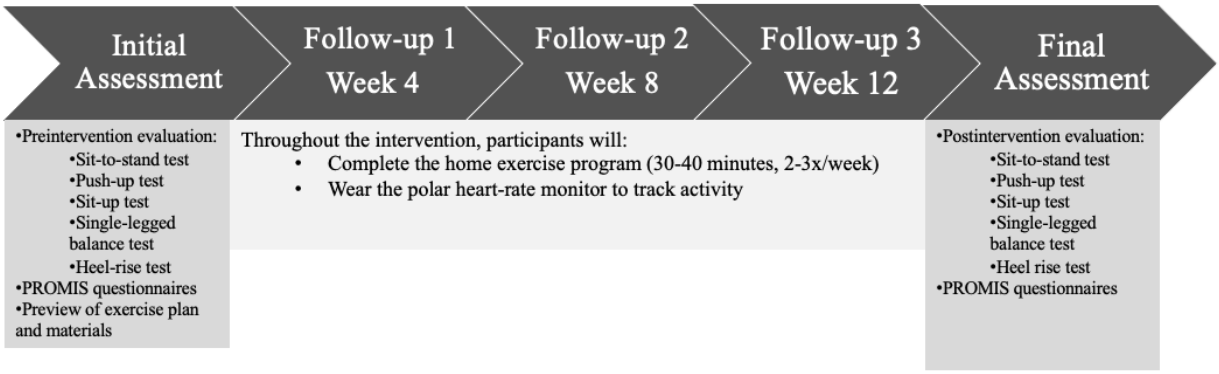


Figure 3. Summary of the 12-week home exercise program for the follow-up group.

Measurement

Feasibility

In determining the feasibility of the telemedicine approaches for the delivery of an exercise intervention, recruitment, adherence, and completion rates will be measured. Recruitment rate will be calculated by dividing the study sample by the total number of contacted potential participants [19]. Adherence rate is defined as the percentage of the exercise intervention sessions completed per participant [20]. To monitor participants' adherence to the exercise intervention, data exported from the activity monitor (Polar watch) will be recorded by study personnel on an activity log for all participants in both groups. Finally, completion rate is defined as the number of participants that completed the exercise intervention as a percentage of the overall number of participants that began the intervention [20].

Cost

To determine the cost comparison between the 2 groups, the number of hours spent by the kinesiologist delivering the exercise intervention to the supervised group will be recorded and compared to the number of hours spent with participants in the follow-up group. The kinesiologist will be paid a rate which is commensurate with their previous experience as well as a wage that aligns with the rate of pay for a kinesiologist in the market in which this study is conducted. The equipment costs (Microsoft Teams, Polar heart rate monitor, resistance band, and weighted exercise ball) will be reported and included in the calculations. When drawing cost comparisons for the 2 approaches, the supervised approach is a group approach, whereas the follow-up approach is an individualized approach. Therefore, a direct comparison between the 2 approaches presents a challenge. Nevertheless, to mitigate the difference in group and individualized approaches, the cost comparison for both the supervised and follow-up groups will be computed and presented as a cost per participant.

Cost-Effectiveness

To compare the cost-effectiveness of the 2 telemedicine approaches, a bottom-up approach will be used, a method for the assessment of each resource required to provide health care and assigning the related costs accordingly [21,22]. For both the supervised and follow-up groups, the mean performance outcome for each of the 5 preintervention evaluation tests will be computed. These means are then compared within their group (supervised or follow-up) to a mean for the same 5 postintervention evaluations, determining the mean outcome (increase or decrease) for each of the 5 tests. These mean outcomes will then be compared to the total cost of each telemedicine approach to determine the cost (on a per-unit basis) of the health outcome. Doing so allows for the assessment of not only which telemedicine approach has a higher cost overall, but most importantly, the per-unit cost of the health outcome for the supervised and follow-up groups. This provides a more accurate comparison, with respect to financial costs, of the 2 methods.

XSL•FO
RenderX

Statistical Analysis

As this is a feasibility study, the testing procedure will be assessed rather than only focusing on the potential outcomes of the intervention. To determine the optimal clinical practice of telemedicine for an exercise intervention, recruitment, adherence, and completion rates of 2 randomized groups (supervised and follow-up approaches) will be investigated. Descriptive statistics will be presented as means and SDs. Based on previous research on home-based exercise interventions [23], the adherence rate will be assessed with a set threshold of 80%. A Wilcoxon rank sum test will be used to evaluate the adherence rate and compare both telemedicine approaches. Whereas both recruitment and completion rates will be compared using descriptive statistics and assessed with a set threshold of 50%. To measure the change in outcome parameters of participants' muscle strength and cardiopulmonary fitness, pre- and postintervention evaluation results will be assessed with a Friedman ANOVA. A Kruskal-Wallis test will be used to determine the differences in outcome parameter changes between the 2 groups (supervised and follow-up groups).

To assess the cost-effectiveness of the 2 telemedicine approaches, a cost-effectiveness plane and an incremental cost-effectiveness ratio will be computed. The incremental cost and incremental effect will be plotted on a cost-effectiveness plane, where the horizontal axis will represent the incremental cost and the vertical axis will represent the incremental effect [24,25]. The costs and clinical outcomes for both telemedicine groups will be plotted on the plane, which will visually demonstrate the additional cost per unit of health gain for each telemedicine approach. To calculate the incremental cost-effectiveness ratio, the difference in costs will be divided by the difference in mean performance outcomes between the supervised and follow-up groups.

Finally, as OI is classified as a rare disorder [1], analyses will be carried out with a significance level (α) of 0.10 [26]. Statistical analyses will be conducted using the statistical analysis software SPSS, version 25 (SPSS Inc).

Results

As the costs associated with both telemedicine approaches can be estimated, the anticipated cost comparison and breakdown of each approach are summarized below (Table 2 and Textbox 1).

Table 2. Estimated cost comparison per telemedicine approach.

Cost estimations	Supervised group, CAD $ (US $)	Follow-up group, CAD $ (US $)

Discussion

Overview

The aim of this study is to evaluate the feasibility of 2 telemedicine approaches for the delivery of a home-based exercise program and determine the most cost-effective approach. The secondary aim of the study is to investigate the effect of a home-based exercise program on muscle function and cardiopulmonary fitness in youth with OI type I. Given the aims of the study, it is hypothesized that the supervised group will have higher adherence and completion rates compared to the follow-up group, and therefore, the physiological benefits will be greater in the supervised group than the follow-up group due to additional benefits from constant supervision. However, the follow-up group will receive individual attention in contrast to the supervised group, in which the specialist will work with groups of 3 patients. Direct comparison of patient performance in the supervised and follow-up groups will allow us to identify which telemedicine approach is more cost-effective and efficient for the delivery of an exercise program to OI pediatric patients.

Greater adherence rates can be associated with benefits such as increased positive reinforcement, improved exercise techniques, and higher self-efficacy [12]. Furthermore, direct supervision is associated with a greater overall volume of exercise achieved and potentially more efficient training, as with this approach, clinicians have the ability to adjust exercises in real time to prevent injury or pain [12]. However, in the follow-up approach, there is schedule flexibility, as participants can perform the intervention sessions when it's most convenient to them. As well, participants may develop autonomy by completing these sessions independently, which in the long term may lead to long-lasting physical activity as individuals feel more confident in their abilities to exercise on their own. Whereas participants in the supervised group rely on study personnel for instruction and motivation and may not develop the same level of autonomy as individuals in the follow-up group. Although there are several health benefits associated with direct supervision, these advantages may not outweigh the increased cost associated with this approach. Thus, the insight gained from this study into the level of participant supervision necessary for a telemedicine approach to be effective will satisfy the current gap in literature. The results pertaining to the feasibility and cost-effectiveness of both the supervised and follow-up telemedicine approaches will provide clinicians with fundamental knowledge regarding which approach is most feasible for the remote delivery of care to a pediatric and youth population.

To date, little is known about the potential effectiveness of exercise for children and adolescents with OI. Previous research has shown that children and adolescents with OI type I experience muscle weakness in addition to bone fragility [4]. Consequently, this muscle weakness may contribute to bone fragility elicited by the genetic mutation in the *COL1A1* or *COL1A2* genes [5]. Given the severe bone fragility in patients with OI and the strong positive relationship between muscle force and bone strength, therapies aiming to improve muscle force may lead to an increase in bone strength [5]. The results of this study will shed light on the physiological response to exercise in children and adolescents with OI. Takken et al [27] evaluated cardiopulmonary fitness and muscle strength in children and adolescents with OI type I and determined that cardiopulmonary exercise tolerance and muscle strength were significantly reduced in patients with OI. To the best of our knowledge, Van Brussel et al [8] is the only published study which demonstrated significant improvements in both aerobic capacity and muscle force and reduced fatigue levels in children and adolescents with OI type I and type IV following a 12-week supervised exercise program. On the contrary, from 2 different OI mice models, results from Tauer et al [28] and Gremminger et al [29] showed very mild improvements in muscle force and

XSL•FO
RenderX

tolerance to fatigue following long-term (multiple weeks) exercise training, suggesting that in OI, there may be a decreased physiological response to exercise. Results from the proposed study will further build upon Van Brussel et al [8], providing insight into the frequency and intensity of the stimulus required to trigger physiological improvements following a 12-week exercise program for youth with OI type I.

Limitations

The limitations of this study are the technical difficulties associated with telemedicine that may arise for both study personnel and participants, such as a poor internet connection, which may lead to low-quality, incomplete, or missed training sessions for those in the supervised group. For the follow-up group, a limitation to consider is the potential that participants will not wear the heart rate monitor during the sessions, as there will not be any direct supervision to provide reminders. This would lead to missed training data, limiting the quantity of data available for comparison between the 2 groups. Although this study was designed primarily to assess the feasibility of delivering a home-based exercise intervention through telemedicine, the data collected regarding the potential change in muscle function and cardiopulmonary fitness and the small sample size of only 12 participants may limit the ability to draw any strong conclusions. As well, given the narrow age range, the results of this study are not a predictor of younger or older patient populations; therefore, a larger-scale study would be beneficial. However, given the paucity of data regarding the physiological response to exercise in youth with OI, preliminary data will provide the basis for a larger intervention study. Additionally, as OI is primarily characterized by bone fragility, given this study's remote delivery methods, it is not possible to assess the skeletal response to the 12-week exercise program. Thus, to build upon this study and given the skeletal deficits associated with OI, future research should investigate the impact of an exercise program on bone mineral content in individuals with OI. Recent research from Sinkam et al [30] demonstrated reduced mechanical tendon properties in a dominant severe OI mouse model. Given these results and the fact that tendons are typically rich in collagen type I, in addition to investigating skeletal parameters, researchers should evaluate the physiological response of tendons in OI from an exercise intervention.

The completion of a 12-week exercise program may present a challenge for some participants, especially during the final 4 weeks of the exercise intervention when the number of sessions increases to 3 times per week. To mitigate this potential concern, study participants in the supervised group will have the flexibility of completing missed training sessions on their own schedule and therefore have access to the exercise plan with detailed instructions, images, and videos of each exercise. Whereas participants in the follow-up group are given the flexibility of completing the training sessions when convenient to the individual rather than a rigid weekly schedule.

Conclusion

Telemedicine provides health care professionals with the opportunity to deliver consistent care to individuals with rare disorders, such as OI, who may have previously been unable to obtain access to such treatments. Given that the COVID-19 pandemic has imposed great challenges in the delivery of health care, this study will provide beneficial insight into the feasibility and cost-effectiveness of remote health care delivery methods. If this study is successful, guidelines and recommendations may emerge, providing individuals with OI with a higher level of targeted care geared toward increasing their quality of life. Finally, the results of this study may be advantageous for the treatment of other rare disorders, furthering the possibility to provide access to care to a far greater patient population.

Acknowledgments

MG was awarded the Le Grand Defi Pierre Lavoie Scholarship for this study in 2019. This study received support from the Canadian Institutes of Health Research (CIHR PJT-152926).

Data Availability

Data sharing does not apply to this study as this is a protocol paper; no data sets were generated or analyzed at this point.

Authors' Contributions

GP, MG, SK, FR, and LNV designed the protocol. GP, MG, and LNV established and wrote the initial protocol and obtained funding for this study. GP wrote the manuscript. MG, SK, FR, and LNV revised the manuscript.

Abstract

Background: Physical activity is a critical target for health interventions, but effective interventions remain elusive. A growing body of work suggests that interventions targeting affective attitudes toward physical activity may be more effective for sustaining activity long term than those that rely on cognitive constructs alone, such as goal setting and self-monitoring. Anticipated affective response in particular is a promising target for intervention.

Objective: We will evaluate the efficacy of an SMS text messaging intervention that manipulates anticipated affective response to exercise to promote physical activity. We hypothesize that reminding users of a positive postexercise affective state before their planned exercise sessions will increase their calories burned during this exercise session. We will deploy 2 forms of affective SMS text messages to explore the design space: low-reflection messages written by participants for themselves and high-reflection prompts that require users to reflect and respond. We will also explore the effect of the intervention on affective attitudes toward exercise.

Methods: A total of 120 individuals will be enrolled in a 9-week microrandomized trial testing affective messages that remind users about feeling good after exercise (40% probability), control reminders (30% probability), or no message (30% probability). Two types of affective SMS text messages will be deployed: one requiring a response and the other in a read-only format. Participants will write the read-only messages themselves to ensure that the messages accurately reflect the participants' anticipated postexercise affective state. Affective attitudes toward exercise and intrinsic motivation for exercise will be measured at the beginning and end of the study. The weighted and centered least squares method will be used to analyze the effect of delivering the intervention versus not on calories burned over 4 hours around the time of the planned activity, measured by the Apple Watch. Secondary analyses will include the effect of the intervention on step count and active minutes, as well as an investigation of the effects of the intervention on affective attitudes toward exercise and intrinsic motivation for exercise. Participants will be interviewed to gain qualitative insights into intervention impact and acceptability.

Results: Enrollment began in May 2023, with 57 participants enrolled at the end of July 2023. We anticipate enrolling 120 participants.

Conclusions: This study will provide early evidence about the effect of a repeated manipulation of anticipated affective response to exercise. The use of 2 different types of messages will yield insight into optimal design strategies for improving affective attitudes toward exercise.

Introduction

Background

Exercising is crucial for maintaining and improving health and fitness and is linked to improvements in both physical and mental health [1,2]. However, only 53% of Americans [3] meet the recommended threshold of 150 active minutes a week [4], and only 23% meet guidelines for both muscle strengthening and aerobic exercise [3], creating a critical need for effective interventions to help Americans exercise. Health researchers have explored ways to leverage technologies such as smartphones and wearables to meet this need, devising interventions that use displays, messages, and other technological channels to encourage physical activity [5]. Reviews of this extensive body of work have found that mobile interventions hold promise [6,7], with a correlation between engagement with the mobile health (mHealth) intervention and efficacy [7]. However, the effects of mHealth interventions on physical activity thus far have often been relatively modest [5,8], when they are effective at all [9,10]. In addition, effects generally do not last long term [11].

Most existing mHealth interventions use a limited set of strategies to encourage physical activity [12,13]. In particular, many interventions rely on goals- and self-efficacy–related strategies, such as supporting goal setting and self-monitoring, providing feedback on performance [5,8], offering rewards [14], and providing some form of social support [8]. However, this range of approaches is relatively narrow compared with a full taxonomy of behavior change techniques [15]. One review found that only 39 out of 93 techniques were used across all top physical activity mobile apps [12]. One potential avenue for improving the efficacy of physical activity mHealth interventions is to devise interventions that expand the range of the targeted mechanisms of behavior change, for example, by developing affective interventions.

The Potential of Affective Interventions for Physical Activity

Interventions that specifically target affect (eg, by using emotion-related behavior change techniques [16]) have the potential to improve the performance of behavior change mHealth apps. Affect is a challenging target for behavior change apps, in part because the relationship between exercise and affect is not straightforward. First, researchers have described a wide variety of separate constructs related to affect [17], including how an individual feels in the moment (incidental affect), their conscious or unconscious assessments of the pleasantness of exercise (affective attitudes and affective associations, respectively), how an individual feels as a result of performing target behavior (affective response), and other aspects of emotional experience [17,18]. Different models of behavior change link these individual constructs differently to health behavior (eg, by listing affect as a component of more general attitudes that factor into behavioral intention [19] or as individual constructs that affect motivation through a variety of conscious and nonconscious processes [17,20-24]). Second, the effect of exercise on individual affective constructs itself varies greatly; for instance, the intensity of exercise has been shown to have an impact on incidental affect during exercise: gentle physical activity is associated with more positive affect, and vigorous exercise is generally associated with a negative affective shift [25].

Despite these complexities, affective constructs are a promising target for intervention. A growing body of work is demonstrating that affective constructs are meaningful predictors of exercise behavior [21]; for instance, positive nonconscious affective evaluations of exercise are associated with higher exercise volume [21] and play a role in both conscious and nonconscious processes regarding exercise behavior [26]. The effect of differences in affective attitudes to exercise can be powerful: 1 study found a 38-minute weekly increase in exercise for every increase of 1 unit on the Feeling Scale (a scale used to measure affective valence [27]) at the 6-month mark of an aerobic exercise program and a 41-minute increase at 12 months [28]. Affective assessments of exercise are even more impactful than other determinants such as self-efficacy [21,29], and 1 study found that sending affectively framed messages yielded more exercise behavior than cognitively framed messages [30].

One affective construct that holds potential for influencing physical activity is *anticipated affective response*, or how an individual expects that a target behavior will make them feel [17]. Generally, affect takes a negative shift during vigorous exercise but rebounds immediately afterward [25]. Much evidence has associated exercise with positive affective states or, at minimum, recovered affective states afterward, starting immediately after exercise and lasting for as long as a day afterward [25,31]. Although the evidence concerning the relationship of positive postexercise affect with exercise intention is somewhat mixed, and there is need for more research on affective responses to exercise to understand individual variation and guard against biased results [32,33], there is some evidence that positive postexercise affect influences affective attitudes toward exercise [34], which themselves are linked to improved exercise behavior [21,34]. Moreover, *anticipated* positive affective response has been positively associated with exercise intention [35] and behavior [17,18], and *priming* people to expect to feel good after exercise has been shown to increase positive affect over the course of exercise [36], postexercise affect [35,36], and exercise intention [35]. The manipulations thus far of anticipated positive postexercise affect have not consistently resulted in increased exercise behavior [35,36], but priming interventions that trigger increased mental elaboration have been associated with more positive postexercise affect [35], suggesting that how a priming intervention is designed may influence its effectiveness. This finding echoes the findings in human-computer interaction literature that reflection at key stages can affect physical activity behavior [37] and suggests that work is needed to understand what forms of interventions can be most effective.

Text Messaging Physical Activity Interventions

One relatively common form of intervention is SMS text messaging. With >95% of American adults owning a mobile phone capable of sending and receiving SMS text messages [38], SMS text messaging interventions are broadly accessible and can reach more populations than interventions that rely on smartphones [39]. SMS text messages may make up stand-alone interventions or act as components in a larger intervention [39]. Reviews of SMS text messaging interventions for physical activity have encouragingly found positive effects in reducing weight and promoting physical activity [39,40], although evidence is more ambiguous for specific populations [39,41]. Importantly, the efficacy of SMS text messaging interventions rests in part on their content [30] and tailoring, as well as other characteristics [39].

Study Contribution

In this study, we will conduct a microrandomized trial [42] (trial registration: ClinicalTrials.gov NCT05582369) to evaluate the effect of a stand-alone SMS text messaging intervention designed to manipulate anticipated postexercise affect to increase exercise behavior. Microrandomization is an efficient trial design that enables causal inference with relatively small samples [42,43]. The primary objective is to determine whether manipulating postexercise affect before planned exercise increases calories burned over the 4-hour period when individuals planned to exercise. Our study extends prior research by examining the influence of anticipated postexercise affect not only on exercise intentions but also on actual exercise behavior. The study will contribute empirical findings on the effect of manipulating anticipated postexercise affect on exercise duration and intensity, actual postexercise affect, and other measures of affective attitudes toward exercise, as well as qualitative findings about how such interventions should be designed.

Methods

We will conduct a 9-week microrandomized trial of an SMS text messaging intervention to make the affective rewards of exercise salient before planned exercise, recruiting adults from the general American population who have an Apple Watch and an iPhone. The field deployment will be followed by interviews to learn about participant experiences with the intervention.

Intervention Description

The intervention consists of SMS text messages about feeling good *after* exercise, which are sent to participants *before* they exercise to manipulate anticipated postexercise affect. There are 2 types of affective intervention messages: high-reflection messages and low-reflection messages (Table 1). High-reflection prompts ask participants to think about and write down, in the reply message, topics related to feeling good after exercise. Low-reflection SMS text messages do not require a response. They contain messages that participants will write themselves at the time of study enrollment, using fill-in-the-blank templates. The research team will review these messages at the time of enrollment to ensure that they are topical. The fill-in-the-blank templates were developed through a series of pilots on Amazon's Mechanical Turk, a website that enables paid crowdworkers to complete web-based tasks. The final set consistently generated topical responses from Mechanical Turk respondents. Out of 18 messages (n=9, 50% high-reflection prompts and n=9, 50% low-reflection prompts, enough for participants to complete the study without repeated messages), participants will receive a randomized subset. Having 2 types of SMS text messages will both generate variety for participants and allow us to explore differences in participant experience resulting from different interaction mechanisms; although both are highly personalized, high-reflection messages provoke reflection and mental elaboration in the moment. In other works, mental elaboration or reflection in written form at different planning or pre-exercise stages has been associated with improved postexercise affect [35] and increased step counts [37].

Table 1. Primary intervention message types and examples.

Message type	Participant involvement	Example messages
High-reflection messages	Researcher generated; participant response via texting required	• What's your favorite thing about the way exercise makes you feel afterwards? • What positive feelings do you want to experience after exercise today? Name three. • When was the last time you did some exercise outside? Tell us what it was and one good feeling you felt afterwards.
Low-reflection messages (templates)	Participant generated based on researcher-created fill-in-the-blank templates; no response required	• Exercise can be its own reward, because _____ makes you feel _____ afterwards. (Fill in the first blank with something you enjoy about exercise. Fill in the second blank with a good feeling that you get from exercise) • Working your body makes you feel _____ after you exercise. (Fill in the blank with a good feeling you get from exercise) • Exercise makes you feel _____ afterwards, because ____. (Fill in the first blank with a good feeling that you get from exercise. Fill in the second blank with a reason exercise makes you feel good)

Study Procedures

Microrandomized Trial

To investigate the effect of the intervention, we will conduct a 9-week microrandomized trial. Participants will complete self-report assessments at enrollment and at the study close. During the 9-week deployment, participants will be randomized twice a week, before planned exercise sessions, to receive an affective intervention message (40% probability), a simple reminder message (30% probability), or no message (30% probability). The study design and measurement points are illustrated in Figure 1 and Table 2. Instruments are listed by study phase in Textbox 1, and specific measures are detailed in Table 3.

Figure 1. Randomization procedure.

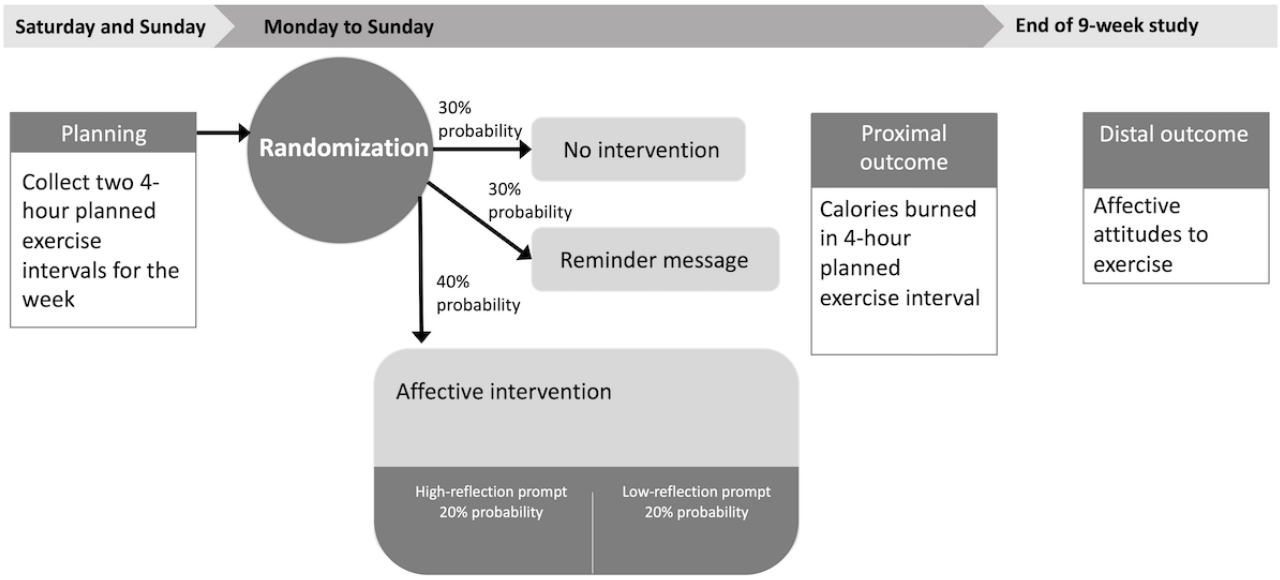

Table 2. Participant activities and measures by study phase.

Study phase	Participant activities	Measures
Enrollment	• Complete low-reflection prompt	• Affective Measures • SRQ-E[a] • PACES-8[b]
Trial period: 9 wk[c]	• Plan 2 exercise sessions/wk • Receive and read study SMS text messages • Respond to high-reflection prompts via texting • Wear Apple Watch • Report exercise afterward	• Planning Questionnaire • Exercise Self-Report Questionnaire
Study close	• Closing Questionnaire	• Affective Measures • SRQ-E • PACES-8
Optional interviews	• Answer questions about experience with the intervention	• N/A[d]

[a]SRQ-E: Exercise Self-Regulation Questionnaire.

[b]PACES-8: Physical Activity Enjoyment Scale.

[c]Affective intervention messages: 40% probability, reminder messages: 30% probability, and no message: 30% probability.

[d]N/A: not applicable.

Textbox 1. Measures used by study phase.

Enrollment

- Consent and enrollment questionnaire (contains affective items)
- Exercise Self-Regulation Questionnaire (SRQ-E)
- Physical Activity Enjoyment Scale (PACES-8)

Microrandomized trial (9 wk)

- Planning questionnaire (a version with a question about anticipated postexercise affective state for the next exercise session included will be sent once halfway through study)
- Exercise self-report questionnaire
- Sensor data collection

Exit

- Closing questionnaire (contains affective items)
- SRQ-E
- PACES-8

XSL•FO

[a]SRQ-E: Exercise Self-Regulation Questionnaire.

[b]PACES-8: Physical Activity Enjoyment Scale.

Study Procedures Overview

At enrollment, we will ask participants to write their low-reflection prompts and to self-report demographic and baseline activity–level information. In addition, we will assess participants' anticipated affect for exercise, their affective association with exercise, and their overall enjoyment of exercise. On top of these measures, we will ask participants to complete the Exercise Self-Regulation Questionnaire [44,45] to measure their intrinsic motivation for exercise and the Physical Activity Enjoyment Scale (PACES-8) [46] to measure their enjoyment of exercise.

For the next 9 weeks, at the start of each week, participants will be asked to list 2 time intervals during which they plan to exercise in the coming week. At the start of each planned exercise time interval, participants will be randomized to receive an affective SMS text message (intervention), a control reminder message, or no message, and at the end of the day, they will be asked to report their actual exercise details (refer to *Exercise Data: Sensor and Self-Report Data* section). Thus, each participant will be randomized to receive an intervention, a control reminder message, or no message 2 times each week.

At the close of the 9-week period, participants will be sent a closing questionnaire that contains questions about their experience with the intervention, all items from the Exercise Self-Regulation Questionnaire and the PACES-8, and the same questions about affect related to exercise that were assessed at baseline.

After the 9-week study period, a subset of participants will be interviewed to gather in-depth data about their experience with the intervention and their perceptions of its impact on their attitudes toward exercise and on exercise behavior. We plan to stratify our interview sample based on participant characteristics such as exercise frequency and participant responses to the closing questionnaire, low-reflection sentences, and responses to high-reflection prompts.

Intervention Delivery

Microrandomized trials are designed around *decision points*—times when it may be appropriate and helpful to provide an intervention [42]. As the intervention in this study operates by increasing the salience of postexercise affective rewards, the intervention is likely to be most helpful when participants have an opportunity to exercise but have not yet exercised. To determine these times, participants will complete a planning questionnaire each weekend where they will specify 2 time intervals during which they intend to exercise in the coming week. Participants are asked to give a day and a 4-hour interval (eg, Thursday, 4-8 PM) during which they intend to exercise. We define an intervention decision point as the start of this interval (eg, Thursday, 4 PM). The 4-hour range was selected to be wide enough to give users some flexibility to accommodate small fluctuations in their schedules but narrow enough to still offer a targeted interval to measure outcomes without the addition of too many sources of noise. The planning questionnaire will be sent on Saturdays and again on Sundays and Monday evenings if not yet completed for the week. Participants who do not complete the questionnaire by the end

XSL•FO
RenderX

of the day on Monday will not be sent any additional messages for the week.

The planning questionnaire will ask participants both when they intend to exercise and what exercise they plan to do. Participants can do any kind of exercise, as long as their session is at least 20 minutes long and is of moderate or greater intensity. Note that participants may exercise more frequently than twice a week, but only 2 of these sessions—those scheduled through the planning questionnaire—will determine the intervention decision points. Additional, unplanned exercise sessions will be assessed through sensor data and the exercise self-report questionnaire (refer to the *Exercise Data: Sensor and Self-Report Data* section).

The planning questionnaire will be delivered on a weekly, rather than daily, basis to minimize user burden and lower the risk of participant dropout. As the questionnaire requires participants to plan ahead, there is some chance that participants' plans will change and that they will not exercise at their planned times. If participants change their plans for exercise after sending the planning questionnaire, the intervention may not reach them when they are truly receptive to it. However, the microrandomization of intervention delivery should balance this inaccuracy in delivery across conditions so that the observed effect of the intervention should not be biased in either direction, although it may be attenuated. In addition, the exercise self-report questionnaire, as well as Apple Watch data, will help in detecting whether participants actually exercised during their planned times (refer to *Exercise Data: Sensor and Self-Report Data* section).

Reminder Message

The planning questionnaire enables the delivery of the affective intervention messages, but, as a form of implementation intention, it could influence behavior in its own right [48,49]. Specifically, the affective messages may work as reminders of previously made plans, which have been shown to improve the effectiveness of planning [50,51]. We control for these effects by including a reminder message whose delivery will be randomized along with that of the affective intervention messages. The reminder message simply reminds participants to fill out the exercise day questionnaire. As in the case of the affective intervention messages, reminder messages will be sent at the start of the planned exercise interval.

Randomization During the 9-Week Trial

Randomization Overview

For each planned exercise interval, participants will be randomly assigned to receive an affective intervention message (40% probability), a reminder message (30% probability), or no message (30% probability; Figure 1). If participants are randomized to receive an affective intervention message, they will be further randomly assigned to receive either a high-reflection message or a low-reflection message with equal probability (ie, 20% each). For each participant, as there will be 9 high-reflection messages and 9 low-reflection messages to choose from, the message to be sent will be chosen from the appropriate set randomly without replacement so that participants will not receive the same message twice.

Randomization Procedure

As the number of decision points is known in advance (2 sessions/wk, or 18 decision points), we can construct randomized treatment sequences of length 18 for each of the 120 participants. These will be consistent with the 18 decision points per person. Before the start of the project, we created 120 randomization schedules to account for the required sample size, allowing for dropouts. Each schedule consists of a sequence of 18 numbers. To ensure that we achieved the right condition balance across participants, we drew these numbers randomly from a uniform number distribution, then placed them randomly into a hundred 18-number sequences. From the numbers that were randomly selected, we assigned the bottom 30% to the control condition, the next 30% to the reminder condition, and the top 40% to the high- or low-reflection affective message conditions. The result is a randomized sequence of condition assignments for the duration of the study, independent of the time and date of planned exercise sessions (refer to Multimedia Appendix 1 for an example randomization schedule). Across all randomization schedules but not within schedules, the conditions are balanced such that 30% of the planned exercise sessions are assigned to control, 30% to the reminder message condition, and 40% to an affective message condition. We then carried out a second round of randomization on the affective message condition sessions to determine which messages would be sent (eg, high-reflection message 1 and low-reflection message 2). As participants will create a set number of low-reflection messages based on fill-in-the-blank templates, we can randomize message selection before message creation. When a participant enrolls, they will be assigned to a randomization schedule. The actual time and date at which each message is sent will be based on the participants' responses to the planning questionnaires each week.

Text Message Delivery

SMS text messages will be delivered through an SMS text messaging service that enables scheduled sending. Low-reflection prompts, high-reflection prompts, reminder messages, and reminders to wear the Apple Watch and fill out the planning questionnaire will not be personalized with participants' names or other identifiers (however, for low-reflection prompts, each participant will receive only the messages that they themselves wrote). SMS text messages will be sent from the same mobile phone number each time so that participants recognize it as coming from the study team. The participants' responses to high-reflection prompts will be received by the same SMS text messaging service and associated with their mobile phone number so that their responses can be tracked and analyzed.

Measures

Study data will include activity data as measured by Apple Watch (primary outcome) and self-report, questionnaires about affect and exercise, and video chat or telephone interview data about participant experience with the intervention. Questionnaires will be hosted on the Qualtrics platform and sent to participants via SMS text message.

XSL•FO
RenderX

Primary Outcome

The primary outcome for the microrandomized trial will be *calories burned*, as assessed by the Apple Watch, over the planned 4-hour exercise periods scheduled through the planning questionnaire. Apple Watch data will be collected through the MyDataHelps platform (CareEvolution, LLC), a secure platform for the collection of sensor (Apple Watch and Fitbit) and self-report data in health research. Participants will install the MyDataHelps app on their mobile phone. As calories burned can be reported by Apple Watch in discontinuous intervals, we will sum the calories burned over the 4-hour planned exercise period. When the intervals of reported calorie data cross the 4-hour planned exercise period boundary, we will assume that the calories burned are equally distributed across the reported interval and include only these calories in the 4-hour planned exercise period. Although Apple Watch's calories burned measurement has moderate rather than high correlation with other energy expenditure measures [52], calories burned were selected as the primary outcome measure because it enables us to assess participants' engagement in a greater variety of exercises compared with a more restrictive measure, such as steps. In this study, participants are instructed to perform any moderate to vigorous exercise they choose and to tell us what they plan to do in the planning questionnaire. Other data (described in the next subsection) will provide secondary records of the exercise performed for secondary analyses.

Exercise Data: Sensor and Self-Report Data

In addition to exercise being assessed via calories burned, it will also be assessed through several additional Apple Watch metrics, including active minutes, steps, and standing time. These metrics will also be collected through the MyDataHelps mobile app. As with calories burned, we will analyze step data and active minutes in the 4-hour planned exercise period.

On the days that participants plan to exercise, they will be asked to complete an exercise self-report questionnaire in the evening asking whether they exercised that day and, if so, how their activity compared with what they had planned; for example, was it shorter or longer in duration than they had planned? Participants will further be asked about their perceived exertion and affective state during and after exercise and, as a manipulation check, whether they received and read an SMS text message from the study team before exercise. If participants say they did not exercise, they will be asked why.

Affect Measures

The exercise self-report questionnaire will ask participants about their affective states during and after exercise, as well as expected postexercise affect for the next exercise session. In addition, at 3 points in the study (baseline, the 3-week check-in, and the end of the study), participants will be asked questions about their affective attitudes toward, during, and after exercise (Table 3).

Participant Experience

A closing survey will ask participants about their subjective perceptions of different aspects of the intervention. In addition, interviews will allow us to explore participant experience with the intervention and their perceptions of its impact on their behavior and attitudes.

Participants

US residents with an iPhone and Apple Watch who are aged at least 18 years and have not been medically advised against physical activity are eligible to participate. Participants will be recruited through web-based channels such as email lists and relevant internet forums. They will be informed about the study and will give consent through a web-based questionnaire.

Sample Size and Power

Sample size was calculated according to the methods published by Liao et al [43]. A microrandomized trial is an efficient trial design that enables causal inference with relatively small samples [42,43]. For this study, proximal treatment effect was estimated at 0.2, significance set at .05, and power set to 0.9. To power our study for the primary analysis (refer to the next subsection)—a contrast between no message and affective messages—availability was set to 0.7 to exclude reminder messages that are randomized at 30% probability. Given these assumptions, 89 participants are needed. We intend to recruit up to 120, allowing for dropouts.

Data Analyses

Primary Analysis

Our primary interest is the average effect of the affective message intervention across time on calories burned during the planned exercise periods compared with no message being sent. To assess this effect, we will use the centered and weighted least squares method, a standard approach for analyzing microrandomized trial data that allows for robust causal inferences about treatment effects [53] and accounts for correlations in longitudinal data by nesting outcomes within participants. The covariates in our analysis will include time in study, the prior week's proximal outcome, self-reported baseline activity levels, age, and gender.

Secondary and Exploratory Analyses

Additional analyses of the microrandomized trial data will investigate the time trend of the effect of affective messages (ie, the change in the effect of the affective messages over the duration of the study), the contrast between affective messages and reminder messages, and separate over-time and time-trend effects of low-reflection and high-reflection messages. In addition, we will investigate the intervention's effect on other outcomes, such as step count and active minutes for the 4-hour planned exercise interval, as collected from the participants' Apple Watches. These analyses, as in the case of the primary analysis, will all be conducted using the centered and weighted least squares method.

In addition to the microrandomized trial analyses, we will conduct a number of exploratory analyses of the affective measure data. We will examine potential changes in the anticipated postexercise affect by investigating changes in pre- and postintervention ratings on the Feeling Scale [27]. Exploratory analyses will include an investigation of changes in other affective measures used and the role of potential moderating factors such as baseline activity level, planned

XSL•FO
RenderX

exercise intensity, and exercise intensity on postexercise affective state predictions. In addition to these quantitative analyses, we will thematically analyze interview data in accordance with the principles described in the study by Braun and Clarke [54]. After transcribing the interviews, we will use an iterative inductive approach to explore themes in the data around participants' underlying needs and the impact the intervention had on their lives. We will triangulate interview responses with observed participant behavior and responses to the closing questionnaire to get a full picture of participant experience with the intervention and insight into appropriate outcome metrics for future iterations.

Missingness

Missing data are likely to occur because participants forget to wear their watch or respond to questionnaires. We will send weekly reminders to participants to wear their Apple Watches. For missing wearable and questionnaire data, we will explore whether any observed variables can be used to explain missingness and include these variables in analyses.

Ethics Approval

This study has been approved by the University of Michigan institutional review board (HUM#00190301).

Informed Consent and Participation

Informed consent will be obtained through a web-based questionnaire; after filling out an eligibility screener survey, eligible participants will be directed to a separate informed consent questionnaire containing information about the study and contact information for the research team. Although some participant identifiers such as name and mobile phone number must be collected to deliver the intervention and participant incentives, these data will be stored on password-protected servers, and data will be deidentified for analysis. All identifying data will be destroyed by the end of December 2024. Participants will be compensated for their participation with Amazon gift cards. Participants will be given US $10 Amazon gift cards on enrollment and another US $20 Amazon gift card on completion of the study. Participants will additionally be entered into raffles for additional gift cards with every study questionnaire they complete, and they will be given an additional US $10 Amazon gift card if they are interviewed, up to a maximum of US $95 in Amazon gift cards.

Results

Enrollment began in May 2023, with 57 enrolled by the end of July 2023. The results will be published after data collection is complete.

Discussion

Implications and Limitations

Researchers have increasingly highlighted the potential of affective and nonconscious motivators to influence exercise behavior [21,55]. Past work has demonstrated the ability of the manipulations of expected postexercise affect to have an impact on during-exercise affect, postexercise affect, and behavioral intention to exercise [35,36]. Our study investigates the impact of repeating that manipulation in a format that is at once highly personalized and highly scalable and that can be carried forward through time at key decision points for exercise behavior. In addition, we extend prior work by examining the impact of the manipulations of expectations of postexercise affect not only on behavioral intentions but also on actual exercise behavior. The findings will elucidate the influence of this intervention over time on both immediate exercise behavior and overall affective attitudes toward exercise. Given recent findings that affective attitudes toward exercise on a particular day have an impact on exercise behavior over and above affective attitudes toward exercise in general [56], there is high potential for an mHealth intervention manipulating affective attitudes in the moment to influence physical activity. As our study design includes qualitative data, we will also gain insight into participants' *experience* with the intervention, yielding findings that can shape the design of other systems and uncover unforeseen complications.

Although researchers are increasingly exploring interventions that target affective judgments about physical activity, the emotional consequences of physical activity remain an underused target [57]. Studies that have used SMS text messages that are either ambiguously [58] or explicitly [59] about postbehavior affective states have found affective messaging to be a critical part of effective interventions for such behaviors as physical activity [58] and even water consumption [59]. However, more work is needed to demonstrate the efficacy of interventions in changing both affective attitudes and resultant behavior. Although this study does use some planning- and self-monitoring–related techniques (planning exercise and self-reporting on the consequences, in addition to requiring possession and use of an Apple Watch that also provides feedback on physical activity), our focus is on the manipulation of salience and beliefs about emotional consequences [15]. Our study represents an early test of an intervention targeting these constructs, and our analyses will investigate the impact of messaging that manipulates affective constructs over and above any potential influences of planning and self-monitoring contained in the study.

The findings from this study will shed more light on which directions are profitable to explore within the complex landscape of affective interventions; for instance, if our intervention is effective at changing both attitudes and behavior, further research will be needed to explore the longevity of this effect. By contrast, an observed movement in only 1 of these domains could point toward the need to explore different design techniques to influence anticipated postexercise affect (eg, by investigating whether timing, modality, or accompaniment with other affective interventions helps us to leverage this intervention target to effect behavior change).

Our study has several limitations. A key limitation is that the intervention decision points rely on participants' understanding on the weekend of when they would be able to exercise in the coming week. Given the messiness of life, participants' plans or ability to execute these plans may change. Although this dependence on predicted ability to be active is suboptimal, microrandomization should help to ensure that the circumstances

XSL•FO
RenderX

that may derail exercise plans will be balanced across the experimental conditions and thus will not bias the estimates of treatment effects. Furthermore, any intervention that is likely to work in the real world will need to be able to deal with a noisy, hard-to-predict environment of people's day-to-day lives. As such, any potential effects that we see in this study may be conservative estimates of the potential of this type of intervention because future work could substantially improve the timing with which such prompts are delivered.

A second limitation of our study is power with relation to the *form* of affective messaging. Although we have 2 types of affective messages, we will lack power to rigorously assess differences in the effect of each type. However, interviews will help to bridge this gap because the participants' testimony will give us a rich depiction of their experience with each type of affective message.

Our findings will also be constrained by the limitations of the Apple Watch. Our primary outcome is calories burned; as noted previously, we have selected this measure because the calories burned metric captures a greater variety of exercise types than step count, but our findings will be limited by the ability of the Apple Watch to measure calories burned with precision and accuracy [52]. In addition, not even calories burned can capture every activity. Early Apple Watch models are not waterproof, and even later models that can capture most aquatic activities cannot be used for activities such as diving. These limitations mean that some activities cannot be captured by Apple Watch sensors. However, participants will be able to report them in a questionnaire, enabling us to identify when the sensor data are not reliable.

Conclusions

Despite the difficulty of promoting physical activity, researchers continue to try new tactics because physical activity is so critical for public health. This study will yield initial evidence about the potential of affective interventions based on anticipated affect to support exercise behavior and will do so based on an intervention that is lightweight, scalable, and can be highly personalized to each individual.

Acknowledgments

The authors thank Dr Alexander Muratov for his help in creating the randomization schedules.

Data Availability

The data sets generated during this study will be available from openICPSR, a service of the Inter-university Consortium for Political and Social Research, after they have been deidentified.

Conflicts of Interest

None declared.

Protocol

A Tailored mHealth Intervention for Improving Antenatal Care Seeking and Health Behavioral Determinants During Pregnancy Among Adolescent Girls and Young Women in South Africa: Development and Protocol for a Pilot Randomized Controlled Trial

Abstract

Background: South Africa, a middle-income country, has an adolescent fertility rate far higher than that of high-income countries. Adolescent girls and young women have an increased risk of pregnancy-related complications and lower antenatal appointment attendance rates than older adult pregnant women. Mobile health (mHealth) interventions to improve health behaviors among pregnant adolescent girls and young women in low- and middle-income countries are scarce.

Objective: This paper describes the development and components of an mHealth intervention to improve antenatal appointment attendance and health behavioral determinants among pregnant adolescent girls and young women in South Africa and details the protocol for a pilot randomized controlled trial that evaluated the intervention's efficacy and user acceptability.

Methods: The intervention, Teen MomConnect, sent tailored motivational behavior change and behavioral reinforcement SMS text messages to participants about antenatal appointment keeping and pregnancy behaviors. The delivery methodology of the intervention was adapted from MomConnect, an mHealth education program for pregnant women in South Africa that has nationwide coverage. In addition, participants received a face-to-face motivational interviewing session delivered by a trained research assistant. Pregnant adolescent girls and young women aged 13 to 20 years were recruited from health facilities and community networks. Participants were randomized into the control group that received the standard MomConnect health SMS text messages or the experimental group that received the Teen MomConnect intervention. Participants completed a baseline questionnaire upon enrollment in the study and a follow-up questionnaire after the end of their pregnancy. The questionnaires assessed demographic characteristics, pregnancy behaviors, and the psychosocial determinants of antenatal appointment attendance (knowledge, attitudes, social support, risk perceptions, self-efficacy, intention, and action planning). Feasibility was assessed using descriptive analyses of acceptability, study implementation processes, and perceived satisfaction with the intervention. The number of appointments attended was obtained from the participants' clinic records. Appointment attendance was compared between the control and experimental groups, as were awareness of HIV status and the psychosocial determinants of antenatal appointment attendance.

Results: Participant recruitment was conducted from May 2018 to December 2018, and the questionnaire-based data collection was completed by December 2019. Overall, 412 participants were enrolled.

XSL•FO
RenderX

Conclusions: This paper describes the Teen MomConnect intervention to improve antenatal appointment attendance and pregnancy health behaviors among adolescent girls and young women. The results on the intervention's preliminary efficacy and user acceptability will inform policy makers and health program officers on how tailored, age-appropriate, and motivational health behavior messages can be delivered via mobile phone to pregnant adolescent girls and young women.

Introduction

Background

South Africa's adolescent fertility rate of 68 births per 1000 girls aged 15 to 19 years is more than quadruple that of high-income countries [1]. Adolescent girls and young women have an increased risk of pregnancy-related complications, including low birth weight, eclampsia, and preterm birth, compared with older women [2-6]. Furthermore, maternal and infant mortality rates are higher in adolescents than in adult women [5,7]. Pregnant adolescents also face problems such as iron deficiency, inadequate nutrition, and higher engagement in tobacco smoking and alcohol and substance use [4] and have more psychological and social needs than older women [4,8].

The adolescent Institutional Maternal Mortality Ratio in South Africa was 76.9 deaths per 100,000 live births in 2014 to 2016 [9]. The Confidential Enquiries into Maternal Deaths found that almost three-quarters of the deaths among adolescent mothers were from factors such as non–pregnancy-related infections (including HIV or AIDS-related infections, tuberculosis, or pneumonia), hypertension, obstetric hemorrhage, and medical and surgical disorders [9].

Maternal health and pregnancy outcomes among adolescent girls and young women can be improved through appropriate antenatal care (ANC) and practicing healthy behaviors during pregnancy. Behaviors that are recommended for a healthy pregnancy include following a healthy diet; practicing physical activity; taking nutrient and folate supplements; practicing oral hygiene; managing preexisting conditions; and avoiding the use of tobacco, alcohol, and illicit substances [10]. Notably, pregnant adolescents often have poor diet quality, inadequate nutritional knowledge [11], and less knowledge of danger signs [12]. These adolescents typically have less knowledge of what to expect and how to appropriately care for themselves during pregnancy [13,14]. Furthermore, environments of lower socioeconomic status hamper the ability to practice healthy pregnancy behaviors. This is relevant as teenage pregnancies in South Africa are more prevalent in areas of lower socioeconomic status [15].

Early initiation and routine attendance to ANC allows for the prevention, early detection, and management of risk factors and pregnancy-related complications and for the provision of pregnancy-related health promotion [16]. In South Africa, where basic ANC is available at public health facilities at no cost, 77% of pregnant adolescents attend the recommended requisite of at least 4 ANC visits [17]. Studies indicate lower ANC attendance and late ANC booking among adolescents and very young women in South Africa than older women [18,19].

Mobile health (mHealth) interventions are increasingly being used to provide educational, motivational, and behavioral content for a range of issues such as smoking cessation, weight loss, and mental and sexual health [20-23]. SMS text messaging has been previously shown to positively influence the uptake of antenatal visits among pregnant women in low- and middle-income countries (LMICs) [24]. SMS text messaging has the ability to reach large populations with no costs incurred by the recipients. The high mobile phone access in South Africa, a middle-income country, provides opportunities for mHealth behavior change programs to reach large numbers of people and improve health behaviors. Currently, 92% of South Africans own a mobile phone [25], with youth being significant contributors to the mobile phone market. As early as 2012, approximately 70% of high school learners reported having their own mobile phone [26].

The MomConnect program [27], launched by the South African National Department of Health in 2014, is one of the largest mHealth programs worldwide. MomConnect uses mobile phones to register pregnancies in a central database and sends SMS text messages containing maternal health information to pregnant women in the language of their choice throughout the course of their pregnancy until 1 year after giving birth. MomConnect messages are based on maternal health SMS text messages from the Mobile Alliance for Maternal Action in South Africa [28]. Pregnant women are routinely assisted in registering on MomConnect when they attend ANC at health facilities. Between August 2014 and April 2017, over 1.1 million women were successfully registered to MomConnect, corresponding to approximately half of the women attending ANC and 60% of those attending ANC that own a mobile phone [29]. Nearly one-third of registrations occur by the end of the first trimester of pregnancy [29].

Given that the MomConnect messages were designed more for adult pregnant women, we posited that it might be beneficial to adapt the message content for adolescent girls and young women. In light of this, a review of MomConnect registrations found that the odds of opting out of MomConnect were higher

XSL•FO
RenderX

for younger women, that is, those aged <25 years [29], thus suggesting a need for retaining younger audiences. In addition, MomConnect sends a fixed set of messages based on the stage of pregnancy. A growing number of mHealth interventions provide tailored messages whereby participants receive content that is matched to a sociodemographic, motivational, behavioral, or personality attribute [30,31]. Therefore, messages that are cognitively, language, age, and context appropriate; motivational in nature; and tailored to the behaviors, attitudes, and health status of pregnant adolescent girls and young women may have the potential to increase uptake of content and induce greater behavior change.

Objectives

There are currently few mHealth studies on interventions that are specifically targeted at improving health behaviors among pregnant adolescent girls and young women in LMICs [32]. Their behavioral, cognitive, and motivational needs and position in society are distinctly different from those of adult women. Therefore, this study sought to develop a mobile-based intervention targeting pregnant adolescent girls and young women. It adapts the MomConnect methodology. It includes motivational behavior change and behavioral reinforcement messages aimed at improving ANC attendance and its psychosocial determinants during pregnancy, as well as tailored message feedback on behavioral and psychosocial determinants. The intervention, titled Teen MomConnect, would be embedded in an SMS text messaging–based system similar to that of MomConnect. An additional component of the Teen MomConnect intervention is a motivational interviewing (MI) face-to-face counseling session delivered by research assistants. This paper describes the development and components of the intervention as well as the protocol for the pilot 2-arm randomized controlled trial (RCT) to evaluate the intervention's preliminary efficacy and user acceptability.

Methods

Development Process

Messaging Content

Formative qualitative research with pregnant adolescents, a review of maternal health education resources, and a review of the existing MomConnect messages provided extensive data that were collectively used to develop and refine the Teen MomConnect intervention messages.

First, key behavioral domains were identified to be included. A multidisciplinary team of researchers in behavioral science, health communication, maternal health, and mHealth and individuals from the technical implementing partner of the MomConnect program reviewed the messages in the existing MomConnect program to categorize them into behavioral domains. To further refine the list of behaviors that place young mothers at risk to be relevant to South African pregnant adolescents, existing maternal health education materials such as the Western Cape Department of Health "Caring for mothers, Caring for you" maternity health education booklet, maternity care guidelines in South Africa, and a review of the literature were used. The data gathered from this work resulted in the selection of 13 behavioral domains for the intervention messages, which are listed in Textbox 1. Health communication specialists from the research team drafted a few examples of intervention messages from each of these behavioral domains and their determinants that were to be pretested.

Textbox 1. List of behavioral domains for the intervention messages.

- Alcohol
- Appointment keeping
- Attitude toward pregnancy
- Clinic attendance
- General health information
- Illegal drugs
- Nutrition
- Self-care and hygiene
- Smoking
- Social stigma
- Social support
- Sexually transmitted diseases
- Tuberculosis

The formative qualitative research with pregnant adolescent girls and young women comprised 4 individual in-depth interviews and 4 mini focus group discussions of between 2 and 5 participants among a sample of 19 pregnant adolescent girls and young women aged 13 to 19 years who attended ANC services in Cape Town, South Africa [33]. The interviews and focus groups investigated experiences with ANC attendance, perceptions of MomConnect, determinants of appointment attendance, and the environmental and social context of participants. In addition, participants were asked to provide feedback on the initial Teen MomConnect sample messages that were drafted by the research team. The findings from the

XSL•FO
RenderX

qualitative research informed the fine-tuning of the messages and the development of new messages. The following paragraphs provide a detailed description of the data gathered and how they were used for the creation of the messages.

Feedback from the participants on the MomConnect program in general was that MomConnect provided valuable information about the baby's development at various stages of pregnancy. The participants valued that the messages communicated directives to attend appointments, practice healthy behaviors, and prepare for labor admission. They found that being able to read the SMS text messages and make sense of them in their own time was more helpful than being told the information all at once at the health facility. Some participants reported that several MomConnect messages contained information that was not applicable to everyone or that they already knew. They expressed the need for language that is simple, concise, and appropriate for young people and suggested including teenage slang to be more understandable. Participants requested more specific information, such as the kind of food to eat rather than generic advice to eat healthily. The need for information on labor, labor signs, hygiene practices, high blood pressure, and the consequences of not exercising was expressed. Some participants reported that they would like to be checked up on regularly to ensure that they were receiving the messages after registering. The feedback indicated an overall need for a more personalized or tailored messaging approach.

Feedback on the Teen MomConnect draft messages was that participants appreciated the specific and practical examples of behaviors and healthy foods provided within the draft messages. They welcomed message content on topics that they were unaware of, such as explanations of why practicing behaviors such as exercise was important. They reported that some messages provided examples that were impractical in their environments, such as exercise activities that were costly or unavailable in their residential areas. Participants suggested including messages that reminded them of their appointment dates. Findings from the focus groups on factors contributing to antenatal appointment attendance and the social context of participants also informed the development and refinement of the intervention messages.

Stakeholder meetings held with professional officers from the Western Cape Department of Health provided further insights into experiences with the MomConnect program, adolescent access to basic ANC services, local health facility operations, and the recruitment of pregnant adolescent girls and young women from the facilities. This information was used to contextualize the proposed intervention content.

Following the stakeholder meetings and the qualitative research findings on experiences with MomConnect and on the perceptions of the Teen MomConnect draft messages, a full set of SMS text messages was developed. The content and tailoring of the messages were based on techniques for tailoring health communication messages used in previous studies [30,31,34] and were grounded in self-determination theory [35]. Therefore, the messages applied an autonomy-supported tone to foster autonomous motivation for behavior change [35]. As such, the messages used phrases such as "consider to," "you can choose to," or "have you been able to" instead of authoritative or definitive phrases such as "you should." Reflective statements and questions rather than commands were often used, such as "What can you do to remind yourself next time?" for participants who forgot to attend their last appointment. The self-determination theory components of enhancing competence and relatedness were incorporated into the message content by providing practical information on behavioral barriers (eg, "giving up [smoking] even now can still have positive effects for you and your baby") and using language that was supportive, respectful, and relatable. The messages were restricted to 160 characters to comply with the required length of an SMS text message. The messages were developed in English and translated and back translated into isiXhosa and Afrikaans. The translated messages were checked to ensure that they maintained the tone and intent of the original messages.

The final message library comprised 66 messages in English, Afrikaans, and isiXhosa and covered the 13 behavioral domains. The messages were tailored by pregnancy week and the week in which the participant joined the intervention program (join week). The logic flow allowed users who had missed messages from earlier pregnancy weeks to be sent relevant *catch-up messages* with the content they missed. There were 48 static or 1-way messages that did not require the user to respond and 18 "two-way" tailored message sets that asked the user a question. The 2-way messages allowed participants to respond by typing a letter corresponding to their response option. The user would receive a tailored feedback message depending on their response to the question. For example, the question assessing smoking asked the following—"During the past month (30 days), on how many days did you smoke cigarettes?"—with the following options: "a. 0," "b. 1 to 15," and "c. 15 to 30." If the participant answered "a," then they would receive the following message: "Well done! By not smoking during pregnancy you will have much lower chances of having a low birth-weight." If they answered "b" or "c" or did not respond to the question, they would receive the following message: "Quitting smoking can be hard but it is one of the most important things you can do for a healthy pregnancy and healthy delivery." Therefore, the logic flow was designed to send a customized response even when the user did not respond to the message. In this way, the intervention would allow each user to receive a unique set of messages based on their pregnancy week and responses to questions. With regard to appointment attendance behavior, the logic flow applied iterative tailoring for 2-way messages on appointment attendance. These included appointment reminders every 4 weeks for those who did and did not know their appointment dates, checkups of whether the appointments were actually attended, and tailored feedback addressing various reasons for not attending each appointment. For affirmative responses to 2-way messages on engaging in smoking, alcohol use, and drug use, users would receive tailored follow-up messages every 4 weeks motivating them to stop these behaviors. Examples of messages on appointment attendance and smoking behavior and their logic flows and timing are presented in Multimedia Appendix 1, whereas brief example messages of the remaining 11 message domains are presented in Table 1.

XSL•FO
RenderX

The MomConnect program used an open-source SMS text messaging platform to distribute the messages, and user registrations occurred via Unstructured Supplementary Service Data (USSD). USSD is a communication protocol for mobile phones to communicate with mobile network operators' computers [29]. The Teen MomConnect intervention messages were delivered via SMS text messages using the same technology platform and user registration process as MomConnect to facilitate comparability. Although a smartphone app was considered to deliver the intervention, SMS text messages were chosen as many adolescents and young people did not have access to a smartphone and an app would incur data costs to users. The intervention messages and the corresponding coding and logic flows were integrated into the technology platform used to implement MomConnect.

Table 1. Extract of SMS text messages.

Message domain	Message	Type
Alcohol	It can be hard to give up drinking but it is one of the most important things you can do for a healthy pregnancy and healthy delivery.	Tailored response to consuming alcohol in the past month
Attitude toward pregnancy	We understand pregnancy can be stressful. Many girls feel the same! You can talk to someone you trust about your feelings, or come to a clinic for support.	Tailored response to feeling stressed about their pregnancy
Clinic attendance	Regular check ups at the clinic will ensure that you and your baby stay healthy. Consider attending all your scheduled clinic appointments.	Static
General health information	Your baby's lungs are starting to develop and its heart beat can be heard.	Static
Illegal drugs	Have you been able to give up hard drugs since you knew that you were pregnant? Reply with a or b. a. Yes b. No	Tailored question
Nutrition	Including iron-rich food like eggs, beans, green vegetables and meat will ensure that your baby develops normally.	Static
Self-care and hygiene	Proper hygiene is important to prevent you from getting sick. Regularly wash your hands with soap, especially before eating and after going to the toilet.	Static
Social stigma	Not everyone is kind to young mothers. We know some people may judge you. Talk to someone you trust, or you can speak to a counsellor at the clinic.	Static
Social support	Emotional support can help with moms' mental and physical health. Think about who you can trust and talk to during this time.	Tailored response to preference for emotional support over informational support
STDs[a]	Finding out about your HIV status can help to make sure you and your baby receive the right medicine on time. You can choose to do an HIV test at your clinic.	Tailored response to unknown HIV status
Tuberculosis	Getting treated can reduce the risk to you and your baby. If you don't have medicines, talk to your health care worker.	Tailored response to positive tuberculosis test

[a]STD: sexually transmitted disease.

Development of the MI Content

The "Difficulty by Motivation" matrix for behaviors and interventions [36] guided the decision to supplement the messaging component with MI. Although tailored messaging can help change behaviors such as attending an appointment, complex behaviors where individuals show higher resistance to changing and require greater motivation and competence to change, such as sustained appointment adherence and substance abuse, often require more intense and interpersonal interventions such as MI. MI [37,38] is an evidence-based, patient-centered style of counseling that has been used in a range of health behavioral interventions in adolescents and adults. MI has been successful in improving health behaviors in pregnant women [39]. The aim of the MI session was to motivate and encourage the participants to attend ANC appointments and improve their health behaviors during pregnancy. MI differs from other types of counseling in that, instead of providing information and directive advice, the participants are encouraged to reflect on and express their own reasons for and against change and how their current behavior affects their life and family goals or core values and explore possible options for making change. Ambivalence and resistance are explored before moving toward action. The development of the MI content was informed by the key themes that emerged from the formative qualitative interviews previously conducted with pregnant adolescent girls and young women; focus group interviews conducted with health care workers and with research assistants who worked with the participants; and an analysis of the behaviors, social norms, and attitudes reported in the baseline questionnaire. The key themes of appointment keeping, substance use, HIV and tuberculosis testing, medication adherence, nutrition, and overall healthy pregnancy behaviors formed the basis of the MI content. The session was tailored to the participants to be relevant to their specific behaviors and questions. The MI sessions were first intended to be conducted by health care workers at the facilities. However, discussions with the facility staff revealed

XSL•FO
RenderX

that they could not accommodate delivering these sessions into their already heavy workloads. Research assistants were then identified to conduct the sessions with the participants. The research assistants attended a training workshop facilitated by an expert counselor in MI. The training session taught reflective listening, asking open-ended questions, formulating affirmations, reflective listening, promoting change talk, and developing an action plan to improve behaviors identified as problematic. The research assistants were taught how to balance the expression of empathy with the need to build room for change. One face-to-face MI session was to be delivered by a research assistant during the participants' pregnancies.

Study Design

The aims of the study were to evaluate the feasibility of the Teen MomConnect intervention and test its preliminary efficacy on antenatal appointment attendance, health behaviors, and psychosocial mediators.

A pilot 2-arm RCT was conducted. Participants were randomized into the intervention or experimental group that received the Teen MomConnect intervention or the control group that received the standard MomConnect mobile messaging. This study was registered in the Pan African Clinical Trial Registry as trial PACTR201912734889796. This study was conducted in Cape Town in the Western Cape province of South Africa from April 2018 to December 2019. Cape Town is predominantly urban, and 9.5% of its 67,485 in-facility deliveries are among adolescents [40]. In the Western Cape province, 29% of pregnant women present late for their first antenatal appointment, that is, beyond 20 weeks of pregnancy. The overall Institutional Maternal Mortality Ratio in the Western Cape is approximately 50 deaths per 100,000 live births, which is lower than the national average. The Western Cape has the second highest provincial percentage of low–birth weight babies (17.3%) and the lowest provincial proportion of stillbirths (16.6%) [41]. In addition, substance use during pregnancy is high in Cape Town, where 9% of women attending ANC use illicit drugs and one-fifth consume alcohol during pregnancy [42].

A sample of 200 (100 participants/group) was decided upon for the pilot RCT. With this sample, it was determined that there would be sufficient power (≥0.80) to detect a Cohen *d* effect size of ≥0.40. This equates to a difference of 0.52 visits between groups at posttest measurement. This assumes a posttest mean of 4.1 (SD 1.3) visits in the intervention group and 3.58 (SD 1.3) visits in the control group (Cohen $d = 0.52 / 1.3 = 0.40$). Owing to the high expected attrition rate in adolescent longitudinal studies and the fact that participants with missing contact details and pregnancy characteristics would be excluded from registration to the mobile intervention, it was decided to recruit as many participants as possible for the baseline survey.

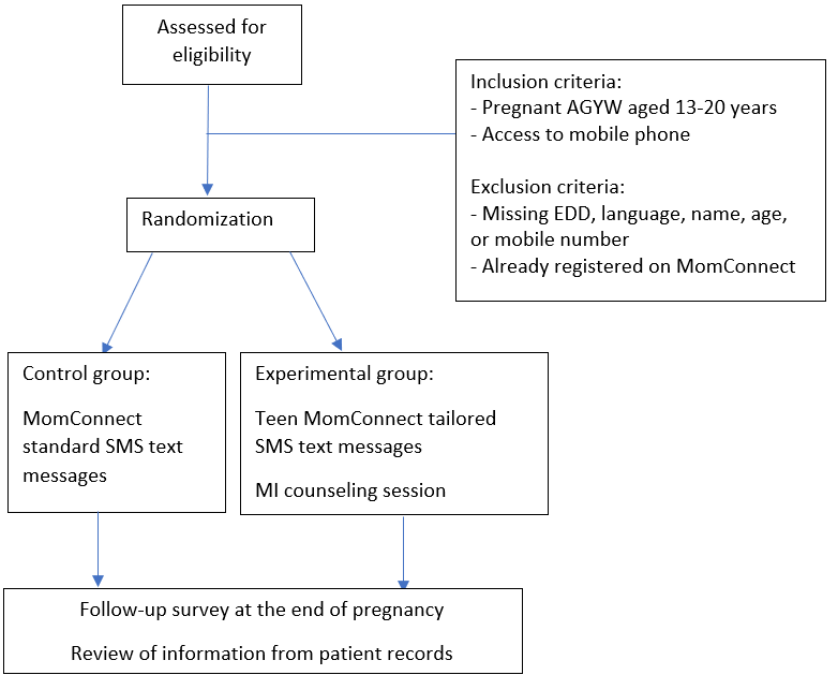
Participants

In South Africa, pregnant girls and women receive ANC and maternity services at outpatient clinics, community health centers, or midwife obstetric units (MOUs) within the primary health care system, which serves over 70% of the population. Pregnant adolescent girls and young women aged 13 to 20 years who had access to a mobile phone were eligible to be recruited to participate in the study. The Western Cape Department of Health provided information on priority communities and clinics where youth pregnancy rates were high and provided guidance on recruitment procedures. On the basis of these discussions, 16 community facilities that provided ANC (comprising public health clinics, community health centers, and MOUs) were identified for recruitment. The facilities were located in 4 of the 8 health subdistricts in Cape Town: Cape Town Eastern, Cape Town Northern, Mitchells Plain, and Tygerberg. Participants were recruited while attending ANC at these facilities. The research team discussed recruitment and data collection activities with the facility managers. Research assistants introduced the study to attendees in the antenatal service waiting areas. In some cases, facility staff referred the research assistants to potential participants. Participants were also recruited from communities via social networks. The research assistants explained the study to potential participants in their language of choice. The research assistants were fluent in English and either Afrikaans or isiXhosa, which are the 3 predominant languages spoken in Cape Town.

The study initially aimed to recruit participants who were up to 24 weeks pregnant to maximize their exposure to the messaging content over the duration of their pregnancies. However, a considerable number of pregnant adolescent girls and young women were beyond 24 weeks when approached during recruitment. Therefore, it was decided to recruit all pregnant adolescent girls and young women.

Recruitment Procedure

A total of 20 trained research assistants conducted recruitment and data collection activities. Recruited participants received information sheets that described the objectives, benefits, and potential risks of the study; the dissemination of findings; the privacy and confidentiality of the study; and their right to withdraw from the study at any time. The participants were asked to complete a consent form (for participants aged ≥18 years) or assent form (for participants aged <18 years) before being enrolled in the study. In addition, parental consent forms were required for participants aged <18 years. Consenting individuals completed a self-administered baseline questionnaire on an electronic tablet or mobile phone. Baseline questionnaire completion was facilitated by the research assistants. In a few cases in which the participant was not comfortable with completing the questionnaire themselves, the research assistant administered the questionnaire. The questionnaire took approximately an hour to complete. Participants received a US $3 incentive for questionnaire completion.



User registration to receive the MomConnect and Teen MomConnect messages required information to be entered on the name, mobile phone number, age, language, and expected date of delivery (EDD) of users. These variables, as well as the estimated last menstrual date (LMD) and current enrollment in MomConnect, were extracted from the baseline data. In the few cases in which the participant did not have their own mobile phone, they were advised to enter into the baseline survey the mobile phone number of someone whom they lived with and whose mobile phone they could use to access the messages sent

XSL•FO
RenderX

during the study. The EDD was required as messages are dependent on pregnancy week. In cases in which the EDD was missing, an estimate was calculated using the reported LMD. In cases in which both dates were missing, the participant was contacted telephonically several times to try to obtain either their EDD or LMD. The language was asked to assess the language in which participants would receive their messages. The options were English, Afrikaans, and isiXhosa. Participants were excluded from enrollment in the intervention study if one or more of their EDD, language, name, age, and mobile phone number was missing or if they were already registered on MomConnect.

Participants were then randomized to the experimental or control group using simple randomization (Figure 1). The study was blinded for participants as they were not told which group they were entered into. Participants were registered on the respective Teen MomConnect and MomConnect messaging programs in weekly or biweekly batches. The control group, which was registered in the MomConnect messaging program, received the MomConnect standard messages according to their pregnancy week and join week. The experimental group participants, who were registered in the Teen MomConnect messaging program, received the messages from the Teen MomConnect SMS text message library based on their pregnancy week, join week, and responses to the tailored questions. In addition, the experimental Teen MomConnect group were to receive 1 face-to-face behavioral counseling group session using MI administered by a trained research assistant.

Figure 1. Diagram of the study procedure. AGYW: adolescent girls and young women; EDD: expected date of delivery; MI: motivational interviewing.

The research assistants contacted participants from September 2018 to December 2018 to schedule MI sessions at times that were convenient for them. Preliminary interview sessions revealed that some participants did not answer their phones, many scheduled sessions but did not attend them, many could not make time to attend a session because of school and other commitments, and it was difficult to allocate participants to times when all group members were available. Therefore, based on the ascertained limited availability of participants between enrollment into the study and the end of their pregnancy, it was decided to conduct motivational interviews with participants until 30% of the sample had received an interview session. Interview sessions could be conducted one-on-one or in groups of up to 5 people. Participants received an incentive of US $6 for attending a session.

Once the EDD had passed, participants in both the experimental and control groups were programmed to receive the standard postpartum messages that users receive in the MomConnect program. Participants were contacted a week after their EDD had passed to schedule voluntary completion of the follow-up questionnaire. Participants who had an abortion, miscarriage, or stillbirth were also contacted. As with the baseline questionnaire, participants completed the follow-up questionnaire on an electronic device facilitated by the research assistants, and they received a US $3 incentive. Electronic administration of both the baseline and follow-up surveys was facilitated using the Qualtrics electronic survey tool (Qualtrics International Inc) [43].

Ethics Approval

The Research Ethics Committee of the Human Sciences Research Council (REC 2/17/08/16) granted ethics approval for this study. Permissions were obtained from the Western Cape Provincial Government and the Department of Health to conduct research within the communities' public health clinics and MOUs.

Measurement Instruments

Data were gathered from the baseline and follow-up questionnaires and from a review of patient clinical records at the facilities.

XSL•FO
RenderX

Questionnaires

Questionnaire development was informed by the reasoned action approach [44] and the Integrated Behavior Change Model (I-Change Model) [45], as well as a literature review on the psychosocial and socioeconomic factors associated with antenatal appointment attendance and health risk behaviors among young pregnant women.

The baseline questionnaire (Multimedia Appendix 2) assessed demographic characteristics; previous pregnancies; attitudes about the pregnancy; mental health status; knowledge of HIV and tuberculosis; HIV and tuberculosis testing; pregnancy risk behaviors (smoking, alcohol use, and illicit drug use); exposure to violence and harassment; perceptions regarding healthy pregnancy behaviors; knowledge regarding appointment attendance; risk perceptions; social support; peer norms; peer, partner, and family attitudes regarding appointment attendance; and participant attitudes, self-efficacy, action planning, and intention toward attending antenatal appointments.

The items on perceptions of healthy pregnancy behaviors, risk perceptions, social support, peer norms, attitudes, self-efficacy, action planning, and intention were all measured on a 4- or 5-point Likert scale, with responses ranging from *strongly disagree* to *strongly agree*.

Perceptions of healthy pregnancy behaviors included items on dietary behavior, nutrient intake, and physical activity. The perception statements were extracted from maternity health information booklets, including the Western Cape Department of Health "Caring for mothers, Caring for you" booklet. Exposure to violence was measured using 13 items on the lifetime frequency of exposure to violence or harassment from relatives, partners, teachers, or health care workers. The questions were adapted from the work by Reddy et al [26]. Knowledge of antenatal appointment attendance was measured using 16 statements informed by maternity booklets. Construction of the attitude, self-efficacy, peer norm, and intention items was based on the reasoned action approach by Fishbein and Ajzen [44], and the action planning, risk perception, and social support items were informed by the I-Change Model [45]. Risk perceptions referred to the perceived implications of not attending or missing antenatal appointments and the risks of pregnancy complications. Social support for attending ANC referred to the encouragement received from family, friends, and partners or boyfriends to attend appointments.

The follow-up questionnaire included the same items as the baseline questionnaire and additional items assessing the outcome of the pregnancy. In addition, evaluation questions were included in the follow-up questionnaire that assessed the participants' experiences with the SMS text messages and the motivational interview content, overall satisfaction with the study, and experiences with the research assistants. Specifically, 21 items evaluated the messaging component by measuring comprehension, tone, appropriateness, and content of the messages; the perceived degree to which the messages motivated behavior change; the frequency of receiving the messages; and whether participants were able to respond to the messages. The items evaluating the MI were administered to those who reported attending a session. A total of 17 items assessed the perceived degree to which the MI session motivated behavior change, with responses on a 5-point Likert scale.

Review of Patient Records

Patient records were accessed from the facilities where the participants were attending ANC or where they gave birth. The patient folder contains the maternity case booklet and other related files, in which facility personnel record information from the patient's antenatal visits, during labor, and after giving birth. Research assistants and the research team captured the following information from the maternity case booklet and its related files: clinical measures such as blood pressure at antenatal visits, dates of antenatal visits by pregnancy week, HIV and sexually transmitted disease testing, clinical measures from the labor process, and birth weight of the infant. The total number of antenatal visits was obtained from the recorded dates of antenatal visits by pregnancy week.

Primary and Secondary Outcomes

The primary outcome variables for feasibility were the perceived satisfaction and user acceptability of the intervention, whereas the outcome variable for assessing initial preliminary efficacy was the number of antenatal appointments attended. The number of antenatal appointments attended was obtained from the patient records at the facility. A secondary approach was to code the number of antenatal appointments attended into a binary variable for <4 versus ≥4 visits to calculate the proportion of participants who attended the requisite of at least 4 appointments during pregnancy [17]. Secondary outcomes were awareness of HIV status, psychosocial determinants of antenatal appointment attendance (knowledge, risk perceptions, attitudes, self-efficacy, intentions, and action planning), perceptions of healthy pregnancy behaviors, number of intervention messages responded to, and variables evaluating the recruitment and study implementation processes.

Statistical Analysis

Analyses will be conducted using SPSS (version 27.0; IBM Corp). Variables on perceived satisfaction with and acceptability of the Teen MomConnect messages and MI sessions in the evaluation section of the follow-up questionnaire as well as the number of messages responded to and MI attendance will be used for descriptive analyses to evaluate how the Teen MomConnect intervention was implemented and received. The outcomes of antenatal appointment attendance and its psychosocial determinants in the experimental (Teen MomConnect) and control (MomConnect) groups will be analyzed using linear regression for continuous outcomes and logistic regression for binary outcomes (including the outcome of percentage that attended ≥4 antenatal sessions) at follow-up. Covariates include age, race, previous pregnancies, school attendance, pregnancy week at enrollment, and exposure to MI. For outcomes related to knowledge, risk perceptions, attitudes, self-efficacy, intentions, and action planning scores that were measured at both baseline and follow-up, the change in mean values between baseline and follow-up in the experimental and control groups will be analyzed using analysis of covariance [46]. For each of these outcomes, moderation effects for race,

XSL•FO
RenderX

gestational age at enrollment, socioeconomic status, age, and number of previous pregnancies will be tested with interaction terms in the regression models.

Data Management, Confidentiality, and Privacy Protection

The data from Qualtrics were protected by log-in ID and password. The server that stored data on message sends and responses was password protected. The data were sent to the statistician and principal investigator upon study completion. The consent forms are kept in a locked storeroom.

Quality Assurance

Practical training on recruitment and data collection procedures, with refresher sessions, was provided to the research assistants throughout the study to ensure its validity and accuracy. The baseline and follow-up data collected were checked for possible errors an average of every 2 weeks. The research assistants encouraged participants to ask questions about any concerns they had with the study. The research team monitored the study to oversee its progress. The research assistants provided feedback to the project manager 3 to 4 times per week on the study progress and any barriers encountered.

Results

Recruitment of participants was conducted from May 2018 to December 2018. A total of 412 eligible participants were enrolled in this trial (Table 2). The participant characteristics did not differ significantly between the experimental and control groups, with the exception of average gestational week (control group: 23.1, SD 7.69; experimental group: 20.8, SD 6.76; P=.002). The mean age was 18.0 (SD 1.56) years; 36.2% (149/412) were attending an educational institution, 75.4% (307/407) lived in formal dwellings, 59.6% (242/406) reported household shortages of important items, and 10.9% (45/412) had been pregnant before. Of the 412 enrolled participants, 256 (62.1%) completed the follow-up questionnaire. Patient records were able to be retrieved for 54.4% (224/412) of the participants. Results on the preliminary efficacy and acceptability of the intervention will be disseminated via publications and conference proceedings throughout 2023.

Table 2. Characteristics of the sample at baseline (n=412)[a].

	Control (n=219)	Intervention (n=193)	Total sample	*P* value[b]
Age (years), mean (SD)	18.1 (1.49)	17.9 (1.64)	18.0 (1.56)	.21
Gestational age (weeks), mean (SD)	23.1 (7.69)	20.8 (6.76)	22.0 (7.35)	.002
Racial group[c,d], n (%)				.29
Black African	59 (27.2)	64 (33.2)	123 (30)	
Coloured	157 (72.4)	128 (66.3)	285 (69.5)	
Other	1 (0.5)	1 (0.5)	2 (0.5)	
Attending an educational institution, n (%)				.29
Do not attend educational institution	145 (66.2)	118 (61.1)	263 (63.8)	
Attend educational institution	74 (33.8)	75 (38.9)	149 (36.2)	
Dwelling type[e], n (%)				.79
Informal	54 (25.1)	46 (24)	100 (24.6)	
Formal	161 (74.9)	146 (76)	307 (75.4)	
Self-perceived cost of living[f], n (%)				.12
Food and clothes shortage	41 (19.2)	51 (26.6)	92 (22.7)	
Shortage of other important things	78 (36.5)	72 (37.5)	150 (36.9)	
Have important basics	95 (44.4)	69 (35.9)	164 (40.4)	
Had been pregnant before, n (%)				.73
Yes	25 (11.4)	20 (10.4)	45 (10.9)	
No	194 (88.6)	173 (89.6)	367 (89.1)	

[a]Counts do not always sum to 412 due to missing observations for some variables.

[b]Testing the difference in estimates between the control and intervention groups using chi-square tests for categorical variables and 2-tailed *t* tests for continuous variables.

[c]Control group: n=217; total sample: n=410.

[d]Race was self-reported by participants. Racial categories provided in the questionnaire were according to Statistics South Africa's standard population groups: Black African, Coloured, White, and Indian. The White and Indian categories were collapsed for analysis due to small sample sizes. Race was reported not with the intention of reifying sociocultural constructs but rather to study ongoing health disparities across groups.

[e]Control group: n=215; intervention group: n=192; total sample: n=407.

[f]Control group: n=214; intervention group: n=192; total sample: n=406.

Discussion

Synopsis

This paper describes the development of the Teen MomConnect intervention and the protocol for the pilot RCT to measure its feasibility and preliminary efficacy. The intervention aimed to improve antenatal appointment attendance among pregnant adolescent girls and young women using tailored 2-way messaging and MI. The results of the pilot study will inform policy makers and health program officers on how tailored, age-appropriate, and motivational health behavior messages can be delivered via mobile phone to large numbers of young people. The intervention expands the messaging content of the MomConnect program, which already has high coverage, to be relevant to youth. If the intervention shows promising results (eg, in terms of feasibility), it can be tested in a formal, fully powered trial. The findings will also show how the intervention was implemented and inform how it can be improved in the future.

Implementational Challenges

This study is subject to some foreseen implementational challenges. mHealth interventions often have high dropout rates, especially among young people. This study aimed to mitigate this by allowing for oversampling of baseline participants. This study will assess retention between baseline and follow-up, and the evaluation can inform retention strategies in future mHealth studies with adolescents. Second, many individuals in South Africa frequently change their mobile phone numbers, and this is expected to be common among adolescents and young adults. Studies on the MomConnect program found that messages were not delivered to a large number of users, which was attributed to users having changed their phone numbers [28]. This study was subject to the same problems. Future mHealth programs, particularly those designed for adolescents, can use smartphone apps rather than SMS text messaging–based systems. Nevertheless, SMS text messages were the most practical delivery option for this study as they facilitated comparison with the MomConnect SMS text message delivery and SMS

XSL•FO
RenderX

text messages can reach all mobile phone users regardless of whether they have a smartphone and have no added costs to the user. This is particularly relevant in LMICs such as South Africa that experience challenges with mobile data costs, speed, and coverage [47]. Third, capturing information on the number of appointments attended is subject to the availability and ease of accessibility of the patient health records and the accuracy with which this information is captured by personnel at the facility. Therefore, the research team included questions on whether the participants attended all their appointments in the follow-up questionnaire. This question, although subject to self-report bias, can be used to supplement the analyses of appointment attendance.

Acknowledgments

The authors thank the participants and their parents for taking part in the study. They thank Ms Nwabisa Tshefu, Ms Gadija Khan, Dr Rachana Desai, Dr Xincheng (Alicia) Sui, and the team of research assistants for their contributions to data collection and operational activities. The authors acknowledge the public health facilities that participated in this study for their support and assistance with recruiting participants. This study was funded by a grant from the UK Medical Research Council (grant MR/N021355/1). The funding body played no role in the study design, data collection, analysis and interpretation of the data, or writing of the manuscript.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Abstract

Background: Adolescents and young adults with HIV repeatedly demonstrate low rates of antiretroviral therapy (ART) adherence as well as low rates of viral suppression. Digital health interventions are a promising way to engage adolescents and young adults with HIV to support ART adherence. However, few digital health interventions have been developed and tested with adolescents and young adults in countries like South Africa, where the HIV burden among adolescents and young adults is greatest. *Masakhane Siphucule Impilo Yethu* (MASI; Xhosa for “Let's empower each other and improve our health”) is a comprehensive ART adherence-supporting app for South African adolescents and young adults with HIV. It was culturally adapted using the HealthMpowerment platform.

Objective: The aim of this paper is to describe the protocol for a pilot randomized controlled trial examining the feasibility, acceptability, and preliminary efficacy of MASI on self-reported ART adherence and social support.

Methods: We will enroll 50 adolescents and young adults with HIV ages 15-21 years. Participants will be recruited from public ART clinics linked to a large government-funded teaching hospital in Cape Town, South Africa. Participants will be randomized 1:1 into either the intervention arm receiving a full version of MASI or the control arm receiving an information-only version of the app (n=25 per arm). Participants will be asked to engage with MASI daily for 6 months. All participants will complete baseline and follow-up assessments at 3 and 6 months.

Results: Study screening began in May 2022 and the first participant was enrolled on June 21, 2022. As of June 12, 2023, 81 participants have completed screeners, and 36 eligible participants have been enrolled in the pilot randomized controlled trial. Recruitment is anticipated to last through August 31, 2023, with study activities anticipated through February 29, 2024.

Conclusions: There is an urgent need for innovative interventions to improve ART adherence among adolescents and young adults in settings like South Africa. If found to be feasible and acceptable, MASI could be implemented with adolescents and young adults with HIV in other parts of the country.

Introduction

Background

Adolescents and young adults with HIV represent a large and growing proportion of people living with HIV globally [1]. Despite considerable progress in prevention and treatment, adolescents and young adults lag behind other age groups with respect to UNAID's 95-95-95 targets for testing and treatment outcomes [2,3]. Consistent adherence to effective antiretroviral therapy (ART) is needed to suppress HIV viral load to undetectable levels, resulting in improved health outcomes and eliminating transmission [4]. Unfortunately, adolescents and young adults repeatedly demonstrate low rates of ART adherence as well as low rates of viral suppression, with estimates of viral suppression ranging from 47% to 59% [3,5]. Adolescents and young adults with HIV face a variety of barriers to ART adherence, including patient-level factors (eg, stigma, misconceptions, secrecy, treatment fatigue, forgetfulness, and lack of self-efficacy), caregiver-related factors (lack of assistance or support), and health system-related factors (eg, inconvenient clinic times) [6]. Given their developmental stage, adolescents are particularly sensitive to contextual influences, such as a lack of social support, and experience greater distress due to social exclusion [7,8].

Over 70% of adolescents and young adults with HIV live in Eastern and Southern Africa, with South Africa accounting for 22% of all adolescents and young adults with HIV globally [1]. Despite having the greatest HIV burden, interventions designed to support ART adherence and care engagement among adolescents and young adults in settings like South Africa remain limited [9-11]. A systematic review of interventions to improve adherence among adolescents and young adults conducted in 2015 identified no studies implemented in Eastern or Southern Africa [9]. A more recent review of interventions published between 2015 and 2019 identified 7 studies conducted in Eastern or Southern Africa [12]. While this is an encouraging increase, and additional trials are underway [13-15], there remains an urgent need for innovative interventions to improve ART adherence within this important population.

Digital health interventions are a promising way to engage adolescents and young adults with HIV to support ART adherence, given their increasing access to and interest in mobile technology [16,17]. Digital health interventions can be used to target multiple factors influencing a behavior (eg, knowledge, attitudes, skills, social support, and norms), which makes them well-suited to address a complex behavior like ART adherence. They can also be used to support web-based communities with the potential to reduce social isolation and loneliness while providing participants with emotional and informational social support [18,19]. Mobile phone access in South Africa was 95% as of 2018, and an estimated 91% of all phones in the country are smartphones [20,21]. Data from South Africa show that smartphone ownership is higher among young people [22], who consistently express more interest in adopting technology, making digital health interventions targeting adolescents and young adults feasible and potentially scalable in this setting.

Despite their promise, few digital health interventions to date have been developed and tested with adolescents and young adults in Eastern or Southern Africa. Among those that have been evaluated, basic applications such as SMS text messaging and phone calls have been the most common [23]. The findings of such SMS text messaging–delivered interventions have been mixed [24], highlighting the limitations of addressing only 1 adherence challenge (eg, forgetfulness), and underscoring the potential of incorporating multiple behavior change techniques (BCTs) to comprehensively address the varied adherence barriers experienced by adolescents and young adults.

To address these gaps, we developed *Masakhane Siphucule Impilo Yethu* (MASI; Xhosa for "Let's empower each other and improve our health"), an ART adherence-supporting app for South African adolescents and young adults with HIV, based on formative research in Cape Town, South Africa [25]. MASI was culturally adapted using our team's evidence-based HealthMpowerment (HMP) platform. HMP was built upon years of human-centered design and research [26-29] and has demonstrated improvements in HIV risk behaviors, HIV care engagement, and stigma among youths in the United States [29,30]. The HMP platform is built to support use in low-resource settings like South Africa; it includes offline support to allow use without internet access and allows participants to customize data use, which is important when wireless coverage is limited and data use fees apply.

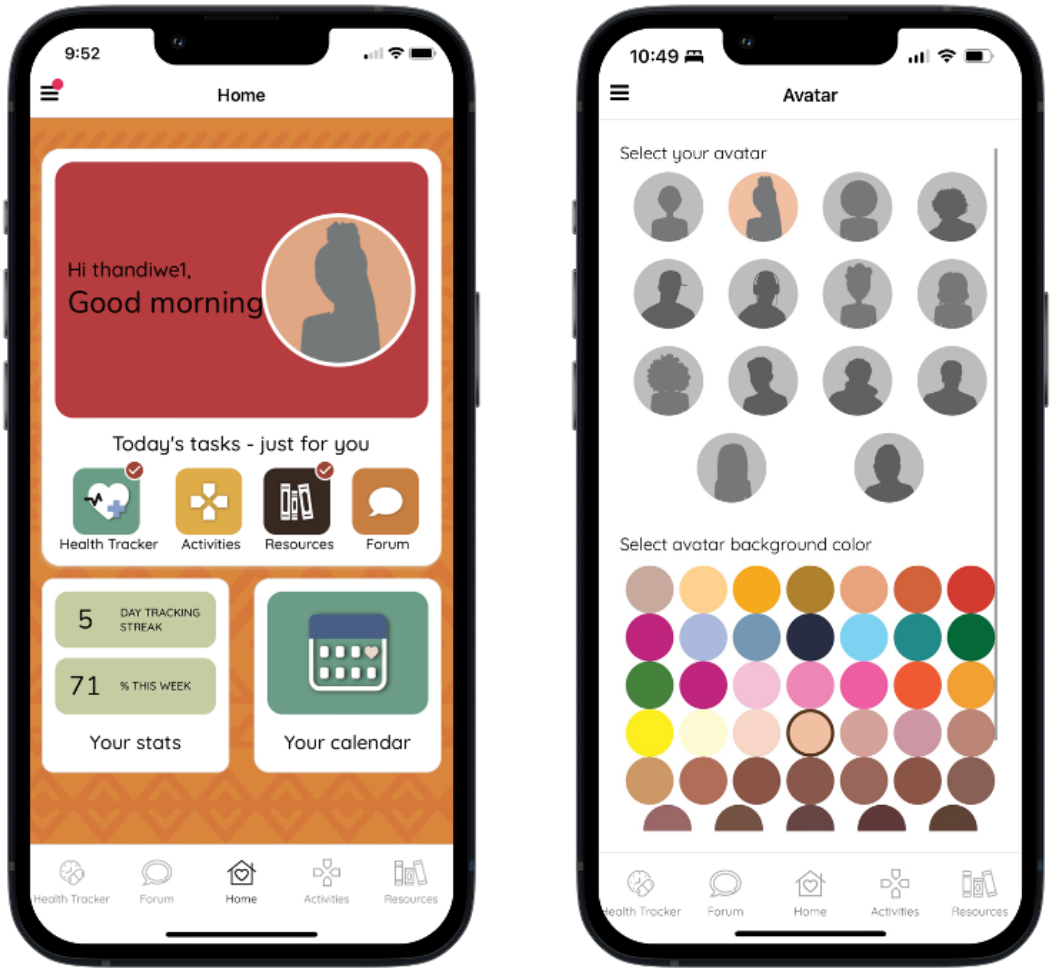
Objectives

The goal of this study is to conduct a pilot randomized controlled trial (RCT) of MASI with 50 adolescents and young adults with HIV, ages 15-21 years, to (1) assess its feasibility and acceptability and (2) explore preliminary effects on ART adherence and social support. This study's protocol is guided by the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines [31], and the CONSORT (Consolidated Standards of Reporting Trials) reporting guidelines for pilot and feasibility trials [32].

MASI Intervention

MASI Mobile App Overview

MASI is a comprehensive intervention designed to promote ART adherence and foster social support using a strengths-based approach. MASI was adapted through formative research with South African adolescents and young adults with HIV, including in-depth interviews with 15 adolescents and subsequent beta testing with 12 adolescents [25]. The interviews, conducted between January and March 2021, addressed participants' health-related challenges and unmet needs to inform the



XSL•FO
RenderX

adaptation process and the development of tailored content to meet their needs. The majority of participants also described their preference for having content in English rather than Xhosa, the predominant home language of our study participants, noting the simplicity of English and the increased comfort with the language among youths [25].

After adaptation, MASI was beta tested with 12 adolescents with HIV between September and December 2021. Beta testing supported the feasibility of using MASI on participants' devices and identified no major technical issues [33]. Our mixed methods analysis of participant paradata (ie, back-end app use metrics [34]) and in-depth interview transcripts after beta testing found MASI to be functional, usable, and highly desirable [35]. Modifications to MASI were made prior to the pilot trial based on findings from beta testing, including the addition of new resources and activities, modifications to the app programing to promote ease of navigation, and a plan for posting new content in the app at the start of the pilot RCT to encourage participant engagement (eg, icebreakers and polls).

The MASI mobile app is available for Android and iOS and smartphones from either Google Play or the Apple App Store; access to the app requires a code provided by the research study. Users select a username and password and are encouraged to pick a username that does not contain any identifying information so that they can remain anonymous to other app users. Users also customize an avatar, which is displayed on the home page, along with time-specific greetings (Figure 1). The home page also includes a list of "Today's tasks" related to 4 of the main app features: Health Tracker, Activities, Resources, and Forum. The Activities and Resources button takes participants to a prespecified activity or resource for the day. Once completed, the home screen displays a red check mark on the feature's button in the "Today's tasks" section.

Figure 1. *Masakhane Siphucule Impilo Yethu* home screen and avatar customization options.

MASI Mobile App Features

Core MASI features are described in Table 1, with their associated BCTs. The BCTs were identified using a taxonomy developed by Michie et al [36], which classified 93 hierarchically clustered techniques (clustered within 16 groups).

The MASI Health Tracker (Figure 2) prompts users to add details about their HIV medications (eg, frequency and time of day), and then allows users to pick a customized, tailored reminder to be sent by the app as a push notification at the selected time. If a user clicks on the reminder, they can track their adherence. If a user indicates that they missed a pill, they are prompted to provide a reason, and the app provides tips on how to overcome that challenge in the future. Users can also track other health behaviors and statistics, including meals, mood, and alcohol consumption. They can view graphs and visuals of their tracked health behaviors over time.

XSL•FO
RenderX

The MASI Forum (Figure 3) allows participants to interact with other MASI users and peer mentors by starting or adding to existing discussion posts. Users can upload images, videos, or links and can favorite posts and follow other users. Research staff, including peer mentors from the clinic who have been hired to support our MASI users, monitor and add to forum posts or create their own icebreaker posts to encourage dialogue.

The Ask the Expert feature (Figure 4) allows users to submit questions that are answered by a doctor or counselor, sourcing credible information. Questions are posted anonymously, and responses are visible to all participants. Responses from the expert often link to further resources within the app related to the topic of interest.

The Activities feature (Figure 5) offers engaging activities covering a range of health-related and lifestyle topics. Example activities include quizzes that test knowledge on a subject and provide instant feedback and explanations of the answers. Goal-setting activities allow for the users to identify action steps they want to take toward a goal and receive tips on improving selected behaviors. Other activity types include self-assessments or fill-it-in activities that allow for users to reflect on a prompt and enter in responses, such as identifying motivations for staying in HIV care.

The MASI Resource feature (Figure 6) provides access to multimedia resources and information on various health topics. There are over 140 articles and videos, with new content added to the resource center as it is developed. All content has been developed or adapted to the South African setting, including links to local websites or resources for more information and support. Resource topics include healthy living, love and relationships, living with HIV, all about sex, life skills, prevention, and creating change. Many of the resources contain links to other articles related to the topics, or to a relevant activity, such as a quiz to test their knowledge or a goal-setting activity.

The MASI app also includes elements of gamification, such as badges (Figure 7) that are awarded to participants based on their app use. For example, users are awarded the “Book Worm” badge after reading 10 articles and earn the “Unshakable” badge once they report that they have taken their medication 30 times.

Table 1. MASI[a] core features and associated behavior change techniques.

MASI feature	Description of feature	Behavior change techniques [36]
Health Tracker	• Tracking available for ART[b] adherence and other health-related behaviors and statistics, including meals, mood, financial stress, smoking, alcohol, drugs, sex life, CD4[c] count, and viral load. • Customizable reminders sent via notifications, with recommended text generated to connect taking medication with the timing of other daily behaviors (eg, brushing teeth). • Feedback based on entered data to encourage behavior change.	• Prompts or cues • Feedback on behavior • Self-monitoring of behavior • Self-monitoring of outcomes of behavior • Habit formation
Forum	• Forum threads can include images, YouTube videos, or text. • Users can start or contribute to existing forum threads or “like” or “favorite” posts. • MASI peer mentors and staff monitor the forum and add posts, including polls, to boost engagement.	• Social support (unspecified) • Social support (emotional) • Role-modeling • Social comparison
Resources	• Multimedia resources and information on health and wellness, stigma, resilience, and life skills. • Information about consequences of various HIV-related behaviors (eg, disclosure and ART adherence). • Resources inclusive of various learning styles and health literacy levels. • Resource articles link to care locator with up-to-date local resources available.	• Instruction on how to perform behavior • Information about health consequences
Activities	• Activities include risk assessments, quizzes, goal setting, sorting, and matching.	• Goal setting (behavior) • Goal setting (outcome)
Ask the Expert	• Direct connection to a health care provider who answers questions submitted within the app.	• Credible source
Game-based elements	• Badges awarded for prespecified targets (eg, 30 min using MASI). • Avatars represent MASI users and can be swapped out for various colors and silhouettes.

MASI Peer Mentors

Our study will hire at least 2 part-time MASI peer mentors to provide support to MASI users. Peer mentors will be between the ages of 18 and 29 years with a track record of good adherence to ART and HIV care engagement, strong communication skills, and demonstrated leadership qualities. We will hire individuals who have been trained to serve as in-person peer mentors and facilitate in-person support groups at local ART clinics. MASI peer mentors will be trained on how to use the app, and they will be asked to interact with MASI intervention participants through the forum feature. Their role will be to post icebreakers, respond or react to participant posts, share their own personal experiences to relate to participants, and help generate ideas for new content.

XSL•FO
RenderX

MASI Content Library

The MASI Content Library is a compilation of the materials shared on the MASI app via the administrative portal, including multimedia resources and activities, "Ask the Expert" questions and responses, and forum posts. It also includes materials to support this content, such as a catalog of images and GIFs to be used in forum posts, articles, and activities.

Content is developed and curated from multiple sources, including the HMP Content Library and web-based resources designed for South African adolescents and young adults (eg, Amaze animated videos on sexual health topics adapted by Marie Stopes International for use in South Africa [37]). All content is adapted and reviewed by the South African research team to ensure cultural relevance, age appropriateness, and accuracy of listed local resources (eg, where to access pre-exposure prophylaxis locally).

The initial content available on the app at the start of the pilot RCT covers a wide variety of topics related to HIV, general health, safe sex, and lifestyle. Additional content will be generated and added to the app in response to participant interests, input from peer mentors, and emerging topics in the news. Topics for additional content will be identified by reviewing Forum posts and Ask the Expert questions for topics of interest, examining the app-generated paradata for content searches by users, and asking participants for feedback during data collection. This process was modeled during our beta testing phase, during which resources related to sexual and gender diversity were developed and added to MASI in response to a participant's searches for resources and a question to experts about same-gender-loving relationships.

MASI Admin Portal

The MASI administrative (admin) portal is a web platform that allows study administrators to manage the content on the MASI app, manage participant access to the app, and review paradata generated by participants' app use. All content that is live on the app is housed in the admin portal, which allows for links across features and content (eg, links within an article to additional resources or related activities). When a participant asks a question to the expert on the app, the response can be drafted and posted within the admin portal to appear on the app, and this study's team can add a forum post alerting participants of a new question. The admin portal allows for scheduling of posts so that content can be developed in advance and released at ideal times. This study's team can also manage notifications that participants receive in-app or via SMS text messaging, which includes notifications about new articles, responses to participant forum posts or messages, or encouragement to log in if users have been away from the app for a few days.

The data analytics feature of the admin portal allows this study's team to run ad hoc queries examining the paradata for quick feedback on app use [34,38]. User data will help inform the development of new content tailored to user's interests or preferences by identifying gaps in content or topics and activity types with a high level of user engagement.

Methods

Study Design

This study is a pilot RCT that will enroll 50 adolescents and young adults with HIV. Participants will be stratified by self-reported sex assigned at birth and randomized 1:1 (n=25 per arm) into 2 parallel arms: the intervention arm receiving a full version of MASI or the control arm receiving an information-only version of the app. Participants will be asked to engage with MASI daily for 6 months.

Study Setting

This study takes place in Cape Town, South Africa. In South Africa, HIV prevalence is significantly higher among Black Africans compared to other racial groups. These racial disparities are rooted in structural and contextual inequalities, including the legacy of apartheid policies that produced economic and health advances for those classified as White [39].

Participants will be recruited from public ART clinics linked to a large tertiary government-funded teaching hospital in Cape Town. As a tertiary hospital, it offers a standard of care to all patients, who are admitted to the facility through referrals from primary and secondary health care facilities. In addition, it offers specialized pediatric and adolescent ART services with a qualified and experienced team of clinicians such as psychiatrists, psychologists, nurses, and HIV lay counselors.

Participants

Participants will be eligible for this study if they meet the following eligibility criteria: (1) they are aged ≥15 years and ≤21 years, (2) they know their HIV status (screened participants who do not know their HIV status will receive information on free voluntary HIV counseling and testing services), (3) they are living with HIV, (4) they have been prescribed medication to treat HIV, (5) they are not attending school for learners with special needs (eg, School of Skills) and have not repeated a grade in school more than once (this is to increase the likelihood that adolescents have the decisional capacity to provide informed consent to participate in this study and to reduce the risk of the research activities causing confusion among participants with diminished capacity or cognitive impairment), (6) they have a smartphone that can download apps, (7) they feel comfortable using an app with content in English, (8) they have no plan to move outside of Cape Town in the next 6 months, (9) they have not previously participated in the MASI beta testing phase of our study, and (10) they are able to successfully install the MASI app on their smartphone.

Procedures

Recruitment and Screening

Participants will be recruited at ART clinics in Cape Town, South Africa. Peer mentors will work with clinic nurses to identify potential participants in clinic waiting rooms to share details about this study, assess their interest in learning more, and collect their contact info for screening. We will also recruit participants from other research studies who have provided consent to be contacted for future research.

XSL•FO
RenderX

Potential participants will be screened by phone after providing verbal consent to see if they meet the eligibility criteria for this study. Participants who meet these criteria will be invited for an in-person appointment. After completing the informed consent or assent process (including consent from an adult caregiver for participants between 15 and 17 years of age), this study's team will confirm that the participant is able to successfully install the MASI app on their smartphone. Screening data will be entered electronically by the interviewer using Research Electronic Data Capture (REDCap), a secure, web-based application hosted at Duke University [40]. REDCap will also be used to track the status of potential participants, including documenting reasons for declining participation and ineligibility.

Baseline Data Collection

Eligible participants will complete a baseline assessment, an interviewer-administered survey with data entered electronically by the interviewer using REDCap. REDCap provides an intuitive interface for validated data entry, audit trails for tracking data manipulation and exporting, and automated export procedures for data downloads to common statistical packages. For survey questions with a higher potential for social desirability bias (eg, sexual behavior and study feedback), participants will be offered the opportunity to self-enter data into REDCap. The assessment items will be displayed on the screen in both English and Xhosa, the most commonly spoken home language among our study participants [33], and assessments will be conducted by bilingual interviewers.

Randomization

After completing the baseline assessment questions, participants will be randomized at a 1:1 ratio to the intervention condition (full MASI app) or control condition (information-only version of MASI). In total, 25 participants will be assigned to each condition and participants will be stratified by self-reported sex at birth. Randomization will be revealed by this study's interviewer using the REDCap Randomization Module, which uses a computer-generated allocation sequence created in Excel and uploaded to the module prior to the start of the trial. This study's interviewers will be unaware of this study condition prior to allocation. Participants will not be blinded to their allocation, as all participants will become aware of the full MASI features during the informed consent process.

Experimental Conditions

Intervention

Participants randomized to the intervention condition will receive access to the full MASI app, including all its features (ie, Health Tracker, Forum, Ask the Expert, Activities, and Resources). Through the Forum feature, participants will be able to interact anonymously with the other intervention participants, along with peer mentors and study staff.

This intervention is intended to supplement existing clinical care, so it will not impact access to routine medical care.

Control

Participants randomized to the control condition will receive access to an information-only version of MASI. Control participants will have access only to the Resources feature (Figure 8). An information-only version of MASI was chosen as the comparator given recommendations from the local study team, the need to download MASI to confirm the final eligibility requirement of this study, and the benefit of equalizing contact with participants to check-in on app access and provide smartphone data.

Figure 8. Home screen for users in the information-only control group.

XSL•FO
RenderX

Onboarding

Once participants have been allocated to their condition, a research assistant will help them set up their profile and username. Participants will be advised to pick a username that does not include their real name, email address, or other social media account names. The research assistant will then walk the participant through the MASI features and demonstrate how to navigate the app and how to contact this study's staff if needed. Participants will be asked to log into the app daily and will be given 1 GB of smartphone data each month to support their app use.

Follow-Up Assessments

Participants will complete assessments at 3 and 6 months after enrollment; follow-up assessments will aim to be scheduled as close to the 3 or 6 month date as possible but may occur within 4 weeks before or after the target dates to accommodate participant scheduling (eg, holidays and school breaks). Follow-up assessments will be administered in the same way as the baseline assessment, using REDCap data collection software. Assessments will include a few open-ended questions to give participants the opportunity to share feedback on things they liked about MASI, note any challenges experienced, or explain periods of lost access to the app (eg, lost phone and forgot password). In the event that it is not possible to conduct in-person data collection, follow-up assessments prioritizing main study outcomes may be conducted by phone.

Participant Tracking and Retention

Research staff will inquire about preferred and acceptable methods of communication, including alternative contacts if participants cannot be reached on a primary phone number. Participants will be contacted each month to send a 1-GB data top-up to support their app use. At this time, study staff will confirm if the participant still has access to their phone and the MASI app and will document any shared reasons for app nonuse. Study staff will also help troubleshoot any app-related technical challenges encountered.

To promote participant retention, research staff will emphasize the importance of attending all assessment appointments. Ahead of the 3- and 6-month study visits, research staff will arrange for a registered transportation company to collect participants (and accompanying adults, if aged 18 years or younger) in their area of residence and bring them to the research site for assessments. We will reschedule appointments as needed and will follow-up with participants who miss appointments.

Reimbursement

Participants will receive R250 (approximately US $14.50) at each visit. Participants (and their adult caregivers, if applicable) will also be given refreshments, including a snack and a drink.

App Access After Conclusion of Study

Participants will consent to 6 months of app access. After 6 months, the app will display a message informing the participant that they have completed this study and no longer have access to the app. The message will thank participants for their participation and encourage them to share any additional feedback by contacting our study team. Content generated by participants (eg, forum posts and Ask the Expert questions), will still be visible to other users on the app after their access ends. The decision to end access to the app was made due to our ethical obligations to monitor and be responsive to content from active users and the nature of on-going data generated from app use.

Outcomes

Primary outcome measures include intervention feasibility measures recorded by app backend paradata (the number of days participants log into the app, the total time participants spend using the app, and the number of days participants log medications using the app) and intervention acceptability (mean composite score from the adapted System Usability Scale [41,42]) at 3- and 6-month follow-ups.

Secondary outcome measures include adherence to ART (30-day recall of missed doses) and perceived social support using the adapted Medical Outcomes Study Social Support Survey scale [43,44] at 3- and 6-month follow-up.

All other measures are exploratory and include HIV/AIDS knowledge and stigma. HIV/AIDS knowledge will be measured using a scale adapted from a United States Agency for International Development toolkit for transition of care for adolescents with HIV [45] and a scale measuring HIV treatment knowledge in context of treatment as prevention [46]. Stigma will also be measured with the Adolescents Living with HIV Stigma Scale, which includes internalized stigma (5 items), anticipated stigma (2 items), and enacted HIV stigma (3 items) [44,47,48]. We will also measure various psychological and behavioral covariates as well as demographic characteristics. HIV disclosure and disclosure intentions will be measured using items previously used with adolescents living with HIV [49]. Disclosure concerns will be measured using 2 items from the HIV Stigma Scale for children [50]. Anxiety will be measured with the General Anxiety Disorder scale [51]. Depression will be measured with the Patient Health Questionnaire-9 [51]. Social isolation will be measured using the National Institutes of Health Toolbox Loneliness Scale (for ages 8-17 years) [49]. Resilience will be measured using the Connor-Davidson Resilience Scale 10 [52]. Demographic information collected will include age, sex assigned at birth and current gender identity [53], population group, and home language. Participants will also self-report if they were born with HIV.

Primary and secondary outcomes are described in Textbox 1 along with potential covariates and proxy outcomes of interest. To the extent possible, outcome measures were selected based on their prior use with adolescents and young adults with HIV in South Africa. Measures without existing Xhosa translations were translated from English into Xhosa and then back-translated, with team discussion to determine the best translation for items. Items will be displayed on the REDCap data collection screen in both English and Xhosa.

XSL•FO
RenderX

Textbox 1. Pilot randomized controlled trial primary and secondary outcomes.

Primary outcomes

- Intervention feasibility:
  - Number of days participants log in to the app as recorded by app backend paradata (3 and 6 months).
  - Total time participants spend using the app (minutes), as recorded by app backend paradata (3 and 6 months).
  - Number of days participants log medications using the app as recorded by app backend paradata (3 and 6 months).
- Intervention acceptability:
  - Average score of an adapted version of the system usability scale [41,42]. Total possible range: 0-100. Higher score indicates higher usability and helpfulness (better outcome). Average System Usability Scale score >68 (average for digital health apps [54]) will be considered acceptable (3 and 6 months).

Secondary outcomes

- Adherence to antiretroviral therapy:
  - Self-reported number of missed antiretroviral therapy doses in the past 30 days (3 months and 6 months).
- Perceived social support:
  - Adapted version of the Medical Outcomes Study Social Support Survey [43,44], which measures 4 domains of social support: emotional or informational support, tangible support, affectionate support, and positive social interaction. Total possible range: 12-48. Higher score indicates higher social support (better outcome; 3 months and 6 months).

Statistical Analysis

This study will enroll 50 adolescents and young adults with HIV into this study (25 males and 25 females based on self-reported sex assigned at birth). This study's sample size (N=50) was selected to be large enough to reasonably evaluate the feasibility and acceptability of MASI while balancing budgetary constraints [55].

Descriptive summaries will be computed for all study outcomes with continuous variables summarized with means and SD (or medians with IQR in the case of skewed distribution) and categorical variables summarized with counts and proportions. Outcomes will be summarized, stratified by treatment group, at each available study time point.

As a pilot study with a primary focus on feasibility and acceptability, the examination of MASI's preliminary efficacy will be exploratory. To explore MASI's preliminary efficacy on ART adherence and social support at 3 and 6 months, we will use linear mixed models to compare outcomes among participants randomized to MASI compared versus the information-only control at each time point. Log transformed outcomes and alternative modeling approaches such as Poisson and negative binomial will be considered in the event that assumptions for the linear model are violated. All models will include a fixed effect for sex assigned at birth (stratification variable) and a random intercept term to account for correlation in the response due to repeated measures within study participants over time. A random slope for participant will also be considered, as will the covariance structure of the errors (eg, exchangeable and autoregressive). Distribution of residuals will be examined to confirm that modeling assumptions are met. Because sample size is small (this study is not powered to detect clinically meaningful effect sizes) and the regression analyses are exploratory in nature, inference will focus on the size and direction of the total treatment effects rather than statistical significance.

Additional exploratory analyses will examine MASI's effects over time on HIV/AIDS knowledge and stigma using methods similar to those used for adherence and social support outcomes. We will also conduct descriptive analyses examining trends and patterns in user engagement with various components of the MASI interface over time.

Monitoring

This study's procedures have been determined to be low-risk, and we do not anticipate any adverse events as a result of study participation. While a data monitoring committee is not needed for this study, the research team will meet regularly to report on study progress and monitor compliance to this study and ethics protocols.

Our team has developed a set of standard operating procedures (SOP) for various scenarios that includes instructions for following up in response to concerns about participant distress, child abuse, sexual assault, underage sex, violence toward others, and suicidal ideation. Study staff are trained to identify situations of concern, including monitoring posts on the MASI app and participant comments or behavior during in-person study activities. Our data collection surveys include 2 items that assess for suicidal ideation [48,56] (ie, endorsement of "thoughts that you would be better off dead or of hurting yourself in some way" and feelings that one "would rather die than live with HIV"). If either item is endorsed, a message will be displayed to the interviewer at the end of the assessment to remind them to initiate the SOP. The SOP includes appropriate follow-up steps and procedures for situations where reporting to outside

XSL•FO
RenderX

authorities is required by South African law (eg, mandatory reporting of child abuse).

Ethics Approval

This study has been approved by the ethical review boards at the University of Cape Town (Ref 600/2020) and Duke University Health System (Pro00103309). The ethical review boards will meet annually to review the trial progress and conduct throughout the trial period. The trial is registered at ClinicalTrials.gov (NCT04661878).

Results

Study screening via phone calls began in May 2022 and the first participant was enrolled on June 21, 2022. As of June 12, 2023, 81 participants had completed screeners, and 56 participants were considered preliminarily eligible for this study. Of these, 38 attended an in-person visit to confirm eligibility (including successful installation of the MASI app) and complete the baseline survey.

In total, 36 participants have been enrolled, have completed baseline, and have been randomized to a study arm. Further, 25 participants have completed a 3-month follow-up survey (100% retention rate to date), and 15 participants have completed a 6-month follow-up survey (79% retention rate to date).

Recruitment is anticipated to last through August 31, 2023, to reach the target enrollment of 50 participants, with study activities anticipated through February 29, 2024, and results available in 2024.

Discussion

Principal Findings

There is an urgent need for innovative interventions to improve ART adherence among adolescents and young adults in settings like South Africa. Digital health interventions are a promising approach allowing for adaptation and customization to unique needs and interests, widespread reach and scalability, and discreet use. They also allow for the integration of multiple strategies to elicit behavior change, promote connection, and support well-being. As access to technology and device ownership becomes more widespread, particularly in low- and middle-income countries, a “new type of digital divide” is emerging, characterized by inequities in access to high-quality web-based opportunities and experiences [57]; in this setting, it is argued that the “most vulnerable youths” also have the most to gain from technological interventions, yet are often the least supported by digital interventions. MASI seeks to address this gap by creating a platform tailored to the needs of adolescents and young adults in Cape Town, South Africa.

MASI is a comprehensive adherence-promoting app adapted for the South African setting that capitalizes on opportunities presented by mobile health (mHealth) platforms. MASI includes multiple BCTs to address the various complex barriers to adherence experienced by adolescents and young adults. Other studies have found that interventions with more BCTs are more effective than those with a limited amount of BCTs [23,58]. The multiple BCTs are integrated into a variety of features within the MASI app that allows users to explore and use features that are most helpful and desirable to them. The collection and analysis of app-generated paradata, in combination with survey data, will allow our team to explore participants’ use of MASI across features and lend insight into what features or BCTs may be most effective or enjoyed by participants.

The comprehensiveness and customizability of MASI are possible because it is built using HMP, an existing platform originally built to support youths in the United States [26,28]. Building mHealth interventions on existing platforms has numerous benefits, including technological sophistication and increased potential for scalability. By building MASI using an existing platform, rather than developing a mobile app from scratch, we benefited from more rapid development, substantial cost savings, and achieved a more sophisticated technological product than we would have otherwise. The use of the HMP platform also allows for the lessons learned from this RCT to be more readily applied to other interventions using the HMP platform, or the potential adaptation of MASI to meet the needs of other populations. If found to be feasible and acceptable, MASI could be implemented with adolescents and young adults in other parts of South Africa.

Limitations

Our team acknowledges limitations in our study design related to a small sample size and therefore limited power to establish the efficacy of MASI. However, the sample size is appropriate for a pilot study focused on feasibility and acceptability as primary outcomes. The follow-up time for this pilot RCT is also limited to 6 months, which will not allow us to establish the feasibility or acceptability of a longer-term intervention.

Although smartphone ownership is widespread among South African youths, not all adolescents and young adults with HIV will be eligible for our study, as participants will be required to have a smartphone to be eligible. Restricting this study to adolescents and young adults who have a smartphone will impact the generalizability of the findings. We also recognize that excluding adolescents and young adults without smartphones may deepen existing inequities and leave out individuals with limited access to resources and social support. Furthermore, participants may lose access to their devices during the course of this study, which may impact study outcomes. Future research is needed to examine best practices for reducing technology-related barriers to participation in the research process.

ART adherence will be analyzed using a self-reported adherence outcome. Self-reported adherence measures may be impacted by social desirability bias, which could lead to measurement error for the adherence outcome. Data from this pilot RCT will be used to inform a fully powered future trial that will also include biomarker data such as viral load.

Finally, it is possible that participants randomized to the intervention arm may discuss or show MASI to participants randomized to the control condition. We do not expect such contamination to be frequent, but we will measure contamination to better understand the extent to which it occurs.

The authors would like to thank study team members Sofia Chodri, Jessica Keenan, Hope Neuling, Ali Saslafsky, Venkat Ravi, Monica Skoko Rodriguez, and Lauren Vaknin for their contributions. The authors are also grateful to all study participants for their participation in this study.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed during this study.

Authors' Contributions

MIM was the principal investigator for this study and conceived and designed this study with significant contributions from LBH-W, JH, KEM, and ETK. BM and MM were involved in the early implementation of this study, adaptation of the protocol to the local context, and continuing implementation of the protocol. THW and MA-M contributed to the implementation and refinement of this study's protocol. JRE and AP contributed to the statistical analysis plan. All authors critically reviewed each draft of the paper and approved the final version publication.

Conflicts of Interest

None declared.

Abstract

Background: Chronic musculoskeletal pain (CMSP) affects between 13% and 47% of the population, with a global growth rate of 20.3% within the last 15 years, suggesting that there is a high need for effective treatments. Pain diaries have long been a common tool in nonpharmacological pain treatment for monitoring and providing feedback on patients' symptoms in daily life. More recently, positive refocusing techniques have come to be used, promoting pain-free episodes and positive outcomes rather than focusing on managing the pain.

Objective: This study aims to evaluate the feasibility (ie, acceptability, intervention adherence, and fidelity) and initial signals of efficacy of the PerPAIN app, an ecological momentary intervention for patients with CMSP. The app comprises digitalized monitoring using the experience sampling method (ESM) and feedback. In addition, the patients receive 3 microinterventions targeted at refocusing of attention on positive events.

Methods: In a microrandomized trial, we will recruit 35 patients with CMSP who will be offered the app for 12 weeks. Participants will be prompted to fill out 4 ESM monitoring questionnaires a day assessing information on their current context and the proximal outcome variables: absence of pain, positive mood, and subjective activity. Participants will be randomized daily and weekly to receive no feedback, verbal feedback, or visual feedback on proximal outcomes assessed by the ESM. In addition, the app will encourage participants to complete 3 microinterventions based on positive psychology and cognitive behavioral therapy techniques. These microinterventions are prompts to report joyful moments and everyday successes or to plan pleasant activities. After

XSL•FO
RenderX

familiarizing themselves with each microintervention individually, participants will be randomized daily to receive 1 of the 3 exercises or none. We will assess whether the 2 feedback types and the 3 microinterventions increase proximal outcomes at the following time point. The microrandomized trial is part of the PerPAIN randomized controlled trial (German Clinical Trials Register DRKS00022792) investigating a personalized treatment approach to enhance treatment outcomes in CMSP.

Results: Approval was granted by the Ethics Committee II of the University of Heidelberg on August 4, 2020. Recruitment for the microrandomized trial began in May 2021 and is ongoing at the time of submission. By October 10, 2022, a total of 24 participants had been enrolled in the microrandomized trial.

Conclusions: This trial will provide evidence on the feasibility of the PerPAIN app and the initial signals of efficacy of the different intervention components. In the next step, the intervention would need to be further refined and investigated in a definitive trial. This ecological momentary intervention presents a potential method for offering low-level accessible treatment to a wide range of people, which could have substantial implications for public health by reducing disease burden of chronic pain in the population.

Introduction

Background

Musculoskeletal pain is defined as chronic if it exceeds a time frame of 3 months or recurs for >3 months [1]. Chronic musculoskeletal pain (CMSP) is estimated to affect between 13% and 47% of the population worldwide (eg, in the European Union [2], the United States [3], Canada [4], Australia [5], and low- to middle-income countries [6,7]). The global disease burden caused by CMSP has been increasing by 20.3% in the last 15 years [8]. Therefore, from a public health perspective, there is an urgent need for accessible and effective treatments. To determine the etiology and treatment of chronic pain, it is now widely suggested that a biopsychosocial model be followed [1,9,10]. CMSP is associated with a range of symptoms and disorders, mainly comorbid depression and anxiety [11-17], as well as low self-esteem [18-20], attention to and fear of pain [21,22], and avoidance behaviors [23-25]. Therefore, targeting psychological and behavioral aspects can be effective in treating chronic pain [26,27].

Diary methods including the experience sampling method (ESM) [28,29], where participants are prompted to answer several questionnaires per day during their daily life, have become common for monitoring psychological and somatic symptoms, yielding sufficient response compliance across health conditions and age groups [30]. Pain diaries, specifically paper or electronic versions, have proven high satisfaction, feasibility, and compliance for patients with CMSP, providing good psychometric properties [31-34]. However, using ESM pain diaries that remind participants to rate their level of pain once or several times per day [35] or provide personalized feedback [36] may hold restrictions, as this may promote attention to pain, that is, hypervigilance [37] or attentional bias [38-40], which in turn may even increase pain intensity [41]. This is why it has been suggested to focus on positive psychological processes [42] that may broaden attentional focus to positive aspects in life [43,44] and away from pain.

Similarly, positive interventions may be a strategy to promote a focus on resources and resilience [42,45,46]. Previous studies have shown that positive interventions that aim to increase awareness of positive aspects of life can improve pain intensity and catastrophizing, happiness, positive affect, depression, and anxiety [47-49]. In addition, targeting psychological aspects and comorbidities of chronic pain, cognitive behavioral therapy for low self-esteem has been shown to increase self-esteem, psychological functioning, and depression in populations with transdiagnostic psychiatric disorders [50,51]. Behavioral activation or activity scheduling aimed at increasing positive activities and experiences has shown a large meta-analytic effect in the treatment of depression [52] and first positive evidence in the treatment of chronic pain [53,54].

Following recent advances in digital technology, mobile health (mHealth) approaches such as ecological momentary interventions (EMIs) that deliver psychological treatment components in daily life [55,56] can be a promising way to provide early, low-level, accessible, and scalable treatment [57,58]. As EMIs are provided via mobile phone apps, they may help overcome barriers that can arise for interventions delivered in the clinical setting [28,55,59]. Several studies have shown that app-based approaches are feasible and can be effective in the treatment of chronic pain [60-62]. Furthermore, when patients with chronic pain are offered digitalized monitoring and feedback, they are willing to accept less frequent physician consultations [63].

Within the PerPAIN consortium investigating whether personalized allocation to psychological treatment approaches can enhance treatment effects in CMSP [64], we developed the PerPAIN app. The PerPAIN app targets positive refocusing of attention to positive events using digitalized monitoring, feedback, and microinterventions in daily life. Thus, the PerPAIN app is a complex intervention comprising several intervention components delivered at varying time points.

To evaluate behavioral interventions that comprise multiple intervention components, Collins et al [65] introduced a new

XSL•FO
RenderX

approach, that is, the multiphase optimization strategy (MOST) [65,66]. In addition to the preparation and evaluation phases of an intervention, MOST introduces an optimization phase in which individual intervention components can be evaluated separately according to predefined optimization criteria [65,66]. This information can then be used to optimize the intervention as a whole to proceed to the evaluation phase [65,66].

Objective

In this paper, we describe an optimization trial to evaluate the intervention components of the PerPAIN app in line with MOST [65,66]. Specifically, we designed a microrandomized trial, an experimental research design developed to evaluate and optimize mHealth interventions (for a comprehensive introduction, see Qian et al [67]). By repeatedly randomizing individuals to different forms of an intervention component (ie, within-person randomization), this research design allows the investigation of the immediate effects of intervention components on repeatedly measured proximal outcomes [68], as opposed to distal outcomes measured once at the end of treatment or follow-up. In this microrandomized trial, we aim to (1) establish the feasibility for conducting a microrandomized trial in patients with CMSP (based on acceptability, satisfaction, compliance, adherence, and fidelity of delivering the intervention) and (2) investigate initial signals of efficacy of the feedback component (ie, daily and weekly feedback presented as texts or graphs) and the exercises delivered in microinterventions (namely, the journal of joyful moments, the positive data log, and the activity planner) on the proximal outcomes.

To this end, we hypothesize that feasibility criteria for conducting a microrandomized trial evaluating the PerPAIN app in patients with CMSP will be met (hypothesis 1).

Second, we hypothesize that within participants, momentary absence of pain (candidate primary proximal outcome) after providing feedback (as text or graph) at the end of a training day on which participants reported at least medium (ie, ≥4) absence of pain, positive mood, or subjective activity will, on average across time, be higher compared with time points when no feedback was provided on such days (within-person control condition; hypothesis 2).

Third, we hypothesize that within participants, momentary (a) positive mood and (b) subjective activity (candidate secondary proximal outcomes) after providing feedback (as text or graph) at the end of a training day on which participants reported at least medium (ie, ≥4) absence of pain, positive mood, or subjective activity will, on average across time, be higher compared with time points when no feedback was provided on such days (within-person control condition; hypothesis 3a and 3b).

Finally, we hypothesize that within participants, momentary (a) absence of pain, (b) positive mood, and (c) subjective activity after delivering a microintervention (ie, journal of joyful moments, positive data log, or daily activity planner) at an individually predefined time point will, on average across time, be higher compared with comparable time points on days on which no microintervention was delivered (within-person control condition; hypothesis 4a, 4b, and 4c).

We will also explore differences between the 2 types of feedback presentation and 3 types of microinterventions in terms of efficacy and time trends across the 12-week intervention period. In this paper, we describe the PerPAIN app and its intervention components in detail as well as the microrandomized trial implemented to investigate the feasibility and initial signals of efficacy. For a description of the clinical trial that this microrandomized trial is embedded in, we refer to the protocol by Beiner et al [64].

Methods

Procedure, Study Design, and Randomization

A total of 35 patients with CMSP will be recruited to undergo the PerPAIN mobile training, an mHealth app targeted at refocusing of attention on positive events, comprising digitalized monitoring using the ESM, personalized feedback, and EMIs. During a one-on-one structured briefing session, the participants will receive the study app preinstalled on a study smartphone. A trained member of the study team will explain the basic functionalities of the device and app to the participant and answer any potential questions before the participant takes the device into their daily life. The app sends different types of prompts each day for 12 weeks, including monitoring questionnaires, feedback presentations, and microinterventions. Answering all prompts requires approximately 15 minutes per day. A trained member of the study team checks in with the participants up to 6 times to answer any potential questions. The app follows a microrandomized design to evaluate the intervention components (see Multimedia Appendix 1 for a visualization). The training follows a fixed schedule across 12 weeks and entails 4 types of randomization procedures, resulting in a total of t=143 decision points, that is, time points when automated randomization of an intervention component takes place in the backend of the app. First, every evening during the 12 weeks (84 decision points), participants will receive microrandomized daily feedback (text vs graph vs none). Second, at the end of each training week (12 decision points), the participants receive microrandomized weekly feedback (text vs graph vs none). Third, in the second half of the training, the exercises participants are prompted to do as microinterventions are randomized (journal of joyful moments vs positive data log vs daily activity planner vs none) every day for 6 weeks (42 decision points). Fourth, starting from week 8, the weekly activity planner is randomized (on vs off) each week for the remaining 5 weeks (5 decision points). The ESM monitoring questionnaires prompted 5 times per day to serve as proximal outcome assessments. This microrandomized trial is nested in and carried out as part of the PerPAIN trial (see the protocol by Beiner et al [64] for a detailed description of this study, adhering to the Standard Protocol Items: Recommendations for Interventional Trials 2013 checklist [69]).

Participants

For this microrandomized trial, we aim to recruit adult patients (aged ≥18 years) experiencing CMSP for >3 months as a symptom of nonspecific chronic back pain, osteoarthritis, fibromyalgia syndrome, or rheumatoid arthritis. Participants must be able to see and use a mobile phone (including visual

XSL•FO
RenderX

aids). Exclusion criteria include insufficient or unclear treatment of the underlying disease; severe visual impairment or inability to use a mobile phone; application for retirement or pension pending; ongoing psychotherapy; and severe physical, psychiatric, or neurological comorbidity (see the protocol by Beiner et al [64] for more details). Participants will be recruited primarily via an outpatient pain clinic.

PerPAIN App

Overview

The PerPAIN app is a stand-alone, app-based, self-help training with a total duration of 12 weeks, entailing 3 core components. First, it uses the ESM to monitor participants' momentary absence of pain, positive mood, subjective activity, and context several times a day in a positive pain diary (ie, monitoring). Second, the app provides personalized feedback to the participants on the basis of the monitoring data. Third, short exercises based on the principles of cognitive behavioral psychotherapy and positive psychology are provided, which are both taught and implemented within the daily life context (ie, microinterventions). Among these components, gamification elements are used to potentially increase compliance and user engagement.

Monitoring and Feedback

The ESM will be used to collect entries for a positive pain diary. The app will prompt participants to answer 4 monitoring questionnaires per day scheduled at semirandom time points within set blocks of time during their waking hours to record their momentary experiences and context. The ESM variables, that is, sleep quality, trust in the intervention, absence of pain, positive mood, and subjective activity, as well as appraisals of momentary and daily context, are rated on a 7-point scale. The monitoring questionnaire consists of 16 to 21 items (depending on the type of prompt and branching rules; see Multimedia Appendix 2 for a full list of items).

The PerPAIN app uses the monitoring data to provide feedback on the three main ESM monitoring and outcome variables: (1) absence of pain, (2) positive mood, and (3) subjective activity. We implemented three types of feedback: (1) immediate feedback presented directly after a monitoring questionnaire, (2) daily feedback presented after the last monitoring questionnaire of the day, and (3) weekly feedback presented after each week of monitoring. In accordance with our aim of refocusing of attention on positive events, immediate and daily feedback is only provided if it qualifies as *positive*. Therefore, immediate and daily feedback on each variable is only displayed if the (mean) score exceeds a predefined threshold of 4, that is, the center of the 7-point scale.

Immediate feedback is designed as a type of gamification. After the participant completes filling out the monitoring questionnaire, the conditions for providing positive feedback are checked. Whenever a variable is ≥4, meaning the participant is considered to be pain-free, in a good mood, or active, feedback is displayed at the end of the questionnaire, that is, the participant collects a pain-free, feel-good, or activity point, respectively (Multimedia Appendix 3).

Daily feedback is made available to the participant in a separate prompt after the last random monitoring questionnaire of the day. Before triggering a prompt for daily feedback, a server checks the conditions for providing positive feedback. Whenever the daily mean score of at least 1 of the 3 main ESM variables is ≥4, daily feedback is generated. If, at the same time, one of the other mean scores is <4, feedback for this variable is masked out. For example, if the mean scores of positive mood and subjective activity are both 5 and the mean score of absence of pain is 2, daily feedback is generated, but no value is presented for the absence of pain. Whenever daily feedback is available, a stratified randomization procedure is applied to determine the type of feedback presentation (1:1:1). Feedback is either presented as a bar chart or as a short text, or, in a control condition, no daily feedback is provided. Immediately after the feedback prompt, a monitoring questionnaire containing only the questions regarding the main ESM outcome variables is presented to assess proximal, that is, immediate effects of the daily feedback component.

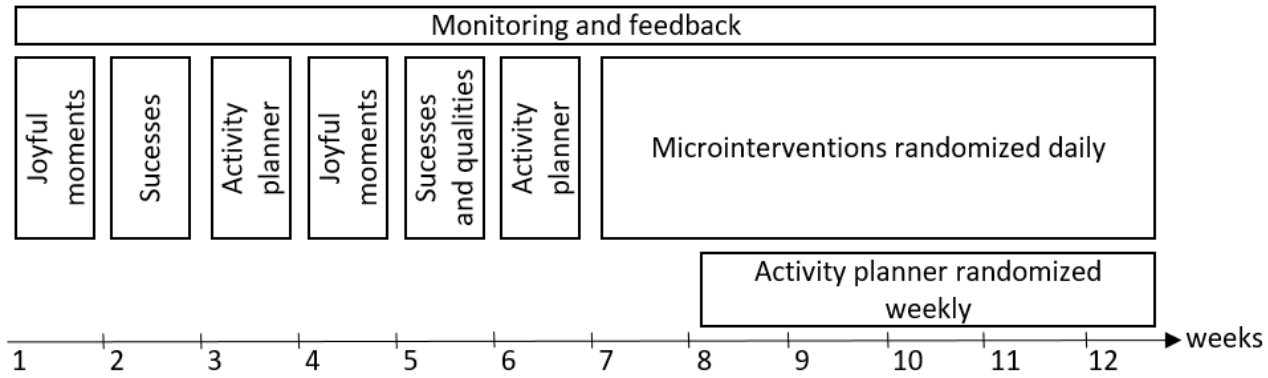
Weekly feedback is made available to the participant in a separate notification after each week of monitoring, that is, in the morning of every 7th day at the earliest possible time for the app to interact with the participant. Unlike daily feedback, weekly feedback is always provided without any restrictions concerning the mean scores of the variables, that is, values <4 are also displayed, as this matches most accurately a paper-pencil positive pain diary that was piloted before this study. Again, a stratified randomization procedure is applied to set the type of feedback presentation (1:1:1). Weekly feedback is either presented as a bar chart or a short text (Multimedia Appendix 3), or, in a control condition, no weekly feedback is provided. Immediately after the feedback prompt, a monitoring questionnaire containing only the questions regarding the main ESM outcome variables is presented to assess the proximal effects of the weekly feedback component.

Microinterventions

In addition to the monitoring and feedback components, the PerPAIN app incorporates the principles of EMI. Specifically, it entails 3 exercises implemented as microinterventions alternating across the 12-week training period (Figure 1). In the first half of the training, participants are prompted to complete 1 exercise presented as a microintervention per week. As previously used in an EMI targeted at ecological translation of principles of compassion-focused therapy to daily life [70], the app will offer enhancing, consolidating, and interactive microinterventions. Initially, each exercise is introduced to the participant in an introduction block at the beginning of a new week (ie, enhancing). Once familiar with the microintervention, the participants set the time they wish to be prompted to complete the exercise once a day in a separate notification (ie, consolidation). In addition, if indicated by the participants' answers on a monitoring questionnaire, an exercise is prompted interactively. In the second half of the training, starting from week 7, consolidating and interactive microinterventions alternate each day according to the randomization procedure described in the *Procedure*, *Study Design*, *and Randomization* section.

XSL•FO
RenderX

The journal of joyful moments is based on a positive intervention called the "3 good things" intervention [71]. In a continuously growing list structured like a diary, participants collect moments that were happy or joyful for them; things that made them smile; or, in general, made them feel good. The aim of this technique is to draw attention to positive things that happen in daily life, increase well-being, and decrease feelings of depression [71]. Participants can make a new entry ("Please note your joyful moment") once per day at the consolidation prompt, manually whenever they wish to make an entry, or during a monitoring prompt whenever they are likely to have experienced a joyful moment, according to their answers in a monitoring questionnaire. For this purpose, the following conditions were defined: (1) the participant indicates that they are in a good mood, that is, ≥4; (2) the participant indicates that their absence of pain is high, that is, ≥4; and (3) the participant indicates a high level of activity, that is, ≥4 (Multimedia Appendix 4). Once the enhancing exercise is completed, the participant can (in all following training weeks) make an entry in the journal and look at the growing list of joyful moments from the home screen of the app (Multimedia Appendix 5).



The positive data log is based on an intervention manual developed to increase self-esteem [72]. The aim of a positive data log is to help correct information-processing errors [73]. The microintervention consists of two parts: (1) collecting small successes during daily life and (2) inferring positive qualities of oneself from the list of successes. When this microintervention is first introduced in week 2, participants collect small or large successes they have experienced in their daily life in a diary. A success can be anything positive or successful the participant does, everything they do well, and anything that they made progress with or put effort into. The aim of this technique is to draw attention to one's own small or big successes in daily life to build self-efficacy and confidence instead of focusing on things that go wrong [72]. Participants can make a new entry ("Please note your success") (1) once per day at the consolidation prompt, (2) manually whenever they wish to make an entry, or (3) during a monitoring prompt whenever they are likely to have had a success according to their answers in a monitoring questionnaire or whenever they do not feel well and will likely benefit from redirecting their attention to something positive. For this purpose, the following conditions were defined: (1) the participant indicates that they have experienced a positive event, (2) the participant indicates that they are at work, school, or university to uncover work-, school-, or university-related successes, and (3) the participant indicates that they are in a bad mood or in pain (Multimedia Appendix 4).

In week 5 of the training, when this microintervention is repeated (Figure 1), the section on positive qualities is added to the positive data log. After collecting several successes in their daily life, that is, observable behavior, participants are guided to infer positive qualities that underlie those successful behaviors by answering the question "What qualities does a person have that shows these behaviors?" Thus, participants start a second list with their own positive qualities. Each time the participant makes an entry into their positive data log, they are invited to add a positive quality. Once the enhancing of each part of the exercise is completed, the participant can (in all following training weeks) make an entry to the positive data log and look at the growing list of successes and positive qualities from the home screen of the app (Multimedia Appendix 5).

The activity planner is based on a manual for behavioral activation [74], a behavioral therapy technique used in the treatment of depression [75] and chronic pain [76]. In behavioral activation, pleasant activities are systematically increased to change corresponding cognitions. In an introductory block, the participant is educated about the interdependence between pleasant activities and positive thoughts and feelings (Multimedia Appendix 5). The participant then creates their own activity plan for the week in a guided process. From a list of activities from different life domains, that is, sociability, hobbies and free time activities, sports and physical activities, culture and education, nature and gardening, and self-care and delight, the participant is invited to choose 3 activities or insert activities they would like to do in the following week. After choosing each activity, the participant is instructed to define the number of times they would like to do the activity. This step is based on the idea that progress toward specific goals can be monitored easily and can therefore be more motivating [74]. During the activity week, the participant can monitor their progress with their planned activities. Each morning, the participant receives a notification reminding them of their planned activities. Optionally, they can plan an additional activity for the upcoming day only (ie, daily activity planner). Participants can make a new entry ("Please tick off all activities you have done today") once per day at the consolidation prompt or manually by entering the activity planner from the home screen of the app. On the last consolidation prompt of the activity week, the planned and actual frequencies of each activity are presented to the participant, and they can indicate whether they have achieved, exceeded, or not accomplished their goal. The achievement or exceedance of goals is rewarded using the gamification elements described in the *Gamification* section.

XSL•FO
RenderX

Figure 1. Timeline of the PerPAIN training intervention components.

Gamification

Gamification is a concept that integrates game elements into nongame contexts. It builds on the engaging and motivating potential of games [77]. In mHealth, gamification elements can be used to increase compliance and shape and reward desired behaviors [78]. After downloading an mHealth app, user engagement can vary greatly (eg, see the study by Rahman et al [79]), which is why it is a common objective of researchers to design apps to optimally support engagement [80]. In the PerPAIN app, we implemented three gamification elements aimed at increasing compliance and providing rewards: (1) an overall training score, (2) immediate feedback designed as points, and (3) a progress bar. The overall training score increases whenever the participant answers a prompt or makes an entry (Multimedia Appendix 3). Hence, this gamification element is aimed at increasing users' overall engagement with the app. In the overall introduction to the app as well as the enhancing blocks introducing the microinterventions, the participant is informed which actions lead to an increase in the training score (eg, answering a monitoring prompt, making an entry in the journal of joyful moments, or achieving an activity goal). After a monitoring prompt, the participant can receive 3 types of points (ie, pain-free, feel-good, and activity points), whenever the values of the 3 scales were ≥4. These points are collected throughout the training and mainly serve as positive feedback but may also reinforce behaviors that lead to reporting higher values of absence of pain, positive mood, or subjective activity in the monitoring questionnaire. The overall user advancement is presented to the participant on a summary page that includes a progress bar displaying progression throughout the training using an icon of a person walking on a path of 12 tiles representing the 12 training weeks. This gamification element aims to increase the transparency and completion rates of the training.

Measures

We will assess the feasibility of delivering the smartphone training and the effects of intervention components.

Feasibility Measures

In line with previous research on the feasibility of delivering EMIs [70,81,82], feasibility measures will include acceptability, intervention adherence, and fidelity. Acceptability will be assessed in a debriefing questionnaire rating satisfaction with the intervention, ease of use, accessibility, and comprehensiveness [70,81,82]. In addition, we will use the user version of the mobile app rating scale [83] to assess the subjective quality of the app. Adherence to the mobile training will be operationalized by the completion rates of the intervention components (ie, mean number of monitoring questionnaires, consolidating or interactive tasks completed/wk, and [mean] number of feedback prompts answered). As a core feature of the PerPAIN training is the delivery of intervention components in daily life, that is, in varying contexts, aiming to support a positive attention focus while reducing transfer effects, we will measure fidelity by the variety of contexts in which participants engage with the app and the proportion of participants who still use the app at the end of the 12-week training period. To establish levels of feasibility, we will classify our feasibility outcomes using a traffic light system into 3 categories, that is, green=feasibility fully established, yellow=feasibility established with a need for modification of the study procedures, and red=feasibility not established [70] (Table 1).

XSL•FO
RenderX

Table 1. Feasibility criteria of delivering the PerPAIN training.

Category	Acceptability	Adherence	Fidelity
Red (feasibility not established)	Low satisfaction in the debriefing questionnaire (ie, mean satisfaction rating of ≤3 on a 7-point scale) and the uMARS[a] (ie, mean subjective quality rating of ≤2 on a 5-point scale)	Poor compliance to the monitoring and feedback component (≥60% of the participants answering on average <50% of the questionnaires/d and ≥60% of the participants viewing their provided feedback on average less than once/wk) and EMI[b] tasks (ie, mean number of consolidating or interactive EMI tasks completed/wk is <0.8)	Poor use of the app overall (≥60% of the participants using the app for <3 wk) and poor variability of intervention contexts (≥60% of the participants using the app in 1 context exclusively, as measured by the "current activity" item)
Yellow (feasibility established but study procedures need modifying)	Fair satisfaction in the debriefing questionnaire (ie, mean satisfaction rating of >3 on a 7-point scale) and the uMARS (ie, mean subjective quality rating of >2 on a 5-point scale)	Fair compliance to the monitoring and feedback component (≥60% of the participants answering on average at least 50% of the questionnaires and ≥60% of the participants viewing their provided feedback on average at least once/wk) and EMI tasks (ie, mean number of consolidating or interactive EMI tasks completed/wk is ≥0.8)	Fair use of the app overall (≥60% of the participants using the app for ≥3 wk) and fair variability of intervention contexts (≥60% of the participants using the app in at least 2 contexts, as measured by the "current activity" item)
Green (feasibility fully established)	Moderate to high satisfaction in the debriefing questionnaire (ie, mean satisfaction rating of >4 on a 7-point scale) and the uMARS (ie, mean subjective quality rating of >3 on a 5-point scale)	Moderate to strong compliance to the monitoring and feedback component (≥80% of the participants answering at least 50% of the questionnaires and ≥80% of the participants viewing their provided feedback on average at least once/wk) and EMI tasks (ie, mean number of consolidating or interactive EMI tasks completed/wk ≥1)	Moderate to high use of the app overall (≥80% of the participants using the app for ≥ 6 wk) and moderate to high variability of intervention contexts (≥80% of the participants using the app in at least 2 contexts, as measured by the "current activity" item)

[a]uMARS: user version of the mobile application rating scale.

[b]EMI: ecological momentary intervention.

Candidate Primary Outcome

The candidate primary outcome of the microrandomized trial is the proximal measure of the absence of pain assessed in the monitoring questionnaires. Specifically, we will investigate the immediate effect of the daily feedback component on the absence of pain rating measured on a 7-point scale in the monitoring questionnaire presented either directly after daily feedback was displayed or in a separate prompt without feedback being displayed (control condition), depending on the microrandomization (Multimedia Appendix 1).

Candidate Secondary Outcomes

The 2 candidate secondary outcomes of the microrandomized trial are the proximal measures of positive mood and subjective activity assessed on a 7-point scale in the monitoring questionnaires. As for the candidate primary outcome, we will use the ratings given in the monitoring questionnaire presented either directly after daily feedback was displayed or in a separate prompt without feedback being displayed (control condition), depending on the microrandomization.

Time-Fixed Covariates

In line with the PerPAIN study [64], we will use the treatment condition (personalized vs nonpersonalized treatment allocation), gender, and baseline pain severity (as measured by the German version of the Multidimensional Pain Inventory [84]) as covariates in all models.

Sample Size

This microrandomized trial forms part of the PerPAIN randomized controlled trial [64]. Given that we expect to include 35 participants in this microrandomized trial, we performed power analysis for microrandomized trials [85] to determine the effect sizes we will be able to detect in the given study setup with sufficient power of at least 80% testing at α=.05 (for a description of the tool, see Seewald et al [86]).

Regarding the daily feedback component with 1 decision time point for a total of 84 days, we will be able to detect an average proximal treatment effect of 0.16 with a power of 80.4% and a sample size of 35, assuming that at least 1 ESM variable is >4 (therefore, available for feedback) on every second day of the study (ie, availability parameter of 0.5). Regarding the microinterventions with 1 decision time point for a total of 42 days, we will be able to detect an average proximal treatment effect of 0.18 with a power of 80.8%, a sample size of 35, and an availability parameter of 1, as microinterventions will be prompted every day without any restrictions. Intervention components randomized weekly (weekly feedback and weekly activity planner) do not produce sufficient power to be tested for proximal treatment effects in this study.

Assessment of Safety in the Microrandomized Trial

Throughout participation in this microrandomized trial, we will monitor any serious adverse events, such as serious incidents resulting in death or hospitalization, and adverse events (see the protocol by Beiner et al [64] for more details). Furthermore, we will record any potential adverse device effects and technical problems reported by participants, such as crashing of the app or bugs. Whenever possible, we will fix technical problems immediately and introduce a new version of the app for future participants using the app.

Statistical Analysis

To address hypothesis 1, we will use descriptive statistics and 95% CIs as appropriate to evaluate the feasibility of delivering

XSL•FO
RenderX

the PerPAIN training in line with the predefined feasibility criteria described in Table 1.

To test initial signals of efficacy on candidate primary and secondary proximal outcomes, we will use the weighted and centered least squares estimator to estimate the causal excursion effect of the daily feedback component [87,88]. To investigate whether there is an overall effect (ie, on average across time) of daily feedback on our candidate primary proximal outcome momentary absence of pain (hypothesis 2), we will calculate the weighted and centered least squares estimator by specifying a generalized estimation equation with absence of pain in the subsequent monitoring questionnaire as the proximal outcome, with a treatment indicator specifying whether daily feedback was delivered (=1) or not (=0), including 84 decision points, that is, once every day for 12 weeks. As feedback is only delivered whenever the daily average of one of the main outcome variables was >4, we will create a new variable *good_day* (1=at least 1 outcome is >4 and 0=no outcome is >4) serving as an availability indicator in the equation. The analysis will be controlled for time-fixed covariates. To address hypotheses 3a and 3b, we will repeat this procedure using our candidate secondary proximal outcomes: (a) momentary positive mood and (b) momentary subjective activity at the subsequent monitoring questionnaire as the proximal outcome. In the next step, to explore the effect of different feedback types individually (ie, as text or graph), we will include 1 treatment indicator for each type of feedback. Furthermore, we will explore whether there is a time trend in the effects of daily feedback by including a variable *training_day* counting the days in the study (with the value 0 on the first day).

To investigate the immediate effects of the microinterventions, we will use momentary absence of pain, positive mood, and subjective activity rated on a 7-point scale in the next monitoring questionnaire prompted after the predefined consolidation time, unless the consolidation prompt was the last prompt of the day, to avoid overnight effects. To determine whether there is an overall effect, that is, on average across time, of the microinterventions (hypotheses 4a, 4b, and 4c), we will specify 3 generalized estimation equations with a treatment indicator specifying whether a microintervention was delivered at the individually predefined consolidation time on that day (=1) or not (=0), that is, control condition, using each outcome: (a) momentary absence of pain, (b) momentary positive mood, and (c) momentary subjective activity at the subsequent prompt as a proximal outcome, including 42 treatment occasions, that is, once every day between week 7 and 12. There will be no availability indicator, and time-fixed covariates will be included. We will then include 1 treatment indicator for each type of intervention to investigate the effects of the 3 microinterventions individually (ie, journal of joyful moments, positive data log, and daily activity planner) and explore the time trend in the effects of the microinterventions by including the *training_day* indicator. Data analysts will be blinded to the treatment indicators.

Results

The Ethics Committee II of the University of Heidelberg approved this study (2020-579N) on August 4, 2020. At the time of submission of this protocol (October 10, 2022), we are working with trial protocol version 6 (October 6, 2021). The outcome assessments are ongoing. The first enrollment in this microrandomized trial was conducted in November 2021. As of October 10, 2022 (the date of submission), 24 participants were enrolled in the microrandomized trial, and 13 participants completed the training. Data will not be accessed for interim analysis before the completion of all outcome assessments. The last assessment for the last participant is scheduled for July 2023, and we expect the results to be published in early 2024.

Discussion

Extending the widely used method of symptom monitoring using pain diaries, we will investigate the feasibility and initial signals of efficacy of a newly developed self-help app targeted at refocusing of attention to positive events with different intervention components based on principles of EMI. EMIs offer the great advantage of delivering intervention components in various contexts in daily life [28,55-59]. EMIs are frequently implemented as hybrid interventions [70,81,82] or stand-alone interventions, such as the PerPAIN app. Owing to the microrandomized design, we will be able to evaluate individual intervention components separately to optimize the intervention as a whole and proceed to the evaluation phase in line with MOST [65,66]. The results of this optimization trial will show whether delivering an app-based self-help training with different intervention components is feasible. Furthermore, we will investigate its acceptability, satisfaction, compliance, adherence, and fidelity in a population of patients with CMSP. The results of this trial promise first insights into the potential proximal effects of delivering daily feedback and prompting microinterventions to improve the absence of pain and increase positive mood and subjective activity. The results of this trial may suggest ways to optimize these intervention components. For instance, the results may point toward 1 type of feedback presentation (eg, as a graph) or microintervention (eg, activity planner) having greater initial effects than another. Alternatively, there may be initial evidence of a time trend across the 12 weeks of the training, which could inform the setup of future studies.

If this trial is successful, the next step will be to proceed to a confirmatory trial with a larger sample powered to detect the expected effect sizes established in this trial.

However, for the interpretation of the results of this study, it should be considered that the effect sizes that will be established may be diminished because of the design of the PerPAIN study this microrandomized trial is nested in. As a result of the randomization procedure to investigate a personalized treatment approach (see the protocol by Beiner et al [64]), 50% (17/35) of the participants in this microrandomized trial will be allocated to participate in the PerPAIN training according to a personalized treatment allocation procedure, whereas the other half will be allocated to the PerPAIN training against the personalization approach.

XSL•FO
RenderX

Positive psychological approaches seem to be promising for the treatment of CMSP [42,45-49]. Therefore, investigating how these approaches can be implemented using mHealth technologies is an important step in tackling the global disease burden caused by CMSP. Overall, EMIs using microinterventions offer a great opportunity to provide low-level treatment in the context of daily life, thereby overcoming barriers to interventions delivered in the clinical context [55-57,59]. After positive scientific evaluation, this type of treatment promises significant public health impact as it is scalable to a large population of patients with CMSP, which may ensure continuity of care and reduce on-site consultations [63].

Abstract

Background: Evidence indicates participation in a diabetes self-management education and support program improves self-care behaviors and hemoglobin A_{1c}. Language and cultural differences may be barriers to program participation resulting in ineffective self-management, but these factors can be addressed with appropriate interventions. Given the high health care costs associated with diabetes complications, we developed a multicomponent, culturally tailored Self-Management Mobile Health Intervention for US Vietnamese With Diabetes (SMart-D).

Objective: This study aims to evaluate the SMart-D intervention's feasibility, acceptability, and effectiveness with intentions to scale up the intervention in the future. This mixed methods study incorporates the Reach, Effectiveness, Adoption, Implementation, Maintenance framework to evaluate the intervention.

Methods: This stepped wedge randomized controlled pilot study will be conducted over 2 years in collaboration with primary care clinics. Eligible participants are patients with type 2 diabetes who are receiving health care from participating clinics. Clinics will be randomly assigned to an implementation date and will begin with patients enrolling in the control period while receiving standard care, then cross over to the intervention period where patients receive standard care plus the SMart-D intervention for over 12 weeks. Focus groups or interviews will be conducted with clinicians and patients after study completion. Qualitative data will be analyzed using NVivo. Outcomes on self-care behavior changes will be measured with the Summary of Diabetes Self-Care Activities scale and clinical changes will be measured using laboratory tests. A generalized linear mixed-effect model will be used to compute time effect, clustering effect, and the interaction of the control and intervention periods using SAS (version 9.4; SAS Institute).

Results: We hypothesize that (1) at least 50% (n=5) of eligible clinics and 50% (n=40) of eligible patients who are invited will participate, and at least 70% (n=56) of patients will complete the program, and (2) patients who receive the intervention will have improved self-care behaviors and clinical test results with at least 75% (n=60) of the patients maintaining improved outcomes at follow-up visits compared with baseline, and participants will verbalize that the intervention is feasible and acceptable. As of August 2023, we enrolled 10 clinics and 60 patients. Baseline data results will be available by the end of 2023 and outcome data will be published in 2025.

Conclusions: This is the first Vietnamese diabetes self-management education and support intervention that leverages mobile health technology to address the barriers of language and culture differences through collaboration with primary care clinics. This study will provide a better understanding of the implementation process, demonstrate the potential effectiveness of the intervention, accelerate the pace of moving evidence-based interventions to practice among the US Vietnamese population, and potentially provide a replicable implementation model that can be culturally adapted to other non-English speaking ethnic minorities.

Introduction

Diabetes is a leading cause of death in the US Vietnamese population [1]. The term US Vietnamese will be used hereafter to indicate Vietnamese individuals living in the United States. Members of racial and ethnic minority groups are at an increased risk for developing type 2 diabetes (T2D) and experiencing complications from this disease [2]. After being diagnosed with T2D, individuals face many physical, emotional, and social challenges including the need to know about the strict diet and medication regimen and necessary lifestyle changes [3].

Nutrition is often the focus of self-management among US Vietnamese with diabetes, and little focus is placed on medication, blood glucose monitoring, risk reduction behaviors, or personal strategies for health promotion [4-6]. Self-management and health behaviors are influenced by cultural beliefs, practices, and availability of resources [7]. Ineffective self-management can lead to complications and increased health care costs. Glycemic control can reduce the risks of diabetes complications, but few resources are available to educate and support self-management among US Vietnamese. Despite the capability of improving health behaviors with evidence-based interventions, efforts to adapt and disseminate linguistic and culturally appropriate diabetes self-management education and support (DSMES) are lacking among this group.

Nguyen and Edwards [6] reported that linguistic and cultural differences as well as transportation issues are the main barriers to participating in existing DSMES programs among study participants. Many US Vietnamese living with T2D receive information from family, friends, and others diagnosed with diabetes for knowledge and decision-making around self-care [6]. Without formal DSMES, knowledge gained from informal education may negatively influence self-care behaviors. Low diabetes literacy hindered effective disease self-management, which is a striking finding among the participants that was revealed in every interview [6]. A needs assessment survey identified the community's desire and need for formal diabetes education and support to be offered in the Vietnamese language in Oklahoma [8]. Studies showed that having limited English proficiency reduced the ability of study participants to obtain appropriate information to manage chronic conditions, such as heart disease and diabetes [9,10].

The 2022 National Standards for Diabetes Self-Management Education and Support [11] emphasized the need to provide services that embrace cultural differences, address social determinants of health, and use technological engagement platforms and systems. These National Standards cited strong evidence supporting DSMES delivery through digital, telehealth, telephone, SMS text messaging, and web-based or mobile phone app [11].

Nguyen et al [12] conducted a systematic review of intervention studies focused on improving health behaviors and health care services using mobile technology among the Vietnamese population and found the main device used was mobile phones. These devices were used for patient remote monitoring, assessment, or counseling for health behavior change through SMS text messaging, internet access, email, and videos. SMS text messaging was most frequently used as the primary intervention, which is consistent with many studies that have evaluated the usage of mobile health (mHealth) to support lifestyle and health behavior changes in other populations [13-16]. Using SMS text messaging to provide health education and monitor chronic diseases was feasible and acceptable mainly due to the low cost and easy operation of SMS text messaging [12]. However, the feasibility and acceptability of SMS text messaging to provide education and support among US Vietnamese patients is unknown and thus the aim of this study's protocol.

In response to the burden of diabetes and the need to afford an opportunity for US Vietnamese with T2D an intervention that meets the National Standards [11], this Self-Management Mobile Health Intervention for US Vietnamese With Diabetes (SMart-D) study protocol will provide linguistically and culturally relevant diabetes education, health behavior change support, and emotional support through secure mHealth technology to help patients understand the disease process and gain skills to manage their condition. This protocol aims to describe a pilot study to test the acceptability and feasibility of the SMart-D intervention, determine the effectiveness, and assess its sustainability using the Reach, Effectiveness, Adoption, Implementation, Maintenance (RE-AIM) framework to measure outcomes. Focus groups or individual interviews will be conducted at program completion to assess intervention acceptability and participant experiences as well as perceived barriers to sustaining the behavior change.

Methods

Study Design

This study is a stepped wedge randomized controlled pilot study to implement a multicomponent intervention among US Vietnamese with T2D. The stepped wedge design allows the practical staggering of intervention delivery while enabling all participants to receive it. The intervention, incorporating both synchronous and asynchronous components over 12 weeks, is based on the patient empowerment and Health Belief Model and intends to target the unique needs of Vietnamese-speaking patients. Participants will receive a print booklet covering

XSL•FO
RenderX

self-management strategies, daily mHealth SMS text messaging to promote self-care and enhance self-efficacy, and weekly nurse calls to coach and provide support for self-management goals. Offering these ongoing contacts will help to motivate participants to follow the care plan and engage in better self-management.

After the 12-week intervention, participants will opt to accept or decline a low dose of 1 monthly SMS text message and 1 monthly nurse call alternating biweekly for the next 9 months. This study will evaluate pre- and postintervention measures at 3, 6, 9, and 12 months from baseline. This framework will allow a comparison of outcomes between the standard care and intervention period as well as between baseline and follow-up data. To ensure the high quality of this pilot, this study will follow the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 checklist [17,18].

Intervention Components

The intervention has 3 components: print materials, mHealth SMS text messages, and nurse coaching telephone calls. Print education materials and follow-up telephone calls have been shown to be incrementally effective on their own [19-23]. Combining these components along with mHealth SMS text messaging may achieve a more significant effect. All 3 intervention components were assessed for usage and usability by piloting the components with 2 nurses and 4 Vietnamese individuals with T2D. Modifications to the intervention components were made based on the participants' feedback.

All participants will receive a copy of printed materials entitled Small Change, Big Impact for People with Diabetes, which covers 8 chapters focusing on patient-centered strategies and incorporating cultural foods and practices. The content focuses on the day-to-day activities of living with diabetes with respect for the US Vietnamese individual's life experiences helping participants (1) understand diabetes, (2) monitor blood glucose, (3) stay physically active, (4) cope with the diagnosis, (5) make healthy food choices, (6) understand Eastern and Western medications, (7) manage hypo- or hyperglycemia, and (8) prevent diabetes complications. The education content incorporates the Association of Diabetes Care and Education Specialists framework [24] and materials developed by the Centers for Disease Control and Prevention [25] diabetes resources and were adapted for cultural relevancy. All printed materials are available in Vietnamese and English language, side-by-side, to help participants learn the terminologies to communicate with their providers.

An mHealth SMS text message will be used to deliver educational content in the Vietnamese language via video, audio, and SMS text messages based on a schedule when specific criteria are met. The prerecorded videos are embedded in the SMS text messages and feature a registered dietician consulting with participants on developing a healthy eating plan that incorporates Vietnamese food and a pharmacist demonstrating insulin injection and self-monitoring of glucose. The secure mHealth platform will enhance both accurate, timely data collection across sites and ensure secure data transmission. During the 12-week intervention at least 1 message will be sent daily; up to 6 messages may be sent depending on the participants' responses. If a participant does not respond to messages for 7 consecutive days, the coach nurse will assess any technical issues during the routine weekly calls. After the 12-week intervention, messages will be sent at a lower dose once monthly for the remaining follow-up period to allow continuing engagement with participants as they desire.

Participants will have a telephone coaching call with a Vietnamese-speaking nurse once per week during the 12-week intervention period. The day and time of these phone calls will be arranged between the participant and the nurse. Every week, participants will be encouraged to set one or more goals related to the scheduled lesson. During these coaching calls, the nurse will follow a script and use a motivational interviewing approach [26,27] to review participants' goals and identify barriers, review status on self-management strategies, help participants build a capacity to problem solve, improve self-efficacy, and support health behavioral change. The use of a motivational interviewing approach by the coach nurse will encourage each participant's intrinsic motivation to engage in self-care, change health behaviors, and improve their glycemic control [28]. Using a checklist, the nurse will document the content of each call and emphasize key educational topics including discussion of weekly goal attainment, discussion of barriers if the goal is not met, setting of goals for next week's lesson, and provision of the opportunity to obtain personalized feedback if participants experience any challenges, and address concerns.

Patient and Public Involvement in Intervention Development

The SMart-D intervention was developed with substantial engagement with the Vietnamese community of Oklahoma, including leaders of the Asian District Cultural Association, faith-based leaders, health care professionals, and people with T2D. This 23-member group served as an advisory board for over a 1-year period and highlighted the need to develop a feasible and appropriate study design as well as the need to incorporate language and culture-relevant information [29]. By incorporating the Health Belief Model, this SMart-D intervention emphasized the need to reduce diabetes complication risks and motivated participants to take into account the central concept of risk, thus encouraging health behavior change [30]. Accordingly, both Vietnamese language and cultural practices are strong components of this intervention, and using the stepped wedge design allowed all consented participants to receive the intervention. In addition, the intervention was preliminarily tested with a group of targeted individuals prior to implementation to ensure the usage and usability of the education content and method of delivery. After this study is completed, reports will be made available to clinics and patients in the form of a newsletter as well as a scheduled in-person seminar where the research team will describe findings with each individual clinic.

Study Procedures

Inclusion or Exclusion Criteria

There are 2 levels of inclusion and exclusion: clinics and patients. Clinics are eligible if they currently serve more than 5 US Vietnamese adults diagnosed with T2D. T2D patients who

XSL•FO
RenderX

identify as Vietnamese adults and receive health care at a participating primary care clinic will be eligible. Patients must be 18 years of age or older, diagnosed with T2D, able to provide verbal or written consent in English or Vietnamese, able to speak or read Vietnamese, and possess or have access to a mobile phone.

The exclusion criteria at the clinic level are those clinics that currently serve fewer than 5 US Vietnamese patients with T2D. At the patient level, individuals younger than 18 years of age, individuals visiting the United States as tourists, those with cognitive impairment, those unable to provide consent in English or Vietnamese, and pregnant women are excluded as pregnancy affects diabetes care differently at each trimester [11]. Patients will be terminated early if they become pregnant or explicitly refuse to have blood drawn as ordered by their physicians.

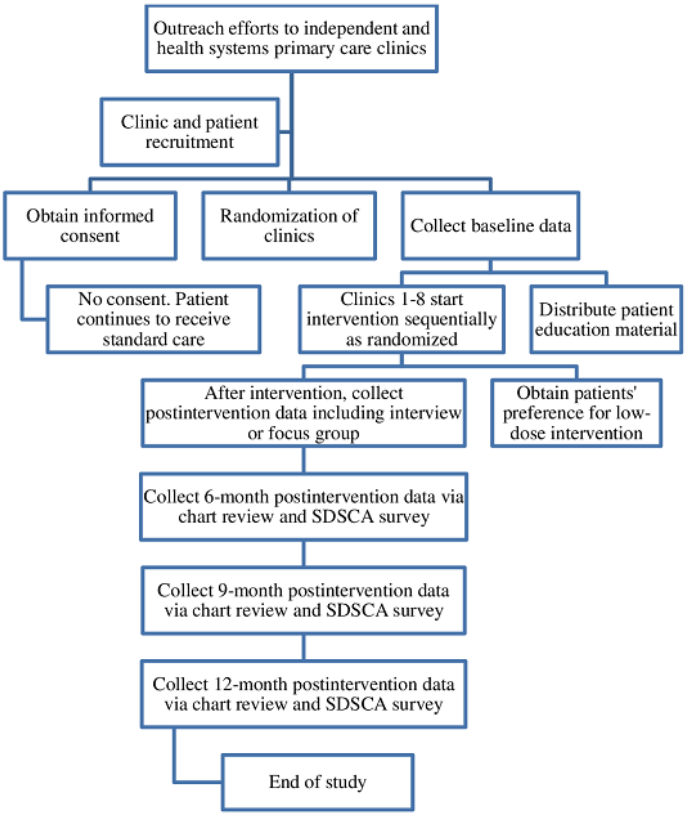
Clinic Recruitment and Consent Process

Primary care clinics will be identified according to the geographical area in which many US Vietnamese patients receive health care services. Prior to recruiting clinics of large health care systems, permission will be sought from the responsible administrators and medical directors. Independent and privately owned clinics will receive an invitation letter describing this study and its aims. Clinics that respond to the invitation will be assessed for eligibility by the principal investigator (PI). Clinics that do not respond to the initial mailed letter within 2 weeks will be contacted by email or phone.

Once the clinics are determined to be eligible, the PI will contact the office manager and the health care provider to ask for approval for the clinics to participate and obtain consent from these individuals. Next, the PI will set up 2 sessions of 1 hour briefing about this study and 1 hour training with clinic staff. Then participating clinics will identify and refer interested patients with a diagnosis of T2D via telephone contact or email.

Patient Recruitment and Consent Process

This study will recruit 80 patients from 10 clinics, approximately 8 patients from each clinic. We expect to have approximately 5 to 6 patients complete this study from each clinic giving a 70% (n=56) study completion rate. The power calculation was conducted by using the linear mixed effect modeling of the R (R Foundation for Statistical Computing) package "*swdpwr*," which gives power of 0.95 for the alternative hypothesis treatment effect change of 0.005 (2-sided type I error 0.05). The recruitment strategy includes a letter and flyer to be sent by the clinics with the research team's contact information. Study information will be provided to those who reach out to a research team member with their interest and an opt-out contact will be applied after 3 days of receiving the letter. A member of the research team will arrange a time to meet with eligible patients to discuss the option to participate in this study, complete the informed consent procedure, complete this study's screener, and enroll them in this study if the individual is both eligible and interested. All patients will have the option of completing the consent and confidentiality forms in English or Vietnamese language. Upon full study enrollment, a member of the research team will collect baseline data.



Randomization

Because individual randomization is not feasible due to potential contamination of the intervention for control participants, this study will use a programmatic roll-out in a stepwise fashion where each clinic that is not yet receiving the intervention will function as a control. Another reason for the selection of a stepped wedge design is that the measurement of outcomes is at the clinic level and individual patient level. Randomization of the intervention sequence will be conducted at the level of the clinics with computer-generated assignment using SAS (version 9.4; SAS Institute) by a statistician blinded to the identity of the clinics and not involved in the intervention delivery. The clinics will be randomized from 1 through 10 and will be allocated a date of implementation which will be concealed until interventions are assigned. Clinics will be informed that the order of allocation to the intervention will be unknown in advance of randomization.

During the initial control period, no clinic will be exposed to the intervention. Subsequently, at each 3-month interval, 1 clinic will transition from the control to the intervention period. This staggered schedule will allow for optimal training, implementation, and supervision of clinic staff. The process will continue until all 10 clinics have crossed over to receive the intervention. Figure 1 illustrates this study's procedures.

XSL•FO
RenderX

Figure 1. Study procedures for a randomized clinical trial in collaboration with primary care clinics. SDSCA: summary of diabetes self-care activities.

Data Collection

At enrollment, participants will complete the self-report demographic information survey, which will include age, gender, years of residence in the United States, and clinical information about their current treatment regimen to characterize the sample. For baseline data, participants will also complete the validated Summary of Diabetes Self-Care Activities (SDSCA) scale to measure self-care behaviors. The SDSCA scale, available in both English and Vietnamese languages, measures the participant's management of diabetes in the last 7 days regarding diet, physical activity and exercise, blood glucose testing, foot care, and smoking. Participants answer 11 questions by indicating the number of days the behavior was followed in the past 7 days (0-7 days). In addition to self-reported behaviors, lab test results including triglyceride, low-density lipoprotein, high-density lipoprotein, hemoglobin A_{1c}, and clinical assessments including BMI, blood pressure, and weight will be collected from their medical chart and entered into Research Electronic Data Capture (Vanderbilt University), a secure database. This information will be collected again at completion of the 12-week program and at 6 months, 9 months, and 12 months from baseline. Table 1 describes the timing of data collection and evaluation plan by the RE-AIM framework.

XSL•FO

[a]RE-AIM: Reach, Effectiveness, Adoption, Implementation, Maintenance.

[b]N/A: not applicable.

[c]mHealth: mobile health.

[d]SDSCA: summary of diabetes self-care activities.

[e]LDL: low-density lipoprotein.

[f]HDL: high-density lipoprotein.

[g]HbA_{1c}: glycated hemoglobin.

[h]BP: blood pressure.

Outcome Measures

The primary outcomes are the degree of reach, effectiveness, adoption, implementation, and maintenance measured by using the RE-AIM framework [31]. Reach is the ability to recruit patients and will be determined by assessing the number of people who received an invitation over the number of those who may be eligible to participate in the same clinic. Data sources include the number of invitations and the number of eligible patients seeking care at the clinic. Adoption will be measured by the proportion of clinicians who used the program and the number of patients who participate in the intervention by assessing the number of enrolled participants over the number of those invited, 3 months after the initiation of the intervention. Program implementation will be assessed by conducting a focus group or interview with the clinicians and patients separately at each clinic to gather feedback. Differences and similarities will be compared within and across clinics to identify emerging themes. Barriers and facilitators to program adoption by clinics will also be identified. See Table 2 for postintervention focus group or interview questions.

XSL•FO
RenderX

Table 2. Postintervention focus group or interview questions for participants.

Measures	Interview questions
Acceptability	• How would you describe your experience of taking part in this tailored DSMES[a] program? • What aspect of the program did you like the most? What was your favorite session? • Suppose a friend of yours was diagnosed with diabetes and came to you for advice. What would you tell them about this DSMES program?
Process of change	• What did you learn from this program? • How has your perspective of living with diabetes changed since completing the program? • What differences have you noticed in your life as a result of taking part in this DSMES program?
Barriers	• What kind of difficulties did you experience taking part in this DSMES program?
Improvement	• What did you least like about the program? What do you think could be improved about this DSMES program?
Implementing change	• How often do you practice the self-care behaviors such as following a healthy eating plan, testing your blood sugar, caring for your foot, etc. learned from this program?

[a]DSMES: diabetes self-management education and support.

The secondary outcomes are self-reported changes in behaviors and clinical test results, which will be compared to determine intervention maintenance and effectiveness. Repeated outcome measures will be assessed at 5 points in time. The translated and validated SDSCA revised scale [32] will be used to measure behavioral changes and assess 5 topics: diet, physical activity and exercise, blood glucose testing, foot care, and smoking. The average interitem correlations within scales were high (mean r=0.47) with the exception of specific diet; test-retest correlations were moderate (mean r=0.40). Correlations with other measures of diet and exercise generally supported the validity of the SDSCA subscales (mean r=0.23). Triglyceride, low-density lipoprotein, high-density lipoprotein, hemoglobin A_{1c}, BMI, weight, and blood pressure will be used to measure clinical changes, which will be obtained from the participants' medical records. Participants will be monitored for an additional 9 months via chart reviews and self-report using the SDSCA scale to determine whether any improvements observed at completion of the intervention will still be evident.

Data Analysis

To evaluate the first hypothesis, descriptive statistics will be used to analyze the acceptability and feasibility of the intervention, which include the proportion of individuals who met the criteria, proportion of eligible participants who agreed to participate, the proportion of mHealth responses completed, and attrition rate at follow-up periods. A linear regression model will be used to examine the association of response rate and attrition rate with other predictors. To evaluate the second hypothesis, continuous variables will be calculated using descriptive statistics including quantiles, mean, and SD. To examine the association of continuous outcome variables and other predictors, a linear mixed effect model will be used to examine time effects, clustering effects, and the interaction of the two. Transformation of outcome variables will be conducted to normalize the nonnormal distributions. To examine the association of categorical outcome variables and other predictors, a generalized linear mixed effect model will be used to examine time effects, clustering effects, and the interaction of the two. In order to handle missing values, sequential multiple imputation will be performed before the analysis. SAS (version 9.4; SAS Institute) will be used for statistical analysis.

To analyze qualitative data from the focus groups and interviews, field notes will be transcribed for coding and analysis. Focus groups and interviews conducted in Vietnamese will be translated into English by the research assistant and verified by the PI before coding and analyzing thematically. Prior to analyzing the transcripts, the researchers will read the transcripts at least twice and compare them with the field notes to ensure accuracy and completeness. Selected transcripts will be reviewed by an experienced qualitative researcher to compare the consistency in developing a coding schema. The NVivo (Lumivero) software will be used to manage and analyze qualitative data.

Intervention Fidelity

The intervention uses 3 fidelity checks to ensure that participants have received the intended information. First, the mHealth SMS text messages will be distributed automatically. Second, progress will be monitored and followed up with participants who abruptly stop reading or responding to our SMS text messages. Third, the nurse coaching call sessions will be monitored randomly by the PI, who will make note of any deviations and will provide further training for the nurse. These fidelity assessments are structured to ensure the intervention is implemented as intended during the delivery process.

Ethics Approval

Ethical approval has been granted by the University of Oklahoma Health Sciences Center institutional review board on October 25, 2022 (IRB#14700). Permission from the large health systems and each clinic has also been granted. The SMart-D intervention involves research with an ethnic minority and understudied population. To ensure the needs of this population are met, the research team has led a prior project with members of this community who contributed to the design, development, and implementation of this study. Ethical procedures include steps for continuation of health education

XSL•FO
RenderX

for participants after study completion by coordinating with local health departments to refer participants to the existing and structured Total Wellness program of Oklahoma. Baseline data and lessons learned will be presented at conferences, and study outcomes will be published in scientific journals. Study results will also be communicated to relevant health care professionals and to the US Vietnamese community through lectures, posters, and pamphlets.

Results

Planning for the SMart-D study began in January 2022, clinic recruitment began October 28, 2022, and patient recruitment began November 4, 2022. Data collection of outcome measures will be completed in 2024. This study was funded during July 2022 to June 2024. As of August 24, 2023, 10 clinics and 60 patients were enrolled in this study. The results are expected to be available by 2025 and will demonstrate intervention acceptability, feasibility, effectiveness, and sustainability.

Discussion

This study is driven by two hypotheses: (1) at least 50% (n=5) of eligible clinics and 50% (n=40) of eligible patients who are invited will participate, and at least 70% (n=56) of patients will complete the program, and (2) patients who receive the intervention will have improved self-care behaviors and improved clinical test results with at least 75% (n=60) of the patients maintaining improved outcomes at follow-up visits compared with baseline, and participants will verbalize that the intervention is feasible and acceptable. This protocol was designed with an interprofessional research group that has many strengths. An overall strength is the stepped wedge design, which allows participating clinics to be randomized with an opportunity for all consented patients to participate in the intervention. The staggering of clinic implementation allows the research team to train clinic staff and monitor potential implementation issues. The mixed method and longitudinal design provide insights into long-term outcomes over time.

Another strength of this protocol is this is the first Vietnamese DSMES intervention to be implemented in collaboration with primary care clinics that leverages mHealth technology to address the barriers of language and cultural differences. Vietnamese-speaking individuals have few opportunities to participate in health-related randomized clinical trials. This protocol allows that opportunity because it is offered in the Vietnamese language to promote self-determination and independence, and improve self-management strategies.

Further, 1 limitation of the stepped wedge design is that patients of clinics that were randomized for implementation later will have to wait months before receiving the intervention. This waiting period may reduce engagement with the researchers and may increase attrition rates. Another limitation is the repeated measurements of questionnaires and clinical tests may lead to a higher respondent burden on patients and clinic staff.

In conclusion, this study will improve understanding of the implementation process, demonstrate the potential effectiveness of the intervention, accelerate the pace of moving evidence-based interventions to practice among the Vietnamese population, and potentially provide a replicable implementation model that can be culturally tailored to other non-English speaking ethnic minorities. Furthermore, successful study results may be implemented across other localities and states and across both primary care and specialty clinics.

Acknowledgments

We acknowledge the financial support by the Presbyterian Health Foundation for the project implementation. We also acknowledge the partnership with the Vietnamese community of Oklahoma for assisting with this study's design and clinic recommendations. We appreciate the collaboration with the participating clinics and their staff. This work was supported by the Presbyterian Health Foundation Research Grant (20005413) awarded to Fran and Ziegler College of Nursing at The University of Oklahoma Health Sciences Center. SC was partially supported by the Oklahoma Shared Clinical and Translational Resources (U54GM104938) with an Institutional Development Award from the National Institute of General Medical Sciences. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

Data sharing is not applicable to this paper, no data sets were analyzed during the development of this protocol. To support scientific transparency, we will publish deidentified data and additional supporting files in the main paper.

Authors' Contributions

AN wrote the first draft. ZN led in the dissemination and implementation of the research design. TB and MB led in the mobile health design and implementation. SC wrote the statistical analysis plan. VE and KD completed the final paper revision. All authors contributed to this study's design and critical review and revision of this paper. All authors read and approved the final version.

Abstract

Background: Although pre-exposure prophylaxis (PrEP) could substantially mitigate HIV risk, sexual minority men who use stimulants commonly experience difficulties with engaging in PrEP clinical services. Motivational interviewing (MI) and contingency management (CM) reduce substance use and condomless anal sex (CAS) in this population, but these motivational enhancement interventions require modifications to promote engagement along the PrEP care continuum.

Objective: PrEP Readiness Interventions for Supporting Motivation (PRISM) is a pilot sequential multiple assignment randomized trial testing the feasibility, acceptability, and preliminary effectiveness of distinct combinations of telehealth MI and CM in 70 cisgender sexual minority men who use stimulants that are not currently taking PrEP.

Methods: A national sample was recruited via social networking applications to complete a baseline assessment and mail-in HIV testing. Those with nonreactive HIV results were randomized to receive either (1) a 2-session MI intervention focusing on PrEP use (session 1) and concomitant stimulant use or CAS (session 2) or (2) a CM intervention with financial incentives for documented evidence of PrEP clinical evaluation by a medical provider (US $50) and filling a PrEP prescription (US $50). At the 3-month follow-up assessment, participants who reported they had not filled a prescription for PrEP were randomized a second time to either (1) *switch* to a second-stage intervention (ie, MI+CM or CM+MI) or (2) *continue* with assessments only. Outcomes for both responders and nonresponders were reassessed at a 6-month follow-up. The primary outcome is documented evidence of filling a PrEP prescription over 6 months. Self-reported secondary outcomes include PrEP clinical evaluation by a medical provider, stimulant use, and CAS. Qualitative exit interviews were conducted with a subgroup of responders and nonresponders to characterize their experiences with the MI and CM interventions.

XSL•FO
RenderX

Results: Implementation of PRISM underscores challenges in reaching sexual minority men who use stimulants to optimize HIV prevention efforts. Approximately 1 in 10 (104/1060) eligible participants have enrolled. Of the 104 who enrolled, 87 (84%) completed mail-in HIV testing. We delivered 5 preliminary HIV-positive results, including posttest counseling with referrals to confirmatory testing.

Conclusions: Lessons learned from PRISM underscore the central importance of a flexible, participant-centered approach to support the engagement of sexual minority men who use stimulants. Leveraging telehealth platforms to deliver motivational enhancement interventions also expanded their reach and potential public health impact with this high-priority population. Further research is needed to determine the effectiveness of telehealth MI and CM for supporting PrEP use in sexual minority men who use stimulants.

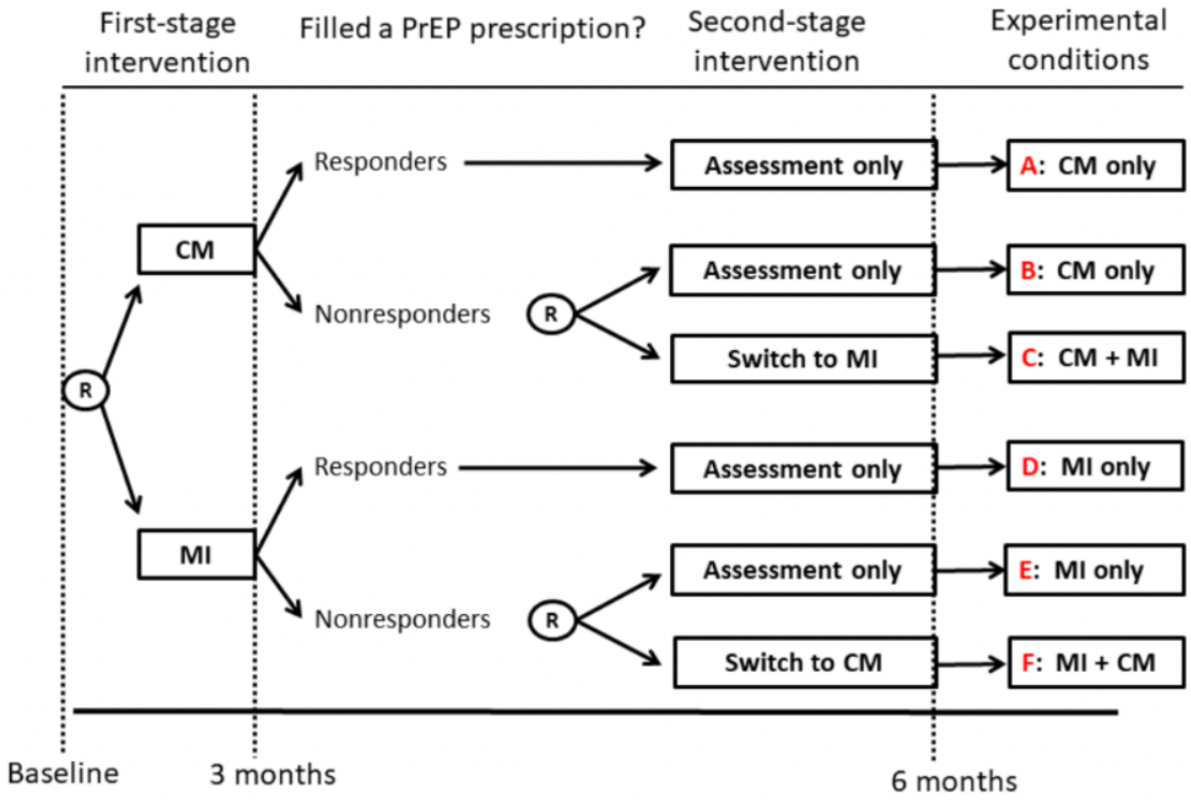
Introduction

Sexual minority men continue to account for more than two-thirds of new HIV infections in the United States [1-4], and it is estimated that 70% of seroconversions in this population occur during receptive condomless anal sex (CAS) [5-7]. Consequently, expanded efforts are needed to optimize the benefits of pre-exposure prophylaxis (PrEP) among sexual minority men at greatest risk for HIV. The Centers for Disease Control and Prevention [2,8] has estimated that 1 in 6 sexual minority men will acquire HIV in their lifetime, including half of Black sexual minority men and one-quarter of Latino sexual minority men. Over and above these profound racial disparities, there is a resurgent epidemic of methamphetamine use among sexual minority men that is disproportionately affecting Black and Latino sexual minority men [9-12]. Although methamphetamine use appeared to decline somewhat after significant public health attention in the early- and mid-2000s [13,14], it is again on the rise [13,15-19]. For over two decades, methamphetamine and other stimulant use has been identified as a prominent driver of the HIV/AIDS epidemic in sexual minority men that is associated with engagement in CAS [20,21], altered rectal immune function [22,23], and faster rates of HIV seroconversion [24-26]. The public health impact of stimulant use is evidenced by recent findings from a cohort of sexual and gender minorities who have sex with men, where 1 in 3 new HIV infections were among those reporting methamphetamine use [26].

Sexual minority men who use stimulants experience substantial barriers to navigating HIV prevention services that undermine the clinical and public health benefits of PrEP. This is evidenced by findings from one study, where sexual minority men who use methamphetamine had 5-fold greater odds of repeat prescription for postexposure prophylaxis and a 3-fold greater rate of HIV seroconversion [27]. This underscores the clear benefits of supporting the entry or re-entry of sexual minority men who use stimulants into the PrEP care continuum. Although some studies found that sexual minority men who use substances report concerns about their hypothetical ability to adhere to PrEP [28,29], actual PrEP use among sexual minority men who use substances such as methamphetamine and amyl nitrites (ie, poppers) appears to be comparable to or greater than their peers who do not use substances [30-38]. At the same time, there is growing evidence that sexual minority men who use stimulants and other substances can experience difficulties achieving prevention-effective levels of daily oral PrEP adherence [33,39,40] that may serve as early indicators of greater risk for disengagement from PrEP care and discontinuing PrEP [41-43]. For example, those engaging in heavy cocaine use have nearly 3-fold greater odds of disengagement from PrEP care compared to nonusers [41]. Taken together, there is a clear need for scalable interventions to promote the entry or re-entry of sexual minority men who use stimulants into the PrEP care continuum.

The effectiveness of motivational interviewing (MI) and contingency management (CM) interventions are supported by decades of clinical research in people with substance use disorders [44], and these are the only interventions that are efficacious for reducing both substance use and CAS in sexual minority men [45-49]. MI is an evidence-based counseling intervention targeting *intrinsic motivation* for health behavior change [50]. CM targets *extrinsic motivation* by providing tangible incentives as positive reinforcement for performing health behaviors [51], and it has also been successfully used to promote HIV-related health behavior change in people who use substances [52-57]. Interestingly, findings from one meta-analysis of the substance use disorder treatment literature indicate that MI achieves small but durable outcomes, while CM leads to moderate short-term outcomes [58]. PrEP Readiness Interventions for Supporting Motivation (PRISM) addresses an important gap by testing sequentially delivered MI and CM interventions for promoting entry or re-entry into the PrEP care continuum.



Cognitive evaluation theory proposes that motivational processes are arranged hierarchically such that the extrinsic rewards for behavior change provided during CM could paradoxically undermine intrinsic motivation in some circumstances [59]. In cognitive evaluation theory, higher-order needs for autonomy and self-determination govern the regulation of intrinsic motivation and self-efficacy, both of which could be partially

XSL•FO
RenderX

undermined by CM incentives. This underscores the need for clinical research to test if there are distinct combinations of MI and CM that optimize durable PrEP use while decreasing stimulant use and CAS among sexual minority men.

This paper describes the protocol for a pilot sequential multiple assignment randomized trial (SMART [60]) testing the feasibility, acceptability, and preliminary effectiveness of the PRISM telehealth motivational enhancement interventions. The primary outcome is documented evidence of filling a PrEP prescription over 6 months. As shown in Figure 1, using sequential randomization procedures allowed for a comparison of 2 first-stage interventions: MI versus CM (randomized 1:1 after baseline). Then, among those who did not fill a PrEP prescription after 3 months (ie, nonresponders), we conducted a second randomization to *switch* to a second-stage intervention (ie, MI+CM and CM+MI) versus *continue* with assessments only (also randomized 1:1 for those not on PrEP at 3 months). Because CM has been shown to yield moderate short-term effects, we hypothesize that a greater proportion of those randomized to receive CM as the first-stage intervention will have filled a PrEP prescription and report being evaluated for PrEP by a medical provider over 6 months. Because MI also targets concomitant HIV risk behaviors, we hypothesize that those randomized to receive it as the first-stage intervention will show greater reductions in self-reported stimulant use and CAS over 6 months. Finally, among nonresponders, we hypothesize that participants randomized to *switch* to a second-stage intervention (ie, CM+MI and MI+CM) will have greater improvements in the primary and secondary outcomes compared to those who *continue* with assessments only.

Figure 1. Pilot SMART of the PRISM telehealth motivational enhancement interventions to facilitate entry or re-entry into the PrEP care continuum. CM: contingency management; MI: motivational interviewing; PrEP: pre-exposure prophylaxis; PRISM: PrEP Readiness Interventions for Supporting Motivation; SMART: sequential multiple assignment randomized trial.

Methods

Study Design

This pilot SMART randomized 70 HIV-negative sexual minority men who use stimulants (ie, methamphetamine, powder cocaine, or crack cocaine) that are not currently taking PrEP, and completion of the final follow-up assessments is anticipated in July 2023. Participants were recruited via social networking applications across the United States. Interested individuals were directed to a web-based screener that assessed the following inclusion criteria: (1) 18 years of age or older; (2) identified as a cisgender man; (3) reported anal sex with a man (past 6 months); (4) reported using methamphetamine, powder cocaine, or crack cocaine in the past 3 months; (5) HIV-negative or unknown serostatus; (6) met Centers for Disease Control and Prevention criteria for PrEP eligibility [61]; and (7) not currently prescribed PrEP. PrEP eligibility was operationalized as any CAS regardless of partner type or any sexually transmitted infection (past 6 months).

Research Team

Master's and doctoral-level staff were trained in assessment administration, randomization, and intervention activities. Ongoing oversight and safety monitoring were provided by the principal investigators. Fidelity monitoring and group supervision for staff delivering MI sessions were overseen by a licensed psychologist who is a member of the Motivational Interviewing Network of Trainers. Follow-up assessments were conducted by staff who were blinded to intervention conditions.

XSL•FO
RenderX

One team member with graduate-level training in qualitative methods conducted qualitative exit interviews with participants.

Ethical Considerations

All procedures for this pilot SMART were approved by the University of Miami Institutional Review Board (UM IRB Study ID: MODCR00000105) with a reliance agreement from the City University of New York Graduate School of Public Health. All participants completed an informed consent before study enrollment. All pilot SMART activities were conducted using Zoom (Zoom Video Communications, Inc), which emerged as a flexible response to the COVID-19 pandemic and represents a scalable platform for reaching the broader population of sexual minority men who use stimulants with the PRISM telehealth motivational enhancement interventions. Potentially eligible participants were invited to an enrollment visit that included informed consent for the first 3 months of the pilot SMART and a baseline assessment via Zoom. Those who completed the enrollment visit received a US $50 Amazon gift card, Venmo, or Zelle cash application payment. In total, participants could make up to US $335 over the course of the pilot SMART, depending on the interventions they received. Information regarding the payment for each study activity is included in the paper where relevant. All data were stored on a Food and Drug Administration and Health Insurance Portability and Accountability Act–compliant University of Miami server, and all electronic files containing identifiable information were password-protected with access limited to institutional review board–approved study staff only.

Sequential Informed Consent

At baseline, participants provided informed consent for the first 3 months of the pilot SMART with trained staff. This consent described the first-stage randomization to MI versus CM as well as the 3-month follow-up assessment. We used sequential informed consent procedures to ensure that participants did not plan to delay filling a PrEP prescription to be eligible for the second-stage randomization and the possibility of additional incentives (eg, those initially randomized to MI would delay filling a PrEP prescription to have another chance to receive CM financial incentives). After the 3-month follow-up assessment, participants completed a second informed consent that described procedures for the second-stage randomization of nonresponders, the 6-month follow-up assessment, and qualitative exit interviews. The follow-up assessments at 3 and 6 months were completed by an independent assessor who had not previously delivered MI or CM to participants. Participants were sent a link to the self-report measures to complete on their own, and they received a US $50 Amazon gift card or cash application payment for completing each assessment.

Mail-In HIV Testing

After the baseline assessment, participants were sent a testing kit to collect a saliva sample with an OraSure HIV-1 (LOT 6691354; OraSure Technologies, Inc) testing device, with instructions on how to take the test and a prepaid return envelope to the HIV testing laboratory. Participants received a US $25 Amazon gift card or cash application payment for mailing this sample to a laboratory for HIV testing [62,63]. Participants who did not complete HIV home testing or those with reactive HIV test results were excluded prior to randomization. Participants with reactive HIV test results were provided with posttest counseling and assisted in connecting with local confirmatory testing [64].

Pilot SMART Procedures

As shown in Figure 1, participants who provided a saliva sample that was nonreactive for HIV were randomized to a first-stage intervention: (1) a 2-session MI intervention or (2) a CM where they received up to US $100 in financial incentives for taking the first step toward starting or restarting PrEP. Randomization at baseline was stratified as a function of whether participants have previously taken PrEP with the randomization schemes created in SAS (version 9.4; SAS Institute Inc) by the data manager using randomly permuted block sizes of 2, 4, and 6. The randomization schemes were administered using REDCap (Research Electronic Data Capture; Vanderbilt University) and were not viewable by staff until the moment of randomization for each participant. Randomization probabilities at each stage were 1:1. Immediately following randomization, participants received their first MI session or a brief introduction to the financial incentives they could earn during the 3-month CM period. All participants received a US $20 Amazon gift card or cash application payment for attending this first-stage randomization visit. After 3 months, participants who reported that they have not filled a PrEP prescription in the prior 3 months are classified as nonresponders. Nonresponders were randomized a second time (no stratification) to either (1) *switch* to a second-stage intervention (MI+CM or CM+MI) or (2) *continue* with assessments only. Finally, responders and nonresponders completed a final follow-up assessment at 6 months to measure the primary and secondary outcomes. Participants received a US $50 Amazon gift card or cash application payment for completing each follow-up assessment at 3 and 6 months.

MI Intervention

The 2-session MI intervention simultaneously targeted PrEP use (session 1) as well as co-occurring substance use and CAS (session 2). Each session was delivered approximately 1 week apart via Zoom, and participants received a US $20 Amazon gift card or cash application payment at each session. Participants had up to 3 months to complete both MI sessions.

Session 1 focused extensively on enhancing intrinsic motivation for starting or restarting PrEP. To begin, participants were invited to tell the facilitator a bit about themselves and describe what they know about PrEP. Using elicit-provide-elicit techniques, the facilitator provided relevant information to address any gaps in knowledge about PrEP. This included topics like the effectiveness and safety of PrEP, prevention effective adherence levels for sexual minority men, different oral dosing strategies (eg, 2-1-1), navigating PrEP care, and the availability of financial support for those without insurance. Then, participants were invited to describe their thoughts and feelings about the possibility of starting PrEP with selective reinforcement of change talk by the facilitator. Using the *change ruler*, participants rated on a scale of 1 to 10 how important it is for them to see a medical provider to learn more about PrEP.

XSL•FO
RenderX

The facilitator used this to elicit change talk by asking participants why they did not pick a lower number (eg, "Why did you pick a 3 and not a 1?"). Next, the facilitator engaged participants in the *roadmap exercise*, where the decision regarding whether to start PrEP was presented as a fork in the road. Participants were asked to consider what life might look like in 1-2 years if they did not start PrEP and then if they chose to start PrEP. The session ended with a summary, and participants were encouraged to examine what (if any) steps they were ready to take toward starting or restarting PrEP. Those who were actively planning to start or restart PrEP were asked to elaborate on the timeline and examine any potential barriers they might encounter in accessing PrEP care.

At the beginning of session 2, participants were asked to describe their current thoughts and feelings about starting or restarting PrEP. The facilitator selectively reinforced change talk and answered any questions participants might have about navigating PrEP care. Next, participants were introduced to the focus of session 2, concomitant stimulant use, and CAS. Participants were presented with a menu of options that reflect possible topics for the session including (1) change how I use stimulants, (2) start substance use treatment, (3) attend a self-help group, (4) abstain from stimulants, (5) fewer sex partners, (6) less sex on stimulants, (7) use condoms, and (8) get tested for HIV regularly. Participants were encouraged to identify a topic of focus for the session that they wanted to discuss at greater length. Our approach to addressing stimulant use and CAS embraces the philosophy of harm reduction such that participants were not required to be ready, willing, or able to abstain from stimulant use or use condoms every time during anal sex [65]. Instead, the facilitator assisted participants with exploring a range of possible behavior change targets such as reducing the frequency of stimulant use, changing the mode of stimulant administration (eg, snorting instead of smoking), and using condoms during receptive anal sex with casual partners. Once a behavior change target was identified, participants were encouraged to elaborate on it to reinforce change talk. Using the *change ruler*, participants rated on a scale of 1 to 10 how important it is for them to make this change. The facilitator used this to elicit change talk by asking participants why they did not pick a lower number (eg, "Why did you pick a 3 and not a 1?"). Next, the facilitator engaged the participant in the *roadmap exercise*, where the decision regarding whether to make this change was presented as a fork in the road. Participants were asked to consider what life might look like in 1-2 years if they did not make a change and then if they chose to change. The session ended with a summary, and participants were encouraged to examine what steps (if any) they were ready to take toward change. Those who were actively planning to make a change in their behavior were asked to elaborate on the timeline and examine any potential barriers they might encounter.

CM Intervention

Facilitators provided a brief overview of the CM protocol and encouraged participants to ask any questions they may have about how to access PrEP in their community. Facilitators provided tailored referrals for local PrEP services [66] and web-based PrEP providers. Participants were provided financial incentives as positive reinforcement for 2 key behaviors that are crucial to PrEP care continuum entry or re-entry. First, participants received a US $50 incentive for documented evidence of completing a medical visit for PrEP clinical evaluation that includes HIV testing. Documentation can include either a note from a medical provider indicating that the participant was seen for a PrEP evaluation or laboratory results consistent with PrEP clinical evaluation (eg, HIV testing and kidney function). Second, participants who provided evidence that they filled a recent PrEP prescription for Truvada or Descovy matched to their photo identification (eg, photo of the medication bottle), received an additional US $50 incentive. Participants on Apretude as injectable PrEP were asked to provide documentation from their provider or medical record demonstrating that they received an injection to obtain the US $50 incentive. Because filling a PrEP prescription requires participants to receive a PrEP clinical evaluation by a medical provider, those who had not previously received US $50 for a PrEP clinical evaluation received US $100 when they provided evidence they filled a PrEP prescription. To provide timely positive reinforcement for these behaviors, incentives were provided via remote payment applications (eg, Venmo and Zelle) within 2 business days.

Fidelity Monitoring

The procedures for monitoring the fidelity of the CM and MI intervention protocols were as follows: (1) detailed curriculum manuals for each intervention, (2) intensive training in delivering MI and CM, (3) incorporation of mock training sessions to ensure staff meet performance criteria for delivery, (4) facilitator checklists, and (5) audio taping of sessions. Audio recordings of facilitator sessions were reviewed to assess adherence to the protocol, delivery, interpersonal skills, facilitator or participant rapport, and session flow. Fidelity monitoring was also crucial to mitigate the risk of contamination (eg, possible delivery of MI counseling during CM). The first 3 participants for each staff member (MI and CM) were reviewed immediately. Staff members also participated in ongoing individual and group supervisions. Fidelity ratings of MI sessions used the MI treatment integrity protocol [67], which is the gold standard approach for monitoring the fidelity of MI. MI treatment integrity scores review 4 global categories (cultivating change talk, softening sustain talk, partnership, and empathy) and are based on a Likert-scale from 1 (low) to 5 (high) [68].

Primary Outcome

The primary outcome is verified evidence that a participant filled a PrEP prescription (ie, photo of a recently filled medication bottle) over the 6-month follow-up. For participants who did not provide evidence of a PrEP prescription as part of CM, those who reported taking PrEP were subsequently notified that they could receive an additional US $20 incentive for providing evidence of a recent PrEP prescription. We chose to implement this strategy to mitigate differential assessment of the primary outcome due to CM incentives. Participants were offered the US $20 incentive for providing evidence only after they self-reported recently filling a PrEP prescription so that it did not function as a CM incentive.

XSL•FO
RenderX

Secondary Outcomes

Participants completed self-report measures over the 6-month follow-up to assess several secondary outcomes that are described briefly below.

PrEP Clinical Evaluation

Participants were asked to indicate if they attended an appointment with a medical provider about starting PrEP in the past 3 months. Those who indicated they attended any medical appointment about starting PrEP over the 6-month follow-up were classified as completing PrEP clinical evaluation.

Stimulant Use Severity

The World Health Organization Alcohol, Smoking, and Substance Involvement Screening Test is a validated self-report measure of substance use [69,70]. We plan to examine changes in the amphetamine-type stimulant and cocaine use composite scores, which measure the severity of symptoms for stimulant use disorders. Where participants reported using multiple stimulants at a given time point, the highest mean score was selected. We will also examine changes in clinically validated cut-points for moderate and severe stimulant use disorders using the Alcohol, Smoking, and Substance Involvement Screening Test (mild=0-3; moderate=4-26; and severe=27 or greater). Again, where participants are using multiple stimulants at a given time point, the cocaine or amphetamine-type stimulant use score that reflects higher severity was selected.

Receptive and Insertive CAS

Participants were asked to separately indicate the number of men with whom they had receptive or insertive anal sex "without a condom at least part of the time" in the past 3 months. If participants reported having CAS partners, they were asked to separately indicate the number of receptive and insertive CAS partners who were taking PrEP or were HIV-positive undetectable to examine the extent to which participants are biomed sorting [71].

PrEP Intentions

A 3-item PrEP intentions scale assessed intentions to complete certain PrEP-related behaviors within the next 3 months (eg, "During the next 3 months, I will talk to a health care provider about PrEP."). Responses were rated on a 4-point scale from definitely will not do (1) to definitely will (4) with higher scores indicating stronger intentions to use PrEP [72].

PrEP Self-Efficacy

An 8-item scale assessed how difficult participants viewed behavior skills related to PrEP use (eg, "How difficult would it be for you to talk openly and honestly with a doctor about your sexual behaviors?"). Participants rated their responses on a 4-point scale ranging from very hard to do (1) to very easy to do (4) with higher ratings indicating greater self-efficacy for PrEP use [72].

PrEP Attitudes

A 5-item scale assessed attitudes toward PrEP use (eg, "PrEP is effective at preventing HIV.") [72]. Participants rated response options on a 5-point scale ranging from strongly disagree (1) to strongly agree (5) with higher scores indicating more positive attitudes toward PrEP use.

PrEP Stigma

This 5-item scale assessed stigmatizing notions around PrEP use (eg, "People who take PrEP are promiscuous.") [72]. Participants rated response options on a 5-point scale ranging from strongly disagree (1) to strongly agree (5) with higher scores indicating more stigmatizing views about PrEP [72].

Intent-to-Treat Analyses

Using logistic regression, we will examine the intent-to-treat effects of first-stage randomization (ie, MI vs CM) on (1) any documented evidence of filling a PrEP prescription (primary outcome) over the 6-month follow-up and (2) any self-reported PrEP clinical evaluation by a medical provider over the 6-month follow-up. These logistic regression analyses will test our primary hypothesis that it is better to start with CM versus MI. Intent-to-treat analyses of secondary outcomes involving longitudinal trajectories of continuous measures will be tested using multilevel random coefficient models (ie, hierarchical linear modeling). These analyses will test our secondary hypotheses that those randomized to receive MI as a first-stage intervention will display a greater decrease in stimulant use severity and number of CAS partners over 6 months. Finally, exploratory analyses using the methods described earlier will be conducted among nonresponders only. We hypothesize that nonresponders randomized to *switch* to a second-stage intervention (ie, CM+MI and MI+CM) will have greater improvements in the primary and secondary outcomes compared to those who *continue* with assessments only.

Power Analysis

Recent statistical modeling clearly demonstrates that it is inappropriate to use effect size estimates from a pilot trial for establishing effectiveness or informing subsequent power analyses [73]. Thus, the most appropriate focus of a pilot is to examine issues relevant to feasibility and acceptability, which do not require adequate statistical power. At the same time, we will examine the preliminary intent-to-treat effects of starting with MI versus CM in this pilot SMART. With 70 randomized participants, α=.05 (2-tailed), power=0.80, and 75% retention at 6 months, minimum detectable standardized mean differences for continuous outcomes ranged from 0.53 to 0.79 for within-subjects correlations r ranging from 0.10 to 0.80. For binary outcomes, using the same inputs as above plus small, medium, and large base rates of 10%, 25%, and 50%, respectively, raw proportion differences for r=0.10 ranged from 21% to 25% (standardized difference=0.55); and for r=0.80, the corresponding raw proportion differences ranged from 34% to 38% (standardized difference=0.80). Statistical power estimates following the second-stage randomization are dependent on the nonresponse rate.

Qualitative Exit Interviews

After the 6-month follow-up assessment, participants were purposively selected for a qualitative exit interview examining their experiences with the PRISM telehealth motivational enhancement interventions received. Participants were purposively selected for in-depth qualitative interviews based

XSL•FO
RenderX

on whether they were responders (n=10) or nonresponders (n=10) after 6 months. Participants invited to complete an in-depth qualitative interview received a US $50 Amazon gift card or cash application payment.

Interviews were conducted by a member of the study team that has not previously interacted with the participants at any point in the trial. Interviews were approximately 60 minutes. The interviewer completed ongoing training and supervision in qualitative methods and the pilot SMART objectives. The semistructured interview guide was tailored based on the responder status (responder at stage 1, responder at stage 2, or nonresponder at 6 months). Topics included likes and dislikes of PRISM telehealth interventions, views on the adequacy of study incentives, thoughts about PrEP, interest in injectable PrEP, and barriers and facilitators to PrEP uptake and adherence.

Qualitative Analyses

Interviews were audio recorded on Zoom with the participants' consent and transcribed verbatim. The transcripts are reviewed for accuracy and quality assurance. A general inductive approach [74] will be used to analyze themes relating to the acceptability and feasibility of the PRISM interventions. Codes will be derived inductively starting with a thorough reading of the transcripts and identification of relevant information expressed by participants. An initial codebook will be developed by the primary data analyst after a comprehensive reading of all transcripts. Next, a random sample of 5 interviews will be selected for a second data analyst to code for interrater agreement. The 2 researchers will review and discuss any discrepancies in the coding, emergent themes, and the need for refined definitions. The researchers will accept all codes where there is agreement and come to a consensus for areas of nonagreement based on their discussions; they will revise the codebook and recode the transcripts based on the revised codebook. Next, a second random sample of 5 interviews will be selected to determine interrater agreement. When the analysts reach an interrater agreement of 85%-90% in the second round of coding, the transcript codes will be finalized [75]. Agreement is defined as whether identical codes are applied to the selected text by both coders. Once interrater agreement is reached, all interviews will be coded by either one of the two analysts based on the final codebook following established guidelines for determining coding saturation [76].

Results

Recruitment of participants via social networking applications reached a large pool of potentially eligible participants. Although 7800 people completed the web-based screener, the large number of screeners completed yielded 1060 (14%) potential participants. Of those who screened eligible, 104 (10%) participants completed a Zoom enrollment visit. As shown in Figure 1, 87 (84%) enrolled participants provided a saliva sample for mail-in HIV testing. Notably, we identified 5 (6%) new HIV infections, and these men were provided with posttest counseling as well as referrals to confirmatory testing. Of the 82 participants with a nonreactive HIV result, 70 (85%) were randomized to a stage 1 intervention in the pilot SMART.

There were no significant differences between enrolled and nonenrolled groups in race or ethnicity, age, and type of stimulants used. As shown in Table 1, 46 (44%) of enrolled participants were ethnic minorities with an average age of 38.5 (SD 8.9) years. Most enrolled participants reported only methamphetamine use in the last 3 months (n=65, 63%), followed by couse of methamphetamine and powder or crack cocaine (n=23, 22%), and then only powder or crack cocaine use in the last 3 months (n=16, 15%). Although enrolled participants were more likely to know about "on-demand PrEP" or "event-based dosing" as an alternative to daily oral PrEP, nearly three-fourths of enrolled and nonenrolled participants expressed interest in this dosing strategy.

XSL•FO
RenderX

Table 1. Comparison of eligible participants who enrolled versus those who did not enroll (N=1060).[a]

	Enrolled (n=104)	Not enrolled (n=956)	*P* value
Age (years), mean (SD)	38.5 (89)	38.1 (10.1)	.69
Stimulant use (past 3 months), n (%)			.76
Powder or crack cocaine only	16 (15.4)	141 (14.8)	
Methamphetamine only	65 (62.5)	630 (65.9)	
Powder or crack cocaine and methamphetamine	23 (22.1)	185 (19.4)	
Interested in on-demand PrEP[b], n (%)	77 (74.0)	714 (74.7)	.89
On-demand PrEP is a good prevention choice for me, n (%)	74 (71.2)	671 (70.3)	.85
It would be difficult for me to use on-demand PrEP, n (%)	9 (8.7)	101 (10.6)	.54
Race or ethnicity, n (%)			.08
Black or African American	16 (15.4)	76 (8.1)	
White	58 (55.8)	548 (58.1)	
Hispanic or Latino	21 (20.2)	212 (22.5)	
Other ethnic minority	9 (8.7)	108 (11.4)	
HIV status, n (%)			.30
HIV-negative	84 (80.8)	729 (76.3)	
Unknown	20 (19.2)	227 (23.7)	
Diagnosed with a STI[c] (past 6 months), n (%)	17 (16.4)	114 (12.0)	.20
Any sex exchange for money or drugs, n (%)	29 (28.4)	303 (31.9)	.47
Aware of on-demand PrEP, n (%)	73 (70.2)	575 (60.2)	.047
Previously used on-demand PrEP, n (%)	4 (3.9)	25 (2.6)	.52[d]

[a]A pooled *t* test was used to compare means across both groups for the continuous characteristic, age.

[b]PrEP: pre-exposure prophylaxis.

[c]STI: sexually transmitted infection.

[d]Chi-square test of proportions was used for all categorical characteristics except for this value, where Fisher exact test was used.

Discussion

Implementation of the pilot SMART of the PRISM telehealth motivational enhancement interventions highlights the challenges associated with launching and sustaining a national recruitment campaign to achieve our target sample size. Additionally, the onset of the COVID-19 pandemic necessitated delivery of the PRISM motivational interventions using a telehealth platform. Participant enrollment, scheduling, and completing intervention activities via telehealth as well as mail-in HIV testing efforts afforded the research team various successes, challenges, and lessons learned.

Enrolling potentially eligible participants proved to be more difficult than anticipated such that only 1 in 10 who screened eligible enrolled in the pilot SMART. This reflects the challenges in optimizing HIV prevention with sexual minority men who use stimulants, a high-priority population that is often difficult to access because many are not actively seeking services. Despite the challenges we experienced in enrolling potentially eligible participants, there were no significant differences between enrolled and nonenrolled groups in race or ethnicity, age, and type of stimulants used. Enrolled participants appear to be generally representative of the broader population of sexual minority men who use stimulants that we screened from social networking applications. Future randomized controlled trials will likely require a substantial investment of time and resources for national recruitment campaigns to examine the effectiveness of the PRISM telehealth motivational enhancement interventions.

Throughout the pilot SMART, we developed and refined strategies to support the engagement of potentially eligible participants through SMS text messages and other communications that emphasized the nonjudgmental, flexible, and participant-centered approach of our team. We devoted substantial resources to enrolling participants with multiple contacts to facilitate scheduling and often multiple missed enrollment visits. Many eligible participants did not respond to multiple attempts to contact them via text; for those who did respond, our staff reported approximately two-thirds no-show rate for scheduled Zoom enrollment visits. PRISM staff implemented procedures regarding appointment reminders that included nonjudgmental language regarding follow-ups for missed appointments (eg, “Sorry we missed each other today. Happy to reschedule for another time.”) and encouraged participants to re-establish contact. This is consistent with

XSL•FO
RenderX

findings from previous studies using social media to recruit sexual minority men most vulnerable to HIV acquisition [63,77] as well as SMS text messages to enhance engagement and retention [78].

The inclusion of HIV testing provided additional successes and challenges for our staff. Staff time was required to assemble and mail HIV testing kits, resending kits as needed, as well as time spent texting reminders to participants to return their saliva specimens. Throughout implementation of the pilot SMART, we refined standard operating procedures for ensuring timely completion of mail-in HIV testing and delivery of reactive HIV results. Although mail-in HIV testing with a US $25 incentive was feasible and acceptable in this pilot SMART, conducting rapid HIV self-testing during the enrollment visit over Zoom would have removed operational barriers to completing HIV testing as a prerequisite for randomization. There were routine delays of approximately 6 weeks in receiving HIV test results from the laboratory. Because nonreactive HIV results were required prior to the randomization visit, these delays may have contributed to the attrition of some otherwise eligible participants during this waiting period.

With the onset of the COVID-19 pandemic in 2020, our team revised the pilot SMART protocol to focus on the telehealth delivery of MI and CM to national sample. Instead of in-person, local sessions, we were able to enroll sexual minority men who use stimulants from over 30 states. Recruiting a national sample also expanded the reach of the pilot SMART to test the potential benefits of delivering telehealth motivational interventions in geographic regions with varying degrees of structural stigma toward sexual minority men and different levels of access to PrEP clinical services. As some of our participants were located in rural areas, many did not have a PrEP provider available within a reasonable traveling distance. This required referrals for web-based PrEP delivery options that were the only source of PrEP access for some participants. Randomized controlled trials are needed to determine whether and how geographic region moderates the effectiveness of telehealth motivational enhancement interventions with this high-priority population.

Although the development and implementation of this pilot SMART have been successful in many ways, we do recognize some limitations. First, the sample size is underpowered because our primary focus was to estimate the feasibility and acceptability of PRISM telehealth motivational interventions. A larger trial is needed to determine the effectiveness of distinct combinations of CM and MI for PrEP use as well as concomitant changes in substance use and CAS. Implementation of mail-in HIV testing also presented some challenges, including delays in the provision of saliva samples and laboratory wait times. Future research should determine the feasibility and acceptability of at-home rapid HIV testing with posttest counseling over Zoom.

Development and implementation of the pilot SMART of the PRISM telehealth motivational enhancement interventions for sexual minority men who use stimulants have afforded our team many successes and learning experiences. Our focus on modification of the MI and CM intervention protocols for telehealth delivery during the COVID-19 pandemic expanded their reach and potential public health impact. We also gained experience with implementing a national recruitment campaign that will guide appropriate resource allocation in subsequent randomized controlled trials. Implementing a waiting period prior to randomization did not meaningfully diminish our randomization rate and highlighted the operational efficiencies of leveraging rapid HIV testing that could be used in subsequent randomized controlled trials. We anticipate dissemination of estimates of feasibility, acceptability, and preliminary effectiveness from the pilot SMART with findings from qualitative exit interviews in the coming year. Lessons learned from this pilot SMART will guide more definitive trials of behavioral interventions to optimize success along the PrEP care continuum with this high-priority population of sexual minority men who use stimulants.

Acknowledgments

This study was funded by the National Institute on Drug Abuse (R34-DA046367; AWC and CG, principal investigators).

Data Availability

The data sets generated during or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

LDE served as project manager and led the writing of the paper. CG and AWC served as project principal investigators and were major contributors to the writing of the paper. RV served as intervention staff and contributed to the writing of the paper. JM served as motivational interviewing trainer and supervisor and contributed to the writing of the paper. SD served as data manager and data analyst for the paper. OV, NO, EC, SC, and MV served as trial staff and editors. SDL served as the scientific advisor for the trial and met with recently diagnosed participants to answer their questions about HIV treatment. INS served as a content expert in sequential multiple assignment randomized trial methods. All authors read and approved the final paper.

Conflicts of Interest

SDL received research support from Gilead Sciences and Merck.

Abstract

Background: In 2020, Greater New Orleans, Louisiana, was home to 7048 people living with HIV—1083 per 100,000 residents, 2.85 times the US national rate. With Louisiana routinely ranked last in indexes of health equity, violent crime rates in Orleans Parish quintupling national averages, and in-care New Orleans people living with HIV surviving twice the US average of adverse childhood experiences, accessible, trauma-focused, evidence-based interventions (EBIs) for violence-affected people living with HIV are urgently needed.

Objective: To meet this need, we adapted *Living in the Face of Trauma*, a well-established EBI tailored for people living with HIV, into *NOLA GEM*, a just-in-time adaptive mobile health (mHealth) intervention. This study aimed to culturally tailor and refine the NOLA GEM app and assess its acceptability; feasibility; and preliminary efficacy on care engagement, medication adherence, viral suppression, and mental well-being among in-care people living with HIV in Greater New Orleans.

Methods: The development of NOLA GEM entailed identifying real-time tailoring variables via a geographic ecological momentary assessment (GEMA) study (n=49; aim 1) and place-based and user-centered tailoring, responsive to the unique cultural contexts of HIV survivorship in New Orleans, via formative interviews (n=12; aim 2). The iOS- and Android-enabled NOLA GEM app leverages twice-daily GEMA prompts to offer just-in-time, in-app recommendations for effective coping skills practice and app-delivered *Living in the Face of Trauma* session content. For aim 3, the pilot trial will enroll an analytic sample of 60 New Orleans people living with HIV individually randomized to parallel NOLA GEM (intervention) or GEMA-alone (control) arms at a 1:1 allocation for a 21-day period. Acceptability and feasibility will be assessed via enrollment, attrition, active daily use through paradata metrics, and prevalidated usability measures. At the postassessment time point, primary end points will be assessed via a range of well-validated, domain-specific scales. Care engagement and viral suppression will be assessed via past missed appointments and self-reported viral load at 30 and 90 days, respectively, and through well-demonstrated adherence self-efficacy measures.

XSL•FO
RenderX

Results: Aims 1 and 2 have been achieved, NOLA GEM is in Beta, and all aim-3 methods have been reviewed and approved by the institutional review board of Tulane University. Recruitment was launched in July 2023, with a target date for follow-up assessment completion in December 2023.

Conclusions: By leveraging user-centered development and embracing principles that elevate the lived expertise of New Orleans people living with HIV, mHealth-adapted EBIs can reflect community wisdom on posttraumatic resilience. Sustainable adoption of the NOLA GEM app and a promising early efficacy profile will support the feasibility of a future fully powered clinical trial and potential translation to new underserved settings in service of holistic survivorship and well-being of people living with HIV.

Introduction

Background

Trauma, violence, and survivorship are often closely intertwined for people living with HIV [1-4]. Among people living with HIV, posttraumatic stress disorder (PTSD) prevalence has been estimated at 28% worldwide [5]. Women living with HIV endure PTSD at rates as high as 35% (nearly 10 times the estimated national prevalence among adults in the United States) [5,6], with up to 97.1% reporting lifetime trauma histories in clinic-based samples [7], including cumulative adverse childhood experiences [8,9]. Early-life adversities are often compounded by syndemic food insecurity [10,11]; poverty [12]; and chronic prolonged exposure to relational, sexual [1,2,13,14], and community violence [15], particularly among Black people living with HIV, who are diagnosed at 22 to 33 times the rate of White American individuals [16]. Among seropositive young Black men who have sex with men enrolled in the Chicago-based Project nGage, which studied personalized social support as facilitator of antiretroviral therapy (ART) adherence, 40% had a close friend or relative die in violent circumstances; most had endured secondhand violence exposure—hearing gunshots (78%) and witnessing a physical assault (59%) [17]. Indeed, the syndemic effects of chronic violence exposure are often multiplicative, compounding, and disruptive to HIV continuum of care (CoC) maintenance, particularly among Black people living with HIV and men who have sex with men [18].

The daily toll of survivorship (regardless of formal PTSD diagnosis) is considerable for violence-affected people living with HIV [18]. Somatoform symptoms, including headaches, muscle ache, sexual discomfort, and fatigue, lacking “organic” etiology [19,20], can affect people living with HIV with trauma histories [5,21]. Continuous community violence, even endured vicariously, can represent a chronic environmental stressor, leading to self-isolation, collapse of social support networks [18], and persistent avoidance of trauma-related settings [1,5,18]; these can include clinical care sites for people living with HIV [1,4], with implications for dropout from the HIV CoC and reluctance to engage in clinic-based social support [8]. Approximately half (48% [22]) of people living with HIV in multisite samples show diagnosable substance use disorder (SUD), the foremost predictor of poor CoC retention [23]. SUD can represent a form of maladaptive coping, which is especially burdensome for violence-affected people living with HIV. In clinic-based samples, high PTSD symptom burden can increase the likelihood of opioid misuse (adjusted odds ratio 1.55, 95% CI 1.31-1.83); hazardous alcohol use (adjusted odds ratio 1.28, 95% CI 0.07-1.52) [24]; and, among New Orleans people living with HIV, membership in heavy-drinking alcohol use typologies [25]. Comorbid PTSD, depressive symptoms, and SUD interact to drive sexual transmission risk behaviors and derail CoC milestones [13,23], incurring risk of individual virologic rebound and immunologic dysfunction [26-28] and endangering population-level, treatment-as-prevention goals [29]. These entanglements of violence, traumatic stress, and biobehavioral sequelae suggest the need for closely tailored, trauma-informed interventions to support both proximal psychosocial and distal CoC goals for violence-affected people living with HIV remains acute.

Among the limited range of trialed interventions that target people living with HIV–specific violence exposure, trauma symptoms, and related sequelae [2,30] in service of CoC and adherence end points, *active, effective (also known as adaptive) coping* has emerged as a key mechanism of action able to mediate intraindividual pathways from lifetime, violence-induced traumatic stress to SUD and sexual risk [1,2,4] and facilitate posttraumatic growth [31,32]. The 15-session group intervention *Living in the Face of Trauma* (LIFT) is exemplary of such an approach [9,33]. LIFT, and the specific coping skills it aims to impart, is grounded in the cognitive theory of stress and coping (CTSC) [33,34]. The CTSC, in translation to an intervention model, recognizes 2 types of coping: “problem-focused” coping—strategies that aim to change or proactively manage a stressor (recognizing it as *changeable*)—and “emotion-focused” coping—strategies that aim to exert control over an emotional reaction to a stressor (acknowledging that it is *unchangeable*) [35]. Examples of the former include structured problem-solving skills, whereas the latter can include techniques such as cognitive restructuring, a technique to challenge and dismantle automatic thoughts such as dwelling on single negative details, which can undermine

XSL•FO
RenderX

self-efficacy and self-esteem [33]. LIFT, notably, is not a PTSD treatment [33]. Among violence-affected people living with HIV, these adaptive coping strategies are meant to reduce the burden of posttraumatic stress, interrupting automatic recourse to maladaptive strategies such as hazardous alcohol use and, by extension, mitigating forward HIV transmission risk behaviors such as ART nonadherence and CoC dropout [8,13,23,33,34].

In an early randomized controlled trial (RCT) among mostly Black (68.6%) people living with HIV with histories of childhood sexual abuse, 40% of whom surpassed Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, diagnostic thresholds for PTSD, LIFT demonstrated clinically significant improvements in intrusive symptom burden [34] and reduction in avoidant coping styles and traumatic stress symptoms longitudinally [36]. A theoretically grounded, Centers for Disease Control and Prevention "Best Evidence"–designated intervention [37], LIFT has been adapted to meet the needs of South African women living with HIV [38] exhibiting exceedingly high (≤76.6%) sexual abuse prevalence, leading to statistically significant reductions in avoidance and hyperarousal symptoms of PTSD and improved ART adherence motivations at the 3-month follow-up in exploratory outcome analyses. However, a group session component was poorly attended, a challenge that the investigators attributed to participant concerns about privacy, stigma, and transportation logistics [39]. The preliminary short-term success of this adaptation, *Improving AIDS Care after Trauma*, points to the "innovation adaptability" of LIFT [40] and to the attunement of its core components to the needs of people living with HIV across high-incidence, resource-constrained settings.

Orleans and Jefferson Parishes, which constitute the New Orleans metropolitan area, Louisiana, were home to 7048 people living with HIV in 2020, a rate of 1083 per 100,000 population—2.85 times the US national rate [41]. With the second highest 2019 Gini coefficient (0.6) in the United States [42] and Louisiana routinely ranked last in national indexes of health care and income equality [43], the New Orleans 2019 murder rate (30.7 per 100,000) was 5 times the national average [44]. Contemporary findings from the *New Orleans Alcohol Use in HIV* study show that an in-care cohort of New Orleans people living with HIV survived an average of 3.5 adverse childhood experiences (vs 1.6 nationally) [45], with 21.2% obtaining high (>3/5) PTSD scores on the *Primary Care PTSD Screen for the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* [46]. Disparate exposure to high-density alcohol outlet environments is conducive to harmful SUD-consistent consumption patterns and depressive symptoms among New Orleans people living with HIV [45], reinforcing previous research implicating place-based drivers of CoC dropout [47,48]. In short, Greater New Orleans presents a setting in which syndemic HIV, traumatic stress, and violence exposure burden may be amenable to accessible coping skills interventions tailored for people living with HIV.

Study Objectives

This study aims to develop, pilot, and refine *NOLA GEM*, a smartphone-delivered LIFT adaptation informed by within-person geographic ecological momentary assessment (GEMA) data on time-variant stressors and symptom profiles among violence-affected people living with HIV in New Orleans [49]. Mobile health (mHealth) and internet-delivered interventions that activate evidence-based, trauma-informed psychotherapies have shown promise in enacting clinically significant PTSD improvement [50,51], with a 2018 Cochrane review pointing toward opportunities to bolster the evidence base and calling for closer attention to mechanisms of change [52]. The benefits of mHealth in advancing CoC milestones are well established [53,54], although innovations in cultural and contextual tailoring are urgently needed to ensure sustainability [55-57]. These benefits can be augmented by in-app geospatial awareness, building on prior work that leverages GPS to (for example) alert mHealth users to the proximity of HIV and sexual and reproductive health clinics [58,59] or, in contrast, use real-time GPS coordinates to (1) describe routine activity paths and (2) apply this geospatial awareness at a hyperlocal level to address the potential of spatial-environmental stressors to evoke traumatic stress and drive CoC churn and, alternatively, identify restorative spaces to reduce stress. By developing NOLA GEM, we engage these opportunities to advance the field; meet the needs of New Orleans people living with HIV [41,45,46]; and address the nonlinear, holistic nature of traumatic stress [1,2,4,8] by delivering effective coping skills education and reinforcement in real time [33].

We will engage these objectives via the following specific aims:

1. *Aim 1*: conduct GEMA with violence-affected people living with HIV to (1) describe activity spaces associated with CoC and (2) assess potential mediated pathways through mood, mental health, substance use, trauma cognitions, and coping to inform novel intervention targets.
2. *Aim 2*: develop NOLA GEM, an mHealth LIFT adaptation, incorporating GEMA-informed mediators of well-being tailored for New Orleans people living with HIV.
3. *Aim 3*: test the feasibility, acceptability, and preliminary efficacy of the NOLA GEM app against GEMA alone on primary CoC (care engagement, ART adherence, and viral suppression) and secondary mental well-being end points.

Throughout, we use "NOLA GEM" to refer exclusively to the app that was developed in aim 2 to record GEMA data and deliver adapted LIFT intervention content.

Methods

Overview

NOLA GEM was developed through a multiphase National Institute on Alcohol Abuse and Alcoholism–funded pilot (R34AA028961) applying GEMA (*aim 1*)- and in-depth interview (*aim 2*)–derived insights to adapt LIFT to a just-in-time adaptive mHealth modality [60,61]. Aim 1 was launched in March 2021 and closed out in September 2021 (although aim 1 eventually recruited a sample of 89, owing to scheduling constraints, a subset of 49 informed intervention development). Aim-2 interviews were conducted in March 2022 and April 2022. This study protocol recounts the concurrent triangulated aim-1 and aim-2 analyses, their findings, and the consequent development of NOLA GEM and describes the

XSL•FO
RenderX

design and conduct of the acceptability, feasibility, and preliminary efficacy (*aim 3*) trial. Throughout, we adhered to the SPIRIT (Standard Protocol Items: Recommendation for Interventional Trials) guidelines [62] as modified for pilot and feasibility trials [63].

Aim 1: GEMA

Overview

A GEMA approach triangulates conventional ecological momentary assessment (EMA) methods, in which repeated assessments of participants' cognitions, affect, behaviors, and biomarkers (eg, salivary cortisol [64]) are taken at multiple daily intervals, contextualized by GPS coordinates [49,65]. Through GEMA, recall bias is mitigated, and naturalistic spatiotemporal influences on individual health can be inferred [65]. It is particularly well suited for detecting context-specific environmental stressors and facilitators of individual resilience [66,67]. Using GEMA, aim 1 intended to describe *activity spaces*, the spatial configurations in which routine events occur with characteristic rhythms [68,69] associated with durable within-person patterns (both risk markers and risk buffers) of adherence and care among people living with HIV in New Orleans. Particular attention was paid to detecting potential mediated pathways via mood, mental health, substance use and misuse, trauma cognitions, coping skills, and domain-general self-efficacy variables, indicating the potential to operationalize these constructs as intervention touch points or proximal outcomes [70,71].

A small observational pilot of the GEMA method was reported by Theall et al [66]. Detailed methods and full (N=89) aim-1 GEMA findings are forthcoming.

Study Setting

As a nested, microlongitudinal study, aim 1 recruited and used the baseline and medical record data of a subset of participants already enrolled in the New Orleans area longitudinal *New Orleans Alcohol Use in HIV* cohort study [72,73]. This parent study recruited through the HIV outpatient clinic of a large university-affiliated medical center at which approximately 50% of New Orleans people living with HIV receive care.

Participants and Procedures

Inclusion criteria for the parent study (N=365) included age of ≥18 years, documented HIV serostatus, and being in care at an HIV specialty clinic; any patient experiencing an acute illness within the previous 6 weeks, acute intoxication, or pregnancy was excluded, with the option to participate once the then-acute medical issue was resolved. Enrolling a longitudinal cohort, the *New Orleans Alcohol Use in HIV* study's primary aims are to advance clinically actionable knowledge on the biological mechanisms and socioenvironmental drivers of HIV- and alcohol-related comorbidities [72,73]. Details of the parent study protocol are available in Appendix 1 of the study by Welsh et al [72]. For the sake of aim-2 intervention development, aim 1 recruited people living with HIV (n=49; a limited subsample because of scheduling delays incurred during the recovery from 2021 Hurricane Ida) on ART who either self-reported a personal history of violence or lived in a high-violence neighborhood in the parent study. These "either/or" multilevel eligibility criteria were formulated pragmatically to ensure sufficient statistical power. History of violence criteria included reporting childhood physical or sexual abuse or physical assault as an adult or endorsing moderate to high stress because of neighborhood crime and family or relational violence. Living in a high-violence neighborhood was defined as the respondent's residential Census tract having violent crime rates at or above the 75th percentile for violent crime rates for tracts within Orleans Parish. According to these criteria, 96% (47/49) of the sample indicated an individual personal history of violence exposure, with 4% (2/49) endorsing tract-level violence exposure exclusively. Parent study participants who met the inclusion criteria were contacted initially by phone after randomizing the order in which outreach was conducted. If interested, they were asked to schedule a 1-hour dedicated baseline appointment at which informed consent procedures were undertaken, a baseline assessment was conducted using REDCap (Research Electronic Data Capture; Vanderbilt University) [74], the daily diary EMA measures were reviewed for comprehension, and a GPS app was installed on participants' smartphones. Eligible people living with HIV who did not possess a smartphone were provided one by study staff. Once enrolled, daily diary and geospatial tracking data were collected for each individual over a continuous 14-day daily diary survey period.

The 49 aim-1 participants whose GEMA responses informed intervention development recounted a range of lifetime violence exposures at baseline: 24 (49%) recounted childhood domestic violence, 18 (37%) recounted childhood sexual assault, 26 (53%) recounted physical assault in adulthood, 20 (41%) recounted current crime and violence exposures, and 9 (18%) recounted current intrafamilial violence. Screener responses suggested a range of potential mental health challenges: of the 49 participants, 13 (27%) had borderline or clinical PTSD as defined by the DSM-5, a total of 19 (39%) had borderline or clinical anxiety, and 12 (24%) had borderline or clinical depression. ART nonadherence was reported by 28 (57%). The broader sociodemographic attributes of aim-1 participants are presented in Table 1.

[a]Computed by subtracting the year of HIV diagnosis in the medical records from the present year (2022); 13 participants lacked a recorded year of diagnosis.

[b]In line with the 2-step approach to ascertaining transgender identity in sociomedical research [75], a "current gender" item is included in the follow-up assessments presently underway.

[c]BL: baseline.

Daily Diaries

The daily diary measures, which operationalized the EMA aspect of aim 1, assessed a range of intrapsychic constructs, behaviors, and environmental stressors, combining brief prevalidated scales with novel study-specific measures. Participants were prompted by SMS text message and asked to complete the daily diary measures within a 3-hour window 3 times daily: 8 AM to 11 AM, 1 PM to 4 PM, and 7 PM to 10 PM Central Time Zone. Qualtrics (Qualtrics International, Inc) hosted the survey measures and administered the preprogrammed SMS text message prompts [76].

The daily diary measures for aim 1, with sample items, is shown in Multimedia Appendix 1.

Geospatial Tracking

At aim-1 baseline appointments, participants were guided through the installation of Actsoft Encore GPS-tracking app [77]. Throughout each individual's 14-day daily diary survey period, Encore captured longitudinal and latitudinal coordinates at 1-minute intervals when moving and 1-hour intervals when stationary (for aim 3, the NOLA GEM app itself will deliver daily diaries and record geospatial trajectories). GPS data were stored on a password-protected cloud server. Participant GPS data were then transformed into activity paths at 50-, 100-, and 200-meter buffers using Python (Python Software Foundation)

XSL•FO
RenderX

[78]. Environmental exposures were assessed through the creation of activity paths and interceptions with the 3 buffer sizes. Both static and dynamic environmental exposures were captured. Static data included, for example, annual rates per US Census tract level of exposure such as alcohol outlet density, community violent crime rate, poverty, and concentrated disadvantage. Dynamic data included time-stamped data linked to daily GPS points, including time-incident violent and nonviolent 9-1-1 calls to service data points and police stop-and-frisk calls. Activity path data were then aggregated to be merged with daily diary data for triangulation.

Aim-1 Formative Insights

In the course of exploratory and interim analyses of baseline and daily diary data, a range of environmental stressors with salience to the everyday lives of New Orleans area people living with HIV emerged. The study's original objective was to understand how local spatial exposure and daily experiences may serve as determinants of traumatic stress or retraumatization connected to downstream maladaptive coping behaviors such as alcohol use and consequent patterns of ART nonadherence [79,80]. Our preliminary analyses did not find associations between outcomes related to alcohol use and daily mood across activity path–based spatial alcohol and violence exposure. These null results necessitated a departure from the original aim-1 goal of building generalizable place-based exposures as just-in-time adaptive intervention (JITAI) inputs into the NOLA GEM app. As such, tailoring variables, and the daily diary items through which they were captured in aim 1, were selected based on their overall prevalence at baseline, capturing past and cumulative experiences and associations with key outcomes within individuals on a given day among aim-1 participants. In recognition of the irreducibly idiographic nature of spatial traumatic stress determinants evidenced in this study, an individually customizable geofencing solution was built into the eventual NOLA GEM app (detailed in the *NOLA GEM App* section).

These stressors, with relevant statistics illustrating the rationale for their inclusion as JITAI tailoring variables, are provided in Table 2.

XSL•FO
RenderX

Table 2. NOLA GEM app just-in-time adaptive intervention tailoring variables—description and rationale.

Stressor	Rationale	Sample item or items[a]
Mental health challenges	• 51.22% endorsed "somewhat" or "very" stressful mental health challenges (past 30 days)[b]	• In the past 30 days, how stressful were the following events? You can say "Not Applicable" if you did not experience this event. • Worried about my mental health (not at all, somewhat, a lot)

Financial challenges	• Within individuals on a given day, more financial stress positively predicted[c]:
	  • Mental health worries: β=1.12, SE 0.36
	• Individuals who had greater financial stress over 14 days also had greater[c]:
	  • PTSD[d] symptom burden: β=1.4, SE 0.44
	  • Pain symptom burden: β=2.6, SE 1.24
		• The next few questions ask about difficult events you might have experienced today. Please mark all that you experienced today:
		  • Financial stress
		  • Had a problem with money (yes, no)
		  • Worried about running out of food (yes, no)
		  • Worried about paying rent or getting evicted (yes, no)

Violence: direct	• 57.32% experienced IPV[e] • 31.71% experienced sexual assault (lifetime)[b]	• IPV was measured using the Composite Abuse Scale (Revised)–Short Form [81]. • The following are a couple of difficult or stressful things that sometimes happen to people either in relationships or not. These things can happen with someone you know, like a caregiver or partner, or someone you don't know well like a stranger or acquaintance. • Sexual assault: rape, attempted rape, made to perform any type of sexual act through force or threat of harm (never happened, happened but not in the past 12 months, happened in the past 12 months)
Violence: indirect	• 37.80% heard gunfire • 17.07% experienced or witnessed police violence or intimidation • 14.63% witnessed robbery, assault, or verbal threats (past 30 days)[b]	• In the past 30 days, how stressful were the following events? You can say "Not Applicable" if you did not experience this event. • Heard gunfire (not, somewhat, very stressful) • Experienced or saw police violence or intimidation (not, somewhat, very stressful) • Saw someone get robbed, injured, or threatened (not, somewhat, very stressful)
Violence: posttraumatic stress	• >82.98% experienced ≥1 PTSD symptom (14-day aim-1 study period)c	• How much were you bothered by avoiding thoughts, activities, or feelings about difficult life events that have happened to you? (not at all, a little bit, moderately, extremely; scale adapted from Erwin et al [82])

Social support deprivation	• Within individuals on a given day, reporting no social support predicted[c]:
	  • Mental health worries: β=1.66, SE 0.58
	  • Negative affect: β=.69, SE 0.23
	• Individuals who reported less social support over 14 days also reported more[c]:
	  • PTSD symptoms: β=10.74; SE 2.5
		• The next few questions ask about difficult events you might have experienced today. Please mark all that you experienced today (checklist):
		  • Didn't feel supported by friends/family (yes, no)

Social support deprivation	• Within individuals on a given day, reporting an argument predicted[c]:
	  • PTSD symptoms: β=.97, SE 0.31
	  • Negative affect: β=.59, SE 0.21
		• The next few questions ask about difficult events you might have experienced today. Please mark all that you experienced today (checklist):
		  • Had an argument with a friend, family member, or romantic partner (yes, no)

Internalized HIV stigma	• Within individuals on a given day, more negative feelings regarding HIV were positively associated with[c]:
	  • Mental health worries: β=1.05, SE 0.36
	  • PTSD symptom burden: β=.25, SE 0.15
	  • Negative affect: β=.31, SE 0.07[c]
		• Since last night/your last diary entry, how have you felt about your HIV status? Check all that apply (checklist):
		  • Ashamed (yes, no)
		  • Stressed (yes, no)
		  • Not as good as other people (yes, no)

XSL•FO
RenderX

[b]Captured at baseline.

[c]Captured via daily diary.

[d]PTSD: posttraumatic stress disorder.

[e]IPV: intimate partner violence.

Aim 2: Intervention Adaptation

Overview

Although GEMA can undergird rich, sophisticated statistical insights on the activity spaces of New Orleans people living with HIV, an overreliance on the "technocratic thrust" of decontextualized mathematical modeling risks overlooking the lived expertise of longtime New Orleanian survivors, with implications for external validity specifically [83,84] and epistemic justice, which is broadly defined as affording appropriate credibility to the knowledge- and sense-making practices of structurally marginalized groups such as people living with HIV [80,85]. As such, aim 2 recruited a subcohort of people living with HIV (n=12) enrolled in aim 1 to contribute their insights on stress, coping, and survivorship via in-depth interviews. This phase aimed to adapt LIFT in a manner that (1) activated the unique, uniquely powerful value propositions of mHealth [51,53,54,86] and (2) interlocked GEMA-derived intervention touch points with the core components of an extant evidence-based intervention (EBI) logic [33,34,36-39] while (3) recognizing the singular cultural and historical context of HIV survivorship in contemporary New Orleans. As such, aim 2 embraced principles of *design justice*, which call for a nonhierarchical, nonexploitative stance toward engaging the lived expertise of local communities [87] while leveraging the pragmatic, product-focused toolkit of *Lean User Experience*, which emphasizes an accelerated, iterative build-measure-learn approach to software development [88].

By invoking principles of epistemic and design justice, we aimed, in practice, to learn about and integrate community perspectives, needs, and especially strengths into the functionality of NOLA GEM [89]. This resulted in JITAI tailoring variables closely attuned to the needs of—and intervention content and proximal outcomes that reliably tap into the inductively derived strengths of—longtime violence-affected HIV survivors in New Orleans as "socially embedded, socially situated" community members [90]. In line with Jaworski et al [91] and Maestre et al [92], we synthesized mixed methods–derived insights in a manner calibrated to (1) appreciate local, culturally congruent nuances in our constructs of interest; (2) understand the precise conditions in which digital tools are used (and not used) among New Orleans people living with HIV; and (3) foreground coping focally and emotional well-being broadly as determinants of distal biomedical outcomes such as virologic control while calling on an extant EBI [33,34,36-39]. This approach is in line with core design justice principles, specifically design intentions committed to healing, sustainment, and empowerment; the catalyzation of people living with HIV end users' lived expertise with formal design techniques; and, in particular, embracing "what is already working," both via an adaptation of a demonstrated EBI and by incorporating aim-2 participants' own drivers of survivorship and resilience while respecting users' personal beliefs and local knowledge [87].

LIFT Intervention

Overarchingly, LIFT activates the CTSC, relying on that theory's distinction between problem- and emotion-focused coping [33-35]. Through this lens, a range of adjunctive coping skillsets is taught, practiced, and discussed by group members in the course of a LIFT implementation in the field. These include breathing awareness and retraining, mindfulness meditation, journaling and distinguishing problem- versus emotion-focused and adaptive versus maladaptive coping styles, setting attainable personal goals, and surmounting common trauma cognitions (eg, all-or-nothing thinking). Theoretically grounded details of their precise trauma-informed mechanisms of action are provided by Sikkema et al [9,34,36] and in the *LIFT Manual* (hereafter, the *Manual*) [33]. The essentials of integrating each skillset into a LIFT participant's daily life are reinforced through a range of skillset-specific handouts (eg, "Handout 4: Guidelines for Journal Writing"). The content of the NOLA GEM app was adapted by combining the *Manual*'s facilitator notes, sample (facilitator) scripts, and handouts [33]. In resituating the provision of this skill-building content from an in-person sequential group modality to a smartphone-delivered just-in-time modality, we envisioned use cases in which, for instance, the stress of hearing gunshots in the morning could be ameliorated via real-time access to breathing awareness or journaling (both emotion-focused coping skills per the CTSC [35]), interrupting the possibility of resorting to maladaptive coping strategies such as alcohol misuse.

JITAI Approach

A JITAI provides individually tailored intervention content precisely when needed, typically by tapping into the key affordances of smartphone-based models of delivery. Key elements of a JITAI include decision points, the time points at which the precise provision of intervention content is decided; tailoring variables, the data inputs that determine the nature of the intervention content offered; and decision rules, which embed the logics of tailoring variables at each prespecified decision point [60,61]. The end points of a JITAI logic are *proximal* (or short-term) outcomes, typically mediators of an intervention's ultimate *distal* outcomes [60]. JITAIs have been reliably demonstrated to drive significant improvements across behavioral health domains in pretest-posttest trials and against waitlist, inert, and active controls [93].

Semistructured Interviews

To attain a balanced age distribution, aim 2 planned, initially, to recruit 5 to 10 participants from two studies: (1) the parent *New Orleans Alcohol Use in HIV* cohort (age range 18-65 years [72,73]), whose participants' ages were concentrated in middle adulthood (median 50, IQR 41-56 years), and (2) the adolescent and young adult–focused Adolescent Medicine Trials Network

XSL•FO
RenderX

for HIV/AIDS Interventions cohort (age range 12-24 years [94]; aim 2 planned to recruit participants aged ≥18 years exclusively). Ultimately, we were only able to enroll participants (n=12; mean age 57.83, SD 10.12 years; 58.33% Black and 75% male) from the parent longitudinal study [72]. Interviews ranged from 34 minutes, 31 seconds to 1 hour, 32 minutes, 18 seconds in length. Participants were given the option of a Zoom (Zoom Video Communications)-conducted [95] versus an in-person interview; 2 preferred Zoom. Adherent to the Tulane University Health Sciences Center COVID-19 control protocols then in place, all participants were required to bring proof of vaccination. Interviewers, who conducted the interviews in pairs, and participants remained masked at all times. Data collection proceeded subsequent to a verbal informed consent script.

The sociodemographic attributes of the aim-2 participants are shown in Table 3.

Table 3. Aim-2 participant (n=12) sociodemographic attributes.

Characteristics	Values
Age (years), mean (SD)	57.83 (10.12)
Years living with HIV, mean (SD)[a]	26 (7.93)
Sex assigned at birth, n (%)[b]	
Female	3 (25)
Male	9 (75)
Racial and ethnic identity, n (%)	
Black or African American, non-Hispanic	7 (58)
Native Hawaiian and Pacific Islander, non-Hispanic	0 (0)
White non-Hispanic	4 (33)
White Hispanic	1 (8)
Sexual identity, n (%)	
Heterosexual or straight	5 (42)
Gay or lesbian	5 (42)
Bisexual	2 (17)
Household income (US $) in the past year at BL[c], n (%)	
<20,000	8 (67)
20,000-39,999	2 (17)
40,000-59,999	1 (8)
60,000-84,999	0 (0)
≥85,000	1 (8)
Housing at BL, n (%)	
Single-family dwelling	9 (75)
HIV-specific group facility	2 (17)
Homeless or shelter	1 (8)
Homeless (lifetime), n (%)	7 (58)
Incarcerated (lifetime), n (%)	6 (50)

[a]Computed by subtracting the year of HIV diagnosis in the medical records from the present year (2022); 2 participants lacked a recorded year of diagnosis.

[b]In line with the 2-step approach to ascertaining transgender identity in sociomedical research [75], a "current gender" item is included in the follow-up assessments presently underway.

[c]BL: baseline.

Interviews were semistructured in format and mixed methods interpretivist in orientation [83]. Initially, participants were prompted to designate how helpful they would find the skillsets offered by LIFT and a range of potential mHealth modalities (eg, SMS text messages or games) on a 4-point forced-choice Likert-type scale. The aim-2 sample was LIFT naive; the particular coping skillsets were introduced via brief interviewer-administered synopses (eg, "When managing daily stress related to life with HIV, how helpful would you find breathing retraining or finding different ways to breathe?"), with scripted in-depth definitions abstracted from the *Manual* available as needed (eg, "The way we breathe can affect the

XSL•FO
RenderX

way we feel. Daily stress and anxiety can change the way we breathe and keep us feeling stressed. Breathing retraining describes ways we can adjust our breathing to help us relax when managing everyday stress"). Unstructured probes reflecting interviewees' own language wherever possible elicited further detail on within-person patterns of successful coping grounded in the lived experiences of violence-affected people living with HIV in New Orleans. In addition, participants were asked to describe stress-inducing and reliably calming places and personal histories of violence, spirituality, relationships, drugs, and alcohol. A series of items grounded in design justice principles [87] prompted participants to reflect on the idiographic influences of their gender, ethnoracial and cultural heritage, and ability or disability on (1) their preferred stress management techniques and (2) the ways in which they interact with and selectively disengage from digital technologies. Each interview culminated in an adapted think-aloud exercise calling upon tenets of human-centered design [96,97] in which participants were reminded of the LIFT skillsets and mHealth modalities that they had previously considered "helpful" or "very helpful" and of particular stressors that they had characterized as "able to throw [their] whole day's plans off track," incite drug and alcohol misuse, or disrupt ART adherence. Aiming to encourage creative leaps [96] while eliciting context-specific JITAI dynamics rooted within the life worlds of New Orleans people living with HIV, participants were asked to narrativize precisely how their preferred LIFT skillsets would aid their coping through their most acute stressors, with impromptu probes (whenever possible) articulating details of their ideal mode of smartphone-based delivery. All interviews were audio recorded using a Sony ICD-PX470 digital voice recorder and transcribed verbatim.

Aim-2 Analysis

The qualitative analyses were subdivided into two phases, each with a dedicated intervention adaptation purpose:

1. A rapid inductive analysis dedicated to identifying *contender proximal outcomes*, a JITAI-specific construct that describes measurable potential mediators on the causal pathway to attaining *distal* (ie, our primary) outcomes.
2. A coding reliability thematic analysis dedicated to identifying survivorship and resilience themes, which would guide the adaptation of manualized LIFT worksheets into in-app NOLA GEM content responsive to the experiences of violence-affected New Orleanian people living with HIV. These themes were not operationalized as potential mediators but, rather, served to prioritize elements of the *Manual* to retain in the necessarily briefer NOLA GEM multimedia content.

The app development timeline necessitated this subdivision. Programming operationalized contender proximal outcomes as "SkillCheck" quizzes (described later in this paragraph) was an early, urgent development milestone, whereas in-app content adaptation could occur on a more generous, investigator-initiated schedule. The analytic procedure of the first phase of aim 2 relied, first, on a variant of rigorous and accelerated data reduction, a rapid matrix analysis technique [98]. Coders (n=7) condensed each interview into its richest, most salient excerpts using matrices in Microsoft Excel (Microsoft Corp) [99]. Independently, each coder inductively developed first-cycle ("open" in grounded theory terminology) descriptive, process, and in vivo codes [100]. Concurrently, each coder, consistent with a causation coding approach [100], identified contender proximal JITAI outcomes—inductively derived potential mediators of the NOLA GEM intervention's predetermined distal outcomes [60,61]. The first author (SJS), in collaboration with LVH, synthesized these initial codes and contender proximal outcomes into second-cycle ("axial") codes. These contender proximal outcomes were then preliminarily operationalized as "SkillCheck" quizzes, which would be provided to end users upon completion of prespecified units of intervention content (a process that is detailed in the *Intervention Design* section).

Subsequently, in the analysis in the second phase of aim 2, the second-cycle coding schema and complete interview data set were migrated to Dedoose (SocioCultural Research Consultants) [101]. In Dedoose, 3 coders, accompanied by the first author (SJS), pilot coded randomly selected full transcripts masked to each other's coding applications, resolved coding discrepancies, and refined the final codebook in conference until a pooled intercoder reliability of κ=0.78 was achieved [102]. After obtaining acceptable intercoder reliability, the balance of transcripts was coded independently (KS, LVH, and MBS).

Aim-2 Formative Insights

A total of 10 contender proximal outcomes were detected through the rapid matrix analyses in the first phase of aim 2. These constructs and the SkillCheck items used to operationalize them as potential mediators are provided in Textbox 1.

Building on the insights from the first phase of aim 2, refined survivorship and resilience themes, with 2 nested subthemes, were detected across the inductive analyses in the second phase of aim 2. Methodologically, we generated second-cycle pattern codes, formatted as process codes, which rely on gerunds to (consistent with dynamic JITAI logics [60]) "imply actions intertwined with the dynamics of time" [100]. The complete set of themes, subthemes, definitions, and illustrative excerpts is provided in Table 4.

XSL•FO
RenderX

Textbox 1. Formative results of the first phase of aim 2—proximal outcomes and SkillChecks. All response options were 4-point forced-choice Likert scales ("strongly agree" to "strongly disagree") in format. Although the phrase Please rate your agreement with the following statement recurs in each SkillCheck, we omitted it from subsequent textbox examples to avoid needless duplication.

Strengthened grounding skills

- "Grounding" refers to focusing on our own bodies, how they occupy time and space, to reclaim our minds from unpleasant thoughts or feelings.
- *Please rate your agreement with the following statement*: This skill helped me: *build grounding into my everyday life*.

Strengthened healthy routines

- Healthy routines that reflect our authentic selves, interests, and practical wisdom can keep our minds occupied and self-care needs met.
- This skill helped me: *build healthy routines into my everyday life*.

Strengthened positive social bonds

- Having a few go-to people in our lives ready to listen and support us through a rough day is essential to our well-being.
- This skill helped me: *take steps toward building a supportive social circle into my everyday life*.

Strengthened awareness of spatial triggers

- Certain parts of the city—certain neighborhoods, corners, bars, or parks—can cause sudden painful memories or unpleasant feelings.
- This skill helped me: *think through certain spaces and places that can trigger my stress*.

Strengthened redirect skills

- "Redirecting" refers to recognizing the unhelpful or hurtful places where our thoughts may be taking us and conscientiously steering our minds in a more meaningful, productive direction.
- This skill helped me: *redirect away from negative coping strategies that arise in everyday life*.

Strengthened insights on self-management capacity

- Being honest with ourselves about the stressful situations that we can handle versus the situations we cannot keeps us out of situations that may compromise healthy decision-making.
- This skill helped me: *better understand the situations I can handle versus those I cannot*.

Strengthened comfort with survivorship disclosures

- It can take great strength to disclose our HIV survivorship, even if it emerges as a source of inner strength or a point of fellowship.
- This skill helped me: *ease stress and build my comfort around disclosing my HIV survivorship*.

Strengthened help-seeking capacity

- It can take self-honesty to admit when we need help sometimes, and reaching out to others when in need can be even harder.
- This skill helped me: *build my comfort in reaching out to others when I need help*.

Strengthened forgiveness skills

- It can take wisdom to let go of resentment, forgiving ourselves and others for past decisions that may have been hurtful or mistaken.
- This skill helped me: *build my ability to forgive myself and others*.

Strengthened insights on spirituality and well-being

- Deeper understandings of the mind, the soul, spirituality, and meditation often guide us away from unpleasant thoughts and feelings whether we consider ourselves religious or not.
- This skill helped me: *connect my inner life with my own day-to-day well-being*.

XSL•FO
RenderX

Table 4. Formative results of the second phase of aim 2—themes, definitions, and illustrative excerpts.

Theme	Definition	Example[a]
Accepting and adapting	Captures any instances in which participants describe accepting difficult or nonoptimal life circumstances, typically through processes of self-reflection or recognition of the limits of control over one's life and its trajectory	"I'm the kind of person that can adapt to really anything. I would have maybe a little hissy fit at first, but I do cope with change well. And I just move on because that's really all you can do in life." [Participant M; Black male individual[b]; aged 42 years[c]]
Accepting and adapting (*self-reflecting*[d])	Captures specific, explicit mentions of the self-reflective processes that facilitate accepting and adapting	"I have made some mistakes, but that's history. They've been paid for, squashed. But you can reflect on that. It's like, 'Mm-hmm [affirmative].' Just, you move on. Be happy about what you do, where you're at. That's the way I look at it." [Participant R; White male individual; aged 63 years]
Affirming shared experience	Subsumes any mentions of forging social bonds regarding shared histories or experiences in common, often emphasizing learning and problem-solving	"Sometimes you just want to be by yourself and think things out. But sometimes, it's also very helpful because you talk with somebody and you're realizing, they have the same situation, and they do something that might help them and you're open to try something else and maybe might help you." [Participant H; White female individual; aged 54 years]
Cultivating spirituality	Captures any mention of the role of self-evolved, personal, idiographic modes of spirituality as preferred or relied-upon modes of coping; spiritual aspect must be explicit	"Well, I pray all the time. Not all the time, but frequently all day long. Just to stay calm. Help me stay calm. Not that I'm stressed out much, but [prayer] help me not get a tone." [Participant F; White male individual; aged 65 years]
Embracing routine	Subsumes mentions of carrying out repeated, cadenced tasks or rituals to occupy the mind and body, typically emphasizing the stress mitigation aspect thereof	"I get up every morning and I clean my whole neighborhood stores up, the laundromat. They don't pay me. I just walk and do it. And they've just been a routine all my life." [Participant U; Black female individual; aged 70 years]
Enacting boundaries	Subsumes acknowledgments that restricting or eliminating contact with select individuals is protective of emotional, spiritual, and physical well-being; relational-interpersonal aspect must be explicit	"Just the idea of waking up being among the living, had something to do to pay attention other than being 'round people with bad influence, making you do something that you regret doing, or make your regret doing something they want you to do [to] satisfy them...why should I make myself miserable just to be your friend, knowing I'm going to pay for it?" [Participant I; Black male individual; aged 58 years]
Finding fellowship	Captures any mention of community as continuity and community as facilitating coping; includes faith communities, organized religion, and social bonds formed therein	"The rest of my relationships and the relationships in my life, they add bits and pieces to help my mental health basically, like talking to friends and when I need to vent, venting to my sisters...Like, 'Hey, I got an issue. Hey, how would you do this, or let me bounce this off of you so I can understand where I'm coming from,' or something like that." [Participant Z; Black male individual; aged 39 years]
Regulating impulses	Subsumes mentions of conscientiously recognizing, confronting, minimizing, or extinguishing impulsive urges and behaviors	"I've experienced violence twice. I witnessed it on somebody else, and I made cognitive decisions that my partner is not going to have to deal with what my friend was dealing with his partner. And my coping mechanism is silence. Just silence. I just, rather than pop off and say things you regret later, I'll just shut down." [Participant E; White male individual; aged 67 years]
Regulating impulses (*rejecting substances*)	Subsumes instances of impulse regulation specifically, explicitly related to overcoming hazardous alcohol and drug use behaviors	"Because I used to use drugs about four years ago. Alcohol too. When I got rid of that, because when I got into my spirituals, I took away the alcohol and the desire for drug." [Participant O; Black male individual; aged 60 years]
Self-soothing	Captures any instances in which healthy, adaptive activities chosen or routinely undertaken to minimize stress and exposure to stressors are described	"Pray. Little deep breaths, calm myself down, talk to myself 'Calm down, don't don't let it get to you.' Give myself my own little pep talk. Calm down, whatever. And just go and hang out with my grandkids and that's destressed right there." [Participant H; White female individual; aged 54 years]
Staying situationally aware	Captures any mention of vigilance with regard to one's surroundings, often emphasizing the potential for violence (inclusive of law enforcement–enacted violence); spatial aspect must be explicit	"Well, [participating in GEMA] brought me to the point to be more observative...that really made me pay attention. Is you in drug free zone? Is it easy to get alcohol? Is it easy to get drug? And when I read those things, that made me alert not to go to those places because I know if I go around some of these places...I smell trouble." [Participant I; Black male individual; aged 58 years]

Intervention Design

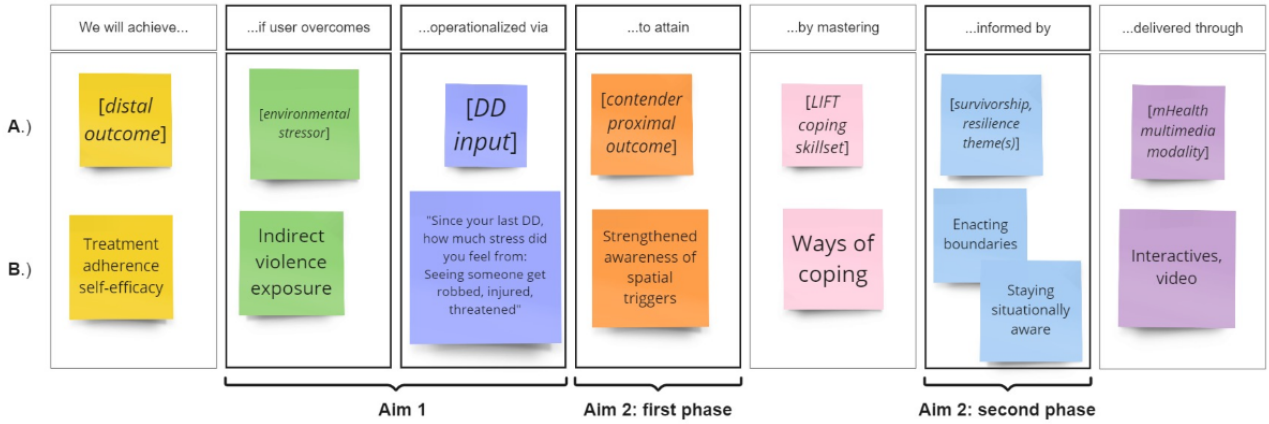
Lean user experience (UX) recognizes the challenge of user-centered outcomes losing focus over the course of complex, multistakeholder technology development cycles—a challenge that is intensified when faced with extant, theoretically grounded EBI logics [33,34]. As such, we called on Lean UX techniques to integrate the full gamut of formative insights cultivated across aims 1 and 2, counteracting the (interrelated) possibilities of stakeholder misalignment or theoretical fragmentation [103] (as an added strength of this approach, Lean UX exists in tandem with the Agile workflows adopted by most contemporary software developers [88]).

Specifically, using the Miro whiteboarding platform [104], we assembled a feature hypothesis chart and conducted a design workshop in which the formative research undertaken to date was organized according to a JITAI-consistent intervention logic [60,61,91]. *Hypothesis* in this context refers to an easily communicable single-sentence association between a user outcome; a software feature; and (in terms by Mohr et al [105]) the usage aims and elements of a behavioral intervention technology logic, whereby each element is positioned as a column header in the feature hypothesis chart. The workshop, facilitated by the first author (SJS) in June 2022, formulated feature hypotheses accordingly: "We will achieve [*distal outcome*] if user can overcome [*environmental stressor* (derived from Aim I descriptives)], operationalized via [*daily diary input* (selected from among Aim I measures)], to attain [*contender proximal outcome* (derived from aim-2 rapid matrix analyses)], by mastering [*LIFT coping skillset* (abstracted from the *Manual*)], in a manner informed by [*survivorship and resilience themes* (derived from Aim IIb thematic analysis)], delivered through [*mHealth multimedia modality*]." All faculty investigators and interviewers (serving as end-user advocates) were present. A mocked-up feature hypothesis chart is shown in Figure 1 [88,104].

Subsequently, these JITAI logics were refined into user story maps, a user experience research technique that uses simple but summative flow diagrams to portray complex in-app interactions and contingencies [88]. An illustrative excerpt of the user story maps that we provided to our developers, Crowdbotics, is shown in Figure 2 (hosted in full resolution [106]).

The complete user story maps, encompassing all possible daily diary–coping skills recommendation–SkillCheck sequences, are provided in Multimedia Appendix 2 (which can be downloaded in full resolution [107]).

Figure 1. (A) Mocked-up feature hypothesis chart displaying column heads representing each element of a theoretically grounded, culturally tailored just-in-time adaptive intervention (JITAI) and (B) a sample JITAI logic tying together formative insights derived from aims 1 and 2. The format was adapted from Gothelf and Seiden, and the graphic was created in Miro. DD: daily diary; LIFT: Living in the Face of Trauma; mHealth: mobile health.



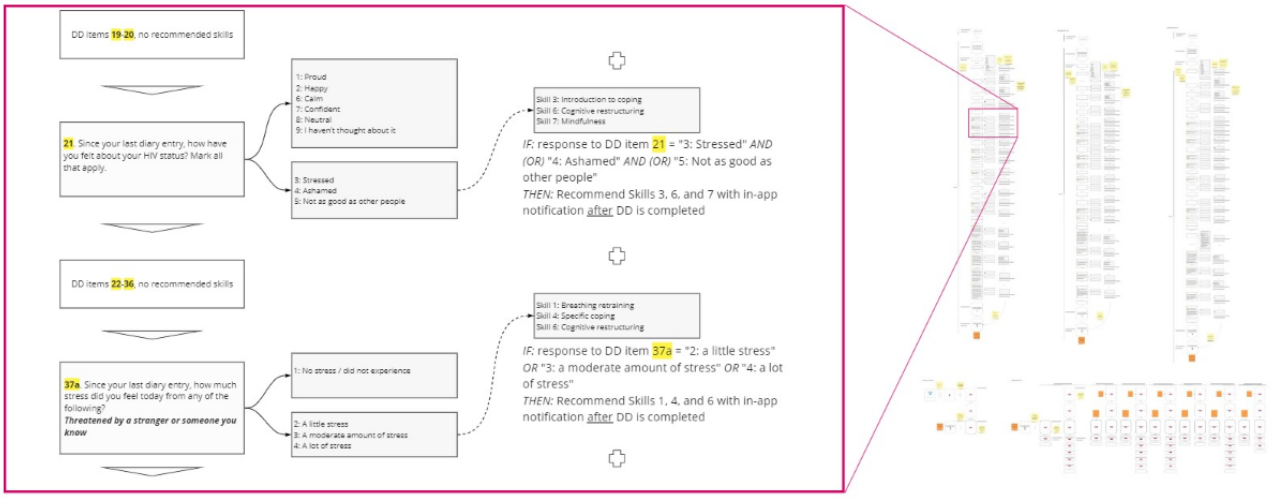


Figure 2. Selected user story map illustrating just-in-time adaptive intervention logic. DD: daily diary.

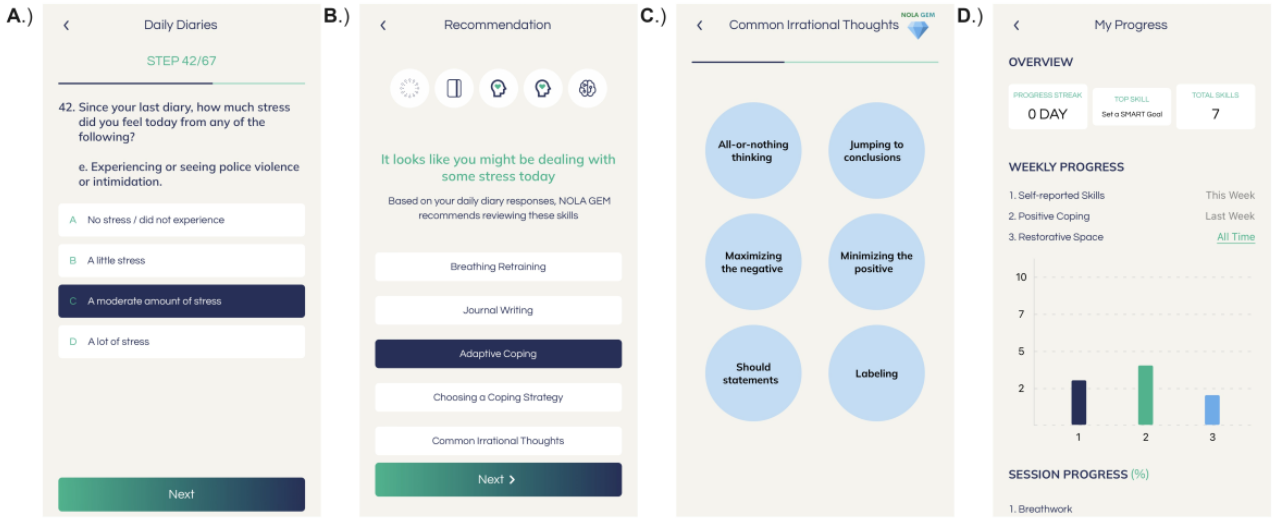
XSL•FO
RenderX

NOLA GEM App



Fundamental to a JITAI adaptation is the determination of (1) tailoring variables; (2) the timely provision of appropriate intervention content, mapped to a plausible contender proximal outcome, at each predefined threshold of a tailoring variable; and (3) clear, succinct, programmable logics defining the mechanisms of (1) and (2) [60,61]. NOLA GEM incorporates a subset of aim-1 daily diary inputs as tailoring variables. On the basis of aim-1 findings, the constructs and environmental stressors that will initialize the NOLA GEM app's JITAI logics are mental health challenges; financial problems; *direct* violence experienced firsthand, such as an assault (with a built-in emergency response management protocol, if warranted); *indirect* violence, witnessed or overheard; *past* violence, resurfaced in the form of intrusive thoughts, memories, or trauma cognitions [82]; interpersonal discord or lack of social support; HIV-related stigma; alcohol-related craving and coping; and a general stress measure, the triggering of which will offer the end user a selection of all LIFT skills.

These stressors are operationalized via the daily diary measures piloted initially in aim 1. If the end user indicates an acute stressor during a daily diary beyond a prespecified cutoff value, they receive an in-app notification after completion of the daily diary inviting them to open a recommended LIFT skill. Should multiple postthreshold stressors be endorsed, the user is given the option to select their preferred LIFT skill. The microcopy of these messages is uniformly strengths-based, encouraging, and nonpathologizing (eg, "It looks like you might be dealing with some stress today. Based on your daily diary responses, NOLA GEM recommends reviewing these skills"). Embedded hyperlinks will automatically launch the recommended LIFT session if a user chooses to. Aiming to minimize "interaction cost," or the cognitive load associated with navigating a user interface [108,109], multifaceted interactivity was largely eschewed in favor of brief, "snackable" content [110] in which practical skills are foregrounded, available in text and audio formats. Each session encapsulates the CTSC-based strategies taught by the manualized LIFT intervention [33,35]. NOLA GEM users are not required to complete each skill within a single session. Upon completion at a user-directed pace, end users are presented with single-item "SkillChecks," which assess the degree to which each LIFT skillset was successfully imparted by the app and operationalize the proximal outcome to which the LIFT session and tailoring variable were mapped on the feature hypothesis chart using dedicated items in a Likert-type format. Structuring SkillChecks in this fashion further reduces interaction costs and permits both knowledge delivery and proximal outcomes to be examined as potentially distinct mediators of distal outcomes in aim 3.

In addition, supplanting the originally envisioned generalized geospatial JITAI triggers [79], NOLA GEM users, during onboarding to the app, can leverage a geofencing feature to prespecify areas or locations that reliably evince stress. With such geofencing established, entering the prespecified area will activate an SMS text message prompt ("It looks like you may be in a stressful place") recommending each user's favored LIFT coping skills. In addition, foregrounding resilience, an option to prespecify a place that end users associate with personal restorativeness is included.

Illustrative screenshots of the NOLA GEM user interface are provided in Figure 3 (hosted in full resolution [111]).

Figure 3. Illustrative screenshots of the NOLA GEM user interface. (A) sample daily diary item, (B) sample just-in-time adaptive intervention prompt, (C) Living in the Face of Trauma skill content, (D) "My Progress" tracker.

Aim 3: Acceptability, Feasibility, and Preliminary Efficacy

Trial Design

The pilot trial will be a single-blind parallel superiority trial assessing NOLA GEM (treatment arm) against GEMA alone (control arm) for a period of 21 days, allocated at a 1:1 ratio. In contrast to aim 1, the NOLA GEM app is capable of delivering SMS text message–linked daily diaries and recording GPS coordinates without recourse to third-party software. The GEMA-alone control was chosen to control for any intervention effects of recording daily mood, experiences, and other psychosocial variables as some research has demonstrated improvements in outcomes such as PTSD, depressive symptoms,

XSL•FO
RenderX

and emotional awareness in participants recording their experiences using EMA methods [112-115] (aim-2 interviewees, unprompted, disclosed similar enhancements in self-awareness during their experience as aim-1 participants). This design establishes a high-resolution comparator to NOLA GEM, capturing GEMA data across both trial arms while potentially isolating the effects of JITAI-based momentary provision of LIFT content as a hypothesized mechanism of action.

Screening

The aim-3 inclusion criteria are equivalent to those of aims 1 and 2, although both HIV outpatient clinic–based as well as community-based recruitment strategies will be used, inviting people living with HIV across the New Orleans metropolitan area to learn about the study through flyers and screening in real time via a QR code. Once the code is scanned, users will be brought to a Qualtrics survey that will ask basic demographic questions to facilitate quota sampling, history of living with HIV, current ART medications, and past violence exposure, which will be assessed via the *Adverse Childhood Experiences Questionnaire* and US Department of Veterans Affairs National Center for PTSD *Life Events Checklist for DSM-5* [116].

An option to screen by phone, with a research assistant manually inputting each potential participant's screener responses, will also be available. Once individuals are determined to meet the eligibility criteria, they will be called to set up an intake appointment.

Sample Size Considerations

The target sample size is approximately 100, which will accommodate an anticipated ≥10% attrition rate based on previous experience enrolling local violence-affected in-care people living with HIV, for an optimal analytic sample of 60 (30 per arm).

Study Settings

Participants will be recruited using flyers from several clinics and community locations in New Orleans that offer services to people living with HIV. Many of the community sites provide linkage to care by guiding people through insurance eligibility, appointments, and medication access. Two of these community sites were founded to provide services specifically to Black and African American women living with HIV. The clinic sites are federally qualified health centers that provide a range of care; however, we are working specifically with their HIV prevention and care teams.

By and large, aim 3 will comprise a digital trial subsequent to NOLA GEM onboarding. Screeners will be completed either on the participants' phones or by calling research staff. Once participants are screened, intake appointments will take place either over Zoom or at private clinical facilities within the Tulane University School of Public Health and Tropical Medicine. All further aspects of the study will take place on the NOLA GEM app or over the phone.

Participants and Procedures

With eligibility determined, participants will be randomized, and a baseline appointment will be scheduled. Quota sampling will ensure a ≥50% female, 50% aged >40 years and 50% aged <40 years, and ≥75% Black sample, reflecting the unique drivers and PTSD symptom constellations endured by women and Black Americans while also reflecting New Orleans people living with HIV demographics.

At baseline, informed consent will be obtained, and an in-person or Zoom assessment will be administered by the research staff. The NOLA GEM app (through which participants can be assigned to either treatment or control user types via an integrated back end) will be installed on participants' smartphones from the Crowdbotics-hosted Apple App Store or Google Play Store, and a detailed onboarding will be conducted by research staff to ensure uniform comprehension of the app's features, the nature of GEMA, and the wording of daily diary items. Although participants will be instructed on the expectations, functional affordances, and user expectations specific to their trial arm, they will be blinded to their explicit treatment versus control assignment.

Smartphones

An iPhone SE smartphone will be provided to participants without access to a personal smartphone. Devices will be provided to participants with a scheduled return date. Once returned, iPhones will be sanitized and recharged, and all device histories (calls, browser, and SMS text message) will be cleared. If participants do not return the study-provided iPhone and become unreachable, they will be considered dropped from the study.

Data Collection and Management

The study app is Health Insurance Portability and Accountability Act (HIPAA) compliant and will transmit daily diary and GPS data to a Crowdbotics-hosted administrator panel, also HIPAA compliant, eschewing sensitive, identifiable data storage on participants' personal devices. GPS data collection will occur continuously, recording latitudinal and longitudinal points at 1-minute intervals. In both arms, participants will be prompted twice each day by SMS text message to complete their daily diary items within a 3-hour window (9 AM-noon and 6 PM-9 PM) whenever ready and able to find privacy.

The aim-3 daily diary items are shown in Multimedia Appendix 3.

Throughout the conduct of the aim-3 trial, data will be securely stored on REDCap, and data sets that are downloaded for analysis will be stored on secure Tulane-hosted Box cloud servers. NOLA GEM user-level paradata, including daily diary responses, will be downloaded from the HIPAA-compliant Crowdbotics-hosted administrator panel, manually cleaned, and transformed into a standard "wide" data format in which each row corresponds to a unique participant using dedicated R scripts (R Foundation for Statistical Computing).

Data Safety Monitoring

All data collected will be monitored weekly by the research staff to ensure the privacy and confidentiality of the participants. General quality assurance checks will also be run on the data during and after collection. Any adverse events or unanticipated problems will be reported immediately to the institutional review board. To ensure the confidentiality of the data, each participant

XSL•FO
RenderX

is assigned a unique identifier that will not be linked to any identifying information. Any technology used (Zoom, Qualtrics, NOLA GEM app, or REDCap) is HIPAA secure. All SMS text message–delivered reminders sent to participants during the research period will be generic and will have no specific content in case participants wish to keep their participation private.

Intervention Arm

Intervention arm participants will be provided access to the SMS text message prompts; daily diary interface; a resource list that covers local health care, housing, domestic violence, family, and mental health services; a "My Progress" screen where they can track elements of their interaction with the app; and the full suite of LIFT sessions, skills, and SkillChecks. Following the submission of each daily diary, the study app will recommend specific LIFT content based on participants' particular patterns of momentary stressors. In addition, participants can access all content in their own time.

Control Arm (GEMA Alone)

Control arm participants will have access to the SMS text message and daily diary functions exclusively plus the resource list provided to treatment arm participants.

Primary Outcomes

Primary, distal outcome measures will be assessed at the immediate postintervention time point (within 1 week of completing the 21-day intervention period) and the 30- and 90-day follow-up assessments, as specified in the following sections.

Acceptability, Feasibility, and Usability

JITAI-specific proximal outcomes have been summarized previously. The aim-3 distal outcomes and their precise operationalization are outlined in this section.

Feasibility and acceptability will be assessed after participation in the 21-day trial period. Feasibility will be operationalized via screening and enrollment rates; completion rates of daily diaries; and paradata describing within-person patterns of use, including JITAI-triggered prompts [61,117]. Acceptability will be operationalized as follows. Intervention arm participants will complete the *User Experience Questionnaire* (short version), with ratings of the NOLA GEM app's pragmatic and hedonic quality User Experience Questionnaire domains assessed against available benchmarks [118]. The single-item *Net Promoter Score* will ask about participants' likelihood to recommend NOLA GEM on a 0 to 10 scale [119]. Both measures will be administered at the immediate postintervention assessment.

Attrition rates will also be recorded, and those who drop out of the study will receive a set of questions exploring motivations for discontinuation wherever possible.

CoC Milestones

Primary outcomes, representing recognized HIV CoC milestones [1,21,23], will be operationalized as follows via a postassessment survey.

Care Engagement

Past-30-day outpatient retention will be assessed using the 12-item *HIV Treatment Adherence Self-Efficacy Scale*. A well-validated measure, the HIV Treatment Adherence Self-Efficacy Scale recognizes care engagement as a holistic, psychosocially, and environmentally contingent construct, with particular attention to personal routine [120]. In addition, participants will self-report the percentage of appointments they missed in the past 90 days at their 90-day follow-up assessment.

ART Adherence

The capacity to maintain ART regimens will be assessed using a novel single-item visual analog scale (VAS) [72]. The VAS asks participants to estimate the percentage of their medication that they have taken in the past 30 days. Details of the VAS format and development are provided by Giordano et al [121]. In addition, daily diary measures operationalizing use of and feelings toward ART medication will be administered over the 21-day trial period (eg, "Did you have difficulty fitting your HIV treatment into your daily routine yesterday [Yes/No]"). These measures are provided in full in Multimedia Appendix 3.

Viral Suppression

Virologic control will be assessed via a self-report item asking participants whether their most recent HIV viral load test result was <50 copies/mL at the 90-day follow-up assessment. This item is adapted from the study by Carter et al [122].

Secondary Outcomes

Mental Well-Being

Diverse domains of psychosocial and emotional well-being will be assessed among all aim-3 participants.

PTSD Assessment

At 30 days after baseline, the *PTSD Checklist for DSM-5*, a 20-item self-report measure that assesses the presence and acuity of *DSM-5* PTSD symptoms, will assess traumatic stress burden for participants [123]. Considered an acceptable means of provisional diagnosis, the PTSD Checklist for DSM-5 has demonstrated psychometric soundness and acceptable continuity between Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, and *DSM-5* PTSD conceptualizations [124]. In addition, a range of daily diary measures (detailed in Multimedia Appendix 3) will record daily fluctuations in posttraumatic stress symptom acuity.

Anxiety and Depression

At 30 days after baseline, the 14-item *Hospital Anxiety and Depression Scale* will assess the presence and severity of anxiety and depression symptoms. Fielded and assessed for decades [125], the Hospital Anxiety and Depression Scale is shown to possess acceptable construct validity and internal consistency among clinical samples [126]. In addition, a mood checklist is administered via the daily diaries prompting participants to mark all moods they have experienced in the interim since their last daily diary (eg, "excited," "relaxed," or "scared"; Multimedia Appendix 3).

XSL•FO
RenderX

Effective Coping

At 30 days after baseline, the Brief *Coping Orientation to Problems Experienced* and *Coping Self-Efficacy Scale* will measure participants' recourse to adaptive versus maladaptive styles of coping [127]. Translated into French, Spanish, Malay, and Russian and fielded successfully among broadly heterogeneous populations, the Brief Coping Orientation to Problems Experienced consistently evidences acceptable psychometric properties, although its internal factor structure remains contested [128]. The Coping Self-Efficacy Scale also demonstrates good reliability and validity, including among samples of in-care people living with HIV [129]. Via a checklist, coping strategies ("getting emotional support from others" and "criticizing myself") will be logged in the aim-3 daily diaries (Multimedia Appendix 3).

Hazardous Substance Use

At 30 days after baseline, the 3-item *Alcohol Use Disorders Identification Test*, a valid instrument for detecting heavy, potentially unhealthy alcohol use patterns [130], will be applied to that end in aim 3. The "Alcohol/Drugs" section of the widely used *Addiction Severity Index* will assess the effects of participants' alcohol and drug use across key domains of daily functioning [131]. Dedicated daily diary items will also prompt participants to describe patterns of alcohol and drug use since "last night" (morning daily diary) or "your last daily diary" (afternoon daily diary; Multimedia Appendix 3).

Domain–General Stress

Finally, at 30 days after baseline, the *Perceived Stress Scale–4* will measure situational subjective stress among aim-3 participants [132]. In addition, a 24-item aim 1–generated novel daily stressor severity checklist operationalizing a wide array of potential sources of stress arousal (eg, community and police violence, intrafamilial strife, and employment challenges) will assess multidomain stress experienced by aim-3 participants at the 30-day follow-up relative to their baseline stress burden.

Analytic Approach

Consistent with aim 1, aim-3 data will be cleaned and saved in SAS data files (SAS Institute), with extensive consistency checks conducted at all levels of data [66]. At the completion of each check, the data will be added to the existing database for analysis. GPS data will be stored on a password-protected server and constructed into activity paths, replicating the aim-1 approach [66].

Preliminarily, descriptive and crude bivariate associations between variables of interest will be generated. Daily diary completion rates and agreement with aggregate retrospective survey data for comparable measures will be calculated. Data reduction techniques, mitigating the high volume and dimensionality of GEMA-derived data, will include the creation of composite indexes of cumulative risk, with exploratory factor analysis, assessment of internal consistency, and Bonferroni correction applied as warranted.

Aim-3 analyses of preliminary efficacy will include analysis of each day-to-day distal outcome as a continuous variable as well as average exposures across the total intervention period. We will explore potential transformations to approach normality on key response variables [133]. Linear mixed-effects models will relate day-level outcomes to day-level indexes of cumulative risk and protective exposure derived originally from aim 1, adjusted for baseline values [134]. Random effects will be included to account for within-subject series correlations. Control variables will be modeled as fixed effects.

Ethics Approval

All methods and materials were reviewed and approved by the Biomedical and Social Behavioral Institutional Review Boards of Tulane University (aim 1: 860463; aim 2: 2021-1220; and aim 3: 2022-1861).

Results

Aim 1, enrolling 89 people living with HIV, was completed in September 2022. Aim 2, informed by a pilot aim-1 sample of 49 participants and a subset of 12 interviewees, was completed with the handover of the NOLA GEM app to investigators in April 2022. NOLA GEM is available to aim-3 participants as a native iOS and Android app hosted in the Apple App Store and Google Play Store, respectively. The app's onboarding and sign-on flow accommodates both intervention (treatment arm) and GEMA-only (control arm) account credentials. Ethics approval was obtained, and recruitment subsequently began, in July 2023. We anticipate that all follow-up appointments will be completed by February 2024, with the final results ready for dissemination by May 2024. The results will be disseminated to key stakeholders via scientific conferences, peer-reviewed academic journals, and Tulane University social media channels. Ultimately, as an R34-supported project, the longer-term objective is to "prune" underused or preliminarily inefficacious JITAI logics to refine a parsimonious NOLA GEM theory of change, consequently supporting an application for National Institutes of Health support for a full-scale RCT.

Discussion

Summary

This study aims to advance knowledge on temporally fluctuant and place-based stressors endured by people living with HIV in New Orleans and assess the acceptability, feasibility, and preliminary efficacy of NOLA GEM, a JITAI-consistent mHealth intervention responsive to these stressors. Key to the significance of NOLA GEM is its capacity to capture and intervene in real time on a holistic range of time-variant psychosocial and behavioral variables [10,15,21,60,61] alongside crucial neighborhood-level factors known to affect CoC outcomes and well-being among people living with HIV [11,12,23,44-48], particularly violence-affected people living with HIV [1,4,7,15]. To our knowledge, NOLA GEM is the first smartphone-delivered, trauma-informed intervention tailored for people living with HIV. As such, it will leverage a well-demonstrated EBI [33,34,36-39]; previous research supporting cognitive behavioral touch points for intervention among people living with HIV with trauma histories [135-137]; and the confidentiality, discretion, and real-time accessibility of mHealth [54,86]. Through the latter strengths in particular,

XSL•FO
RenderX

we hope to address participant privacy and in-person group attendance concerns that may have stemmed the uptake and, possibly by extension, the longer-term efficacy of *Improving AIDS Care after Trauma* [39], the LIFT adaptation preceding NOLA GEM [38].

Notably, the mean ages of aim-1 and aim-2 participants were 57 and 58 years, respectively. This skew toward older adulthood relative to the intended user base of many people living with HIV–tailored mHealth interventions [138] may have influenced the design of NOLA GEM. Since 2014, smartphone adoption has accelerated among older adults, reaching 86% among adults aged >50 years and 62% among adults aged >70 years [139]. With motivation (both intrinsic and extrinsic) and proper feedback and support, mHealth and eHealth tools can find success among older adults [140], including older people living with HIV who, for example, engaged with the features of the *PositiveLinks* platform in a significantly more dedicated, sustained manner than younger (aged <50 years) users [141]. Success among this user base relies on a baseline degree of digital readiness [140], which is itself often contingent on device familiarity—a strength of NOLA GEM, which leverages common SMS text message and native app functional affordances, distinct from, for example, a wearable actigraphy sensor. Though some aim-2 participants attached their preferred coping techniques to their age (accepting and adapting: "You're getting older and you can't do anything about it. Just accept it and let move on" [participant F]), few, when prompted, described personal traits such as age or disability influencing their personal technology use. Post hoc, open-ended usability interviewing conducted during or shortly after intervention offboarding will allow us to examine the role of participant age (among both younger and older adults) qualitatively within the specific context of the NOLA GEM user experience.

Overarchingly, our objective is to introduce an innovative model of adaptive coping support in a periurban US Gulf South context characterized by elevated rates of HIV prevalence [41], poverty and economic inequality [42,43], and violent crime [44], reinforcing a focus on traditional HIV CoC end points with precision-tailored support for person-centered proximal outcomes grounded in the lived experience of local people living with HIV.

Limitations

As a small-scale pilot trial, aim 3 is subject to a number of inherent limitations. First, and by design [142], it is underpowered to examine efficacy in a formal hypothesis-driven manner. Mediation analyses of proximal outcomes will necessarily be exploratory in nature and inform the causal pathway hypotheses for the planned RCT. Although the selection of control conditions for mHealth trials remains an area of active investigation and debate [143], a passive GEMA-alone control may inflate preliminary estimates of NOLA GEM (incorporating GEMA+LIFT coping skills) efficacy on primary outcomes, an issue that is potentially exacerbated by the small sample size [144]. Adaptations of complex, sequential, and multicomponent group interventions risk dismantling key mechanisms of action that undergird effectiveness in their original contexts [33,34,101]. Adaptation to mHealth across HIV science remains a highly active but often methodologically impromptu area [145]. Pragmatic considerations required us to deprecate certain components of LIFT as originally manualized [33] and demonstrated to reduce traumatic stress [34,36]. Group cohesion and dedicated in-person facilitation of the group member disclosure and support processes define the LIFT intervention trajectory, which is sequenced across 15 sessions [33]. We abstracted the CTSC-based strategies built into NOLA GEM from their original, in-person, session-by-session framework to activate the "just-in-time" aspect of a JITAI adaptation while mitigating ethical concerns that, if faced with an acute stressor, a NOLA GEM user would be denied the best-suited coping support if they had not yet reached the appropriate session had a strictly linear intervention model been retained. Similarly, although a peer-to-peer support forum or social media–style feature [146,147] in which users could interact pseudonymously was briefly considered, lacking active human (vs algorithmic) content moderation, such a space could become consumed with off-topic, inane, or even outrage-inducing user-generated content and external media [86,148]. In addition, by recruiting people living with HIV who were either violence-affected individually or lived in a high-violence neighborhood, a degree of heterogeneity in needs was introduced into the aim-1 and aim-2 samples, which may have swayed the formative insights—and, by extension, intervention design—derived from the *New Orleans Alcohol Use in HIV* study subsamples. Although violence exposure at the within-person and neighborhood levels is associated with distinct sequelae among people living with HIV, it is our intention that the multitude of possible NOLA GEM user journeys can offer the necessary support to a wide range of personal violence histories. By nature, an acceptability and feasibility trial will provide insights on many of these concerns, whereas merged paradata and GEMA data will permit high-resolution analyses of users' engagement with and navigation of NOLA GEM [149].

Conclusions

Aligning user-centered development practices with principles that elevate the lived expertise of people living with HIV, mHealth-adapted EBIs can sustain well-specified theories of change while leveraging the affordances of mobile technologies. The results of the aim-3 trial will generate needed evidence concerning the value of such a locally tailored JITAI approach while pointing toward opportunities to improve upon the initial release of NOLA GEM in anticipation of a fully powered RCT offering definitive evidence of the potential of mHealth-delivered effective coping support that operationalizes the self-knowledge of communities of end users.

Acknowledgments

The authors extend their gratitude to Kathleen J Sikkema; Keith J Horvath, Meghna Daga, and Anudnya Durgule of Crowdbotics; the nursing and research staff at the Louisiana State University Clinical and Translational Research Center; and the participants of aims 1 and 2 for sharing their day-to-day experiences and contributing their lived expertise. This study is funded by the National Institute on Alcohol Abuse and Alcoholism (R34AA028961 and P60AA009803). Additional support was provided by the National Institute of General Medical Sciences (U54GM104940), which funds the Louisiana State University Clinical and Translational Science Center. SJS is supported in part by a Garvin Shands Saunders Foundation scholarship.

Data Availability

Deidentified aim-1 data are deposited and deidentified aim-3 data will be deposited upon completion of the pilot trial on the National Institute on Alcohol Abuse and Alcoholism Data Archive of the National Institute of Mental Health Data Archive [150].

Conflicts of Interest

SJS was a paid advisor to Waverider, which builds customizable cognitive behavioral therapy–dialectical behavior therapy eHealth tools, for the duration of this work. All other authors declare no other conflicts of interest.

Abstract

Background: Mental health problems affect 1 in 6 workers annually and are one of the leading causes of sickness absence, with stress, anxiety, and depression being responsible for half of all working days lost in the United Kingdom. Primary interventions with a preventative focus are widely acknowledged as the priority for workplace mental health interventions. Line managers hold a primary role in preventing poor mental health within the workplace and, therefore, need to be equipped with the skills and knowledge to effectively carry out this role. However, most previous intervention studies have directly focused on increasing line managers' understanding and awareness of mental health rather than giving them the skills and competencies to take a proactive preventative approach in how they manage and design work. The Managing Minds at Work (MMW) digital training intervention was collaboratively designed to address this gap. The intervention aims to increase line managers' knowledge and confidence in preventing work-related stress and promoting mental health at work. It consists of 5 modules providing evidence-based interactive content on looking after your mental health, designing and managing work to promote mental well-being, management competencies that prevent work-related stress, developing a psychologically safe workplace, and having conversations about mental health at work.

Objective: The primary aim of this study is to pilot and feasibility test MMW, a digital training intervention for line managers.

XSL•FO
RenderX

Methods: We use a cluster randomized controlled trial design consisting of 2 arms, the intervention arm and a 3-month waitlist control, in this multicenter feasibility pilot study. Line managers in the intervention arm will complete a baseline questionnaire at screening, immediately post intervention (approximately 6 weeks after baseline), and at 3- and 6-month follow-ups. Line managers in the control arm will complete an initial baseline questionnaire, repeated after 3 months on the waitlist. They will then be granted access to the MMW intervention, following which they will complete the questionnaire post intervention. The direct reports of the line managers in both arms of the trial will also be invited to take part by completing questionnaires at baseline and follow-up. As a feasibility pilot study, a formal sample size is not required. A minimum of 8 clusters (randomized into 2 groups of 4) will be sought to inform a future trial from work organizations of different types and sectors.

Results: Recruitment for the study closed in January 2022. Overall, 24 organizations and 224 line managers have been recruited. Data analysis was finished in August 2023.

Conclusions: The results from this feasibility study will provide insight into the usability and acceptability of the MMW intervention and its potential for improving line manager outcomes and those of their direct reports. These results will inform the development of subsequent trials.

Introduction

Background

Common mental health problems (eg, stress, anxiety, and depression) were estimated to account for the majority of days lost due to work-related ill health in the United Kingdom in the year 2021 to 2022 (7.0 million and 7.3 million, respectively) [1]. The annual cost of absenteeism, presenteeism, and turnover associated with mental ill health in the United Kingdom has increased by a quarter since 2019 and is now estimated to be £53-£56 (US $67.51-$71.33) billion [2]. Despite these costs, many employers are unaware of the actions they could take to support their employees' mental health and of the potential return on investment of workplace mental health and well-being practices. Recent estimates suggest a return, on average, of £5.30 (US $6.75) for every £1 (US $1.27) invested [2].

There are 3 main categories of interventions that aim to mitigate the impact of poor mental health in the workplace. Primary interventions are preventative in focus and aim to remove or minimize work stressors (eg, excessive job demands, time pressure, and bullying at work) associated with work-related stress and poor mental health at work. Primary prevention involves changing the way that work is designed and managed to reduce the risks to employees' work-related stress and mental health. Secondary interventions target the identification of employees already experiencing work-related stress and poor mental health through raising awareness and knowledge of common mental health symptoms and associated workplace behaviors, such as problems concentrating, feeling uptight, distressed, and fatigued [3], and aim to provide the skills and resources to bolster coping for those employees affected. Finally, tertiary interventions aim to provide treatment of symptoms, for example, return-to-work programs, employee assistant programs, occupational therapy, and medical stress interventions [3], to minimize any effects of poor mental health at work and support the return-to-work and retention of an employee. While employers should incorporate all 3 types of intervention, a primary preventative approach is widely acknowledged as the priority [4-6].

Line managers have a key role in the operationalization and impact of such preventative approaches in the workplace. They play a vital role in designing jobs, managing work tasks and workload, treating employees with respect and clarity, creating a work environment that is supportive and psychologically safe, and encouraging open and honest conversations about mental well-being at work [7]. However, line managers need to be equipped with appropriate skills and knowledge to effectively fulfill this role.

Limited mental health or stress prevention training interventions targeting line managers exist, with only a small number using a randomized trial methodology to evaluate their impact [8-10]. These intervention studies have demonstrated effectiveness in improving line managers' knowledge of mental health [8], their skills in communicating about mental health and related resources [9], their confidence in creating a mentally healthy workplace [11], and lowered sickness absence of the employees they supervise [10]. Most of these line manager training packages have focused exclusively on increasing their awareness and knowledge of mental health at work and providing guidance on how to support and signpost employees who are already experiencing poor mental health. However, few line manager training interventions exist that aim to improve the behavioral competencies and skills of managers in preventing work-related stress and promoting mental health at work.

Equipping line managers to enable primary preventative approaches is a critical next step. Stansfeld et al's [12] study assessed the effectiveness of an evidence-based e-learning package that aimed to improve line managers' competencies in preventing work-related stress [13,14]. However, this study only used employee-related outcome measures of psychological

XSL•FO
RenderX

distress and sickness absence, which remained unchanged, and did not examine changes in line managers' confidence, knowledge, or behavior.

This study takes a preventative approach by training line managers but broadens the content of the training beyond that of Stansfeld et al's [12] intervention to include multiple components (based on evidence and theory-driven) on the causes of work-related stress and poor mental health at work. The development of the MMW digital learning intervention is fully described in Blake et al's paper [15].

In terms of the outcome measures studied in trials to date, most studies have used primary outcomes relating to line managers (such as changes in their confidence and knowledge about mental health), which are closely linked to the content and purpose of the training. A small number of studies have explored employee outcomes such as well-being and sickness absence [12], employee distress [11], employees' perceptions of changes in their manager's behavior [9,11], and employees' use of resources available [9]. This study will build on the methods adopted by others to consider the feasibility of collecting data on the outcomes more closely related to digital training for line managers as well as outcomes related to employees, specifically their well-being and productivity.

The delivery of the training for line managers in previous trials has largely been based on face-to-face sessions [8-10] although 2 studies used web-based delivery [11,12]. With a rapid increase in the use of web-based workplace training due to the COVID-19 pandemic, the use of e-learning and digital training packages has been embraced by many employers as a way of offering more flexible learning to employees [16] and is advocated to be cost-effective as a delivery method [17]. Furthermore, providing more control to individual learners may increase motivation for, and satisfaction with, learning [18,19]. Therefore, the evaluation of digital learning and training resources has relevance in the modern workplace, and studies are needed that explore their use and acceptance by learners when related to workplace mental health. This study will primarily use qualitative data to explore the usability and acceptability of the digital mode of training and how this could be further enhanced to increase engagement and support the transfer of learning into practice.

Study Aims and Objectives

Aims

This study is part of a larger research program, the Mental Health and Productivity Pilot (MHPP) which is funded by Midlands Engine [20]. The broader aims of the MHPP program are (1) to reduce the impact of poor mental health in the workplace and barriers to employability and productivity; (2) to reduce stigma around workplace mental health; and (3) to deliver evidence-based, locally relevant, tested, and sustainable workplace programs to suit the needs of employers and employees.

This study describes a pilot and feasibility trial of a digital intervention with interactive training materials delivered on the internet to line managers (ClinicalTrials.gov NCT05154019). The intervention aims to increase managers' confidence, knowledge, and behavioral competencies to prevent work-related stress and promote mental health at work among the people they manage. The MMW training for line managers includes existing evidence-based resources that support line managers in reducing work-related stress and developing a workplace that actively promotes and supports the mental health and well-being of the people they manage (their direct reports). This study aims to determine the feasibility of a full cluster randomized controlled trial (RCT), testing the effectiveness of the MMW training on improving line managers' outcomes (confidence, knowledge, and behavior) and direct report outcomes (well-being, perceptions of line manager behaviors, and sickness absence).

Objectives

To assess the feasibility of a full trial of the MMW intervention, our specific objectives are to test:

1. The potential for uptake within small, medium, and large organizations by identifying and monitoring the:
   - willingness of employers to register interest in participating in the trial and allow line managers to take part in the trial;
   - recruitment and retention rates of line managers in the trial; and
   - recruitment and retention of managers' direct reports.
2. The perceived suitability and effectiveness of the MMW intervention for line manager training by determining the:
   - acceptability, usability, and utility of the training among line managers and stakeholders within the participating organizations;
   - potential for improving line managers' confidence (primary outcome), knowledge, and behaviors (secondary outcomes) to inform the planning of a larger trial;
   - potential for improving direct report outcomes (well-being, absence, and self-reported productivity) by assessing changes to inform the planning of a larger trial; and
   - barriers and facilitators to the intervention implementation and effectiveness.
3. The data collection methods for primary and secondary outcome measures are to:
   - inform key parameters for a larger trial relating to sample size and clustering.

How these research objectives map onto the data collection methods and measures is depicted below (Table 1).

XSL•FO
RenderX

Table 1. Mapping of research objectives onto data collection methods and measures.

Research objective	Method of data collection	Data source or measure
Willingness of organizations to take part in trial	• Study records • Interviews with stakeholders	• % conversion from interest to participating • Qualitative data
Acceptability of waitlist control	• Interviews with stakeholders • Researcher diaries	• Qualitative data
Willingness to allow access to organizational level data on absence	• Interviews with stakeholders • Researcher diaries	• Qualitative data
Recruitment of line managers	• Study records	• % eligible line managers who consent
Retention of line managers	• Web-based survey data	• % consenting managers who complete follow-up
Recruitment of managers' direct reports	• Study records	• % eligible direct reports who consent
Retention of managers' direct reports	• Web-based survey data	• % consenting direct reports who complete follow-up
Acceptability, usability, and utility of the intervention	• Interviews with managers and stakeholders • End of module feedback from line managers	• Qualitative data • Qualitative feedback and quantitative data: fidelity delivery and engagement, implementation qualities [21]
Barriers and facilitators to the intervention implementation and effectiveness	• Interviews with line managers and stakeholders • End of module feedback from line managers	• Qualitative data • Qualitative feedback
Improvement in line manager confidence	• Web-based survey	• Confidence to create a mentally healthy workplace [11,22]
Improvement in line manager mental health knowledge	• Web-based survey	• Mental Health Knowledge Scale [23] • Mental Health Literacy in the Workplace [24]
Improvements in line manager ratings of their managerial behavior	• Web-based survey	• Management Competency Indicator Tool-manager version [13]
Improvement in direct reports' well-being	• Web-based survey	• Warwick-Edinburgh Mental Well-Being Scale 14-item [25]
Improvements in ratings of manager behavior	• Web-based survey	• Management Competency Indicator Tool-employee version [13]
Improvement in direct reports' sickness absence and productivity	• Organizational records • Self-reports	• Sickness absence rates • Productivity rating

Methods

Ethics Approval

The study will be conducted in accordance with the ethical principles that have their origins in the Declaration of Helsinki, 1996; the Principles of Good Clinical Practice; and the UK Department of Health Policy Framework for Health and Social Care, 2017. Ethics approval has been granted by the University of Nottingham's Faculty of Medicine and Health Sciences Ethics Committee (Ref. FMHS 299-0621, with amendment approved June 6, 2022). No recruitment, data collection, or intervention delivery will take place before ethical approval is in place. Informed consent will be collected for each participant in the study, following the provision of detailed information about the study. This will emphasize that participation in the study is entirely voluntary, and participants are free to withdraw at any time. Participants will not be compensated for taking part in the study. All data are to be stored securely in password-protected storage with any identifiers removed in adherence to the General Data Protection Regulations (GDPR, 2018). Any quotes from interview participants used in reports and articles will be anonymized.

XSL•FO
RenderX

Design

This feasibility pilot study is a multisite, 2-armed cluster RCT taking place in work organizations of different sizes and sectors across the Midlands area of England. The organizations are the units of randomization (the clusters), with data collected from individual line managers (the participants) and the direct reports who are supervised by managers within those organizations. If large, multisite organizations are recruited for the study, we will consider the option of using an internal control group within that organization if there is a low risk of contamination between the intervention arm and control arm within that large organization. The data collection schedule for the study is summarized below for the intervention arm (Table 2) and the control arm (Table 3). A repeated measures design will be adopted, whereby participating line managers in the intervention arm will complete web-based questionnaires at baseline, on completion of the MMW training (approximately 6 weeks after baseline), and at 3- and 6-month follow-up periods after baseline. A 3-month waitlist control group will be used with participating line managers. They will be asked to complete web-based questionnaires at baseline, 3-month follow-up (before starting the intervention), and after completion of the training (6 months after baseline).

Table 2. Data collection schedule for the intervention arm.

Control arm				
Managers	✓	✓	✓	
Direct reports	✓	✓	✓	
Stakeholders				✓

Setting

The study setting will be any organization with line managers and their direct reports within the Midlands area of the United Kingdom.

Sample Size

A minimum of 8 clusters (randomized into 2 groups of 4) will be sought to inform a future trial, as recommended for pilot clinical trials [26]. We will aim to recruit 30 line managers for each arm as per guidance for feasibility trials [27].

Recruitment

Organizations

Participating organizations will be recruited through the communication channels (Twitter, newsletters, and website) related to the wider MHPP program. A flyer advertising the study will inform organizations about the aims of the study and ask them to register their interest in participating through a web-based form. Organizations that register their interest will receive a follow-up phone call from a study researcher to provide further information about the study. We will identify the "gatekeeper," the person within the organization who will support the implementation of the study within that organization by facilitating communication with line managers and promoting the study within the organization. We will share study details, including program content and randomization. Organizations may want to provide the intervention to managers within certain departments or divisions or at certain levels of seniority within their organization. These options will be discussed as part of the organization's recruitment for the study to identify whether all managers or specific groups of managers will be approached for participation in the study. Once agreed upon in principle, we will request written informed organizational consent at the site level for the research.

Line Managers and Direct Reports

Managers within the participating organizations will be approached to participate in the study through a poster or flyer about the study, which will be shared with them by the gatekeeper within the organization. Line managers who express interest in taking part will be given information about the study and asked to provide written informed consent before participating in the study. To take part in the study, line managers must be aged 18 years or older (no maximum age but must be employed with managerial responsibilities); have direct managerial or supervision responsibility for 3 or more staff; have a work computer or mobile phone and email address with which to access the training and receive reminders; and be able to provide informed consent. Line managers will be excluded from the study if they are due to retire or be made redundant in

XSL•FO
RenderX

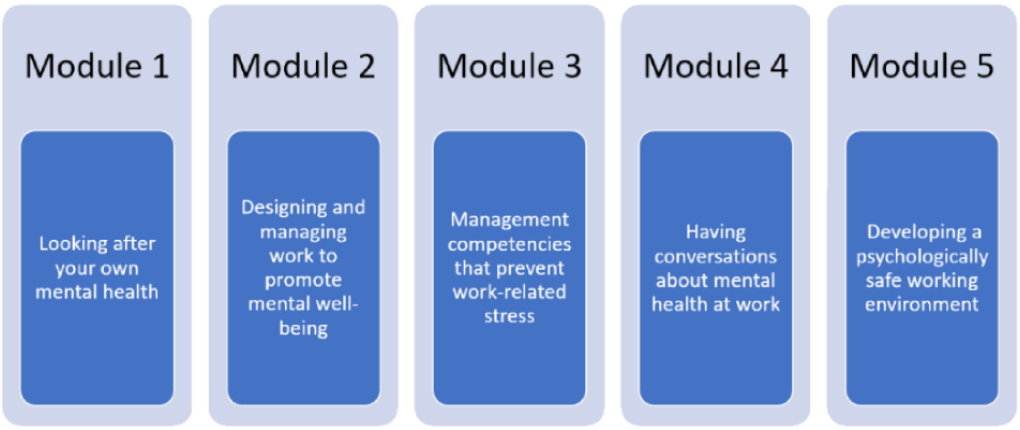
the next 6 months or have undertaken work-based training on mental health at work within the past 6 months.

To assess any changes in outcomes of line managers' direct reports, all participating managers will be asked to share details of the study with their direct reports to invite them to also participate in a web-based survey at at baseline, 3-month and 6-month follow up. Participant information sheets and consent forms will be provided on the internet before these surveys are completed. Direct reports will not have any access to the training intervention itself.

All participant information sheets and consent forms will be in English. As the intervention we are testing will only be delivered in English, it will not be possible to include non-English speakers in this feasibility and pilot study. It will be explained to all potential participants that entry into the study is entirely voluntary and that they can withdraw from the study at any time without negative repercussions.

Allocation to Intervention

Organizations (clusters) will be randomly assigned (1:1) to either the intervention or waiting list control group using a web-based random sequence generator [28]. This allocation will be stratified to ensure a spread of different sizes of organizations within the intervention and control arms. Where the organization is sufficiently large to have distinct departments, divisions, or units with minimal risk of contamination between them, we will randomly assign 2 of these different departments, divisions, or units to either intervention or waiting list control using the same approach.



The research team and participants will not be blinded to the outcome of randomization due to practical reasons (ie, sending reminder emails to participating managers). The lead researcher will enroll participating organizations and line managers and will assign organizations (clusters) to the intervention or control arm.

The MMW Intervention

Developing the MMW Intervention

The intervention was co-designed with stakeholders to ensure it addresses employer needs and supports the engagement of participating organizations. The intervention development process was guided by Agile Science approaches as used in 2 previously published studies by Blake and colleagues [29] and fully described in Blake et al's study [15]. Stakeholder consultation and review was an iterative process, allowing for continuous delivery and a resource-efficient approach to training development. See Figure 1 for an overview of the MMW content. The MMW intervention materials were developed with considerable input from a range of stakeholders, including academic experts, learning and development experts, well-being managers, organizational representatives, and line managers. The MMW intervention is described throughout as a digital training course, and the modules therewithin refer to the various stages of this training.

Figure 1. Overview of the content of the Managing Minds at Work modules.

The MMW Training Intervention

The intervention is a digital, interactive training course delivered on the internet that includes evidence-based material, guidance, and practical exercises. It will be made accessible to participants through a secure website using a personal computer, laptop, tablet, or mobile phone. Although larger screen devices (eg, personal computer or standard laptop) are recommended to maximize readability. Individual usernames and passwords will be provided to each participating line manager to gain access to the training. The training materials are presented using a web-based, interactive, and multimedia software called Xerte [30]. The training material includes evidence-based guidance, interactive tasks with opportunities for reflection, short videos, embedded links, and downloadable checklists (an in-depth overview of the modules, using the TiDiER [Template for Intervention Description and Replication] checklist, is described in the MMW intervention development paper) checklist [15]. The training covers 5 topic areas, presented as a series of independent, stand-alone modules:

- Module 1: looking after your own mental health
- Module 2: designing and managing work to promote mental well-being
- Module 3: management competencies that prevent work-related stress
- Module 4: developing a psychologically safe workplace
- Module 5: having conversations about mental health at work

XSL•FO
RenderX

Each module is designed to take between 20 and 30 minutes to complete. Participants will be permitted by their employer to complete the training within their work hours. The training is self-led, so each participant can progress through each module at their own pace and at a time that suits them. At the start of the intervention, a suggested schedule will be provided to each participant, whereby line managers are encouraged to schedule and complete 1 module per week. Reminder emails will be sent to participants on a weekly basis to encourage engagement and completion of that week's module.

Organizations (clusters) will communicate with line managers (either all line managers or those in selected divisions, departments, or levels of seniority) about the intervention and study. Managers in the intervention arm will be invited to register for the training and start it right away. Managers in the control arm will be invited to register for the training and start it after a 3-month wait.

Outcome Measures

Trial Feasibility and Acceptability-Related Outcomes

To address objectives 1a, 1b, 1c, 2a, and 2d, we will collect data on the following to assess the feasibility of a trial and acceptability of the intervention:

1. Number of employers registering interest in participating in the study
2. Number of employers consenting to take part in the study (minimum of 8 organizations recruited within a 6-month period)
3. Number of line managers sent information about the study
4. Recruitment of line managers into the study in both the intervention and control arms, and retention of those recruited through the follow-up points to completion in the intervention and control arms (70% at 3 months and 50% at 6 months)
5. Recruitment and retention of line managers' direct reports
6. Line manager views on the acceptability, usability, and utility of the intervention through postmodule feedback forms and end-of-study interviews
7. Stakeholders' views on the acceptability, usability, and utility of the intervention through interviews
8. Possible barriers and facilitators to the intervention implementation and effectiveness through interviews with line managers and stakeholders.

Research-Related Primary and Secondary Outcomes

In relation to objectives 2b, 2c, and 3a, we will collect the following data to assess the potential for improving line manager and direct report outcomes and inform the planning of a larger trial. The primary outcome we will assess is line managers' confidence in creating a mentally healthy workplace [11,22,31]. The secondary outcomes will be line managers' mental health knowledge [23]; line managers' workplace mental health literacy [24]; line managers' self-rating of behavior (Stress Management Competency Indicator Tool [SMCIT]–manager version) [13]; line managers' psychological well-being (Warwick-Edinburgh Mental Well-Being Scale [WEMWBS]) [25]; direct reports' psychological well-being (WEMWBS) [25]; direct reports' rating of line manager behavior (SMCIT-employee version) [13]; direct reports' sickness absence (organizational records); and direct reports' productivity (self-reported).

Data Collection Procedure in Intervention Arm

In the intervention arm, line managers will be invited to complete the digital training. Participants will be encouraged to complete the modules in succession, from introduction through to modules 1 to 5, aiming to complete a module a week. The training program should, therefore, be completed in 6 weeks. Data will be collected as per Table 2, at baseline, on completion of the MMW training (approximately 6 weeks after baseline), and at 3- and 6-month follow-up periods from baseline. Line managers' direct reports will be invited to take part in the study to determine whether they notice any change in their line manager's behavior or whether their own mental health outcomes are affected by the line manager training. Line managers' direct reports will therefore be invited to complete web-based questionnaires at baseline when the line manager starts the training, and 3 and 6 months later. Where available, data will also be collected from organizational records on the sickness absence levels of employees managed by the participating line managers.

Data Collection Procedure in Control Arm

Line managers in the organizations within the control arm will receive the intervention after a 3-month wait and will complete web-based questionnaires at baseline, just before the start of the training (3 months after baseline), and after completing the training (ie, approximately 6 months after baseline). Line managers' direct reports will be invited to complete web-based questionnaires at baseline, 3 and 6 months later. Where available, data will also be collected from organizational records on the sickness absence levels of employees managed by the participating line managers.

Measures for Line Managers (Intervention and Control)

The web-based questionnaire will contain the following items (Table 4). Demographics (including age, gender, number of years as a manager, and number of direct reports) were collected at baseline only.

XSL•FO

[a]WEMWBS: Warwick-Edinburgh Mental Well-Being Scale.

Line managers' confidence to create a psychologically healthy workplace will be quantified by a self-report measure used previously by Gayed et al [11,22] by modifying a previously published supervisor scale [31]. This measure includes 6 workplace scenarios (eg, "creating a work environment that prevents and reduces stress within my team"), which require line managers to rate their confidence on a scale of 1 ("not very confident") to 5 ("very confident"). The items are summed to create a composite score with a range of 6 to 30, with higher scores indicative of more in creating a mentally healthy workplace.

The mental health knowledge schedule (MAKS) [23] will be used to measure the line manager's mental health. It is a 6-item measure consisting of 6 key areas, such as help-seeking, recognition, support, employment, treatment, and recovery. MAKS is measured on a 5-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree"). Items are summed to create a composite score ranging from 6 to 30, with higher scores indicating better knowledge of mental health.

Workplace Mental Health Literacy [24] aims to measure line managers' workplace literacy. It consists of 16 items, 4 vignettes featuring various manifestations of mental ill health within the workplace, and parallel questions exploring 4 dimensions of mental health literacy. These items are rated on a 5-point Likert scale ranging from 1 ("very low") to 5 ("very high"). A higher score represents better workplace health literacy (range 16-80).

The SMCIT [13] measures management competencies surrounding the prevention and management of work-related stress. This measure consists of 36 items examining 4 key competencies: "managing emotions and having integrity," "managing and communicating existing and future work," "managing the individual within the team," and "reasoning and managing difficult situations." Items are measured on a scale of 1 ("strongly disagree") to 5 ("strongly agree"). Each subscale is summed together, with higher scores indicating higher levels of competency. The measure has a version for both line managers (manager version) and employees (employee version), with the same content adjusted to suit the audience.

The WEMWBS [25] aims to quantify both line managers' and employees' psychological well-being over time. This measure consists of 14 items asking participants to rate a series of statements (eg, "I have been feeling useful") on a scale of 1 ("none of the time") to 5 ("all the time"). Summed scores range from 14 to 70 with higher scores representing better mental well-being.

After each of the training modules has been completed, participating managers will also be asked to complete a web-based feedback form, giving quantitative and qualitative feedback on the module. This will include questions on fidelity delivery and engagement with the training module [29]; questions on implementation qualities [29]; and open questions about how long the module took them to complete, which aspects of the module they found most useful, what they plan to change in their managerial practice, and how the module could be improved.

XSL•FO
RenderX

Measures for Direct Reports (Intervention and Control)

Overview

On registering for the training, all participating line managers in both the intervention and control arms will be asked to send an invitation to participate in a web-based survey to their direct reports. The purpose of this is to assess whether completion of the training by line managers affects their direct reports' perception of line managers' behavior or the mental health and sickness absence outcomes of direct reports. The web-based survey for direct reports will contain the following items: demographics (age, gender, and number of years in the organization) collected at baseline only, WEMWBS 14-item [25], SMCIT-employee version [13], and a single-item self-reported productivity rating.

The web-based survey for direct reports at follow-up will contain the same items (as above) with the addition of open-response questions about any changes to how they are managed or their line manager's behavior.

Organizational Sickness Absence Records

We will collect information from the organizations regarding the sickness absence records of those the participating line managers directly manage. Preintervention data will cover the 6 months before the intervention starts. Postintervention data will cover the 6 months after intervention completion. All organizational absence records will be anonymized at source before being securely transferred to the research team.

Data Analysis

Statistical analysis will produce summary statistics to assess the parameters for a full trial. Missing data will be imputed using multiple imputations. SPSS (version 26; IBM Corp) will be used for statistical analysis. As this is a pilot trial, no emphasis will be put on the *P* values for any inferential statistical tests conducted. The primary analysis will use an intent-to-treat approach with repeated measures. Differences between the intervention and waiting list control groups at follow-up will be examined against baseline. The pilot data will provide information on the parameters needed for a realistic sample size calculation (mean, SD, and treatment effects of the primary outcome for the 2 arms) for a future main cluster RCT.

Economic Measures

We will consider the feasibility of collecting data on costs and savings from the perspective of the employer. The costs considered will be the working hours lost to complete training during working hours, and, in turn, the cost or saving of any change in sickness absence rate over the follow-up will be calculated based on the median hourly wage (£15.6 [US $19.87] per hour) [32] of employees in the United Kingdom.

Process Evaluation

Overview

A qualitative process evaluation will run alongside the pilot trial to explore the experience of the intervention with line managers and other stakeholders (eg, human resource managers and well-being coordinators) within participating organizations; assess the acceptability, usability, and utility of the intervention; and identify barriers and facilitators to implementation. Semistructured interviews will be used to collect the data to inform the process evaluation. In addition, module feedback forms will be completed by line managers after each of the 5 modules in the training course to allow more specific feedback relating to each module, including any changes in their managerial practice that participants are planning to make as a result of completing each module.

For the process evaluation interview study, participants will be invited to take part in interviews after the 6-month follow-up. Interviews will take place with (1) line managers in the intervention arm and (2) stakeholders in both the intervention and control arms.

Interviews will be conducted face-to-face, by video call, or by telephone at the participant's preference and arranged at a mutually convenient time and location. The interview schedule will cover the following research questions and topics: acceptability, usability, and utility of the intervention; changes the line manager has introduced since undertaking the training; barriers and facilitators to the intervention implementation and effectiveness; and suggested improvements to the intervention. The interviews with stakeholders will cover the following research questions and topics: barriers and facilitators to taking part in the study; acceptability of the waitlist control condition (control arm only); acceptability, usability, and utility of the intervention; and barriers and facilitators to the intervention implementation and effectiveness. For stakeholders, the gatekeeper for each participating organization (intervention and control arms) will be asked to email an invitation to participate in an interview to all relevant stakeholders within their organization (eg, human resource managers, well-being managers, learning and development managers, and trade union representatives). Principles of data saturation will be used to guide the final sample size, but as a guideline, we would expect there to be interviews with approximately 20 line managers and 1-2 stakeholders per participating organization. All interviews and analyses will be conducted by members of the research team (CB, BV, and LT). Interviews will be guided by the interview schedules and audio recorded where consent is given. Digital audio files will be transcribed and fully anonymized.

Data Analysis

The qualitative data collected will be analyzed using thematic analysis [33,34] guided by the principles of framework analysis [35,36]. The Consolidated Framework for Implementation Research [37] and the Technology Acceptance Model [38,39] will be used to provide overarching frameworks for the qualitative analysis.

Study Management

The study management group will be the research team based at the University of Nottingham and Nottinghamshire Healthcare National Health Service Foundation Trust's Institute of Mental Health. A wider advisory group will include researchers from other UK universities who are part of the wider MHPP team and who will meet monthly to monitor progress. All data will

XSL•FO
RenderX

be managed according to the GDPR, anonymized as soon as possible, and kept securely on a database that can only be accessed by the research team.

The study duration will be 24 months, with participating organizations starting to be enrolled in June 2021, and the study will cease at the end of May 2023.

Criteria for Terminating the Study

The study may be stopped as a result of a formal or informal interim analysis and based on overwhelming evidence of efficacy or inefficacy, major safety concerns, new information, or issues with study conduct (eg, poor recruitment and loss of resources). The study may be stopped at a single site as a result of a formal or informal interim analysis and based on major safety concerns at that site, new information, or issues with study conduct at that site (eg, poor recruitment and loss of resources).

Results

Recruitment for the study opened in September 2021 and closed in January 2022. A total of 24 organizations have consented to take part in the study, and 224 line managers have been recruited within these organizations. Data analysis was finished in August 2023, and we aim to publish the results later in 2024.

Discussion

This protocol describes a feasibility trial that aims to assess the recruitment and retention rates for the study; the acceptability, usability, and utility of the MMW digital training intervention; the potential for improving outcomes for line managers and their direct reports; and the barriers and facilitators to the intervention implementation and effectiveness. This type of intervention fills an important gap as its primary focus is on the prevention of poor mental health at work through the design and management of work in a way that has been shown to promote mental well-being and prevent stress. Line managers have a critical role in this regard, and the initial testing of a digital intervention that is able to engage and be used effectively by line managers in a range of contexts is an important development. The results from this pilot and feasibility study will be a first step in informing the development of subsequent trials for MMW by providing insight into the usability and acceptability of the MMW digital training in a range of employment contexts and some initial indications of change in outcome variables for line managers and their direct reports.

We acknowledge that there are some limitations to the design to be adopted in this study. The intervention has been designed as general and relevant to line managers and supervisors across all sectors and contexts. Recruiting line managers from a wide variety of organizational contexts and sectors introduces a range of potential factors that could affect the delivery of the intervention (eg, work demands, reducing the time available to complete the intervention, and a lack of support from senior managers for mental health interventions), which could in turn affect the acceptability and usability of the results. However, the planned process evaluation interview data should help us identify some specific contextual factors that act as barriers to the intervention being accessed and used by participants. The use of a waitlist control group has been chosen to allow us to recruit more organizations and line managers into the pilot feasibility trial by offering the intervention to all participants by the end of the study. This design is often used in organization or workforce intervention studies due to the complexities of engaging businesses and public sector organizations in research and the ethics of ensuring control participants have the opportunity to potentially benefit from the intervention [40-42]. However, this is a limitation as it introduces possible biases. For example, we cannot rule out contamination of the waitlist control group. All organizations, both those allocated to the intervention and those in the waitlist control, were informed by the research team about the active components of the intervention to obtain organizational consent to participate in the study. Blinding organizations to their allocation to the intervention or waitlist control was not possible, as the research team had to explain the timing of the intervention delivery to the organizational stakeholders. To try to mitigate this, the research team ensured that organizations did not know who else was taking part in the study to avoid further contamination between sites. While we acknowledge the advantages of using single- and double-blinded designs to reduce such bias, this needs to be balanced with the pragmatism of conducting research in businesses and public sector environments.

Acknowledgments

This study is funded by the Midlands Engine as part of the Mental Health and Productivity Pilots project.

Data Availability

The data sets generated during the study will be made available from the corresponding authors upon reasonable request.

Authors' Contributions

LT, JH, and HB conceived and designed the study. All authors are coinvestigators and helped to develop and refine the study design. JH developed the quantitative statistical analysis plan. LT, JH, HB, BV, CB, JY, and FM contributed to developing the intervention components. AF created the first draft of the manuscript. All listed authors read and approved the final manuscript.

Abstract

Background: Exergame-based motor-cognitive training in older adults has been associated with improvements in physical, cognitive, and psychological functioning. The novel Cocare system (Dividat GmbH), developed through a user-centered design process, allows motor-cognitive training in a telerehabilitation setting. It includes (1) a stationary stepping platform for supervised exergame training (Dividat Senso; Dividat GmbH), (2) a home-based version (Dividat Senso Flex, which is a rollable pressure-sensitive mat; Dividat GmbH), (3) an assessment system (including motor-cognitive tests), and (4) a rehabilitation cockpit for remote training supervision and management.

Objective: The aim of this study is to test the feasibility and effectiveness of this novel training system.

Methods: A total of 180 older adults from Switzerland, Italy, and Cyprus aged ≥60 years with a prescription for rehabilitation are randomly allocated to an intervention group or a control group. Both groups continue with their usual care, whereas participants in the intervention group additionally perform a 2-week supervised exergame training program at rehabilitation centers, followed by a 10-week home training program under remote supervision. The assessment system is used to indicate the start level of each participant, and, in both intervention periods, standardized progression rules are applied. The measures of feasibility include adherence, attrition, exergame enjoyment, willingness to perform such a training program, and the number and types of help requests. Effectiveness is assessed in terms of cognitive and physical functioning, balance confidence, and quality of life.

Results: Data collection started in February 2023 and is ongoing. Final measurements are expected to be performed in January 2024.

Conclusions: Owing to the user-centered design approach, the Cocare system is expected to be user-friendly and offers several novel features to cover the whole continuum of care. This pragmatic trial will provide valuable information regarding final necessary adaptations and subsequent implementation efforts.

Introduction

Background and Rationale

A steep growth in the number of people aged ≥60 years is expected by the end of the 21st century [1]. Age-related declines in physical and cognitive functioning and the associated adverse outcomes, such as restricted mobility, cognitive impairment, and falls, ultimately result in a decrease in the quality of life of older adults. Therefore, the term "active and healthy aging" (AHA) [2] is becoming increasingly important in policy frameworks worldwide.

A common strategy to promote healthy aging is to engage in physical activity. Previous research has shown that physical activity has a number of positive effects on physical and psychological health outcomes as well as on cognition in older adults [3-5]. Furthermore, it has been demonstrated that older adults benefit similarly from cognitive training programs targeting various cognitive functions such as memory, executive functions, attention, visuospatial skills, and information processing speed [6].

Given the comprehensive positive effects of physical activity and cognitive training, it has been suggested that a combination of both might be promising. Indeed, previous studies have revealed that simultaneous motor and cognitive training may be equally effective as, or even more effective than, separate or sequential training of both functions [7-13]. In fact, simultaneous motor-cognitive training can lead to improvements in physical functions such as balance [14-16], aspects of gait (eg, gait initiation) [17], and movement quality [18] as well as in cognitive functions such as executive control and processing speed [19,20], exercise enjoyment [21], decreased depressive symptoms, and an increased mental health–related quality of life [22].

However, several issues are limiting the success of such training programs; for instance, because most physical and cognitive training programs are provided face-to-face, accessibility is a major concern for older adults owing to potential mobility limitations, transportation issues, or a lack of facilities in their nearby community. Furthermore, demographic changes are increasing the need for long-term care and treatment [23] and pose financial, time, and personnel challenges to health care systems. As a result, training interventions can often not be provided for long enough durations, thus preventing patients classified as geriatric from reaching their full recovery potential and from leading an active and healthy lifestyle [24].

A solution to the aforementioned obstacles is offered by information and communication technologies, which can support the provision of care through telerehabilitation. Telerehabilitation is a broad term and can be defined as the remote provision of rehabilitation services [25]. Such a transfer of postacute rehabilitation to the home setting potentially offers a cost-effective solution to meet the increased demands on health care services, may solve the problem of accessibility, and can therefore play a key role in AHA. In addition, telerehabilitation is especially important during lockdown periods, such as those experienced during the recent COVID-19 pandemic.

Exergames are a promising option to provide telerehabilitation by means of simultaneous motor-cognitive training. They can be described as interactive whole-body movement game-based training approaches that efficiently connect motor and cognitive tasks [10]. This is the basic idea of the Cocare system (Dividat GmbH), a novel multicomponent exergame-based telerehabilitation system, including a stationary (Dividat Senso; Dividat GmbH) as well as a portable (Dividat Senso Flex; Dividat GmbH) exergame hardware device, an assessment system, and a digital training management system—the so-called rehabilitation cockpit. A more detailed description of the system can be found in the study by Seinsche et al [26].

Interventions with the Cocare system can be defined as complex interventions considering "the number of components involved; the range of behaviors targeted;...the number of groups, settings, or levels targeted; or the permitted level of flexibility of the intervention or its components" [27]. Implementation-based complex intervention research is primarily focusing on how to develop interventions that are implementable, cost-effective, and transferable to real-world settings and across different contexts [27,28]. Thereby, complex intervention research comprises four phases: (1) development of the intervention, (2) testing its feasibility, (3) evaluating the intervention, and (4) implementation of the intervention. In each phase, a major core element is the engagement of appropriate stakeholders, including those who will deliver and use the intervention [27,28]. Following this framework for the design and evaluation of complex interventions, the Cocare project was initiated to develop and validate the Cocare system applying an iterative user-centered design process to constantly refine the components of, and interventions with, the Cocare system. Previously, a focus group study was conducted to identify primary (older adults) and secondary (health care professionals) end-users' needs and requirements regarding an exergame-based telerehabilitation system in general as well as the Cocare system specifically [26]. On the basis of the results, the Cocare system was adapted before being tested in a usability study that examined the perceived usefulness as well as the ease of use, acceptability, and enjoyment of the training approach [29]. In this usability study, the Cocare system received good acceptance by primary and secondary end users, with the primary end users indicating high enjoyment while playing the exergames. However, barriers such as difficulties in understanding certain assessment and game instructions were mentioned as well. After repeated adjustments, phases 2 and 3 of complex intervention research are now targeted (ie, testing the system's feasibility and conducting a preliminary evaluation of its effectiveness).

Objectives

The objectives of this study are (1) to test the feasibility of a personalized exergame-based motor-cognitive telerehabilitation training approach using the Cocare system in older adults with a prescription for rehabilitation (inpatient or outpatient) and (2) to obtain first insights into the effects of this training approach on cognitive and motor functions, balance confidence, and quality of life.

Methods

Trial Design

To be useful for decision makers, complex intervention research should take into consideration the complexity based on the intervention's components as well as on its interaction with the context in which it is being implemented [27], which is why a pragmatic design approach was chosen. Thus, this study is conducted as an international pragmatic pilot randomized controlled trial (RCT) with 2 arms (parallel groups). The SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 checklist was used for the reporting of this pragmatic RCT [30]; however, the item order has been modified slightly for good comprehensibility of our study procedures.

Ethical Considerations

The study protocol was approved by all local ethical committees, including the Cantonal ethics committee in Zurich, Switzerland (2022-01746); the Don Carlo Gnocchi Foundation ethics committee in Italy (06_16/12/2022); and the Cyprus National Bioethics Committee (ΕΕΒΚ ΕΠ 2021 51). It has been registered at ClinicalTrials.gov (NCT05751551). Any amendments of the protocol are noted, and substantial changes will be reported to the ethics committees. All interested participants receive an information sheet and a consent form describing the study and providing sufficient information for the participant to make a decision regarding study participation. A team member (ie, the principal investigator or other investigators involved) arranges a personal meeting with the prospective participants and informs them again about all study procedures, benefits, risks, and their rights regarding study participation. Afterward, the consent form is signed by both—the participant and the investigator—before the participant undertakes any study procedure. The informed consent process is documented in REDCap (Research Electronic Data Capture; Vanderbilt University).

Participants

Study Setting

This study is an international multicenter RCT, involving an intervention group (IG) and a control group (CG), conducted in three countries or trial sites: (1) Switzerland (ETH Zurich in collaboration with VAMED Rehabilitation Center Zurich Seefeld, Zurich), (2) Italy (Don Carlo Gnocchi Foundation, Milan), and (3) Cyprus (Materia Group, Nicosia). Each trial site follows detailed standard operating procedures that have been developed before the study start for each step of the study, including recruitment, measurements, intervention, and data management.

Eligibility Criteria

Interested participants are screened for eligibility via telephone and in person. The inclusion criteria are (1) aged ≥60 years (2) a prescription for rehabilitation (as inpatient or outpatient) within the past 6 months, (3) Mini-Mental State Examination (MMSE) score ≥24, (4) physically able to independently stand for at least 2 minutes, (5) able to give informed consent, (6) internet access at home, and (7) availability of a television or a large screen at home.

The exclusion criteria are (1) permanently living in a nursing home, (2) mobility limitations or comorbidities impairing the ability to perform a step-based motor-cognitive training program, (3) cognitive limitations or comorbidities impairing the ability to perform a step-based motor-cognitive training program, (4) severe sensory impairments, (5) previous or acute major psychiatric illness (eg, schizophrenia, bipolar disorder, and recurrent major depression episodes), (6) a history of drug or alcohol abuse, (7) terminal illness, (8) participation in another clinical trial, and (9) absence from home of >2 weeks during the study period.

Intervention

Overview

The study comprises two intervention periods: (1) a 2-week supervised exergame-based intervention period at the rehabilitation center and (2) a home-based exercise intervention period of 10 weeks (a total of 12 wk considering a maximum permitted interruption of 2 wk). The first period serves as the supervised familiarization of the participants with the training approach before continuing training in their homes without direct supervision. The second period starts with the study investigators visiting the participants at home to provide guidance and safety instructions for the training program and to set up the system. After 5 weeks of home-based training, the study investigators visit IG participants again for major adaptations in the training plan. For the second half of this intervention period (week 6-week 10), a new selection of games is implemented to create sufficient variety and thus minimize boredom. In addition, participants in both groups receive biweekly telephone calls by a study investigator to collect data about their usual care as well as daily physical and cognitive activities and to ask about the perceived level of training difficulty. Adherence to, and performance in, the training sessions are supervised remotely using the rehabilitation cockpit, which also serves for remote training management or progression setup.

Description of the Training Device and the Motor-Cognitive Intervention

The device that delivers the exergame training at the clinic is the Dividat Senso, which is a stepping platform with 5 pressure-sensitive plates connected to a screen on which the stimuli of the exergames appear. The exergames are played by taking steps in 4 directions (front, back, left, and right) or body weight shifting. This approach has been shown to be feasible for motor-cognitive training in older adults and has proven effective in improving various motor and cognitive outcomes [14,31-33]. For the home-based training program, Dividat Senso

XSL•FO
RenderX

Flex (a portable version of the Dividat Senso hardware) is used. This is a foldable pressure-sensitive mat that is also connected to a television or screen. The Senso Flex system allows the same functionalities as the stationary Senso system. The motor-cognitive training with the game software targets different cognitive functions, such as attention, executive functions, and memory, and visuospatial functions as well as balance and strength.

Before starting the first intervention period, a series of physical and cognitive assessments are conducted to evaluate the participants' functional status and to create individual training plans. In both intervention periods, participants are instructed to train 3 times per week for 20 minutes, but they are allowed to divide total training volume (3 × 20 = 60 min) into more training sessions or to merge training sessions (eg, 2 × 30 = 60 min) if they wish. A training plan consisting of 15 levels of difficulty for each trained function (cognition, balance, and endurance) has been created with the levels progressing in terms of (1) choice of more difficult games and (2) increasing game duration. The initial training level is determined based on each participant's functional status.
