JMIR Research Protocols

Impact Factor (2023): 1.4
Volume 12 (2023) ISSN 1929-0748 Editor in Chief: Xiaomeng (Simone) Ma, PhDc, MS, BS

Contents

Protocols

A Universal Mental Health–Promoting Mobile App for Adolescents: Protocol for a Cluster Randomized Controlled Trial (e42119)
Sabine Kaiser, Marte Rye, Reidar Jakobsen, Monica Martinussen, Helene Høgsdal, Henriette Kyrrestad. 57

The Evaluation of Web-Based Communication Interventions to Support Decisions About COVID-19 Vaccination Among Patients With Underlying Medical Conditions: Protocol for a Randomized Controlled Trial (e42837)
Minjung Lee, Bumjo Oh, Nan-He Yoon, Shinkyeong Kim, Young-Il Jung. 64

Enhancing Self-care Among Oral Cancer Survivors: Protocol for the Empowered Survivor Trial (e39996)
Sharon Manne, Matin Imanguli, Deborah Kashy, Morgan Pesanelli, Sara Frederick, Janet Van Cleave, Lisa Paddock, Shawna Hudson, Michael Steinberg, Patrick Clifford, Mara Domider, Neetu Singh. 78

Facebook Intervention for Young-Onset Melanoma Survivors and Families: Protocol for a Randomized Controlled Trial (e39640)
Sharon Manne, Sherry Pagoto, Susan Peterson, Carolyn Heckman, Deborah Kashy, Adam Berger, Christina Studts, Rosalyn Negrón, David Buller, Lisa Paddock, Joseph Gallo, Alexandria Kulik, Sara Frederick, Morgan Pesanelli, Mara Domider, Marissa Grosso. 103

Comparing Smartphone Virtual Reality Exposure Preparation to Care as Usual in Children Aged 6 to 14 Years Undergoing Magnetic Resonance Imaging: Protocol for a Multicenter, Observer-Blinded, Randomized Controlled Trial (e41080)
Zita van Spaendonck, Koen Leeuwenburgh, Marjolein Dremmen, Joost van Schuppen, Daniëlle Starreveld, Bram Dierckx, Jeroen Legerstee.
1 2 5

Digitally Delivered Dietary Interventions for Patients with Eating Disorders Undergoing Family-Based Treatment: Protocol for a Randomized Feasibility Trial (e41837)
Megan Hellner, Dori Steinberg, Jessica Baker, Camilla Blanton. 135

The Effects of a Web-Based Intervention to Reduce Alcohol Consumption Among Middle-Aged Women: Protocol for a Randomized Controlled Trial (e34842)
Mia Miller, Cassandra Wright, Emmanuel Kuntsche, Sandra Kuntsche. 144

Assessing the Feasibility of a Text-Based Conversational Agent for Asthma Support: Protocol for a Mixed Methods Observational Study (e42965)
Rafael Calvo, Dorian Peters, Laura Moradbakhti, Darren Cook, Georgios Rizos, Bjoern Schuller, Constantinos Kallis, Ernie Wong, Jennifer Quint. 154

XSL•FO
RenderX

Mobile Mental Health in Women's Community-Based Organizations: Protocol for a Pilot Randomized Controlled Trial (e42919)
Amritha Bhat, B Goud, Bharat Kalidindi, Johnson Ruben, Dhinagaran Devadass, Abijeet Waghmare, Pamela Collins, Tony Raj, Krishnamachari Srinivasan. . . . 163

Tough Talks COVID-19 Digital Health Intervention for Vaccine Hesitancy Among Black Young Adults: Protocol for a Hybrid Type 1 Effectiveness Implementation Randomized Controlled Trial (e41240)
Henna Budhwani, Allysha Maragh-Bass, Elizabeth Tolley, Maria Comello, Marie Stoner, Margo Adams Larsen, Donald Brambilla, Kathryn Muessig, Audrey Pettifor, Christyenne Bond, Christina Toval, Lisa Hightow-Weidman. . . . 172

Layperson-Facilitated Internet-Delivered Cognitive Behavioral Therapy for Homebound Older Adults With Depression: Protocol for a Randomized Controlled Trial (e44210)
Jay Kayser, Xu Wang, Zhenke Wu, Asha Dimoji, Xiaoling Xiang. . . . 183

The Design, Development, and Implementation of a Web-Enabled Informatics Platform to Enhance the Well-being of Individuals Aged 18-24 Years: Protocol for an Experimental Study (e38632)
Bhavya Malhotra, Jagannath Sahoo, Mansi Gupta, Ashish Joshi. . . . 194

A Relational Agent Intervention for Adolescents Seeking Mental Health Treatment: Protocol for a Randomized Controlled Trial (e44940)
Emil Chiauzzi, Athena Robinson, Kate Martin, Carl Petersen, Nicole Wells, Andre Williams, Mary Gleason. . . . 203

Attitudes of Physicians and Individuals Toward Digital Mental Health Tools: Protocol for a Web-Based Survey Research Project (e41040)
Diogo Nogueira-Leite, Ricardo Cruz-Correia. . . . 214

Evaluation of Two Web-Based Interventions (Res-Up! and REMOTION) in Routine Outpatient Psychotherapy (Therapy Online Plus—TOP): Protocol for a Randomized Controlled Trial (e41413)
Leonie Trimpop, Laura Bielinski, Thomas Berger, Ulrike Willutzki. . . . 227

Shoulder Rehabilitation Exercises With Kinematic Biofeedback After Arthroscopic Rotator Cuff Repair: Protocol for a New Integrated Rehabilitation Program (e35757)
Ilaria Parel, Valeria Candoli, Maria Filippi, Antonio Padolino, Giovanni Merolla, Stefano Sanniti, Riccardo Galassi, Paolo Paladini, Andrea Cutti.
2 3 9

An Evidence-Based Serious Game App for Public Education on Antibiotic Use and Antimicrobial Resistance: Protocol of a Randomized Controlled Trial (e45833)
Zhilian Huang, Wern Tang, Huiling Guo, Karthiga Natarajan, Tau Lee, Tsin Yeo, Angela Chow. . . . 257

Evaluation of the Effectiveness of Therapy for Anxiety in Williams Beuren Syndrome Using a Smartphone App: Protocol for a Single-Case Experiment (e44393)
Natacha Lehman, Raphaël Trouillet, David Genevieve. . . . 268

A Probiotic Intervention With Bifidobacterium longum NCC3001 on Perinatal Mood Outcomes (PROMOTE Study): Protocol for a Decentralized Randomized Controlled Trial (e41751)
Melissa Toh, Chui Yang, Phei Lim, Hui Loh, Gabriela Bergonzelli, Luca Lavalle, Elias Mardhy, Tinu Samuel, Elvira Suniega-Tolentino, Irma Silva Zolezzi, Lisa Fries, Shiao Chan. . . . 279

Personalized, Naturalistic Virtual Reality Scenarios Coupled With Web-Based Progressive Muscle Relaxation Training for the General Population: Protocol for a Proof-of-Principle Randomized Controlled Trial (e44183)
Susanna Pardini, Silvia Gabrielli, Silvia Olivetto, Francesca Fusina, Marco Dianti, Stefano Forti, Cristina Lancini, Caterina Novara. . . . 294

XSL•FO

Action Observation Treatment for Upper Limb Rehabilitation in Patients With Stroke: Protocol for a Multicenter Randomized Controlled Trial (e42094)
Peppino Tropea, Francesco Infarinato, Irma Sterpi, Marco Ottaviani, Paola Antoniotti, Paola Romano, Michela Picardi, Michela Goffredo, Riccardo Re, Sanaz Pournajaf, Agnese Seregni, Antonio Caronni, Marco Franceschini, Massimo Corbo. 308

Breaking Down Barriers to a Suicide Prevention Helpline: Protocol for a Web-Based Randomized Controlled Trial (e41078)
Margot van der Burgt, Saskia Mérelle, Willem-Paul Brinkman, Aartjan Beekman, Renske Gilissen. 322

A Medicoeconomic Evaluation of a Telehealth Platform for Elective Outpatient Surgeries: Protocol for a Randomized Controlled Trial (e44006)
Florian Robin, Maxim Roy, Alexandre Kuftedjian, Laurelie Perret, Frédéric Lavoie, Alexandre Castonguay, Marie-Pascale Pomey, Cedrick Zaouter, Guy Pare. 331

Combining Behavioral Economics–Based Incentives With the Anchoring Strategy: Protocol for a Randomized Controlled Trial (e39930)
Chad Stecher, Sara Cloonan, Sebastian Linnemayr, Jennifer Huberty. 340

Effect of the Red Bull Energy Drink on Perfusion-Related Variables in Women Undergoing Microsurgical Breast Reconstruction: Protocol and Analysis Plan for a Prospective, Multicenter Randomized Controlled Trial (e38487)
Nicole Speck, Michal Michalak, Kathrin Dreier, Doris Babst, Alessia Lardi, Jian Farhadi. 357

Acceptability and Feasibility of a Patient-Oriented Music Intervention to Reduce Pain in the Intensive Care Unit: Protocol for a Crossover Pilot Randomized Controlled Trial (e40760)
Melissa Richard-Lalonde, Nancy Feeley, Sylvie Cossette, Linda Chlan, Céline Gélinas. 366

Clinical Assessment of Eye Movement Desensitization and Reprocessing in Memory Distress: Protocol for a Double-Blinded Randomized Controlled Trial (e38552)
Nazanin Babaei, Camrie Kerry, Kisha Goode, Kevin Dang, Parsa Mirzadeh, Meysam Pirbaglou, Megan Kirk, Paul Ritvo. 378

Feasibility, Usability, and Safety of ParaGym, an Intelligent Mobile Exercise App for Individuals With Paraplegia: Protocol for a Pilot Block-Randomized Controlled Trial (e45652)
Janika Bolz, Adrian Löscher, Rainer Muhl, Andreas Badke, Hans-Georg Predel, Claudio Perret. 387

Coping After Breast Cancer: Protocol for a Randomized Controlled Trial of Stress Management eHealth Interventions (e47195)
Karianne Svendsen, Lise Nes, Anders Meland, Ine Larsson, Ylva Gjelsvik, Elin Børøsund, Christine Rygg, Tor Myklebust, Kristin Reinertsen, Cecilie Kiserud, Helle Skjerven, Michael Antoni, Trudie Chalder, Ingvil Mjaaland, Linda Carlson, Hege Eriksen, Giske Ursin. 405

Internet-Delivered Dialectical Behavioral Therapy Skills Training for Chronic Pain: Protocol for a Randomized Controlled Trial (e41890)
Nell Norman-Nott, Negin Hesam-Shariati, Chelsey Wilks, Jessica Schroeder, Jina Suh, Nancy Briggs, James McAuley, Yann Quidé, Sylvia Gustin. 421

Adaptation of a Mobile Interactive Obesity Treatment Approach for Early Severe Mental Illness: Protocol for a Mixed Methods Implementation and Pilot Randomized Controlled Trial (e42114)
Ginger Nicol, Madeline Jansen, Amanda Ricchio, Julia Schweiger, Katie Keenoy, J Miller, Elaine Morrato, Zhaohua Guo, Bradley Evanoff, Joseph Parks, John Newcomer. 440

Coach-Supported Versus Self-guided Digital Training Course for a Problem-solving Psychological Intervention for Nonspecialists: Protocol for a Pre-Post Nested Randomized Controlled Trial (e41981)
Sonal Mathur, Helen Weiss, Melissa Neuman, Andy Field, Baptiste Leurent, Tejaswi Shetty, James J, Pooja Nair, Rhea Mathews, Kanika Malik, Daniel Michelson, Vikram Patel. 456

Audit, Feedback, and Education to Improve Quality and Outcomes in Transurethral Resection and Single-Instillation Intravesical Chemotherapy for Nonmuscle Invasive Bladder Cancer Treatment: Protocol for a Multicenter International Observational Study With an Embedded Cluster Randomized Trial (e42254)

Kevin Gallagher, Nikita Bhatt, Keiran Clement, Eleanor Zimmermann, Sinan Khadhouri, Steven MacLennan, Meghana Kulkarni, Fortis Gaba, Thineskrishna Anbarasan, Aqua Asif, Alexander Light, Alexander Ng, Vinson Chan, Arjun Nathan, David Cooper, Lorna Aucott, Gautier Marcq, Jeremy Teoh, Patrick Hensley, Eilidh Duncan, Beatriz Goulao, Tim O'Brien, Matthew Nielsen, Paramananthan Mariappan, Veeru Kasivisvanathan. 468

Positive Psychological Intervention Delivered Using Virtual Reality in Patients on Hemodialysis With Comorbid Depression: Protocol and Design for the Joviality Randomized Controlled Trial (e45100)

Rosalba Hernandez, Ken Wilund, Killivalavan Solai, David Tamayo, Drew Fast, Prasakthi Venkatesan, James Lash, Claudia Lora, Lizet Martinez, Geovana Martin Alemañy, Angela Martinez, Soonhyung Kwon, Dana Romero, Matthew Browning, Judith Moskowitz. 483

Prevention and Treatment of Social Anxiety Disorder in Adolescents: Protocol for a Randomized Controlled Trial of the Online Guided Self-Help Intervention SOPHIE (e44346)

Noemi Walder, Thomas Berger, Stefanie Schmidt. 496

Evaluating the Feasibility of a Multiplayer Role-Playing Game as a Behavioral Health Intervention in Adolescent Patients With Chronic Physical or Mental Conditions: Protocol for a Cohort Study (e43987)

Dmitriy Babichenko, Ana Radovic, Ravi Patel, Alexis Hester, Koehler Powell, Nicholas Eggers, David Happe. 514

Improvement in Quality of Life With the Use of a Technological System Among Patients With Chronic Disease Followed Up in Primary Care (TeNDER Project): Protocol for a Randomized Controlled Trial (e47331)

Cristina Lozano Hernández, Rodrigo Medina-García, Mª de Hoyos-Alonso, Araceli Garrido-Barral, César Minué Lorenzo, Teresa Sanz-Cuesta, Javier Serrano, Alberto del Rio Ponce, Tomas Gómez-Gascón, Isabel del Cura-González, TeNDER Group Primary Care. 528

Remote Patient Monitoring and Teleconsultation to Improve Health Outcomes and Reduce Health Care Utilization of Pediatric Asthma (ALPACA Study): Protocol for a Randomized Controlled Effectiveness Trial (e45585)

Mattienne van der Kamp, Vera Hengeveld, Nico Willard, Boony Thio, Pascal de Graaf, Inge Geven, Monique Tabak. 538

Adaptive P300-Based Brain-Computer Interface for Attention Training: Protocol for a Randomized Controlled Trial (e46135)

Sandra-Carina Noble, Eva Woods, Tomas Ward, John Ringwood. 552

Leveraging Electronic Health Record Technology and Team Care to Address Medication Adherence: Protocol for a Cluster Randomized Controlled Trial (e47930)

Saul Blecker, Antoinette Schoenthaler, Tiffany Martinez, Hayley Belli, Yunan Zhao, Christina Wong, Cassidy Fitchett, Harris Bearnot, Devin Mann. 563

The Effect of Catgut Embedding at Acupoints Versus Nonacupoints in Abdominal Obesity: Protocol for a Multicenter, Double-Blind, 16-Week Randomized Controlled Trial (e46863)

Qifu Li, Gaoyangzi Huang, Xianmei Pei, Xin Tang, Renrui Zhang, Ya Huang, Zili Liu, Rong Yi, Chonghui Xing, Xinghe Zhang, Taipin Guo. . . .
5 7 4

Does an Internet-Based Emotion Regulation Intervention Provide Added Value for Acute Psychiatric Inpatient Care? Protocol for a Randomized Controlled Pilot Trial (e47656)

Laura Bielinski, Gwendolyn Wälchli, Christoph Nissen, Thomas Berger, Franz Moggi. 587

Creating an Innovative Artificial Intelligence–Based Technology (TCRact) for Designing and Optimizing T Cell Receptors for Use in Cancer Immunotherapies: Protocol for an Observational Trial (e45872)

Joanna Bujak, Stanisław Kł k, Martyna Balawejder, Aleksandra Kociniak, Kinga Wilkus, Rafał Szatanek, Zofia Orzeszko, Joanna Welanyk, Grzegorz Torbicz, Mateusz J ckowski, Tomasz Kucharczyk, Łukasz Wohadlo, Maciej Borys, Honorata Stadnik, Michał Wysocki, Magdalena Kayser, Marta Słomka, Anna Kosmowska, Karolina Horbacka, Tomasz Gach, Beata Markowska, Tomasz Kowalczyk, Jacek Karo , Marek Karczewski, Mirosław Szura, Anna Sanecka-Duin, Agnieszka Blum. 599

Personalized Integrated Care Promoting Quality of Life for Older People: Protocol for a Multicenter Randomized Controlled Trial (e47916)
Elda Judica, Peppino Tropea, Raquel Bouça-Machado, Mayca Marín, Elisa Calarota, Liviu Cozma, Raluca Badea, Mona Ahmed, Michael Brach, Joaquim Ferreira, Massimo Corbo. . . . 610

Evaluation of 2 Artificial Intelligence Software for Chest X-Ray Screening and Pulmonary Tuberculosis Diagnosis: Protocol for a Retrospective Case-Control Study (e36121)
Muhammad Mohd Hisham, Noor Lodz, Eida Muhammad, Filza Asari, Mohd Mahmood, Zamzurina Abu Bakar. . . . 626

Evaluation of a Web-Based Self-Help Intervention for Patients With Generalized Anxiety Disorder: Protocol for a Randomized Controlled Trial (e41440)
Julian Rubel, Jannis Quest, Luise Pruessner, Christina Timm, Steffen Hartmann, Sven Barnow, Lisa Rittmeyer, David Rosenbaum, Christopher Lalk. . . . 635

Effects of the Pregnancy and Newborn Diagnostic Assessment (PANDA) App on Antenatal Care Quality in Burkina Faso: Protocol for a Cluster Randomized Controlled Trial (e37136)
Abou Coulibaly, Séni Kouanda. . . . 646

Identifying the Most Effective Recruitment Strategy Using Financial Reimbursements for a Web-Based Peer Network Study With Young People Aged 16-18 Years: Protocol for a Randomized Controlled Trial (e44813)
Michelle Raggatt, Cassandra Wright, Rachel Sacks-Davis, Paul Dietze, Margaret Hellard, Jane Hocking, Megan Lim. . . . 660

Effects of Increased Standing and Light-Intensity Physical Activity to Improve Postprandial Glucose in Sedentary Office Workers: Protocol for a Randomized Crossover Trial (e45133)
Shannon Wilson, Rachel Crosley-Lyons, Jordan Junk, Kristina Hasanaj, Miranda Larouche, Kevin Hollingshead, Haiwei Gu, Corrie Whisner, Dorothy Sears, Matthew Buman. . . . 669

Evaluating the Effectiveness of a Codeveloped e-Mental Health Intervention for University Students: Protocol for a Randomized Controlled Trial (e49364)
Angel Wang, Melissa Vereschagin, Chris Richardson, Hui Xie, Kristen Hudec, Richard Munthali, Lonna Munro, Calista Leung, Ronald Kessler, Daniel Vigo. . . . 683

Just-In-Time Adaptive Intervention to Sit Less and Move More in People With Type 2 Diabetes: Protocol for a Microrandomized Trial (e41502)
Reza Daryabeygi-Khotbehsara, David Dunstan, Sheikh Islam, Yuxin Zhang, Mohamed Abdelrazek, Ralph Maddison. . . . 696

An eHealth Program for Insomnia in Children With Neurodevelopmental Disorders (Better Nights, Better Days): Protocol for an Economic Evaluation of a Randomized Controlled Trial (e46735)
Xiao Jia, Pantelis Andreou, Cary Brown, Evelyn Constantin, Roger Godbout, Ana Hanlon-Dearman, Osman Ipsiroglu, Graham Reid, Sarah Shea, Isabel Smith, Jennifer Zwicker, Shelly Weiss, Penny Corkum. . . . 706

Evaluating a WeChat-Based Health Behavioral Digital Intervention for Patients With Hypertension: Protocol for a Randomized Controlled Trial (e46883)
Ting Sun, Huanhuan Zhao, Zenghui Ding, Hui Xie, Linlin Ma, Yu Zhang, Yingying Wang, Yinju Yang, Chunyi Xu, Yining Sun, Xuejie Xu, Zuchang Ma. . . . 714

Internet-Based Cognitive Behavioral Therapy and Virtual Reality Exposure Therapy for Social Anxiety Disorder: Protocol for a Randomized Controlled Trial in Hong Kong (e48437)
Jia-Yan Pan. . . . 726

Effectiveness, Acceptability, and Feasibility of a Telehealth HIV Pre-Exposure Prophylaxis Care Intervention Among Young Cisgender Men and Transgender Women Who Have Sex With Men: Protocol for a Randomized Controlled Trial (e47932)
Rebecca Braun, Rebecca Erenrich, Karin Coyle, Thuan-Huong Doan, Jeffrey Klausner. . . . 738

XSL•FO
RenderX

Obstructive Sleep Apnea and a Comprehensive Remotely Supervised Rehabilitation Program: Protocol for a Randomized Controlled Trial (e47460)
Jakub Hnatiak, Lujza Zikmund Galkova, Petr Winnige, Ladislav Batalik, Filip Dosbaba, Ondrej Ludka, Jan Krejci. 751

Working Memory Training for Children Using the Adaptive, Self-Select, and Stepwise Approaches to Setting the Difficulty Level of Training Activities: Protocol for a Randomized Controlled Trial (e47496)
Regine Lau, Peter Anderson, Joshua Wiley, Derek Huang, Faisha Surjatin, Paul McIntosh, Susan Gathercole, Megan Spencer-Smith. 760

Guided Internet-Based Cognitive Behavioral Therapy for Women With Bulimia Nervosa: Protocol for a Multicenter Randomized Controlled Trial (e49828)
Sayo Hamatani, Kazuki Matsumoto, Gerhard Andersson, Yukiko Tomioka, Shusuke Numata, Rio Kamashita, Atsushi Sekiguchi, Yasuhiro Sato, Shin Fukudo, Natsuki Sasaki, Masayuki Nakamura, Ryoko Otani, Ryoichi Sakuta, Yoshiyuki Hirano, Hirotaka Kosaka, Yoshifumi Mizuno. . . .
7 7 3

Comparing the Efficacy of an Electronically Delivered Cognitive Behavioral Therapy Program to a Mental Health Check-In Program for Generalized Anxiety Disorder: Protocol for a Randomized Trial (e48899)
Callum Stephenson, Anchan Kumar, Niloufar Malakouti, Niloofar Nikjoo, Jasleen Jagayat, Tessa Gizzarelli, Charmy Patel, Gilmar Gutierrez, Amirhossein Shirazi, Megan Yang, Mohsen Omrani, Nazanin Alavi. 784

A Suicide Prevention Intervention for Emerging Adult Sexual and Gender Minority Groups: Protocol for a Pilot Hybrid Effectiveness Randomized Controlled Trial (e48177)
Lily Brown, Jessica Webster, Jennifer Tran, James Wolfe, Jesse Golinkoff, Esha Patel, Amanda Arcomano, Jennifer Ben Nathan, Alexander Azat O'Connor, Yiqin Zhu, Maria Oquendo, Gregory Brown, David Mandell, Danielle Mowery, José Bauermeister. 792

Testing the Effects of App-Based Motivational Messages on Physical Activity and Resting Heart Rate Through Smartphone App Compliance in Patients With Vulnerable Coronary Artery Plaques: Protocol for a Microrandomized Trial (e46082)
Sayan Mitra, Cynthia Kroeger, Jing Xu, Leah Avery, Andrius Masedunskas, Sophie Cassidy, Tian Wang, Imre Hunyor, Ian Wilcox, Robin Huang, Bibhas Chakraborty, Luigi Fontana. 809

Testing a Model of Care for Patients on Immune Checkpoint Inhibitors Based on Electronic Patient-Reported Outcomes: Protocol for a Randomized Phase II Controlled Trial (e48386)
André da Silva Lopes, Sara Colomer-Lahiguera, Célia Darnac, Stellio Giacomini, Sébastien Bugeia, Garance Gutknecht, Gilliosa Spurrier-Bernard, Michel Cuendet, Fanny Muet, Veronica Aedo-Lopez, Nuria Mederos, Olivier Michielin, Alfredo Addeo, Sofiya Latifyan, Manuela Eicher. 821

Pilot Testing of an mHealth App for Tobacco Cessation in People Living With HIV: Protocol for a Pilot Randomized Controlled Trial (e49558)
Maeve Brin, Paul Trujillo, Haomiao Jia, Patricia Cioe, Ming-Chun Huang, Huan Chen, Xiaoye Qian, Wenyao Xu, Rebecca Schnall. 835

Applying AI and Guidelines to Assist Medical Students in Recognizing Patients With Heart Failure: Protocol for a Randomized Trial (e49842)
Hyeon Joo, Michael Mathis, Marty Tam, Cornelius James, Peijin Han, Rajesh Mangrulkar, Charles Friedman, VG Vydiswaran. 845

Improving Mild to Moderate Depression With an App-Based Self-Guided Intervention: Protocol for a Randomized Controlled Trial (e46651)
Ina Beintner, André Kerber, Clara Dominke, Ulrich Voderholzer. 857

Optimization of a Transdiagnostic Mobile Emotion Regulation Intervention for University Students: Protocol for a Microrandomized Trial (e46603)
Tajda Laure, Rutger Engels, Danielle Remmerswaal, Donna Spruijt-Metz, Stefan Konigorski, Marilisa Boffo. 870

XSL•FO
RenderX

A Multisite Electronic Health Record Integrated Remote Monitoring Intervention for Hypertension Improvement: Protocol for a Randomized Pragmatic Comparative Effectiveness Trial (e45915)
David Lee, Matthew Chenoweth, Linh Chuong, Chad Villaflores, Miguel Cuevas, Sitaram Vangala, Jeff Borenstein, Hannah Kwak, Chidinma Chima-Melton, Maria Han, Samuel Skootsky, Therese Chan Tack, Linda Branagan, Heather Martin, Reshma Gupta, Linda Phan, Michael Sanchez, Mina Malaak, Anna Dermenchyan, Kandyce Pearson, Marine Altunyan, Peter Barakat, Ray Pablo, Catherine Sarkisian. 889

Online-Mediated HIV Pre-exposure Prophylaxis Care and Reduced Monitoring Frequency for Men Who Have Sex With Men: Protocol for a Randomized Controlled Noninferiority Trial (EZI-PrEP Study) (e51023)
Marije Groot Bruinderink, Anders Boyd, Liza Coyer, Sophie Boers, Laura Blitz, Jean-Marie Brand, Hannelore Götz, Martijn Stip, Joey Woudstra, Kenneth Yap, Koenraad Vermey, Amy Matser, Allard Feddes, Vita Jongen, Maria Prins, Elske Hoornenborg, Frenk van Harreveld, Maarten Schim van der Loeff, Udi Davidovich. 900

Use of Immersive Virtual Reality Spaces to Engage Adolescent and Young Adult Patients With Cancer in Therapist-Guided Support Groups: Protocol for a Pre-Post Study (e48761)
Asher Marks, Amanda Garbatini, Kimberly Hieftje, Vidya Puthenpura, Veronica Weser, Claudia-Santi Fernandes. 917

Effects of a Virtual Reality Game on Children's Anxiety During Dental Procedures (VR-TOOTH): Protocol for a Pilot Randomized Controlled Trial (e49956)
Wenjia Wu, Sylvie Le May, Nicole Hung, Olivier Fortin, Christine Genest, Maxime Francoeur, Estelle Guingo, Kate St-Arneault, Annie Sylfra, An Vu, Janick Carmel, Laurence Lessard, Stephany Cara-Slavich, Katheryn De Koven, Julie Paquette, Hunter Hoffman, Marie-Eve Asselin. . . .
9 2 8

Behavioral Activation for Comorbid Depression in People With Noncommunicable Disease in India: Protocol for a Randomized Controlled Feasibility Trial (e41127)
Rayeesa Zainab, Arun Kandasamy, Naseer Bhat, Chrishma Dsouza, Hannah Jennings, Cath Jackson, Papiya Mazumdar, Catherine Hewitt, David Ekers, Gitanjali Narayanan, Girish Rao, Karen Coales, Krishna Muliyala, Santosh Chaturvedi, Pratima Murthy, Najma Siddiqi. 937

Assessing the Efficacy and Safety of a Digital Therapeutic for Symptoms of Depression in Adolescents: Protocol for a Randomized Controlled Trial (e48740)
Daniella Furman, Shana Hall, Claudia Avina, Vera Kulikov, Jessica Lake, Aarthi Padmanabhan. 949

Usability and Efficacy of Artificial Intelligence Chatbots (ChatGPT) for Health Sciences Students: Protocol for a Crossover Randomized Controlled Trial (e51873)
Mirella Veras, Joseph-Omer Dyer, Morgan Rooney, Paulo Barros Silva, Derek Rutherford, Dahlia Kairy. 961

Design Research to Embed mHealth into a Community-Led Blood Pressure Management System in Uganda: Protocol for a Mixed Methods Study (e46614)
Josephine Schwab, Jonas Wachinger, Richard Munana, Maxencia Nabiryo, Isaac Sekitoleko, Juliette Cazier, Rebecca Ingenhoff, Caterina Favaretti, Vasanthi Subramonia Pillai, Ivan Weswa, John Wafula, Julius Emmrich, Till Bärnighausen, Felix Knauf, Samuel Knauss, Christine Nalwadda, Nikkil Sudharsanan, Robert Kalyesubula, Shannon McMahon. 972

Repetitive Transcranial Magnetic Stimulation With and Without Text4Support for the Treatment of Resistant Depression: Protocol for a Patient-Centered Multicenter Randomized Controlled Pilot Trial (e46830)
Medard Adu, Raquel Dias, Belinda Agyapong, Ejemai Eboreime, Adegboyega Sapara, Mobolaji Lawal, Corina Chew, Karen Diamond Frost, Daniel Li, Michael Flynn, Sameh Hassan, Ahmed Saleh, Sanjana Sridharan, Matt White, Vincent Agyapong. 991

Analgesic Effect of Intraoperative Intravenous S(+)-Ketamine During Total Knee Arthroplasty Surgery: Study Protocol for a Randomized Controlled Clinical Trial (e53063)
Shiyuan Deng, Lina Chen, Xiao Song, Liang Guo, Fei Zhao, Jing Liu, Ling Dong. 1006

Effect of Baduanjin Qigong on Sleep Quality and Hyperarousal State in Adults With Chronic Insomnia: Protocol for a Randomized Controlled Trial (e53501)
Chaoqun Xie, Fangfang Xie, Jianwen Ma, Hongyu Yue, Yanli You, Fei Yao. 1014

A Machine Learning Model to Predict Patients' Adherence Behavior and a Decision Support System for Patients With Metastatic Breast Cancer: Protocol for a Randomized Controlled Trial (e48852)
Marianna Masiero, Gea Spada, Virginia Sanchini, Elisabetta Munzone, Ricardo Pietrobon, Lucas Teixeira, Mirtha Valencia, Aline Machiavelli, Elisa Fragale, Massimo Pezzolato, Gabriella Pravettoni. 1026

XSL•FO

Digital Support Systems to Improve Child Health and Development in Peru: Protocol for a Randomized Controlled Trial (e50371)
Stella Hartinger Pena, Daniel Mäusezahl, Lena Jäggi, Leonel Aguilar, Milagros Alvarado Llatance, Andreana Castellanos, Maria-Luisa Huaylinos Bustamante, Kristen Hinckley, Dana Charles McCoy, Ce Zhang, Günther Fink. . . . 1038

A Relationship-Based Resilience Program for Promotores: Protocol for a Randomized Controlled Waitlist Trial (e51427)
Daniela Arcos, Lyric Russo, Kelly Kazmierski, Elayne Zhou, Gloria Montiel, America Bracho, Nancy Mejia, Jessica Borelli. . . . 1050

Teaching Adolescents With Type 1 Diabetes Self-Compassion (TADS) to Reduce Diabetes Distress: Protocol for a Randomized Controlled Trial (e53935)
Saunya Dover, Alexandra Ahmet, Karen Bluth, Brian Feldman, Ellen Goldbloom, Gary Goldfield, Sarah Hamilton, Omar Imran, Adam Khalif, Karine Khatchadourian, Sarah Lawrence, Andrew Leonard, Kuan Liu, Yongdong Ouyang, Corien Peeters, Jai Shah, Noah Spector, Caroline Zuijdwijk, Marie-Eve Robinson. . . . 1065

Follow-Up of Patients With Axial Spondyloarthritis in Specialist Health Care With Remote Monitoring and Self-Monitoring Compared With Regular Face-to-Face Follow-Up Visits (the ReMonit Study): Protocol for a Randomized, Controlled Open-Label Noninferiority Trial (e52872)
Inger Berg, Anne Tveter, Gunnstein Bakland, Sarah Hakim, Eirik Kristianslund, Siri Lillegraven, Gary Macfarlane, Ellen Moholt, Sella Provan, Joseph Sexton, Emil Thomassen, Annette De Thurah, Laure Gossec, Espen Haavardsholm, Nina Østerås. . . . 1079

FLASH Radiotherapy for the Treatment of Symptomatic Bone Metastases (FAST-01): Protocol for the First Prospective Feasibility Study (e41812)
Emily Daugherty, Anthony Mascia, Yong Zhang, Eunsin Lee, Zhiyan Xiao, Mathieu Sertorio, Jennifer Woo, Claire McCann, Kenneth Russell, Lisa Levine, Ricky Sharma, Deepak Khuntia, Jeffrey Bradley, Charles Simone II, John Perentesis, John Breneman. . . . 1095

Neural Correlates of the DEEPP (Anti-suicidal Response to Ketamine in Treatment-Resistant Bipolar Depression) Study: Protocol for a Pilot, Open-Label Clinical Trial (e41013)
Yuliya Knyahnytska, Reza Zomorrodi, Tyler Kaster, Daphne Voineskos, Alisson Trevizol, Daniel Blumberger. . . . 1106

The Effect of Prophylactic Intravenous Amiodarone Administration on Reperfusion Ventricular Fibrillation in Patients With Left Ventricular Hypertrophy Undergoing Cardiopulmonary Bypass Surgery: Protocol for a Randomized Double-Blind Clinical Trial (e40115)
Xiaokai Zhou, Zhenfeng Zhang, Chanjuan Gong, Yin Fang. . . . 1117

A Text Messaging–Based Support Intervention to Enhance Pre-exposure Prophylaxis for HIV Prevention Adherence During Pregnancy and Breastfeeding: Protocol for a Randomized Controlled Trial (e41170)
Jerusha Mogaka, Felix Otieno, Eunita Akim, Kristin Beima-Sofie, Julia Dettinger, Lauren Gomez, Mary Marwa, Ben Odhiambo, Kenneth Ngure, Keshet Ronen, Monisha Sharma, Grace John-Stewart, Barbra Richardson, Joshua Stern, Jennifer Unger, Jenna Udren, Salphine Watoyi, Jillian Pintye, John Kinuthia. . . . 1126

Effectiveness of an Individualized Exergame-Based Motor-Cognitive Training Concept Targeted to Improve Cognitive Functioning in Older Adults With Mild Neurocognitive Disorder: Study Protocol for a Randomized Controlled Trial (e41173)
Patrick Manser, Lars Michels, André Schmidt, Filip Barinka, Eling de Bruin. . . . 1141

Physiological and Psychological Effects of Parent-Delivered Traditional Thai Massage in Children With Autism: Protocol for a Randomized Controlled Trial (e41839)
Hui Ruan, Wichai Eungpinichpong, Hua Wu, Chanada Aonsri. . . . 1171

Nitric Oxide on Extracorporeal Membrane Oxygenation in Neonates and Children (NECTAR Trial): Protocol for a Randomized Controlled Trial (e43760)
Adrian Mattke, Kerry Johnson, Kristen Gibbons, Debbie Long, Jeremy Robertson, Prem Venugopal, Antje Blumenthal, Andreas Schibler, Luregn Schlapbach. . . . 1183

XSL•FO

Abstract

Background: In times of increasing mental health problems among young people, strengthening efforts to improve mental health through mental health promotion and prevention becomes increasingly important. Effective measures that support young people in coping with negative thoughts, feelings, and stress are essential, not just for the individual but also for society.

Objective: The aim of this paper is to provide a description of a cluster randomized controlled trial that will be conducted to examine the effectiveness of Opp, a universal mental health–promoting mobile app for adolescents aged 13 to 19 years that provides information and exercises to better cope with stress, negative thoughts, and negative feelings. The protocol was developed in accordance with the SPIRIT checklist.

Methods: An effectiveness study will be conducted with 3 measurement points: preintervention (T1), 2 weeks after the intervention (T2), and about 1 month after the intervention (T3). Adolescents will be recruited from middle and high schools in Norway and randomly assigned to the intervention or control groups. Randomization will be conducted on the school level. Opp can be downloaded from the Google Play or App Store but is password protected with a 4-digit code, which will be removed after study completion. Participants in the intervention group will receive a text message with the code to unlock the app. The participants in the intervention group can use Opp without limits on length or time of use. Objective data on how long or how often the participants use the app will not be collected. However, the second and third questionnaires for the intervention group contain app-specific questions on, for example, the use of the app.

Results: Recruitment and data collection started in August and September 2022. So far, 381 adolescents have answered the first questionnaire. Data collection was expected to end in December 2022 but has had to be prolonged to approximately June 2023. The results of the study will be available in 2023 at the earliest.

Conclusions: This project will contribute unique knowledge to the field, as there are few studies that have examined the effects of universal health-promoting mobile apps for adolescents. However, several limitations have to be taken into account when interpreting the results, such as randomization on the school level, the short time frame in which the study was conducted, and the lack of objective data to monitor the use of the app.

Introduction

Background

The World Health Organization defines mental health as a "state of well-being in which the individual realizes his or her own abilities, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her community" [1]. Good mental health is essential to good health in general and is strongly related to quality of life and participation in school and leisure activities. A scoping review that underlined how difficult it is to define and operationalize good mental health identified 14 core domains of good mental health in young people, including attitudes toward mental disorders, self-perceptions, emotions, behaviors, self-management strategies, social skills, family and significant relationships, and quality of life [2]. The authors wrote that mental health promotion "leads to increasing well-being, competence and resilience and makes individuals improve their mental health and increase their control over it" [2]. Mental health promotion focuses on promoting the positive factors associated with mental health. On the individual level, these factors are, for example, coping with negative thoughts, negative feelings, and stress, as well as increasing resilience and self-esteem [3]. The World Health Organization defines health promotion as "the process of enabling people to increase control over, and to improve their health" [4].

It is widely acknowledged that public health work should focus on universal health-promoting and preventive measures rather than on the treatment of disorders [5,6]. Preventing mental disorders and promoting good mental health is more cost-effective for society and has greater benefits for public health [7]. Working preventively and promoting good mental health is particularly important for young people. On the one hand, adolescence is a vulnerable period in which young people transition from being children to being adults; many mental disorders develop during this period [8]. On the other hand, adolescence is a time when young people can learn and adopt healthy habits and choices from which they can benefit throughout their lives.

In order to reach adolescents, mental health–promoting interventions should be conducted where adolescents actually spend their time. This can, for example, be at schools, at places where adolescents carry out their leisure activities, or online. In Norway, most adolescents have their own smartphones, which they use daily and often for multiple hours [9]. This may open new opportunities to implement mental health–promoting interventions through mobile apps. Despite potential barriers, apps can reach a large proportion of adolescents. This is especially important in countries like Norway that are geographically large and where health services are not always easily accessible. Furthermore, apps are also cost-effective and might be appealing to adolescents, who have a relatively high threshold for seeking help face-to-face [10]. Adolescents prefer to be anonymous, and app-based interventions may therefore be important for promoting good mental health [11]. Also, adolescents often look for health-related information online [9]. However, the quality of the information they find can vary. It is therefore important to offer information that is both high quality and easily accessible to adolescents, especially when it comes to mental health.

Reviews from 2013 and 2014 [12,13] concluded that digital self-management resources were promising, but that there was a need for more research. A recently conducted meta-review that synthesized the results of 14 meta-analyses concluded, on the other hand, that mobile phone–based interventions already have potential for mental health promotion, especially when it comes to reducing psychological symptoms (ie, stress, anxiety, and depression) and increasing quality of life [14]. Although the effects of apps are generally of small magnitude, they could have an important societal impact if they were made available to large groups.

Kenny et al [15] conducted the first and, to the best of our knowledge, only cluster randomized controlled trial to examine the effectiveness of a mental health mobile app–based intervention in a general population of adolescents. They recruited 560 subjects aged 15 to 18 years from 10 schools that were randomly assigned to an intervention or control condition. Participants in the intervention group used the app for about 4 weeks. However, no significant differences in well-being, emotional distress, emotional self-awareness, or coping strategies were found.

One of the largest cluster randomized controlled trials of the effectiveness of universal school-based mindfulness training on mental health and well-being in early adolescence, the MYRIAD (My Resilience in Adolescence) project, found no evidence that it was more effective than the provision of usual social-emotional learning [16]. A meta-analysis of the effectiveness of relaxation techniques to reduce distress, anxiety, and depression in adolescents, on the other hand, had promising results with small to moderate effect sizes [17].

Identifying effective interventions for improving mental health among adolescents is necessary, and studies that have no or negative results also play an important role in determining what helps to improve mental health and what does not [18]. Or as Kuyken et al [16] conclude, "There is need to ask what works, for whom and how, as well as considering key contextual and implementation factors."

The Current Paper

The aim of the current paper is to describe a cluster randomized controlled trial that will be conducted to evaluate the effectiveness of Opp. Opp is a universal mental health–promoting mobile app for adolescents that provides information about mental health, feelings, and help seeking, as well as exercises and techniques to better cope with negative thoughts, negative feelings, and stress.

XSL•FO
RenderX

Opp is part of the research project UngRisk, which aims to develop and evaluate 2 mental health–promoting mobile apps that will be made available as free resources for easy access by young people. The other mobile app is called NettOpp and is aimed at young people aged 11 to 16 years who have experienced negative incidents online. A study similar to the one that is described here has already been conducted to examine NettOpp's effectiveness [19]. Data analysis is in progress.

Methods

Eligibility Criteria and Setting of the Effectiveness Study

Both the adolescents and participating schools are convenience samples. Adolescents aged 13 to 19 years are eligible for participation in the study and will be recruited through middle and high schools in Norway.

Inclusion and Exclusion Criteria

Adolescents aged 13 to 15 years need consent from their guardians, while adolescents that are 16 years or older can consent for themselves. Adolescents need a smartphone to use the app and need to be able to read Norwegian.

Intervention

Opp is a universal mental health–promoting mobile app that is aimed at adolescents aged 13 to 19 years. The Norwegian word *opp* means "up" in English. In Norwegian, *opp* also evokes the word *opplysning*, which means "enlightenment" or "information"; *opp* also evokes the word "uplifting," meaning to lift someone's spirit.

The overall goals of Opp are to (1) increase well-being and mental health, (2) increase knowledge about mental health, (3) increase coping skills to deal with stress, (4) increase help-seeking behavior, (5) increase self-esteem, (6) increase sleep quality, and (7) reduce mental health problems.

To achieve these goals, Opp is theoretically divided into psychoeducational and resource modules (modules 1 and 2, respectively). Module 1 contains information about mental health (eg, "What is mental health?" "How are thoughts, feelings, and behavior connected?" "Why is good mental health important?" "How to get and maintain good mental health?" "What are mental health problems?" and "When should one seek help for their challenges?"), about feelings (eg, "What are feelings?" "Why are feelings important?" "Can you control your feelings?" and "What do you do when feelings take over?"), and about help seeking (eg, "When should you seek help?" "How to tell somebody about problems?" "What should happen when you have told somebody about your problems?" and "Here you can get help").

Module 2 provides exercises and techniques on how to cope with difficult thoughts, feelings, and stress. For the latter, exercises include breathing and meditation exercises with animation and sound. Another exercise is inspired by cognitive behavioral therapy and aims at helping adolescents to recognize and challenge negative thoughts. Adolescents are guided through this exercise and can choose different statements (eg, "Nobody likes me"), how this thought makes them feel (eg, "sad"), and alternative thoughts (eg, "There are people who love and care about me"). In addition, there is an exercise in which the adolescents can choose different situations, choose what they might think and feel if they were in such situations, and choose how they would behave. This exercise also aims at raising awareness about the relationship between thoughts, feelings, and behavior. In addition, the app contains sleep hygiene advice, tips for maintaining good social relationships, and suggestions on how to increase self-esteem. The information is displayed through text, sound, and animation.

Opp can be downloaded from the Google Play and App Store, but the app is password protected. The password will be removed after study completion to make the app freely available to all users. Adolescents in the intervention group that have answered the first questionnaire can install Opp on their phone and will be provided with a 4-digit code via text message to unlock the app. It is up to the young people themselves to decide when they want to use the app and how much time they want to spend using it. It is not possible to monitor how much time the adolescents actually spend using Opp. However, there are app-specific questions in the second and third questionnaires, which the adolescents will be asked to fill in after approximately 2 and 4 weeks, respectively, that ask how often the adolescents have used the app. The participants are not provided with any training in using the app, but are instructed via text message on how to download the app. Also, the participants are given a phone number that they can call or send a text message to if they experience any problems with downloading or using the app.

User Involvement

Users, that is, adolescents aged 13 to 19 years, were involved in the project from the development of the content of the intervention to its evaluation. Approximately 15 adolescents were involved in 2 workshops to provide input on the content, design, and name of the app. Two adolescents critically read through a manuscript that described the content of Opp and provided feedback on wording and terminology. There was also an extended reference group consisting of teachers, school-health nurses, nurses from a health care center for adolescents, and a community psychologist who contributed to the development of Opp through a workshop.

In addition to this, 27 adolescents participated in a user survey. The study indicated that Opp had good usability, and the overall mean star ranking of the app was 3.78 (SD 0.42) on a 5-point scale. A large proportion of the adolescents thought that Opp was interesting to use (20/27, 74%), that the design was good (25/27, 93%), and that it was appropriate for the target group (24/27, 89%) [20].

Control

The waiting-list control group will receive the code to unlock the app after study completion.

Randomization

This study is a cluster randomized controlled trial with intervention and waiting-list control groups. Schools will be randomly assigned to one of the groups by a statistician after

XSL•FO
RenderX

baseline assessment. SPSS (IBM Corp) will be used to generate a random number between 0 and 1 that will be assigned to each school. The half of the schools with lower values for the random number will be assigned to the control group and the half of the schools with higher values will be assigned to the intervention group.

Blinding

Neither schools, guardians, nor adolescent participants will know if they are assigned to the intervention or the control group prior to the baseline assessment.

Outcomes

Data will be collected at 3 measurement points: baseline (T1; preintervention); approximately 2 weeks after the intervention (T2; postintervention); and approximately 1 month after the intervention (T3; follow-up) through self-report measures that the adolescents fill in using the secure online tool Nettskjema (University of Oslo).

Primary Outcomes

Mental health will be assessed using the World Health Organization–5 Well-being Index (WHO-5) [21] and the Strengths and Difficulties Questionnaire (SDQ) [22]. Both the WHO-5 [23] and the SDQ [24] have been found to have adequate validity as outcome measures. The primary hypothesis is that there will be significant differences in changes in the mental health scores of the intervention and the control groups in favor of the intervention group.

Secondary Outcomes

Coping skills will be measured with the Norwegian version of the General Self-Efficacy Scale [25]. A Norwegian study found that this scale had satisfactory internal consistency, test-retest reliability, and factor structure [26]. Help-seeking behavior will be assessed with 3 items that measure if the adolescents sought help, who they sought help from, and if they received the help they needed. The Self-liking and Competence Scale [27,28] will be used to measure self-liking and self-competence; this scale has been found to have good internal consistency and factor structure in a Norwegian validation study [29]. Sleep quality will be measured with six questions from the Bergen Child Study [30].

In addition to these measures, there will be app-specific questions in the second and third questionnaires for the intervention group that ask about how often and for how long the adolescents used the app and what features of the app they liked best.

Power Calculations

Power calculations were conducted with PASS 16 (NCSS, LLC). Using multilevel analysis with a significance level of .05 will require a total sample of 1250 adolescents (625 in both the intervention and control groups, including 25 schools with 25 students per school) to achieve a power of .79 and to detect a small effect corresponding to Cohen d=0.20 when the expected interclass correlation at the school level is 0.02. Anticipating a drop-out rate of approximately 25%, a total of 1563 adolescents should be recruited [15].

Data Management

Data will be collected with the secure Nettskjema platform and will be directly sent to and stored on a secure server that only members of the research team have access to. Data collection, data cleaning, and statistical analyses will also only be performed by members of the research team. The statistical analyses will be conducted on anonymized data from the secure server.

Planned Statistical Analysis

Data analyses will be conducted using SPSS. Attrition analyses will be conducted to examine differences between those who complete the questionnaires and those who do not at different time points. A missing-values analysis will also be conducted. Variables for which there are a significantly greater number of missing values will be included as covariates in the analyses.

Correlations will be used to examine whether the different outcomes are related to each other at T1, and linear mixed models will be used to test the hypotheses. We will run 3-level mixed models with time nested within participants nested within schools, and model repeated measures using the *repeated* command in SPSS. We will assess the covariance structure of the repeated measurements by comparing models with different structures (ie, unstructured, compound symmetric, first-order auto-regressive, or others) using the Akaike information criterion.

Ethics Approval and Consent to Participate

The study, including the information letter sent to the guardians and study participants and the consent forms, has been approved by the regional Research Ethics Committee (279207) and by the Norwegian Center for Research Data (715456). The study has been registered on ClinicalTrials.gov (NCT05211713). Active parental consent from 2 guardians is required for adolescents that are younger than 16 years to participate in the effectiveness study. Adolescents that are aged 16 years or older can consent by themselves. Consent, as well as the answers adolescents provide, will be collected digitally using Nettskjema and stored using the services for sensitive data of the University of Oslo in Norway [31]. It is possible that there will be unintended adverse effects of using the app or answering the survey that adolescents might find distressing [18]. Therefore, we will provide information about where the adolescents can receive help if they need it in the app, in the information letter, and at the end of the survey. Participants that fill in the 3 questionnaires will be entered in a raffle for 1 of 100 gift cards with a value of NOK 300 (approximately US $29). The app itself does not collect personal or sensitive information about the users, nor does it need access to GPS, the camera, contact lists, or anything else on the mobile phone.

Results

Recruitment and data collection started in August and September 2022. However, teachers were on strike at that point for about 6 weeks, which made recruitment challenging as the schools were partly closed. Data collection was expected to end in December 2022 but had to be prolonged until approximately June 2023. So far, 381 adolescents have answered the first

XSL•FO
RenderX

questionnaire. The results of the study will be available at the earliest at the end of 2023 or later, and will be published in international and national journals and presented at conferences.

Discussion

Principal Aims

The current paper describes a cluster randomized controlled trial that is being conducted to evaluate the effectiveness of a universal mental health–promoting mobile app (Opp) in Norway. Its evaluation will lead to new knowledge in the field, as there have been only a few studies published on the effectiveness of such universal interventions [15]. Fusar-Poli et al [2] wrote that "Promotion of good mental health in young people with and without mental disorders has received little empirical research attention and interventions for improving mental health in young people are not well established." Conducting well-designed effectiveness studies is challenging. However, they are necessary in order to identify interventions effective at improving child and adolescent mental health. Randomized controlled trials are considered the gold standard for evaluating the effectiveness of interventions [18].

After the effectiveness study is conducted, Opp will be made freely available in the Google Play and App Store. Results of the study will continue to be published as they are obtained.

Limitations

Several limitations will have to be considered when interpreting the results. Both the adolescents and schools are convenience samples, which could lead to selection bias and limit the conclusions that can be drawn from the study [32]. Another limitation is related to the randomization, which will be conducted on a school level and not an individual level [33].

Other limiting factors are related to adherence to the intervention and intervention fidelity. The app does not collect personal data from its users, and it is therefore not possible to objectively track if and how often the adolescents have used the app. However, the intervention group will answer app-related questions on the frequency of use. Both the intervention and control groups receive the same information letter, and participants that are randomized to the intervention group are informed that they can use the app whenever they want and as often as they want, without further instructions. In addition, the intervention group receives a text message with a code to unlock the app after the baseline assessment and randomization.

Another limitation is related to the length of follow-up, which should ideally be longer than 1 month. Kenny et al [15] wrote the following regarding this: "Findings suggest that a 4-week app-based intervention may not be enough to elicit intrapersonal changes in mental health outcomes in a general adolescent population." Furthermore, the study is based on self-report measures and not on more objective indicators or assessments from other informants, such as parents or teachers, which might be a limitation.

Conclusion

There are only a few studies that have examined the effects of universal health-promoting mobile apps for adolescents. Therefore, this project will contribute unique knowledge to the field. Opp can theoretically reach up to 420,000 adolescents aged 13 to 19 years in Norway (in 7 cohorts, each with 60,000 adolescents). However, a main challenge will be to implement Opp after its evaluation so that as many adolescents as possible know about the app and can use it if they need to. The findings of this effectiveness study will play an important part in informing decisions on how much effort should be put into implementing Opp in Norway.

Acknowledgments

The authors would like to thank the adolescents that participated in the workshop and that helped with the development of Opp for their valuable feedback and comments. We would also like to thank the adults that worked in child and adolescent mental health services who participated in workshops. We would like to thank Charlotte Elvedal at the Norwegian Council for Mental Health for her collaboration, as well as the team from Bouvet that designed and programmed Opp: Mari Søpstad Eggen, Ingrid Ødegaard, Jan Erik Kirkevold Nilsen, Hilde Stenvold, Eirik Aflekt Thommesen, Magnus Gaustad Eriksson, and Renate Kristiansen. The development of Opp was funded by a grant from Foundation Dam through the Norwegian Council of Mental Health (2020HE2-328433). The study was funded by the Norwegian Directorate of Health and UiT The Arctic University of Norway. The funding organizations were not involved in the design of the study, in the collection, analysis, or interpretation of the data, or in writing the manuscript.

Authors' Contributions

HK is the principal investigator of the study. HK, SK, MR, RJ, and MM developed the app. HK, SK, MR, RJ, HH, and MM provided substantial contributions to the study protocol in terms of conceptualization of the study, the study design, and the methods. SK wrote the first draft of the manuscript and MR, RJ, MM, HH, and HK read, edited, and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: The timeliness of raising vaccine acceptance and uptake among the public is essential to overcoming COVID-19; however, the decision-making process among patients with underlying medical conditions is complex, leading individuals to vaccine hesitancy because of their health status. Although vaccine implementation is more effective when deployed as soon as possible, vaccine hesitancy is a significant threat to the success of vaccination programs.

Objective: This study aims to evaluate the effectiveness of a communication tool for patients with underlying medical conditions who should decide whether to receive a COVID-19 vaccine.

Methods: This 3-arm prospective randomized controlled trial will test the effect of the developed communication intervention, which is fully automated, patient decision aid (*SMART-DA*), and user-centered information (*SMART-DA*-α). The web-based intervention was developed to help decision-making regarding COVID-19 vaccination among patients with underlying medical conditions. Over 450 patients will be enrolled on the web from a closed panel access website and randomly assigned to 1 of 3 equal groups stratified by their underlying disease, sex, age, and willingness to receive a COVID-19 vaccine. *SMART-DA*-α provides additional information targeted at helping patients' decision-making regarding COVID-19 vaccination. Implementation outcomes are COVID-19 vaccination intention, vaccine knowledge, decisional conflict, stress related to decision-making, and attitudes toward vaccination, and was self-assessed through questionnaires.

Results: This study was funded in 2020 and approved by the Clinical Research Information Service, Republic of Korea. Data were collected from December 2021 to January 2022. This paper was initially submitted before data analysis. The results are expected to be published in the winter of 2023.

Conclusions: We believe that the outcomes of this study will provide valuable new insights into the potential of decision aids for supporting informed decision-making regarding COVID-19 vaccination and discovering the barriers to making informed decisions regarding COVID-19 vaccination, especially among patients with underlying medical conditions. This study will provide knowledge about the common needs, fears, and perceptions concerning vaccines among patients, which can help tailor information for individuals and develop policies to support them.

Introduction

Background

Given the large-scale impact, timing, and unpredictability of the COVID-19 pandemic and the threat this has posed to the health care system's routine capabilities, the battle against COVID-19 is still ongoing. The development of effective vaccines was highly anticipated, and several are now available. The timeliness of raising vaccine acceptance and uptake among the public is essential to overcoming COVID-19. A sizable proportion of the population must be vaccinated to achieve herd immunity and prevent the continued spread of the virus. When COVID-19 vaccination was first implemented, the government of the Republic of Korea specified that herd immunity would be achieved by November 2021 and proposed the goal of vaccinating 70% of the population by the end of October 2021 [1]. Recent studies have shown that third shots (boosters) of COVID-19 vaccines effectively provide additional protection from infection, and some countries are now offering fourth doses [2].

The decision to receive a vaccine is complex and reflects one's values, attitudes, and experiences and the information one receives about vaccination. Although vaccine implementation is more effective when deployed as soon as possible, vaccine hesitancy is a substantial threat to the success of vaccination programs [3-5]. A well-known aspect of COVID-19 vaccination is that it may induce side effects. Data on the short-term and long-term side effects of vaccination have been reported [6,7], raising concerns regarding these side effects [8]. Although possible severe side effects are comparatively rare, the risk of their occurrence may considerably influence one's decision not to receive the vaccine, thereby leading to vaccine hesitancy [9,10].

For patients with underlying diseases, the decision process becomes even more complex, ultimately leading them to avoid vaccination owing to the risk of harming their health [10,11]. In Korea, individuals with underlying diseases are classified as high risk and selected as the priority demographic for vaccination [1]. Previous studies have shown inconsistent COVID-19 vaccination intentions among populations with medical conditions [12,13]. Korea Centers for Disease Control and Prevention data from 2021 show that patients with chronic diseases had a lower vaccination rate than the general population of Korea. More recent data from May 2022 show that although the vaccination rate among those aged 40 to 59 years in the general population is 96.7%, that among patients with chronic disease is approximately 2% to 7% lower (94.7% among patients with hypertension, 93.7% among patients with diabetes, and 90.3% among patients with solid organ malignancy) [14]. A study in Brazil showed that concurrent malignancy, fibromyalgia, hydroxychloroquine use, and recent corticosteroid pulse therapy were independently associated with higher odds of COVID-19 vaccine hesitancy [13]. Conversely, a Japanese study revealed that a higher COVID-19 vaccine rate was positively associated with underlying disease, as patients with underlying diseases perceived themselves as being more vulnerable to COVID-19 [12].

Communication interventions such as decision aids (DAs) may yield promising results in addressing this issue. The International Patient Decision Aid Standards (IPDAS) Collaboration defines DAs as "tools designed to help people participate in decision making about health care options" [15]. They provide information on different health care options and help patients by clarifying and communicating personal values while guiding them through the decision-making process [16]. DAs aim to include high-quality epidemiological evidence on the benefits, risks, and associated probabilities of outcomes [17]. Their most common forms are web-based tools, pamphlets, and videos, and they fall within the broader field of shared decision-making—a process by which patients and clinicians work together to (1) clarify treatment goals and (2) review information about the available options and their outcomes to reach a mutual agreement [18,19]. DAs have improved patients' perceptions of the decision-making process and increased their knowledge about the options that align with their values [20]. Although they effectively assist patients in making health treatment and screening decisions, less is known about the impact of DAs on vaccination uptake. A study that examined the impact of DAs on health care personnel's decisions regarding immunization against influenza [21] and hepatitis B [22] found that DAs could be good tools for addressing the phenomenon of vaccine hesitancy [19,23].

Goal of This Study

Several intervention studies attempting to increase the acceptance of COVID-19 vaccination via informational messages, behavioral nudges, web-based interventions, and videos appear in the academic literature [24-28]. However, interventions targeting patients with underlying medical conditions could not be uncovered in the literature. Therefore, the implementation of interventions with proven effectiveness targeting patients with underlying medical conditions are highly needed [29].

This study aims to evaluate the effectiveness of a communication tool for patients with underlying medical conditions for deciding on whether to receive a COVID-19 vaccine. This study develops a web-based communication intervention called "*SMART*," a COVID-19 vaccination DA, and a vaccine-related information program tailored to the target the population with underlying diseases.

XSL•FO

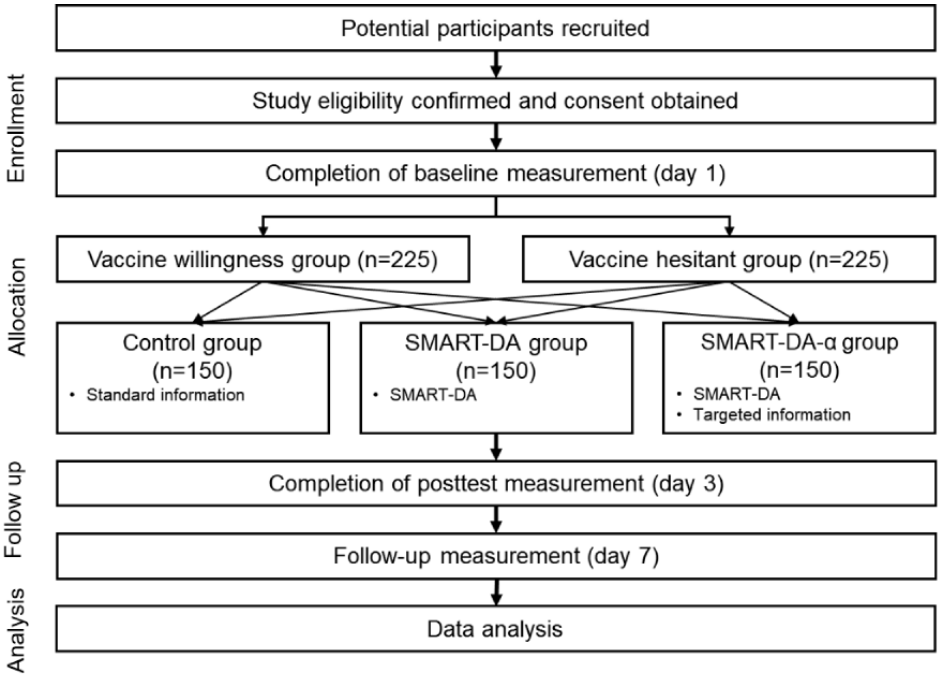
Methods

Study Design



A randomized controlled trial (RCT) will be conducted and reported according to the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist, and the protocol timeline is shown in Table 1. This study is a 3-arm prospective RCT enrolling >450 participants with underlying medical conditions (Figure 1). The participants who complete their baseline web-based questionnaire will be recruited into the study and randomly assigned to 3 equal groups, stratified by their underlying disease, sex, age, and willingness to receive a COVID-19 vaccine (willingness and hesitation). The participants will be randomized to receive (1) standard information about COVID-19 vaccination (control group), (2) COVID-19 vaccination DA (intervention group *SMART-DA*), or (3) COVID-19 vaccination DA with targeted information provision (intervention group *SMART-DA*-α). Each group is described in detail in the following sections. After 1 week, we will follow-up with the participants and use an intention-to-treat (ITT) approach to determine the effects of their COVID-19 communication intervention on COVID-19 vaccination. There is no expected harms or unintended effects in each group.

Participants and Setting

Recruitment will be conducted on the web to reflect the web-based nature of the intervention. The intervention study will be conducted via a web-based platform from a research company. The company will recruit participants by sending study invitations via emails or SMS text messages containing general information about the study (eg, the study aims and consent statement), and a URL to access the platform to survey panel members who meet the inclusion criteria. The inclusion criteria are as follows. First, the participants must have received a diagnosis of at least one of the following diseases: hypertension, diabetes, cancer, angina, myocardial infarction, or stroke. Second, the participants must be aged between 18 and 70 years. Third, the participants must have a fluent in the Korean language and be a resident of the Republic of Korea. Fourth, the participants must have access to the internet and the necessary internet literacy skills to use the interventions. Finally, those who have completed the COVID-19 vaccination (those who have received 2 or more doses and those who have been revaccinated regularly) will be excluded. Upon meeting all the inclusion criteria of the study, the participants will provide their informed consent electronically. The informed consent will appear on the study's first page, and the research company will ensure the confidentiality of all the participants. The participants will be informed that they may discontinue participation in the research study at any time without any penalty or loss of benefits. All the researchers in this project will be given access to the cleaned data sets, and all data sets will be password protected. To ensure confidentiality, the data dispersed to the project team members will be blinded of any identifying participant information.

Study Procedures and Implementation Strategies

Randomization

A representative sample of 450 individuals will be randomly selected through a proportional stratified sampling method based on sex and age from a list of candidates registered with the research company. The D-optimal blocking procedure proposed in a recent study [30] will be used for random assignment to reduce interference on the intervention effect by covariates such as the individual's underlying disease, sex, age, and intention to receive COVID-19 vaccination. D-optimality is based on the determinant of the information matrix for the design, which is the same as the reciprocal of the determinant of the variance-covariance matrix for the least squares estimates of the linear parameters of the model. The D-optimal blocking procedure uses a SAS/QC procedure OPTEX (version 9.4; SAS Institute) to randomly allocate the participants to 1 of the 3 arms by all the researchers. The assigned participants will be blinded so that they do not know whether they belong to the intervention group or control group. Both the assigned participants and data analysts will be blinded, and the data analysts will conduct effect analysis of the anonymized groups 1, 2, and 3 without being aware of whether the group is an experimental or control group. However, because the researcher providing the intervention is aware of which group the participants belong to, the study is single blind.

Intervention Group A: COVID-19 Vaccination DA (SMART-DA)

Initial Development of the COVID-19 Vaccination DA (SMART-DA)

The development process of the *SMART-DA* was based on the IPDAS guidelines for DA development. In line with these guidelines, the needs of end users and clinicians were assessed. In addition, we asked public health education experts for additional input. For the end users' needs assessment, 20

XSL•FO
RenderX

interviews were used to determine end users' needs regarding COVID-19 vaccination decision-making that should be described in the DA. The input of these qualitative studies informed the design and content of the DA, supplemented by IPDAS background papers, other relevant literature in the field, and consultation with established experts.

Next, a prototype was developed and alpha tested with 30 potential end users and 5 public health experts. During the alpha test, the participants were asked to focus on the content of the DA. Before the beta test, the comprehensibility of the DA text for people with limited health literacy was evaluated by 3 coauthors. On the basis of this evaluation, some sections and sentences were rephrased or simplified.

Usability Testing of SMART-DA

After the alpha test, the DA was beta tested among 10 medical experts and 10 potential end users. The participants were given access to the DA to assess its usability using the heuristic evaluation method (medical experts) and think-aloud method (potential end users). Using the heuristic evaluation method, the medical experts were asked to evaluate the DA against a list of recognized usability principles: (1) uses simple and natural dialogue, (2) is in the user's language, (3) minimizes memory load, (4) is consistent, (5) provides feedback, (6) offers clearly marked exits, (7) includes shortcuts, (8) provides helpful error messages, (9) prevents errors, and (10) provides help and documentation. Using the think-aloud method, the end users used the DA while verbalizing their thoughts. The think-aloud method is particularly useful in understanding the processes of cognition and is of high value in evaluating an intervention's design for usability flaws [31]. The data gathered through these tests are compared and compiled into a summary describing the usability flaws of the DA.

Description of SMART-DA

The *SMART-DA* follows a stepwise approach and encourages decisions consistent with the participant's values and health condition. The *SMART-DA* consists of five steps: (1) clarify the decision; (2) explore the decision in terms of knowledge, values, and certainty; (3) clarify decisional support; (4) identify the decision-making needs; and (5) plan the next steps based on the needs.

Step 1 consisted of 4 questions that required the participants to consider the key decision. The following questions were addressed: (1) "What options are available when deciding to be vaccinated against COVID-19?" (2) "What is making your COVID-19 vaccination decisions difficult?" (3) "When do you think it is time to make a COVID-19 vaccination decision?" and (4) "How far have you reached the final decision on the COVID-19 vaccination?" Multiple options were provided to increase the participants' convenience. For question 1, we provided 3 options for COVID-19 vaccination decision-making: "Get vaccinated as soon as possible," "Delay vaccination as much as possible," and "Refuse vaccination." If necessary, they could write their responses in the "other" column.

In step 2, the participants explored their knowledge and values related to each option to clarify how certain they were in their decision-making. A list of reasons to choose and not to choose each option (eg, "Get vaccinated as soon as possible," "Delay vaccination as much as possible," and "Refuse vaccination") was provided, and the participants rated how much each reason mattered to them using a 6-point Likert-type scale. If necessary, they could write their reasons in the "other" column and rate how much they mattered. After the rating was completed, the total score for choosing each option and the reasons for not choosing it were calculated and shown. The participants were then asked what their preferred options were.

In step 3, the participants were asked to think about who supports their decision-making and how the support affects them. We asked them to identify whether other people supported their decision-making and, if so, who those individuals were. In addition, we asked them what role they preferred to play in decision-making and provided the response options "share the decision," "decide myself after hearing views," and "someone else decides."

In step 4, the participants identified their decision-making needs concerning knowledge, values, support, and certainty. The participants considered whether (1) they had adequate knowledge of the risks and benefits of each option (knowledge), (2) they identified their values related to the risks and benefits of each option (value), (3) they had sufficient support to make choices (support), and (4) they were certain of their choices (certainty). The responses were collected with a yes or no option; if the participants had ≥1 "no" responses, they were encouraged to start over from step 2.

In the final step, the participants received information about the actions they could perform based on their decision-making needs. For instance, if the value of each option was unclear, we recommended revising the scores given in step 2 after listening to others' experiences of COVID-19 vaccination or asking for advice from others.

As shown in Figure 1, the intervention group A is supplemented with *SMART-DA*. The participants were allowed to access and use *SMART-DA* whenever available, and as much as needed.

Intervention Group B: COVID-19 Vaccination DA With Targeted Information (SMART-DA-α)

As shown in Figure 1, the intervention group B is supplemented with targeted information in addition to the contents of intervention group A. The participants were allowed to access and use *SMART-DA*-α whenever available, and as much as needed. An educational program was planned to provide accurate and targeted information on COVID-19 vaccination to support decision-making among patients with underlying medical conditions. Educational material was developed with a tailored message to enhance the participants' intuitive understanding and provide information to those who hesitated to make decisions on vaccination. Tailored messages were developed based on the participants' interests in and perception of COVID-19 vaccination identified from the interview, such as their perception of COVID-19 vaccine safety, efficacy, and side effects. The findings revealed that the main messages in the educational material should be as follows:

1. COVID-19 vaccination: How effective is it?
2. COVID-19 vaccination: Is it safe?

XSL•FO
RenderX

3. Refusal to be vaccinated: critical cases

Tailored messages targeting the information needs of patients with underlying medical conditions were developed and structured around actual cases in clinical settings.

Control Group

The participants in the control group will receive standard information about COVID-19 vaccination provided by the Korean Disease Control and Prevention Agency. This easy-to-understand information about COVID-19 vaccination is publicly available. The material is accessible on the Korean Disease Control and Prevention Agency web page or YouTube (Google LLC) [32].

Follow-up Measurements

After the intervention, the participants will complete follow-up surveys, 3 and 7 days after the intervention, amounting to a total of 3 surveys during the study period. The participants in all the study groups will receive automated text message notifications to complete their surveys to improve study retention.

Incentives

The participants will be able to earn up to KRW 15,000 (approximately US $13) in gift cards for completing the study's requirements. These incentives include a gift card worth KRW 5000 (US $4.01) for completing the initial baseline survey and engaging with the SMART-DA or SMART-DA-α intervention or control group material on the web; a gift card worth KRW 5000 for completing the 3-day survey; and a gift card worth KRW 5000 for completing the 7-day survey. All the incentives will be sent to the participants via their mobile phones.

Measures

Participant's Characteristics

Sociodemographic factors include sex (1=male and 2=female), age, family size (ie, living alone or with 1 or more person), the presence of children at home who attend school (more than one=1 and none=0), marital status (ie, married, single, divorced, or bereaved), and residence (urban=1 and rural=2). We will also assess educational level (1=middle school or below, 2=high school graduate, and 3=college and above) and monthly household income in KRW (1=<KRW 200 million, 2=KRW 200 million to 399 million, 3=KRW 400 million to 599 million, and 4=KRW ≥600 million).

Health-related factors include the respondent's seasonal influenza vaccination history, underlying diseases, and prior COVID-19 diagnosis. For seasonal influenza vaccination history, the participants will be asked, "Have you been vaccinated against the seasonal influenza flu in the last five years?" The responses include "every year," "more than once," "maybe once," "never," and "don't know." We will also investigate the presence of underlying diseases by asking the participants to indicate all diagnosed underlying diseases (eg, hypertension, dyslipidemia, diabetes, chronic cardiac disease, asthma, and cancer). The participants who have not been diagnosed with underlying diseases are excluded from further study.

To examine health literacy related to COVID-19, we adapt the HLS-COVID-Q22 that has been translated into Korean. The HLS-COVID-Q22 was developed in Germany in 2020 by Okan et al [33] based on the European Health Literacy Survey Questionnaire. Its validity and reliability were verified among the German population aged ≥16 years (α=.94; ρ=0.891) [33]. The HLS-COVID-Q22 contains 22 items organized into 4 subgroups: accessing (6 items), understanding (6 items), appraising (5 items), and applying (5 items) health-related information in terms of COVID-19. It is answered on a 4-point scale, ranging from "4=very easy" to "1=very difficult."

Primary and Secondary Outcomes

The primary and secondary outcomes and potential mediators are listed in Table 2. Our primary outcome is COVID-19 vaccination intention, which will be an important outcome during the 1-week follow-up period. The baseline, posttest (3-day), and follow-up (1-week) surveys will assess the participants' vaccination intention. A 5-point Likert scale questionnaire will measure the intention to be vaccinated against COVID-19. The participants will be asked, "If a vaccine for Coronavirus (COVID-19) becomes available, would you want to receive it?" and provided the response options "1=Definitely Would Not Want It, 2=Would Likely Not Want It, 3=Neutral or Unsure, 4=Would Likely Want It, and 5=Definitely Would Want It." The level of vaccine acceptance is defined as willing ("Definitely Would Not Want It," and "Definitely Would Want It") or hesitant ("Definitely Would Not Want It," "Would Likely Not Want It," and "Neutral or Unsure"). The secondary outcomes include knowledge level related to COVID-19, which will be assessed using a validated questionnaire that has been used in numerous studies [34,35], and decisional conflict, which will be assessed using the decisional conflict scale [36]. In addition, psychological stress owing to decision-making regarding COVID-19 vaccination will be measured.

XSL•FO
RenderX

Table 2. Study outcome measures.

	Baseline measurement (day 1)	Posttest measurement (day 3)	Follow-up measurement (day 7)

Secondary outcomes			
Knowledge about COVID-19 vaccination	✓	✓	✓
Decisional conflict	✓	✓	✓
Stress related to COVID-19 vaccination	✓	✓	✓
Perceived benefits of COVID-19 vaccination	✓	✓	✓
Perceived barriers to COVID-19 vaccination	✓	✓	✓

Data Collection and Management

We collected quantitative data on the potential mediators of implementation effects, including attitudes toward COVID-19 vaccination (eg, perceived benefits and barriers). Questionnaires which were validated for web-based use and apply Checklist for Reporting Results of Internet E-Surveys items were designed to measure primary and secondary outcomes. Data collection is performed according to standard guidelines. To improve the reliability of data quality, real-time support through instant messages or phone calls regarding data collection were provided during the entire data collection period. The respondents entered a web-based data collection program, self-assessed through web-based questionnaires, which the research team reviews and rechecks for anomalous responses according to a defined monitoring strategy. If an error was found in the data, the research team asked the rater to correct or explain it, and all corrections were made after the research team confirms them. In addition, to facilitate retention, respondents reported any issues with the respondent. In the event of study discontinuation, a report was generated in a concise format. All available data were checked by the research team members. Every respondent was assigned a unique study ID, and the research team trained the researchers to protect the study data to ensure data safety. The data collection form does not contain any personally identifiable information. The password-protected electronic files were stored on a password-protected computer. Data managers and analysts independently conducted inspections for each evaluation.

Sample Size and Power

We sought to detect the main effects of the communication intervention within the 3 groups with at least 90% power using a 2-sided α of .05. We used G*Power (latest version 3.1.9.7; Heinrich-Heine-Universität Düsseldorf) to calculate the sample size for 3 repeated measurements (in-between interaction, small effect size of 0.2). Our target analytic sample size was 450 (150 per study group) participants. To achieve this analytic sample size, we randomized a projected 630 participants (210 per study group) and expected approximately 30% of the initial participants to drop out during the 7-day follow-up period.

Statistical Methods

Evaluation of Efficacy

We will also examine the descriptive statistics for the participants' baseline characteristics and compare them across the 3 study groups. The main analysis will be performed based on the ITT principle, involving all the randomized participants to investigate the effectiveness of the interventions. The ITT principle can minimize potential bias owing to dropouts and can be applied while performing further preprotocol analyses. The effects of the interventions on the primary outcome (eg, vaccination intention) and secondary outcomes (ie, knowledge related to COVID-19 vaccines, decisional conflict, psychological stress related to vaccination, perceived benefits of COVID-19 vaccines, and perceived barriers to COVID-19 vaccines) will be estimated using linear mixed-effects models for continuous outcome variables and generalized linear mixed-effects models for categorical outcome variables. The test statistic will be calculated to assess any significant intervention benefit; we will use 2-sided *P* values with α=.05 to calculate the level of significance.

Subanalyses

We will perform a path analysis to examine the theoretical constructs as potential mediators following the effect evaluation. For each outcome, a path analysis will be performed to describe the direct and indirect relationships, including the perceived benefits of and barriers to the COVID-19 vaccine. Path models are statistical methods that, compared with multiple regressions, allow for the simultaneous assessment of several regression paths occurring between multiple dependent and independent variables and for the computation of direct, indirect (mediated), and total effects. Standardized parameter estimates (standardized β) will be used to compare the magnitude of associations between media use and mediators. The model parameters and SE estimates are to be calculated. The participants with missing data will be excluded from analysis. Statistical analyses will be conducted using STATA (version 15; StataCorp LLC), SAS (version 9.4; SAS Institute), and R (version 4.2; R Foundation for Statistical Computing) software.

In addition, we will conduct subgroup analyses according to the preintervention intent for vaccination. We will observe how the degree of vaccination intention changes in the 2 groups. Among those who have already been willing to receive a

COVID-19 vaccine, there are cases in which their decisions are passive or involuntary owing to social pressure or economic activity. Therefore, we seek to identify whether the nature of their decisions changes through the intervention.

The Data Monitoring Committee comprises the Principal Investigator, independent external data managers, and statisticians. The committee is responsible for data quality throughout the data collection, analysis, and reporting processes. The Data Monitoring Committee is independent of the research funding agency and has no competing interests.

Ethics Approval

Ethics approval for this study was obtained from the Korea National Open University's institutional review board on December 1, 2021 (IRB number ABN01-202111-21-13), and was registered with the Clinical Research Information Service Registry. The current protocol version is version 1.1, and there is no plan to change it. The risk of negative effects on participant outcomes is minimal. The possibility of SMART-DA not having a positive effect on the participants is present, but the risk of negative participant outcomes because of this is limited. The data will be analyzed at the completion of the trial, and the study findings will be published in major peer-reviewed journals. Upon meeting all the inclusion criteria of the study, all the study participants will provide their informed consent electronically.

Results

Data were collected from December 2021 to January 2022. This paper was initially submitted before data analysis began. The results are expected to be published in the winter of 2023.

The number of individuals who initially expressed their intention to participate was 1066. Of these 1066 individuals, 515 (48.31%) people participated in the first survey, excluding 551 (51.69%) people who did not meet the inclusion criteria. All dropouts were individuals without underlying diseases. Of the 515 participants in the first survey, 466 (90.5%) participated in all 3 rounds and 69 (13.4%) dropped out. No significant differences were observed in sex, age group, residence area, education level, marital status, or willingness to receive a COVID-19 vaccine between those who participated in all 3 surveys and those who dropped out based on the first survey (Table 3). The results of the chi-square test conducted to confirm the distribution bias of the participants assigned to the intervention groups (SMART-DA and SMART-DA-a) and those assigned to the control group, in terms of sex, age group, region of residence, education, marital status, and intention to receive a COVID-19 vaccine, showed that no significant differences were observed (Table 4). Among the 515 individuals who completed the first survey, 294 (57.1%) were male and 221 (42.9%) were female, and the age distribution was even (18-29 years, n=90, 17.5%; 30-39 years, n=98, 19%; 40-49 years, n=124, 24.1%; 50-59 years, n=123, 23.9%; 60-69 years, n=80, 15.5%). The rate of college education or higher (418/515, 81.2%) was higher than that of high school graduation (97/515, 18.8%), and the most common marital status was having a spouse (310/515, 60.2%). The proportion of those who responded that they had low or no intention of receiving a COVID-19 vaccine was 46% (237/515), and the proportion of those who responded that they had high intention of receiving a COVID-19 vaccine was 53.9% (278/515), indicated a rather high initial willingness among the participants to receive a COVID-19 vaccine.

Discussion

Principal Findings

This study is conducted to evaluate the effectiveness of a web-based communication intervention in assisting people with underlying diseases in making decisions about whether to receive a COVID-19 vaccine. This RCT will test the effectiveness of the developed communication intervention, patient DA, and user-centered information as implementation strategies to help patients with underlying medical conditions in making decisions regarding COVID-19 vaccination. This communication intervention aimed to shed light on how a DA for patients with underlying diseases with decision-making needs about COVID-19 vaccination should be designed to facilitate an informed decision-making process. Moreover, this intervention study aimed to contribute to a deeper understanding of individuals' preferences, attitudes, and values regarding COVID-19 vaccination and their impact on decisions.

A set of implications for interventions, communication strategies, and future research can be drawn from this study. First, the outcomes from this study provide valuable new insights into potential DAs for supporting informed decision-making regarding COVID-19 vaccination and discovering barriers to making informed decisions regarding COVID-19 vaccination, especially among patients with underlying medical conditions. Findings about what kind of information is especially misleading can help clinicians focus on these aspects in their consultations [37,38]. Moreover, knowledge about common needs, fears, and perceptions can help tailor information for individuals and develop policies to support them.

Second, this study is a critical step toward achieving the aim of increasing COVID-19 vaccination among patients with underlying diseases. It will comprehensively evaluate *SMART-DA* and *SMART-DA*-α. The results will explain the efficacy of the intervention and its potential mediators. If proven efficacious, *SMART-DA* could fill an important gap as a web-based intervention that allows patients to learn about COVID-19 vaccination and promotes vaccination by stimulating informed decision-making. Moreover, this intervention could be used not only to defeat the battle against COVID-19 but also to prepare for future epidemics. This tool could be potentially distributed on the web before and during the implementation of vaccination programs. As implementation planning is an important part of the process of implementing evidence-based practices [39], this study will enable public health authorities to use these tools as means of support for patients.

Limitations

This study has several limitations. First, we could not investigate the study participants' COVID-19 vaccination status as a

XSL•FO
RenderX

primary outcome, as their medical records are not accessible. Therefore, we will investigate the participants' self-reported willingness to receive a COVID-19 vaccine. However, there is a risk of bias in self-reported willingness and actual vaccination behavior. Second, our study participants might have different underlying medical conditions; therefore, the findings will not be generalizable to all patients. Third, the sample of this study is limited to certain underlying conditions; for example, it did not include patients who receive immunosuppressive therapy, who have a high need for COVID-19 vaccination. However, the diseases targeted in this study are major chronic diseases with high prevalence in Korea, for which the Korean government or medical society recommends vaccination against COVID-19. In addition, because the vaccination rate among this population is generally lower than that among the general population, it can be considered a meaningful group to study. Finally, because the recruitment of participants and implementation of the intervention are conducted through the internet, it is limited to those who have no problems using the internet. Therefore, the participation of those with limited internet use, especially older adults, is restricted; therefore, caution is required in interpretation. Finally, as participants are recruited through the internet, we limit participation to individuals aged <70 years, as those aged >70 years tend to have poorer control over internet use in Korea. Nonetheless, we acknowledge that the older adult group is an important group with high rates of underlying conditions and decision-making needs for which the development of alternative in-person modes of DA may be required in future studies.

Conclusions

We initiated an intervention study to improve the situation in which people with underlying conditions requiring COVID-19 vaccination have lower vaccination rates compared with the general population. In this paper, we have outlined the study procedure and data management. This interventional study aimed to evaluate improvements in vaccination intention to control COVID-19. We plan to comprehensively analyze the data and continuously present new research to improve vaccination intentions.

Acknowledgments

This work was supported by the Ministry of Education of the Republic of Korea and the National Research Foundation of Korea (NRF-2021S1A5B5A16075887) and by a grant from the Patient-Centered Clinical Research Coordinating Center and COVID-19 Public Health Research funded by the Ministry of Health and Welfare, Republic of Korea (grant number HC20C0008). These funders did not play any role in the study design; collection, management, analysis, and interpretation of data; writing of the report; or the decision to submit the report for publication.

The authors are grateful for the support from the Patient-Centered Clinical Research Coordinating Center, Republic of Korea.

Data Availability

Data sharing does not apply to this study, as no data sets have been analyzed during this study. Data construction and analysis have been completed, and the data are available to the authors upon reasonable request and permission from the Korea National Open University's institutional review board.

Authors' Contributions

ML, BO, NHY, SK, and YIJ made substantial contributions to the design of the work; ML and drafted the manuscript, and YIJ substantively revised it. All the authors revised the manuscript critically for intellectual content, have read and approved the final manuscript, and have agreed both to be personally accountable for their own contributions and to ensure that questions related to the accuracy or integrity of any part of the work, even those in which they were not personally involved, are appropriately investigated and resolved, and the resolution will be documented in the literature.

Conflicts of Interest

The authors are owners of the web-based communication interventions.

Abstract

Background: Survivors of oral cavity and oropharyngeal cancer frequently experience difficulties in swallowing; tasting; speaking; chewing; and maintaining comfortable movements of the head, neck, and shoulder. Engagement in regular self-care can reduce further loss of function and mitigate late effects. Despite the substantial self-care requirements, there are no empirically based interventions to enhance the skills and confidence of these survivors in managing their ongoing care.

Objective: The aim of this study is to describe the rationale and methodology for a randomized controlled trial evaluating Empowered Survivor (ES) versus Springboard Beyond Cancer, a general web-based program for cancer survivors, on self-efficacy in managing care, preparedness for managing survivorship, and health-related quality of life (QOL).

Methods: This study will recruit a total of 600 individuals who were diagnosed with oral cavity or oropharyngeal cancer in the past 3 years and are currently cancer free primarily from state cancer registries; these individuals will be randomly assigned to either the ES or Springboard Beyond Cancer condition. The participants complete measures of self-efficacy in managing care, preparedness for survivorship, health-related QOL, and engagement in oral self-examination and head and neck strengthening and flexibility exercises at baseline and 2 and 6 months after baseline. The primary aim of this study is to evaluate the impact of ES versus Springboard Beyond Cancer on self-efficacy, preparedness, and health-related QOL. The secondary aim is to examine the mediators and moderators of ES's impact on self-efficacy in managing care, preparedness, and health-related QOL at 6 months. The exploratory aim is to conduct a process evaluation of ES to identify potential oncology or community settings for future implementation.

Results: Multilevel modeling will be used to examine whether there are significant differences between the ES and Springboard Beyond Cancer interventions over time. Mediational models will evaluate the indirect effects of ES on outcomes. Quantitative analyses will evaluate the predictors of ES use, and qualitative analyses will evaluate the preferred timing and settings for the implementation of ES.

XSL•FO
RenderX

Conclusions: This randomized controlled trial evaluates a completely web-based intervention, ES, versus a general web-based program for cancer survivors, Springboard Beyond Cancer, on self-efficacy in managing care, preparedness for managing survivorship, and health-related QOL and identifies the putative mediators and moderators of the intervention's effects. If an effect on the primary outcomes is illustrated, the next step could be an implementation trial to evaluate the intervention's uptake in and impact on an oncology care setting or nonprofit organizations.

Introduction

Background

In the United States, the American Cancer Society (ACS) estimates that there will be 54,000 new oral and oropharyngeal cancer cases, which will result in 11,230 deaths, in 2022 [1]. There are approximately 91,000 people living with oral cancer in the United States [1]; 50% of these are diagnosed with regional disease, and 17% are diagnosed with distant disease. Traditionally, the main risk factors for oral cancer have been tobacco and alcohol consumption [2]. The incidence also increases with age, with >90% of oral cancer cases occurring in individuals aged >45 years [3]. Gastroesophageal reflux disease has been associated with oral cancer [4]. Human papilloma virus (HPV) has been associated with oropharyngeal cancer and few other oral cancers [5]. This patient population differs from the population with non-HPV–associated oral cancers in that they are primarily White, nonsmoking, nondrinking males aged between 35 and 55 years who do not have other health issues [6,7]. The 5-year survival rate for all forms of oral cancer has increased from 52.5% to 66.3% over the past 30 years [8]. However, patients with HPV-associated oropharyngeal cancers have a much higher survival rate (80% at 5 years) and longer disease-free survival rate, largely because they are more responsive to therapy [9,10]. There are known disparities in oral cancers. Mortality from oral cancers is higher among Black men [11-15], among men in general [16], and increasing among individuals aged between 55 and 64 and those aged between 65 and 74 years [3,17,18]. In summary, there is a growing population of oral and oropharyngeal cancer survivors, particularly those with HPV-associated cancer [3].

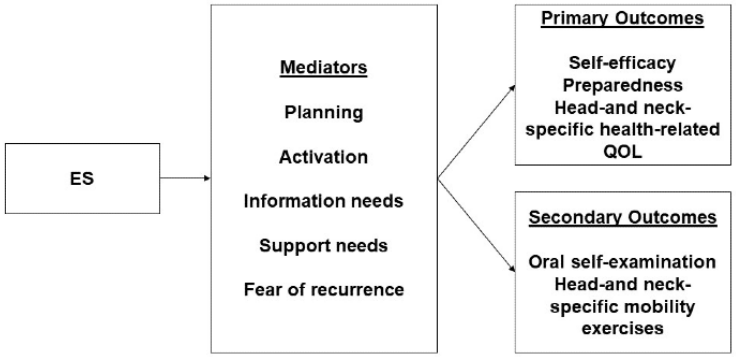
Oral and oropharyngeal cancer survivors experience challenges in both the treatment regimen and long-term self-management and surveillance needs. Treatment can entail surgery, chemotherapy, or radiation. Because of the location of the structures involved, the disease, and the treatment, this cancer can result in debilitating and permanent disfigurement and functional changes that interfere with the ability to swallow, taste, speak, eat, and move the shoulders and neck [19-23]. Long-term medical maintenance needs are complex and can require a diverse care team that can include oncologists, reconstructive surgeons, dentists, physical rehabilitation specialists, speech and swallowing experts, and nutritionists to restore functions or prevent the deterioration of functions [24-27]. Current models of survivorship care place most of the day-to-day responsibility on self-management and care coordination. Even with rehabilitation, many survivors recover their precancer functioning. Thus, the primary goal is to prevent the deterioration of function and maintain comfort. These self-care needs persist throughout the survivor's lifetime.

Adding to these self-management needs are surveillance expectations. Because 20% of survivors develop a recurrence or metastatic disease within the first 2 years after treatment [28], the recommended follow-up regimen includes frequent surveillance by the oncology care team and survivors [1,29,30]. Regular self-examinations to locate suspicious areas in the mouth and neck are recommended [31], as lesions that are not evident on positron emission tomography scans can be detected earlier and checked by a professional. Early detection can reduce morbidity and mortality [32,33]. Adherence to this demanding care regimen is less than optimal: 30% to 50% do not adhere to follow-up appointments, and up to 80% do not adhere to oral care or swallowing recommendations [34-37]. More than half of the survivors continue to drink alcohol, which increases the risk of mortality [38].

This cancer can result in a deterioration in health-related quality of life (QOL). Both cross-sectional studies conducted over the survivorship trajectory [39] and longitudinal studies suggest that patients experience lower health-related QOL [40]. Cross-sectional studies have indicated that global QOL, oral function (chewing, swallowing, tasting, salivating, and speaking), dental issues, and appearance are low over the decade after diagnosis, and studies illustrated higher levels of depression and anxiety (Rogers et al [41]) [41-53]. Longitudinal studies have had variable findings depending on sample composition, time of assessments, and time since diagnosis. As a whole, results suggest that some domains of QOL improve over time (eg, depression, anxiety, appearance, speech, and pain), some return to baseline levels (leisure time activities and swallowing), but many deteriorate or continue to illustrate decrements (eg, dry mouth, shoulder mobility, taste, problems with teeth, sexuality, and role function for work and leisure activities) [54-56]. The literature consistently suggests that survivors report persistent support needs, which include the desire for more information and support regarding long-term effects, recommended follow-up, monitoring symptoms that prompt contacting a physician, maintaining nutrition, improving speech and swallowing, maintaining oral health, and addressing psychological concerns [57-63]. The fact that more than half of the survivors do not receive a survivorship care plan complicates

XSL•FO
RenderX

matters and may reduce their ability to manage their posttreatment care [64-67]. Due to the ongoing care needs and compromised QOL, it is not surprising that survivors report low self-efficacy in managing their self-care regimen, particularly with regard to conducting oral self-examinations, maintaining proper nutrition, and managing dry mouth and swallowing issues [65,66,68].



Effective self-management provides survivors with the ability to monitor their cancer-related symptoms and self-care and implement practices needed to maintain satisfactory functioning [69]. Despite the substantial care needs, low self-care self-efficacy, and low participation in self-care, there are only a few self-management interventions for this population. To date, the few published studies have focused on single-symptom pilot studies (eg, swallowing or couple communication) [65,70-72]. To address the need for improved self-management and bolster the self-efficacy in managing self-care, we developed and evaluated the feasibility and preliminary efficacy of a web-based self-management intervention for oral cancer survivors' care called Empowered Survivor (ES).

Theoretical Framework

The development of the ES intervention is guided by the theoretical construct of self-efficacy, which is drawn from social cognitive theory [73,74]. Social cognitive theory focuses on the development of competencies and self-regulation [73,74]. Self-efficacy is a competency defined as the belief in one's ability to execute actions to deal with a situation successfully and comprises 3 domains: knowledge and skills to accomplish the task, confidence in one's ability to motivate oneself and the resources available to accomplish the task, and confidence in one's ability to execute the task [75]. Self-efficacy is a task-specific expectation: people estimate their confidence in their ability to manage a task by evaluating the tasks involved in the successful completion of that task [73,74]. Individuals with high self-efficacy beliefs and abilities regarding a task call upon themselves to execute the task. Confidence in one's ability to execute a task is the most widely studied dimension of self-efficacy. Self-efficacy is linked to the initiation and maintenance of health behaviors [75-83], and greater efficacy is associated with better health behaviors among cancer survivors [84]. Efficacy also predicts psychosocial and functional outcomes among cancer survivors [85,86]. Social cognitive theory has formed the basis of effective intervention programs for improving health behaviors [87-89], disease management among chronically ill individuals, and [90] the health and well-being of cancer survivors [91].

Bolstering self-efficacy in survivorship care is a primary outcome and target of ES. To delineate the mediators of ES's impact, we propose a heuristic framework based on social cognitive theory. First, we use the work of Gollwitzer and Schwarzer, which proposes that planning is a key component of self-management and goal achievement [81,92-94]. In our pilot study, planning was associated with greater efficacy and survivorship preparedness [65]. Second, we integrate the construct of patient activation, defined as the willingness to take actions to manage care and understanding one's role in survivorship care [95]. Greater activation is associated with higher self-efficacy in our study [65] and is targeted by ES. Third, we include information needs, defined as the knowledge about treatment effects and care responsibilities. Knowledge of tasks improves self-efficacy, and lower information needs are associated with higher self-efficacy. Fourth, we include support needs, defined as the level of assistance required to accomplish self-care tasks. Unmet support needs are strongly linked to lower self-efficacy [65]. Finally, the fear of cancer recurrence is a common issue among oral cancer survivors and is associated with poorer QOL and lower self-efficacy [49,96,97]. Reducing the fear of recurrence by teaching coping strategies should increase self-efficacy. Our heuristic framework is illustrated in Figure 1. We have selected 3 long-term outcomes to reflect the key components of survivorship self-management: self-efficacy to manage care, preparedness for survivorship, and head- and neck-specific QOL. Finally, the role of self-management interventions in improving the engagement in self-management tasks among survivors has not been well studied. There is extensive literature suggesting that self-efficacy interventions have an impact on self-management among adults with chronic illness [98-101]. This study explores the impact of ES on self-management behaviors. We chose self-management behaviors that are commonly recommended for oral cancer survivors: oral self-examinations and head and neck mobility exercises. Self-examinations assist survivors in finding suspicious lesions early, and head and neck mobility exercises maintain the ability to easily eat, speak, and move. Engagement in both is low. There are other self-management behaviors (eg, not drinking alcohol and not smoking), but they are not issues for all survivors.

Figure 1. Heuristic framework for Empowered Survivor (ES). QOL: quality of life.

Study Objectives

Overview

The purpose of this study is to evaluate the efficacy of a web-based intervention, ES, against a free, publicly available web-based self-management intervention developed for cancer survivors by the National Cancer Institute (NCI) and the ACS called Springboard Beyond Cancer [102]. A total of 600 patients diagnosed with a first primary oral or oropharyngeal cancer within the past 3 years are being recruited via the New Jersey State Cancer Registry (NJSCR), Cancer Registry of Greater California, and Pennsylvania State Registry and randomly assigned to ES or Springboard Beyond Cancer. The participants complete measures at baseline and at 2 and 6 months after baseline. A process evaluation of ES is completed. The study has 3 primary aims and 1 exploratory aim.

Primary Aim 1

The first primary aim is to evaluate the impact of ES versus Springboard Beyond Cancer on the primary outcomes of self-efficacy in managing care, preparedness for managing survivorship, and head- and neck-specific QOL. We hypothesize that the participants randomized to ES will report significantly greater improvements in self-efficacy for managing their care, preparedness for survivorship, and head- and neck-specific QOL at 6 months.

Primary Aim 2

The second primary aim is to evaluate the mediators (planning, information needs, support needs, activation, and fear of recurrence) and moderators (age, race and ethnicity, HPV status, baseline self-efficacy, and preparedness) of ES's impact on self-efficacy in managing care, preparedness, and health-related QOL. The primary outcomes are self-efficacy in managing self-care, preparedness for managing survivorship, and health-related QOL at 6 months. We hypothesize that the impact of ES on self-efficacy, preparedness, and health-related QOL will be mediated by improvements in survivorship care planning, reductions in information and support needs, and reductions in the fear of recurrence. Little is known about which survivor subgroups benefit the most from self-management interventions. In addition, we hypothesize that the survivors with fewer resources (survivors who belong to people of color, with lower education, who have not received a written survivorship care plan, with less baseline self-efficacy, and with less baseline preparedness) will benefit more from ES.

Primary Aim 3

The third primary aim is to evaluate the impact of ES versus Springboard Beyond Cancer on the secondary outcomes of engagement in oral self-examinations and head and neck mobility exercises.

We hypothesize that the participants randomized to ES will report more frequent engagement in and comprehensiveness of oral self-examinations and head and neck mobility exercises than the participants randomized to Springboard Beyond Cancer at 6 months.

Exploratory Aim

The exploratory aim is to conduct a process evaluation of ES to inform future implementations.

We hypothesize that the participants randomized to ES will use the intervention more, evaluate it more highly, have greater improvements in self-efficacy, preparedness, and QOL.

Methods

Ethics Approval

This study was reviewed and the protocol procedures were approved by the Rutgers University Institutional Review Board (protocol number Pro2020000768). All the participants had a discussion with a member of the research team and read and acknowledged electronic informed consent by clicking "agree to participate" before completing the baseline survey. The participants are assigned a study ID upon entry, and data are stored under the assigned ID. The participants are compensated for their participation in the form of e-gift cards worth US $150 after the completion of 3 surveys and up to US $120 after the completion of the web-based modules if randomly assigned to the ES intervention.

Design

This 5-year study comprises 2 phases. Phase 1 involves additional program development of 2 modules and a maintenance module. This phase of the work has been completed and will be described next. Phase 2 is a randomized clinical trial testing ES against Springboard Beyond Cancer on the web. In the last year, the team will complete the implementation planning to evaluate potential medical and community settings for implementing ES for future scale-up.

Phase 1: Enhancements to the Original Empowered Survivor Content

Original Content

The development of original web-based intervention ES was described in the study by Manne et al [65]. Briefly, it had 4 modules: Introduction, Oral Care, Swallowing and Muscle Strength, and Long-term Follow-up Care and Detecting Lesions. These modules are listed in Table 1. Module 1, Introduction, orients participants and reviews modules. Module 2, Oral Care, reviews the causes, contains a symptom self-assessment, and provides information on how to manage dry mouth. Module 3, Swallowing and Muscle Strength, provides information on the symptoms of swallowing difficulty, methods to reduce swallowing difficulty, and methods to improve flexibility and range of motion in the head and neck. Module 4, Long-term Follow-up Care and Detecting Lesions, describes the importance of head and neck self-examinations; provides information on how to conduct a head and neck self-examination, signs to pay attention to, goal setting, and managing barriers to self-examination; and provides a link to a survivorship care plan website that includes follow-up information, assesses alcohol and tobacco use, and reviews the participant's care team and recommendations. The original ES program had >20 interactive activities to engage participants and foster skill acquisition. An example is symptom assessment, which is followed by

XSL•FO
RenderX

goal-setting feature. Participants rate symptom severity, frequency, concern about symptoms, and confidence in and importance of managing symptoms. Next, the participants select a goal related to the symptom; rate the importance of the goal; choose strategies to address the goal from a list of ideas; and rate benefits and barriers to achieving the goal, confidence in achieving the goal, and support needed to achieve the goal. This function is in modules 3 and 4.

Table 1. Empowered Survivor intervention modules.

Module	Goal	Activities
Original modules		
1: Introduction	• Orient participants and introduce team • Review program modules and navigation • Provide recommended modules • Enhance engagement with survivor stories • Introduce rationale, importance, and steps for self-management	• Narrated introduction by oral surgeon to introduce self-management • Discuss the importance of self-care and set expectations • Sample goal-setting exercise
2: Swallowing and Strength	• Understand the symptoms of swallowing difficulty • Optimize swallowing ability • Improve strength and mobility in head and shoulder • Improve lymphedema management • Facilitate personal goal setting	• Self-assessment of swallowing difficulty, lymphedema, and flexibility • Videos of swallowing and strengthening exercises • Videos of exercises for lymphedema • Goal setting, barriers, and strategies
3: Oral Care	• Understand causes of dry mouth and what exacerbates it • Assess dry mouth symptoms and severity • Understand strategies to keep one's mouth moist • Assess nutritional needs • Understand ways to improve nutrition • Facilitate goal setting for dry mouth and nutrition	• Videotaped introduction by surgeon • Patient experiences with dry mouth • Self-assessment of dry mouth symptoms • Tips for managing dry mouth • Food preparation for dry mouth • Choose high caloric foods (quiz) • Goal setting, barriers, and barriers
4: Long-term Follow-up Care	• Understand how to do a self-examination • Set goals and manage barriers for self-examination • Develop a survivorship care plan that includes follow-up recommendations • Create a personalized follow-up care plan • Identify your care team and unmet care team needs and create a list of health care resources • Learn strategies to communicate with oncology care team • Assess current smoking and alcohol use • Increase motivations to stop smoking and drinking • Understand and manage other medical issues	• Videotaped demonstrations of examinations • Self-management tool to plan oral examination • Get your survivorship care plan • Unmet need assessment for survivorship care • Who is your care team? Who does what? • Do you have any communication concerns? • Communicate with providers about survivorship • Create a plan for managing comorbid illnesses • Assess tobacco and alcohol use and treatment motivation • Education about the health impact of continued use of alcohol • Link to Drinkerscheckup and BetheMatch
New modules		
5: Calm and Connect	• Improve the understanding of psychological concerns • Enhance awareness about how feelings may affect self-care and that self-care of emotions is self-care • Devise strategies to manage emotions and worries • Assess and address special concerns for HPV[a]-associated oral cancer • Unique concerns for young adult survivors • Learn about survivors' emotional reactions and coping	• Rate worries and fears about cancer • Distress assessment • Rate confidence in the ability to manage worries and fears • Videotaped stories of how survivors coped • Link to meditation and mindfulness apps • Choose coping strategy and goals • Assessment of knowledge and worries about HPV-associated oral cancer
6: Maintaining	• Continue working on skills and goals • Learn new information about oral cancer • Communicate with other participants	• Select exercises and skills to move to "Favorites" • Goals are migrated to this module and can be updated and reworked • News posted regularly • Message board

[a]HPV: human papilloma virus.

XSL•FO
RenderX

Enhancements to the Existing Modules

Enhancements were selected based on feedback from the pilot study participants as well as the team's experience with participants during the ES intervention. In module 1, a section containing information about self-care and goal setting to enhance self-care was added to familiarize the participants with the process. In module 2, the ability to set an email reminder to work on the oral care goal was included to optimize continued implementation. In module 3, because the participants liked the videotaped swallowing exercises and indicated that they would like to see more of them, additional exercises were developed with the team's speech pathologist. The strengthening exercises were originally presented as illustrations but were very highly rated. To foster engagement, the team's physical therapist developed videotaped demonstrations of exercises. Because lymphedema was mentioned as a survivorship concern in participant feedback from the pilot study, information about it and its management was added along with demonstrations of home exercises to manage lymphedema by the team's physical therapist. Finally, additional information on how to add caloric content to food was added. In module 4, to bolster the existing content and address common concerns that were not addressed previously, additional resources were added for tobacco cessation, alcohol use, comorbid medical issues, managing hearing loss, and survivorship care planning. More content on interest in quitting tobacco use and the risks of continued use was added. For current smokers, a link to Becomeanex [103] was provided. If the person indicated a desire to continue smoking, material on the increased risk for cancer recurrence and mortality and reduced treatment benefits for smokers and an assessment of the readiness to quit were added by the team member MBS. As for alcohol use, if the participant indicated a desire to continue drinking, a link to Drinkerscheckup [104], an empirically based, web-based treatment, was provided [105]. As comorbid medical issues are common in this survivor population, a section was added on "other medical issues." This section assesses comorbid medical problems, associated medications, and interest in improving the management of medical conditions and offers tailored input on the barriers to medication adherence based on an assessment of barriers. Finally, the team's audiologist added additional material to address the management of hearing loss and tinnitus.

New Modules

A total of 2 new modules, which were originally planned but not developed, were created: module 5, Calm and Connect, and module 6, Maintenance. The goals of Calm and Connect are to describe common psychological concerns patients experience after treatment, increase the awareness of how cancer has affected the participant's emotional well-being, assist the participant in developing useful methods to deal with emotions, provide free web-based resources on coping with stress, and discuss psychosocial aspects of having HPV-related oropharyngeal cancer. The introduction portion contains a video introduction by a psychologist portrayed by an actor and audiotaped narratives presenting patients' emotional experiences. In the next 3 sections, the following coping skills are addressed: (1) managing stress with relaxation, (2) increasing the tolerance for upsetting emotions using acceptance-based strategies, and (3) talking it out with others. A fourth section was developed to address the unique concerns experienced by the survivors of HPV-associated cancers, including common worries (eg, transmission to others), managing questions from friends and family about HPV, and feeling embarrassed about HPV, and the unique experiences of young cancer survivors**.** All sections include interactive activities. For example, the participants can select their key signs of stress, which activates a patient narrative about the signs of stress and narrated educational content. There are also audio relaxation exercises led by a psychologist portrayed by an actor, self-reflection exercises in which the participant types in responses, and links to outside resources such as web-based apps for meditation and mindfulness exercises (Headspace and Calm).

The goal of module 6, Maintenance, is to facilitate ongoing engagement in self-management, evaluate the progress on goals, provide opportunities for interaction with other study participants, and provide new information. This module has 4 features, namely (1) Favorites: the participants choose their favorite content and exercises from screens throughout the program. Across the ES program, 28 pages can be chosen as favorites. These pages are migrated to the Favorites section for future reference, and participants can log in directly to this content; (2) Goals: goals set by the participants in each module are automatically migrated to this section, where the participants can directly access, review, revise, and update them and set up email reminders about them to send to themselves; (3) News: articles of interest from science and medicine sources are posted by study staff on a regular basis; and (4) Message Board: the participants have access to the Message Board throughout their participation in this study. Every month or two, interesting news articles about oral cancer are placed on the board by the project team. When there is a post, the participants receive an email notification that a message has been posted. They can review the post and post messages at that time. They can also access the message board at any time.

Both enhancements to the existing content and new material were developed in collaboration with ITX, incorporated. ITX is a web-development company and the developer of the original ES intervention. Content was reviewed and implemented during a series of regular meetings between the study team and the ITX development team over a 6-month period. The videotaped and narrated content was created in collaboration with Mindful Designs.

Patient Advisory Board Feedback

The Patient Advisory Board consisted of 3 oral and oropharyngeal cancer survivors. The board members reviewed the Calm and Connect module after it was developed and provided feedback in a web-based meeting. Notes from the meeting were reviewed by the study team. No substantive content changes were made, other than those intended to fix grammatical and navigation issues.

After the new modules were finalized and enhancements were incorporated into the existing modules, the Patient Advisory Board reviewed ES. Board members were sent a link to ES and asked to review the content and note recommended changes and any feedback. Next, web-based 1:1 interviews were

XSL•FO
RenderX

conducted to review content and collect feedback. The following key suggestions were given: several modules: correct navigation errors; module 1: provide more clarity with regard to navigating the menu bar, reduce expectations for goal setting by reminding participants that it may be easier to choose small goals, and add definitions of additional key terms; module 3: provide the ability to print the swallowing exercises; and module 5: add content to normalize the desire to get one's life back to normal. The study team reviewed the interviews to select modifications. All of the listed changes were made. There were several suggested changes that were evaluated as less relevant to most survivors and were not incorporated. Content changes were implemented using ITX. The final content is shown in Table 2. The sample content from modules 6 and 7 are shown in Figures 2-8. There are more than 75 interactive activities in ES, including in-session exercises, live links, self-assessments, and video and audio narratives. Multimedia Appendix 1 [106] outlines these activities.

Phase 2: Randomized Controlled Trial

Design

This is a prospective, randomized controlled trial to evaluate the effect of ES on confidence in managing self-care, preparedness, and health-related QOL and on the secondary outcomes of oral self-examination and engagement in head and neck strengthening exercises. This is evaluated in 2 groups with a total of 600 survivors (ES vs Springboard Beyond Cancer) and by 3 assessments (baseline, 2 months, and 6 months). The participants complete surveys at baseline and 2 months and 6 months after baseline. Figure 9 illustrates the participant flow. A free, publicly available general survivorship-focused web-based program, called Springboard Beyond Cancer, was selected for comparison based on a review of the literature on the design of behavioral interventions [98,107,108]. This review suggested that there are pros and cons to all comparison conditions and that selection should be guided by the phase of the research. We selected a comparison condition that had the same method of delivery (web-based delivery), same frequency of delivery, and similar topics.

Figure 9. Study flowchart.

Participants

The participants are recruited from 2 state registries and through clinic recruitment. The eligibility criteria are as follows: participants should (1) be aged >18 years, (2) be diagnosed with a first primary oral cavity or oropharyngeal cancer in the last 3 years, (3) be currently cancer free (but could have experienced a recurrence), (4) have computer access, and (5) be able to read English. Children are not included because the incidence of

XSL•FO
RenderX

these cancers in children is exceedingly rare (0.2 cases/100,000 children).

Among the cancer registries, approximately 1600 patients are diagnosed with a first primary oral or oropharyngeal cancer per year. Our pilot study suggested that 26% of eligible patients will consent and complete the baseline survey. This enrollment rate is consistent with or higher than that of other intervention trials recruiting from cancer registries (18%-30%) [99,100]. Recruitment will be conducted for approximately 27 months. The sample size is based on the power to detect the effects on our primary outcomes. With 1600 patients available each year and 3 years of data collection, we have a large pool: given the 4800 total participants available and 26% acceptance, we have about 1104 potential participants. The power analysis suggests that the study requires 600 participants.

To achieve this, we include pictures of minority patients on our recruitment materials and oversample Black males in our registry recruitment. We have set a goal to ensure that of the total number of participants enrolled, 8% (n=48) are Black men.

Recruitment

Recruitment was primarily conducted using state cancer registries. Recruitment procedures differ between state registries. For the NJSCR, the registry confirms patient eligibility and, if eligible, sends a letter to the patient's diagnosing physician, making the physician aware that their patient is eligible. If the NJSCR does not receive a disapproval from the physician within 2 weeks, the patient is sent a cover letter and an "agreement to contact" sheet. Potential participants are called by registry staff to discuss the study. The participants have the option of verbally consenting at that time. The participants who consent have their contact information and a copy of verbal consent forwarded to the members of the study staff, who call the patient. Patients deemed eligible are provided with a web-based consent and survey. The staff members contact patients weekly if they do not return the consent. Patients are considered passive refusers if they do not return a survey after repeated call attempts during days, nights, and weekends over a 3-week period after the consent is sent. For the Cancer Registry of Greater California and the Pennsylvania State Registry, the registry provides a list of patients and their contact information to the staff members. The staff members call patients, and those deemed eligible are provided with a web-based consent and survey, and the same procedures for enrollment as described above for the NJSCR are implemented. A maximum of 8 recruitment calls are allowed: 4 calls can be followed with a voicemail message, and 4 calls are counted as missed calls. Of these 8 contacts, 1 can consist of a text message. Once the electronic consent and survey are completed, the participants are automatically randomly assigned to the ES or Springboard condition using a data management system. Separate assignment schemas are set up for each registry by the study's statistician.

Participants who do not complete the consent and baseline are contacted by phone or email on a weekly basis for 1 month to facilitate survey completion. The participants are automatically linked to one of the web-based interventions (ES or Springboard) as soon as they are randomized upon the completion of the baseline survey.

Interventions

Empowered Survivor

The ES program is described in Table 1, and Figures 2-9 provide examples of the content. The content is accessible via any device that is connected to the internet such as a tablet, an iPad, a phone, or a computer. If the participants experience issues in viewing information, they are contacted by phone to troubleshoot. The ES program can be completed in 1 sitting however, the orientation encourages the participants to complete ES over a longer period and emphasizes setting and implementing self-care goals and building self-management skills. A week after randomization, a team member contacts the participants to conduct a brief motivational discussion, the goals of which are to go over the content and benefits of the intervention, ask the participant whether they were able to log into the program, ask whether the participant whether they have questions, and offer to log in with the participant to review the Introduction module. The participants who do not log in by day 3 are sent a reminder email to log in, and the participants who do not log in by day 5 are sent a second reminder email to log in. When "News" or "Message Board" content is added, an email alert is automatically generated for the participants. The participants are provided a small incentive for completing the modules (US $20). The participants who do not log into the program within a month are entered into a lottery for a gift card worth US $20. These methods are recommended in systematic reviews and meta-analyses of factors important for revisits and continued use of internet interventions [101].

Springboard Beyond Cancer

Springboard Beyond Cancer is a self-management program developed by the ACS and the NCI. The program covers 4 main topics: Symptoms, Stress and Mood, Wellness, and Get Support. Each topic has several pages describing the topic and providing information on signs and symptoms, tips on how to manage the issue, and links to resources. The participants can move the tips to their Action Deck for future reference. Unfortunately, at the end of 2020, the NCI ended its contract with the ACS, and no longer hosted the Springboard website. The website was moved to an archive status [102], and the dynamic features of the site (eg, videotaped content) were disabled. After discussions with the NCI and ACS, an archived version of Springboard Beyond Cancer was shared with the study staff, and the NCI confirmed that the link would remain active throughout the study period. The team was able to provide the disabled videotaped content as a Springboard YouTube playlist [102]. This playlist houses all videos embedded in the Springboard website that were deactivated. In addition, the participants are provided with the ACS Survivorship: Before and after treatment website [109], which includes information on coping with cancer, maintaining a healthy lifestyle after treatment, and managing cancer as a chronic illness and survivorship resources (ie, care plans). The participants receive the Springboard YouTube link in the welcome email once they are randomized to the Springboard arm. A week later, they receive a second welcome email, which contains live links to ACS and Cancers survivor network. Sample pages are shown in Figures 10-13.

XSL•FO
RenderX

To facilitate engagement, within a week of sending the link to Springboard Beyond Cancer, the coordinator will reach out via phone to conduct a brief motivational discussion. The goals of this discussion are as follows: review program content and benefits, ask the participant whether they were able to log into the website, ask the participant whether they have questions, and offer to log in with the participant to review the Introduction. A week after the Springboard website is emailed to the participants, we will send another email with the ACS Survivorship website link. This email highlights sections of the website that the study team believes will be most useful for the participants. The coordinator manually sends an email or text to the participants 1 month after randomization, reminding them to return to the websites.

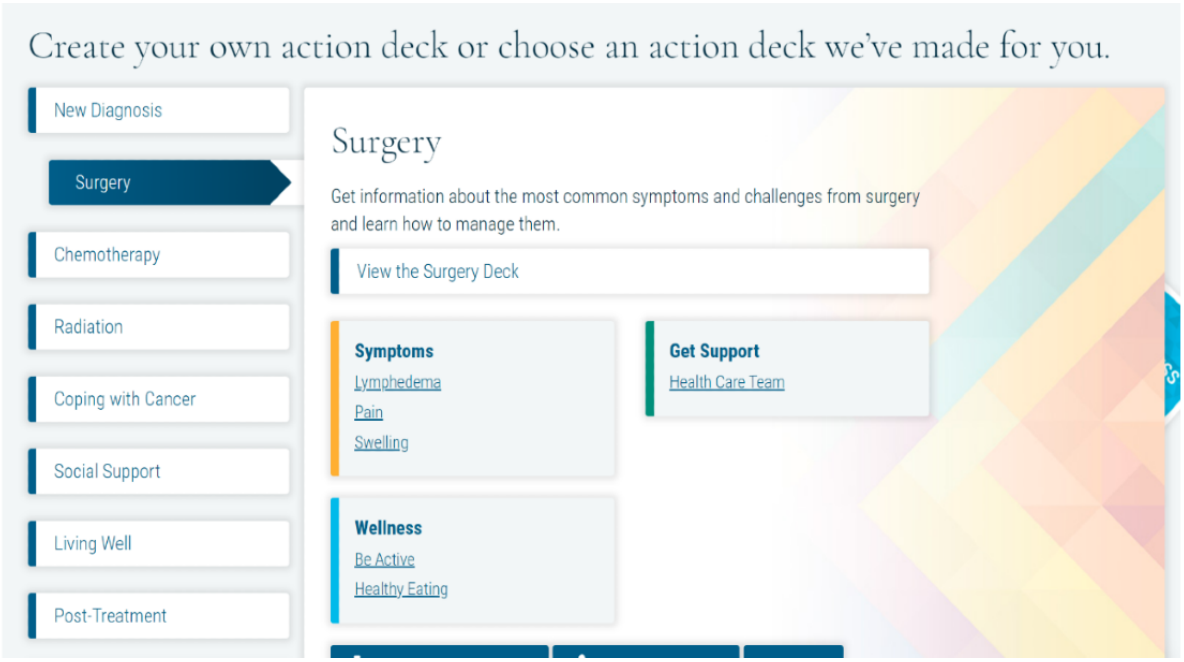

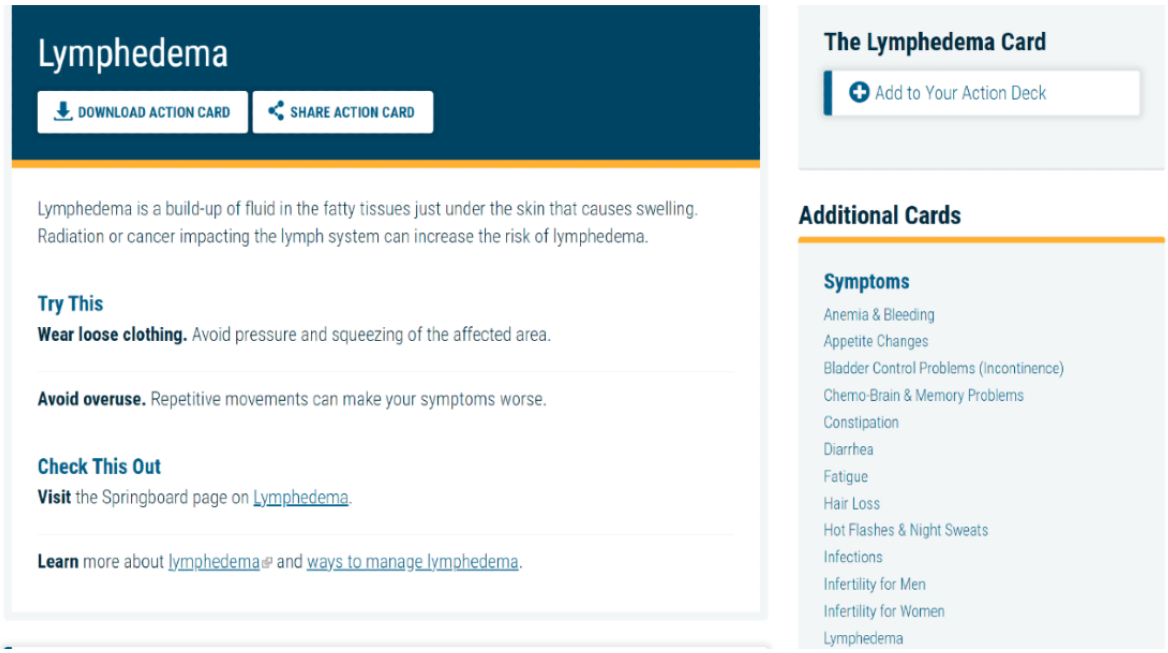

Figure 13. Sample page from Springboard Beyond Cancer (4).

Survey Procedures

The participants complete electronic surveys via a web-based data management system (DatStat) at 3 time points: baseline and 2 months and 6 months after baseline. Table 2 presents the timing of the measures. At the 2- and 6-month time points, regardless of the intervention progress, the participants are sent an email with a link to the follow-up survey. To the participants who do not complete the survey within a week, 3 weekly email and phone call reminders will be sent. After 4 weeks, the participants who do not complete the survey will be considered noncompleters for that survey but will be sent a link to the next follow-up survey. The participants will receive a web-based gift certificate worth US $50 for completing each survey. Each survey takes approximately 30 minutes to complete.

Primary Outcome Measures

Oral Cancer Self-management Self-efficacy

This scale was developed for the pilot study [65] and consists of 22 items assessing participants' confidence in dealing with 11 areas: management of dry mouth symptoms, dental care, proper nutrition, swallowing and speaking difficulties, neck and shoulder muscle flexibility and strength, follow-up care appointments, communication with providers, detecting lesions through self-examination, emotional responses, smoking, and alcohol use. One of the items assess the overall confidence in managing head and neck survivorship care. Ratings ranged from 1 (*not at all confident*) to 5 (*very confident*).

XSL•FO
RenderX

Preparedness

This 10-item scale assesses whether the information received about survivorship care was sufficient, helpful, comprehensive, and covered self-care tasks (1=*strongly disagree*; 5=strongly *agree*) [65,110-112]. Of the 10 items, 2 items assess how satisfied the cancer survivors are with the quantity of the information provided and the way in which the information was provided (1=*not at all satisfied* and 4=*very satisfied*).

Head and Neck Health–Related QOL

The European Organization for Research and Treatment of Cancer-Quality of Life Questionnaire-Head and Neck-43 (EORTC-HN-43) is the updated version of the EORTC H&N 35. This measure has strong convergent validity with EORTC H&N 35 [113-115]. The EORTC-HN-43 is the most widely used measure of head and neck QOL and has been rigorously and systematically validated in 18 countries.

Secondary Outcome Measures

Performance of Oral Self-examinations

The participants are asked whether they conducted a comprehensive examination of the inside of their mouth, the outside of their mouth (the face), and their neck to look for signs of oral cancer in the last month. The participants who report conducting an examination are asked whether they checked 11 different areas (eg, face, neck, inside of cheek, floor, and roof of mouth) and asked the degree to which they know what to look for when conducting an examination (1=*not at all*; 5=*completely*).

Engagement in Swallowing and Jaw and Neck Strengthening Exercises

The participants are asked whether they engaged in exercises to improve swallowing (tongue, jaw, Masako maneuver, Mendelsohn maneuver, and effortful swallow) in the last month (*yes/no*) and whether they engaged in exercises to improve or maintain muscle strength in the jaw and neck (jaw relaxation, turtle, and neck flexion and extension) in the last month (*yes/no*).

Sociodemographic Measures

The participants report sex, age, education level, marital status, insurance status, race and ethnicity, income, and financial hardships in the last month ("Did you have adequate financial resources to meet the daily needs or you and your family?").

Medical and Clinical Measures

At baseline, the time since diagnosis, whether the survivor had been diagnosed with a second cancer, recurrence status, treatments received (radiation, chemotherapy, and surgery), and comorbidities (Charlson index [116]) are reported by the participants. At all time points, oncology-related service use is reported by the participants. Tumor location and cancer stage are extracted from the tumor registry data. Tumors are characterized as oral, oropharyngeal, or salivary cancers. The participants also report the receipt of a survivorship care plan, their HPV tumor status, their current tobacco and alcohol use, and their current insurance status.

Mediator Measures

Action Planning

This 8-item measure assesses the degree to which a detailed plan has been made for self-care tasks (related to dry mouth, swallowing, muscle strength, detecting lesions, and long-term follow-up care) and how to manage interference in these plans (1=*strongly disagree*; 5=*strongly agree*) [94,117].

Patient Activation

This measure consists of 13 items measuring attitudes toward adopting an active role in care [118]. These items were adapted to assess head and neck cancer care. The following are a couple of sample items: "When all is said and done, I am the person who is responsible for managing my head and neck cancer care" and "I am confident that I can take actions that will help prevent or minimize some symptoms or problems associated with my head and neck cancer care" (1=*disagree strongly*; 5=*agree strongly)*.

Information Needs

This 23-item scale, adapted from the Health-Related Topics section of the Follow-up Care Use Among Survivors [119] and prior work, assesses [67,119] the desire for more information about oral cancer topics (1=*yes* and 0=*no*).

Support Needs

The Supportive Care Needs Survey [120] is a 34-item scale assessing physical, psychological, and health care system needs (1=N/A [not applicable]; 5=*high need*).

Concerns About Recurrence

Five items assess the worry about the recurrence of oral cancer (eg, "How much does the possibility that your head and neck cancer could recur upset you?") [121]. An additional 27 items assess the degree to which worries about recurrence interfere with different life domains (eg, possibility of death, future treatment, femininity, sexuality, and body image).

Psychological Distress

The Patient Health Questionnaire-9 [122] is a self-report measure of depression that assesses key diagnostic criteria for depression based on the original PRIME-MD. It is a widely used measure and has demonstrated strong reliability and construct validity [123] in nonill populations as well as cancer populations [123]. Scores from 0 to 4 indicate no or mild depression, from 5 to 9 indicate mild depression, from 10 to 14 indicate moderate depression, from 15 to 19 indicate moderately severe depression, and from 20 to 27 indicate severe depression.

Treatment Evaluation

In both interventions, the following are assessed: (1) 17 items assess general features and content (use, helpfulness, learning something new, interesting, and valuable) and the degree to which the program improved confidence in managing symptoms and (2) 5 items assess website features (eg, for ES, survivor stories, goal setting, and discussion board and for Springboard, action card decks, symptoms page, stress and mood page, and wellness page). For ES, an additional 19 items assess the content of each module. Open-ended feedback is solicited.

XSL•FO
RenderX

Semistructured Interviews With ES Participants and Providers

A total of 30 participants from the ES condition participate in a brief web-based or phone interview. The survivors will be contacted after they complete the 6-month follow-up. The questions ask the participants about the best timing for the intervention (during or after treatment or another time), delivery schedule (all at once or one module at a time), best setting to offer the intervention (eg, dental visits or oncology care), and whether the participant would be willing to pay for the intervention.

In year 5 of this project, the team will conduct key informant interviews with 30 oral cancer providers (eg, oncologists and physical therapists) who have contact with this population. Questions will focus on the timing (eg, right after treatment), duration (weekly vs all at once), and settings (eg, during dental visits) that they feel would make ES most useful.

Results

Approach to Missing Data

To account for missing values owing to loss to follow-up, we will adapt the sensitivity analysis method proposed by Scharfstein [124] to estimate effects over ranges of assumptions about the relationship between dropout and response. To evaluate bias, we will examine the predictors of dropout at follow-up. We will evaluate demographic and medical factors, baseline alcohol use and smoking, and baseline self-efficacy as predictors.

We will use an intent-to-treat approach to analyze primary and secondary outcomes. Our approach to recruitment and retention minimizes missing data by contacting participants who do not complete sections of the survey and by incentivizing participation. Initial analyses will examine the characteristics of noncompleters. As recommended by Lang and Little [125], multiple imputations (using 50 imputed samples) will be used to impute missing values.

The treatment of covariates also warrants attention. Possible covariates include the demographic variables, objective risk variables, and medical variables of the survivors. Finally, to determine which covariates should be included in the analyses, preliminary analyses in which each outcome is predicted by the full set of qualifying covariates will be conducted. Only those covariates that significantly predict at least 1 outcome will be included in the analyses. Once the set of covariates is determined in this manner, the same set of covariates will be included in all analyses.

Aim 1: Approach and Analysis Plan

Approach

The primary aim is to examine the relative impact of ES versus Springboard Beyond Cancer on our primary outcomes of self-efficacy in managing self-care, preparedness for managing survivorship, and health-related QOL at 6 months. We anticipate that 600 survivors will enroll (300 in each condition), and we conservatively estimate, based our ES pilot, that 80% (n=480) will complete the 1-month follow and 75% (n=450) will complete the 6-month follow-up. However, all available data will be included in the analyses.

Analysis

Multilevel modeling (MLM) will be used to examine whether there are significant differences between the ES and Springboard Beyond Cancer interventions over time. In our primary analysis, both time and treatment will be treated as categorical. This approach yields a main effect for treatment, a main effect for time, and an interaction between time and treatment. Covariates will include 3 effect-coded variables representing sex, race and ethnicity, marital status, education, age, tumor location, stage, time since diagnosis, whether the cancer recurred over the study period, whether the participant received a survivorship care plan, HPV status, and baseline tobacco and alcohol use. The MLM approach has the advantage that it does not exclude participants with missing data at some time points, as would be the case if a traditional ANOVA were used. Thus, this analysis used all available data.

Power and Sample Size

Power is calculated for the intent-to-treat effect sizes from the pilot study**,** assuming that 2-sided *z* tests are conducted at the $P<.05$ level. With an intent-to-treat analysis and a total sample of 600 participants, there is >99% power to detect significant differences between ES and Springboard Beyond Cancer in our primary outcomes of self-efficacy and preparedness for survivorship. There is 90% power to detect significant differences in health-related QOL at the 6-month follow-up.

Aim 2: Approach and Analysis Plan

Approach

This aim evaluates the hypothesized mediators of the expected association between the intervention and outcomes and hypothesized moderators of the intervention effects. Mediators include action planning, information needs, support needs, patient activation, and the fear of recurrence. Moderators include race and ethnicity, education, receipt of a survivorship care plan, baseline self-efficacy, and preparedness. Figure 2 depicts the proposed mediational model in which the intervention impacts the survivors' planning skills; reduces their information and support needs; and reduces their fear of recurrence, which ultimately impacts their self-efficacy, preparedness, and health-related QOL.

Analysis

Analyses will be conducted using 3 separate mediational models for the 3 primary outcomes. The indirect effects of ES on outcomes will be tested using changes in outcomes from baseline to 6 months as dependent variables, changes in the mediators from baseline to 2 months, and changes in mediators from baseline to 6 months. The SPSS macro (IBM Corp) will generate 5000 bootstrapped samples using random sampling with replacement to generate estimates and CIs around the indirect effects [126,127]. The mean of the 5000 indirect effect estimates based on the bootstrapped samples will be examined. Within a multiple mediator model, the indirect effect of each mediator is its unique effect on the outcome when controlling for the

XSL•FO
RenderX

other mediators included in the model. We propose that ES will have stronger mediating effects than the Springboard Beyond Cancer intervention.

Treatment moderators will also be evaluated. Very little is known about which survivor subgroups benefit the most from self-management interventions. The available research suggests that survivors with fewer resources (eg, lower education) benefit more [128-132]. We will adopt a similar hypothesis and examine the role of low resources, people of color, lower education, not having received a written survivorship care plan, less baseline self-efficacy, and less baseline preparedness, in ES's effects. For moderation analyses with continuous or dichotomous (eg, care plan receipt; White race or people of color) moderators, we will simplify the analysis by using MLM with a regression approach in which condition will be effect-coded (ES=1 and generic=−1) and time will be treated as a quantitative variable that was coded in months (0, 2, and 6) and then grand-mean centered. Moderator variables will be grand-mean centered (eg, baseline self-efficacy) or effect-coded (eg, care plan receipt). Moderation analyses will include the same set of covariates used in the primary analyses described for the primary aims.

Power and Sample Size

On the basis of the simulations and corrected bootstrap method outlined in Fritz and Mackinnon [130], there is at least a power of 0.85 to detect small effects (Cohen *d*=0.26) from both the independent variable to the mediators and the mediators to the dependent variable.

Aim 3: Approach and Analysis Plan

Approach

This aim focuses on 3 recommended self-care tasks: oral self-examinations and the level of comprehensiveness of self-examinations, engagement in swallowing exercises, and engagement in head and neck mobility exercises.

Analysis

We will use the same approach as that outlined in the analysis of the primary aim.

Power and Sample Size

Assuming an intent-to-treat analysis and a total sample of 600 participants, we have 99% power to detect significant changes in oral self-examination and comprehensiveness of oral self-examination and 85% power to detect improvements in performance of swallowing exercises. Owing to low power, the performance of head and neck exercises is exploratory.

Exploratory Aim: Approach and Analysis Plan

Approach

The broad implementation of a survivorship-focused intervention involves a community-based implementation. It is premature to broadly implement ES before determining its efficacy. However, as a first step in this process, we will conduct a process evaluation. First, we will use participant treatment evaluations and use data from ES. Systematic reviews have found that the average adherence to web-based health interventions is 50% to 53% [132,133]. ES use was higher in the pilot study in that 75% of the participants viewed 3 to 4 modules [65]. Most web-based interventions are designed to be used at least weekly for several weeks, but many participants access the interventions only once [132-134]. We will examine the predictors of ES use and evaluate the association of ES use with the primary outcomes. This analysis assists in identifying subgroups for targeting to improve the use of the intervention. Second, we interview a randomly selected subset of 30 ES participants to provide feedback upon the completion of the last follow-up. Third, we conduct key informant interviews with 30 oral cancer providers (eg, oncologists and physical therapists) who have contact with this population to identify potential settings for implementation.

Analysis

As for the participants, we record whether, how frequently, and for how long the participants logged into ES and how many modules are completed. In the analyses, we (1) examine whether these variables are associated with the primary outcomes, (2) evaluate the association of demographic factors (race and ethnicity, alcohol use, and tobacco use) with ES use, and (3) use an evaluation survey and web-based use data from ES.

For the survivor and provider interviews, interview data are transcribed. The analysis explores feedback on barriers to ES use in clinical practice and the preferred timing of ES (eg, should ES be introduced at a follow-up visit, in the waiting room, and by a navigator or health coach?). Analysis of interview transcriptions follow the "constant comparison" analytic approach [135], a method of explanation building in which the findings of an initial case are compared with a provisional category and revised as needed with new cases. This process is continued until an area of interest is fully explicated, reaching theoretical saturation [135]. Central to this process is "thematic" coding. We will develop an initial set of codes. For each code, we will develop ≥1 "secondary codes" that represent more specific aspects of the phenomenon. The schema organizes and assimilates data. The transcripts will be coded by at least 2 coders. Discrepancies will be resolved, and the process will be repeated until an acceptable level of intercoder reliability is achieved (using chance-corrected statistics such as κ for nominal data) [136]. Coded transcripts will be analyzed using the ATLAS.ti qualitative software (ATLAS.ti Scientific Software Development GmbH) [137].

This information will be used to create a website that serves as a storage house for all the study materials. On this website, the team will publish a free manual that details how to access ES and the methods to enhance ES use and contains information on hard-to-reach survivors and our publications and presentations.

Data Safety and Monitoring

A serious adverse event (AE) is defined in this study in 2 ways. First, if the participant dies between baseline and follow-up, this is an AE. This situation will not be a study-related AE but will be reported to the Institutional Review Board. Second, if a participant endorses elevated depression at any of the 3 study survey time points, this is an AE. We monitor depression using the Patient Health Questionnaire-9 at each assessment time

XSL•FO
RenderX

point. Scores in the moderate to severe range (defined as a score over 19) of depression indicate an AE. The procedure for handling AEs is that the study's principal investigator will reach out to these participants by phone to assess distress, immediate need for intervention, interest in psychosocial services, insurance needs, and financial needs to determine the appropriate type of service. After assessing distress and support resource needs, our procedures include (1) a mailed list of national cancer patient resources (eg, the Cancer Support Community toll free hotline, Cancer Care support line, and the ACS support line); 2) a mailed list of cancer support groups at hospitals located close to the participant's home, which will be prepared at the beginning of the study and updated regularly; and 3) a list of psychosocial providers within a 30-mile distance of the participant's home, which will be provided by mail and over the phone. We monitor the participants who have endured distress at one time point during the course of the study using the follow-up surveys.

Discussion

Overview

The diagnosis and treatment of oral cavity and oropharyngeal cancers can adversely impact oral functioning and QOL. The management of disease- and treatment-related effects can be complex and involve oncology and rehabilitation experts to restore and prevent further deterioration of function. Survivors carry the primary responsibility for managing their follow-up and self-care. Adherence to this regimen is less than optimal, and negotiating the return to normal life can be challenging. Survivors experience decrements in QOL and desire information and support regarding long-term effects, recommended follow-up, oral symptoms that prompt contacting a physician, maintenance of nutrition, improvement of speech and swallowing, maintenance of oral health, and psychological concerns. In addition, survivors report low self-efficacy in managing their self-care regimen. Despite the substantial self-care needs, compromised QOL, low self-care self-efficacy, and low participation in self-care, there are only a few self-management interventions for this population. In our prior work, we developed and evaluated a self-guided web-based intervention to assist in self-management, called ES, which illustrated a promising impact in formative studies [65]. The goal of this study is to bolster the ES intervention by enhancing the existing content and adding 2 new modules focused on managing psychological concerns and maintaining oral cancer self-care routines and to assess the impact of the intervention on self-efficacy, preparedness, and QOL.

This study will provide important information regarding the impact of this self-management intervention when compared with a less-intensive intervention as well as information on the levels of engagement and predictors of engagement in ES. Further impact of this study lies in the information that will be gathered on its potential dissemination in the last phase of the study, which will identify the settings in which it may be implemented and incorporated into survivorship care.

Limitations and Unanticipated Problems

The limitations of this study are the challenges related to recruitment into an intervention for cancer survivors, feasibility concerns associated with recruiting survivors via state cancer registries, reliance on self-report measures of oral self-examination and engagement in head and neck strengthening exercises, and well-described difficulties in engaging individuals in web-based interventions [138,139]. We leverage several strategies to enhance engagement, including lotteries for logging into the first module for those who do not log in after 2 weeks and incentives that will be provided after the completion of each module. In terms of feasibility, recruiting the participants via registries, although a way to increase diversity in a sample, can be challenging. Finally, although self-reported oral self-examinations and engagement in exercises are not the only self-care behaviors recommended for survivors, other self-care behaviors such as engagement in mouth care, changes in food intake to minimize swallowing difficulties, tobacco cessation, and alcohol use are less prevalent and less likely to apply to most survivors.

The findings of this study will provide important information on the efficacy of a web-based intervention on self-care among oral cancer survivors as well as initial information about the potential timing and settings for future scale-up. If efficacious, future research could evaluate potential implementation strategies to reach the survivors of oral cavity and oropharyngeal cancer.

Acknowledgments

The authors would like to thank the following individuals for their valuable contributions to this project: Carolina Lozada (database development), Alexandria Kulik (content development), Nicole Raia (audiologist), Victoria Larken (physical therapist and lymphedema expert), Lori Magoulas (nutritionist), and Lauren Solomon (speech and language pathologist).

This project was supported by the National Cancer Institute under R01 CA240344, awarded to Sharon Manne. Services, results, and products in support of the research project were generated by the Rutgers Cancer Institute of the New Jersey Population Science Research Support Shared Resource. The content is entirely the responsibility of the authors.

Abstract

Background: Individuals diagnosed with melanoma before the age of 40 years (young-onset melanoma survivors) and their first-degree relatives (FDRs) are a growing population at risk for developing recurrent melanoma or new melanomas. Regular surveillance using clinical skin examination (CSE) and skin self-examination (SSE) and engagement in preventive behaviors including sun protection are recommended. Given the growing population of survivors and their families who are at increased risk, it is surprising that no behavioral interventions have been developed and evaluated to improve risk-reduction behaviors.

Objective: We describe the rationale and methodology for a randomized controlled trial evaluating the efficacy of a Facebook intervention providing information, goal setting, and peer support to increase CSE, SSE, and sun protection for young-onset melanoma survivors and their FDRs.

Methods: Overall, 577 survivors and 577 FDRs will be randomly assigned to either the Young Melanoma Family Facebook Group or the Melanoma Family Healthy Lifestyle Facebook Group condition. Participants will complete measures of CSE, SSE, and sun protection, and mediator measures of attitudes and beliefs before and after the intervention. The primary aim is to evaluate the impact of the Young Melanoma Family Facebook intervention versus the Melanoma Family Healthy Lifestyle Facebook intervention on CSE, SSE frequency and comprehensiveness, and sun protection among FDRs. The secondary aims examine the efficacy of the Young Melanoma Family Facebook intervention on survivors' SSE frequency and comprehensiveness and sun

XSL•FO
RenderX

protection behaviors and mechanisms of intervention efficacy for intervention impact on FDR and survivor outcomes. The exploratory aim is to evaluate the efficacy of the 2 interventions on perceived stress, physical activity, and healthy eating.

Results: This project was funded by the National Institutes of Health (R01CA221854). The project began in May 2018, and recruitment started in January 2019. We anticipate completing enrollment by November 2023. Power calculations recommended a sample size of 577 survivors and 577 FDRs. Multilevel modeling treating family as the upper-level sampling unit and individual as the lower-level sampling unit will be the primary data analytic approach. Fixed effect predictors in these models will include condition, role, sex, all 2- and 3-way interactions, and covariates.

Conclusions: The Young Melanoma Family Facebook intervention aims to improve primary and secondary skin cancer prevention for young-onset melanoma survivors and their family members. The intervention's delivery via a popular, freely available social media platform increases its impact because of the potential for dissemination in many contexts. If efficacious, this program could be disseminated by dermatologist practices, public health or nonprofit organizations focused on melanoma, and existing melanoma and skin cancer Facebook groups, thereby expanding its reach. This project will produce a content library of posts and a moderation guide for others.

Introduction

Background

Young adults diagnosed with melanoma, defined as individuals diagnosed at or before the age of 39 years, have been identified by the National Cancer Institute as a growing population [1]. Melanoma risk is ≥6 times higher among young adults than it was 40 years ago [2] and is the most common malignancy for young adults aged between 25 and 29 years [3]. Young adult survivors are at a 9-fold risk for developing another melanoma and a higher relative risk for a second malignancy than adults diagnosed with cancer who are >39 years of age [4]. First-degree relatives (FDRs) of patients diagnosed with melanoma before the age of 40 years are also at an elevated risk of developing melanoma. Having an FDR with melanoma more than doubles the risk of melanoma [5].

The incidence of a second melanoma is increased in melanoma survivors, with cumulative risk ranging from 2% to 5% during the periods of 5 to 20 years after initial diagnosis [6-11]. Existing guidelines vary only slightly among specialty organizations. The National Comprehensive Cancer Network recommends lifelong clinical skin examination (CSE) at least annually for those with early-stage disease and more frequent follow-ups for the first 2 years for those with later stage disease (ie, every 3-6 months) [12]. The National Comprehensive Cancer Network guidelines and other professional agencies also recommend education in regular skin self-examination (SSE) and principles of sun safety exposure (avoidance of sun during peak hours or use of sun protective clothing, hat, or eyewear) [12-14]. Similarly, many professional societies suggest routine CSE and SSE and regular sun protection behaviors for FDRs [11,15].

Despite the growing population of young melanoma survivors and their FDRs, engagement in CSE, SSE, and sun protection behaviors in this population remains low. Bergenmar and Brandberg [16] evaluated young adults with a family history of melanoma and found that engagement in sun protection was low and levels of sun exposure were high. Zwemer et al [14] evaluated sun protection practices among melanoma survivors <30 years and reported low levels of sun protection in one-third of the sample. More than half of the participants reported sunbathing for >1 hour a week. Our preliminary data suggest that engagement in sun protection, SSE, and CSE is also relatively low among FDRs. Approximately 44% of FDRs never had a CSE, 73% had not conducted a comprehensive SSE in the past 2 months, and 33% had rarely or never used sunscreen or a wide-brimmed hat when outdoors during daytime hours (SL Manne, PhD, unpublished data, March 2019).

Given the growing population of young melanoma survivors and their family members who are at increased risk, it is surprising that no behavioral interventions have been developed and evaluated to improve risk-reduction behaviors in this population. Behavioral interventions have been evaluated to improve sun protection and skin surveillance among melanoma survivors and FDRs of patients of all ages [17-19], as well as SSEs among patients with melanoma of all ages [20-23]. However, no study has specifically targeted the growing population of young-onset patients and their FDRs. Furthermore, only 1 study has adopted a family-focused approach that delivers the intervention to both survivors and their FDRs [24]. This web-based intervention improved the comprehensiveness of SSE in hard-to-reach areas but did not affect CSE or sunscreen use [17].

The Young Melanoma Family Facebook Intervention

To address this gap, we developed the Young Melanoma Family Facebook intervention to increase the performance of risk-reducing behaviors for young melanoma survivors and their FDRs. We selected a social media delivery platform for this intervention. Other than the web-based intervention evaluated by Bowen et al [17], prior behavioral interventions for FDRs

XSL•FO
RenderX

and patients have been delivered via individual print materials or telephone counseling [18,22,23,25-27]. Our intervention work extends prior research by using a social media platform, Facebook, as the intervention delivery method. Given the ubiquitous use of social media, its potential for reach and communication presents a unique opportunity for health-promotion interventions. To date, most health communication research has used social media as a tool to improve knowledge and awareness of cancer risks [28], such as human papillomavirus awareness [29] and awareness of breast cancer risk [30]. Social media has also shown promise as a platform for behavior change interventions, including promising results in weight loss [31], physical activity [32], and tobacco use [33].

Facebook was a particularly suitable way to deliver intervention content to a group of young melanoma survivors and their FDRs for 2 reasons. First, this demographic has high rates of Facebook use [34], and most Facebook users are already connected to family members via Facebook. Our multiple-family Facebook group intervention approach includes both young survivors and their family members, and thus addresses the unique needs of the young adult survivor population, who have higher needs for peer and family support [35-37], prefer to interact with other young adult survivors [34], and prefer to obtain support from peer survivors rather than from other sources [38]. Our use of Facebook as an intervention platform is also a good match for this population's preferences for information delivery, as they are frequent users of social media for health information [39]. Peer-to-peer and within- and between-family interactions have the potential to facilitate attitude and behavior change and set positive social norms for sun safety behavior.

The Young Melanoma Family Facebook intervention provides information, goal setting, and peer support to increase CSE, SSE, and sun protection behaviors for young-onset melanoma survivors and their FDRs. Content was guided by the Preventive Health Model [40-42] and the Theory of Normative Social Behavior [43,44]. The Preventive Health Model [41,42] is an integrative framework that includes the following constructs: risk, salience or coherence (benefits and barriers), and social and normative influences. The normative social influence construct is particularly important because of the family and group focus. The Theory of Normative Social Behavior proposes that normative influences are transmitted through interactions with family and peers about health behaviors, and these result in the internalization of norms. Facebook group participants may modify their own behavior and attitudes because of the norms about sun protection, CSE, and SSEs set by the intervention content and group members. If group members observe other members endorsing sun protection benefits and supporting regular self-examinations and CSE, normative changes may occur. Research on other group-based interventions supports this contention [45].

The Melanoma Family Healthy Lifestyle Facebook Intervention

The literature on Facebook interventions is emerging, and there is no clear guidance on comparison groups. To select an appropriate comparison group, we reviewed the literature on the design of behavioral interventions [46]. This review suggested that there are pros and cons to all comparison conditions and that selection should be guided by the phase of the research. We selected a comparison condition that had the same method of delivery, same frequency of postings and group duration, and the same group composition. The key differences in the comparison intervention are as follows: (1) content is focused on healthy lifestyle (eg, nutrition, physical activity, and smoking cessation) and cancer survivorship and (2) content does not contain any material relevant to skin cancer, sun protection, SSEs, CSE, or tanning. This comparison condition offers a similar level of interactivity to that offered by the Young Melanoma Family Facebook intervention.

Objectives

The purpose of this randomized clinical trial is to determine the efficacy of a Facebook intervention that provides information, goal setting, and peer support to increase CSE, SSE, and sun protection behaviors in young-onset melanoma survivors and their FDRs.

Primary Aim

The primary aim is to examine the efficacy of the Young Melanoma Family Facebook intervention versus a Melanoma Family Healthy Lifestyle Facebook intervention on CSE (primary outcome), SSE frequency and comprehensiveness, sun protection behaviors, and indoor tanning (secondary outcomes) of FDRs of young-onset melanoma survivors.

- Hypothesis: participants in the Young Melanoma Family Facebook intervention will report more CSE, more frequent and comprehensive SSEs, more sun protection behaviors, and less tanning at the 6-month follow-up compared with those in the Melanoma Family Healthy Lifestyle Facebook condition.

Secondary Aim 1

One secondary aim is to examine the efficacy of the Young Melanoma Family Facebook intervention on survivors' SSE frequency and comprehensiveness and sun protection behaviors. Survivors' behaviors are considered a secondary aim because the vast majority are compliant with CSEs. However, many survivors are not adherent to comprehensive SSE and sun protection behaviors; thus, we will focus on these outcomes.

- Hypothesis: survivor participants in the Young Melanoma Family Facebook intervention will report more frequent and comprehensive SSEs and higher sun protection at the 6-month follow-up compared with those in the Melanoma Family Healthy Lifestyle Facebook intervention condition.

Secondary Aim 2

Another secondary aim is to determine the mechanisms of intervention efficacy for both interventions' impact on FDR and survivor outcomes.

- Hypothesis: based on the Theory of Normative Social Behavior [43] as well as the Preventive Health Model [40-42], we propose that the effects of the Young Melanoma Family Facebook intervention on FDR's CSE, SSE, and sun protection behaviors and on survivors' SSE and sun

XSL•FO
RenderX

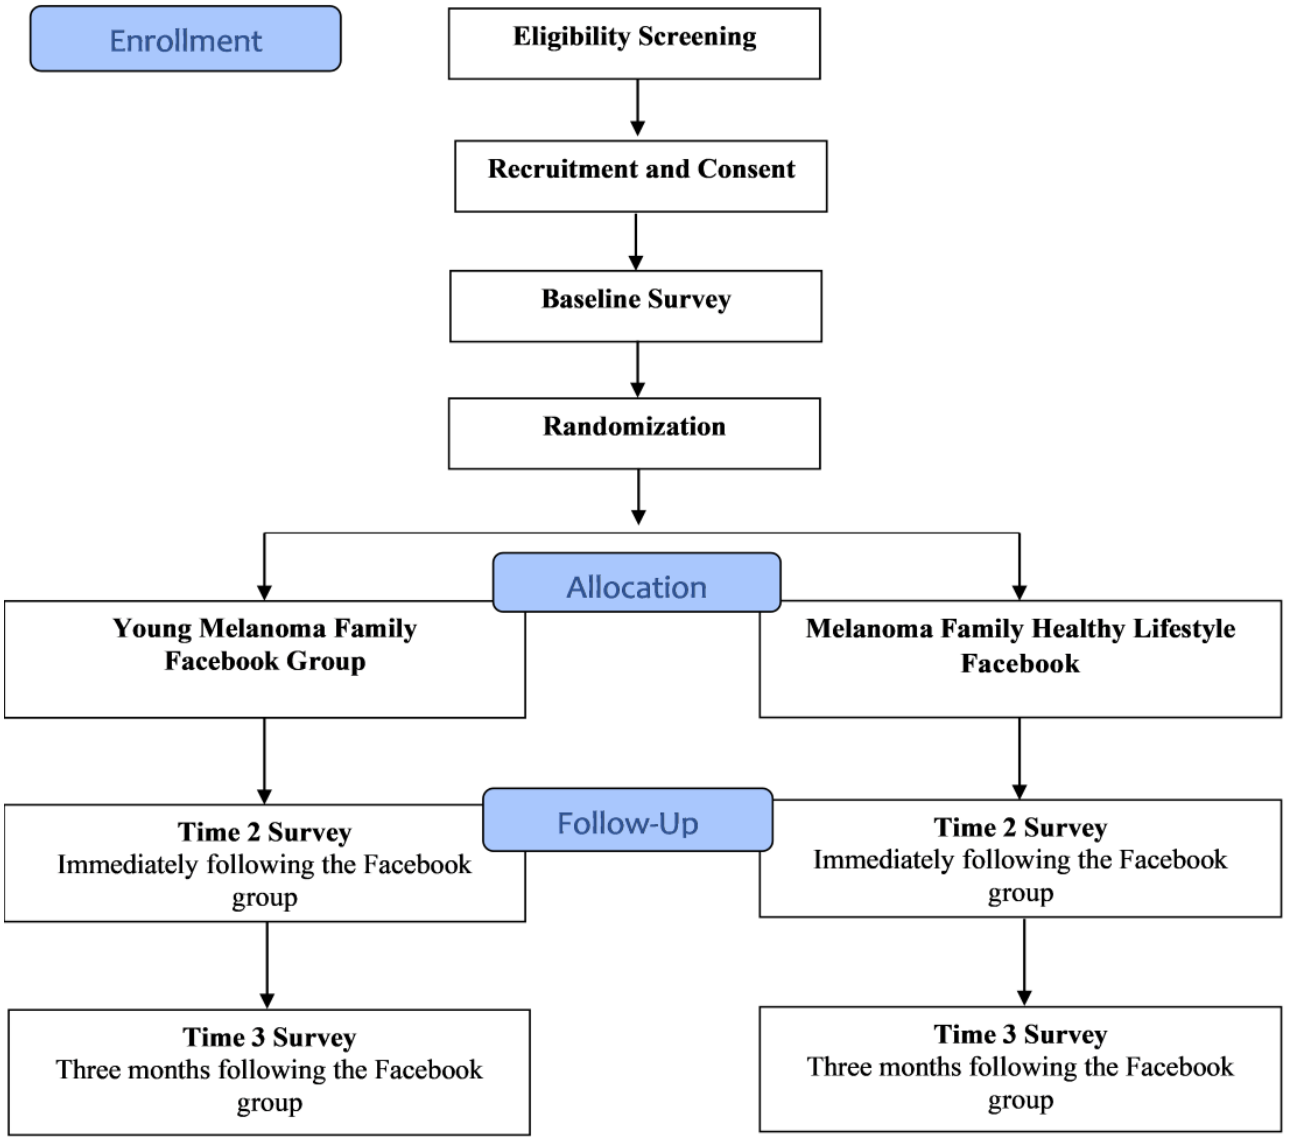
protection will be mediated by increased normative influences, family support and discussion, risk, benefits, barriers, self-efficacy, and use of change strategies.

Exploratory Aim

The exploratory aim is to evaluate the efficacy of the Melanoma Family Healthy Lifestyle Facebook intervention versus Young Melanoma Family Facebook intervention on perceived stress, physical activity, and healthy eating patterns among FDRs and survivors.

- Hypothesis: participants in the Melanoma Family Healthy Lifestyle Facebook intervention will report less stress, more physical activity, and healthier eating patterns at the 6-month follow-up compared with those in the Young Melanoma Family Facebook condition.

Methods



Ethics Approval

Study procedures were approved by the Rutgers University Institutional Review Board (IRB; Pro2019000158).

Design

This is a prospective, randomized controlled trial to evaluate the efficacy of the Young Melanoma Family Facebook intervention to increase engagement in CSE, SSE, and sun protection behaviors among young-onset melanoma survivors and their FDRs. Both the survivor and at least 1 FDR must consent and complete a baseline survey to be randomized. Eligible participants are randomly assigned to either the Young Melanoma Family Facebook intervention group or the Healthy Lifestyle Facebook intervention group and are asked to complete assessments at 3 time points: baseline, immediate postgroup intervention, and 3-month postgroup intervention. Members of the same family are assigned to the same condition. Figure 1 illustrates the overall design and participant flow of the study.

Figure 1. Participant flow.

XSL•FO
RenderX

Participants

Participants include melanoma survivors who have completed treatment within the last 5 years and their FDRs. We define treatment completion as the date of the last cancer treatment (eg, surgery). Spouses of survivors are considered eligible for the trial if 1 FDR consented to the study and if the survivor nominated their spouse for the study. This accommodation is created because of the family nature of this study. Spousal data are not included in the analyses.

Recruitment

We use 2 different methods to recruit participants**:** state cancer registries and cancer centers. Survivors are recruited from the state cancer registries across the United States. Registry recruitment methods vary according to state laws. For some state registries, the registry confirms eligibility, approaches patients, and provides contact information to the main study site or sends contact information to the main study site. For other state registries, the registry identifies cases meeting the diagnosis time frame and current age and sends the list to the main site for recruitment. Eligible survivors are sent an electronic link to the informed consent. Once eligible, survivors provide the names, emails, and phone numbers of their parents, children aged >18 years, and full siblings. FDRs are contacted by telephone, and eligibility is confirmed. If eligible, FDRs are invited to participate. If interested, the electronic link to the consent and survey are provided by email. For both survivors and FDRs, calls are made 4 evenings per week and on weekends to ensure participants are reached. Up to 10 attempts are made to contact prospective participants by phone before they are deemed unable to locate.

To confirm eligibility before enrollment, the staff administer a series of screening questions to interested participants (Textbox 1). During eligibility screening, all survivors are asked to verify their date of birth, date of cancer diagnosis, internet access, and Facebook account status. All FDRs are asked to confirm their date of birth, internet access, and Facebook account status.

Textbox 1. Study eligibility.

- Survivor
  - Inclusion
    - Diagnosed with stage 0-3 melanoma in the last 5 years
    - Age at diagnosis 18-39 years
    - Completed treatment at least 3 months previously
    - At least 1 family member consents
  - Exclusion
    - Concurrent cancer diagnosis
    - Cannot speak and read English
    - Does not have access to computer, internet, and has a Facebook account
    - Physical Activity Readiness Questionnaire [47]: this is a 7-item scale that used as a disclaimer to identify individuals who should consult a physician for medical clearance (if they mark yes to any of the 7 items) before engaging in physical activity in the event they are in the control group.
- First-degree relative
  - Inclusion
    - Current age 18-80 years
    - First-degree relative of survivor
    - Survivor consents to the study
    - Has only 1 first-degree relative with melanoma (survivor)
    - Has not had a clinical skin exam in the past 3 years, has done SSE fewer than 3 times in the past year, OR has a sun protection habits average score ≤4 (“often”)
  - Exclusion
    - Does not have a personal history of melanoma
    - Cannot speak and read English
    - Does not have access to computer, internet, and has a Facebook account
    - Physical Activity Readiness Questionnaire [47]: this is a 7-item scale that used as a disclaimer to identify individuals who should consult a physician for medical clearance before engaging in physical activity in the event they are in the control group.

XSL•FO
RenderX

Consent, Enrollment, Randomization, and Follow-up Survey Procedures

Once the prospective participant's eligibility is confirmed, informed consent is obtained using an electronic consent form hosted on DatStat. Participants are informed of the study requirements, the potential risks and benefits of study participation, and a breakdown of study compensation. After obtaining informed consent and baseline surveys, participants are assigned a study ID number. Both the survivor and at least 1 FDR must consent and complete a baseline survey to be randomized. Thus, randomization occurs only after both the survivor and 1 FDR complete these tasks. Participants are randomized to either the Young Melanoma Family Facebook Group or the Melanoma Family Healthy Lifestyle Facebook Group. The randomization scheme was developed by the study statistician. Clusters of participants (survivor + FDRs) are randomly assigned to conditions in blocks of 50 FDRs to achieve our target group size of approximately 25 survivors and 25 FDRs assigned to each group (Young Melanoma and Healthy Lifestyle). Members of the same family are assigned to the same condition. If additional FDRs join the study, they are assigned to the same condition. The team's project coordinator allocates participants to their randomized condition and notifies them of the study assignment via email.

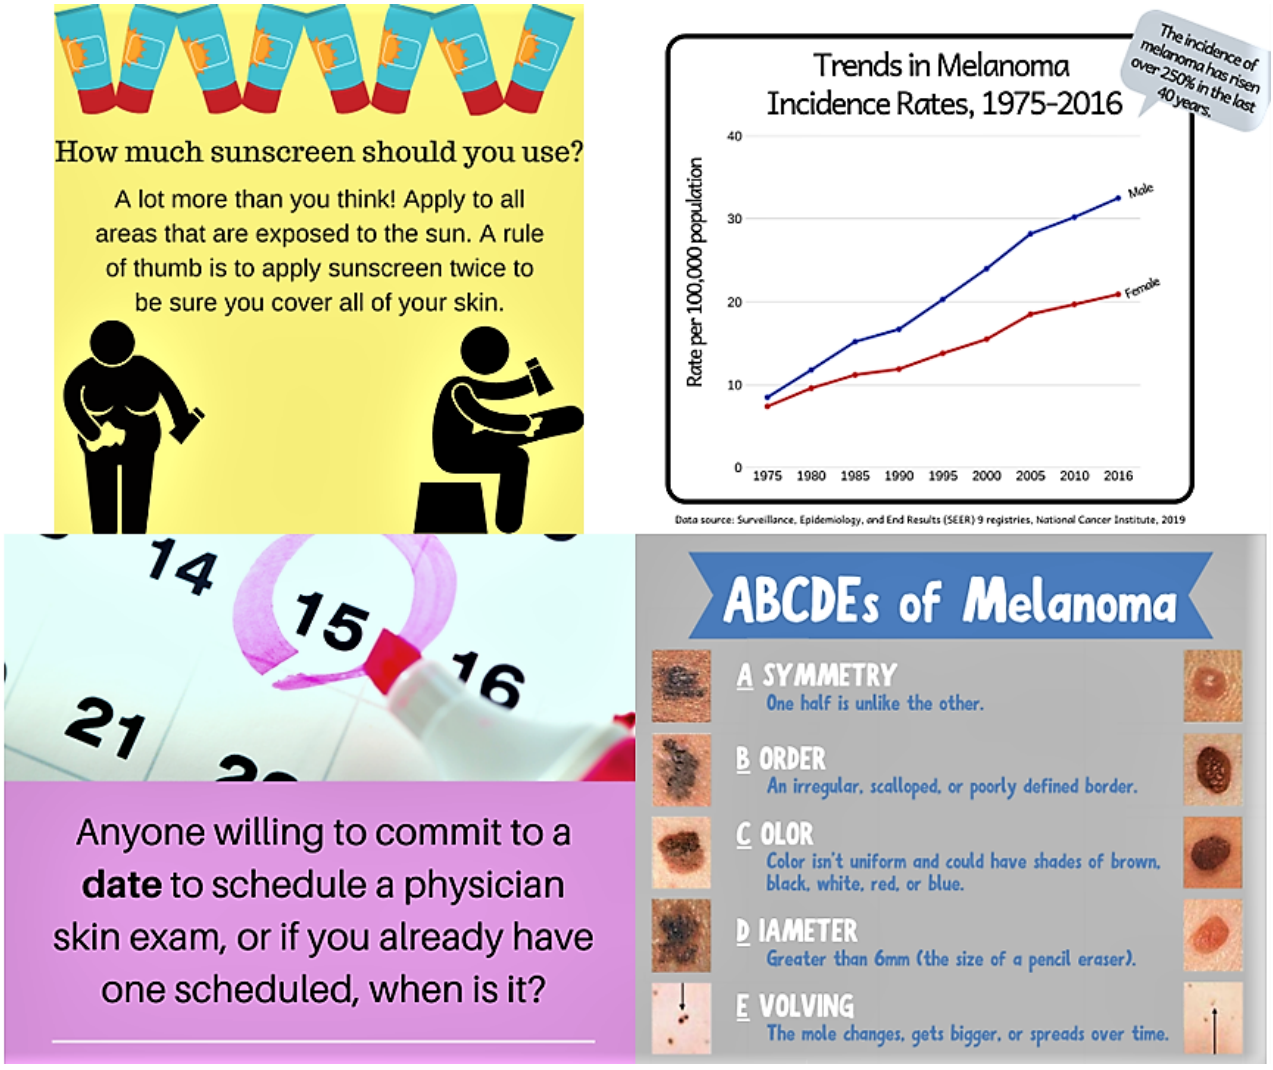
Upon family randomization, participants are provided with the Facebook name of the intervention account that they have been randomly assigned to and asked to "friend" that respective account. Once participants "friend" the Facebook group account, the staff member posts a link into the intervention Facebook group account that participants use to authorize the Grytics software to capture their engagement data [48]. When a participant clicks the opt-in button, it redirects the participant to their own Facebook settings and provides more details about the information the app will be collecting (Facebook name, profile picture, posts, comments, and reactions). The participants have the option to indicate which of their Facebook groups the Grytics software can see by clicking "choose what you allow." When the participant accepts the invite, their request to join the group stays in "pending" status until the group administrator approves all members on day 1 of the group. The study staff contact those who do not "friend" the Facebook accounts.

After group completion, the participants are sent a link for the first follow-up survey and intervention evaluation, which is completed on the web. Three months after group completion, the participants are sent a link for the second follow-up survey, which is completed on the web.

Intervention Conditions

Young Melanoma Family Facebook Group

Participants are asked to join a secret Facebook group in which membership and content is only viewable by invited group members. The participants' group membership and activities are not publicly viewable to external Facebook users. The groups run for 12 weeks and contain up to 54 members (25 survivors and their FDRs). Posts are made twice a day for the first 8 weeks of the group, which is the frequency suggested by social media marketers to engage participants without overburdening them [49]. For weeks 9 to 12, a total of 4 to 6 posts are made each week. Each week is organized around one of the following topics: melanoma risk, physician skin examination, skin self-check, and sun protection habits. The first 4 weeks are organized according to the following topics: risk factors, CSE, skin self-check, and sun protection habits. Behavior change strategies such as goal setting and increasing support for CSE, SSE, or sun protection are woven into posts. During weeks 5 to 8, content is expanded for each topic, special topics are addressed, and news and stories about skin cancer are presented. Messages reinforce regular sun protection, CSE, SSE (eg, mole map pictures), and group discussions. The surgical oncologist and content expert on skin cancer (AB) will reply to the "Ask the Expert" postings in the Young Melanoma Family Group for questions that are not already included in the Question and Answer Library (Textbox 2).



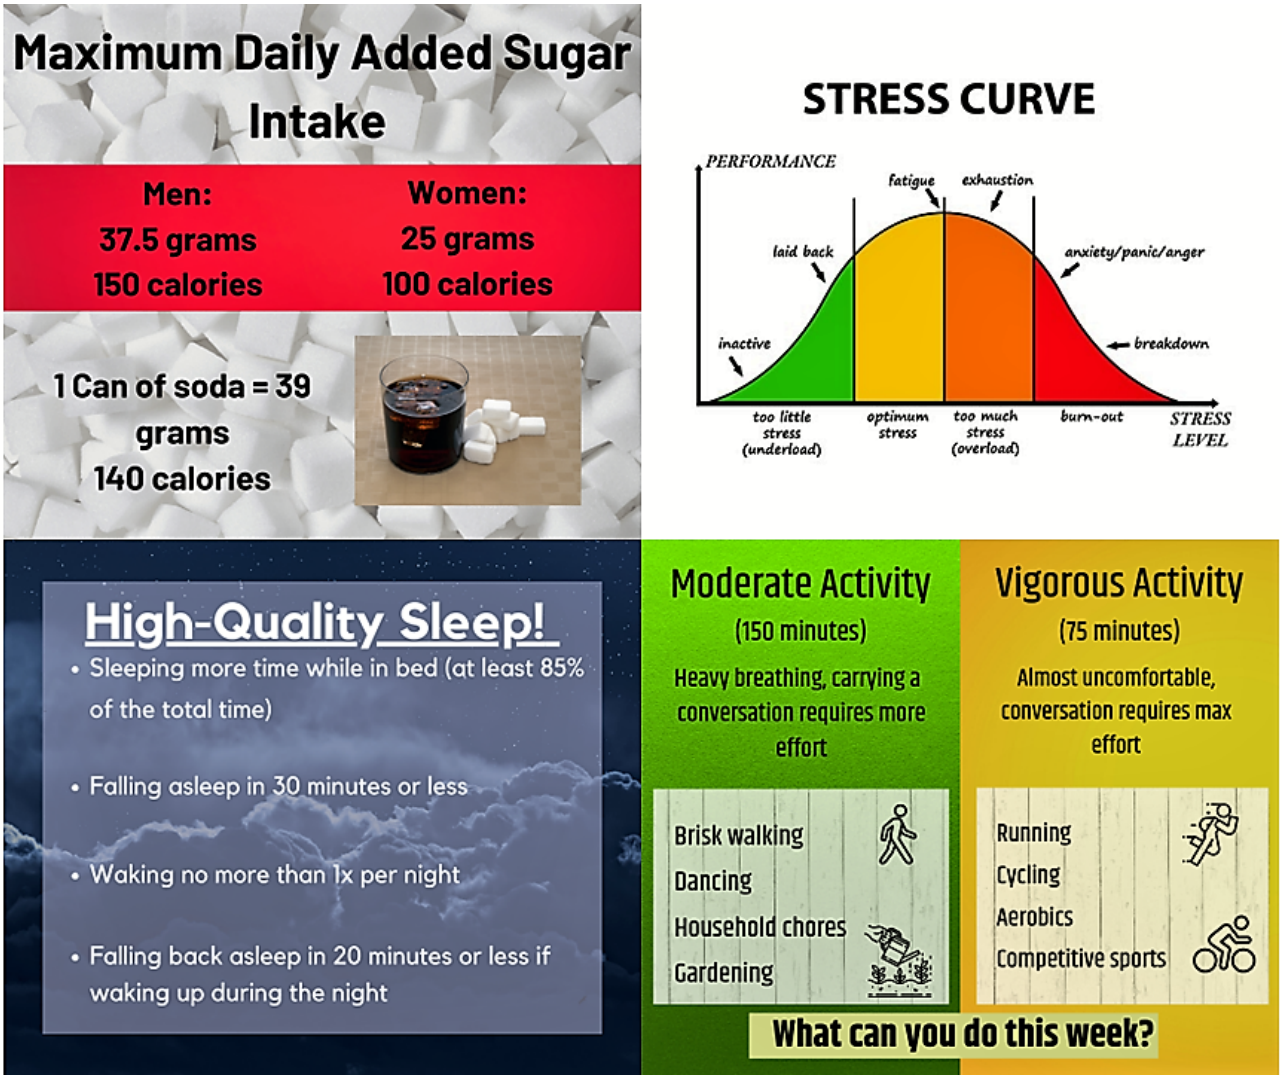
Sample posts are shown in Figure 2. Engagement is enhanced by engaging with humorous pictures, links to educational materials, polls, questions ("What is the ultraviolet light index in your town today?" "What is your favorite brand of sunscreen?"), memes, and holiday greetings. Each group ends at 12 weeks, at which time participants are no longer able to post. However, participants will be able to review the previous 12 weeks of postings.

Textbox 2. Young melanoma Facebook group content.

- Risk: information about elevated risk among relatives, information about skin cancer incidence among young adults, phenotypic risk factors, association between UV light exposure and skin cancer, Fitzpatrick skin type quiz.
- Clinical skin exams: information about clinical skin examination recommendations for persons at higher risk for melanoma, information about what is involved in a clinical skin examination, benefits of having an examination, barriers to having an examination, and opportunities to ask questions to a skin cancer expert.
- Skin self-check: professional recommendations regarding skin self-examination, how to prepare for and perform a skin self-check, how to recognize a suspicious growth, why skin self-examination is important in melanoma risk reduction, how to find a dermatologist, benefits of skin self-examination, barriers to skin self-examination, goal setting for skin self-examination, finding assistance in conducting a skin self-examination, what to do if something suspicious is found.
- Sun protection habits: sun safe behaviors, what sun protection factor means, importance of clothing that covers the body, why wide-brim hats are more protective, common barriers to sun safe behaviors and ways to address barriers.
- General engagement: fun and engaging posts such as holiday memes.

XSL•FO
RenderX

Figure 2. Sample Facebook posts for the Young Melanoma Family Facebook Group.



Melanoma Family Healthy Lifestyle Facebook Group

The procedures for joining the group, Facebook privacy settings, moderation guidelines, frequency of posts, group duration, and access after the group ends are the same as for the Young Melanoma Family Facebook Group. Each week is organized around one of the following topics: nutrition, physical activity, sleep, and stress. Sample posts are shown in Figure 3. Engagement is enhanced by including humorous memes, polls, conversation starters, and seasonal greetings (Textbox 3).

XSL•FO
RenderX

Figure 3. Sample Facebook posts for the Melanoma Family Healthy Lifestyle Facebook Group.

Textbox 3. Melanoma Family Healthy Lifestyle Facebook Group content.

- Nutrition: content focuses on maintaining a healthy diet, benefits of a healthy diet, barriers to maintaining a healthy diet, and ways of improving dietary practices.
- Physical activity: content focuses on recommended levels of physical activity, types of physical activity, benefits of regular physical activity, barriers to achieving recommended levels of physical activity, and ways of improving physical activity levels.
- Sleep: content focuses on recommended number of hours of sleep, symptoms of sleep deficits, common reasons why people do not sleep well, benefits of getting a good night's rest, and strategies to improve sleep habits.
- Stress: content focuses on signs and symptoms of stress, benefits of reducing stress, reasons why people have problems managing stress, and strategies to reduce stress.
- General engagement: content includes fun and engaging posts, such as memes about exercise

Moderator Activities

The moderator logs in 2 to 3 times a day to review the activity and facilitate engagement by "liking" participants' comments and replying with supportive responses. Because Facebook norms are for brief and frequent interactions, moderator responses will be brief, but engage participants in discussions, reinforce engagement (eg, using a "like" reaction), and answer questions. The study collaborator, SP, reviews Facebook activity on a regular basis.

Facebook Group Privacy and Appropriate Behavior in Groups

To ensure the privacy and safety of participants in the Facebook groups, the study team takes the following measures. First, the study's informed consent documentation process includes a description of the privacy settings for Facebook groups. Second, during a phone contact with each participant before the group's initiation, the research staff describes what a "secret" Facebook group means in terms of privacy (eg, group and its contents are not visible to the public), the privacy limitations for a "secret"

XSL•FO
RenderX

Facebook group (eg, cannot guarantee that other participants will not share content posted with others), and the confidentiality rules of the group. Third, if the study team learns that a participant has breached confidentiality in any way, we contact the participant to discuss confidentiality. Any breach in confidentiality is reported as a study adverse event and is reviewed by the study team on a bimonthly basis. In terms of appropriate posts by members, the moderator notifies the principal investigator (PI; SM) if unanticipated, distressing, or inappropriate comments are posted in the Facebook group. The study team will discuss the appropriate response to the issue and will provide guidance to the moderator on how best to proceed.

Enrollment Timeline

Enrollment began in January 2019. Recruitment is ongoing, and we anticipate completing recruitment in November 2023.

Measures and Assessment Periods

Participants complete electronic surveys via DatStat at 3 time points. Each self-report survey takes approximately 30 minutes to complete. The baseline survey is completed between 1 and 2 months before the initiation of a new Facebook group. The second survey is completed immediately after the group ends (approximately 3 months after group initiation). The third survey is completed 3 months after the group ends. To facilitate completion, research staff members reach out to participants who do not return a weekly survey. The data management program, DatStat, is programmed to send 3 reminder emails. Staff members complete a minimum of 1 phone call for incomplete surveys.

Primary and Secondary Outcome Measures

Clinical Skin Examination

The participants are asked about the last time a physician checked any part of their body for early signs of skin cancer (within the last month, 1-6 months ago, 7-12 months ago, >1 year ago, and never). CSE is defined as whether the participant had undergone such an examination in the previous year (yes or no). We expect that close to 100% of survivors will have had a CSE in the past year; thus, analyses of this outcome will focus on FDRs.

A randomly selected subset of 50% of the reported CSEs are confirmed by the physician or facility completing the CSE. The participants are asked to complete an electronic Health Insurance Portability and Accountability Act medical release form to provide the name and contact information of the provider or medical facility to verify the procedure and the date on which it was performed. The study staff member contacts the provider through either email or fax and requests verification of the procedure and the procedure date.

Skin Self-examination

Participants are asked whether they had checked any part of their body for early signs of skin cancer in the last 12 months. Participants who report that they checked their skin at least once indicate the number of times they checked their skin in the last 12 months, the last time they checked their body, and the specific areas that they thoroughly examined during their last skin check. Two outcomes are used: SSE performance in the past year (*yes or no*) and SSE comprehensiveness (the number of body parts [out of 15] checked in the last SSE). Note that because SSE (yes or no) overlaps with the number of body parts such that everyone with a "no" will have 0 body parts, we limit the analysis of the number of body parts to scores ranging from 1 to 15, omitting zeros from the analysis.

Sun Protection Behaviors

Participants rate how often they engaged in 6 behaviors in the last month: stay in the shade, wear a long sleeve shirt, wear long pants or cover legs, wear a wide-brimmed hat, wear sunglasses, and wear sunscreen with a sun protection factor ≥15 (1=*never* to 5=*always*) [50].

Indoor Tanning

Participants rate how many times they engaged in indoor tanning (tanning bed, sun lamp, and tanning booth) in the last 3 months.

Exploratory Outcome Measures

Perceived Stress

The Perceived Stress Scale-4 [51], designed for use in community populations, is a widely used psychological instrument for measuring the perception of stress. It is a measure of the degree to which situations in one's life are appraised as stressful in the previous month ("How often have you felt that difficulties were piling up so high than you could not overcome them?" 1=*never* to 5=*very often*).

Physical Activity

The Godin Leisure-Time Exercise Questionnaire [52] is a 4-item widely used self-report measure for describing patterns of vigorous and moderate physical activity during the last 7 days (eg, "How many days did you do vigorous physical activities like heavy lifting, aerobics, or fast bicycling?" *number of days/week with no vigorous activities*).

Healthy Dietary Practices

Four items assess how many days per week, over the last 7 days, that the participant has consumed fast food (*<1, 1-3, or ≥4*), daily servings of fruits and vegetables (*≥5, 3-4, or ≤2*), daily servings of nondietary soft drinks (*<1, 1-2, or ≥3*), and times per week desserts or other sweets are consumed (*≤1, 2-3, or ≥4*) [53].

Mediator Variables

Perceived Risk for Skin Cancer and Recurrent Melanoma

The perceived risk of melanoma is assessed using 4 items [54]. Sample items are "How would you rate your chances of developing melanoma as compared with other people with a similar family history of melanoma?" (1=*much higher than other people*, 5=*much lower than other people*) and "I may get a skin cancer if I don't protect my skin from the sun" (1=*strongly disagree*, 5=*strongly agree*).

Benefits

Six items assess benefits of engaging in sun protective behaviors (1=*strongly disagree* to 5=*strongly agree*) [55,56]. Nine items

XSL•FO
RenderX

assess the benefits of engaging in CSE [55,57,58]. Ten items assess the benefits of engaging in SSE (1=*strongly disagree* to 5=*strongly agree*) [55,57,58]. An average is computed, and higher scores indicate more benefits.

Barriers

Fifteen items assess common barriers to using sunscreen and wearing sun protective clothing (1=*strongly disagree* to 5=*strongly agree)* [55,56]. Seven items assess common barriers to having a CSE, and 8 items measure common barriers to having an SSE [55,57,58]. The averages are computed for each scale, and higher scores indicate more barriers.

Self-efficacy

Eight items measure confidence in using sunscreen in various settings: 1=*not at all confident*, 5=*very confident* [55,56]. Eight items assess confidence in being able to conduct SSE [57,58].

Family Norms

Perceived attitudes and practices of other family members regarding tanning and sun protection are assessed using 9 items (1=*strongly disagree*, 5=*strongly agree*) [59], perceived attitudes and practices of other family members regarding CSE with 5 items [60], and perceived attitudes and practices of other family members regarding SSE with 6 items [60]. Higher scores indicate stronger norms.

Family Benefits for Engaging in Risk-Reduction Practices

Nine items measure perceived benefits to one's family if the individual engages in risk-reducing practices, as well as benefits for the individual if their family engages in risk-reducing practices. Items were adapted from our prior work on the relationship between the benefits of cancer screening [61] and sun protection [62]. Higher scores indicate more benefits for the family.

Family Discussion

The frequency of discussions regarding sun protection with the participant's sibling, parent, spouse, and children in the past month are reported in 4 items (eg, "How often did you discuss sun protection with your siblings, parents, children, or spouse?" *never*=0, *once*=1, *twice*=2, or *more than two times*=3) [59,61]. A sum of these items will be computed. However, because a participant may not have one or more of these family members (eg, they are not married or they do not have children), the family discussion variable will be computed by dividing the sum score by the number of available family member types. For example, a person with a parent, spouse, and child could have a maximum score of 9 on the sum measure. Therefore, the family discussion variable is computed by dividing the sum by 9 and multiplying by 100 to create a score that could range from 0 to 100. This approach was used in our prior work [63].

Three items assess the frequency of discussions about CSE and 3 items assess the frequency of discussions about SSE with the participant's siblings, parents, and spouses (ie, participants were not asked whether they discuss CSE or SSE with their child; *never*=0, *once*=1, *twice=2*, or *more than two times=3)*. As with sun protection, the family discussion variables for SSE and CSE will be computed by dividing the sum of the frequency of discussions by the number of available family member types to create a score that could range from 0 to 100. A score of 100 indicates that the person has discussed CSE (or SSE) at least 2 times with all available family members. Note that although we know that the person discussed CSE and SSE with at least 1 sibling, for example, we do not know if they discussed it with every sibling they have.

Action Planning

On the basis of prior work [59,64], 4 items were created to assess whether the participant made a detailed plan regarding when, where, and how to engage in sun protection behaviors and what to do if anything interferes. Using 4 items, we ask whether the participant made a detailed plan regarding when, where, and how to have a CSE and what to do if something interferes; 4 items assess whether the participant made a detailed plan regarding when, where, and how to do an SSE and what to do if something interferes (1=*strongly disagree*, 5=*strongly agree*). Higher scores indicate more planning.

Facebook Group Social Network Influence

Overview

Social network analysis (SNA) and content analysis of participant posts, comments, and reactions will be used to understand the mechanisms through which interactions in Facebook groups result in behavior and attitude change. This measures how much participants engaged with each other and whether these peer-to-peer engagements are predictive of the outcomes. Social influence is a function of three contextual factors: (1) traits of members of the reference group, (2) content of Facebook messages, and (3) social network exposure. We use SNA to derive individual, dyadic, and group-level measures to examine the role of the social structural context on normative influence [65-67]. Ties will be measured using the following Facebook data: (1) reactions (likes); (2) comments to member posts and comments; and (3) existing familial relationships. Tie measures will be combined to measure tie strength (0=*no tie*, minimum of 1=*tie*, strength=*sum of all ties across the weeks the group is running*; Textbox 4).

In addition, comments will be content analyzed using a codebook. The codebook will be developed through an iterative process that first started with a literature review to identify common themes that emerge in social media health intervention studies [72-77]. Examples of content-type themes from our review of the literature include "awareness," "support," "promotion," "information seeking," and "support seeking," among others. In addition to content-type themes, we will use themes that characterize content expression. This regards how comments are expressed and include "supportive," "humorous," "evaluative," and sentiment (positive, negative, and neutral affect). More themes will be identified through an initial reading of a randomly selected subset of 200 comments, across the 6 intervention waves. This open reading process will identify recurring themes [78] for an initial codebook. These codes will be applied to another randomly selected subset of 200 comments by a team of 2 trained coders, to establish an acceptable interrater reliability score (Cohen κ of at least 0.70). In

XSL•FO
RenderX

discussions between coders and research team leads, the codebook will be refined by adding any additional emergent themes and merging similar themes into broader categories. This refined codebook will then be applied to a final subset of 200 comments to ensure improved interrater reliability among the team's coders. The coding team will then code the entire data set of comments. Comments could be coded for multiple themes. Each comment will include information on the number of "likes" and comments that it received [74]. The content analysis will be used in two ways: (1) determine theme frequency for each group and (2) codes (presence=1, absence=0) will be aggregated across all comments made by each group member (excluding project team). Thus, we will have summaries of each code for each participant, which will be used, along with network measures, to assess participants' levels of engagement, helpfulness (eg, number of informational comments), supportiveness (eg, number of supportive comments), and any other themes our team deems to be relevant for influence at the codebook development stage.

Textbox 4. Facebook-based social network context measures.

- Individual traits
  - Centrality: assess influence based on network position [68]
  - Survivor vs first-degree relative: as melanoma survivors, Facebook posts about risk or prevention are assumed to be influential
- Message content
  - Posts: information, stance, and sentiment communicating attitude about intervention and participant-posted content [69]
- Social Network exposure
  - Dyadic: ties between group members Feedback: likes and comments that communicate support, agreement, and encouragement [67] Reciprocity: likes and comments in response to feedback [70]
  - Group-level: group structure Subgroups: Subgroup formation based on high frequency interaction and consistent interests [71]

Facebook Engagement

General Use of and Connectedness With Facebook

Facebook use will be measured with 3 items (eg, log-ins per week, membership in private groups, or in public groups). Participants will complete the Facebook Intensity Scale [79], which consists of a 5-item experiential measure of Facebook use separate from behavioral measures of frequency and duration, incorporating emotional connectedness to the site and its integration into individuals' daily activities (eg, "I feel I am part of the Facebook community"). Ratings range from 1=*strongly disagree*, 5=*strongly agree*, and higher scores indicate more connections with Facebook.

Facebook Group Engagement

Facebook data will be extracted to assess behavioral engagement using Grytics extraction software to capture views, likes, and comments on posts. We will calculate descriptive information for each post, group cohort, and individual participant. Participant engagement (ie, reactions, replies, poll votes, and posts) will be analyzed as a predictor of response to treatment in the analyses.

Intervention Evaluation

Participants in both intervention conditions rate 18 items based on helpfulness, value, relevance, and accuracy of the materials posted, as well as aspects of group participation, such as comfort with participation, feeling connected with, actively involved with, enjoying expressing opinions, and reading posts (1=*not at all*, 7=*extremely*).

Covariate Measures

Demographic Information

Participants report their age, sex, race or ethnicity, education level, insurance status (*yes or no*), and whether they see a primary care provider at least once a year (*yes or no*).

Objective Risk Factors

Skin color, natural hair color (higher score: blonde or red hair), eye color (higher score: blue or green eyes), history of sunburns, skin reactivity to the sun (the degree to which the individual burns or tans when exposed to the sun, tanning ability, and depth of tan), freckling, and sensitivity to the sun (very sensitive to very resistant) are assessed.

Medical Factors (Survivor Only)

Data on months since melanoma surgery, stage of disease, and location of cancer are collected from medical charts.

Stakeholder Interviews

To inform future potential dissemination and implementation of the Young Melanoma Family Facebook Group intervention, we will conduct semistructured key informant interviews with three types of stakeholders: (1) 5 providers (cutaneous oncologists, dermatologists); (2) 5 cancer advocacy group leaders (eg, Stupid Cancer); and (3) 30 study participants (survivors and FDRs). Study participants will be purposively selected from the Young Melanoma Family Facebook Group condition, including approximately 15 survivors and 15 FDRs, and representing variation in participation in the intervention and scores on the 18 intervention evaluation items. Interviews (45-60 minutes in length) will be conducted using videoconferencing software and audio recorded with

XSL•FO
RenderX

participant's permission. Interview participants will be compensated US $50.

Interview guides will be tailored to each of the 3 stakeholder types to assess multiple perspectives on the acceptability, feasibility, and appropriateness of the intervention. Providers and cancer advocacy group leaders will be introduced to the intervention at the beginning of their interviews. Interview questions and probes (as appropriate for each stakeholder group) will focus on (1) current approaches and practices to promote CSE, SSE, and sun protection; (2) perceived benefits and shortcomings of the Young Melanoma Family Facebook intervention; (3) actual and potential barriers to its use and delivery; (4) possible dissemination channels [80] to reach survivors and their families (eg, communication modes, provider recommendation, and social marketing); (5) pros and cons of suggested dissemination channels and strategies; (6) the "fit" of the intervention with the preferences of survivors and FDRs and the missions and objectives of providers and organizations [81]; and (7) resources, infrastructure, and other factors needed to implement and sustain the intervention outside of the research context.

Results

Approach to Missing Data

We will use an intent-to-treat approach to the analyses of primary and secondary outcomes. Our approach to recruitment and retention minimizes missing data by contacting participants who do not complete sections of the survey and by incentivizing participation. Initial analyses will examine the characteristics of noncompleters. As recommended by Lang and Little [82], multiple imputations (using 50 imputed samples) will be used to impute missing values (Table 1).

Approach to Data Management

Although survivors are asked specifically to nominate parents or siblings as FDRs, experience indicates that some survivors will nominate spouses who are not FDRs. If this occurs, the spouse's data will be excluded from the analyses. A second complication in this area is when children are nominated. Although children are FDRs, our focus on young-onset melanoma survivors will likely result in a sample of survivors who rarely have children who are old enough to participate in the study. Given the distinct roles played by the different FDRs (ie, parental relationships and influence that likely differ from sibling relationships and influence), children will be included in analyses as FDRs only if they represent at least 5% of the FDRs in the study, so that the differences among parents, siblings, and children can be examined. Finally, after excluding spouses (and possibly children if the sample of children FDRs is small), there may be survivors with no valid FDRs in the study. Those survivors will be removed from analyses.

The treatment of covariates warrants further investigation. Possible covariates include demographic variables, objective

XSL•FO
RenderX

risk variables, and medical variables for the survivor. To determine which covariates should be included in the analyses, preliminary analyses will be conducted in which each outcome is predicted by the full set of qualifying covariates. Only those covariates that significantly predict at least 1 outcome will be included in the analyses. Once the set of covariates is determined in this manner, the same set of covariates will be included in all analyses. Any covariates that are limited in their variation will be excluded from the analyses. Consider race or ethnicity as an example: rates of melanoma are strongly tied to race and ethnicity, with the highest rates for White, non-Hispanic individuals. If the distribution of race or ethnicity in the sample is limited (ie, 90% or more of the sample is White, non-Hispanic), race or ethnicity will not be included in the analyses. In addition to race or ethnicity, we anticipate that insurance status, visits to a primary care provider, and stage at diagnosis for the survivor may also show low variation; if so, they will be excluded from the analyses.

Survivors and FDR ages also present potential problems as covariates. The analysis described in subsequent sections systematically tests whether there are differences in outcomes as a function of role (survivor, parent, or sibling), sex, and their interaction. The interaction tests differences for mothers versus fathers, sisters versus brothers, and male survivors versus female survivors. Participant age will likely correlate strongly with the role variable (ie, parents will be relatively older than siblings and survivors) and, if so, age will not be included as a covariate in analyses to avoid multicollinearity.

Primary Aim, Secondary Aim 1, and Exploratory Aim Analysis Plan

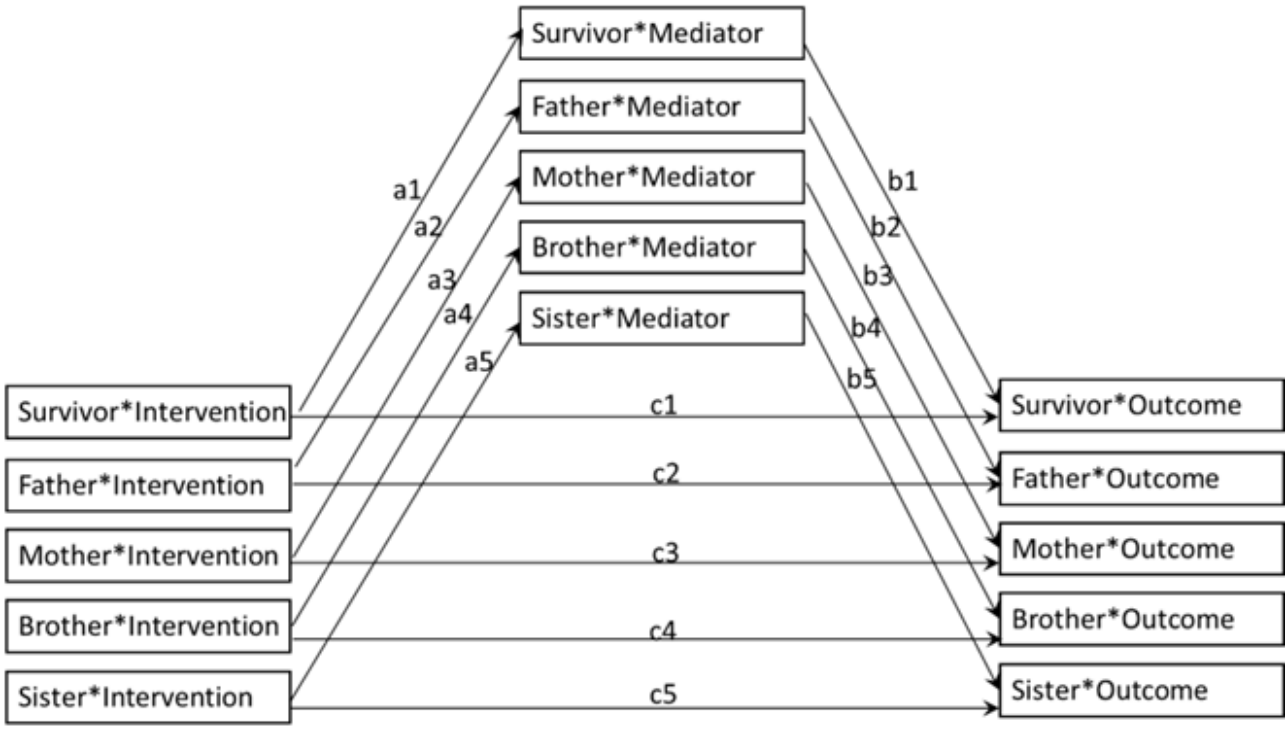
The primary aim is to examine the efficacy of the Young Melanoma Family Facebook intervention on CSE, SSE frequency, comprehensiveness, and sun protection behaviors of FDRs after completion of the intervention, and the first secondary aim is to examine the efficacy of the intervention on *survivors'* SSE frequency and comprehensiveness and sun protection behaviors after completion of the intervention. These 2 aims (*primary aim and secondary aim 1*) will be addressed together using multilevel modeling (MLM) because the data from FDRs and survivors are assumed to be interdependent. The *exploratory aim* of testing whether the intervention is effective in reducing perceived stress and improving other outcomes such as physical activity will also use this approach. MLMs with the following attributes will be used to address the primary aim and secondary aim 1:

- Family is the upper-level sampling unit and individual (FDR or survivor) is the lower-level unit.
- Fixed effects variables include condition (Young Melanoma versus Melanoma Family Healthy Lifestyle Facebook), respondent role (parent, sibling, or survivor), respondent biological sex, all 2- and 3-way interactions, and the set of covariates, including the individual's baseline score on the outcome.
- Random intercepts will model interdependence within families.
- Models predicting dichotomous outcomes (CSE and SSE yes or no, any indoor tanning) will be estimated using binary logistic multilevel models.
- A standard multilevel analysis will be conducted to predict the SSE comprehensiveness of sun protection behavior, perceived stress, physical activity, etc, using the same fixed- and random-effect parameters.
- Exploratory analyses of moderators of intervention efficacy will be conducted using this MLM approach by including each moderator (eg, melanoma risk factors and month of the year enrolled) as an additional fixed effect factor in the model.

Power Calculations

Power analyses were computed assuming a total of 1154 participants (577 survivors and 577 FDRs). Outcomes were assumed to correlate within families with r=0.5. Given those values, the effective sample size taking clustering into account is a total of 773. Using a .05 significance level and 90% power, this sample size is sufficient to detect small effects for CSE (Cohen d>0.12). For SSE, the effect size was an overall increase in SSE in the Young Melanoma Family Facebook condition of 16.1% across FDRs and survivors. Using pretest-posttest pilot data, we found Cohen d=0.14 for sun protection behaviors across FDRs and survivors.

Secondary Aim 2: Analyses



This aim evaluates hypothesized mediators of the expected association between the intervention and outcomes (FDR engagement in CSE, FDR, and survivor engagement in self-examinations and sun protection behaviors). Mediators that are outcome-specific (eg, benefits of engaging in CSE, SSE, and sun protection) include benefits, barriers, family norms, family discussions, and action planning. Mediators that are not outcome-specific include sunscreen self-efficacy and family benefits for risk reduction.

Mediation analyses will assess whether the effects of the intervention on outcomes are mediated by changes in family and normative factors (family discussion, family norms, and family benefits) and individual attitudes (eg, risk, benefits, barriers, self-efficacy, and action planning). MLM will be used to estimate the key mediation paths using 4-component steps [83]. These MLMs will include dummy-coded variables to denote the combination of biological sex and participant role (eg, mother or father). Each of these dummy variables will also interact with the treatment condition, and the overall intercept in this type of simple slope model is suppressed. To assess mediation (Figure 4), these predictors are included in a model that predicts the proposed mediator, and the coefficients from the interaction between the dummy variables and condition estimate the "a" path for each role. To assess the "b" paths, the interactions between the dummy variables and mediator are added to the model, and the outcome (CSE, SSE, or sun protection) is predicted. The contribution of the mediated effect will be assessed directly by using the approach recommended by Kenny et al [84] for multilevel models. Specifically, the product of the 2 pieces of the mediating path (ie, "a*b" from intervention group assignment to mediating variable and from mediating variable to outcome) will be calculated. Bootstrap

XSL•FO
RenderX

procedures will be used to test the significance of the mediating pathway.

Figure 4. Mediation model.

To inform our interpretation of outcomes, we will examine social influence dynamics in both conditions. We conceptualize social influence as a function of three contextual factors: (1) traits of members of reference group; (2) content of messages; and (3) social network exposure. We will use SNA and content analysis of posts to understand the mechanisms through which interaction in Facebook groups results in behavior and attitude change. We use SNA to derive individual, dyadic, and group-level measures to examine the role of social structural context on normative influence. Ties will be measured as (1) reactions (likes); (2) comments to member posts; and (3) existing familial relationships. Tie measures will be combined to measure tie strength (0=no tie, minimum of 1=tie, strength=sum of all ties across the weeks the group is running). Once ties are established, SNA software Ucinet [85,86] will be used to compute network measures. We will derive variables from the content analysis of comments posted to the group that, along with network variables, will assess Facebook group members' influence—both individual members and in terms of broader group dynamics (eg, multiple members expressing consensus on a particular topic). Information, support, stance, and sentiment are some of the content-related characteristics that can drive influence. Other relevant variables may arise through the content analysis, as described earlier.

Secondary Aim 2: Sample Size and Power

Sample size calculations for mediated effects are based on simulation studies that model the 2 pieces of the mediating path (study arm to mediator; mediator to outcome) [87]. Assuming 583 survivors with 22% dropout, there is greater than 80% power to detect paths with regression coefficients of 0.33 (small-to-moderate effects) [88]. Assuming 577 FDRs with 22% dropout, there is 80% power to detect paths with regression coefficients between 0.20 and 0.23 (small effect sizes). With smaller intraclass coefficients, the effective size could be closer to 0.20.

Qualitative Analyses of Stakeholder Interviews

The audio recordings of key informant interviews will be transcribed verbatim. Transcript data and notes will be imported into ATLAS.ti software to facilitate analysis. Both deductive and inductive coding processes will be used [89]. Deductive directed content analysis will allow specification of constructs of interest a priori for coding (eg, acceptability, feasibility, appropriateness, and barriers), whereas an inductive coding process will allow development of additional codes identified through immersion in the transcripts. All qualitative coding procedures will follow rigorous procedures to ensure consistency and a close connection among the data and identified codes and categories [90] (eg, independent initial code development by multiple qualitatively trained research staff, iterative refinement of the codebook based on team meetings to review codes and resolve discrepancies, 6 randomly selected transcripts double-coded with the final codebook). Once coding is complete, the team will develop a summative grid of themes across and within stakeholder groups (providers, cancer advocacy group leaders, and survivors and FDRs), yielding multiperspective insights into multilevel dissemination and implementation strategies needed for future scale-up, dissemination, and implementation. Reporting of qualitative results will follow the Consolidated Criteria for Reporting Qualitative Research [91].

Data Safety and Monitoring

An adverse event in this study is defined as follows: (1) a participant dying between baseline and follow-up (not a

XSL•FO
RenderX

study-related adverse event), (2) a participant reporting distress associated with study participation or (3) if the participant has breached confidentiality in the Facebook group (eg, sharing a group member's post that contains their name outside of the Facebook group). Participants reporting distress will be contacted by the site's PI. During this telephone contact, the causes and degree of distress will be discussed. If the site PI feels there is a need for referral of the participant for psychological intervention, they will identify providers near the participant and provide the referral information. Participants breaching confidentiality will be contacted to let them know that they cannot share posts outside of the group. All adverse events will be documented by the study staff and reviewed on a monthly basis by the study PI and the project coordinator and reported to the safety officer. The IRB and Rutgers Cancer Institute of New Jersey's Protocol Monitoring Committee reviews all adverse events. The National Institutes of Health and Rutgers IRB will be notified immediately in the event of serious adverse reactions or any unanticipated (not mentioned in the consent form) occurrence of physical or psychological harm or unexpected threat to privacy (eg, lost records) or safety of the participants.

Discussion

Principal Findings

Once the analyses are completed, we anticipate that FDR participants in the Young Melanoma Family Facebook intervention will report more CSE, more frequent and comprehensive SSEs, and more sun protection behaviors at the 6-month follow-up compared with those in the Melanoma Family Healthy Lifestyle Facebook condition. We also predict that survivor participants in the Young Melanoma Family Facebook intervention will report more frequent and comprehensive SSEs and higher sun protection at the 6-month follow-up compared with survivor participants in the Melanoma Family Healthy Lifestyle Facebook intervention condition. Indoor tanning is an exploratory outcome, and we propose that participants in the Young Melanoma Family Facebook intervention will report lower engagement in indoor tanning at the 6-month follow-up than participants in the Healthy Lifestyle Facebook intervention.

In terms of moderators and mediators, we expect that younger participants, those who engage more in the intervention and are heavier Facebook users will respond more favorably to the Young Melanoma Family Facebook condition. We expect that the effects of the Young Melanoma Family Facebook intervention on FDR's CSE, SSE, and sun protection behaviors and on survivors' SSE and sun protection will be mediated family support and discussion, risk, benefits, barriers, self-efficacy, use of change strategies, and by increased normative influences. The latter will be measured through variables derived from the SNA (eg, social network variables like centrality, reciprocity, and subgroup formation) and from the content analysis (eg, member comment informativeness, supportiveness, and sentiment). Finally, we expect that participants (FDRs and survivors) in the Melanoma Family Healthy Lifestyle Facebook intervention will report less stress, more physical activity, and more healthy eating patterns at the 6-month follow-up compared with those in the Young Melanoma Family Facebook condition.

Limitations

The results of this trial will be evaluated in the context of its limitations. For example, there are challenges with the Facebook delivery platform, recruitment of family members of survivors, and reliance on self-report measures of SSE and sun protection. First, Facebook posts tend to be brief, which may not be conducive for explaining complex concepts. Although videos can be used to explain complex concepts, many Facebook users may not be able to view lengthy videos. Furthermore, some group members may not engage in the group (eg, "lurk") or view all posts. Studies of Facebook interventions have shown that total group engagement tends to decline over time [65]. We leverage a number of strategies to enhance engagement, including use of polls, conversation starters, and Questions and Answers with experts in Facebook posts. Future studies may need to include only regular Facebook users. Second, recruiting a sufficiently large number of participants to populate multifamily groups of 50 to 60 family members within a relatively short period can be challenging. Timely enrollment is important when enrolling a cohort of 100 participants to randomize them into 2 groups. Finally, self-report sun protection measures show moderate correspondence with behavioral observations and diaries [92,93] and have moderate to high reproducibility and internal consistency [94-96].

Strengths and Significance

Despite these limitations, this is the first randomized controlled trial to evaluate a Facebook family group intervention to improve surveillance and prevention for young melanoma survivors and their family members, an understudied at-risk population who are not adherent to risk-reduction recommendations. The use of SNA will offer insights into the normative influences in Facebook family groups. SNA, which is the study of the pattern of ties between social actors, allows for more than a simple count of the number of individuals in a person's social network or the level of support that the individual receives from the network. SNA goes further to examine the social structures that emerge from the pattern of ties, and social network theory proposes that, through social influence processes, these network structures act as mechanisms that promote the adoption of health-related behaviors. We advance the science of social media–delivered interventions by examining the mechanisms by which the social networks that developed over the course of the Facebook intervention influence change. Although there is compelling evidence that behavior appears to "spread" through social networks, few studies (primarily in the laboratory setting) [97,98] have examined mechanisms by which this occurs. This knowledge will provide critical insights for improving the design of the next generation of web-based behavioral interventions. Finally, the use of key informant interviews with providers, cancer advocacy group leaders, and survivors and FDRs will elicit multiperspective, multilevel data regarding the acceptability, feasibility, appropriateness, and barriers to delivery and engagement in the Young Melanoma Family Facebook. From a "designing for dissemination"

XSL•FO
RenderX

perspective [99], these qualitative findings will be essential in understanding the potential for and strategies needed to support widespread scale-up, dissemination, implementation, and maintenance of the intervention outside the research context, if it is found to be efficacious.

Future Directions

The impact of this trial lies in its implementation and dissemination potential in a variety of contexts given the use of a familiar, popular, freely available social media platform. We will produce a content library of posts and a user guide that can guide implementation by others. If efficacious, the intervention could be disseminated and delivered via dermatologist practices, public health organizations such as the American Cancer Society, nonprofit organizations focused on melanoma, or in partnership with existing melanoma and skin cancer Facebook groups. The ability to interact with a skin cancer expert and other families affected by melanoma synchronously and asynchronously on Facebook may not only be convenient, but it may also be interesting to participants and may lead to a more impactful intervention. Knowledge gained will provide important information about potentially cost-effective ways to reach survivors and their families. If efficacious, future research should evaluate potential implementation strategies to reach young survivors and their family members with social media interventions.

Abstract

Background: A magnetic resonance imaging (MRI) procedure can cause preprocedural and periprocedural anxiety in children. Psychosocial interventions are used to prepare children for the procedure to alleviate anxiety, but these interventions are time-consuming and costly, limiting their clinical use. Virtual reality (VR) is a promising way to overcome these limitations in the preparation of children before an MRI scan.

Objective: The objective of this study is (1) to develop a VR smartphone intervention to prepare children at home for an MRI procedure; and (2) to examine the effect of the VR intervention in a randomized controlled trial, in which the VR intervention will be compared to care as usual (CAU). CAU involves an information letter about an MRI examination. The primary outcome is the child's procedural anxiety during the MRI procedure. Secondary outcomes include preprocedural anxiety and parental anxiety. We hypothesize that the VR preparation will result in a higher reduction of the periprocedural anxiety of both parents and children as compared to CAU.

Methods: The VR intervention provides a highly realistic and child-friendly representation of an MRI environment. In this randomized controlled trial, 128 children (aged 6 to 14 years) undergoing an MRI scan will be randomly allocated to the VR intervention or CAU. Children in the VR intervention will receive a log-in code for the VR app and are sent cardboard VR glasses.

Results: The VR smartphone preparation app was developed in 2020. The recruitment of participants is expected to be completed in December 2022. Data will be analyzed, and scientific papers will be submitted for publication in 2023.

Conclusions: The VR smartphone app is expected to significantly reduce pre- and periprocedural anxiety in pediatric patients undergoing an MRI scan. The VR app offers a realistic and child-friendly experience that can contribute to modern care. A smartphone version of the VR app has the advantage that children, and potentially their parents, can get habituated to the VR environment and noises in their own home environment and can do this VR MRI preparation as often and as long as needed.

Introduction

Magnetic Resonance Imaging (MRI) is a commonly used imaging technique that provides detailed images without the use of ionizing radiation. Research has shown that pediatric patients can experience a range of negative emotions during this procedure [1]. There are several components within an MRI procedure that can induce anxiety such as the loud noises generated during an MRI scan and the prolonged time spent in a confined space [2]. Although there is little research on how children experience an MRI scan, one study found that about 50% of children between aged 5 to 12 years with nonacute medical conditions experienced anxiety and discomfort during an MRI scan [3]. Younger children can be overwhelmed by the MRI environment with noises they have never heard before and by the MRI machine, whereas older children can experience claustrophobic feelings [4]. This can result in poor cooperation, eg, following breathing instructions or excessive movements, which has a negative effect on the scan quality since up to 90% of the MRI artifacts can be attributed to movement [5]. To combat MRI-related anxiety and discomfort, children are often sedated or completely anesthetized up to the age of 6 years [6,7]. The use of general anesthesia is not without risks. Pediatric patients can experience side effects such as emerging delirium, respiratory depression, nausea, vomiting, agitation, and cardiovascular bradycardia [8-11]. Different methods have been implemented to reduce the need for anesthesia and pre- and periprocedural anxiety, such as behavioral rehearsal using mock MRI scans [12], play therapy [13], and distraction during the procedure using MRI-compatible audiovisual tools [14]. The use of these interventions has been found to be effective but are time-consuming and often rely on the guidance by a professional [2].

To alleviate MRI-related anxiety, virtual reality (VR) offers a promising alternative to prepare children for the procedure. VR is a way to experience computer-generated scenarios that can be used to create experiences similar to or completely different from reality. With audiovisual stimulation, the user can interact with the virtual environment [15]. Research has shown that VR can positively affect self-reported pain and anxiety during several medical procedures [16]. Most VR studies focused on distracting patients during a medical procedure. Exposure, however, is one of the most effective interventions to reduce anxiety, and only a few studies investigated the impact of VR exposure before a medical procedure [17-20].

To our knowledge, there has been little research into the effectiveness of VR as preparation for an MRI in a clinical setting. In a cross-sectional study of 23 pediatric patients by Ashmore and colleagues [21], the VR preparation was highly rated on enjoyment, helpfulness, and ease of use. They also showed that for some pediatric patients, VR preparation helped them to undergo an MRI scan without general sedation. In an exploratory study, Nakarada-Kordic and colleagues [22] compared the feeling of being inside an MRI scanner in VR versus being in a mock MRI scanner in a sample of 20 adult participants. The authors did not find a significant difference between the experience of VR MRI and mock MRI scans, and 86% of the participants reported that the VR simulation could be a helpful way to prepare for a real MRI exam. Stunden and colleagues [19] studied VR exposure based on a 360-degree movie versus a standard preparatory manual and a hospital-based Child Life Program on anxiety in a simulated MRI scan in 92 children aged 4-13 years but could not demonstrate a difference between the 3 groups. While this study failed to find a significant effect of VR exposure on procedural anxiety, it did have several drawbacks. They used a simulated MRI scan instead of an actual clinical MRI scan to test intervention effectivity. This may have limited the emotional response generated. Finally, the use of 360-degree recorded images instead of rendered 3D graphics may have limited immersion, which could be an important mediator of intervention effectivity as shown in VR-based pain distraction [23].

VR preparation of pediatric patients for medical procedures is often done with a head-mounted displays tethered to a powerful computer within the hospital setting. A disadvantage of this approach is that it requires a trained professional to do the VR preparation and that the time a child can be prepared is often limited. An alternative is to deploy the VR preparation to a smartphone, head-mounted by means of a Google cardboard. With a smartphone VR app, children can get prepared in their own home environment under parental supervision at their own pace and as often and as long as they need. Another advantage of a smartphone VR app is that it can be employed on a large scale and requires limited involvement of health professionals, ultimately saving costs associated with the traditional VR goggles tethered to a powerful computer. Moreover, costs associated with a Google cardboard are negligible compared with computer-tethered or dedicated head-mounted VR displays.

The objective of this study is (1) to develop a realistic VR smartphone app to prepare children for an MRI scan, using an immersive, interactive VR approach with a fully rendered environment; and (2) to present a methodological approach to conduct a randomized controlled trial (RCT) that can test the effectiveness of the VR intervention in children who need to undergo an MRI scan. The clinical effect of the VR smartphone app will be compared with routine clinical care (care as usual [CAU]). The primary outcome is periprocedural anxiety. Secondary outcomes include preprocedural anxiety, user experience, child behavioral and emotional problems, and parental anxiety. We hypothesize that the VR preparation will result in a larger reduction of the periprocedural anxiety of both parents and children as compared to CAU. We further hypothesize that VR preparation will lead to a larger reduction in parental anxiety and preprocedural child anxiety as compared to CAU.

Methods

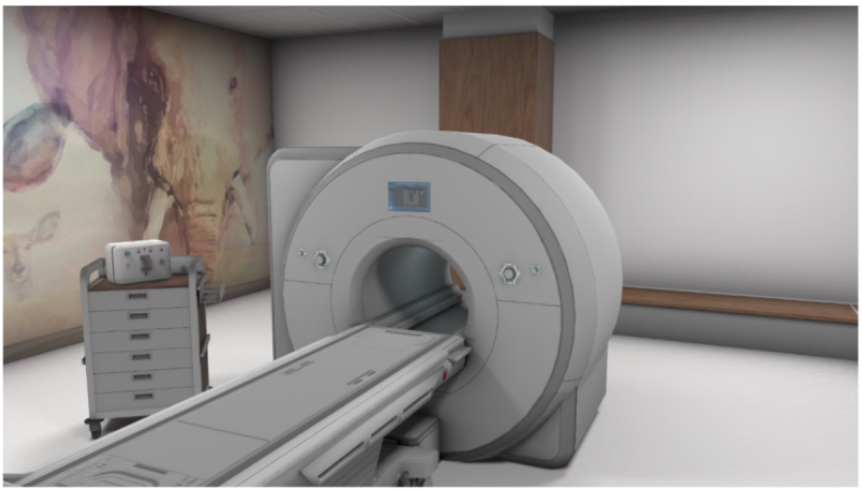
VR Design

The VR tool encompasses a highly realistic virtual environment that replicates the MRI experience of the Erasmus University Medical Center (MC)–Sophia Children's Hospital, Rotterdam, the Netherlands. The designed virtual MRI environment does not significantly differ from that of the Amsterdam University Medical Centers (UMC).

A multidisciplinary team, consisting of child-life specialists, child psychologists, a child psychiatrist, anesthesiologists, a 3D-acting director, and a 3D project manager designed the script of the VR experience. Working together with specialized VR developers and animators, multiple 3D characters, asset, and environment artists created the scenery and character modeling. During the design and development phases, team meetings were held to review the process and make any necessary adjustments. Overall, the main goal was to create a dynamic and interactive environment that will prepare children for the MRI procedure in a realistic and child-friendly manner. Once the VR software was created, it was pilot-tested in healthy children (n=10). Based on the observations and responses of the pilot test, final adjustments were made.

Technical Specifications

Software and Hardware Details



The 3D software in the VR smartphone app was developed using the Unity games engine, a cross-platform game engine developed by Unity Technologies. The app is designed to be used in a Google cardboard–like VR goggle, meaning a VR goggle relying on the use of a smartphone for its VR capabilities. The cardboard includes adjustable lenses and head straps—this makes the cardboard suitable for children. The software is usable on iPhone 5s or above or Android smartphones with operating system 4.4 or above. Participants can download the app in the Apple App Store or Google Play Store.

VR Storyline

The duration of the VR MRI smartphone intervention is approximately 5 minutes. The VR app takes place in a typical MRI room as seen in Figure 1 (and Multimedia Appendix 1), with an explanation given to a child by MRI technicians depicted on a monitor in the virtual MRI room. This design has been chosen to maximize the ease of program portability between different hospital settings and even between different languages by making it easy to switch out the supporting video with a localized alternative.

Participant can choose between 2 versions: one version for an upper body MRI and another version for a lower body MRI. The MRI experience starts with a technician that is visible on a screen on the wall of the MRI room. The technician introduces herself and explains that the participant is in the MRI room, what an MRI scan is, and that it makes a lot of noise but is not painful. She also explains that no metals are allowed in the MRI environment and that participants are not allowed to wear jewelry during the actual MRI examination. After this initial explanation, the participant is allowed to move around the virtual MRI room. The MRI room and machines are visible in 360 degrees and can be seen if the participant moves with his head. The participant can move around the MRI machine by looking at marked focus points (feet symbol) on the floor of the MRI room. When the participant is located behind the MRI machine, the technician explains that the MRI bore is open from the front to the back. When the participant is back at the starting position in the front of the MRI machine, the technician explains that some children like their parents to be present during the MRI, that they will get earplugs because of the MRI noise, and that it is important that they lie still within the MRI machine. After that, the participant can look at a focus point on the ceiling above the table of the MRI machine and is then transferred to this location. Subsequently, the participant is slowly transferred within the bore of the MRI machine. Depending on the version of the MRI machine, the participant is transferred within the bore of the MRI machine headfirst (upper body MRI) or feetfirst (lower body MRI). A scan with the duration of 1 minute is performed accompanied by varying MRI noises. When the scan is completed, the VR experience is finished, and the app returns to the home screen.

RenderX

Study Design

This multicenter, single-blinded, RCT is being performed at the Erasmus MC–Sophia by the Departments of Child and Adolescent Psychiatry/Psychology, Radiology, and Pediatric Anesthesiology and at the Amsterdam UMC–Emma Children's Hospital by the Department of Radiology. Children (N=128) will be randomly allocated to 2 parallel groups: VR smartphone application (n=64) or CAU (n=64). CAU involves an information letter given to the parents that consists of information about the MRI examination, the screening questionnaire that is used, and how to best explain the MRI exam to their child. Randomization will be performed as block randomization with a 1:1 allocation.

Ethics Approval

The study was approved by the medical ethical committees of the Erasmus MC (NL68075.078.19) and Amsterdam UMC (MEC-2019-0242).

Inclusion and Exclusion Criteria

Eligible participants are children aged between 6 and 14 years undergoing an MRI scan at the Erasmus MC–Sophia Children's Hospital or the Amsterdam UMC–Emma Children's Hospital (2 specialized children's university hospitals in the Netherlands) in the period between May 2021 and December 2022. Children that meet the following criteria will be excluded from participating: any intellectual disability, inability of parents to read or write in the Dutch language, epilepsy, visual impairments, and the need of general anesthesia during the scan.

Sample Size

To conduct analysis of covariance (ANCOVA) on the level of periprocedural anxiety at time point (T) 3 (primary outcome) with a Cohen *d* of 0.5, an α of .05 (2-tailed), and a power of .80, a sample size of 128 patients is needed (64 patients per group). Based on earlier studies, we anticipate finding a medium effect size [16].

Randomization

Participants will be randomly allocated to the intervention (VR) or control group (CAU) with a 1:1 allocation. A computer-generated randomization schedule will be used, stratified by age group (aged 6-10 vs 10-14 years) and the type of MRI (upper body vs lower body).

Patient Recruitment and Procedure

For the prospective recruitment of patients, in concert with the radiologist, the planned MRIs will be scanned a month ahead for eligible patients. They will be informed about the study by mail or phone. If needed, they will be reminded by phone in the following weeks. Besides the reminder, this will help to overcome doubts, because the staff can answer questions or motivate the patients to participate.

All participants will receive an invitation, information folders, and an informed consent form. Participation is not obligatory, and all data will be anonymized. Parents of all the patients will be asked to sign informed consent. Children aged 12-14 years will also be asked to provide informed assent themselves. Patients aged younger than 12 years will give their verbal permission.

After receiving signed informed consent, the participants will be stratified by the type of MRI scan (head or body scan). Then, they will be randomly assigned to the VR group (n=64) or the CAU group (n=64).

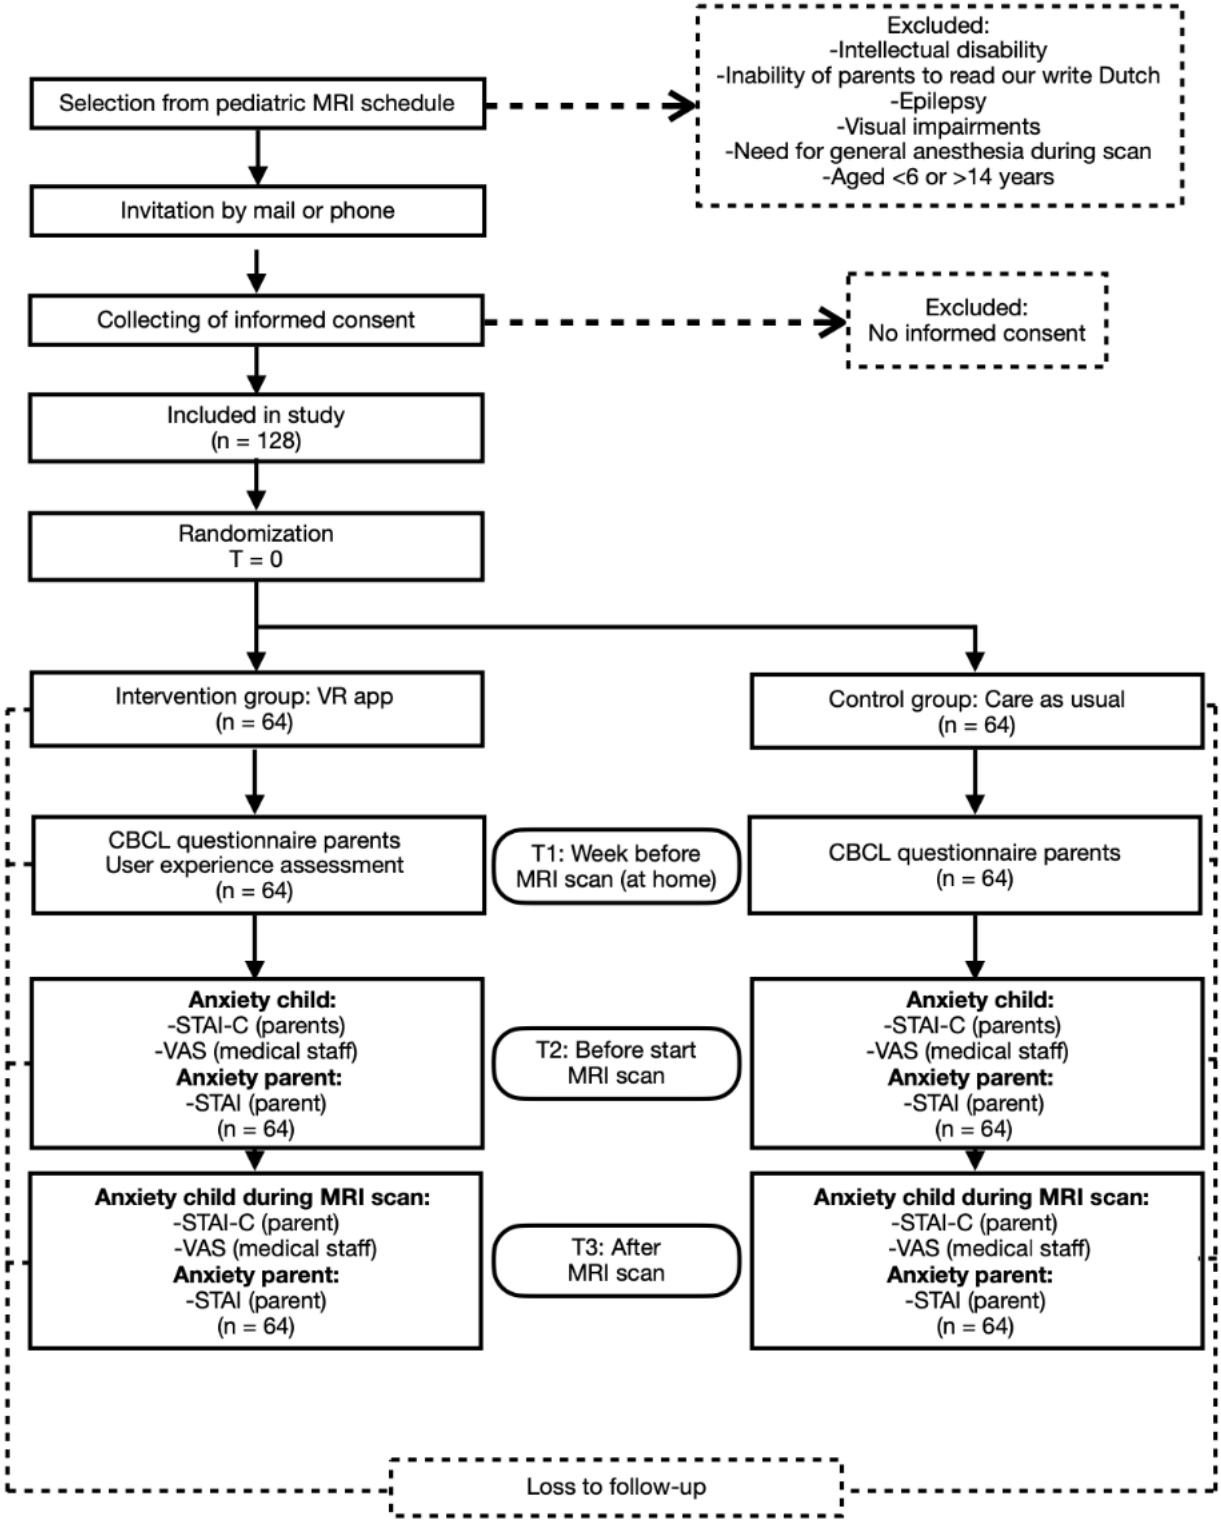
The children assigned to the VR group will receive Google cardboard–like VR glasses and instructions on how to download the VR app on their phone and use the VR intervention at home. They will receive a log-in code to use the smartphone VR app. Adherence will be promoted by giving the participants detailed information about the purpose of the study and how to use the VR preparation app and explaining how they can get help from the contact support staff if there are difficulties with the app or VR glasses.

The allocation sequence was executed by a researcher who is not involved in the assessment phase. The psychologist who assesses the child's anxiety state is blinded to the group assignment. This way, blinding for the treatment allocation will be guaranteed. Parents and children in both groups will be asked not to discuss their treatment allocation with the nurse, radiologist, or research psychologist.

Questionnaires will be assessed at the following time points: (1) T1, the weeks before the MRI scan (at home); (2) T2, the day of the MRI scan, before the procedure will start (in the waiting room); and (3) T3, right after the MRI scan (in the waiting room). The T3 questionnaires will retrospectively assess the child's experience during the MRI scan. In this way, we can measure the anxiety during the MRI scan without the interruption of the procedure.

The children assigned to the CAU group will receive an information letter in which child-friendly information is provided about the VR examination.

Participant Withdrawal



Participants can withdraw from the study for any reason at any time if they wish to do so, without any consequences. The investigator can decide to withdraw a participant from the study for urgent medical reasons.

Outcome Measures

The study design and variables at each time point are presented in Figure 2. The primary outcome is periprocedural anxiety at T3 (State-Trait Anxiety Inventory for Children [STAI-C] and Visual Analog Scale [VAS]). Secondary outcomes include preprocedural anxiety (VAS and STAI-C), user experience, child behavioral and emotional problems (Child Behavioral Checklist [CBCL]), and parental anxiety (State-Trait Anxiety Inventory [STAI]).

XSL•FO
RenderX

Figure 2. Flow chart of the study design with the instruments at each time point. CBCL: Child Behavioral Checklist; MRI: magnetic resonance imaging; STAI: State-Trait Anxiety Inventory; STAI-C: State-Trait Anxiety Inventory for Children; T: time point; VAS: Visual Analog Scale; VR: virtual reality.

Background Variables

The following background variables will be collected: age, gender, and socioeconomic status (SES). Age and gender will be collected from the electronic record. SES will be based on a child's postal code.

Child Anxiety

The anxiety level of participants is measured before and after the MRI scan (T2 and T3) with the STAI-C, a questionnaire where parents and children evaluate statements on a scale from 0 (not at all) to 4 (completely true). The STAI-C is a widely used and validated self-report instrument for measuring state and trait anxiety [24]. The STAI-C has a good-to-excellent interobserver and intraobserver reliability and was validated in

XSL•FO
RenderX

Dutch [25]. The VAS will be used to assess the child's anxiety level by the child himself, the parents, and the medical staff. The VAS shows 6 faces in order from not scared at all (most left face) to extremely scared (most right face; see Figure 3) [26]. The participants select the expression that fits their feeling before and after the MRI scan (T2 and T3). Because of the nonverbal character and the simplicity, this instrument offers a quick and reliable assessment that can be used in different settings [27,28]. The VAS is a widely used and studied instrument, has been shown to have a good reliability and validity, and is validated in Dutch [29]. The medical staff who accompanied the child were instructed to observe the anxiety of the child before the procedure in the MRI room and during the MRI scan (T2 and T3) by using the VAS [30].

Figure 3. The Visual Analogue Scale (VAS) with faces from not anxious (most left) to extremely anxious (most right).

Child Behavior Problems

In the weeks before the MRI scan (T1), the parents/guardians complete the CBCL to examine behavioral or emotional problems in the last 6 months. The version used for children between the age of 6-18 years consists of 113 items, has been proven valid and reliable, and is validated in Dutch [31]. The respondent evaluates each item as not true (0), a bit/sometimes (1), or obviously/often (2). An internalizing problem and externalizing problem scale can be calculated.

Parental Anxiety

Parents/guardians rate their own feelings of anxiety with the STAI at T2 and T3. This self-report instrument contains 2 separate scales for trait and anxiety, combined into 40 items that the respondent rates as not at all (0), somewhat (1), moderately (2), or very much (3). Earlier studies identified the STAI as a validated and reliable instrument to measure the anxiety state of the parents, and it is validated in Dutch [24,32].

User Experience

Children will provide subjective assessments of the VR MRI app using a 0-100 graphic rating scale at T1. They are asked (1) to rate the amount of "fun" they had during the VR preparation (no fun to most fun); (2) to what extent they felt nausea as a result of experiencing the virtual world (no nausea to severe nausea/vomiting [VR condition only]); (3) how real the objects in the virtual world seemed ("completely fake" to "indistinguishable from a real object" [VR condition only]); and (4) to what extent they felt like they went into the virtual world while experiencing VR ("I did not feel like I went into the virtual world at all" to "I went completely into the virtual world" [VR condition only]). Adherence will also be addressed in the user experience questionnaire by asking children and parents how often and how long they used the VR preparation app.

Monitoring and Harms

Monitoring of the study will be done by the Erasmus MC and will take place once a year. During the monitoring, the following will be monitored: (1) study documents and agreements; (2) patient inflow, consent, compliance, and source document verification; (3) patient safety; (4) the investigational intervention (VR); and (5) the study procedures.

The risk associated with the VR intervention is negligible and the burden should be considered minimal.

Protocol Amendments

Modification to the protocol, which may impact on the conduct of the study and potential benefit of the patient or may affect patient safety, will require a formal amendment to the medical ethical committee of the Erasmus MC.

Confidentiality

The handling of patient data will comply with the General Data Protection Regulation. All study data will be handled confidentially and coded with a unique study number. Only the research team involved in the study will be able to identify participants and have access to the data.

Statistical Analysis

Overview

The primary analysis will be conducted using an intention-to-treat basis. All patients recruited into the study will be included in this analysis. Patients will be analyzed within the group to which they were randomized, irrespective of what care they received. Regarding missing data, first, it will be analyzed if missing data/loss to follow-up reflects information bias or selection bias. Second, multiple imputation will be used to control for bias due to missing data.

Primary Study Parameter(s)

To test the efficacy of the VR intervention, we will compare the VR group to the CAU group with an ANCOVA. The primary outcome variable is the child's situational anxiety during MRI scan (T3; VAS child, continuous score), corrected for age, sex, baseline anxiety, and CBCL scores as well as type of MRI. In case of nonnormality, we will perform a Mann-Whitney *U* test.

Secondary Study Parameter(s)

The main secondary outcomes are child preprocedural anxiety at T2 and parental anxiety both before and during the procedure.

For the child's preprocedural anxiety, we will employ an identical analysis as for the primary end point. For parental anxiety, a repeated measures ANCOVA will be conducted with parental anxiety at T2 and T3 as within variable and group (VR vs CAU) as between variables. The analysis will be corrected

XSL•FO
RenderX

for age, sex, baseline anxiety, and CBCL scores as well as type of MRI.

To identify medical or psychosocial moderators for treatment response to VR, we will perform exploratory linear regression analyses with child anxiety at T2 and T3. Predictor variables that will be examined are SES, age, sex, type of MRI, preprocedural child and preprocedural parental anxiety, and child emotional and behavioral problems. The user experience of children in the VR condition will be examined with descriptive analyses.

Results

The final version of the VR app has been approved. The recruitment of participants started in May 2021 and is currently ongoing and expected to be completed in December 2022. Data will be analyzed, and scientific papers will be submitted for publication in 2023.

Discussion

Expected Findings

Children often experience an MRI scan as an anxiety-provoking situation, and therefore, it is urgently needed that effective psychological preparations that are easy to use and cost-effective are developed and offered. VR has the potential to become a promising tool in the psychological preparation of pediatric patients for MRI. VR exposure has already been shown to be effective as a treatment for specific phobias in children. However, despite the fast-growing field of VR in medical care, there has been little research into the effectiveness of VR as preparation for an MRI scan in a clinical setting. Since VR is a promising tool for improvement in health outcomes, high-quality studies investigating innovative VR interventions are needed. Here, we describe the development of a smartphone-based VR intervention to prepare children for MRI scanning as well as an RCT to test its efficacy.

Strengths and Limitations

This study design has both strengths and limitations. A strength of this study is the RCT design and the multiple informant assessment of anxiety in children before and during the MRI scan. Most of the current preparation materials for children undergoing an MRI scan involve verbal explanation. The use of VR combines verbal explanation with visual information that can be beneficial for younger children or children who do not speak or understand the language. Additionally, the use of mobile phone–based VR creates the possibility to prepare children in their own time, at their own pace, and in the comfort of their own home. It also alleviates the personnel and space demands imposed by mock-scanner preparation. Due to the use of a smartphone-based VR experience that can be used at home, we can reduce the costs associated with using a tethered VR experience. The app presents a typical MRI room and thus can be used in any hospital without adjustments. Moreover, the app is designed to be easily localized to other languages. Furthermore, due to the use of 3D models instead of 360-degree video recordings, adjustments and adding or subtracting certain elements can be easily and cheaply done.

A limitation is that although we ask participants in the user experience questionnaire how often and for how long they have used the VR preparation app, we do not have more accurate measures of VR use. In addition, as the VR intervention is designed to be used at home in an environment that is comfortable for a child, we do not have information if the children used the VR MRI app with enough attention. The smartphone used by each child varies greatly in screen quality, size, and processing power. These differences might influence the VR experience, its image quality, and ultimately, the immersivity of the VR. Another limitation is that only children who do not need general anesthesia during the MRI scan are included, thereby potentially excluding the most highly anxious children. This may limit the generalizability of this study to children with less severe levels of anxiety. If this study shows that the VR MRI preparation app is efficacious, it would be important to study whether VR preparation can also reduce the need for anesthesia.

Conclusion

Most children experience anxiety before and during an MRI scan. To reduce this and reduce the need of anesthesia, there is a need to develop a more effective preparation method. VR offers a child-friendly and realistic environment where children can experience the procedure, without the use of real machines or medical staff. To examine the effect of this VR intervention, an RCT will be performed. If VR exposure is proven to be effective for preparation for an MRI scan, this easy-to-use tool can be implemented into standard medical care. We would like to emphasize though that even with the use of modern technology, education provided by health care professionals for both pediatric patients and their parents is still necessary, especially for older children.

Acknowledgments

We thank Marly Koursarou for her help with the virtual reality magnetic resonance imaging app development. We also thank the Friends of Sophia Foundation and the Coolsingel Foundation for their financial support of this study.

This study was funded by the Friends of the Sophia Children's Hospital Foundation (Wytemaweg 80, 3015 CN, Rotterdam, the Netherlands). The funder had no role in the design of this study and will not have any role in the execution, analyses, interpretation of the data, or decision to submit results.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during the current study.

Abstract

Background: Eating disorders (EDs) affect 9% of the United States population, and anorexia nervosa (AN), specifically, has the second highest mortality rate of all psychiatric disorders. Yet, only 20% are able to access treatment. Access to care issues include long waitlists, lack of trained specialists, financial, and geographic barriers, all of which highlight the need for effective telehealth interventions. Family-based therapy (FBT) is a first-line treatment for adolescents and young adults with EDs, and weight gain early in treatment is considered a primary predictor of success with FBT. However, nutrition requirements for patients with EDs are uniquely complex. A variety of dietary interventions for guiding the renourishment process are used in practice, but empirical data on the effectiveness and acceptability of the various interventions are sparse. The significance of nutritional restoration and issues with access to first-line treatments underscore the need for further research exploring virtually delivered dietary interventions.

Objective: Our objective is to compare the effectiveness and acceptability of 2 digitally delivered dietary interventions frequently used in eating disorder treatment settings: (1) calorie-based meal plans and (2) the Plate-by-Plate approach. Specifically, we will explore any potential differences in weight restoration achieved over 8 weeks of treatment as a primary measure of effectiveness, as well as additional treatment outcomes (ED symptoms, anxiety, depression, caregiver burden, and perceived effectiveness and acceptability for both caregivers and clinicians).

Methods: Patients (N=100) with either AN or avoidant restrictive food intake disorders (ARFID) aged 6-24 years seeking treatment at a nationwide virtual eating disorder treatment program, were enrolled between May and August 2022. Upon admission, patients were randomly assigned to receive either the calorie-based intervention or Plate-by-Plate approach from their registered dietitian, all of whom have received training as study interventionists. While we were primarily interested in responses during the first 8 weeks of treatment, patients will be followed for up to 12 months. Descriptive statistics were used to describe patient characteristics and demographics. Weight changes and other treatment outcomes between groups will be compared using generalized linear models. Semistructured caregiver and clinician interview transcripts will undergo qualitative analysis.

Results: Enrollment ran from March to August 2022, and we anticipate completion of data collection by November 2022. Analyses will be completed in January 2023.

Conclusions: This study contributes to existing FBT literature by thoroughly exploring the acceptability of dietary interventions and their influence on weight restoration, an area in which research is sparse.

Introduction

Background

Eating disorders (EDs) are serious mental illnesses characterized by how one experiences a marked disturbance in weight and shape [1], afflicting people across all ages, genders, races, ethnicities, and body sizes. National prevalence estimates are 9%, and EDs have the second highest mortality rate (specifically anorexia nervosa [AN]) following opioid addiction [2]. The economic burden is also substantial, with an annual cost of US $64.7 billion [3]. Further, the COVID-19 pandemic has resulted in a staggering increase in new ED cases, as well as exacerbation of ED symptoms and decreased motivation for recovery for those with preexisting EDs [4,5]. The rise in demand and challenges with access to care were compounded by long waitlists, lack of trained specialists, financial and geographic barriers, and underscored need for improving access to effective ED treatments [6].

Telemedicine or digitally delivered ED treatment options offer an opportunity to meet the rising demand while addressing geographic barriers and providing patients with timely access to trained specialists and reduce barriers associated with accessing care. Telemedicine ED treatments have been on the rise primarily as a result of the COVID-19 pandemic, and recent research supports their effectiveness and comparability to in-person care [7-11]. Family-based treatment (FBT) is an approach through which caregivers are tasked with renourishing their child at home while given guidance by a team of specialists. FBT is a first-line treatment for adolescents and young adults with AN and shows promise as an effective modality for other ED subtypes as well [12,13]. Recent research supports the efficacy of digitally delivered FBT as outcomes rival those of in-person treatment options [14-16]. Nutritional restoration is a central treatment element across all ED subtypes, and weight gain in the first several weeks of FBT is considered a primary predictor of remission [17,18]. However, nutrition requirements for patients with EDs are uniquely complex and varied, with kilocalorie needs reaching 70-100 kcal per kg per day, and caregivers generally require ongoing support to successfully navigate home-based refeeding. The importance of nutritional restoration for remission highlights the need for a better understanding of the dietary interventions most commonly used in ED treatment settings. While the inclusion of the registered dietitian (RD) on multidisciplinary teams is standard in other ED treatment settings and modalities aside from FBT, historically, FBT was led by a family therapist who was also responsible for giving guidance around feeding. In recent years, the need for specialized nutrition support has become more apparent, and the presence of RD is more commonplace. The RD can skillfully address issues that arise in treatment (management of malnutrition, refeeding syndrome, weight plateaus, erroneous belief systems around food and weight, lack of diversity in food choices, and needs adjustments for patients return to sport) that may be unaddressed by therapists, but are vital for achieving remission [19,20]. Additionally, the RD assists by giving guidance on optimization of energy density, determination of goal weight range, alleviation or management of physical symptoms that arise secondary to refeeding, and identification of nutrients of concern, which is of particular importance for patients with avoidant restrictive food intake disorder (ARFID) [21]. However, a variety of dietary interventions are used in practice across the ED field, and the evidence comparing effectiveness of dietary approaches, in person or digitally delivered, is sparse.

Dietary Interventions

An overview of the interventions most commonly used in practice when treating ED patients are as follows: 1. Daily Calorie Target: caregivers or patients are provided a daily kilocalorie goal, and generally, the number of meals and snacks will also be prescribed, each with an associated kilocalorie goal. Provision of a daily calorie goal and discussions of calories in foods are generally discouraged in settings, where dietary interventions are patient-facing, as doing so may exacerbate ED thoughts and behaviors. Calorie targets may, however, be provided to caregivers as a means of guiding home-based refeeding efforts.

2. Plate-by-Plate approach: the Plate-by-Plate is a visual approach with primary intent for use in FBT, whereby caregivers are instructed to serve “normal” portions or plates versus using calories to guide meal or snack planning (Multimedia Appendix 1). This approach is regarded as a more flexible and intuitive, as calorie counting and measuring are discouraged. For patients requiring weight restoration, caregivers are instructed to create a plate consisting of 50% starch, 25% protein, and 25% vegetables and fruits, with dairy and fat servings specified by the RD for the meals. Key features of this approach include primary caregivers making the decision around what and how much to serve, with an emphasis on dietary variety and exposure to all foods. These features are thought to be important as they uphold parental empowerment, a core tenet of FBT [22].

3. Exchange system: this approach is most widely used in residential and partial hospitalization programs, where guidance is given directly to the patient [22]. The exchange system was developed by the American Diabetes Association as a way to categorize foods into 6 groups, and each “exchange” in a given food group is associated with a particular macronutrient range [23]. For example, 1 dairy exchange can be 1 oz of cheese or 8 oz milk. A number or range of exchanges are assigned to each meal and snack, thereby encouraging the patient to consider balance and dietary variety. The exchange system is seldom used in FBT given the different needs of caregivers versus patients.

This feasibility study will compare the acceptability of 2 digitally delivered dietary interventions and preliminary effectiveness in early stages of treatment: (1) calorie-based meal plans and (2) the Plate-by-Plate approach [24]. Our primary outcome of interest is weight restoration achieved after 8 weeks

XSL•FO
RenderX

of treatment, as this is the best predictor of remission. We will also examine the following treatment outcomes by intervention: ED symptoms, anxiety, depression, caregiver burden and self-efficacy, and caregiver's acceptability and perception of effectiveness. Acceptability and perceived effectiveness will also be measured for clinicians once week 8 outcomes have been captured for all participants. While we are most interested in early treatment response, patients will be followed and clinical outcomes for patients and caregivers reported throughout the entirety of their treatment course as part of standard practice. We anticipate that the findings from this study will help us better understand the needs and experiences of caregivers undergoing FBT and ultimately, whether 1 approach is superior in terms of influence on treatment outcomes. We will also gain insight around commonly held assumptions, such as the running hypothesis that providing caregivers with a calorie target may undermine parental empowerment and self-efficacy. This study will add to existing FBT literature by exploring the impact of dietary interventions that guide caregivers' process for renourishing their child, for which there is currently no research.

Methods

Participants

We will examine the aspects of treatment outcome in patients aged 6-24 years self-selecting for web-based ED treatment at Equip Health. The inclusion criteria are as follows: (1) aged 6-24 years, (2) ED diagnosis of AN or ARFID, (3) consented to participate in treatment approach comparison research upon admission, (4) apparent need for weight restoration upon admission, (5) first time recipients of treatment at Equip Health, and (6) assigned to RD interventionist.

Setting

This single-site study takes place at Equip Health. Equip Health provides web-based ED treatment to children and adolescents ages 6-24 years across the United States using an FBT approach.

Ethical Considerations

This study was reviewed by the Biomedical Research Alliance of New York (BRANY) institutional review board (protocol number 22-016-1096), and it was determined that it does not meet the criteria for human subject's research as this is a quality improvement study of Equip Health treatment. Thus, institutional review board oversight was not required. Patients or caregivers consented to participate in treatment approach comparison studies upon admission and consented for treatment information to be evaluated and disseminated. Data will be stored in Equip's Health Insurance Portability and Accountability Act–compliant medical record platform and will be deidentified upon extraction by trained research personnel. Interviews with the RD interventionists will be conducted via a Health Insurance Portability and Accountability Act–compliant Zoom platform. The final study results will be reported in aggregate, and will not contain any personally identifiable information.

Recruitment

Patients seeking treatment at Equip inquire through Equip's web-based form through direct email or phone. We randomized 100 eligible patients who enrolled in ED treatment on a rolling basis from May through August 2022.

Group Assignment

As part of standard of care at Equip Health, all patients receiving FBT are assigned an RD as part of their multidisciplinary treatment team. Upon admission, patients eligible for this study and who consented to be a part of treatment comparison studies at Equip will be randomly assigned using a block design to receive either the calorie-based approach or the Plate-by-Plate approach during renourishment treatment with the RD. Participating patients were randomized for the purpose of having an equal number of participants in each treatment group. All other treatment procedures followed the standard of care for all Equip patients.

Assessments and Measures

Overview

Outcome measures are described below and summarized in Table 1. Additionally, the following demographic data will be extracted from the medical record: age, state of residence, biological sex, gender identity, ED diagnosis, and height. Patients will be followed for up to 12 months, and clinical assessment measures are taken throughout treatment as part of standard practice. However, our primary time point of interest is week 8 of treatment, as this will provide important information about the patient's response in the early phases of treatment, a critical time period for predicting remission.

XSL•FO
RenderX

Table 1. Primary and secondary outcome measures.

Measure	Outcome	Frequency assessed and timepoints of interest
Primary outcome		
Weight	Weight change	Twice weekly (baseline, week 8)
Secondary outcomes		
Eating Disorder Examination Questionnaire Short Form	Global total score, Eating concern scale score, Weight concern scale score, and Shape concern scale score	Upon admission, weekly thereafter (baseline and week 8)
Burden Assessment Scale	Caregiver burnout	Every 40 days (baseline and week 8)
Parent versus Eating Disorders	Caregiver self-efficacy	Day 14, every 40 days thereafter (baseline and week 8)
Patient Health Questionnaire	Symptoms of depression	Upon admission, monthly thereafter (baseline and week 8)
Generalized Anxiety Disorder Scale	Symptoms of anxiety	Upon admission, monthly thereafter (baseline and week 8)
Clinician semistructured interview	Acceptability and perceived effectiveness of intervention	End of study
Caregiver semistructured interview	Acceptability and perceived effectiveness of intervention	Treatment week 8 (approximate)

Weight

Upon admission, caregivers receive instructions from their assigned Equip medical provider on proper procedure for checking weight. Weights are taken in the morning, after voiding, prior to any oral intake and patients are asked to wear light clothing. The patient's weight (in pounds) is taken twice weekly by caregivers and communicated via text message from caregivers to Equip's Health Insurance Portability and Accountability Act–compliant medical record platform. For each patient, the RD calculates a target weight for weight restoration. Target weight is calculated using expected weight data from each patient's CDC BMI-for-age Growth Charts. Our primary end point of interest is weight change during the first 8 weeks of treatment, which will include an average weekly rate of weight gain and total weight change from admission to treatment week 8.

Eating Disorder Examination Questionnaire Short Form

The Eating Disorder Examination Questionnaire Short Form is an abbreviated 12-item version of the 28-item Eating Disorder Examination Questionnaire survey. The Eating Disorder Examination Questionnaire Short Form is a well-validated and reliable measure, which assesses ED symptom severity. Scores range from 0 to 36, with higher scores suggesting increasing severity of ED behavior [25].

Patient Health Questionnaire

The Patient Health Questionnaire-9 is a brief, well-validated, and reliable diagnostic tool for depression. Patients are asked to rate 9 items pertaining to depression symptoms they have found bothersome over the last 2 weeks from "0" (not at all) to "3" (nearly every day). Higher scores indicate greater levels of depression [26].

Generalized Anxiety Disorder Scale

The Generalized Anxiety Disorder Scale is a widely used, validated, and reliable self-report tool for screening, diagnosing, and assessing the severity of an anxiety disorder. Patients are asked to rate 7 items pertaining to anxiety symptoms, which are scored from 0 to 3, and the score is totaled. Higher scores indicate increasing severity of anxiety [27].

Burden Assessment Scale

The Burden Assessment Scale is a 19-item validated questionnaire that focuses on specific objective and subjective caregiver consequences of individuals with mental illness. Ten items assess objective burden (eg, financial problems) and 9 items assess subjective aspects of burden (eg, feelings and attitudes). Caregivers were asked to indicate the extent to which they experienced the described problem on a 4-point scale, with higher scores indicating greater levels of caregiver burden [28,29].

Parent versus Eating Disorders

Parental self-efficacy will be assessed with the Parent versus Eating Disorders, which was adapted from the Parent Versus Anorexia scale. The Parent versus Eating Disorders was designed to capture caregivers' belief in their ability to overcome their loved one's eating disorder. Seven items are ranked on a 5-point scale with higher scores indicating greater self-efficacy [30].

Caregiver Semistructured Interviews

A semistructured interview (Multimedia Appendix 2) will be completed with caregivers to assess their experience with the assigned renourishment strategy. Caregivers will be contacted directly by a member of the research team via their preferred email address to schedule and the interviews will be conducted via phone. If the caregiver does not respond to contact efforts, a Health Insurance Portability and Accountability Act–compliant

XSL•FO
RenderX

Google Forms link will be provided via preferred email through which the caregiver can answer the interview questions, after which efforts to reach the caregiver will be discontinued.

Clinician Semistructured Interviews

A semistructured interview (Multimedia Appendix 3) with the RD interventionist will also be completed to assess the interventionists' general experience with each approach. Interviews will be completed by a member of the Equip research team and completed remotely via Health Insurance Portability and Accountability Act–compliant Zoom platform.

Statistical Analysis

The treatment outcomes will be collected via our Health Insurance Portability and Accountability Act–compliant medical record platform and will be extracted by trained research personnel. Descriptive statistics will be used to describe patient characteristics and demographics of our patients and treatment outcomes defined in Table 1. To examine any differences in effectiveness between the 2 interventions, we will compare the rate of weight change between the groups using generalized linear models in R version 4.1.1 (R Core Team). We will also look at outcomes across ED subtypes.

Procedures

Upon beginning treatment at Equip Health, eligible patients will be randomly assigned to receive either the calorie-based approach or the Plate-by-Plate intervention within their first 1-2 sessions with their assigned RD. In the first phase of treatment, the RD meets exclusively with caregivers (eg, parents or guardians) at a weekly meeting cadence for the first month, and thereafter in accordance with the RD's judgment.

A high-level summary of each approach is as follows: (1) calorie-based nutrition prescription: following the completion of a nutrition assessment by the RD, caregivers will be prescribed a calorie goal and be instructed to aim to reach that goal daily as a primary focus of treatment. In collaboration with caregivers, a calorie goal will be assigned to 3 meals and 3 snacks daily. For example, the goal may be 3000 kcal per day, comprised of 700 kcal meals 3 times per day, and 300-kcal snacks 3 times per day. Additionally, caregivers are provided 7-day sample menus that align with their calorie prescription. If clinically indicated, they may also receive education on how to increase the caloric density of meals while maintaining low volume. Adjustments will be made throughout the treatment course to calorie prescriptions per RD's judgment to accommodate the weight restoration goal of 2 lbs per week. During the initial session, caregivers are instructed to send photos and density estimates of all foods consumed by the child to the RD, and feedback will be given speaking to the adequacy of calorie content of meals and snacks in the follow-up sessions. (2) Plate-by-Plate approach is summarized for caregivers in the following steps:

1. Choose 10-inch plate
2. Plate all food groups
3. Fill plate
4. Parent decides number of meals or snacks
5. Include variety
6. Does the meal make sense?
7. Final review: Does the plate make sense?

Caregivers are instructed to prompt the patient to complete the plate, and in the case of food refusal, oral supplements are provided to replace the remaining food.

Training and Fidelity

All Equip RDs have experience in treating EDs using a variety of dietary interventions within and outside of the FBT framework. Upon hiring, Equip RDs complete an in-depth video training on various interventions commonly used in ED treatment, including the Plate-by-Plate approach and calorie-based meal plans. RD interventionists undergo a live training session overviewing study protocols and each intervention, and a prerecorded training on the Plate-by-Plate intervention (led by authors of the Plate-by-Plate intervention). Interventionists will receive ongoing training as needed and supervision to ensure adherence to the respective approaches and will additionally be trained to notify research staff of any fidelity issues or protocol deviations by other providers on a treatment team.

Electronic records will be reviewed by study personnel on a weekly basis to ensure adherence to the assigned treatment approach. Specifically, session documentation, chat communications, and any document exchanges will be reviewed. Any fidelity issues (and the subsequent potential need for participant withdrawal) will be discussed by research personnel and interventionists. Further, should a patient discharge prior to week 8 of treatment, or if the RD determines that the assigned intervention is a poor fit for the patient, the patient may be withdrawn.

Results

Demographics

A total of 100 patients (with average age of 15 years) were enrolled on a rolling basis from March through August 2022. Fifty patients were assigned to the Plate-by-Plate group and 50 to the calorie target group. Overall, 83% of participants were cisgender females, 9% were cisgender males, 6% were nonbinary, and 2% were transgender. Furthermore, 66% of participants were diagnosed with AN restricting subtype, 18% with the AN binge-purge subtype, and 16% with ARFID. We anticipate completion of data collection by November 2022 and analysis by January 2023.

Significance

We anticipate that, following completion of this study, we will be able to (1) address common myths, assumptions, and misconceptions associated with each intervention; (2) identify differences in outcomes and emerging themes from interview data, and use findings to adapt interventions and the supporting digital resources; (3) identify a preferred, or "best practice" approach for improving outcomes in the early phase of FBT, as early response is predictive of remission; and (4) understand any potential differences or nuances that may exist by intervention across the 2 ED subtypes (AN and ARFID).

XSL•FO
RenderX

Design Considerations

While a variety of interventions may be used in practice, we selected Plate-by-Plate and calorie-based approaches due to their common use in FBT. Discussions of calories and the use of calorie targets to guide renourishment are generally discouraged in ED treatment settings in an effort to decrease preoccupations with calorie counting. Building upon this hypothesis, Plate-by-Plate authors cite the following rationale for use of a visual approach: (1) informed by a study that found an association between calorie-tracking application use and either maintenance or worsening of ED symptoms [31], authors hypothesized that a visual and simplistic versus numbers-based approach may have a beneficial influence on eating disorder symptoms and would allow for a seamless transition to "normal," independent eating in later stages of treatment and beyond. Further, any calorie counting done by caregivers may "trickle down" to the patient and may thereby reinforce or exacerbate ED symptoms or thoughts. (2) A visual approach offers more flexibility by accommodating dietary restrictions, culturally appropriate food preferences, and easy adaptation for meals and snacks consumed outside of the home. (3) Given the lack of nutritional guidance due to exclusion of RDs in early FBT models, Plate-by-Plate was created to help parents with refeeding efforts using a more specialized approach, while still honoring the "parental empowerment" tenant central to FBT by allowing parents to select foods served.

With this study, we aim to test and challenge these assumptions through direct comparisons with a calorie-based approach. As part of standard practices at Equip Health, digital "food journals" (ie, photos and descriptions of foods) are provided by caregivers for assessment by RDs. In the absence of photos, the calorie-based approach allows parents to share calorie totals, which we suspect offer a more precise estimate of intake, and are less subject to parent interpretations and verbal description of portions or foods served and consumed. A calorie-based target may offer flexibility in "how" needs are met, and, like Plate-by-Plate, honors cultural preferences and dietary restrictions. We will further test the assumption that calorie targets trickle down to the patient, as caregivers are explicitly instructed not to share calorie information with patients, and ED patients have an existing general awareness of calorie content of foods and are able to quickly estimate upon provision of a meal or snack. Further, it is common practice in FBT to encourage parents to prepare and plate foods without the child present to minimize negotiations, resistance, and opportunity for patients to scrutinize components or portions.

Participant Selection

The decision was made to exclude ED subtypes other than AN and ARFID for the following reasons:

1. Need for weight restoration was an important part of the inclusion criteria as weight restoration is typically first priority and a core component of ED treatment. Given that we are less likely to encounter a need for weight restoration in other ED subtypes, and would thus yield a small sample size within those subtypes, we opted to include only patients with AN and those with ARFID, which are the primary presenting subtypes in our patient population. In addition, while caregiver feedback is important, various aspects of FBT can be challenging for caregivers. We felt it important to have an outcome measure (weight) that is most predictive of remission and success with FBT.
2. In addition to there being little research on dietary interventions in the ED space in general, research looking at dietary interventions for ARFID, and particularly for patients undergoing FBT, is especially sparse. Given the differences in symptoms and presentation between patients with ARFID and those with AN, we felt it is important to better understand the benefits and challenges associated with the use of a visual approach. For example, patients with ARFID may present with a very limited number of acceptable foods and the lack of variety may make it challenging for parents to present meals or snacks with multiple components from numerous food groups. It is our hope that the outcome data, coupled with rich insights from clinicians and caregivers, will help us understand which aspects of our interventions may be most appropriate for patients with ARFID, and the ways in which they differ from patients with AN.

Discussion

Strengths and Limitations

To our knowledge, this will be the first comparison of digitally delivered dietary interventions for the treatment of EDs. Given access issues faced by patients seeking ED treatment, and increasing acceptability and use of telehealth, it is of particular value to test interventions in the digital space. Testing assumptions upon which approaches are developed is also valuable as we were able to gain insights that help us tailor approaches that better resonate with caregivers and providers.

It should be noted that the majority of patients who present for ED treatment at Equip have engaged with numerous prior programs and providers, and as such, they may have encountered various dietary approaches. While it was not realistic nor warranted to exclude those with prior treatment histories, we addressed this by instructing RD interventionists to notify study personnel should it prohibitive to orient caregivers to the assigned approach. At that point, a determination will be made as to whether the patient should be withdrawn from the study. Further, although with FBT caregivers are tasked with renourishing their child between ages 6 and 24 years, it is possible that there may be differences in intervention across age ranges, particularly for patient-facing interventions. However, it should be noted that individual (patient) nutrition therapy is provided only in later stages of FBT (generally following several months of nutritional restoration).

Future Work

In this study, we compare 2 digitally delivered dietary interventions most commonly used by dietitians in eating disorder treatment settings and subsequent outcomes. Future research is needed to examine the effectiveness of interventions delivered directly to patients and across the broad range of ED subtypes.

Abstract

Background: In the last decade, alcohol consumption among middle-aged women (40-65 years old) in Australia increased, despite declines in overall population consumption. Web-based, brief interventions are promising for reducing alcohol consumption, with efficacy shown in a wide range of populations. However, no published interventions have been designed specifically for and tested with middle-aged women.

Objective: This study aims to design and implement a web-based intervention intended to reduce alcohol consumption among middle-aged women.

Methods: The study is a 3-arm randomized controlled trial with a web-based intervention plus ecological momentary assessment (EMA) group compared to an EMA-only and a pre-post only control group. The study is aimed at middle-aged women, defined as women aged between 40 and 65 years, who consume alcohol at least weekly or who have consumed 4 or more drinks on 1 occasion in the last month. The intervention aims to reduce alcohol consumption through 4 modules that provide information on the health impacts of alcohol, mindfulness, social influences, and alcohol marketing. Intervention participants will also fill out biweekly EMA assessments. The comparators are EMA-only and pre-post control only. The primary outcome is alcohol consumption at 8 weeks compared between groups. Secondary outcomes are awareness of alcohol-related harms, readiness to change alcohol consumption, health status, mental health, and social support.

Results: Ethics approval for this project was received on September 11, 2019. The trial was registered on August 14, 2020. Recruitment has commenced, and the expected results will be available in 2022.

Conclusions: This web-based intervention aims to reduce alcohol consumption among middle-aged women, a currently understudied cohort in alcohol research.

Trial Registration: Australia New Zealand Clinical Trials Registry (ANZCTR) ACTRN12620000814976; https://www.anzctr.org.au/Trial/Registration/TrialReview.aspx?ACTRN=12620000814976

Introduction

Background

Historically, men have been larger consumers of alcohol than women, but recent evidence has shown a gender convergence in rates of alcohol consumption [1]. In Australia, this is particularly notable among middle-aged women; rates of long-term risky drinking (measured as 2 or more standard drinks a day) have increased significantly among women aged 40-65 years from 8.8% in 2001 to 11.7% in 2019 [2]. Similarly, rates of risky single-occasion drinking (measured as 5 or more standard drinks on 1 occasion) rose from 13.5% to 19.8% over this same period [2]. This increase is of concern as women are more susceptible to the long-term negative health effects of alcohol including cardiovascular disease, cancer, and diabetes [3]. Women are also more likely to develop alcohol-use disorders from lower levels of consumption than men and are more vulnerable to the neurotoxic effects of alcohol [3].

Several systematic reviews have been carried out to determine the overall efficacy of web-based interventions aimed at reducing alcohol consumption. The most recent, a review of systematic reviews [4], found that web-based interventions were effective in reducing alcohol consumption, albeit effect sizes were mostly small, reflecting a weekly reduction of between 2 and 3 UK units (1 unit=8 grams of ethanol) or between 1 and 2.5 European units (1 unit=10 grams). Studies of interventions that have included women in the sample have often found that higher proportions of women than men take up the intervention [5], suggesting web-based interventions are an appropriate medium for female drinkers. Of studies demonstrating the efficacy of web-based interventions with women, the majority have only included college students [6,7].

There is a specific need for interventions designed by, and targeted at, middle-aged women for several reasons. Firstly, men and women have different patterns of alcohol use and different motives for consumption [3,8,9]. For example, women are lighter drinkers than men, and use alcohol to experience respite from their traditional female domestic and caring responsibilities. Further, most web-based interventions that are female-centric have been aimed at pregnant women or those of childbearing age, with the content heavily tailored to these specific groups and a particular focus on the harms of alcohol to unborn babies [10,11]. Lastly, it has been shown that tailoring interventions using co-design with a target population is particularly efficacious in ensuring the effectiveness of an intervention or program [12,13]; thus, an intervention designed by and for middle-aged women is likely to have amplified effectiveness.

To our knowledge, there are no web-based interventions targeted specifically at middle-aged women that have been documented in the literature. Our study aims to fill this gap by developing and testing the effectiveness of a web-based intervention in reducing alcohol consumption among women aged 40-65 years. The primary aim of this study is to test the effectiveness of a 3-arm web-based intervention in reducing both the frequency of alcohol consumption as well as the alcohol intake per occasion among middle-aged women. Secondary aims include testing the effectiveness of the intervention in increasing awareness of the long- and short-term harms associated with alcohol consumption, increasing motivation to reduce alcohol consumption, reducing alcohol-related harm, improving reported health status and mental health, and increasing social support. We will also test reactivity to the ecological momentary assessment (EMA) by comparing a control group with weekly assessment to a pre-post control group.

Hypothesis 1

We hypothesize that by the end of the intervention period, participants in the web-based intervention group will report significantly lower alcohol consumption compared with participants in the pre-post control group (H1).

Hypothesis 2

We hypothesize that by the end of the intervention period, participants in the web-based intervention group will display significant increases in their awareness of harms associated with alcohol consumption (H2a), their motivation to reduce their alcohol consumption (H2b), social support (H2c), and current health status (H2d); they will also display significant decreases in alcohol-related harm (H2e) when compared to the pre-post control only group.

Hypothesis 3

We hypothesize that by the end of the intervention period, participants in the control group with weekly assessment will have greater reductions in alcohol consumption compared with participants in the pre-post control group (H3a). We further hypothesize that participants in the intervention group will report a greater reduction in alcohol consumption compared with participants in the control group with weekly assessment.

Methods

Study Design

This study is a 3-arm randomized controlled trial including 1 intervention group, 1 pre-post control group and 1 control group with weekly assessment. The trial was registered with Australia New Zealand Clinical Trials Registry (ACTRN12620000814976) on August 14, 2020.

Ethics Approval and Consent to Participate

This study has received ethics approval from the La Trobe University Human Research Ethics Committee (HEC19938). Participants who are eligible for the intervention will be emailed a consent form with brief information about the study, prior to completing the baseline survey. Upon randomization, participants will complete a second short written consent form which will contain information specific to their intervention arm.

Participants

For this study, participants will be eligible if they are aged between 40 and 65 years, identify as female, reside in the Australian Capital Territory or a surrounding postcode that covers the Australian Capital Territory, are able to understand written English, are able to provide informed consent, own a mobile phone with SMS text messaging capabilities, have access

XSL•FO
RenderX

to the internet, and consume alcohol at least weekly or consume 4 or more standard drinks at least once a month.

Women will be ineligible for the study if they are currently receiving treatment for a substance use disorder or are not in Australia for the duration of the study.

Sample Size Calculation

The effect sizes obtained in brief interventions, that is, change in the intervention group compared to the control group, are usually relatively small [4]. Power analyses in the statistical software G*Power 3.1.9.4 [14] were conducted to determine the power (probability) to successfully find differences between the intervention group and the 2 control groups. In this study, we aim to recruit 3000 participants. However, we may be short on this aim by one-third and have one-third attrition leaving us with a sample of 1333. Using repeated measures ANOVA with within-between interactions (ie, 2 measurements over time [pre-post assessments; note that in any case the EMA assessments will have a higher test power] interacting with the membership in 1 of 3 groups), this reduced sample will still have a power (probability) of more than 99% to detect even small effect sizes (P=.99; [15]) with an α-error threshold of .001. In other words, the intended sample size is sufficient to test all hypotheses successfully.

Recruitment

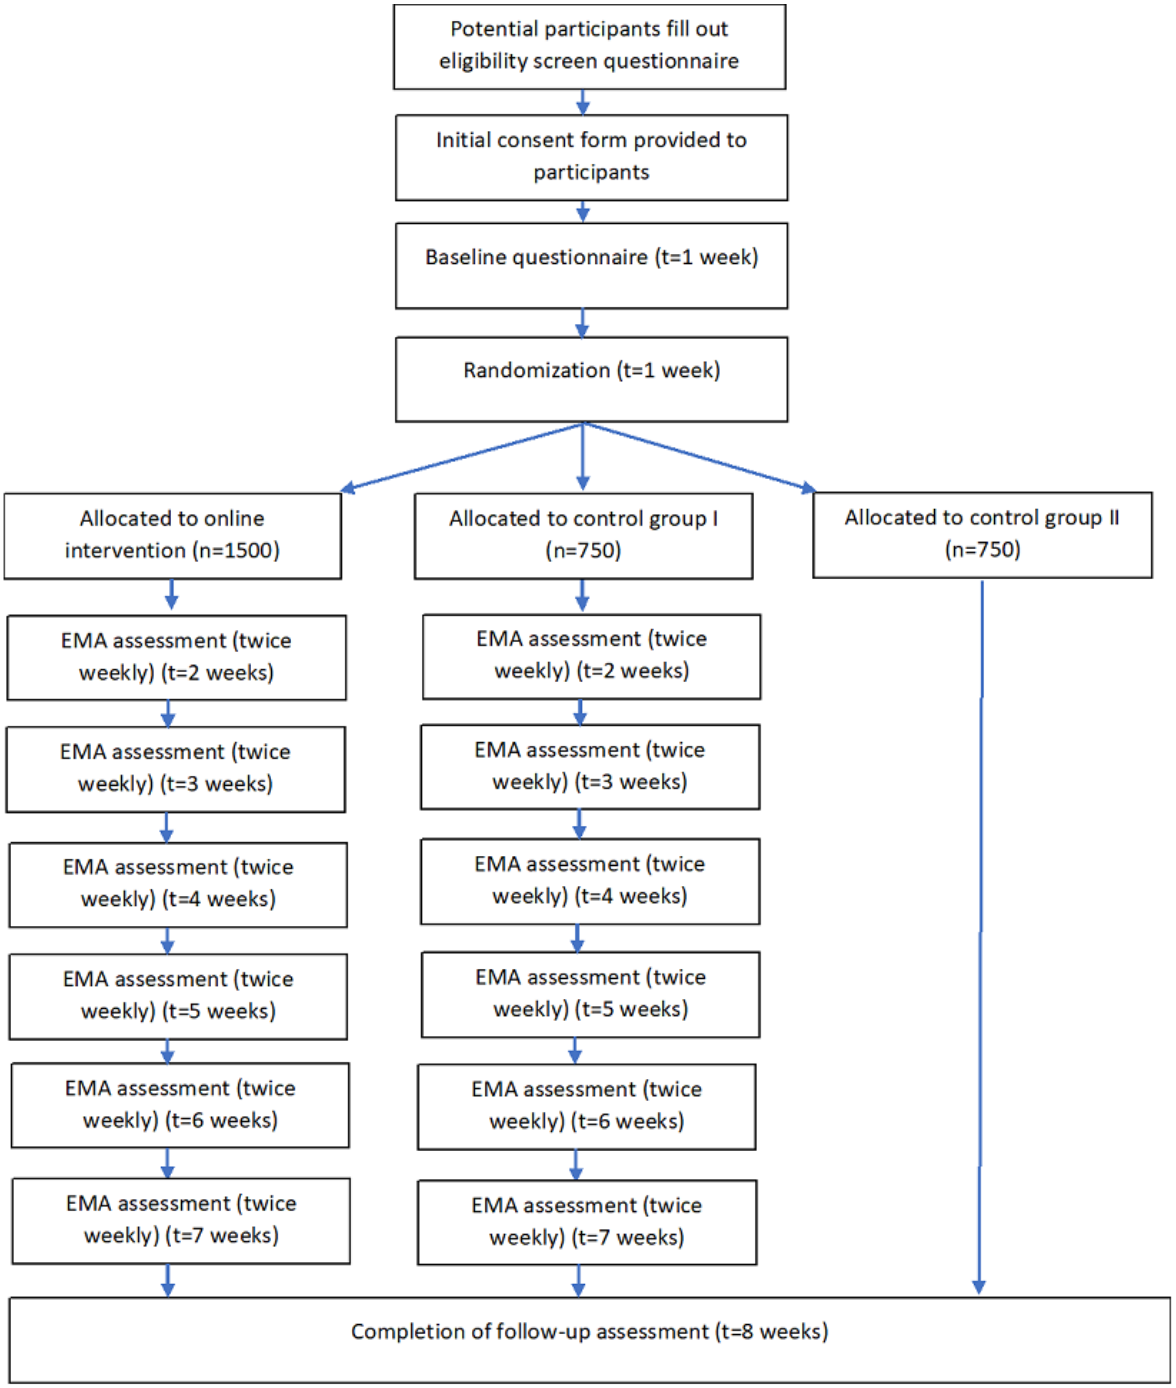
Recruitment will be carried out through a multipronged approach using both "online" and "offline" access points. Online recruitment will occur through media outlets such as Facebook, Twitter, websites, web-based newsletters, and magazines. Offline recruitment will include advertisements in school newsletters, local community group newsletters, general practitioner clinics, libraries, and gyms. Advertisements will include a link and QR code for a brief web-based screening questionnaire to assess participant eligibility.

We will undertake rolling recruitment, such that participants will be recruited continuously until 3000 individuals are participating in the study. Each participant will undertake the baseline assessment immediately after recruitment to ensure retention.

Procedures

This study is a 3-arm randomized controlled trial of a web-based intervention to reduce alcohol consumption in middle-aged women.

Potential participants responding to an advertisement will be linked to the study website, which will provide them with a brief description of the study and an eligibility screener. Participants who are eligible will be electronically sent an initial consent form with brief information about the study and will be asked to complete the baseline survey. Participants who do not respond to the initial prompt to complete the baseline survey will be sent 3 reminders over 2 weeks. Upon completion of the baseline survey, participants will be randomized into 1 of 3 groups through the back-end platform specifically designed for the intervention, using a computer-generated number allocated to each participant. Participants will then complete a second short consent form that contains information specific to their intervention arm. As with most behavioral interventions, although it is not possible to blind participants to the procedures relating to their own group, they will not be aware of the procedures relating to the other groups. The researchers responsible for analysis will also be blinded. Only 1 member of the research team, who will be the contact point for any participants experiencing technical difficulties or presenting with queries, will be aware of participant allocation, if required to provide support.



The study will include 3 parallel conditions, of which all 3 will complete a baseline and follow-up questionnaire. The intervention design is shown in Figure 1. Beyond that, the 3 conditions will include the experimental condition (web-based intervention and EMA), and 2 control groups (control group 1: baseline and follow-up assessment only, and control group 2: baseline and follow-up assessment plus EMA). They will undertake assessments of their alcohol consumption over an 8-week period, providing EMA measurements of their alcohol consumption on a twice-weekly basis (measuring their daily alcohol consumption retrospectively). Screenshots of the intervention are shown in Multimedia Appendix 1.

Participants will be able to withdraw from the intervention at their request. If a participant reports an adverse event or complaint, they will be unblinded by matching their participant ID with the contact details database to enable us to establish contact and respond to any issues accordingly. A risk management database will be maintained where records of any issues will be logged.

To promote retention, all participants who complete the study (ie, complete the final assessment measures) will be entered into a draw to win 1 of 24 vouchers. There will be 12 AUD $50 vouchers, 9 AUD $100 vouchers, and 3 AUD $250 vouchers available (AUD $1=US $0.67). The large number of vouchers available reflects the repeated engagement required of participants as well as the intended large number of participants.

Figure 1. Intervention design. EMA: ecological momentary assessment; t: time point.

Intervention

The underlying theory for this web-based intervention is based on the assumptions of the Integrated Behavioral Model. This model posits that the most important determinant of behavior is the intention to perform the behavior, informed by individuals' attitudes, perceived norms, and personal agency [16]. Within this model, intention to perform a behavior is modified by four key factors: knowledge and skills, environmental constraints, the salience of the behavior to the individual, and the role of habits [16]. The Transtheoretical Model of Change [17] will also be used to determine each participant's readiness to change their alcohol use to understand how the intervention impacts motivation to change. The intervention also follows the principles of brief interventions for substance use [18]. Additionally, the intervention is based on the outcomes of interactive focus group workshops that were run by the research team with women aged 40-65 years.

The Integrated Behavioral Model

Initially, participants will be surveyed on their alcohol use and provided with feedback on their current consumption, in line with brief intervention practice. Following this, participants will *set goals* around their intentions to reduce their alcohol use over the period of the intervention in order to promote personal agency or self-efficacy. Participants will also be able to *track their alcohol use* throughout the intervention period to become more aware of their habits and behaviors. Participants will work

XSL•FO
RenderX

through four *modules of content*, which will provide information aimed at changing participants' attitudes and perceived norms. This will include the following: (1) the Low-Risk Drinking module, which will provide evidence on the harms of alcohol use and information on what a standard drink is; (2) the Mindful Drinking module, which will provide information about drinking motives and provide participants with skills to both learn to consume alcohol mindfully and to apply the broader techniques of mindfulness to their lives to reduce the common antecedents of alcohol use (such as stress); (3) the Social Drinker module, which will explore the social influences of drinking, including facts about how people influence each other both consciously and unconsciously, encourage participants to reflect on where alcohol currently fits into their social lives, and help build participant's skills to talk about their alcohol consumption with others; and (4) the Alcohol is Everywhere module, which will look at the broader factors that influence alcohol consumption, including information about the normativity of alcohol in Australian society and how alcohol availability and outlet density impact consumption, the ways in which the alcohol industry specifically targets women, how alcohol advertising impacts children, and the broader alcohol industry tactics used to promote their products. The overall aim of the content is to make participants more aware of their alcohol use and the impacts it has on their lives and on the lives of others, in order to produce attitudinal and normative changes, while building skills to cope with stress and increase self-efficacy for reducing consumption in social situations.

To improve participants' knowledge and skills to reduce their alcohol use, and to remove environmental constraints, each module will have between 1 and 3 associated *challenges*. The challenges include, for example, an opportunity for participants to write a script for a conversation with a friend or family member on how to say no when offered alcohol, information on alternate activities participants can do to relax, and an opportunity to track how they engage in these activities over a 1-week period.

Participants will be sent reminders to complete their assessments, and upon completion of the assessment, will be redirected back to the intervention content. Participants can complete the intervention content in any order and will have the entire intervention period to access and work through all of the content.

At the conclusion of the trial, participant summaries will be developed and distributed to those participants who request one.

Comparator

Participants in control group 1 will not be contacted again until the 8-week follow-up questionnaire. Participants in control group 2 (baseline and follow-up assessment plus EMA) will undertake the web-based repeated measures assessment of their alcohol consumption retrospectively twice a week. After they are recruited and randomized, these participants will be sent a link via text message to a web-based EMA. The assessment on Sunday at 12 PM will ask them about their drinking patterns over the weekend (ie, Thursday afternoon until Sunday morning), and the assessment on Thursday at 12 PM will ask about their drinking patterns during the week (ie, Sunday afternoon until Thursday morning). All participants in the control groups will be given access to the web-based intervention at the completion of the study.

Outcomes

The primary outcomes include frequency of alcohol consumption, as well as alcohol intake per drinking occasion. The secondary outcomes are awareness of alcohol-related harms, willingness to change alcohol consumption, alcohol-related harm, current health status, mental health, and social support or loneliness.

Measures

The following measures will be used, administered at baseline, EMA, and follow-up.

Baseline Survey: Demographic Questions

The baseline survey will assess a series of demographic characteristics, including educational level, country of birth, marital status, income, whether the participating women have children, the number of dependent children living in the household, employment status, as well as smoking status and frequency.

Alcohol-Related Measures

Typical Drinking (Baseline and Follow-up)

Participants will also be asked to report on how much they typically drink each day of the week (eg, "How many drinks containing alcohol do you consume on a typical Monday?")

Frequency of Risky Single-Occasion Drinking (Baseline and Follow-up)

Frequency of binge drinking will be assessed by asking participants how often they have had 4 or more standard drinks (containing 10 grams of pure ethanol) on 1 drinking occasion over the last 12 months.

Daily Alcohol Consumption (Baseline, EMA, and Follow-up)

Participants' daily alcohol consumption will be measured using a drinking diary, where twice a week they will retrospectively report on the number of beverages they consumed each day (eg, "Thinking back over the last three days, how many standard drinks containing alcohol did you have on each day of the week?")

Alcohol-Related Harm (Baseline and Follow-up)

A total of 15 items from the Rutgers Alcohol Problem Index [19] and the Young Adult Alcohol Consequences Questionnaire [20] were selected based on their age-appropriateness to our target group. Participants will be asked the following: "How many times has this happened to you while you were drinking or because of your drinking during the last year?": "Got into fights with other people," "Went to work drunk," "Missed out on other things because you spent too much money on alcohol," "Caused shame or embarrassment to someone," "Neglected your responsibilities," "Friends or relatives avoided you," "Felt that you needed more alcohol than you used to in order to get the same effect," "Tried to control your drinking (tried to drink only at certain times of the day or in certain places, that is, tried to change your pattern of drinking)," "Had withdrawal

XSL•FO
RenderX

symptoms, that is, felt sick because you stopped or cut down on drinking," "Noticed a change in your personality," "Felt that you had a problem with alcohol," "Missed a day (or part of a day) of work," and "Kept drinking when you promised yourself not to," with four possible answer categories ranging from 0 (none) to 3 (more than 5 times).

Pressures From Different Sources to Drink More and to Drink Less (Baseline and Follow-up)

Two questions on pressures to drink have been adapted from the core questionnaire from the GenACIS project [21], which are as follows: "During the last 12 months, have any of the following persons attempted to influence your drinking so that you would drink less or cut down?" and "During the last 12 months, have you felt influenced to drink or drink more by someone who drinks more than you do?" with each question having the following response options: "Your spouse/partner/romantic partner?" "Your child or children?" "Some other female member of your family?" "Some other male member of your family?" "Someone at your work?" "A female friend or acquaintance?" "A male friend or acquaintance?" and "A doctor or health worker?" with yes or no answer categories for each option.

Awareness of Alcohol Harms (Baseline and Follow-up)

As no validated scale currently exists to measure awareness of alcohol harms, 2 questions will be taken from the scale used in the 2017 study by Coomber et al [22]: (1) "Which of the following do you think are likely consequences of a single occasion of heavy drinking (ie, short-term consequences)?" with participants asked to rank the accuracy (ranging from definitely untrue to definitely true) of the following consequences: "Lack of coordination and slower reflexes," "Reduced concentration," "Motor vehicle, bicycle and pedestrian accidents," "Injuries associated with falls, accidents, violence and intentional self-harm," "Alcohol poisoning," "Drownings," "Coma and death," and (2) "Which of the following do you think are likely consequences of consuming alcohol over many years (ie, long-term consequences)?" with participants asked to rank the accuracy of the following consequences: "Harm to unborn babies," "Cirrhosis of the liver," "Brain damage," "Stomach problems," "Heart and blood disease," "Pancreatitis," "Bowel cancer," "Pharyngeal cancer," "Oesophageal cancer," "Mouth cancer," "Larynx cancer," and "Breast cancer."

Drinking Motives Questionnaire (Baseline and Follow-up)

Drinking motives will be assessed using the Drinking Motives Questionnaire-Revised [23].

Baseline and Follow-up Survey: Other Measures

Readiness to Change (Baseline and Follow-up)

Readiness to change will be measured using the 12-item Readiness to Change Questionnaire [24].

Current Level of Stress (Baseline, EMA, and Follow-up)

Current level of stress will be measured using the 4-item Perceived Stress Scale [25].

Self-efficacy (Baseline, EMA, and Follow-up)

Self-efficacy will be measured using the 10-item General Self-Efficacy Scale [26].

Relationship Quality (Baseline and Follow-up)

Relationship quality will be measured using the second item of the Relationship Assessment Scale [27], "In general, how satisfied are you with your relationship?" with five possible answer categories ranging from 1 (not satisfied) to 5 (very satisfied).

Current Health Status (Baseline and Follow-up)

Current health status will be measured using the first item of the General Health Questionnaire [28]— "In general, would you say your health is," with five possible answer categories ranging from 1 (poor) to 5 (excellent).

Mental Health (Baseline and Follow-up)

Mental health will be measured using the 5-item Mental Health Inventory [29].

Social Support or Loneliness (Baseline, EMA, and Follow-up)

Social support or loneliness will be measured using the 8-item UCLA Loneliness Scale-8 [30].

Current Use of Technology (Baseline)

Five items from the Media and Technology Usage and Attitudes Scale [31] will be used to capture attitudes toward technology. Participants will be asked how strongly they agree with the following questions: "I feel it is important to be able to access the Internet anytime I want," "I think it is important to keep up with the latest trends in technology," "I get anxious when I don't have my cell phone," "I get anxious when I don't have the internet available to me," and "New technology makes people waste too much time." Participants will also be asked to report how many hours per week on average they spend on their computer (for leisure and for work), on their mobile phone, on a tablet, searching the internet on any device, and using apps on any device.

Client Satisfaction Survey (Follow-up)

The 8-item Client Satisfaction Questionnaire Adapted for Online Interventions [32] will be used.

Participant's Use of Intervention (Follow-up)

The intervention's back-end system will record the number of times participants log in to view the intervention content, and the time they spend on the website each time they log in. It will also record whether participants complete the requested number of follow-up EMAs. These data (number of visits, time spent on website, and number of EMAs completed) will be extracted from the system to assist in assessing the fidelity of the implementation of the intervention.

Data Management

Participants will complete all assessments and access the intervention online; data will be stored on a secure server based in Australia. Access to the data will be password protected and limited to the members of the research team.

XSL•FO
RenderX

Data Analysis

The reporting and presentation of this trial will be in accordance with the CONSORT (Consolidated Standards of Reporting Trials) guidelines for randomized controlled trials, and data on screening, refusals, and dropout will be coded and reported on per the guidelines [33]. The comparative analysis will be analyzed in accordance with the intention-to-treat principle and the completers-only framework. Participants will have to sign up to the intervention and complete approximately 30% of the EMA surveys to be considered for inclusion in the analysis; missing data will be handled accordingly. The intention-to-treat analyses' multiple imputation methods will be used, while completers-only analyses will be conducted on participants providing scores for all measurements.

All data that are collected will be analyzed using statistical software packages such as STATA (StataCorp) and Mplus (Muthén & Muthén). ANOVAs, contrasting the intervention groups against both control groups, will be run, and logistic and linear regression models will be used to determine potential influencing variables. Longitudinal analyses will be conducted to test group differences in EMA assessments over time.

Besides testing the main effects of the intervention, moderating effects of age, drinking status (whether participants are "risky" drinkers according to the Australian Alcohol Guidelines [34]), educational status, and presence of dependent children in the household will be investigated to establish whether specific subgroups are more likely to benefit from the intervention.

Results

Ethics approval for this project was received on September 11, 2019. The trial was registered on August 14, 2020. Recruitment has commenced, and the expected results will be available in 2022.

Discussion

Expected Outcomes

This paper describes the study protocol of a randomized controlled trial to assess the benefit of a targeted web-based intervention to reduce alcohol consumption among middle-aged women. Intervention with this group is imperative because their alcohol consumption has increased at a time when that of other groups has remained stable or declined [35]. The primary aim of the study is to test whether a web-based intervention can reduce alcohol consumption, increase awareness of alcohol-related harms, increase motivation to reduce alcohol consumption, increase social support and reported health status, and decrease alcohol-related harms, when compared to a no-intervention control group.

Strengths and Limitations

Most web-based interventions aimed at reducing alcohol consumption have been designed for the general adult population, youth, or pregnant women. This study will be, to our knowledge, the first web-based intervention designed by and tested on middle-aged women. Additionally, the use of repeated-measured assessment (EMA) will allow us to gain rich data on participants' alcohol consumption over an 8-week period, which is a strength. Further, the use of 2 control groups (1 with EMA and 1 without) will enable us to assess the true effect of the intervention, as well as determine whether EMAs alone may result in reduced alcohol consumption. As with most alcohol research, the reliance on self-report data can lead to reporting bias; however, it is not anticipated that this bias will differ among the 3 groups. The intervention will only be tested initially on women residing in 1 Australian state, so generalizability may be limited in the first instance.

Acknowledgments

We acknowledge the contribution of the Foundation for Alcohol Research and Education (FARE) and greatly thank the women who participated in our focus groups.

The study is supported by a subcontract with FARE based on a collaboration between the Centre for Alcohol Policy Research (CAPR) and FARE funded by a grant from Australian Capital Territory Health under the Health Promotion Grants Program (HCG18/19 - 20/21_055). The funding source had no role in the study design, collection, analysis, or interpretation of the data, writing the manuscript, or the decision to submit the paper for publication.

Availability of Data and Materials

The data generated and analyzed during the study are not publicly available due to privacy issues but are available from the corresponding author on reasonable request.

Authors' Contributions

EK and SK conceived the original concept of the study. All authors contributed to the design of the intervention and trial. MM drafted the manuscript. All authors provided comments on the draft and read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Despite efforts, the UK death rate from asthma is the highest in Europe, and 65% of people with asthma in the United Kingdom do not receive the professional care they are entitled to. Experts have recommended the use of digital innovations to help address the issues of poor outcomes and lack of care access. An automated SMS text messaging–based conversational agent (ie, chatbot) created to provide access to asthma support in a familiar format via a mobile phone has the potential to help people with asthma across demographics and at scale. Such a chatbot could help improve the accuracy of self-assessed risk, improve asthma self-management, increase access to professional care, and ultimately reduce asthma attacks and emergencies.

Objective: The aims of this study are to determine the feasibility and usability of a text-based conversational agent that processes a patient's text responses and short sample voice recordings to calculate an estimate of their risk for an asthma exacerbation and then offers follow-up information for lowering risk and improving asthma control; assess the levels of engagement for different groups of users, particularly those who do not access professional services and those with poor asthma control; and assess the extent to which users of the chatbot perceive it as helpful for improving their understanding and self-management of their condition.

Methods: We will recruit 300 adults through four channels for broad reach: Facebook, YouGov, Asthma + Lung UK social media, and the website Healthily (a health self-management app). Participants will be screened, and those who meet inclusion criteria (adults diagnosed with asthma and who use WhatsApp) will be provided with a link to access the conversational agent through WhatsApp on their mobile phones. Participants will be sent scheduled and randomly timed messages to invite them to engage in dialogue about their asthma risk during the period of study. After a data collection period (28 days), participants will respond to questionnaire items related to the quality of the interaction. A pre- and postquestionnaire will measure asthma control before and after the intervention.

Results: This study was funded in March 2021 and started in January 2022. We developed a prototype conversational agent, which was iteratively improved with feedback from people with asthma, asthma nurses, and specialist doctors. Fortnightly reviews of iterations by the clinical team began in September 2022 and are ongoing. This feasibility study will start recruitment in January 2023. The anticipated completion of the study is July 2023. A future randomized controlled trial will depend on the outcomes of this study and funding.

Conclusions: This feasibility study will inform a follow-up pilot and larger randomized controlled trial to assess the impact of a conversational agent on asthma outcomes, self-management, behavior change, and access to care.

Introduction

Asthma and Digital Health Interventions

It is estimated that 334 million people worldwide have asthma, which, in some countries, is 15%-20% of the population [1]. Despite effective treatments and extensive efforts, the UK death rate from asthma is the highest in Europe. Moreover, 65% of people with asthma in the United Kingdom do not receive the professional care they are entitled to (including a yearly review, feedback on how to use their inhaler correctly, or an asthma action plan). One of the reasons for this is believed to be poor self-assessment of risk by those with asthma. According to the charity Asthma + Lung UK, the illness is often not taken seriously enough. For example, 1 in 6 people in the United Kingdom do not know or are unsure if the condition can be fatal [2].

Mobile health interventions can help address these gaps in knowledge, self-assessment, and basic care. Mobile technologies can provide just-in-time, anywhere approaches to self-care or mixed mode care. They have been shown to be cost-effective in a number of health domains, and according to a recent systematic review, 87% improved adherence and 53% demosnstrated improved health outcomes [3]. Most often they are used to deliver clinical information, but efficacy has also been shown for providing elements of basic care and health risk feedback as well as supporting behavior change through personalized dialogue with conversational agents (CAs; as reviewed in [4-6]). For example, in the asthma domain specifically, Rhee et al [7] described an automated SMS text messaging system able to interpret conversational English SMS text messages, particularly around asthma symptoms. The system was tested by 15 adolescent-parent dyads, the results of which indicated that the messaging system was well received, easy to use, and convenient. More recently, Kadariya et al [8] tested kBot, a chatbot supporting pediatric asthmatic patients, integrated as part of an Android app. kBot was tested by clinicians and researchers (but not patients). Another study [9] described MAX, a CA focused on helping children learn about asthma and better use of their inhalers. MAX interacted with patients through SMS text messages and did not require a dedicated app. This single-arm feasibility study recruited patients' family members in primary and secondary care (again patients were not included) and showed that using a CA can lead to improved cognitive and behavioral skills. These studies show the promise of this new digital health care approach and ways that it can complement primary and secondary care. What they do not contribute is a better understanding of what drives users to engage with such tools.

The Collaborative Design Process

The larger project surrounding the study described in this protocol aims to develop a text-based automated CA to provide asthma risk assessment and follow-up support for improving asthma self-management. The design process entails development of the conversational scripts (conversational design) for the chatbot and technical development of the CA. The design process has involved patients, asthma nurses, and doctors (including 2 respiratory specialists) from the earliest stages. Stakeholder input was gathered in a variety of ways, including a stakeholder design workshop at the launch of the project, sample dialogue sessions with patients and doctors, a large patient survey (n=1257), and regular reviews of the chatbot and its conversational texts by 3 asthma nurses and 3 doctors.

Regular stakeholder involvement has shaped the content, format, and conversational style of the chatbot. A first critical design decision arising from stakeholder consultations was the choice to provide the chatbot through the popular WhatsApp platform rather than through a new dedicated app. The advisory team based the decision on WhatsApp's lower barrier of entry for users. For example, because WhatsApp is used by a majority of people with asthma (85% in our survey) and does not require computer expertise or high-end hardware, it is more easily accessible for users than downloading and using a new app. Easier access is especially important for helping harder-to-reach populations.

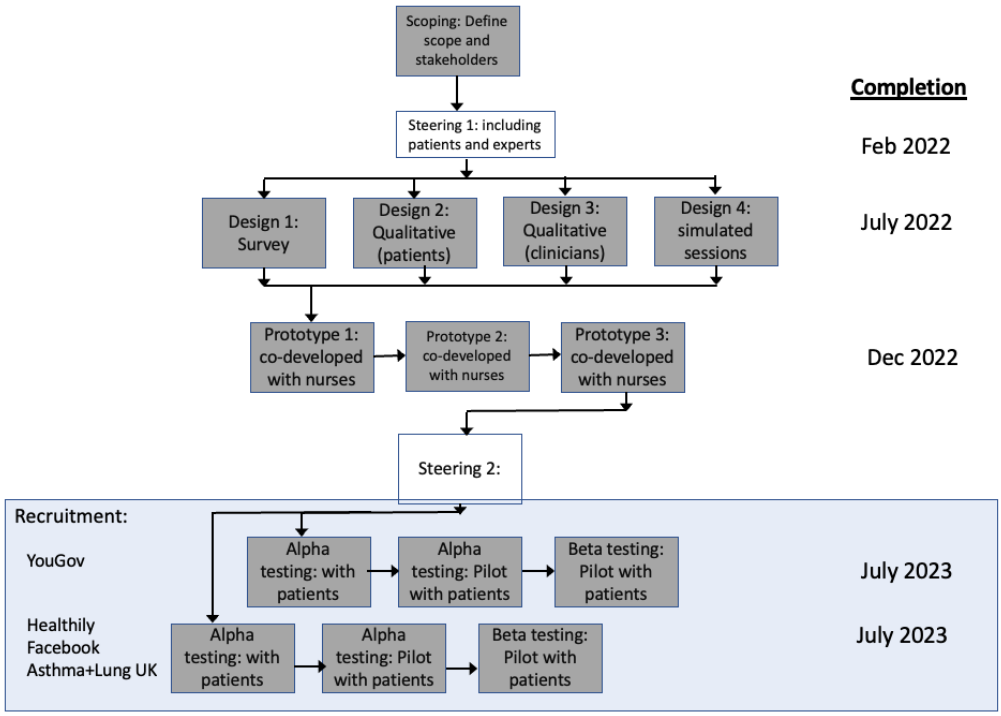
Design and development of the chatbot was informed by a user research survey (N=1257) with adults with asthma. The survey explored prospective user preferences with respect to an asthma chatbot and perceptions around chatbots and technologies for health more broadly. Survey results indicated that 53% of respondents were very or somewhat interested in an asthma chatbot, yet only 7% had used an asthma app. The survey complemented previous surveys commissioned by Asthma + Lung UK, which also provide evidence for user interest in digital technologies for self-care [10].

Design of the conversational dialogues for the chatbot were also informed by qualitative research activities including analysis of a series of asthma conversations held between patients and clinicians. The complete results of the survey and qualitative studies have not yet been published. The conversational design was also informed by existing literature, input from our steering committee, and survey results.

Privacy is of utmost importance in health conversations. While a chatbot using WhatsApp may not be Health Insurance Portability and Accountability Act compliant, conversations are encrypted "end-to-end," meaning that the messages are not readable by WhatsApp. Asthma + Lung UK and many other organizations already provide support, for example, by asthma nurses communicating through this channel.

XSL•FO
RenderX

Exacerbation Risk Models



Machine learning experts and epidemiologists within the project have so far developed two risk models. One is based on the Clinical Practice Research Datalink (CPRD) data sets, while the other implements a machine learning model trained on voice recordings of individuals with or without a self-reported asthma diagnosis.

For the first model, we used the unique medical records of 1,277,745 patients and logistic regression. These were divided into three parts to implement temporal validation: 948,934 (74.3%) in the training sample; 244,588 (19.1%) in the testing sample; and 84,223 (6.6%) in the validation sample.

The voice-based risk model is intended to detect the level of asthma control and is based on the sound of their voice. It is based on a similar approach used successfully for COVID-19 diagnosis. The asthma risk model has been initially trained with a database available to researchers upon request and after signing a use agreement [11]. The database contains multilingual voice recordings and other metadata, including age, smoking status, and health information such as COVID-19 or other pulmonary diseases. Voice recording data submitted by participants will help to improve the voice risk model.

The findings from developing these models will be reported when completed and are out of scope for this feasibility protocol. Overall, the design engineering process, described in Figure 1 is similar to the systematic development process for patient decision aids described by Coulter et al [12].

Figure 1. Design engineering process. The highlighted area describes the scope of this feasibility study. The rest shows the iterative and multistakeholder design process so far.

Engagement With Health Care and Technology

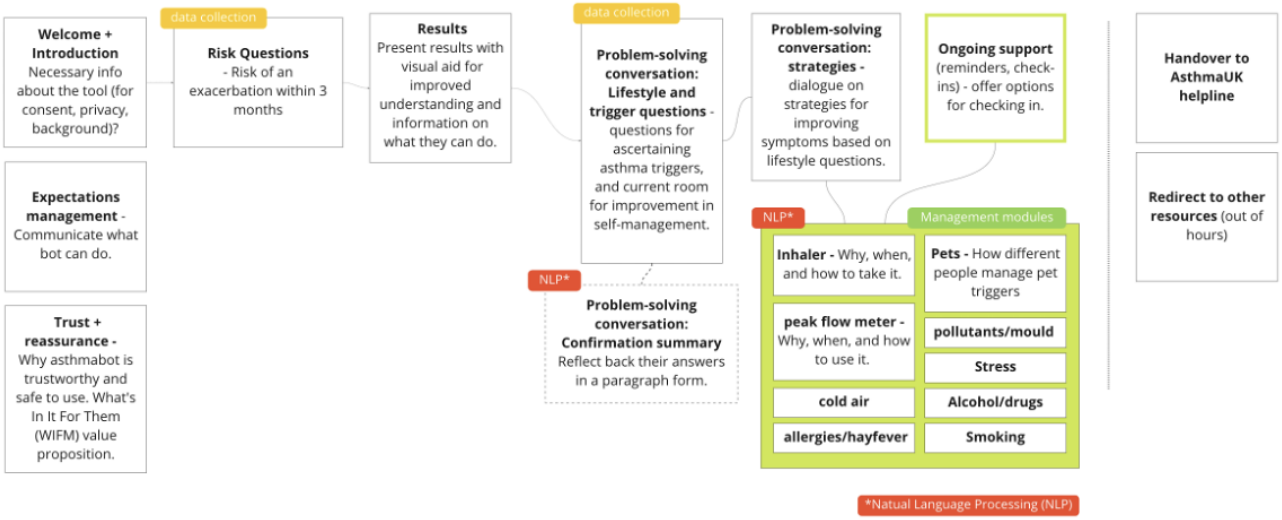
Self-determination theory (SDT) has been used as a theoretical framework for assessing efficacy of both health care environments and technologies. For example, it has been shown that a health care environment can improve health outcomes by supporting the basic psychological needs of patients [13]. Likewise, SDT can be used to predict the conditions for motivation to engage with a technology [14] as well as user satisfaction with that technology [14] (D Peters and R Calvo, unpublished data, 2023). As such, the conditions for need-supportive design of technology and health care environments from the SDT literature [15,16] will be incorporated into the design of the chatbot. Accordingly, we will include a set of SDT measures [14] in the postquestionnaire.

Of the different categories of clinical communication identified by Street Jr and Epstein [17], *information exchange* is the most readily used with CAs. In other words, CAs are typically used for collecting data from users by asking questions (eg, gathering a clinical history) and for disseminating information to them (eg, general information about an illness or how it can be managed). Other functions described in the Street Jr and Epstein [17] model, such as helping clients with managing uncertainty or decision-making, are less common because they rely more on open-ended exchanges. As such, exploring the feasibility of supporting such decision-making, including through a mix of closed- and open-ended dialogues, is among the aims of our project.

Person-centered care focuses on "understanding the patient as a unique human being" [18]. As such, our CA will focus on customizing conversation as much as possible, for example, by asking questions to understand the user's unique asthma triggers, lifestyle factors, and risk of exacerbation, and then tailoring advice accordingly. Critically, this information gathering and sharing will be delivered as part of a natural dialogue that can

XSL•FO
RenderX

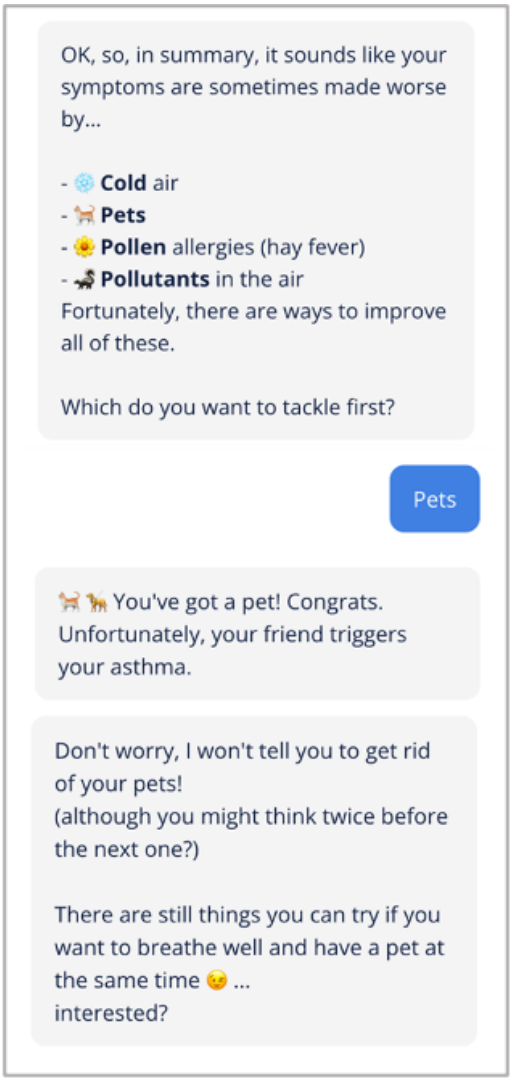
adapt to user responses and convey information in gradual conversational chunks, where the user can control the pacing and focus. These features differentiate it from a more traditional questionnaire and results approach.



For example, the risk assessment form on the Asthma + Lung UK website presents the user with a series of form questions and then presents a collection of information based on their results. The form is easy to fill out and the results are personalized and carefully presented to make the information as useful as possible. However, the result is still similar to an information sheet. This relies on the user reading all the information and being able to absorb a large amount of mixed information at once. In contrast, we anticipate that the added adaptive agility, familiarity, and progressive disclosure of information that occurs as part of a conversation may provide benefits to understanding, retention, and behavior change, at least for some groups. In this initial feasibility study, we will include a number of self-report measures with respect to understanding and behavior change to begin to test this possibility. However, to compare the two approaches rigorously in a future study, we hope to arrange a controlled experiment comparing the chatbot with an online questionnaire to determine the advantages of each.

Chatbot Content and Features

Following best practices for person-centered care technologies [19], the chatbot system described herein has been designed collaboratively with asthma patients, asthma nurses, and specialist doctors. Based on this approach, the chatbot was designed with a number of dialogue components each representing a topic about which the chatbot can engage in a conversation with the user (Figure 2). In short, the bot assesses a user's risk of having an asthma exacerbation and then provides guidance on how to reduce this risk. The risk reduction guidance process proceeds by first supporting the user to identify their triggers and presenting strategies for managing their specific triggers based on their specific situation (see the example dialogue excerpt in Figure 3). The strategy dialogues will include referrals to Asthma + Lung UK or National Health Service content (eg, inhaler technique videos, smoking cessation clinic sites) with direct links to these resources. We will track click-throughs on these links as an indicator of engagement and impact.



The various dialogues can be triggered either by arriving at them naturally at the end of another dialogue (eg, the risk assessment component leads users to the problem-solving conversation component), selecting them from a list of options (like a menu, users can choose to skip the risk assessment and jump to a conversation about their asthma triggers), or through open-text input (a user can type "what about my dog?" and the system will respond with the dialogue on strategies for managing pet triggers). Free text is processed by a dedicated natural language processing server. For example, the chatbot asks for a description of the perceived triggers and maps it to specific categories. If none are automatically identified, a multiple-choice menu is offered.

Figure 2. Diagram of conversational components. Boxes marked "NLP" include dialogues that may be generated based on a synthesis of user text input or that may be triggered by open-text input.

XSL•FO
RenderX

Figure 3. Example dialogue excerpt from the problem-solving component.

Methods

Recruitment

Participants for the alpha and beta phases will be patients with an asthma diagnosis, as described above. Participants should be 18 years or older, able to communicate fluently in English, and willing to use WhatsApp on their mobile phones.

Participants will be compensated for their time (which involves trying the chatbot at least once and filling out a pre- and postquestionnaire on day 1 and 28, respectively) with a £10 (approximately US $12) voucher. The research study questionnaires will be provided in Qualtrics, separate from the chatbot so as not to interfere with the experience of the chatbot itself.

A total of 300 individuals will be recruited in three waves. Only approved phone numbers (of people who have consented to the study) will be able to interact with the chatbot.

Recruitment will be done over four channels:

1. YouGov: 120 adults with diagnosed asthma will be recruited through YouGov. We expect roughly 10% of the cohort who participated in the survey or 20% of those who expressed interest in the chatbot.
2. Facebook: 60 participants with self-reported asthma will be recruited through Facebook's advertising engine.
3. Healthily: 60 participants with self-reported asthma will be recruited through Healthily (a medically approved self-care platform). Healthily will advertise the study in the "Asthma Hub" accessed by people with, or interested in, asthma. The timeline will be as the one above. People using Healthily are interested in self-care and pay £29.99 (approximately US $36.70) per year to access it.
4. Asthma + Lung UK social media: 60 participants with self-reported asthma will be recruited through social media channels managed by our partner organization.

The social media channels will direct people to a web page that will screen for inclusion criteria. Those who meet the criteria will be invited to participate, asked for informed consent, and directed to the prequestionnaire and then to the chatbot in WhatsApp on their mobile phones.

Recruitment and chatbot use will be phased to allow for iterative improvements. We will start recruitment through YouGov. The first batch of 20 individuals will use it for 1 week, and their feedback and engagement measures will be used to inform a

XSL•FO
RenderX

new iteration of improvements. The same will be done with a second batch of 20 people. We refer to these groups as alpha testing in Figure 1. The third and final batch of 260 people will be drawn from the remaining recruitment channels and will use the system for 28 days. We refer to this group as beta testing in Figure 1.

Procedure

We estimate that the average conversation will take less than 15 minutes. Participants will be sent randomly timed messages once a week to invite them to track their asthma risk during the period of the study. After the data collection period (28 days), participants will respond to survey items related to the quality of the interaction. At day 28, they will be sent a final reminder inviting them to complete the exit questionnaire with a link to a Qualtrics form. A follow-up WhatsApp message sent 3 months later will ask users to report if they had an asthma exacerbation within the last 3 months (since they used the bot), and they will have one additional month (which means 4 months from using the bot) to provide this information on exacerbations.

For clarity, if the project were to start on January 1, the first group would finish on January 7. Feedback would take a week to address, and the second group would start on January 14, finishing on January 21. The third batch would start on February 1 and finish on March 1; a follow-up message asking about any asthma exacerbations would be sent on June 1 (allowing them to respond until July 1).

The outcome variables and associated measures are presented in Table 1.

Table 1. Outcome variables and associated measures.

Variable	Measure
Acceptability, usability, and satisfaction of the chatbot, including the risk assessment dialogue and follow-up dialogues on asthma triggers and management strategies for improvement of asthma control	We will combine the following standard technology satisfaction measures: • Task completion (% complete risk assessment process vs drop-out rate) • Net Promoter Score question: "how likely are you to recommend the chatbot to someone else with asthma on a scale from 0 to 10" • User satisfaction questions for each dialogue topic (eg, "Did you measure your risk using the chatbot? How useful did you find this feature?") • Open-ended questions on what worked well and what did not, and how the chatbot could be improved
Motivational quality, engagement, and user experience in relation to basic psychological needs	• Motivation, Engagement, and Thriving in User Experience questionnaire [14]
Alignment between expected and calculated risk, and whether the calculated result changes risk self-assessment	• Self-report questions on risk score expectation vs result and trust in result
Changes to asthma understanding, attitudes, and behaviors following use of the app	• Self-report questions on changes to understanding, attitudes, and behaviors related with asthma self-management
Self-reported level of asthma control and symptoms, including changes over time	• The Asthma Control Questionnaire [20] will be asked at the beginning and end of the study
Patterns of engagement and satisfaction for different types of users, particularly those who do not access professional services and those with poor asthma control	• Analysis of pre- and postquestionnaires and additional self-report questions on use of professional services (eg, "when was the last time you spoke to a GP about asthma")

Ethics Approval

The study protocol will be submitted to the Imperial College London research ethics committee. The user research survey informing the chatbot development was approved by the Imperial College London Ethics committee 21IC7403.

Data Management and Plan

Transcripts (and data extracted from them) will be stored in a secure database. Responses to the pre- and postquestionnaires will be stored on Qualtrics' servers.

Each user's WhatsApp number will be recorded by the system to ensure that the user has provided consent to take part in the research study, track engagement by the same participant over time as well as link engagement patterns to questionnaire data, and improve the user experience (eg, the bot can then store the answers users gave in a previous session and does not start from scratch each time the conversation is returned to). Emails will be stored to send the £10 (approximately US $12) electronic voucher rewards.

Quantitative analysis of dialogue transcripts, use statistics, and questionnaire data will explore patterns and seek findings in relation to the variables and measures in Table 1.

Analysis Plan

We seek to answer the following questions:

- Are there differences among the dialogue topics with regards to engagement? If so, which topic is most engaging? Do participants engage more, less, or equally with the artificial intelligence–enhanced motivational interviewing informed dialogues versus the health education branching

XSL•FO
RenderX

dialogues? Does engagement with any topic correlate with better health or technology satisfaction outcomes?
- Although the goal of the study is not assessing the efficacy of the intervention, will the group's asthma control improve at the end of the 4 weeks? A future randomized controlled trial will explore the efficacy with appropriate power and rigor, but this study might give initial indications of effect sizes.
- Did the iterative development approach improve outcomes? To test if the alpha and beta predict different effects, and assuming they have nonnormal distributions, we will use the nonparametric Kruskal-Wallis test.

Results

This study was funded in March 2021 and started in January 2022. We plan to publish the results from the user research survey and qualitative studies in the near term and results from the feasibility study in the following term. We have already developed the CA and several risk assessment algorithms. The conversational design and algorithms will be improved and validated with the data collected during phase 1, started in September 2022.

Phase 2 of this feasibility evaluation will start recruitment in January 2023. The anticipated completion of the study is July 2023.

We hope the results will identify the extent to which the chatbot is a viable product that users find valuable, in particular for those who do not access professional services and whose asthma is poorly controlled. We expect that the level of engagement of all users will be positively related to how well the system supports their psychological needs.

Discussion

People living with asthma need support to improve the accuracy of their risk self-assessment and asthma self-management, increase their access to professional care, and ultimately reduce asthma attacks and emergencies. Digital health technologies like apps offer new ways to address these but are often not used. In our survey, only 7% of people with asthma had used an asthma app. On the other hand, most use messaging platforms; in particular, 85% use WhatsApp. This has led us to develop a chatbot intervention to be delivered through WhatsApp that estimates the risk of an asthma exacerbation and provides recommendations on how to manage it better.

Our proposed study will evaluate the feasibility of this WhatsApp chatbot, with a particular focus on improving our understanding of the drivers and obstacles of engagement. While the chatbot has been designed and developed using the best practices available, such understanding will allow for better health chatbots in the future.

With respect to study limitations, since this is only a feasibility study, we are recruiting a relatively low number of participants (N=300). As such, we do not expect to find sex or age differences within the current sampling, and we do not expect to measure statistically significant improvements in asthma control over the 28 days. Furthermore, as we rely on self-report of diagnosed asthma (including having been prescribed a blue reliever inhaler that is only available through prescription), we could get some responses from someone who incorrectly answered the screening questionnaire.

In the future, findings from this study will be validated as part of a randomized controlled trial to determine whether the chatbot can measurably improve health outcomes. All these results will inform the development process of future chatbots in the health domain.

Acknowledgments

This research was made possible by grant EP/W002477/1 from the UK Engineering and Physical Sciences Research Council and Asthma + Lung UK.

Data Availability

Risk models were created with Clinical Practice Research Datalink data and are available from the UK's Medicines and Healthcare products Regulatory Agency, as described at [21]. Pending ethics approval and to support scientific transparency, dialogue data will be made available upon request to the corresponding author.

Conflicts of Interest

EW received honorarium from Chiesi Limited for lectures, received conference sponsorship from Chiesi Limited and has a joint working agreement for a project between Imperial College Healthcare NHS Trust and AstraZeneca UK. JQ has received grants from MRC, Health Data Research UK, GSK, Bayer, Boehringer Ingelheim, Asthma + Lung, Chiesi, and AstraZeneca, and personal fees for advisory board participation or speaking fees from GlaxoSmithKline, Boehringer Ingelheim, AstraZeneca, Chiesi, Teva, Insmed, and Bayer.

Abstract

Background: Of every 10 women in rural India, 1 suffers from a common mental disorder such as depression, and untreated depression is associated with significant morbidity and mortality. Several factors lead to a large treatment gap, specifically for women in rural India, including stigma, lack of provider mental health workforce, and travel times. There is an urgent need to improve the rates of detection and treatment of depression among women in rural India without overburdening the scarce mental health resources.

Objective: We propose to develop, test, and deploy a mental health app, MITHRA (Multiuser Interactive Health Response Application), for depression screening and brief intervention, designed for use in women's self-help groups (SHGs) in rural India.

Methods: We will use focus groups with SHG members and community health workers to guide the initial development of the app, followed by iterative modification based on input from a participatory design group consisting of proposed end users of the app (SHG members). The final version of the app will then be deployed for testing in a pilot cluster randomized trial, with 3 SHGs randomized to receive the app and 3 to receive enhanced care as usual.

Results: This study was funded in June 2021. As of September 2022, we have completed both focus groups, 1 participatory design group, and app development.

Conclusions: Delivering app-based depression screening and treatment in community settings such as SHGs can address stigma and transportation-related barriers to access to depression care and overcome cultural and contextual barriers to mobile health use. It can also address the mental health workforce shortage. If we find that the MITHRA approach is feasible, we will test the implementation and effectiveness of MITHRA in multiple SHGs across India in a larger randomized controlled trial. This approach of leveraging community-based organizations to improve the reach of depression screening and treatment is applicable in rural and underserved areas across the globe.

Introduction

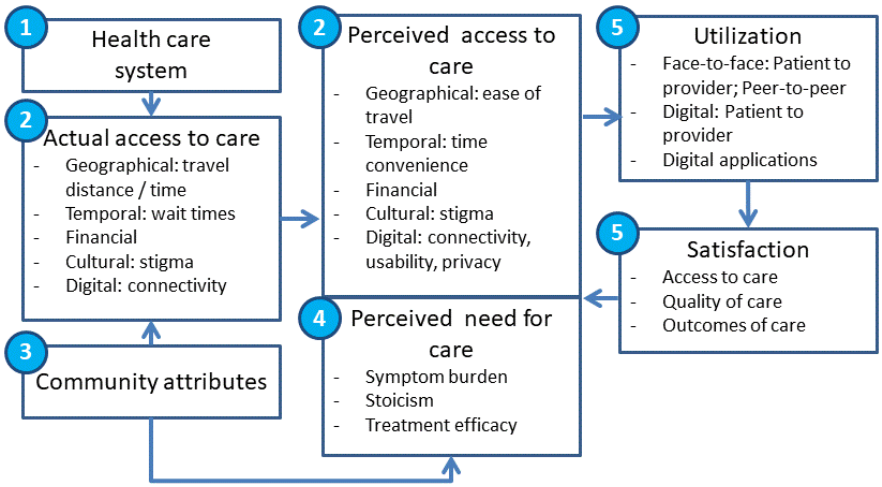
Background

Treatment rates for major depression range from 23% in high-income countries to 3% in low- and lower-middle–income countries [1]. The treatment gap is higher in rural populations, especially among women [2], despite the fact that 1 in 10 women in rural India has a common mental disorder (CMD) such as depression [3]. Untreated depression is associated with significant morbidity and mortality [4,5]. Risk factors that are more prevalent in rural areas, such as low levels of education, financial difficulties, intimate partner violence, and alcohol use in the husband [6], directly influence the outcomes of CMD and help seeking, creating barriers to care [7]. Factors contributing to the treatment gap include the dearth of psychiatrists and other mental health professionals [8,9], poor transportation infrastructure, and stigma, leading to patients not accessing care [10]. Integrating a mental health program into rural primary health centers can improve access but cannot fully address concerns about high rates of medication nonadherence and treatment dropouts [11]. In previous studies [12] and in our recent qualitative analysis [13], women cite travel times and inability to take time off from work as a significant barrier to seeking mental health care in the primary health center (PHC), and as a reason for treatment discontinuation. This barrier is relevant throughout the country, as although India's District Mental Health Program aims to provide community-based accessible mental health care, 40% of patients still travel more than 10 km to access mental health services [14].

Partnering with community-based organizations (CBOs) is one way to address barriers to accessing mental health treatments [15]. CBOs for women (called "mahila mandals" or "sthree shakthi"–women power or self-help groups [SHG]) are instrumental in increasing women's empowerment and participation in microfinancing systems in rural India. Each group consists of about 15 to 20 women members from a defined geographic area who meet regularly (weekly, biweekly, or monthly) [16]. SHG activities include pooling of resources and extending microcredit, discussion of social issues, and supporting skill development and education [17]. Rates of positive depression screens among SHG attendees range from 10% to 13% [18].

Even mild depression is associated with decreased work productivity and presenteeism (working while sick) [19], and costs associated with presenteeism tend to be 5-10 times higher than those associated with absenteeism across different countries [20]. Identifying and treating mild depressive symptoms adequately can prevent major depression [21]. There is therefore an urgent need and opportunity to identify and treat mild-to-moderate depression without increasing burden on the strained health care system. Self-administered treatments are effective in reducing mild-to-moderate depressive symptoms [22]. Self-administered treatments include bibliotherapy and online or app-based online psychotherapy modules, and when combined with regular monitoring of symptoms, can be an effective treatment for mild-to-moderate depression. There is a strong evidence base for the stepped care approach to mental health treatment in which treatment begins with low-intensity interventions, which are then stepped up if symptoms persist [23] or if the patient declines the first-line treatment. Patients with high-level symptomatology are triaged to more intense interventions at the outset. This approach is especially useful in leveraging the available workforce in resource-constrained settings [24,25]. App-based depression interventions can improve access to treatment for CMD due to ease of access and availability even in resource-poor settings [26,27]. India has the second largest wireless communication subscriber base in the world [28], and most people have access to a mobile phone and network coverage [29]. However, there are differences in usage patterns that prompted us to develop a multiuser app on a tablet rather than an app designed to be used on a personal cell phone. For example, in rural India, while 87% of people own a cell phone, only 14% of them use text messaging [26], perhaps because of the high rate of illiteracy [30]. In addition, although women in rural India do report owning a mobile phone, this is often a shared family phone that is with the husband for most of the day [13].

We propose, in this funded grant, to develop, with end user feedback, a multiuser mobile app (MITHRA [Multiuser Interactive Health Response Application]="friend" in Kannada, the regional language) for use in CBOs in rural India, to support the identification, initial treatment, and referral of women with depression. Our app will account for barriers such as illiteracy and lack of access to a personal mobile device. Our participatory approach will ensure that the app is responsive to local perceived needs by obtaining end user or consumer feedback at every stage of development [13]. The app will deliver education about depression and activity scheduling, based on the Healthy Activity Program (HAP), which is an evidence-based intervention delivered from 6 to 9 sessions; is acceptable, efficacious, and cost-effective in the treatment of depression; and has been tested in rural India [31]. Moreover, it is effective in the treatment of moderate-to-severe depression [32] and can benefit mildly depressed individuals who may not require the involvement of a mental health professional. Mild-to-moderate symptoms will be addressed by delivering the HAP via multimedia modules. This ensures that most women with mild-to-moderate depression receive initial treatment without having to overcome transportation barriers. Those with severe or nonresponsive symptoms will be directed to the PHC for assessment and treatment.



Conceptual Model

Our conceptual model is based on the access to care model by Fortney et al [33] (Figure 1). MITHRA targets each of the barriers to access to care (actual and perceived) commonly identified by patients and integrates them into both the health care system and the community. By using non–encounter-based screening, tracking, and low-intensity interventions, MITHRA improves access among women for whom stigma and travel times are a barrier. By providing education about depression, it addresses the perceived need for care among women who may not be proactive in seeking mental health care and supports adherence among those who initiate care. By integrating into existing social systems such as SHGs and using existing health care systems such as community health workers (CHWs) and

XSL•FO
RenderX

the PHC, MITHRA will efficiently increase the scalability and reach of mental health treatments.

Figure 1. MITHRA conceptual model. 1. MITHRA will refer to Primary Health Center women with severe symptoms or nonresponse. 2. MITHRA provides depression screening and tracking in the community. 3. MITHRA leverages scheduled gatherings of women from the same community. 4. Education delivered through MITHRA will influence perceived need for care 5. MITHRA will potentially improve utilization rates and satisfaction with care.

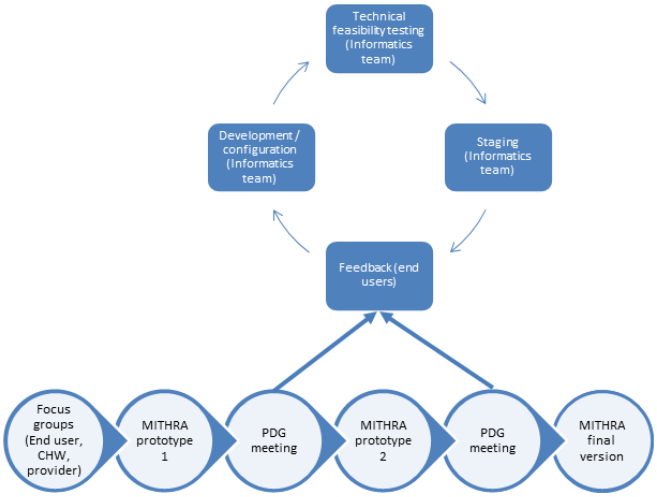
Methods

Overview

This study will be conducted in two phases—user-centered app development in Phase 1 and a pilot cluster randomized controlled trial (RCT) in Phase 2. The study site will be within the Anekal taluk, including 10 villages with functional SHGs with a total population of 9724 [34]. Focus groups and individual interviews, usability testing, and deployment of the tablet-based apps for the pilot RCT will all be conducted in these SHGs.

Study Population

In Phase 1, during app development, we will recruit women SHG participants aged 18 to 59 years and residents of the village (ie, not a guest attendee at the SHG) for focus groups. We will also recruit community health workers and administrators of the SHGs who have their current role for at least 6 months. Those who are unable to participate in the informed consent discussion will be excluded. In Phase 2, for the pilot RCT, we will recruit women aged 18 to 59 years, who are residents of the village (ie, not a guest attendee) and are planning to attend SHG meetings regularly. Women who have been diagnosed with a severe mental illness such as bipolar disorder or schizophrenia, those who have had a suicide attempt or severe alcohol or substance use in the past 6 months, and those who are unable to participate in the informed consent discussion will be excluded from the pilot RCT.



Focus Groups for App Development

App development will follow a user-centered iterative design approach (Figure 2). The process of administering the assessment questions and HAP modules will be based on the inputs provided by the SHG participants through the focus groups. One focus group will include community health workers (CHWs) and SHG administrators, and 1 will include SHG participants. We will develop interview guides [35,36] based on the acceptability on the interventions framework [37]. We will include questions on specifications such as simplified touchscreen, length of modules to be viewed, and women's preferences regarding viewing HAP modules at home or at the SHG. We will record and transcribe focus group content and analyze it using Dedoose (SocioCultural Research Consultants), a qualitative analysis software. Using a thematic content analysis approach, we will identify common themes to help guide app development.

Next, we will enroll 5 to 6 members (including CHWs and SHG participants, representing the end users of the proposed app) from the focus groups into a participatory design group (PDG). During Phase 1, the team will build a prototype for the app, which includes video content based on the HAP modules, iteratively modifying the content and interface based on discussions with the PDG. We will complete the standard life cycle of software development, which includes development and configuration. We will then deploy the working prototype on the staging environment and complete further configurative iterations based on technical feasibility testing conducted with the PDG. Once iterative modifications are complete, the final version of the app will be deployed on the production environment for the RCT.

XSL•FO
RenderX

Figure 2. Stages of development of the MITHRA (Multiuser Interactive Health Response Application) app. CHW = Community Health Worker; PDG = Participatory Design Group (CHWs and women who attend CBO meetings).

Data Analysis

We will record, transcribe, and translate the focus group content and analyze it using Dedoose. Using thematic content analysis, we will identify common themes to help guide app development. For the PDGs, we will collect end-user feedback on app prototypes until saturation of issues raised in PDG meetings is reached.

Description of MITHRA

The MITHRA app will be available on tablets placed in SHGs in an assigned private place. Each SHG will be provided with 2-3 tablets. Women can log in to MITHRA with a fingerprint-secure, single-user sign-on to complete the depression screening using the Patient Health Questionnaire-9 (PHQ-9). On completion of the PHQ-9, each woman will receive a prompt based on her total score. Those who score <5 will receive a prompt to watch general information on depression; those who score 5 or higher will watch select HAP modules, which will be short interactive multimedia-based modules, each 10 to 15 minutes long (or of other duration, based on findings from the focus group). They will also receive information on how to seek mental health care. Users can unlock virtual reward points or badges upon completion of the required questionnaires, modules, and activities. Any woman who scores anything other than 0 on question 9 of the PHQ-9 (suicidal ideation item) will be asked to call the CHW associated with that SHG. For these women, the app will also trigger an alert to the CHW, who will immediately contact the SHG administrator on site and call the patient to complete a risk assessment based on the suicidal ideation protocol [38].

The app will include a dashboard for the study team to access participant summary data and provide necessary alerts. Offline capabilities will ensure seamless use in areas with low to no internet connectivity. Data synchronization will occur at times of network connectivity, and the study team will ensure periodic synchronization of data between the study devices and servers hosted at the study team headquarters in India to ensure data security and to align with the institutional review board guidelines.

Pilot RCT

Once app development is complete, we will randomize 3 SHGs to use MITHRA and 3 SHGs to enhanced usual care (EUC). Randomization will be clustered to account for distance from the PHC. In SHGs randomized to the intervention (MITHRA), a CHW will encourage women to use the MITHRA app. At each app use, women will complete the PHQ-9 screening and modules based on their individual depression score. Women typically attend SHG meetings 2-3 times a month, and the use of MITHRA at every attendance will be encouraged.

In the EUC SHGs, CHWs will offer monthly 45-minute group education regarding the symptoms of depression. The CHWs will in turn be trained in depression, screening and common treatments, resources, and referrals by study investigators to help support group education. In both MITHRA and EUC SHGs, CHWs will conduct community outreach to encourage women to attend meetings, as depression can lead to amotivation, and women with depression may be less likely to attend SHG meetings. CHWs will maintain rosters of SHG attendees at MITHRA SHGs and EUC SHGs. In monthly review sessions with the study investigators, the CHWs will review questionnaire completion and scores and directly contact the woman (by phone or home visit or at a SHG meeting) if there is a need to step up care beyond that advised by the app. We will aim to recruit approximately 60 women across 3 SHGs. The total number of participants will depend on the number of members in each enrolled SHG, which varies. We estimate an average of 10 in each SHG, or approximately 30 each in the intervention and control arms.

At recruitment, 3 months, and 6 months, a research assistant blinded to randomization status will administer outcome assessments in person or over the telephone. To avoid unblinding of SHG randomization status (eg, the presence of tablets in the SHGs), research assessments will be carried out by phone or in the PHC.

Outcome Measures

The outcomes measures can be listed as follows: (1) app usage rates—we will obtain data on women's rates of use of the MITHRA app; (2) depression measured by Quick Inventory of

XSL•FO
RenderX

Depressive Symptoms [39] at baseline, 3 months, and 6 months. Quick Inventory of Depressive Symptoms is a measure of depression symptoms severity that is sensitive to change; (3) behavioral activation—Behavioural Activation Depression Scale [40]. We will administer the Behavioural Activation Depression Scale to all women to calculate adherence to behavioral activation recommendations (for women enrolled in the intervention arm) and to measure degree of behavioral activation (for women enrolled in the EUC arm); (4) mental health services use—we will obtain information on rates of utilization of mental health services, including number of contacts with mental health providers and details of medications taken; and (5) System Usability Scale (SUS) [41], which is a widely used validated 10-item Likert scale that can be used to determine the usability of a wide variety of products and services, including hardware, software, mobile devices, websites, and applications, and it will be measured at the end of app usage from each woman enrolled in the intervention arm. Scores are "normalized" to produce a percentile ranking. Based on research, a SUS score of above 68 would be considered above average, and anything below 68 is below average.

Data Analysis

We will descriptively summarize rates of initiation and continued use of the app in MITHRA sites. Usage rate calculations will be enabled by the single-user sign-on. We will also collect data on the usability of the app by administering the SUS to users of the app at 3 months and 6 months. For our primary outcome measures, we will perform intent-to-treat analyses. Although we expect that randomization will be successful and the 2 groups will be similar, we will compare baseline variables for differences, and in our analyses, control for variables were found to be significantly different between the 2 groups. We will use these preliminary data to examine the feasibility of randomization and measurement, as well as a methodological approach for a future larger trial, and initial signals regarding efficacy of the intervention.

Ethical Considerations

This study has been reviewed and approved by the University of Washington Institutional Review Board and the Institutional Ethics Committee at St. John's Medical College (approval number STUDY 00010415). All participants will be given adequate opportunity to ask for clarifications on study participation and procedures and will be recruited only after they provide informed consent; for those who cannot read, we will explain the study details and obtain consent by thumbprint and by recording verbal consent. A unique identifying code for each participant's data will maintain confidentiality. Any forms with identifying information, such as the informed consent forms and participant list with assigned identification numbers, will be kept separate from study data in locked cabinets or on password-protected computers. Encryption will be used wherever data are transferred. At the end of the data retention period, all patient identifiers will be deleted in compliance with Health Insurance Portability and Accountability Act regulations. The app will be available on a tablet in the CBO, in a private location with headsets to maintain privacy. Each participant will be given a unique secure single-user sign on (which can be signed in using fingerprint for illiterate participants), thereby ensuring privacy of their information on this multiple-user app. All participants will receive Rs 200 (approximately $3) for participation. This amount represents a payment for the time and potential stress associated with the study procedures, which is comparable with other similar studies at this location and commensurate with the average income in the region, ensuring that consent is not unduly influenced by financial consideration.

Results

This study was funded in June 2021. As of September 2022, we have completed both focus groups, 1 PDG, and the development of app wire frames.

Discussion

Principal Findings

The use of app-based screening in an SHG on a tablet that can be used by multiple women is in line with the description of mobile instruments as a "collectivist machine" rather than an individuality-enhancing device in rural areas of India [42]. Leveraging SHG meetings helps address the stigma and transportation-related barriers to access to depression care and overcomes the cultural and contextual barriers to mobile health use. MITHRA will support population-level symptom surveillance and tracking, monitoring adherence to recommendations, health education, and communication between patient and health worker. In addition, it can help promote awareness in the community about mental illness and help reduce stigma [43]. App-based delivery of brief psychotherapeutic interventions can address the mental health workforce shortage. In this study, we propose to iteratively develop an app to screen for depression and deliver brief psychological interventions in women's CBO. We have successfully completed focus groups with women and administrators to inform the development of the app.

Limitations

It is possible that we will encounter difficulties in developing an app that is audio enabled. However, the informatics team has substantial experience developing similar health care apps and will be able to troubleshoot accordingly. Participating women may not be enthusiastic about the use of the app. As we include input from potential users from the initial stages of app development, we hope to incorporate in our design specific features that women identify as desirable. EUC CBOs will only receive depression education from CHWs; however, this is still an enhancement compared to usual care, which is that these CBOs do not typically have depression-screening or health-education sessions.

Impact and Future Directions

If we find that the MITHRA approach is feasible, we plan to further test the implementation and effectiveness of MITHRA in multiple CBOs across India. In India, women's mental health is especially relevant to the health of the entire family as they play a multidimensional role in the family. The benefits of adequately treating depression in women will therefore accrue

XSL•FO
RenderX

in their family as well. In the future, similar apps can be deployed in men's CBOs. This approach of leveraging CBOs to improve the reach of depression screening and treatment is also applicable in rural and underserved areas across the globe. For example, in the United States, many low-income women receive support from CBOs such as Women's Infant and Children [44] and other nutritional programs and peer-support groups, and these might be appropriate platforms for app-based screening and stepped care treatment.

The next steps could include examining the feasibility of making telepsychiatry available for women with severe depressive symptoms or those who do not respond to the first-line app-based treatment. Since the onset of the COVID-19 pandemic, telemedicine is being used in many settings and is acceptable to patients. There is emerging evidence for the feasibility of telepsychiatric consultations to district hospitals from academic centers [45], and this approach could be extended to examine the feasibility and effectiveness of telepsychiatry to SHGs. If the delivery of app-based screening and brief psychological interventions is found to be feasible in this study, we will test the effectiveness of this approach in a large RCT.

Acknowledgments

We would like to thank all focus group participants and CBO (community-based organization) members and administrators for their support. This project is funded by the National Institutes of Health (NIH 1R21MH124073).

Abstract

Background: Interventions for increasing the uptake of COVID-19 vaccination among Black young adults are central to ending the pandemic. Black young adults experience harms from structural forces, such as racism and stigma, that reduce receptivity to traditional public health messaging due to skepticism and distrust. As such, Black young adults continue to represent a priority population on which to focus efforts for promoting COVID-19 vaccine uptake.

Objective: In aims 1 and 2, the Tough Talks digital health intervention for HIV disclosure will be adapted to address COVID-19 vaccine hesitancy and tailored to the experiences of Black young adults in the southern United States (Tough Talks for COVID-19). In aim 3, the newly adapted Tough Talks for COVID-19 digital health intervention will be tested across the following three southern states: Alabama, Georgia, and North Carolina.

Methods: Our innovative digital health intervention study will include qualitative and quantitative assessments. A unique combination of methodological techniques, including web-based surveys, choose-your-own-adventures, digital storytelling, user acceptability testing, and community-based participatory approaches, will culminate in a 2-arm hybrid type 1 effectiveness implementation randomized controlled trial, wherein participants will be randomized to the Tough Talks for COVID-19 intervention arm or a standard-of-care control condition (N=360). Logistic regression will be used to determine the effect of the treatment arm on the probability of vaccination uptake (primary COVID-19 vaccine series or recommended boosters). Concurrently, the inner and outer contexts of implementation will be ascertained and catalogued to inform future scale-up. Florida State University's institutional review board approved the study (STUDY00003617).

Results: Our study was funded at the end of April 2021. Aim 1 data collection concluded in early 2022. The entire study is expected to conclude in January 2025.

Conclusions: If effective, our digital health intervention will be poised for broad, rapid dissemination to reduce COVID-19 mortality among unvaccinated Black young adults in the southern United States. Our findings will have the potential to inform

XSL•FO
RenderX

efforts that seek to address medical mistrust through participatory approaches. The lessons learned from the conduct of our study could be instrumental in improving health care engagement among Black young adults for several critical areas that disproportionately harm this community, such as tobacco control and diabetes prevention.

Introduction

Background

Interventions for increasing the uptake of COVID-19 vaccination among young adults are central to ending the pandemic [1]. Given their high rate of asymptomatic infection [2], young adults represent a priority population on which to focus efforts for promoting COVID-19 vaccine uptake [1]. The acceptance of COVID-19 vaccination is lower among African American or Black (henceforth referred to as *Black*) young adults aged 18 to 29 years. In 2020, a population-based study indicated that only 42% of Black Americans reported being likely to accept vaccination against COVID-19, whereas 63% of White and Hispanic or Latinx adults were likely to accept COVID-19 vaccination [3]. In a nationally representative survey on the same topic, lower vaccine acceptance was associated with younger age [4]. Although the vaccination gap between the Black and White adult populations has narrowed, the disparity between Black and White young adults aged 18 to 29 years persists, with Black young adults being at about a 14% disadvantage when compared to their White peers [5]. COVID-19 has exacerbated the disparities experienced by Black young adults, particularly those residing in the southern United States, where health care access continues to be a barrier, and the vaccination gap between White and Black southern US adults is about 7.2% [5,6]. From May to August 2020, Black individuals accounted for 18.7% of COVID-19 deaths despite making up just 12.5% of the US population [7]. Stigma, discrimination, and distress are highest among those with intersectional identities (eg, Black, young, rural, etc) [8], reinforcing health inequities [9,10]. Recent studies found that respondents who reported experiences of racial discrimination had increased odds of higher vaccine hesitancy when compared to those who did not report such experiences and that vaccine hesitancy was intertwined with institutional distrust [11,12].

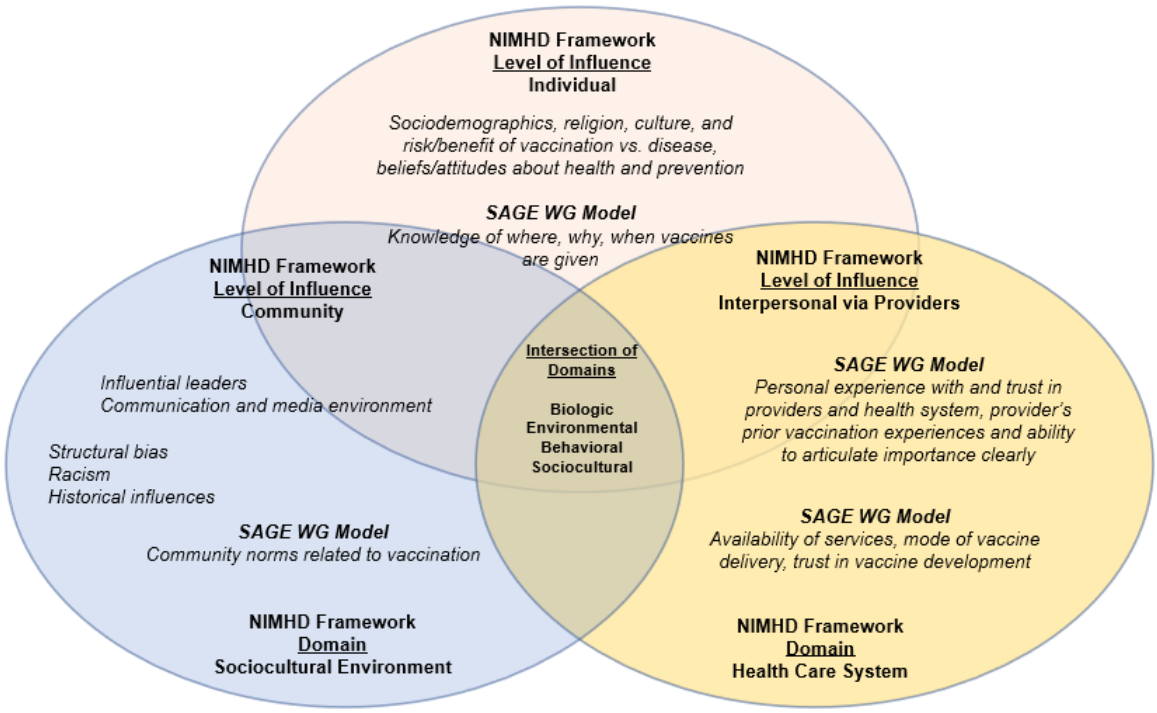
Over the past year, there have been notable changes in the epidemiology, public health recommendations, and pandemic-related mitigation strategies surrounding COVID-19. The rates of COVID-19 vaccination are currently at 61.8% in Alabama, 64.3% in Georgia, and 82.2% in North Carolina, and these rates continue to be lower among Black populations in these southern states [13]; yet, only 34.1%, 34.9%, and 25.1% of Alabama, Georgia, and North Carolina residents, respectively, have accepted a booster. Those who remain unvaccinated may be highly resistant toward accepting vaccination or overwhelmingly apathetic due to the numerous, fast-paced changes in COVID-19 knowledge and messaging that occurred during the course of the past year.

Digital health interventions (DHIs) can reach young adults regardless of geographic location and stigmatizing experiences with health care institutions [14]. DHIs can enable young adults to make informed decisions about their health, using a familiar modality that young adults value and trust. DHIs are well suited for young adults, given the ubiquity of technology use. A recent report found that 96% of 18- to 29-year-old adults in the United States owned a smartphone [15]. As such, smartphones are suitable for delivering content that is tailored to each user's unique needs. Further, DHIs have been shown to increase knowledge, self-efficacy, and motivation for change while also ameliorating distrust, fear, and stigma across a variety of health conditions [16-21]. Young adults already rely on digital technologies to build their social networks, receive social support, and obtain health information [18,22,23]. Access to credible web-based resources is critical, given that the majority of young adults access COVID-19 information from web-based news and social media sites [24].

Considering these factors, we developed this protocol to adapt a previously developed DHI in the domain of HIV status disclosure (Tough Talks) to a COVID-19 vaccine decision-making context (Tough Talks for COVID-19 [TT-C]) [25]. The TT-C intervention aims to enable Black young adults in the southern United States to make informed, autonomous decisions about COVID-19 vaccine receipt via nonstigmatizing and tailored messaging. Through engaging activities and narrative communication, TT-C will address the structural contexts (eg, issues of confidence, distrust in medicine, and stigma), misinformation (eg, vaccination knowledge), environmental barriers (eg, access to care and health insurance), and potential consequences (eg, outcomes related to accepting or refusing vaccination) [26] related to vaccine decisions. Using community-based participatory research (CBPR) methods to cocreate TT-C with Black young adults will promote personal agency, bolster resilience in the face of the pandemic, strengthen intervention quality, and increase intervention relevance and engagement [27-29].

The CBPR Approach

CBPR is a collaborative approach to science that involves authentic partnerships between researchers and the community being supported [30]. The goals of CBPR are to collaboratively create solutions, such as an intervention (as is the case in our study), that are meaningful and helpful to the community and



XSL•FO
RenderX

to partner with the community to address potential concerns or barriers. CBPR acknowledges that the community has expertise and that active participation and community feedback are essential to project success [30,31]. Considering the persistent mistreatment of Black communities within health care institutions that has resulted in skepticism and distrust toward new health interventions and research studies, the study team felt that it was imperative to adopt CBPR within the TT-C DHI research project.

Framework

Vaccine hesitancy is influenced by factors at the individual, community, provider, health care system, and societal levels [32]. As espoused by the World Health Organization Strategic Advisory Group of Experts, individual and social group influences, contextual influences, and vaccine-specific issues must be identified and targeted through multicomponent and tailored interventions to increase vaccine uptake within key populations [33]. We will therefore utilize the National Institutes of Health/National Institute of Minority Health Disparities research framework to assess multilevel factors at the individual (knowledge, attitudes, and normative beliefs), interpersonal (peer and family influences), institutional (provider communication and health care system), and structural levels (stigma and discrimination) that influence COVID-19 vaccine hesitancy and refusal. We have created a model (informed by the Strategic Advisory Group of Experts Working Group; Figure 1) that depicts the determinants that are relevant to understanding and addressing vaccine hesitancy among Black young adults [34]. This model will be used to guide the development of our intervention.

Figure 1. Vaccine hesitancy model for US-based minoritized populations. The model is informed by the NIMHD research framework and the World Health Organization Strategic Advisory Group of Experts. NIMHD: National Institute of Minority Health Disparities. SAGE WG: Strategic Advisory Group of Experts Working Group.

Objectives

Our protocol includes 3 objectives (ie, specific aims). For aim 1, we conducted multimethod formative research to elicit the behavioral, cognitive, and environmental determinants influencing COVID-19 vaccine hesitancy among Black young adults. For aim 2, in collaboration with expert advisors, community partners, and Black young adult end users, we will leverage the ADAPT-ITT (assessment, decision, administration, production, topical experts, integration, training, and testing) framework [35] to develop and refine TT-C. For aim 3, we will conduct a hybrid type 1 effectiveness implementation randomized controlled trial (RCT) with 360 Black young adults from Alabama, Georgia, and North Carolina to assess the effectiveness of TT-C in increasing COVID-19 vaccine uptake while concurrently evaluating the implementation contexts that affect intervention delivery.

Timeline

Ours is a 4-year (48-month) study, and regulatory activities will be conducted between months 1 and 6 of the study. The development team will work to adapt the Tough Talks platform to create TT-C during months 6 to 18, which will include the internal testing of the platform's features and usability (aims 1 and 2). Following feedback from the full investigative team, our expert advisors, the community, and youth advisory members, the intervention will be tested for feasibility and acceptability with youth through a technical pilot during months 18 to 24 (aim 2). We plan to launch the RCT by month 24, which will conclude at month 48 (ie, at the end of 4 years; aim 3).

XSL•FO
RenderX

Methods

Ethics Approval

All study materials and procedures were reviewed and approved by the University of North Carolina, Chapel Hill Institutional Review Board (approval number: 21-1746) and by the Florida State University Institutional Review Board (STUDY00003617). Informed consent will be collected digitally from all study participants prior to data collection and randomization. Study data will be deidentified and stored on a secure server. Study participants will receive an incentive of a US $50 gift card payment for each data collection.

Young Adult Advisory Board

Young adults from 3 states will be recruited for the TT-C young adult advisory board (YAB) through our community and academic partners, and we will pay special attention to ensuring diversity in age, gender, and vaccine-related perceptions. The TT-C YAB will be formed in the first quarter of the study and will meet monthly for the entire project period. The TT-C YAB will provide guidance on (1) young adults' knowledge, beliefs, and attitudes toward COVID-19 vaccination; (2) sources of vaccine misinformation and disinformation, support, and resource needs; and (3) strategies for communicating with Black young adults to address vaccine hesitancy. The health inequities laid bare by the pandemic and the calls for social justice for racial minorities will be the center of this approach. We will ensure that TT-C YAB members are supported to share their lived experiences and advise the investigator team on addressing racism and discrimination in TT-C.

Community Advisory Group

We include respected experts in health disparities, social justice and equity, CBPR, community activism and advocacy, and stigma. Our advisory board includes scientists of color, leadership from historically Black colleges and universities, and community advocates. Members will provide guidance on all aspects of the study. The full board will meet biannually; individual board members will meet with the study team as needed to provide feedback.

Recruitment

For all aims, our recruitment strategy includes (1) free and paid advertising and posting on social media sites; (2) information distribution through national organizations working with Black young adults, including historically Black colleges and universities; and (3) information distribution through our community partners and other network collaborations. We will use methods that were successfully deployed in our prior studies to recruit participants through social media sites that are frequented by Black young adults and rely on our network of community and academic partners for additional dissemination [36,37]. The recruitment procedures may vary slightly depending on the community organization and study phase, but all recruitment materials will use consistent messaging that frames the study as a mechanism for learning more about COVID-19 vaccines.

Eligibility Criteria

The aim 1 eligibility criteria include being aged 18 to 29 years; identifying as Black; being proficient in English; having access to a personal smartphone; and being a current resident of Alabama, Georgia, or North Carolina. The aim 2 eligibility criteria include being aged 18 to 29 years; identifying as Black; being proficient in English; having access to a personal smartphone; being a current resident of Alabama, Georgia, or North Carolina; and being hesitant toward COVID-19 vaccines. The aim 3 eligibility criteria include being aged 18 to 29 years; identifying as Black; being proficient in English; having access to a personal smartphone; being a current resident of Alabama, Georgia, or North Carolina; and being out of compliance with vaccination guidelines [38]. Participants who do not comply with vaccination guidelines include both individuals who have never received a COVID-19 vaccine and those who have not received any booster.

Screening for Eligibility

All potential participants (whether recruited via the internet or in person) will complete a web-based screening survey via Qualtrics (Qualtrics International Inc) to provide consent for screening and verify all inclusion criteria. For those who met the eligibility criteria for aim 1, the screening survey directed participants to an informed consent video with accompanying text. Those who meet eligibility criteria for aims 2 and 3 will be asked to record their first name, email address, and phone number if they are interested in participating in the study. Those who are disinterested in participating can decline by exiting the website. Potential participants who do not meet the eligibility criteria will be asked if they would like to be contacted about other research studies and, if so, to provide contact information.

Aim 1

Overview

At the time of publication, data collection for aim 1 has already been completed. Aim 1 included the following two distinct phases: a web-based survey and digital storytelling workshops. A total of 150 Black young adults were recruited from Alabama, Georgia, and North Carolina to participate in a web-based survey. A subsample was invited to participate in a web-based digital storytelling workshop to produce digital stories that will become part of the TT-C intervention.

Aim 1 Survey

Participants completed a one-time web-based survey through the Qualtrics survey platform, which included both validated survey constructs and choose-your-own-adventure formats [39,40]. Within the choose-your-own-adventure portion, participants were presented with culturally and contextually realistic scenarios, and we asked them to make decisions and reflect on the outcomes of these decision. Each story path included multiple branch points where participants made a behavioral choice. Each choice impacted the subsequent information presented and later scenario branches. Short multiple-choice questions and open-ended questions were included within each path to assess how participants made their choices and to capture their reflections on these decisions. This survey took about 30 to 45 minutes to complete. Participants

XSL•FO
RenderX

who reported high levels of vaccine confidence were invited to participate in the digital storytelling workshop.

Aim 1 Digital Storytelling Workshop

Interested and eligible survey respondents were directed to informational text that described the digital storytelling workshop and its purpose [41]. Once the participants consented, they were invited to participate in 1 of 2 web-based digital storytelling workshops; each consisted of 3 sessions. Each workshop session lasted about 3 hours, and sessions were conducted 1 week apart. Participants were informed that the goal was to develop a video that would be included in an intervention that aims to help peers learn from their COVID-19 pandemic–related lived experiences. During the workshops, participants created digital stories (1- to 3-minute videos) that included still and moving images, voice-over recordings of the participants telling their stories, and background music or text to document their experiences related to the COVID-19 pandemic and why they chose to be vaccinated. Select digital stories will be incorporated into a TT-C module entitled "Hear from you peers." This module will be available to aim 3 participants who are randomized to the intervention condition.

Aim 2

Overview

Up to 16 young adults who have expressed COVID-19 vaccine hesitancy will participate in web-based focus groups. The focus groups will consist of 2 rounds of usability testing activities that will be conducted 1 to 2 months apart. During round 1, participants will review TT-C content, generate additional ideas, and identify assets on which to build, guided by the ADAPT-ITT framework (Table 1) [35]. Young adults will provide recommendations and context-relevant insights regarding any requested additions or changes. The study team will collectively review the recommendations and prioritize and address the actionable ideas to be presented for further feedback and testing with YAB members. Beta testing will (1) allow for a full assessment of intervention content (eg, identification of any remaining spelling, text, or graphical errors) and technical functionality, (2) ensure that the back-end collection of app analytics data is being performed appropriately, and (3) help finalize pilot test procedures. All errors and technical bugs will be addressed or optimized prior to the RCT.

Table 1. ADAPT-ITT[a] model: Phases and methodology.

ADAPT-ITT phase	Aim	Study method
Assessment	1	Formative research with Black young adults via a web-based survey, digital storytelling, and focus groups
Decision	2	Adapt Tough Talks based on established feasibility, acceptability, and early effectiveness data
Administration	2	Usability testing with Black young adults in Alabama, Georgia, and North Carolina
Production	2	Produce initial intervention prototype
Topical Experts	2	Review TT-C[b] with identified scientific and community experts and young adult advisors
Integration	2	Integrate content from topical experts, young adult advisors, and Black young adult participants of the technical pilot
Training	2	Train staff on TT-C app functionality
Testing	3	Conduct hybrid type 1 effectiveness implementation randomized controlled trial

[a]ADAPT-ITT: assessment, decision, administration, production, topical experts, integration, training, and testing.

[b]TT-C: Tough Talks for COVID-19.

TT-C Intervention and Control Condition

The TT-C intervention will be finalized to be self-directed and fully asynchronous, so that there will be no need for the participants to engage with an interventionist. The initial assessments suggest that to complete all activities and review all content, the study participants will need to dedicate about 2 to 4 hours of time (spread across 1 month). Our standard-of-care control will be the provision of COVID-19 vaccine materials, which will be adapted from the Centers for Disease Control and Prevention and shared via email. Standard-of-care materials will be hosted via the internet and will be accessible to the general public. In the final phase of aim 2, the YAB and community partners will participate in an assessment of the TT-C intervention to assess intervention feasibility and acceptability and finalize RCT study procedures.

Aim 3

Overview

In aim 3, we will conduct a hybrid type 1 effectiveness implementation RCT. We will enroll 360 Black young adults from Alabama, Georgia, and North Carolina who are unvaccinated, have only received 1 dose of a 2-dose series, or have not received boosters against COVID-19 in accordance with current Centers for Disease Control and Prevention booster eligibility criteria [42]. After collecting informed consent, using block randomization by state, we will allocate 180 participants to each arm. The web-based screener will automatically randomize participants (N=360) to the control condition (n=180) or the TT-C intervention arm (n=180). Self-report data, including vaccination status, will be collected at baseline and at 1 and 3 months after baseline.

XSL•FO
RenderX

Statistical Power

Power calculations were conducted based on the assumptions that dropout would be equivalent across arms and approximately 15% of participants would be lost to follow-up; therefore, we assume that 306 participants will complete the primary end point assessment. If the rate of COVID-19 vaccination in the control arm is between 10% and 20%, we will have 80% power to detect an odds ratio of 1.92 to 3.21 when comparing vaccination uptake between arms, assuming a sample size of 306 and a 2-sided α of .05. We anticipate that the vaccination rate in the control arm will be low, given that COVID-19 vaccines have been available for some time. Therefore, we expect that a total sample size of 360 will provide sufficient power to detect a clinically meaningful difference in vaccine uptake.

Aim 3 Effectiveness Measures and Analysis

The aim 3 primary effectiveness outcome is COVID-19 vaccine uptake, which will be defined as the receipt of any COVID-19 vaccine (primary series or boosters). The secondary effectiveness outcomes are vaccine hesitancy and confidence [43], as well as vaccine knowledge, attitudes, and beliefs [44]. We will also collect quantitative data on implementation outcomes, the social cognitive theory constructs targeted by TT-C, COVID-19–specific risks and behaviors, and pertinent constructs that have been validated in the extant literature on Black young adults (Table 2).

Table 2. Effectiveness measures.

	Baseline	Follow-up
Number and percentage of participants who receive any new vaccine during the study period (eg, participants who accept the first dose of a COVID-19 vaccine, complete the vaccine series, or receive a booster shot)		✓
Vaccine hesitancy [32], confidence [43], knowledge [45], attitudes, and beliefs [32]	✓	✓
Usability (including acceptability; ie, TT-C[a] satisfaction and completion), demand (including the number of youths screened, enrolled, and retained), and practicality (based on the TT-C intervention's cultural appropriateness and fit) [46]		✓
Physical environmental factors (access, utilization, and vaccine misinformation), social environmental factors (discrimination, as measured via the Adapted Everyday Discrimination Scale for Medical Settings [47]; stigma; social support, as measured via the MOS[b] social support survey [48]; social norms; and medical mistrust, as measured via the Group-Based Medical Mistrust Scale [49]), outcome expectations (COVID-19–specific knowledge, attitudes, and beliefs), observational learning (vaccination [eg, flu or HPV[c]] experiences of self or others), and perceived self-efficacy (vaccination barriers and facilitators)	✓	✓
Sociodemographic characteristics (age, race, ethnicity, gender identity, income, employment, and education [eg, current student])	✓	✓
Pre-existing conditions (eg, diabetes, cardiovascular conditions, etc)	✓	✓

[a]TT-C: Tough Talks for COVID-19.

[b]MOS: Medical Outcomes Study.

[c]HPV: human papillomavirus.

We will use logistic regression to determine the effect of the treatment arm on the probability of vaccination uptake ("yes" or "no") at month 3. We will focus on the odds ratios for comparing the probability of vaccination in the treatment group with the probability of vaccination in the control group. As an exploratory analysis, we will examine primary and secondary outcomes by enrollment vaccination status (not vaccinated vs vaccinated with 1 or 2 doses and no booster shot). The secondary outcomes—vaccine hesitancy [4]; vaccine confidence [43]; and vaccine knowledge, attitudes, and beliefs [44]—will all be assessed by using previously validated scale scores, of which each will consist of the continuous sum of responses to a series of questions with Likert scale responses. We will use linear regression models with treatment group as the exposure to determine whether continuous secondary outcomes vary among treatment groups. Lastly, we will use the causal mediation framework proposed by Valeri and Vanderweele [50] to understand the mechanisms for any intervention effects through each of our hypothesized mediators [50-53]. We will use the *g-formula* command in Stata (StataCorp LLC), which uses the mediational g-formula, to estimate the controlled direct effects, natural direct effects, and natural mediated (indirect) effects [54].

In sensitivity analyses, we will also use inverse probability of treatment weights to account for missing data and potential differential retention between study arms over the study period. We will weight outcome models by using stabilized inverse probability of censoring weights that include the treatment arm as a predictor to account for differential loss to follow-up.

Aim 3 Implementation Outcomes and Analysis

We will conduct qualitative interviews with a group of purposively selected participants (we estimate 18-24 participants) to assess how the intervention was internalized and experienced. We will conduct in-depth exit interviews on a rolling basis after participants have concluded the 3-month study cycle. All interviews will be audio-recorded and transcribed verbatim. Qualitative analyses will be conducted in the NVivo (QSR International) coding program. Study participants will be asked questions on how sociocultural nonintervention contexts affected the likelihood of vaccine acceptance, vaccine series completion, and vaccine hesitancy.

XSL•FO
RenderX

Interviews will last about 1 hour. We will perform a rapid content analysis, which is routinely used in implementation science to assess and disseminate results quickly and accurately [55]. The findings will be explored as a function of participant age, sex, and state. Qualitative findings will provide direct insight into real-world implementation considerations.

Results

Our study was funded at the end of April 2021. Approval from the University of North Carolina, Chapel Hill Institutional Review Board was obtained shortly thereafter. Aim 1 data collection concluded in early 2022. The entire study is expected to be complete at the end of January 2025.

Discussion

Overview

The TT-C intervention will address COVID-19–related vaccine hesitancy among Black young adults in Alabama, Georgia, and North Carolina by including tailored content to engage Black young adults and promote agency and autonomy in decision-making related to vaccination, while also addressing the persistent effects of historic contexts and structural stigma and racism against Black populations in the United States. The TT-C DHI will address issues that not only impact COVID-19 vaccine uptake but also influence the acceptance of other vaccines and health services, such as addressing medical distrust, highlighting the role of Black scientists in vaccine development and medicine, and providing tailored content on how to assess misinformation. The TT-C app will be developed to retain relevance as the pandemic shifts, and it can be adapted to address other conditions that disproportionately affect Black young adults.

Limitations

In assessing trial designs, we considered stepped wedge and waitlist formats. However, since our aim is to reach Black young adults who are often not engaged in care, particularly those in the southern United States, we determined that multipronged recruitment and individual-level randomization would be the best approaches. Because the landscape of COVID-19 prevention and related science are quickly changing (eg, masking, the definition of *fully vaccinated*, etc), ideally, the app should be flexible and responsive. Although the content delivered through the TT-C app is adaptable, not all components can be adjusted once they are developed.

Conclusion

If the TT-C DHI is effective in increasing COVID-19 vaccination uptake among Black young adults in the southern United States, we will be poised for rapid dissemination and broad implementation to reduce COVID-19 morbidity and mortality among unvaccinated or partially vaccinated Black young adults in the southern United States.

Acknowledgments

The research reported in this publication was supported by the National Institute of Minority Health Disparities of the National Institutes of Health under award number R01MD016834. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

The data sets generated during aim 3 of our study will be shared in compliance with National Institutes of Health data sharing policies and will be made available from the senior author on reasonable request.

Authors' Contributions

LBHW (contact principal investigator) and HB are co–principal investigators of the study. HB is the first and lead author. LBHW is the last and senior author on this protocol manuscript. MAL is the mobile app development lead. EET, ACMB, and MLGC provided leadership on digital storytelling and community engagement. MCDS and DB are statistical and quantitative experts. KEM and AP are epidemiology and intervention scholars who are contributing their expertise to the study. CT and CLB are part of research operations. All authors contributed to the writing and editing of this protocol.

Conflicts of Interest

None declared.

Protocol

Layperson-Facilitated Internet-Delivered Cognitive Behavioral Therapy for Homebound Older Adults With Depression: Protocol for a Randomized Controlled Trial

Abstract

Background: Depression in older adults has serious biological, psychological, and social consequences. Homebound older adults experience a high burden of depression and significant barriers to accessing mental health treatments. Few interventions to address their specific needs have been developed. Existing treatment modalities can be challenging to scale up, are not tailored to unique population concerns, and require significant staffing support. Technology-assisted, layperson-facilitated psychotherapy has the potential to overcome these challenges.

Objective: The aim of this study is to assess the efficacy of a layperson-facilitated internet-delivered cognitive behavioral therapy program tailored for homebound older adults. The novel intervention, Empower@Home, was developed based on user-centered design principles and partnerships between researchers, social service agencies, care recipients, and other stakeholders serving low-income homebound older adults.

Methods: This 2-arm, 20-week pilot randomized controlled trial (RCT) with a waitlist control crossover design aims to enroll 70 community-dwelling older adults with elevated depressive symptoms. The treatment group will receive the 10-week intervention immediately, whereas the waitlist control group will cross over and receive the intervention after 10 weeks. This pilot is part of a multiphase project involving a single-group feasibility study (completed in December 2022). This project consists of a pilot RCT (described in this protocol) and an implementation feasibility study running in parallel with the pilot RCT. The primary clinical outcome of the pilot is the change in depressive symptoms after the intervention and at the 20-week postrandomization follow-up. Additional outcomes include acceptability, adherence, and changes in anxiety, social isolation, and quality of life.

Results: Institutional review board approval was obtained for the proposed trial in April 2022. Recruitment for the pilot RCT began in January 2023 and is anticipated to end in September 2023. On completion of the pilot trial, we will examine the preliminary efficacy of the intervention on depression symptoms and other secondary clinical outcomes in an intention-to-treat analysis.

Conclusions: Although web-based cognitive behavioral therapy programs are available, most programs have low adherence and very few are tailored for older adults. Our intervention addresses this gap. Older adults, particularly those with mobility difficulties and multiple chronic health conditions, could benefit from internet-based psychotherapy. This approach can serve a pressing need in society while being cost-effective, scalable, and convenient. This pilot RCT builds on a completed single-group feasibility study by determining the preliminary effects of the intervention compared with a control condition. The findings will provide a foundation for a future fully-powered randomized controlled efficacy trial. If our intervention is found to be effective, implications extend to other digital mental health interventions and populations with physical disabilities and access restrictions who face persistent disparities in mental health.

Introduction

Background

Depression in older adults has serious consequences, including worsened physical health and chronic disease progression [1-3], increased functional limitations and disabilities [4,5], institutionalization [6], and premature mortality due to comorbid conditions and suicide [7,8]. Low-income and homebound older adults are especially at high risk for experiencing depression. In one US representative sample, estimates for rates of depression in homebound older adults were approximately 40% [9]. Further complicating this burden of depression is a recent steep increase in the number of homebound older adults, likely in part driven by COVID-19 [10].

Although evidence-based pharmacological and nonpharmacological treatments exist, not all options are readily accessible to all populations of older adults [11]. Low-income and homebound older adults face significant access barriers to mental health treatments due to mobility, transportation, and financial difficulties. In addition, few providers have specialized training in working with older populations [12,13]. Given the lack of service providers, high rates of depression in specific subpopulations of older adults, and demographic trends toward a higher number of homebound older adults, interventions that are both accessible and scalable are urgently needed.

Digital mental health interventions have the potential to address the gaps in mental health treatment faced by low-income and homebound older adults. Affirming this, a recent national panel of expert stakeholders recommended that digital mental health interventions be broadly adopted and that insurers expand their coverage and reimbursement [14]. Cognitive behavioral therapy (CBT) is an evidence-based form of psychological treatment and has been adapted to multiple age groups [15-17] as well as medical and social contexts [18,19]. CBT is well suited for digital-based delivery, given its highly structured format and skill-based learning [20]. Hundreds of clinical trials have taken place in the last decade to test internet-delivered CBT (iCBT) and presented robust findings supporting the acceptability and effectiveness of this treatment modality [21-25]. iCBT is convenient and self-paced, less expensive than traditional psychotherapy, and scalable due to content delivery automation.

Research has consistently shown that tailoring treatment to specific populations, contexts, and settings is associated with increased uptake, acceptability, and sustainability [26,27]. In the case of older adults, procedural and content modifications to CBT have been discussed that incorporate differences in thinking styles in older adults and age-related adjustments [28]. However, when packaged for internet delivery, empirically supported iCBT programs often employ a one-size-fits-all approach, and very few have been designed to consider the needs of older adults [29-31]. In general, older adults are underrepresented in iCBT trials. A review found that only 3% of iCBT trial participants were older adults [32]. Since then, older adults' participation has increased. However, a recent systematic review found that older adults are still largely under-represented as participants in rigorously designed studies [25].

Recent studies involving homebound older adults have shown that modifications to both contents (eg, adding aging-related themes) and web interface (website or app) are needed to improve adherence and engagement with iCBT [33,34]. These studies suggest that older adults had difficulty applying lessons when presented with content that failed to address aging-related topics and were less tolerant to poor usability issues, possibly due to a combination of age-related changes (eg, cognitive, vision, motor control, speech, and hearing), physical disabilities, and their lack of familiarity with modern technology. Most well-established iCBT programs contain a large amount of text, are highly didactic, and are hosted on interfaces that are not age-friendly (eg, small text and buttons). Usability issues and technical challenges are frequently reported, which can lower adherence and ultimately reduce treatment effects. The lack of tailored solutions may be more problematic for homebound older adults, who tend to be older, less tech-savvy, have more cognitive and functional limitations, and are more likely to experience usability issues [35].

Objective

The primary aim of this study is to evaluate the efficacy of a 9-session iCBT program in treating depression in low-income homebound older adults. Additional outcomes and potential covariates will be captured, including anxiety, loneliness, and health-related quality of life.

A lack of iCBT products suitable for homebound older adults reflects and contributes to the digital divide experienced by them. Barring treatment innovation, older adults will continue to be left behind and face persistent mental health disparities related to access. This study aims to fill this void by testing the preliminary effects of a novel iCBT program designed for homebound older adults.

Intervention Model

Empower@Home is an iCBT program designed to treat the core symptoms of depression in older adults. It consists of 9 web-based sessions grounded in CBT principles and homework assignments (ie, weekly practices) made available over 10 weeks. Each lesson is presented as a series of short videos with

XSL•FO
RenderX

voice-overs that include didactic text, images of diverse older adults, inspirational quotes, and interactive exercises. Sessions are written at an eighth-grade reading level, and all spoken content is captioned. The weekly home practice tasks are modest and typically require 20 minutes or less of commitment from the user. A workbook with summarized session content and home practices is also provided to participants.

The sessions are enhanced with an animated case story series featuring a 74-year-old homebound woman named Jackie. The animated story is embedded within each session, like an episode of a television show. This content serves to reinforce core skills and techniques taught. Prior research has found that including short multimedia entertainment is a useful approach for communicating learning objectives in psychoeducational materials [36].

The session scripts of Empower@Home were developed by a team of researchers, clinicians, older adults, and social service providers via a co-design process. The web platform that delivers Empower@Home is a custom learning management system built using state-of-the-art, agile development processes. All interface features are compatible with accessibility standards and current best practices for making an age-friendly user interface and experience design [37]. For example, the main user interface features large buttons, text, icons with text descriptions, high-contrast color schemes, and intuitive navigation.

Informed by the Efficiency Model of Support [38], support from trained laypersons called Empower Coaches supplements the core web-based sessions of Empower@Home. Human support aims at increasing a participant's ability to use the technology to obtain the intended treatment outcome [38]. Previous studies have shown that supported iCBT is more effective and associated with better adherence than unsupported interventions [39-41]. However, support mechanisms are generally underspecified and understudied, and it is not entirely clear what type and intensity of support are needed for homebound older adults to engage in iCBT successfully.

Informed by our previous research and the Efficiency Model of Support, we provide weekly check-ins with a supportive guide (ie, Empower Coach). The weekly check-ins are Coach-initiated contacts designed to prevent and address potential failure points, including engagement, working knowledge of the iCBT platform, and implementation of iCBT. All weekly check-ins are telephone-based. The Empower Coaches are laypersons without specialized mental health training or independent clinical licensure. The support content includes simple feedback, encouragement, homework review, and assistance with self-help tools without additional traditional therapy. Coaching sessions are highly individualized to meet the particular needs of the participants. On the basis of participants' preferences, they may use the weekly check-in sessions to go over the web-based program with their coaches, whereas others complete the web-based portion on their own before the phone-based check-in sessions. Coaching sessions can range from 5 minutes to an hour per week, depending on the participants' needs and preferences.

Coach training involves reviewing all web-based sessions of Empower@Home (takes approximately 4-5 hours to complete), a self-directed asynchronous web-based training (approximately 1.5 hours), and a synchronous training workshop (approximately 3 hours). The total training burden is approximately 9-10 hours per coach.

Methods

Preliminary Study

The procedures described in this protocol, including recruitment, assessments, coaching calls, and device shipments and returns, have been tested in a completed single-group uncontrolled feasibility study. Findings from the single-group study have not yet been published, but preliminary analysis shows that the intervention is feasible and acceptable, with high satisfaction ratings, and is associated with significant within-group reductions in depressive symptoms and several secondary clinical outcomes. Study procedures for the pilot randomized controlled trial (RCT) are refined based on lessons learned from the feasibility pilot.

Study Setting and Aims

The study will be managed from the University of Michigan in collaboration with community agencies serving older adults. Participants will reside throughout Michigan in both rural and urban areas. All participants will be 60 years or older and are expected to be predominantly low income. Participants will complete the intervention in their own homes, with all assessments and technological support provided remotely by phone.

Eligibility Criteria

To be eligible for the trial, participants must be at 60 years or older and have at least mild depression (score of ≥8 on the Patient Health Questionnaire-9 [PHQ-9]). Participants will be excluded if they (1) have probable cognitive impairment based on the Blessed Orientation-Memory-Concentration Test (score ≥10), (2) do not speak English, (3) have moderate to high risk of suicide based on the Columbia-Suicide Severity Rating Scale, (4) have a terminal illness or are in unstable physical health with a high risk of repeated hospitalizations within the next 3 months, (5) have a visual impairment based on self-reported inability to use a screen with correction, (6) have a current or recent history of substance use based on a score of ≥2 on the CAGE-AID Substance Abuse Screening Tool, (7) have a psychotic disorder based on self-report, or (8) are currently receiving psychotherapy. The study will not exclude participants based on racial or gender identification. Completing the intervention will require a tablet and internet accessibility. Participants are not required to have a computer or internet access; those who lack 1 or both resources will be provided a tablet and access to the internet at no cost during the active intervention period.

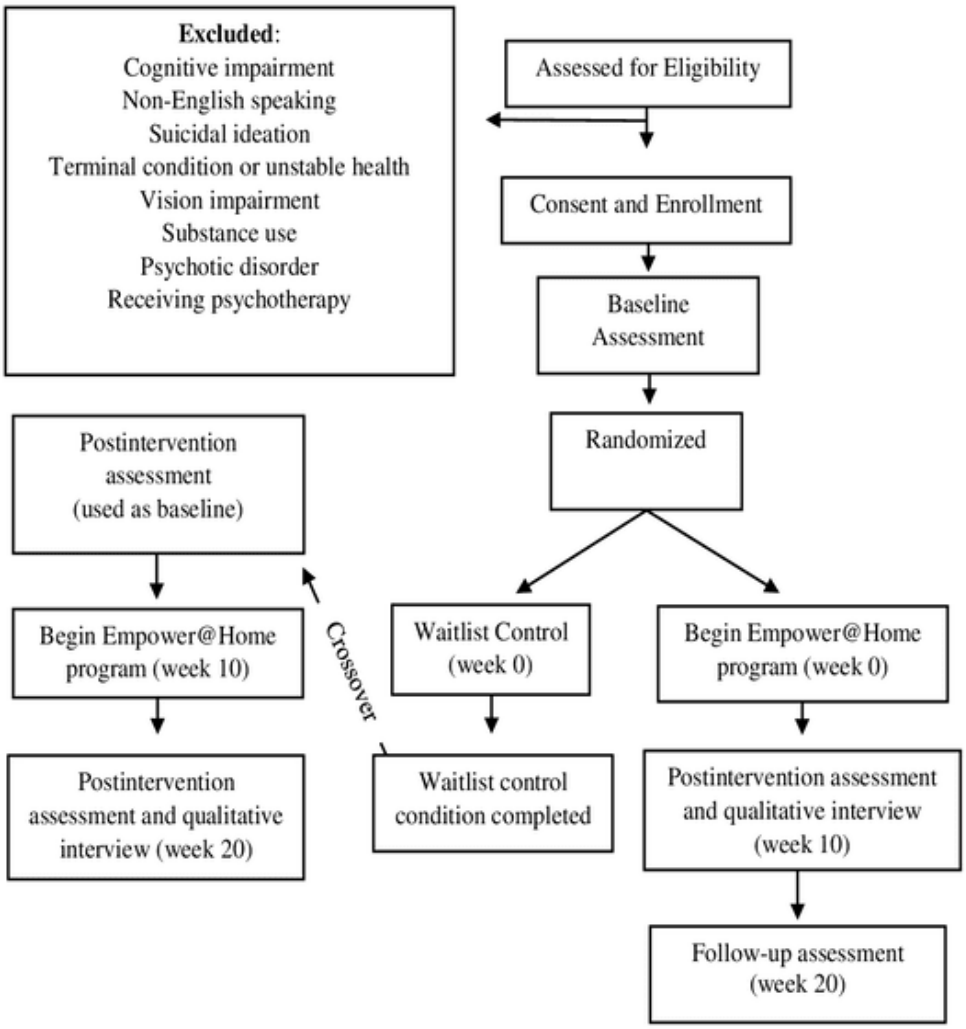
Recruitment and Compensation

Participants will be recruited into the study on a rolling basis and will be drawn from multiple community agencies as well as other public places, including social media and local news

XSL•FO
RenderX

outlets. The social service agencies that participated in this study's intervention development and implementation feasibility phase were predominantly Area Agencies on Aging based throughout Michigan. These agencies serve older adults by offering services to enable their clients to maintain independence. These services may involve case management, caregiver services, and meals on wheels. These agencies will refer participants to the study based on their judgment of the appropriateness of the intervention for their clients.

After receiving referrals, study personnel will contact potential participants via phone to screen for eligibility. The initial screening is expected to take 20 minutes to complete. Participants will provide recorded verbal consent. Those who decline to participate will be referred back to their case managers or agency when possible. Advertisements placed via social media (eg, Facebook and Nextdoor) and through research registries will also allow participants to self-refer and be screened for eligibility.



Those who qualify for the trial will be paid up to US $100. Compensation is determined based on the number of assessments completed. Partial compensation is available (eg, participants who complete only the baseline assessment will receive US $30).

Study Design

Eligible and consented participants will be assigned either to an active treatment or a waitlist condition group that will cross over to the intervention at 10 weeks. A computer-generated random sequence will be used for assignment into either condition at a ratio of 1:1. Given the content of the intervention and study design, blinding the participant and evaluator to the condition will not be feasible.

All participants will be assessed using the same schedule. All will be invited to complete the comprehensive baseline assessment, postintervention or control assessment at week 10, and a follow-up assessment at week 20. Participants on the waitlist control will receive the intervention after their post-test at week 10 (Figure 1).

Figure 1. Study design.

Waitlist Condition

The attention control waitlist condition involves a comparable amount of phone contact to the intervention condition, with roughly 20 minutes of companionship calls per week. However, in the attention control, participants will not be exposed to CBT-related content. The purpose of companionship calls is to

XSL•FO
RenderX

provide socialization and contact with supportive individuals without introducing structured therapeutic content.

Discontinuation

Consented participants may still be deemed ineligible during study participation if they develop significant clinical worsening of depression, suicidal ideation, or other circumstances (eg, terminal illness or prolonged hospitalization) that preclude their ongoing involvement with the trial. Participants will be consulted regarding potential removal. Should a participant report suicidal ideation, a protocol will be in place that involves the participation of the study principal investigator and a clinical social worker. Should a participant's circumstance interfere with their ongoing participation in the trial, the study team will discuss the risks and benefits of the participant's ongoing involvement with the trial until a consensus is reached. If there is a clinically significant worsening of depressive symptoms, considerable effort will be made to expedite entry into the best available treatment outside the research protocol.

Clinical Management and Storage

All data related to the study (screening, pretest, coaching sessions, posttest, and follow-up) will be entered directly by project staff into REDCap [42]. During the active intervention, participants will be asked to fill out the PHQ-9 every other week, administered as a part of the web-based therapy lesson. These assessment data are stored in a HIPAA (Health Insurance Portability and Accountability Act)–compliant database hosted by the University of Michigan.

Measures

All measures are presented in Table 1. The primary clinical outcome in the study will be depressive symptoms as measured by the PHQ-9. The PHQ-9 is widely used in clinical research and has been used to evaluate older adults with medical and psychiatric illnesses in and outside of health care settings [43,44]. The PHQ-9 has been found to perform comparably to the Geriatric Depression Scale in identifying depression in older adults [45]. Scores on the PHQ-9 can range from 0 to 27 and indicate minimal, mild, moderate, moderately severe, or severe depression symptom severity. Sample items include "In the last week, have you had little interest or pleasure in doing things?" and "In the last two weeks, have you been feeling down, depressed, or hopeless?" Respondents indicate answers on a 4-point Likert scale ranging from "not at all" to "nearly every day." In primary care patients, the measure has a sensitivity of 88% and a specificity of 88% [43]. The PHQ-9 will be administered at initial screening, baseline, after intervention, and 20-week follow-up. In addition, participants will complete a PHQ-9 self-assessment built into the web-based sessions every other week. To mimic the additional assessment patterns in the treatment group, participants in the control condition will also be administered the PHQ-9 every other week via phone during the 10-week waiting period.

Table 1. Study measures and time points.

Variable	Assessment or activity	Screening	Baseline	Postrandomization		Follow-up
				Biweekly	Post	
Depression	PHQ-9[a]	✓	✓	✓	✓	✓

Health self-assessment	PROMIS-GH[d]		✓		✓	✓
Well-being and quality of life	EQ-5D-5L		✓		✓	✓
Skill acquisition	CBTSQ[e]		✓		✓	✓
Acceptability	Modified TEI[f]				✓	
Adherence	Session completion				✓	
Participant background	Sociodemographic, health status, and physical functioning	✓	✓			

[a]PHQ-9: Patient Health Questionnaire-9.

[b]GAD-7: Generalized Anxiety Disorder-7.

[c]PROMIS-SI 8a: Patient-Reported Outcomes Measurement Information System–Social Isolation 8a.

[d]PROMIS-GH: Patient-Reported Outcomes Measurement Information System–General Health.

[e]CBTSQ: Cognitive-Behavioral Therapy Skills Questionnaire.

[f]TEI: Treatment Evaluation Inventory.

Anxiety will be assessed with the General Anxiety Disorder-7, which has been validated in populations of older adults [46]. Sample items include "How often have you been bothered by feeling nervous, anxious, or on edge in the last two weeks?" and "How often have you been bothered by worrying too much about different things in the last two weeks?" Like the PHQ-9, respondents answer on a 4-point Likert scale ranging from "not at all" to "nearly every day." In primary care patients, the measure has a sensitivity of 89% and a specificity of 82% [47].

Social isolation will be measured using the Patient-Reported Outcomes and Measures Information System–Social Isolation

XSL•FO
RenderX

(PROMIS-SI 8a). This measure has been used extensively in older adults with chronic health conditions and depression [48-50]. This 8-item measure uses a 5-point Likert scale with responses ranging from "always" to "never." Sample items include "I feel isolated from others" and "I feel that people avoid talking to me." The PROMIS-SI has high internal consistency (Cronbach α=.91) [51].

The PROMIS–General Health (PROMIS-GH) will be used as a global measure of health and health-related quality of life. This 10-item measure uses a 5-point Likert scale ranging from "excellent" to "poor." It contains items such as "In general, would you say your health is...?" and "In general, how would you rate your satisfaction with your social activities and relationships…?" The PROMIS-GH has been validated in older adults with chronic health conditions, demonstrating moderate internal reliability (ordinal α=.82-.88) [52].

Quality of life will be measured using the EQ-5D-5L. Respondents answer on a 5-point Likert scale ranging from "I have no problems with…" to "I am unable to…/I have extreme…" They rate their experience in 5 life areas (mobility, self-care, usual activities, pain, and anxiety or depression). It also includes an overall health ranking on a scale of 0-100. In a systematic review including 99 studies that included a diverse range of medical conditions, the EQ-5D-5L exhibited overall excellent psychometric properties [53].

To explore the role of CBT skill acquisition, participants will complete the Cognitive-Behavioral Therapy Skills Questionnaire. This validated 16-item questionnaire assesses a respondent's ability to apply cognitive restructuring, behavioral activation, and other CBT-related skills [54]. Participants are asked how often they currently do sample activities, such as making plans over the weekend, motivating themselves to do things, and socializing even though they do not want to. Items are answered on a 5-point Likert scale ranging from "I don't do this" to "I always do this."

Acceptability will be assessed by the number of sessions participants completed (ie, adherence) and the modified Treatment Evaluation Inventory. This 11-item inventory has been previously used to evaluate the acceptability of cognitive therapy for depression interventions among older adults and has good convergent validity and internal consistency (α=.92) [55]. The measure will be administered after the intervention. The measure is answered on a 5-point Likert scale ranging from "never" to "always."

Qualitative Interviews

After completing the intervention, participants will complete a semistructured qualitative interview lasting roughly 30 minutes. The interview probes several domains, including their experience with the program, likes and dislikes, and experience with specific program components (eg, storyline, home practice, materials, and ease of use). Additional questions will relate to participants' relationship with their Empower Coach.

Sample Size

A sample size of 70 (n=35 per group) should provide at least 80% power, allowing for a 20% attrition rate for both arms. Specifically, we considered the case where the 2 arms are compared in terms of weekly changes in the mean PHQ-9 survey responses between the baseline, 5 interim in-app PHQ-9 assessments (roughly at weeks 1, 3, 5, 7, and 9), and the 10-week follow-up PHQ-9 survey. We assume that the changes in the mean response can be expressed in terms of a linear trend, and the treatment effect can be expressed in terms of the difference in slopes or rate of change ($\delta = -0.8 \times 5$ in the total PHQ-9 score over 10 weeks; 5 is the SD in the change scores in our feasibility study). Sample size estimates used the following inputs: (1) type I error rate (α)=.05; (2) the smallest meaningful difference to be detected (δ) over the 10 weeks; (3) power (γ)=.80; (4) we assumed that outcome within-subject variance ($\sigma^2=6^2$; estimated from our feasibility study data) is constant over time; (5) the number of repeated measurements per person (n): 1 baseline, 5 in-app assessments, 1 final postbaseline for a total of 7 repeated assessments; and (6) regarding between-subject variation of the slopes, we assumed a variance of random slopes $\tau^2=0.2$ (estimated from our feasibility study data). The sample size is 52 for both arms with equal randomization probabilities; with an attrition rate of 20% for both arms, the total required sample size is 65. We set the final target sample size to 70 to allow room for higher attrition and lower adherence.

Analytic Plan

To reduce bias, analyses will involve an intention-to-treat design. Linear mixed models will be used to test within-group changes over time and to compare changes between the treatment and control groups in outcomes of interest. The LASSO (least absolute shrinkage and selection operator [56,57]) variable selection technique will be used to find the optional selection of covariates for the final model. Exploration of mechanisms of change variables involves a procedure described by Hayes [58] that uses bootstrapping to test indirect effects. Statistical analysis will be conducted using Stata 15 SE. Although this trial is not fully powered for mediation analysis, findings from these analyses will inform future research to identify mechanisms of change.

We will use a pragmatic approach involving inductive and deductive coding for qualitative data. Qualitative analysis of the interview data collected from the completed single-group feasibility study is underway, and a codebook will be created during the process. The codebook from the single group study will serve as a framework for us to code the qualitative data collected from the pilot RCT. The codebook will be iteratively refined by reviewing the data and themes several times. Qualitative analysis will be conducted using Dedoose, a web app for mixed methods research.

Ethics Approval

This study was reviewed and approved by the Health Sciences and Behavioral Sciences institutional review board (IRB) at the University of Michigan. Approval was granted on April 19, 2022 (HUM00212950).

A waiver of documentation for written consent was approved by the IRB. Consent to participate in the study will be obtained orally from participants. Consent will be obtained at 2 points. At first contact, participants will provide consent to be screened.

XSL•FO
RenderX

Second, after screening and before the baseline interview, study-eligible participants will be asked to provide oral consent to participate in the study. This will be recorded via a tape recorder after a verbal review of an informed consent document. To ensure the quality of consent, all participants will reconsent at the beginning of the first web-based session of the intervention. This will be accomplished by providing a brief written consent document on the first page of the web-based session. Participants must confirm their understanding of the document to proceed to the first web-based session.

The privacy of participants will be protected in several ways. All participants will complete web-based therapy sessions by themselves in their private homes. Direct identifiers are not stored in the web-based program. Mental health assessment data collected as part of the web-based sessions are stored in a HIPAA-compliant database. Other study data (eg, baseline and posttest assessments) are entered and managed on REDCap. Only the study team members directly authorized by the principal investigator will have access to study data with identifiers. Access is typically restricted to the principal investigator and project coordinators. As the study involves follow-up, direct identifiers will be retained for this purpose. After completion of the study and data cleaning, all direct identifiers will be removed from the database, rendering the final data set anonymous.

Those who qualify for the trial will be paid up to US $100 for participation. Compensation is determined based on the number of assessments completed. Partial compensation is available (eg, participants who complete only the baseline assessment will receive US $30). Participants will be provided US $30 for the baseline, US $50 for the posttest, and US $20 for the follow-up. Payment will be provided directly to the participant via mailed check or Visa gift card, whichever is preferred by the participant.

Results

Funding for this multiphase project was awarded in November 2020. IRB approval for the single-group feasibility study and the proposed RCT was attained in April 2022. Enrollment for the single-group study began in May 2022, and all subjects completed the intervention by December 2022. Recruitment for the RCT began in January 2023, and the study completion is anticipated by December 2023. The trial is registered at ClinicalTrials.gov (NCT05593276).

Discussion

Principal Findings

To our knowledge, this is the first RCT of layperson-facilitated iCBT for low-income homebound older adults with depression. We hypothesize that the Empower@Home intervention will be feasible and acceptable, reduce depressive symptoms, and improve psychosocial functioning and health-related quality of life. Existing evidence-based mental health treatments are often inaccessible to homebound older adults, who have been largely excluded from digital mental health interventions. This trial addresses that gap by testing an intervention specifically designed to the needs of this population.

iCBT participants are exposed to the same components as conventional CBT, though they receive psychoeducational materials through a self-directed internet platform. A meta-analysis of iCBT trials with older adults found a large pooled within-group effect size, although most studies adopted weak designs [24]. In a recent iCBT pilot trial led by the last author, homebound older adults with low computer literacy found that iCBT was an acceptable way of treating depression and resulted in significant reductions in depressive symptoms at the posttest [33]. A recent RCT showed that iCBT also effectively prevented depression among older adults with multiple chronic conditions [29].

As a result of the COVID-19 pandemic, virtual care is gaining rapid traction, which provides unprecedented opportunities for integrating digital mental health interventions into community aging services. The COVID-19 pandemic has accelerated the adoption of technology and virtual care in community settings, which is likely to stay after the pandemic. Although notable age differences in technology use remain, the adoption of key technologies by older adults has grown markedly, and the age-related digital divide continues to narrow. For example, smartphone ownership increased from 46% in 2018 to 61% in 2021 among those 65 years and older [59]. Given the increased focus on digital inclusion, there is likely to be continued growth in access to broadband internet. The Affordable Connectivity Program (formerly Emergency Broadband Benefit), a long-term, US $14 billion program authorized by the 2021 Infrastructure Investment and Jobs Act, provides up to US $30 per month toward internet service and up to US $100 to purchase a computer or tablet device for eligible households. With providers and clients more willing to use technology, increased funding, regulatory changes, and improved technology infrastructure, digital mental health interventions are ripe for implementation in community aging services, where many homebound older adults receive services.

The pilot RCT will provide crucial data for a fully-powered effectiveness trial in the future. If confirmed effective, several probable funding mechanisms can facilitate long-term sustainability. These funding sources include Medicaid, federal grants, private pay, and commercial insurance. For example, community agencies can apply for federal grants authorized by the Older Americans Act that support community-based health-promotion programs. Many commercial insurance providers are already reimbursing for iCBT services [60,61]. Agencies could also charge a sliding scale fee to cover operating costs and raise revenues. In terms of training, most of the provider training materials are web-based, making it relatively easy to scale up.

Strengths and Limitations

The strengths of this study include an iteratively developed intervention incorporating patient and provider feedback, randomized design, use of laypersons as interventionists, and recruitment of an underserved, hard-to-reach population with high unmet mental health needs. For limitations, this study uses a small sample size and a waitlist control design, which may

XSL•FO
RenderX

lead to an overestimation of treatment effects [62]. Though this intervention is intended to address depression in older adults, it may also address related conditions not measured in this study, such as demoralization [63,64].

Conclusions

The planned study addresses the shortage of iCBT products suitable for homebound older adults. Our treatment innovation, if found effective, will contribute to closing the digital divide and mental health disparities in homebound older adults. Study implications extend to other digital mental health interventions and populations with physical disabilities and access restrictions who face persistent disparities in mental health.

Abstract

Background: Well-being is multidimensional, complex, and dynamic in nature. It is an amalgam of physical and mental health, essential for disease prevention and the promotion of a healthy life.

Objective: This study aims to explore the features that impact the well-being of individuals between 18 and 24 years of age in an Indian setting. It further aims to design, develop, and evaluate the usefulness and effectiveness of a web-based informatics platform or stand-alone intervention to enhance the well-being of individuals aged 18-24 years in an Indian setting.

Methods: This study follows a mixed method approach to identify factors influencing the well-being of individuals in the age group of 18-24 years in an Indian setting. The college-going students in this age group from the states of Uttarakhand (urban settings of Dehradun) and Uttar Pradesh (urban settings of Meerut) will be enrolled. They will be randomly allocated to the control and intervention groups. The participants in the intervention group will have access to the web-based well-being platform.

Results: This study will examine the factors that influence the well-being of individuals aged 18-24 years. It will also facilitate the design and development of the web-based platform or stand-alone intervention, which will enhance the well-being of individuals in the age group of 18-24 years in an Indian setting. Furthermore, the results of this study will help generate a well-being index for individuals to plan tailored interventions. The 60 in-depth interviews have been conducted as of September 30, 2022.

Conclusions: The study will help understand the factors that influence the well-being of individuals. The findings of this study will help in the design and development of the web-based platform or stand-alone intervention to enhance the well-being of individuals in the age group of 18-24 years in an Indian setting.

Introduction

Background and Rationale

Well-being combines physical and mental health, essential for disease prevention and the promotion of a healthy life. It is complex and multidimensional in nature. Well-being consists of objective and subjective measures. The objective measures indicate the quality of life, whereas the subjective measures comprise spiritual, social, psychological, affective, and cognitive judgments [1].

Psychological well-being refers to the psychological aspect. It consists of hedonic well-being (eg, the feeling of happiness), evaluative well-being (eg, contentment from life), eudaimonic well-being (eg, self-actualization, to know the meaning of life), and the other aspects of feeling well (eg, optimism) [1].

Mental health is described as a condition of well-being in which the person understands his or her ability to manage the usual pressures of life, can work effectively and productively, and can also contribute to the community [2]. As per Global Health Estimates 2016, the leading cause of nonfatal disease is mental and substance use disorders [3]. In the United States in 2017, more than 46.6 million adults were reported to have mental illness in the previous year [4]. In the entire world, in 2017, mental health was the second leading cause of the burden of disease in terms of years lived with disability and the sixth main factor of disability-adjusted life-years, which is a substantial threat to health systems, especially in low- and middle-income countries. Mental health is considered a crucial factor around the world; therefore, it is included in health policies and Sustainable Development Goals [5].

One-fourth of the entire world population is between 10 and 24 years of age, and in South Asia and Africa, 1 in 3 people are young. Mental health problems range from 10% to 20% worldwide among children and young people [6]. A study in 27 countries assessed the pooled prevalence of global mental health problems to be 13.4% among children and young people [7]. Disruptive behavior was commonly observed among children and young people. It is estimated that, in young people aged 16-24 years, 1 in 4 has experienced a minimum of 1 mental health issue in the previous year. The literature has shown that young people worldwide are less aware of mental health. To promote the mental well-being of young individuals, there is a need to educate them, raise awareness, and develop interventions [8].

As per the Registrar General of India, 34.8% of India's population is between 15 and 34 years of age, and it is projected to be 34.1% by 2021. In India, in 2017, the prevalence of mental disorders was 197.3 million, which comprised 45.7 million people with depressive disorders and 44.9 million with anxiety disorders [9]. This was due to an increase in issues like nutritional disorders, phubbing, sedentary lifestyles, social media addiction, and substance abuse in lower-income countries. A study has been carried out in rural India to find the effectiveness of delivering evidence-based psychological treatment for depression by training community health workers [10]. One of the prior studies has shown an association between unhealthy eating and anxiety, stress, and depression in university students [11].

Research has demonstrated the usefulness and effectiveness of web-based interventions in youth with mental health issues [8]. It has been seen that young people feel more comfortable gathering mental health information through the internet for sensitive and personal matters. Therefore, studies recommend that there be a need to promote personalized digital health interventions (DHIs). The intervention should have the ability to engage individuals by sending personalized messages, reminders, or alerts to increase motivation. Research has also shown that technology acceptance and user engagement can be increased by using pictures and interactive content [12].

The findings of one study depicted that, to promote well-being to a significant population level, there is a need for intervention and educational programs in all segments of society [13].

However, there is limited literature on DHIs to improve the well-being of youth in India [14,15].

Study Objectives

The following are the proposed study objectives:

1. To examine factors that influence the well-being of individuals aged 18-24 years in an Indian setting
2. To design and develop the web-based platform or stand-alone intervention to enhance the well-being of individuals in the age group of 18-24 years in an Indian setting
3. To evaluate the usefulness and effectiveness of the proposed informatics-enabled decision aid platform to enhance the well-being of individuals aged 18-24 years in an Indian setting

Methods

Study Design and Population

A mixed methods approach will be adopted that uses both qualitative and quantitative data to identify factors influencing the well-being of individuals in the age group of 18-24 years in an Indian setting. In this study, 100 individuals will be enrolled each in the intervention and control group at Uttarakhand and Uttar Pradesh colleges.

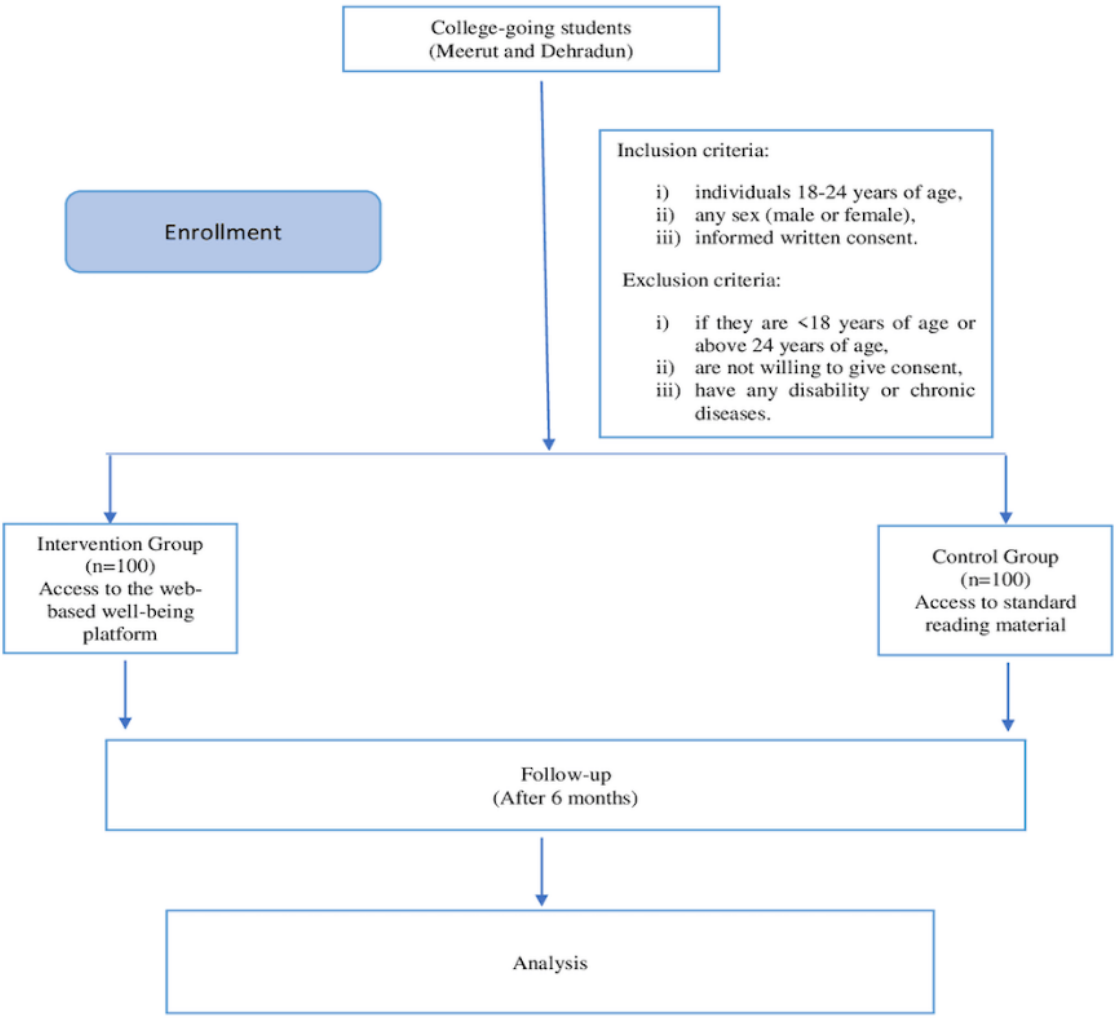
We will design and develop the proposed platform using human-centered design principles. Individuals will be randomly allocated to an intervention group (access to the proposed well-being platform) and a control group (standard education). The standard educational material will be mailed to the participants in pdf format on the following topics:

- Importance of physical activity
- Role of a balanced diet
- How to cope with depression, anxiety, and stress
- Steps to lead a healthy life

Study Setting

We will recruit college-going students aged 18-24 years from the states of Uttarakhand (urban Dehradun) and Uttar Pradesh (urban Meerut).

XSL•FO
RenderX



Study Eligibility

The inclusion criteria are as follows: (1) individuals 18-24 years of age, (2) of any sex (male or female), and (3) willing to give informed written consent.

Participants will be excluded if they are younger than 18 years or older than 24 years, are not willing to give consent, or have any disability or chronic diseases. Figure 1 shows a schematic illustration of the methodology.

This study will follow a mixed methods pre- and postapproach for data collection using electronic data collection tools for qualitative and quantitative data from the study participants.

Figure 1. Schematic illustration of the methodology.

Achieving Objective 1

We will conduct 60 in-depth interviews by enrolling participants from Dehradun and Meerut. These interviews will be conducted through Zoom meetings, and the sessions will be recorded after having consent from the participants. Both quantitative and qualitative data will be gathered from the participants. In the interview, the participants will be asked questions to assess their awareness of well-being, the challenges they come across, how they deal with them, and the impact of COVID-19 on their well-being. Each interview will take around 15-45 minutes.

The data collected will help us examine the factors that influence the well-being of students in the age group of 18-24 years. Emphasis will also be placed on understanding individuals' prior knowledge and attitude related to stress, unhealthy diet, and physical inactivity.

The data will be gathered on the following variables: sociodemographic profile, medical history, and anthropometric status; familiarity with technology; health behavior; Depression, Anxiety, and Stress Scale (DASS-21); General Self-Efficacy Scale; psychological well-being scales; global physical activity; and dietary diversity.

In addition, content analysis of the qualitative data will help generate critical themes on the well-being of students in the age group of 18-24 years in an Indian setting.

Achieving Objective 2

We will use principles of a human-centered approach to design and develop a web-based informatics platform to improve the well-being of individuals in the age group of 18-24 years in an Indian setting.

The usability of the web-based informatics platform will be evaluated by individuals who will use it and will provide

XSL•FO
RenderX

feedback. The literature has shown that a 10-item Likert scale questionnaire called System Usability Scale calculates the usability of websites, mobile devices, hardware, software, and other technological applications. Based on the feedback on usability evaluation, system modification can be done. Finally, the proposed web-based well-being platform will be implemented in a randomized controlled trial to evaluate its usefulness and effectiveness.

Achieving Objective 3

We will perform a randomized controlled trial with 100 college-going students from Dehradun and Meerut each in the intervention and control group. So the total number of students enrolled will be 200. The students will be randomly allocated to either a control group or an intervention group. The students in the intervention group will have access to the web-based well-being platform. A study was carried out to evaluate the efficacy of a web- and mobile-based intervention on college-going students (n=150) [16].

The data will be collected on the following variables: sociodemographics, health behavior, health literacy, depression, stress, anxiety assessments, general efficacy, physical activity, and dietary pattern at baseline and a follow-up at 6 months.

Study Groups

The study participants will be randomly allocated either to the intervention group or the control group.

Intervention Group

The participants in the intervention group will have access to the web-based well-being platform. It can be accessed from an Android smartphone or web-based platform. The proposed platform will have the following components: (1) screening component, (2) learning component, and (3) evaluation component.

- Screening component: Variables recorded in the screening component include sociodemographics; health behavior (eg, physical activity levels and anthropometric assessments); health literacy; family history; familiarity with the use of technology; well-being scale; depression, stress, and anxiety assessments; and self-efficacy levels. In the screening component of the intervention, we will evaluate the health literacy level according to the education that will be given to the individual. Based on the data collected, a well-being index will be constructed to reflect on the variables attributing to the well-being of the youth. As the literature shows, well-being is dependent on various factors and is affected by the physical, social, and economic environment, life experience in every stage, family, poverty, and activity pattern [17,18].
- Learning component: Based on the well-being index generated for each individual, tailored messaging will be done using a series of culturally and contextually relevant messages. In this component, the individuals will get personalized feedback after interpreting the information gathered on all the parameters asked. In addition, they will receive weekly reminder messages to follow healthy behavior for their excellent well-being.
- Evaluation component: We will assess the usefulness and acceptance of the system using the system usability scale and monitor the usage. In addition, we will determine youth well-being using the well-being scale at baseline and a follow-up at 6 months.

Informed Consent

The ethics committee of the university has approved the informed consent form. The research team will obtain the consent from all the individuals participating in the study. The research team will also explain them the analysis, duration, and need of the study. Individuals who are willing to participate will be asked to sign the consent form, and a copy of the consent form with study details will be given to them. The study is on college-going students, so everyone will be able to read and write. The research team is aware of both English and Hindi language, so they will be able to understand the response. The data captured will be stored safely and protected. The confidentiality of data will be maintained. The participants will be allowed to withdraw from the ongoing study anytime by giving reasons to withdraw. All the data gathered, including those from the participants who will withdraw, will be reported for the final analysis. No monetary compensation will be given to the participants enrolled in the study. The voluntary participation and time of the participants will be respected.

Data Collection, Data Entry, and Quality Assurance

The data will be collected and entered by following standard techniques and protocols. Complete confidentiality of the information obtained from the study participants will be ensured. Frequent backups will retain all the data gathered, and all computers and specific data files will be password protected and kept in a locked file cabinet.

Variable Assessment

Sociodemographic and Family History

The questionnaire included questions regarding the demographic factors of the respondents, like age, sex, family history, educational status, occupation, and income levels.

Health Behavior

Four crucial behavioral risk factors will be collected: tobacco consumption, alcohol consumption, impact of COVID-19, and sleep duration.

Familiarity With Technology

Individual assessment will include access to the type of smartphone, familiarity with the use of the internet, and knowledge of texting.

Anthropometric Measurements

Variables assessed include duration of diabetes, recent blood sugar report, type of medication, and height and weight measures that would help calculate BMI.

The measures in Textbox 1 will be administered.

XSL•FO

Access to the smartphone and internet and knowledge of texting
Health behavior
Information on smoking, alcohol, physical activity, and substance abuse disorders
Well-being scale
Ryff scale
Depression, stress, and anxiety assessments
Depression, Anxiety, and Stress Scale
Self-efficacy
General Self-Efficacy Scale
Dietary diversity
Food and Nutrition Technical Assistance Diet Diversity
Anthropometric measurements
Height, weight, BMI
Physical activity
Global Physical Activity Questionnaire
System usability
System Usability Scale

Data Security and Privacy

The data security will be done through regular backups, and all computers and specific data files will be password protected and kept in a locked file cabinet. In addition, the computers in which data is stored will be password protected and safely stored for 3 years after the completion of the study.

Outcomes

The well-being index generated from this study can be used in other geographic regions for a similar population. If the youth of a nation is healthy, it will lead to the country's growth.

The primary outcome of the study will be development of the student well-being index among urban settings. This will also facilitate the understanding of the various factors that affect the student well-being.

The secondary outcome of this study will further help us to understand the relationship between sociodemographic factors with dietary diversity, physical activity, depression, stress, and anxiety among college-going students.

A cross-sectional study was conducted, and the results showed significant associations between physical activity levels and sleep quality with mental health. The mental health issues are the same in both male and female college students [19].

The outcomes will be assessed by using the following tools.

Health Literacy

Health literacy is defined as the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health [20]. Conversely, low literacy can create misunderstanding of the environment and impact health outcomes [21].

Health literacy requires acquiring information, processing it, and then understanding the data to develop the reasoning required to make the decision. Many studies have shown that literacy level is related to cost and health characteristics like knowledge, health status, and health facilities. However, little work has been done on the health literacy of adolescents and young adults. The literature also shows the association between poor health literacy and adverse health outcomes such as smoking and obesity [22].

The Rapid Estimate of Adult Literacy in Medicine is one of the most accepted tests to assess health literacy. This test is performed by seeing the patient's potential to pronounce 66 words, including lay terms for parts of the body, illnesses, and common medical words. It is a quick tool that can be administered in less than 2 minutes. As a result, it is one of the most popular tools for assessing health literacy levels. The scoring is divided into 2 groups: 0-44=low health literacy and 45-66=higher health literacy.

XSL•FO
RenderX

Well-being Scale

The Ryff scale is a 42-item scale that measures 6 dimensions of well-being and happiness: environmental mastery, self-acceptance, purpose in life, positive relations with others, autonomy, and personal growth [20].

Depression, Anxiety, and Stress Scale

A randomized control trial was conducted on young adults to reduce the symptoms of depression with a brief diet intervention. In this study, the DASS-21 tool will be used to assess the symptoms of depression [23].

This scale evaluates depression, anxiety, and stress associated with a negative emotional situation. It is a 42-item self-report questionnaire that has been concise to a scale of 21. It measures on a 0-3 pointing scale, where 0 is for "did not apply to me" and 3 stands for "applicable to me or majority of the time."

Dietary Diversity

In lower-income countries, dietary diversity tools are used to study dietary adequacy. Dietary diversity is a significant problem among poor people as they usually consume starchy staples with or without limited consumption of animal products, fruits, and vegetables [24].

The Food and Nutrition Technical Assistance Diet Diversity score will be computed based on the information obtained regarding consuming several food items within each food group.

General Self-Efficacy Scale

It is a 10-item tool validated in Asia [7]. It can also be applied to diverse cultural backgrounds and positively correlated with depression, anxiety, and optimism. To calculate the total score, the total of all items is considered. The total score ranges between 10 and 40, with a higher score indicating more self-efficacy. It is universally accepted and considered an adequate scale to measure self-reported self-efficacy. A relation has been seen in general self-efficacy and social cognitive variables, health behavior, and well-being [25,26].

International Physical Activity Questionnaire

The International Physical Activity Questionnaire is considered a validated tool to monitor physical activity among youth and older adults in diverse settings [27].

The participants will complete the questionnaire so that their physical activity can be assessed. The total time spent in physical activity for recreation, occupation, household work, and transportation in the past 7 days will be calculated. The total weekly physical activity (metabolic equivalents of task [MET-hour/week]) will be calculated as the weighted sum of the reported time spent at each intensity using an MET value specific to each category.

Data Analysis Plan

The data gathered at baseline will include sociodemographics, KAP (knowledge, attitude, and practice), diet assessment, physical activity, health literacy, social media, and familiarity with technology. Baseline and follow-up data collected will be statistically analyzed.

For continuous and categorical variables, means and SDs and frequencies, respectively, will be calculated. Finally, cross-tabulation of the data from the intervention group against outcome variables will be done to calculate the direction and degree of association in this initial stage. The analysis will be done using SAS v9.3 (SAS Institute), and the results will be reported at 95% CIs and P=.049.

Project Timeline and Milestone

A detailed timeline is presented in Table 1.

Table 1. Scheduled timeline of the tasks in the study.

Ethics Approval

This study has received ethical approval from the University Research Ethics Committee of Dehradun Institute of Technology University, Dehradun, India (Protocol DITU/UREC/2021/07/9, dated July 21, 2021). The study results will be presented at conferences and webinars to disseminate information to researchers. The results will also be published in national and international scientific journals.

XSL•FO
RenderX

Results

This study will bring forward the factors that influence the well-being of individuals aged 18-24 years. The 60 in-depth interviews had been conducted by September 30, 2022. Thematic analysis of the qualitative data gathered through the in-depth interviews will be performed. The evidence-based well-being index will be generated for the youth.

Discussion

Principal Findings

This research will help understand the factors that influence the well-being of individuals aged 18-24 years. It will also provide in-depth information on the barriers and challenges among youth for well-being. As this is the most critical period of their development, these barriers and challenges will affect their productivity and will indirectly affect their families and community if left unresolved. The findings of this study will help in the design and development of a web-based platform or stand-alone intervention to enhance the well-being of individuals and evaluate the usefulness and effectiveness of the proposed informatics-enabled decision aid platform to improve well-being in the age group of 18-24 years in an Indian setting.

Well-being is the fundamental human goal, which includes feeling good and functioning well [28]. Considering all the variables on which data have been collected, we will develop the well-being index. The World Health Organization-5 Well-Being Index is a simple, short measure of subjective well-being. This scale is used for screening for depression [29] and will also consider other aspects of well-being.

The well-being index generated from this study can be used in other geographic regions for similar populations. If the youth of a nation is healthy, it will lead to the country's growth.

Limitations

The first limitation of this study will be the recalling bias as the participants have to fill out the questionnaires on their own. Second, the small sample size will make it difficult to generalize the results on a large number of students.

The study results will be presented at conferences and webinars to disseminate information to researchers. The results will also be published in national and international scientific journals.

Conclusions

This study will be able to bridge the gap of well-being in college-going students. It is seen that mental health issues are prevalent in low- and middle-income countries due to lack of mental health care. It has a negative impact on the academic performance of university students [30]. As digital health technologies are getting popular and will play a key role in future, it is important that a multidisciplinary approach should be undertaken; only this can bring a change from digital health to digital well-being [31].

The evidence-based digital mental interventions that can be implemented using smartphones or web-based platforms are required for college-going students as they can reduce the existing barriers to getting traditional mental health services that include time and sigma as well [32].

Protocol

A Relational Agent Intervention for Adolescents Seeking Mental Health Treatment: Protocol for a Randomized Controlled Trial

Abstract

Background: Unmet pediatric mental health (MH) needs are growing as rates of pediatric depression and anxiety dramatically increase. Access to care is limited by multiple factors, including a shortage of clinicians trained in developmentally specific, evidence-based services. Novel approaches to MH care delivery, including technology-leveraged and readily accessible options, need to be evaluated in service of expanding evidence-based services to youths and their families. Preliminary evidence supports the use of Woebot, a relational agent that digitally delivers guided cognitive behavioral therapy (CBT) through a mobile app, for adults with MH concerns. However, no studies have evaluated the feasibility and acceptability of such app-delivered relational agents specifically for adolescents with depression and/or anxiety within an outpatient MH clinic, nor compared them to other MH support services.

Objective: This paper describes the protocol for a randomized controlled trial evaluating the feasibility and acceptability of an investigational device, Woebot for Adolescents (W-GenZD), within an outpatient MH clinic for youths presenting with depression and/or anxiety. The study's secondary aim will compare the clinical outcomes of self-reported depressive symptoms with W-GenZD and a telehealth-delivered CBT-based skills group (CBT-group). Tertiary aims will evaluate additional clinical outcomes and therapeutic alliance between adolescents in W-GenZD and the CBT-group.

Methods: Participants include youths aged 13-17 years with depression and/or anxiety seeking care from an outpatient MH clinic at a children's hospital. Eligible youths will have no recent safety concerns or complex comorbid clinical diagnoses; have no concurrent individual therapy; and, if on medications, are on stable doses, based on clinical screening and as well as study-specific criteria.

Results: Recruitment began in May 2022. As of December 8, 2022, we have randomized 133 participants.

Conclusions: Establishing the feasibility and acceptability of W-GenZD within an outpatient MH clinical setting will add to the field's current understanding of the utility and implementation considerations of this MH care service modality. The study will also evaluate the noninferiority of W-GenZD against the CBT-group. Findings may also have implications for patients, families, and providers looking for additional MH support options for adolescents seeking help for their depression and/or anxiety. Such options expand the menu of supports for youths with lower-intensity needs as well as possibly reduce waitlists and optimize clinician deployment toward more severe cases.

Introduction

Background

In 2021, leading child-focused organizations declared a national emergency in child and adolescent mental health (MH) [1], echoed by the Surgeon General's advisory on youth MH [2]. The prevalence of MH concerns among youths has increased exponentially since the onset of the COVID-19 pandemic [1], with recent estimates indicating a doubling of clinically elevated depression and anxiety symptoms [3]. Depression onset in adolescence confers risk for long-term depression as well as other psychiatric sequelae [4,5]. Similarly, persistent untreated anxiety in adolescence can interfere with typical development, potentially affecting the foundation for longer-term well-being, resilience, and functioning [6]. The World Health Organization states that depression and anxiety are the leading cause of illness and disability among adolescents [7], but only 41.6% of adolescents with a major depressive episode were treated in the past year [8]. Lack of access to child MH clinicians skilled in high-quality, evidence-based psychotherapy is an unfortunately common and familiar treatment barrier for many adolescents [9]. The rising incidence of MH concerns coupled with unmet needs for care underscores that innovative alternative approaches for adolescent MH care are urgently needed.

"Stepped care," a MH service delivery approach recommended by the National Institute for Health and Care Excellence, suggests that individuals (including youths) with lower-acuity symptoms initially receive low-intensity services, such as guided self-help, bibliotherapy, or brief therapeutic or supportive interventions, as the first "step" in their care [10]. Those with initial higher-acuity or persistent symptoms after low-intensity intervention receive more intensive services. Stepped care models attempt to distribute limited clinical intervention resources optimally [10]. Early low-intensity intervention options may include technology modalities such as smartphone app-delivered interventions. Integrating such technology-leveraged treatment options within a health care ecosystem increases the total continuum of service offerings and may reduce waitlists as well optimize clinician deployment toward more severe cases.

Technology-Leveraged MH Care Interventions

Decades of research and treatment guidelines suggest that cognitive behavioral therapy (CBT) is the treatment of choice for adolescents with depression and/or anxiety [11,12]. Indeed, CBT is efficacious when delivered in guided self-help and group-based formats [13,14] or via telehealth [15]. Computer-delivered, rather than clinician-delivered, CBT programs are also effective among an adolescent population [16]. However, these programs suffer from poor adherence, as well as limited tailoring and interactional styles typical in CBT treatment [17,18]. Recently, the availability of MH applications for youths, including video games, mood trackers, journals, and text-based solutions [16], has grown exponentially, yet data on their clinical efficacy remain limited. More meaningful interactions may be possible through the use of interactive technology, such as conversational agents. This may be particularly advantageous in adolescent MH interventions, as this group is well-versed in conversational agent and texting interactions [19]. Such interactions may improve users' treatment responsiveness to interventions [20,21].

Woebot for Adolescents (W-GenZD) is an investigational mobile app with a relational agent, "Woebot," that offers a CBT-guided self-help program designed to reduce symptoms of depression and/or anxiety. Although primarily based in CBT, W-GenZD also includes elements of other well-researched and scientifically validated psychotherapeutic interventions including interpersonal psychotherapy for adolescents and dialectical behavior therapy [22,23]. Previous research on other Woebot programs have demonstrated feasibility, acceptability, and preliminary efficacy among various populations including young adults with depression [18], adults with substance abuse concerns [24], and adult women with postpartum mood concerns [25]. A retrospective analysis with over 35,000 adults found that users reported forming a therapeutic alliance with Woebot [20]. Therapeutic alliance, a construct familiar in psychotherapeutic treatment outcomes research, refers to the therapeutic relationship and affective bond between provider and patient and is associated with the efficacy of psychotherapy [26,27]. A randomized controlled pilot among adolescents aged 13-17 years (n=17) demonstrated W-GenZD's preliminary feasibility and utility in an outpatient primary care pediatric setting [28], but further evaluation of its feasibility and acceptability as well as clinical efficacy is warranted.

The proposed study (trial registration: ClinicalTrials.gov NCT05486611) seeks to understand the feasibility and acceptability of W-GenZD among adolescents seeking treatment for depression and anxiety. The study will also compare 2 forms of technology-leveraged interventions, W-GenZD and brief telehealth-delivered CBT-based skills group (CBT-group), among adolescents presenting with depression and/or anxiety. Both interventions are conceptualized as potential "first-step" interventions within a stepped care model. The setting for the study is an outpatient children's hospital that currently deploys a brief telehealth-delivered CBT-group as a first step for youths screened and triaged into low-intensity intervention.

Methods

Objectives

The primary aim of this randomized controlled study will be to evaluate the feasibility and acceptability of W-GenZD for adolescents with depression and/or anxiety in an outpatient children's hospital system. Feasibility and acceptability will be assessed through self-report measures rating intervention feasibility, acceptability, and satisfaction, as well as study

XSL•FO
RenderX

enrollment, app engagement, and group attendance. The secondary aim will be to compare the clinical impact of both the W-GenZD and skills group to reduce depression symptoms at 4 weeks end of treatment (EOT) relative to baseline (BL), with a corresponding hypothesis that W-GenZD will be noninferior to the skills group. As tertiary aims, therapeutic working alliance, mood, and anxiety levels in both groups will be assessed. Exploratory aims will include the observation of the utilization and performance of the safety procedures utilized within this study (please see below for a description of the safety net protocol and adverse event and serious adverse event assessment).

Study Design

This study will randomize adolescents aged 13-17 years seeking treatment for depression and/or anxiety to the W-GenZD or CBT-group. The study will include 3 core assessments at screening/BL, EOT at week 4, and end of study (EOS) at week 8, plus 2 brief surveys to be completed 5 days and 2 weeks after randomization. The primary outcomes for feasibility and acceptability will be assessed at EOT; app engagement and group attendance metrics will be collected throughout the intervention period. Self-reported depression symptoms (secondary aim) will be collected via the 8-item Patient Health Questionnaire (PHQ-8) [29] at BL, week 2, EOT, and EOS. Therapeutic working alliance (tertiary aim) will be assessed at day 5 as well as at EOT. Mood and anxiety levels (tertiary aims) will be assessed via the Mood and Feelings Questionnaire (MFQ) [30] and Generalized Anxiety Disorder questionnaire (GAD-7) [31], respectively, at BL, EOT, and EOS. Exploratory outcomes, specifically the utilization of safety procedures will be collected throughout the study.

Ethics Approval

This study was reviewed and approved by WIRB-Copernicus Group institutional review board on March 31, 2022 (#20221397). Subsequent modifications were implemented to refine eligibility criteria, enhance recruitment language, and provide further clarification within the informed consent forms.

Study Population

Study Setting

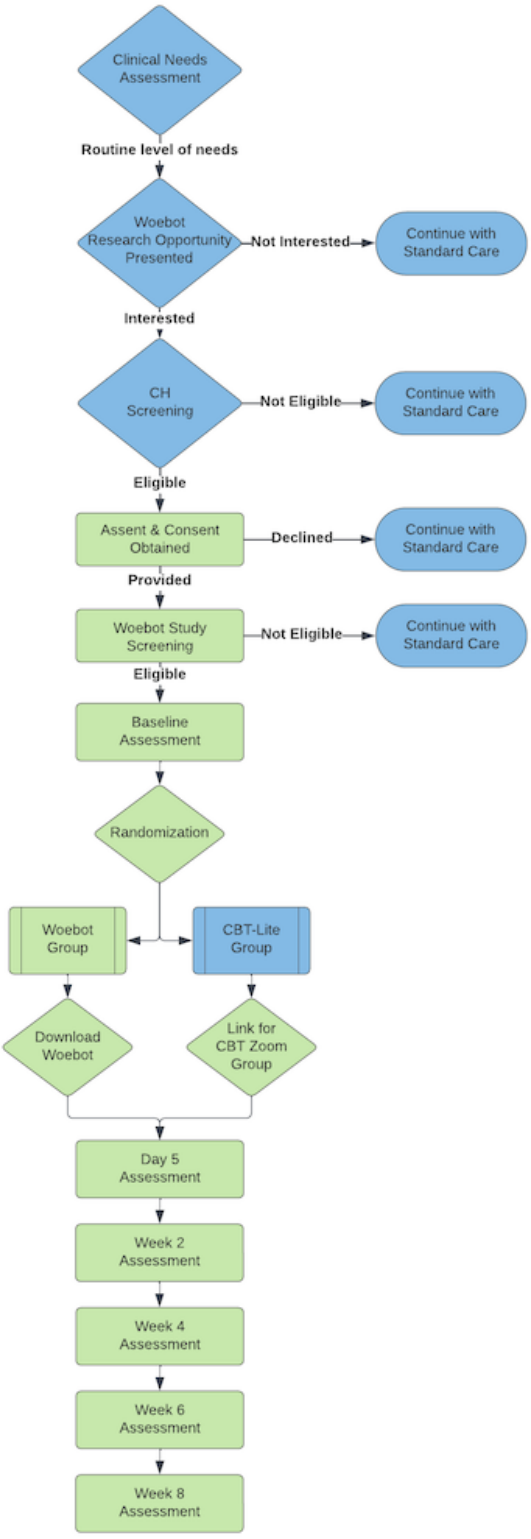
The study site is a 206-bed, freestanding not-for-profit children's hospital and the heart of an integrated pediatric health care system. Situated in the southeastern United States, the hospital serves a racially and economically diverse region that is home to approximately 500,000 youths younger than the age of 21 years. The outpatient practice's stepped care model begins with a semistructured brief clinical needs assessment, which identifies unmet basic needs and the level of care needed. Youths who meet 1 or more of the following criteria indicate a higher level of needs and are fast-tracked to comprehensive assessment and individual treatment: have had suicidal ideation within the last 2 weeks or is a current risk to self/others, present symptoms of psychosis, meet criteria for an active eating disorder, have a history of mania, have a substance use disorder as the primary clinical problem, are at an imminent risk of expulsion, or are currently prescribed 4 or more psychotropic medications. Most patients with routine level of needs are offered low-intensity, telehealth skill-based group interventions while waiting for individual treatment. Patients who decline or are not appropriate for the specific groups are placed on a waitlist for individual treatment. The proposed study did not influence or change these prescreening criteria.

Recruitment

Youths with low-intensity needs who are not currently in therapy and who have not had recent medication changes are invited to learn more about the proposed study. Families receive information about the study through a flyer in a practice registration packet, the elevators, and waiting room. Caregivers of all children seen in the practice are invited to provide verbal or written consent for contact from the research team for more information about the study. Clinicians are encouraged to provide information about the study after the initial clinical needs assessment for youths who may be eligible. Study staff will reintroduce the study over the phone and assess the family's (adolescent and parent/guardian) interest in participating.

In terms of waiting list management, participants in need of additional care are able to access individual treatment after the study concludes. If a waiting list opening becomes available during the study, participants are informed of this and can choose to accept it. If accepted, they are withdrawn from the study. If participants access treatment from another provider during the study, they are withdrawn from the study.

Inclusion and Exclusion Criteria



Youths eligible for participation in the proposed study must also meet all of the following study-specific inclusion criteria: (1) have a routine level of need based on a brief clinical needs assessment; (2) have a diagnosis of depression and/or anxiety; (3) be 13-17 years of age, inclusive; (4) be a US resident; (5) be able to read and write in English (adolescent and parent/guardian); (6) own or have reliable access to a smartphone and reliable Wi-Fi access or sufficient data to engage with assigned treatment condition for the duration of the study; (7) be on a stable dose of any psychiatric medications for at least 60 days; (8) not be currently engaged in psychotherapy; (9) be available and committed to engaging with the program and complete assessments for an 8-week duration; and (10) have a family member who can engage in the discussion of safety planning in the event of suicidal ideation.

Youths who meet any of the following exclusion criteria will not be eligible for participation: (1) lifetime diagnosis of a psychotic disorder (including schizophrenia or schizoaffective disorder), bipolar disorder, autism spectrum disorder, or pervasive developmental disorder; (2) current diagnosis of developmental delay or intellectual disability; (3) reported suicidal ideation with a plan or intent or a suicide attempt within the past 12 months; (4) history of diagnosis of substance abuse within the past 12 months; (5) current use of benzodiazepines or certain sleep aids (zolpidem, eszopiclone, and zaleplon); (6) previous Woebot application use; and (7) enrollment of more than 1 member of the same household. Participants who meet all inclusion criteria and none of the exclusion criteria will complete BL assessments and be randomly assigned to a study

XSL•FO
RenderX

treatment condition. Figure 1 shows the participant flow through the study.

Figure 1. Participant flow through the study. CBT: cognitive behavioral therapy; CH: children's hospital.

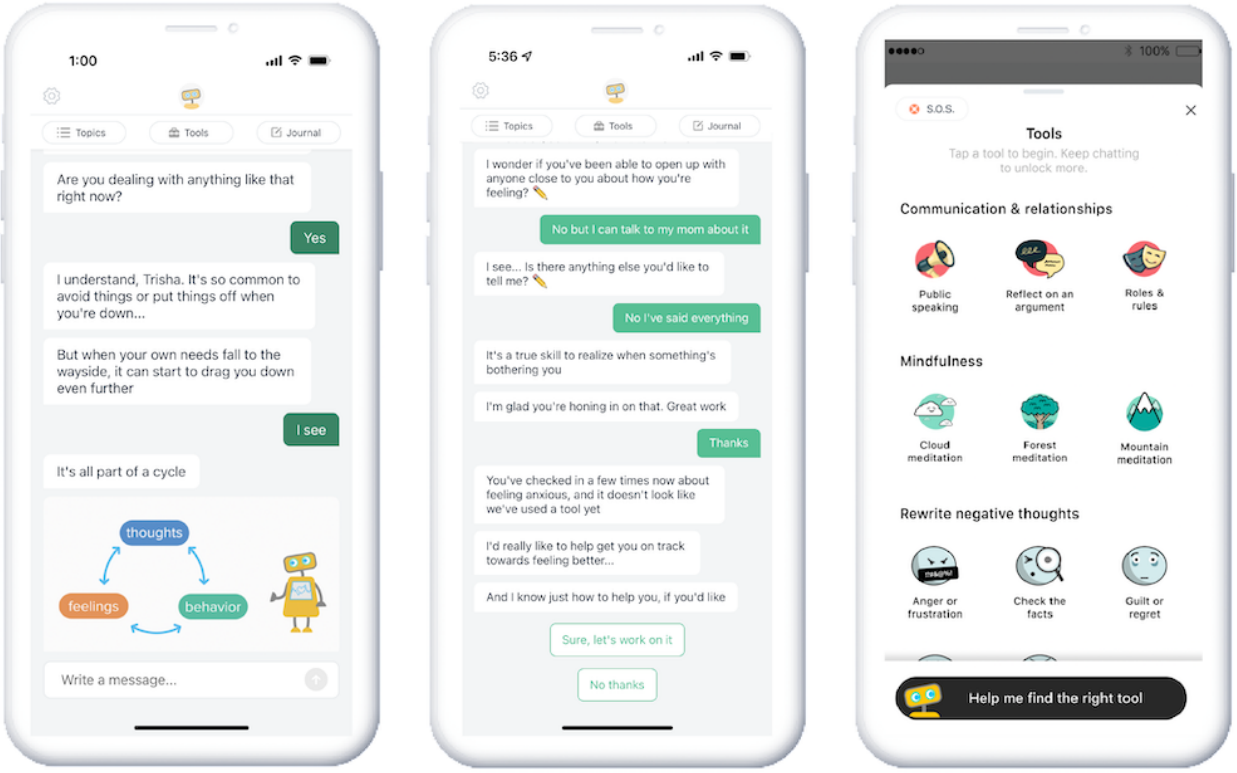
Sample Size

The noninferiority analysis for comparing the 2 study conditions will be based on self-reported depressive symptom (PHQ-8) outcomes. In contrast, an exploratory analysis will be conducted on self-reported anxiety symptom (GAD-7) outcomes. In order to perform the noninferiority analysis, 260 participants (130 participants/arm) will be enrolled. Group sample sizes of 86 and 86 will achieve 81% power to detect noninferiority using a 1-sided, 2-sample *t* test. The margin of noninferiority is 2.0 [32]. The actual difference between the means is assumed to be –0.5. The significance level (α) of the test is .025. The data are drawn from samples with SDs of 5.3 and 4.3. Based on a sample size estimate of 172, the final sample size was set to 260 to

XSL•FO
RenderX

account for 33% attrition (current recruitment status is provided in the *Results* section).

Randomization and Masking



Adolescents who meet inclusion criteria will be randomized 1:1 to the treatment groups. All clinical outcome measures are completed directly by participants accessing links to the measures in an electronic data capture platform. Neither participants nor staff are blinded to group assignment.

Interventions

W-GenZD App

W-GenZD is accessible as an iOS or Android app and is a relational agent–guided self-help program. It is only available to study participants using an access code for the investigational device. Using proprietary natural language processing and artificial intelligence, Woebot, the relational agent embedded in W-GenZD, guides users through a program that is personalized each day, in real time, to the user's needs. Push notifications will prompt users to check in, and the cadence is based on the level of user activity (higher activity=higher cadence). The W-GenZD user experience is centered around mood and symptom tracking and goal-oriented conversations with Woebot. These conversations are tailored to the adolescent's real-time report of the presenting situation, to help the adolescent develop emotion regulation skills in the context of their everyday life for the problem at hand, in their moment of need (see Figure 2). Users become familiar with Woebot as a friendly, helpful character that is explicitly not a human nor a therapist. Participants in the W-GenZD arm of the study will have access to W-GenZD for 4 weeks after randomization and are encouraged to use the app for a minimum of 5-10 minutes per day during the treatment period.

Figure 2. Screenshots of Woebot for Adolescents (W-GenZD), including examples of tools available to users.

Safety Considerations

W-GenZD follows safety recommendations from the American Psychiatric Association [33] and American Medical Association [34]. W-GenZD's safety features include providing the app's privacy policy and terms of service, informing the user that they are talking to a robot and not a real person, stating that the app is not a crisis intervention for suicidal ideation, encouraging them to seek additional support if they are feeling unwell, and providing helplines for assistance. In addition, W-GenZD's "safety net protocol" is based on a natural language processing algorithm that is designed to detect concerning language. The algorithm detects if a user inputs, via free-response text entry, concerning phrases or words that match an a priori identified and thorough list that may be used in crisis situations. When this occurs, the user is reminded that the app is not a crisis intervention service and helplines for additional support are offered.

For the purposes of this study, we have developed an escalation procedure that combines W-GenZD's language detection capabilities with follow-up by trained clinicians. After the algorithm detects concerning language and if the adolescent confirms this, Woebot will let the adolescent know that someone on the hospital's care team will be notified. W-GenZD will then send a Health Insurance Portability and Accountability Act (HIPAA)–compliant alert to designated clinical staff who will be on call to provide 24/7 follow-up of these messages. The licensed clinician on the study team will contact the adolescent, assess their safety and well-being, and refer to emergency services as necessary. Triage decisions resulting from the

XSL•FO
RenderX

follow-up assessment will be logged separately, in accordance with the hospital's standard procedures. Participants will continue in the study if they continue to meet the study inclusion criteria and do not require a higher level of care.

Study personnel may also learn of participant safety concerns in CBT-groups or by family or participant reports to the study team. In these instances, the follow-up procedure will be the same; the licensed clinician will contact the adolescent to assess their safety and well-being, with triage as needed and corresponding documentation.

Brief Telehealth-Delivered CBT-Group

The open CBT-groups are a rotating, 4-week intervention held once weekly for an hour. At least 2 groups are offered per week to allow the participants to attend the one that best fits their schedule. A licensed clinician facilitates each teletherapy group with up to 10 adolescents in each session. Group sessions begin with orientation and reviewing group rules, individual check-ins with each participant (rating stress level and hopefulness), followed by a guided mindfulness moment. Group attendees may choose to have their cameras on or off during group sessions but will be asked to have their cameras turned on for introductions and again at the very end of the session before they leave.

Groups are conducted on an open enrollment, rolling topic basis, allowing participants to join the next available session following randomization and complete all 4 sessions during their study treatment period. The 4 topics include: (1) building a coping toolbox, (2) accepting your feelings, (3) challenging negative thoughts, and (4) problem-solving.

The decision to use a 4-week CBT intervention was made to ensure that the duration of intervention of W-GenZD and CBT-group were equivalent. Both interventions are considered brief in duration.

Measures

There will be 5 categories of measures that will be collected in this study: participant demographics and psychiatric history, feasibility and acceptability, clinical outcomes, safety data and engagement. Table 1 describes each category and its included measures, the source and content of data for each measure, and corresponding administration points. Participants complete assessments at BL, day 5, week 2, week 4 (EOT), and week 8 follow-up (EOS). After EOT, participants will no longer participate in the CBT-group nor have access to W-GenZD. Parents participate in telephonic check-ins at weeks 2, 4, 6, and 8 to identify changes in their child's medications or logistical or safety concerns; if the latter is identified, the aforementioned safety follow-up protocol is initiated. Participants will receive reminders via email and SMS text messages for assessments with corresponding links to the surveys. Participants can be compensated up to US $125 in Amazon gift cards for the completion of all assessments.

XSL•FO

Table 1. Assessment measures and administration schedule.

Assessment type and measure	Description	Administration
Participant demographics and psychiatric history		
Survey questions	• Demographic: gender and sexual identity, racial and ethnic background, highest level of education completed, etc • Psychiatric history: psychiatric diagnoses and any prior or concomitant medications and prior therapy	BL[a]
Feasibility and acceptance		
Client Satisfaction Questionnaire [35]	• 8-item measure used to assess client's satisfaction with treatment on a 4-point scale (1="very dissatisfied" to 4="very satisfied") [35]	EOT[b]
Satisfaction Questionnaire	• 3 open-ended questions about what they found most helpful about their treatment, what would make it better, and if there is any other feedback they would like to share	EOT
URPI[c]-Feasibility and URPI-Acceptability (from the URPI-Revised scale [36])	• 6-item subscales inquire about factors that impact treatment usage (ie, intervention quality)	BL and EOT
Clinical outcomes		
PHQ[d] [29]	• Abbreviated version of the PHQ-9, the PHQ-8, will be used to assess mood and anxiety symptoms	BL, week 2, EOT, and EOS[e]
GAD[f] [31]	• Self-report tool to assess the frequency and severity of anxious thoughts and behaviors over the past 2 weeks; it is a widely utilized, reliable, and valid measure of anxiety	BL, EOT, and EOS
MFQ[g] [30]	• Short version is a child self-report assessment consisting of a series of 13 descriptive phrases related to the participant's recent feelings and behaviors	BL, EOT, and EOS
WAI-SR[h] [37]	• 12-item Working Alliance Inventory–Short Revised version with minor changes to language, replacing "therapist" with the name of the assigned treatment group measure of therapeutic bond; consists of a composite score and 3 subscales: Bond, Goal, and Task	Day 5 and EOT
Safety data		
Incident reports	• Utilization data, including frequency, type, and outcomes to report on incidents of "safety net protocol" triggers and the occurrence and relatedness of adverse events or serious adverse events	Throughout study
Engagement		
W-GenZD[i] use and CBT-group[j] attendance	• W-GenZD: days in app and content engagement • CBT-group attendance	Throughout treatment until EOT

[a]BL: baseline.

[b]EOT: end of treatment.

[c]URPI: Usage Rating Profile–Intervention.

[d]PHQ: Patient Health Questionnaire.

[e]EOS: end of study.

[f]GAD: Generalized Anxiety Disorder.

[g]MFQ: Mood and Feelings Questionnaire.

[h]WAI-SR: Working Alliance Inventory.

[i]W-GenZD: Woebot for Adolescents.

[j]CBT-group: cognitive behavioral therapy–based skills group.

Data Collection

All study data, from participant self-report and on-site study personnel, are gathered through a HIPAA-compliant survey and electronic data capture platform. All data obtained via the mobile app will be encrypted and stored on Amazon Web Services and/or Google Cloud Platform; Woebot Health data-gathering and storage procedures are compliant with both HIPAA and the

XSL•FO
RenderX

European Union's General Data Protection Regulation. Only members of the research team will have access to identifiable study data. Deidentified data will be accessible to the product development team (designers, user researchers, and product managers) as well as the research team.

Statistical Analysis

Data will be reported per treatment arm and overall, for all time points in the study. For continuous variables, means and SDs will be reported if the data are normally distributed; for nonnormal data, medians and IQRs will be reported. For categorical variables, frequencies and percentages will be reported.

To assess the primary aim (feasibility and acceptability of W-GenZD), the descriptive statistics to be reported include the Usage Rating Profile–Intervention (URPI), Client Satisfaction Questionnaire, Satisfaction Questionnaire, and URPI-Feasibility and URPI-Acceptability scales, as well as app engagement and group attendance metrics. For the secondary aim (comparison of the clinical impact of W-GenZD and the skills group to reduce depression symptoms), a test of noninferiority (1-sided) will be used to determine if EOT PHQ-8 change scores for W-GenZD are noninferior to the CBT-group. α will be set to .025. CIs will be reported for the EOT clinical outcomes. The main analyses will be conducted within the intent-to-treat group and with a sensitivity analysis in the per-protocol group. If the data are nonnormally distributed, a suitable nonparametric model will be used. For the tertiary aim (assessment of therapeutic working alliance, mood, and anxiety levels in both groups), descriptive statistics will be reported for the Working Alliance Inventory–Short Revised version, GAD-7, and MFQ at all time points.

Additional sensitivity analysis will be performed. Although randomization should ensure the equality of the 2 groups at BL, tests of potential between-group differences will be conducted. If differences are found, a regression-based approach will be used for the noninferiority test-based CIs. Any BL covariate where a significant difference between the 2 treatment groups was achieved would be input into the model. If the model is a poor fit, a suitable nonparametric alternative will be selected. All statistical analyses will be performed using R statistical software (R Foundation for Statistical Computing).

Results

Recruitment began in May 2022. At the time of submitting this paper for review (December 8, 2022), we have randomized 133 participants. The study's a priori planned end of recruitment date was November 30, 2022, which has been extended to December 16, 2022, to allow for those presently in the queue in the children's hospital screening process to be assented/consented and screened for study eligibility. Final enrollment numbers will be reported in the outcome's manuscript.

Discussion

Significance of Study

This paper describes the rationale, design, and corresponding methodology for testing the feasibility and acceptability of W-GenZD, which includes Woebot, a relational agent that offers a CBT-guided self-help program delivered through a smartphone app. Embedding the study within a MH treatment environment, a children's hospital's outpatient MH clinic, allows for learnings specific to real-world clinical practice settings. In this study, adolescents diagnosed with depression and/or anxiety and who are treatment seeking will be randomized to 1 of 2 technology-leveraged treatments, W-GenZD or CBT-group, both of which are potential "first step" interventions within a stepped care treatment paradigm. Participants in the study must meet both existing criteria for participation in a low-intensity treatment as well as the study-specific inclusion and exclusion criteria. Thus, enrolled youths randomized in the study are representative of treatment-seeking youths with depression and anxiety within this hospital's community. This study will also evaluate if the outcomes yielded by the W-GenZD and brief telehealth-delivered CBT-group are analogous. We anticipate that W-GenZD will be noninferior to the CBT-group in reducing adolescent depression (PHQ-8) at 4 weeks. We will also explore self-reported mood (MFQ) and anxiety symptom levels (GAD-7) in both treatment groups as a tertiary aim.

Working alliance has been long identified and studied as an important construct in the psychotherapeutic literature, including across treatment modalities and theoretical foundations. Not only has it been associated with positive treatment outcomes, but it also holds face validity as a meaningful manifestation of a productive and aligned therapeutic relationship. Previous data demonstrated Woebot's ability to establish and sustain working alliance at levels analogous to human-delivered CBT interventions [20]. The inclusion of working alliance in this study allows for further exploration of this construct as it applies to a sample of treatment-seeking adolescents diagnosed with depression and/or anxiety engaged in a technology-supported MH intervention. By evaluating therapeutic alliance levels in both study conditions, we can gain a greater understanding of therapeutic bonding in both a relational agent and a telehealth-delivered brief CBT-group, with the latter being a more relatively familiar group treatment modality. In future work, the potential relationship of therapeutic alliance to improvement in symptoms among adolescents can be explored.

This protocol integrates a real-world safety assessment into the use of W-GenZD as well as the CBT-group to ensure a safety net is available to adolescents who may express ideation of self-harm. This allows the study of responses to safety concerns with a vulnerable research population receiving either a relational agent (W-GenZD) intervention or a telehealth-delivered group CBT intervention. The application and refinement of this protocol may provide an opportunity for the expansion of real-world digital MH intervention to other adolescent clinical populations.

This study goes beyond self-report measures alone and will invite perspectives from both caregivers and adolescents. This

XSL•FO
RenderX

multireporter approach is critical in providing multiple perspectives about the adolescent's functioning. It is consistent with real-world clinical practice, in which the youth's voice is a primary source of clinical information and family perspectives are integrated into the formulation [38].

Limitations

Study participants include treatment-seeking youths who present alongside their parent/guardian's request for MH care and therefore may not be representative of non–treatment-seeking symptomatic youths in the community. For safety reasons, our study excluded youths with high-acuity symptoms such as active suicidal ideation and bipolar disorder. As a result, findings may not be generalizable to youths with more acute symptoms and treatment needs. In addition, in a study of depression and anxiety, group therapy as a treatment arm may limit the representativeness of the sample due to the potential discomfort of some young people with a group modality. Finally, to ensure equal durations of intervention, the group therapy intervention was designed as a brief course of treatment, which may be less representative of typical longer courses of group CBT treatment.

Conclusion

We have described a randomized controlled trial that seeks to establish the feasibility and acceptability of a relational agent digitally delivering CBT within a pediatric outpatient MH hospital setting. Demonstrating W-GenZD as noninferior to a CBT-group may have implications for the expansion of options for adolescents seeking MH treatment for depression and/or anxiety. Providing technology-leveraged effective treatment options for those at lower-acuity levels may help reserve limited resources for those with more severe MH needs.

Acknowledgments

This study was funded by Woebot Health, which covered the cost of on-site staffing, participant payments, and the platform for electronic data capture. MMG received research funding from the Hampton Roads Biomedical Research Consortium. We would like to thank Alison Darcy, PhD; Michael Tapella; Robbert Zusterzeel, MD, PhD, MPH; and Stephanie Rapoport, MA, for their helpful comments on the manuscript.

Authors' Contributions

EC, KM, AR, and MMG contributed to the conceptualization, study design, implementation, and manuscript preparation of this study. AW reviewed the study design and provided the statistical analysis plan. CP and NW provided input on on-site procedures and reviewed the manuscript.

Conflicts of Interest

EC, KM, AR, and AW are employees of Woebot Health. This study was funded by Woebot Health, which included support for the percent effort dedicated to the project by the Children's Hospital of The King's Daughters (CHKD) on-site team including CP, NW, and MMG.

Abstract

Background: Digital transformation is impacting health care delivery. Great market dynamism is bringing opportunities and concerns alike into public discussion. Digital health apps are a vibrant segment where regulation is emerging, with Germany paving the way with its DiGA (Digitale Gesundheitsanwendungen, in German, meaning digital health apps) program. Simultaneously, mental ill-health constitutes a global health concern, and prevalence is expected to worsen due to the COVID-19 pandemic and its containment measures. Portugal and its National Health System may be a useful testbed for digital health interventions.

Objective: The paper outlines the protocol for a research project on the attitudes of physicians and potential users toward digital mental health apps to improve access to care, patient outcomes, and reduce the burden of disease of mental ill-health.

Methods: Web surveys will be conducted to acquire data from the main stakeholders (physicians and the academic community). Data analysis will replicate the statistical analysis performed in the studies from Dahlhausen and Borghouts to derive conclusions regarding the relative acceptance and likelihood of successful implementation of digital mental health apps in Portugal.

Results: The findings of the proposed studies will elicit important information on how physicians and individuals perceive digital mental health app interventions to improve access to care, patient outcomes, and reduce the burden of disease of mental ill-health. Data collection ran between September 26 and November 6, 2022, for the first study and September 20 and October 20, 2022, for the second study. We obtained 160 responses to the first study's survey and 539 answers to the second study's survey. Data analysis is concluded, and both studies' results are expected to be published in 2023.

Conclusions: The results of the studies projected in this research protocol will have implications for researchers and academia, industry, and policy makers concerning the adoption and implementation of digital health mental apps and associated interventions.

Introduction

Digital Transformation in Health

Digital transformation and its impact on health [1] is evermore present [2]. Investment inflow into the digital transformation in the health care market registered a 10.4% compounded annual growth rate from 2016 to 2020, with a further 14% compounded annual growth rate expected in 2021-2031, denoting strong market dynamics [3]. According to IQVIA Institute for Human Data Science's Digital Health Trends 2021 report [4], mobile apps in the business-to-consumer market registered at "(…) top app stores worldwide are now over 350,000 in number, with more than 90,000 digital health apps added in 2020—an average of more than 250 apps per day."

The growth of digital tools applied to health has, however, been largely achieved without regulatory scrutiny appropriate to the needs of a digital society and due consideration for the quality, safety, and effectiveness of tools. There is rising concern that mobile apps, for one, do not meet enough clinical or technical validation standards or even register any type of empirical support [5-8]. Further, following a rush of optimism as the COVID-19 pandemic became a global challenge and research organizations tried to leverage technological tools, the evidence showed that, for instance, artificial intelligence–based mechanisms often failed to deliver on their promise [9], thus making the discussion more relevant. If COVID-19 brought concerns about the tools used for digital health delivery, it is also true that it provided a very significant impulse to their adoption, laying the ground for their widespread use in a postpandemic world [10], including in fields such as digital mental health (MH) [11].

Physicians and prospective patients alike have several concerns regarding digital health, and there are myriad challenges and risks ahead. These include lack of digital literacy, barriers to health care access that stem from the digital divide, and worries about losing touch with a familiar model such as face-to-face consultation [12-16]. Further questions arise around legal and ethical questions around topics such as confidentiality, privacy, patient autonomy, or the trustworthiness and accountability of care delivery [17-20].

The scope of our research protocol encompasses 2 different concepts that need clarification: digital health and, more particularly, digital mental health apps (DMHAs). This clarification is important as none of these constructs has a stabilized definition due both to the evolving nature of their underlying fields and to the heterogeneity of stakeholders that work with them, ranging from academia to governmental institutions and industry.

For this research protocol and its papers, digital health will be defined as technologies that connect and empower people and populations to manage their health and wellness by augmenting workforce capacity while leveraging digital tools and technologies to shape care delivery [21]. It uses information and communication technologies to facilitate the understanding of health problems and challenges faced by people receiving medical treatment and social prescribing in more personalized and precise ways [22-25].

Within digital health, we will be focusing on DMHAs—a type of digital MH [26] tool that uses the format of a mobile app to aid MH assessment, support, prevention, and treatment [27,28].

The Rise of Digital Health Apps—Regulatory Concerns

Digital health apps promise to empower users and provide a unique opportunity for access to health (eg, by expanding remote care) while increasing the volume and variety of information available to physicians. More than 350,000 health apps are available from various app stores, with 110 downloaded over 10 million times and accounting for almost 50% of all downloads [4]. According to the same source, COVID-19 increased app use, and MH, cardiovascular, and diabetes condition management apps accounted for nearly 50% of disease-focused apps. However, considering the difficulty in assessing the impact of digital health apps [29] on health, policy makers have recently taken measures to reduce the uncertainty surrounding digital health apps by introducing standardized processes for evaluation akin to medicines or medical devices [30].

The identification of digital health apps that are safe and effective presents a significant challenge for health systems across the globe, making proper regulation essential to minimize risks and magnify benefits. Apps that tackle high-risk or chronic conditions, or that attempt to perform diagnosis or treatment, are especially relevant in this scenario given the time one is expected to use them or the sensitivity of associated information. Regulation constitutes an aprioristic need to produce payment and reimbursement pathways that balance costs and benefits while ensuring access and defining clear use policies aside from those that are market based (eg, star ratings in app stores) [31].

When it comes to implementing a regulatory framework aimed at digital health apps and their market access and reimbursement, Germany assumed a pioneering role. Its DiGA (Digitale Gesundheitsanwendungen, in German, meaning digital health apps) [32] program was inaugurated in October 2020, and, on December 20, 2022, 34 apps had qualified for statutory insurance reimbursement (of these, 14, or 41%, were classified as being DiGA for mental disorders) [33]. An app is accepted into the DiGA program after the German Federal Agency for Medicines and Health Products evaluates it in terms of general requisites (concerning technical safety and user-friendliness) and positive clinical effects. If an app has not yet proven the latter, it has 12 months to do so and is included in a provisory listing; if it fails to comply, it is withdrawn. If the app can prove both compliances with general requisites and positive clinical effects, German Federal Agency for Medicines and Health Products approves it, and price and reimbursement negotiations follow with the association of statutory insurers (GKV-SV), after which it is included in the DiGA Directory [33]. France is studying a replication of the DiGA approach and is expected to implement it until the end of 2022 [34].

Belgium ranks second in implementation—even though the mHealthBelgium [35] initiative was launched in 2018, it officially started conducting appraisal and reimbursement

XSL•FO
RenderX

processes in January 2021. Its selection process is based on a 3-level validation pyramid [36] consisting of criteria related to legal and regulatory issues (level 1), safe communication and privacy (level 2), and financing and reimbursement (level 3, subdivided into 3^-, if it has provisional reimbursement while proving socioeconomic benefits, and 3^+, if it already has proven those same benefits). On June 2, 2022, 23 apps had level 1 clearance, and 12 apps had level 2 clearance. Moreover, 1 app received 3^- clearance, and none had been cleared for level 3^+.

Other European countries have so far opted for softer, more decentralized approaches, with legal obligations and compliance rules based on the General Data Protection Regulation [37] or the Medical Devices Regulation [38]. Singapore and the United States, on the other hand, resort to their own medical devices regulations, with the Food and Drug Administration issuing guidance in 2021 [39] regarding a pilot project at the federal level and, thus far, assessing software as a medical device [40].

Mental Health, Anxiety and Depression, and Pandemic: A Troublesome Cocktail

Mental disorders are globally responsible for 4.92% of total disability-adjusted life years (DALYs) and 13.04% of all disease prevalence cases. Depressive disorders are accountable for 1.84% of global DALYs and 3.76% of total disease prevalence, while anxiety answers for 1.13% of global DALYs and 4.05% of disease prevalence in the globe [41]. The 2 conditions accounted for more than half of the impact MH disorders had on global health in 2019 according to the GBD Compare tool developed by the Institute for Health Metrics and Evaluation.

Table 1 presents a breakdown of the impact mental disorders as a category, alongside anxiety and depression, had not only in global health but also on the health status of some geographies of concern for us in this protocol—the United States, the European Union, and Germany—in 2019, measured in DALY and disease prevalence cases. Data were gathered using the previously mentioned GBD Compare tool [41].

Table 1. Share of DALY[a] and disease prevalence (in percentage points) per condition and geography.[b]

	World		United States		European Union		Germany	
	DALY (%)	Prevalence (%)	DALY (%)	Prevalence (%)	DALY (%)	Prevalence (%)	DALY (%)	Prevalence (%)
Mental disorders	4.92	13.04	6.56	17.03	6.65	15.34	6.43	15.59
Depression	1.84	3.76	2.38	4.92	2.42	4.6	2.16	4.32
Anxiety	1.13	4.05	1.68	6.51	1.69	5.82	1.95	7.07

[a]DALY: disability-adjusted life year.

[b]Institute for Health Metrics and Evaluation [41].

In all geographies considered in the paradigm, depression and anxiety account for over half of the burden of disease generated by mental disorders. Furthermore, these conditions are always a relevant public health issue in any of the mentioned contexts due to their prevalence, thus making the importance of addressing them undisputable.

These data are with regard to 2019, and consequently do not factor in the consequences of the COVID-19 pandemic and its containment measures in MH deterioration. Many experts have alerted to the deleterious impact [42-44] of this pandemic, especially for children and adolescents [45], and have issued calls to action on the need to tackle this issue heads on [46,47]. It has been suggested that digital MH tools could help manage the burden of the disease brought about by mental disorders, in particular anxiety and depression [48]. Rapid and affordable mechanisms of population screening and follow-up are necessary in a postpandemic world; otherwise, the burden of the disease will be unbearable for any health system [49-51].

Portugal and Its Mental Health Landscape

The Portuguese National Health Service (NHS) is a publicly owned, tax-financed health system that aims at ensuring wide, universal, and mostly free-of-charge care [52]. Regarding total health care activity in Portugal in 2019 (the most recent and pandemic-free full-year available), the NHS delivered 59.8% of 21.1 million outpatient consultations, 76.5% of 8.2 million emergency room episodes, and performed 66.2% of 1.21 million surgeries. The NHS was also responsible for 82.1% of 180.3 million uses of complementary means of medical diagnosis and therapy, as well as for 71.5% of 1.1 million hospitalizations and 84.7% of 86.4 thousand births [53]. The Portuguese NHS was therefore accountable for 79.5% of the health care delivered in Portugal. Regarding funding, the government financed 63.8% of total health care expenditure, with out-of-pocket family spending representing 30.5% and private insurance companies accounting for 3.8% of the total [54].

The data point to an eminently public health system both in funding and activity, with significant household financial strain and a modest contribution of private insurers. It also means that most of the Portuguese population relies on the care provided by the publicly financed and managed NHS. This is a significant difference from health systems such as those of Germany [55] or the United States [56], where health and care are largely privately owned, financed, and managed. In these countries, the government only intervenes in specific cases, mostly related to income deprivation or market failures. Such differences entail different economic, managerial, and organizational incentives, reflecting different cultures and preferences [57].

Several studies draw attention to a lack of MH and care resources within the scope of the Portuguese NHS, chief among them is the first (and so far, sole) national epidemiological questionnaire on MH [58]. This constitutes an alarming background considering the Portuguese population's particularly

XSL•FO
RenderX

worrisome MH status: 51.4% of the population is expected to have a MH issue at some point in their lives. This datum reports to 2013; the Order of Portuguese Psychologists reported, in its factsheet on depression dated December 2021, that depression alone affected 10% of the population [59].

Evidence on the quasiepidemic nature of MH issues grows; the prevalence of MH disorders in 2019 was estimated at 8.27% of DALYs and 19.27% of disease cases. The statistics for anxiety and depressive disorders were, respectively, expected to be 2.58% and 3.16% of total DALYs and prevalence valued at 9.08% and 5.88% [60].

These data add to the public health relevance of these conditions, and several experts point out that, due to socioeconomic constraints ranging from stigma to lack of accessibility or affordability, these figures might be altogether underestimated [61-64]. At the same time, the World Health Organization expects the COVID-19 pandemic to have a detrimental effect on these statistics, further exacerbating the issue [65]. Children and adolescents at risk due to both family context and the COVID-19 pandemic [66-68] constitute further cause for worry.

Primary care services and digital health tools for self-management have been singled out as an opportunity to tackle this and other issues concerning health and care [69-72], namely chronic illness and quality of life, rising health costs, or significant burden of disease [73,74]. Portugal has registered a very significant uptake of telemedicine consultations [75] in its NHS, and the pandemic has arguably played a role in catalyzing this change. In context, the country ranks 16th (ie, slightly below average) in the European Commission's 2021 Digital Economy and Society Index [76], which assesses the digital maturity of each Member State.

Unleashing the eventual potential of digital health to help manage health conditions overall and MH issues (such as anxiety and depression) in the Portuguese context implies understanding the agents, their incentives, and interconnections. The problem at its core has 2 main primary actors: physicians (defined as psychiatrists or psychologists) and patients.

Doctors are important since patients usually delegate medical decisions to doctors [77,78]; therefore, MH professionals' attitudes toward digital health apps are a key success factor likely to steer not only adherence but also outcomes as well [79]. By the same token, we can expect doctors to be more willing to use digital tools if patients demand them. Consequently, patient buy-in is needed to make this system work, and that will only be possible if digital health developers and companies consider their expectations and concerns [80]. These can range from user interface and user experience [81] considerations to confidentiality and privacy issues [82-84].

Portugal has no direct equivalent to prescription apps or the German Ministry of Health's DiGA program. The Portuguese reimbursement scheme for pharmaceuticals is centrally negotiated and decided by the Regulatory Authority for Medicines and Medical Devices (INFARMED). Medical devices in the European Union market are subject to a conformity assessment [38], being the definition of medical devices already extended, in law, to software and software apps. INFARMED is the authority responsible for notified bodies and has a coordinating role in verifying conformity assessments and selecting third parties to become notified bodies responsible for conformity assessments in high-risk cases.

In turn, the Shared Services of the Portuguese Ministry of Health (SPMS), largely responsible for the development of the country's eHealth strategy, make adhesion to their health app store (MySNS Seleção [85]) conditional on an assessment system that evaluates apps concerning performance, safety, public utility, and information quality and security according to European Union Law [86]. Even though these 2 regulatory players display some level of scrutiny in European Union terms, ample room remains for economic, social, and regulatory development, showing a lag vis-à-vis German, Belgian, or French ambitions [87].

This research project is an opportunity to assess whether DMHA would be welcomed in Portugal and in a health care system with its political economy. By comparing Portugal with Germany (from the physicians' point of view) and the United States (from the individual's point of view) in similar settings, we hope to enrich the comparison between health systems with a very significant private sector role and systems where government plays a key function in ensuring access to and funding of health care, particularly concerning MH and the use of electronic or digital tools.

This constitutes a relevant contribution to the scientific literature not only of life sciences and their digital potential but also in terms of the industrial characterization of health economics for these subtopics and the mapping of expectations and perceptions from both supply and demand sides of MH and care.

Aim and Objectives

The research project we refer to is composed of 2 papers, both aimed at publication in the context of a doctoral research project being pursued by the first author of this paper under the supervision of its second author.

In this research project, we aim to understand how physicians and individuals might perceive digital MH tools. These constitute, respectively, the supply and demand sides of this market. Furthermore, we seek to provide a more precise landscape of the digital health setting in Portugal and provide grounds for academic, policy, and business development. Finally, we speculate on the potential use of digital health interventions for quantifying and providing tools to tackle the increasingly unmanageable burden of mild to moderate anxiety disorder and depression.

We will try to answer the following research questions: (1) How do physicians perceive digital health apps? (2) How digitally literate do physicians perceive themselves and their patients to be? (3) How do physicians see their own role in digitalizing health care provision? (4) What are the largest benefits, risks, barriers, and opportunities in digital health apps? (5) How do individuals perceive MH apps? Which factors determine the decision of using MH apps, and how do individuals feel about doing it? (6) What are individuals' preferences concerning resources and strategies for getting MH care? (7) How do

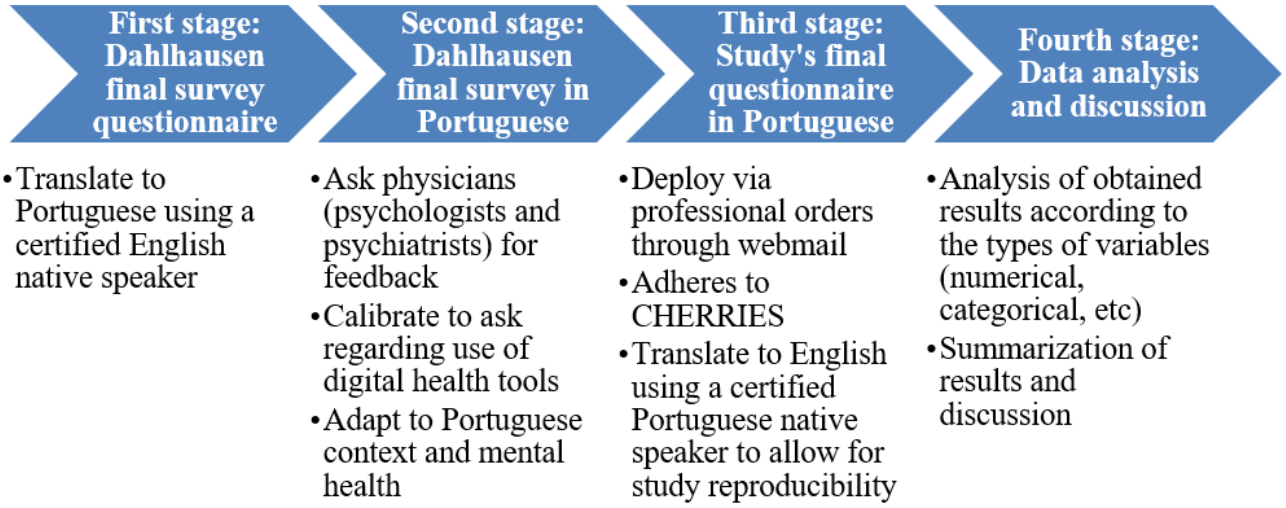
XSL•FO
RenderX

individuals rate their MH and what impacts it? and (8) What perceptions do individuals have regarding MH and its treatment?

Methods

First Paper (Physicians)

The first paper will replicate the study performed by Dahlhausen et al [88] with adaptations. It will seek to understand the attitudes of physicians (both psychiatrists and psychologists) toward DMHA. The paper will allow us to characterize the implications of the supply side (ie, physicians who constitute the labor for the provision of MH services) for the adoption of DMHA in Portugal.



The study will be based on a cross-sectional, web-based survey. We will not include the qualitative part of Dahlhausen study as it was destined to complement the literature's findings to develop a survey. Instead, we will take the final survey questionnaire made available on Dahlhausen's study as given.

We will first translate it to Portuguese using a licensed translator and deliver it to physicians (both psychologists and psychiatrists, 5 each) for input. Physicians' feedback will be focused on how to calibrate it to (1) reflect important questions to ask regarding the usage of digital health tools by doctors and (2) adapt to a Portuguese MH care context.

The feedback obtained from physicians will be incorporated to produce a final web-based survey questionnaire for this study. This survey will be deployed via Inqueritos@UP (the University of Porto's internal survey manager, powered by LimeSurvey) as widely as possible and with the support of the Portuguese Order of Psychologists and the Psychiatry Specialty College of the Portuguese Order of Medical Doctors.

The survey will adhere to and be reported following the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines. For the certified translation of the Dahlhausen et al [88] questionnaire to Portuguese, as well as our final survey questionnaire in both Portuguese and English (the latter produced by a certified native Portuguese speaker translator from Portuguese to English), refer to Multimedia Appendix 1. Figure 1 summarizes the study's stages.

Figure 1. First study workflow. CHERRIES: Checklist for Reporting Results of Internet E-Survey.

There is no public information concerning the number of psychologists registered with the Order of Portuguese Psychologists. Registered psychiatrists (summing the stand-alone specialty with the subspecialty of children and adolescents) are a total of 1528. All will be invited to participate in this web-based survey via their respective professional orders.

To preserve privacy, respondents will not be asked to provide any identifiable information for completion of the survey. Additionally, invited participants will not be tracked for having started or completed the survey, increasing privacy but limiting the possibility of reminders. To establish a basis for comparison with a reimbursable apps system, we will ask physicians who answer the survey to bear in mind a scenario where these apps fulfill regulatory requirements and address safety, quality, and efficacy concerns. This establishes an equivalency between the definition of DiGA apps as outlined in the "Introduction" section and the definition of DMHA used in our study.

To maximize response, the only inclusion criterion will be that of being registered and of good standing (ie, not responsible for any infractions) with the physician's respective professional order. No exclusion criteria will be introduced. There will be no financial incentives for filling the survey.

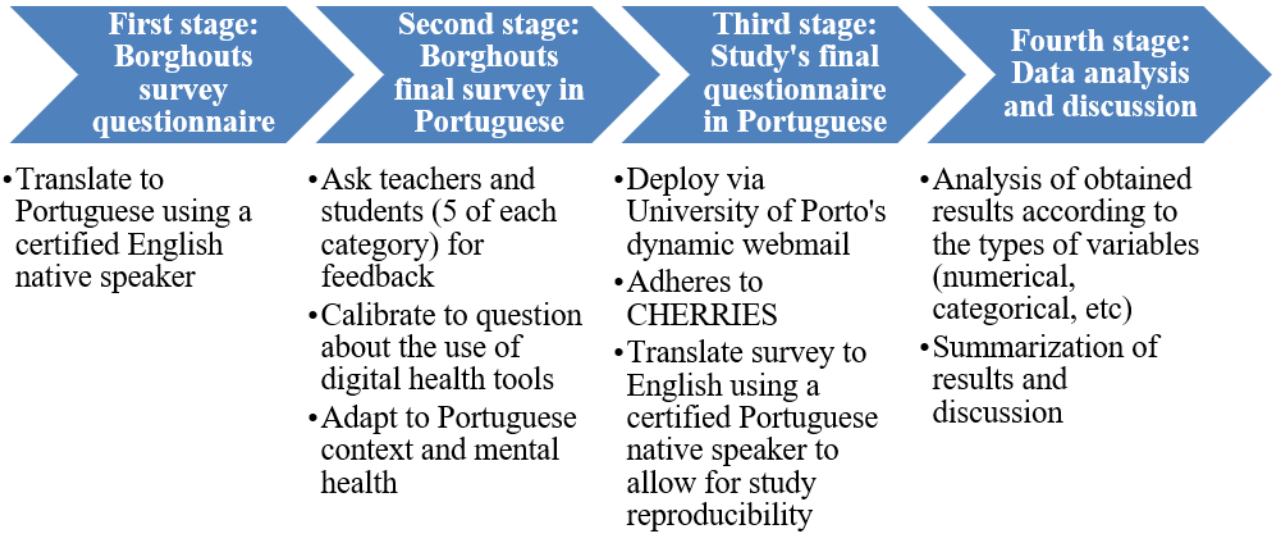
Gathered data will be assessed according to the same model as in the Dahlhausen et al [88] paper to allow for maximum comparability between results. This entails the breakdown between the sociodemographic characteristics of the sample and the answers to the questions in the survey concerning the 4 main topics at hand: perceived benefits, potential barriers to, measures to support adherence to, and prescription intentions for DMHA. All variables that allow for it will be characterized by descriptive statistical analysis. Estimates of association for the variables that correspond to the Dahlhausen et al [88] "Perceived Benefits From and Attitudes Toward DiGA" and "Prescription Intentions" subsections will also be computed.

XSL•FO
RenderX

Only data excluded due to different health system organizations and their consequences for citizens or physicians (eg, statutory health insurance in Germany vs little to no point-of-care payments in Portugal) or to reasonable suggestion during the foreseen feedback period will be treated differently, being subjected to either descriptive statistical analysis or association estimation according to the nature of the variable at hand.

Second Paper (Individuals)

The second study produced in the context of this doctoral research project will replicate the paper by Borghouts et al [89]. The paper's aim is to ascertain which factors determine public acceptance and usage of MH apps. The definition of MH apps in Borghouts study encompasses generic apps that can fall, for example, into the category of wellness, and our survey instrument will not impose any restrictions, thereby considering DMHA as an equivalent of MH apps in a broad sense.



The described study will simultaneously allow us to illustrate the demand side (ie, people who may potentially request MH services and care) for the adoption of MH apps in Portugal. Even though it is limited to an academic community, it is expected that it will have a reasonable mix of population characteristics. Limitations, both ex-ante and ex-post data collection, will be documented in the paper.

The study will start with a cross-sectional, web-based survey delivered through the University of Porto's dynamic email function. The web-based survey will be based on the survey questionnaire made available in Borghouts paper. This questionnaire will be translated into Portuguese using a licensed translator. Afterward, it will be circulated between an equal number of students and teachers (estimated to be 5 each) affiliated with the Faculty of Medicine of the University of Porto for input. Received input will concentrate on how to adjust it to (1) include important questions to ask regarding the usage of digital health tools with a focus on MH and (2) adapt to a Portuguese MH context.

Obtained feedback will be incorporated to produce a final web-based survey questionnaire for this study. This survey will be deployed via Inqueritos@UP (the University of Porto's internal survey manager, powered by LimeSurvey) as widely as possible and with the support of the University of Porto's services.

The survey will abide by and be reported following CHERRIES guidelines. For the certified translation of the Borghouts et al [89] questionnaire from English to Portuguese, as well as our final survey questionnaire in both Portuguese and English (the latter produced by a certified native Portuguese speaker translator from Portuguese to English), refer to Multimedia Appendix 2. Figure 2 summarizes the study's stages.

Figure 2. Second study workflow. CHERRIES: Checklist for Reporting Results of Internet E-Survey.

It is estimated that the dynamic email function of the University of Porto will allow us to reach approximately 36,700 members of the University's community and invite them to take part in this anonymous web-based survey. We will also ask the University of Porto's website management team to divulge the survey, providing a link to access it and following all privacy-related issues.

To preserve privacy, respondents will not be asked to provide any identifiable information. Additionally, invited participants will not be tracked for having started or completed the survey, increasing privacy but limiting the possibility of reminders.

High comparability with the Borghouts et al [89] study is expected due to the nature of the questions in the Borghouts et al [89] survey instrument and their relevance in a Portuguese population, leading us to believe that few questions will be dropped or significantly altered. Gathered data will be assessed according to the same pattern as that offered in the Borghouts et al [89] paper to allow for maximum comparability between results. This means that, aside from a sociodemographic depiction of the sample, we will measure the same constructs as the Borghouts et al [89] paper: barriers to MH resources, important aspects of MH apps, activities people wish for in MH apps, the presence of MH issues, past use of professional MH services, perceived stress, perceived need to seek help, MH

XSL•FO
RenderX

concerns, perceived stigma, the impact of other people's expectations, and privacy concerns. Factor analysis and multicollinearity checking will be performed to limit the analysis to relevant constructs. Direct effect and full mediation models will be built.

All variables will be characterized by descriptive statistical analysis except when not possible. Only data that are excluded due to reasonable suggestion during pretest interviews will be treated differently, being subjected to either descriptive statistical analysis or association estimation according to the nature of the variable at hand.

To maximize response, the only inclusion criterion will be active registration with the University of Porto, defined as the ability to receive the email containing the invitation to answer the questionnaire. No exclusion criteria will be introduced. There will be no financial incentives for filling out the survey.

Ethical Considerations

Ethical considerations and safeguards for the 2 manuscripts to be produced and their supporting documents include the following and incorporate advice received from the Data Protection Officer of the University of Porto:

- To preserve the privacy of participants, they will not be asked to provide any personally identifiable information. In addition, participants will not be tracked for having started or completed the survey, increasing privacy but limiting the possibility of reminders.
- Informed consent and consenting capacity: All potential participants (physicians and academic community members) will be given web-based written information on the study and its objectives and will be asked to provide consent (click-to-agree) that they are happy to participate, and that nonparticipation will not compromise their current roles. Participation in the study will be voluntary, and no inducements or incentives to participate will be offered.
- Confidentiality: Any data or personal details that could potentially reveal the identity of individuals will be removed. Only anonymized, deidentified information will leave the place of origin. A database with responses will be maintained on a password-protected database. All research data will be stored on a password-protected desktop computer at the host organization. Study participants will be invited, through a link provided on the last page of the survey, to provide their name and electronic address to allow the research team to facilitate their receiving a synopsis of the study findings on publication. This list will be kept separately on a password-protected database and a password-protected desktop computer at the host organization. All data will be stored securely at the host institution and destroyed 3 years after the PhD defense date.
- General Data Protection Regulation compliance will be adhered to in terms of the following:
  - Data privacy rights: Participants will have the right to request information about their data throughout the research process.
  - Transfer of data: Participants will be informed about the circumstances under which their data may be transferred and safety measures that will be taken to protect the data (eg, data are encoded).
  - Retention of data: Participants will be informed how long their data will be stored.

By using Inqueritos@UP, survey data will be stored at the University of Porto's servers, and thus not shared with external entities, constituting another layer of privacy protection.

The Ethics Committee of the Faculty of Medicine of the University of Porto has pronounced itself favorable to the research project on June 30, 2022.

Ethics Approval

The research protocol was approved by the Doctoral Program in Health Data Science Director and the Ethics Committee of the Faculty of Medicine of the University of Porto (Rapport 52/CEFMUP/2022 of June 30, 2022). Data collection ran from September 26 and November 6, 2022, for the first study, and between September 20 and October 20, 2022, for the second study.

Results

The findings of the proposed studies will elicit important information on how physicians and potential users perceive and respond to the usage of DMHAs to improve access to care and patient outcomes, along with the reduction of the burden of disease.

Discussion

Principal Findings

This will be the first research project known to the authors with the specific aim of assessing whether DMHA would be welcomed in Portugal and in a health care system with its political economy. It will do so by mapping the expectations of agents that determine the demand and supply sides for DMHA.

As such, the research project will provide valuable inputs on what would be the key success factors for any market- or government-based actors who decide to enter the market by collecting key information to advise health policy and service development in Portugal and in international settings by providing a key benchmarking tool by comparing Portugal with Germany (from the physicians' point of view) and Portugal with the United States (from the individual's point of view) in similar contexts.

It is also the first research project establishing a comparison between health systems with a very significant private sector component and systems where government plays a key role in ensuring access to and funding health and care, particularly concerning MH and the use of digital tools. Finally, in characterizing the market's industrial organization by mapping the expectations of demand and supply sides, it adds to the literature on digital health economics.

Strengths and Limitations

Potential limitations of the research project include bias associated with the method chosen to select the sample in the

XSL•FO
RenderX

second paper, as it considers that the academic community replicates the country's population distribution. Bias may impact external validity as this community may not necessarily replicate the Portuguese population's digital literacy or access to information and communication technology tools, and therefore the implicit digital divide.

In addition, the sample's average age may be younger than the country's average due to the teacher-student ratio and the respective average ages of these groups. Lack of generalizability may also derive from participant self-selection; those more interested in research or in using digital health tools will more likely fill the survey. Question-order, interviewer, and acquiescence biases may have a minor influence on conducted surveys. Notwithstanding these limitations, our research project is expected to provide important information on physicians' and individuals' attitudes toward digital MH tools.

To counter the previously identified limitations and enhance the comparability of results, the authors have produced a "Checklist for a future researcher" (Multimedia Appendix 3). Its aim is to facilitate further research both in Portugal and abroad by listing the main points requiring adaptation to reproduce this protocol in different settings.

Conclusions

The results of the studies projected in this research protocol will have implications for researchers and academia, industry, and policy makers concerning the adoption and implementation of digital health mental apps and associated interventions. Rapid and accessible screening, diagnostic, and treatment care strategies are needed to provide postpandemic access to MH care, and this project will inform key factors in designing and implementing successful digital health interventions based on DMHA both in Portugal and abroad.

Acknowledgments

This work has been done under the scope of, and funded by, the Health Data Science PhD Program of the Faculty of Medicine of the University of Porto, Portugal [90].

Data Availability

The data sets generated and analyzed during this study are not publicly available but are available from the corresponding author upon reasonable request.

Conflicts of Interest

This study was conducted as part of the doctoral research project at the Health Data Science PhD Program, Faculty of Medicine of the University of Porto, Portugal. All authors participated in these projects while employed by the Faculty of Medicine of the University of Porto. Both are working on a project co-funded by the European Union concerning the digitalization of clinical trials in the North of Portugal (CR—Digital: Digitize clinical research in the North of Portugal: NORTE-01-0145-FEDER-083448). This research protocol was executed during the authors' personal time. The European-funded project or the Faculty of Medicine of the University of Porto was at no point involved in the research aside from required administrative approvals. There was also no funding, pay, or other commercial interest provided by the Faculty of Medicine of the University of Porto aside from the costs related to the publication of this paper.

Abstract

Background: Only 11%-40% of those with a mental disorder in Germany receive treatment. In many cases, face-to-face psychotherapy is not available because of limited resources, such as an insufficient number of therapists in the area. New approaches to improve the German health care system are needed to counter chronification. Web-based interventions have been shown to be effective as stand-alone and add-on treatments to routine practice. Interventions designed for a wide range of mental disorders such as transdiagnostic interventions are needed to make treatment for mental disorders more accessible and thus shorten waiting times and mitigate the chronification of mental health problems. In general, interventions can be differentiated as having either a capitalization (CAP) focus—thus drawing on already existing strengths—or a compensation (COMP) focus—trying to compensate for deficits. Up to now, the effectiveness of transdiagnostic web-based interventions with either a CAP or a COMP focus has not yet been evaluated.

Objective: This study is the first to examine the effectiveness of two transdiagnostic web-based interventions: (1) the activation of resilience and drawing on existing strengths (CAP: Res-Up!) and (2) the improvement of emotion regulation (COMP: REMOTION), compared with care as usual (CAU) in routine outpatient psychotherapy.

Methods: Adults with at least 1 mental health disorder will be recruited at 4 outpatient centers in Germany. Participants will then be randomized equally into 1 of the 2 intervention groups Res-Up! (CAP) and REMOTION (COMP) or into the control group (CAU). Assessments will be made at baseline (T0), at 6 weeks after treatment start (T1), and at 12 weeks after treatment start (T2). A primary outcome will be symptom severity (Brief Symptom Inventory-18). Secondary outcomes will focus on emotion regulation and resilience.

Results: Participant recruitment and data collection started in April 2020 and were ongoing as of July 2022. We expect participants to benefit more from the interventions than from the CAU control on the dimensions of symptom severity, resilience, and emotion regulation. Furthermore, we expect to find possible differences between CAP and COMP. The results of the study are expected in 2023.

Conclusions: This randomized controlled trial will compare CAU with the transdiagnostic web-based interventions Res-Up! and REMOTION, and will thus inform future studies concerning the effectiveness of transdiagnostic web-based interventions in routine outpatient psychotherapy.

Introduction

Overview

Approximately 1 in 6 people worldwide have met the criteria for a mental disorder in the last 12 months (17.6%); 29.2% have been identified as having experienced a mental disorder at some time in their life [1]. Mental health problems and disorders have a profound impact on individuals affected by symptoms and society as a whole. Still, in Germany, only 11%-40% of patients receive treatment [2], often due to the long waiting times for psychotherapy (20.1 weeks in 2019) [3]. Therefore, the German mental health care system needs innovative intervention concepts, using approaches beyond standard face-to-face therapy and serving a wide range of mental disorders. Transdiagnostic web-based interventions can provide such an approach [4-6].

Web-Based Interventions

Recent global developments have fast-forwarded digitalization, and thus the use of web-based tools to support mental health care has rapidly increased all over the world. Research on web-based interventions in psychotherapy supports the effectiveness of different intervention programs for a variety of mental disorders [5,7,8]. With limited access to psychotherapy, web-based interventions are an economical, flexible, and practical alternative or addition to conventional treatment [5]. Particularly when face-to-face psychotherapy is not available because of limited resources (like insufficient availability of therapists), web-based interventions can help to avoid long waiting times for treatment and thus mitigate the chronification of mental health problems [4].

Among web-based interventions, stand-alone web-based programs can be differentiated from blended treatment (BT)—the combination of face-to-face psychotherapy and a web-based intervention [9]. Although BT can take on many different forms [10], a differentiation can be made between integrated blends (eg, conceptual coordination between web-based intervention elements and face-to-face psychotherapy sessions via a specified protocol) and add-on blends (eg, a web-based intervention provided in parallel before or after face-to-face psychotherapy without conceptual coordination or integration between the two). BT, where a web-based intervention was provided as an add-on to face-to-face psychotherapy, has been shown to be more effective than psychotherapy alone [11]. A transdiagnostic approach might be particularly relevant for add-on conceptualizations as coordination with a potential face-to-face therapy focusing on a specific disorder is less relevant.

Although even unguided web-based interventions (without any contact between the patient and the provider of the intervention) seem to be effective, therapist-supported web-based interventions are most likely more effective than self-guided treatments [5,12,13]. Although the exact mechanism behind the benefit of guidance remains unclear, this may be due to higher adherence and lower dropout rates resulting from the positive effect of the accompanying support on motivation and on engagement with the intervention [5,11].

Capitalization or Compensation: Basic Orientations in Psychotherapy

Overall, a differentiation has been made in psychotherapy research between capitalization (CAP)–oriented versus compensation (COMP)–oriented *interventions*. CAPs aim to draw on the person's already existing strengths (in a wide sense: action repertoire, resilience strategies, and external and internal resources), and COMPs identify dysfunctional maintenance factors of psychopathology and teach (respectively train) the person to use new strategies or build new behavior against relative deficits [14-18]. In an early study, Wingate et al [18] compared the outcomes of compensation versus capitalization in the treatment of suicidality in young adults, finding results favoring COMPs, whereas other studies find results favoring CAPs [14,17]. According to the current sparse research, there is no agreement on which of these 2 strategies should be pursued in psychotherapy [14,17,19-22].

Certain interventions in psychotherapy are inherently more focused on capitalization (eg, focusing on action repertoire, resilience strategies, and external and internal resources) or on compensation (eg, focusing on the building of new strategies for deficit compensation). Although outcome differences between CAPs and COMPs in face-to-face psychotherapy seem to be small [14], there are no studies comparing the 2 approaches for web-based therapy. Web-based therapy involves less therapeutic guidance and thus relies more strongly on the person's self-management capacities. Thus, the possible effects of therapists' support in face-to-face therapy compensating deficits in both CAP and COMP cease in a web setting. Thus, this randomized controlled trial explores, for the first time, the effect of 2 transdiagnostic web-based interventions inherently capitalization or compensation oriented: activation of resilience (CAP) (respectively improvement of emotion regulation [COMP]) compared with a care-as-usual (CAU) group.

As discussed above, capitalization and compensation can be conceptualized as features of interventions. Another possible conceptualization is via the interaction of intervention focus with patient variables. If particularly patients with a high level of adaptive emotion-regulation strategies profit from an intervention focusing on the improvement of emotion-regulation strategies, this would point toward a capitalization change process. If patients with a low level of adaptive emotion-regulation strategies profit particularly from an intervention focusing on the improvement of emotion-regulation strategies, this points to a compensation change process. Thus, in this trial, differential effects of patients' initial resilience (respectively emotion-regulation competencies) on the outcome of a resilience and emotion-regulation intervention will also be explored.

Resilience

Resilience as psychological resistance to adversity was originally conceptualized in the context of developmental psychology [23,24]. Today, resilience and resources are often discussed in the field of positive psychology [25], which focuses on factors that make and keep people healthy rather than ill. Although most research on resilience and resources has a compensation focus, aiming to create new resources and building up new strengths [26], the personal model of resilience (PMR) is a CAP intervention that was developed by Padesky and Mooney [27] from a cognitive perspective.

The PMR focuses on individuals' pre-existing resources and resilient strategies to increase awareness and implementation of these strengths. The basic assumptions of the PMR are as follows: every person is resilient and has resilience strategies that are already part of their action repertoire and have the potential to also be used in challenging situations. The model is based on evidence-based standards for cognitive behavioral therapy [28].

The model was evaluated in a pilot study with students [29], a randomized study with a waiting control group [30], and in a web version with active plus waiting control groups (web-based intervention program vs face-to-face vs ABC [activating events, belief systems, emotional and behavioral consequences] model vs waiting control group) [31]. Medium effect sizes for the face-to-face model and small effect sizes for the web version were observed. Based on the feedback of participants, the web version was redesigned and is being re-evaluated [32]. The redesigned version of the program (Res-Up!: Resilience program of the University of Witten/Herdecke) showed medium effect sizes in preliminary results for resilience (d=0.51-0.55) and emotional competence (d=0.51), greater effect sizes for self-compassion (d=0.70), and small effect sizes for self-esteem (d=0.41) [32].

Emotion Regulation

Emotion regulation refers to the way individuals attempt to influence emotions and includes the upregulation and downregulation of positive and negative emotions in accordance with regulatory goals [33]. Emotion regulation and specifically the fostering of flexible use of different emotion-regulation strategies are important topics in the treatment of mental health disorders and more specifically in psychotherapy research. This is made evident by the large number of publications that focus on the topic of emotion regulation [34-37]. Interestingly, emotion regulation has been discussed as a transdiagnostic factor related to psychopathology and the treatment of mental health disorders [34,38-40]. More recently, several mental health interventions that address or target emotion regulation have been developed as web- or mobile-based programs. For example, Böhme and Berking [41] describe the application of an emotion regulation app based on Affect Regulation Training.

By using the extended process model of emotion regulation as a theoretical framework to structure an emotion-regulation intervention [42], Bielinski et al [43] developed REMOTION. The web-based program aims to reduce the symptom severity of patients with a range of different diagnoses while improving their emotion regulation [43]. REMOTION is currently being examined as a blended intervention in an outpatient psychotherapy setting in a pilot randomized controlled trial [43]. It is also currently being examined as an add-on to acute inpatient psychiatric care in another pilot randomized controlled trial (ClinicalTrials.gov NCT04990674). Results for both trials are expected in 2023.

Aims

Web-based interventions have been efficient and helpful in considering different mental disorders and in self-selected samples in many controlled studies [7]. Nevertheless, little is known about the efficacy of web-based interventions in routine psychotherapeutic practice and their usefulness as an add-on to conventional psychotherapy (BT).

The *first goal* of this study is to assess the effectiveness of 2 web-based interventions (Res-Up! and REMOTION) in an outpatient psychotherapeutic routine setting in comparison with CAU.

The *second goal* of this study is to explore, in a web-based therapy context, the implementation of interventions with either a CAP or COMP focus by using 2 transdiagnostic web-based intervention programs, centered either on activating resilience (CAP; "Res-Up!") or on emotion regulation (COMP; "REMOTION").

Further subanalyses considering differences in patients' benefits depending on their diagnoses will be conducted. In addition, the differential effects of initial resilience and emotion-regulation competencies on the effectiveness of Res-Up! and REMOTION will be explored. To accomplish this, the initial status of resilience and emotion-regulation competencies will be assessed and related to intervention effects in the intervention groups.

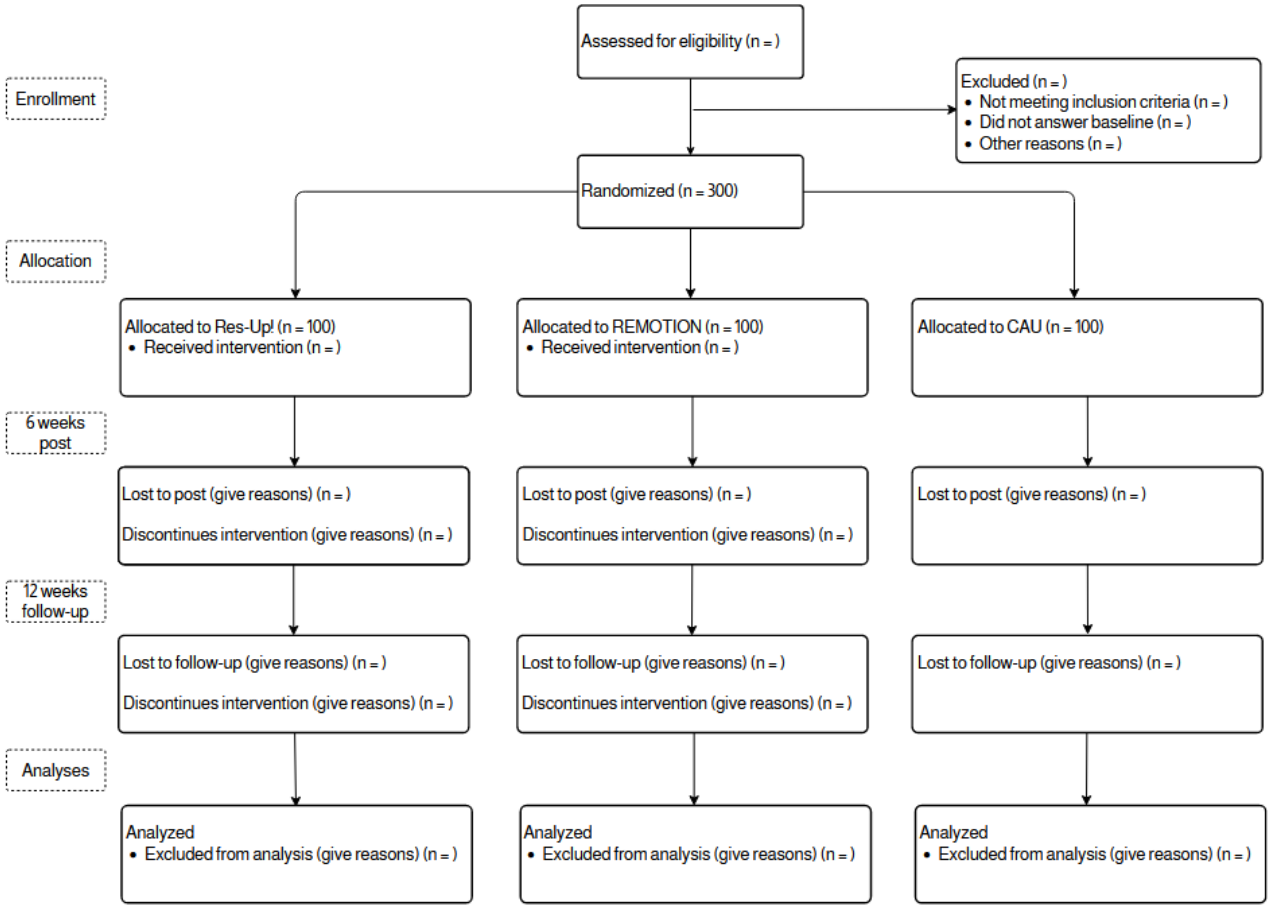
Methods

Study Design

The study is a multicenter 3-arm randomized controlled trial in which a CAU approach will be compared with 2 different web-based intervention programs (CAP: Res-Up! and COMP: REMOTION), which will be administered as an add-on to CAU.

Participants in the intervention groups will be given access to Res-Up! and REMOTION immediately, whereas participants in the CAU group will receive access to one of the interventions after 12 weeks (participants in the CAU group can choose which intervention they want to access). Assessments will be made at baseline, 6 weeks (post), and 12 weeks (follow-up) for all participants. Assessments at 6 and 12 weeks will be made irrespective of whether the participant is in face-to-face treatment.

The multicenter trial will take place at the outpatient clinics of the Training Center for Psychological Psychotherapy OWL (Bielefeld, Germany), the Centers for Psychotherapy Dortmund and Muenster (all German Association of Behavioral Therapy—Deutsche Gesellschaft für Verhaltenstherapie [DGVT]), and the Center for Mental Health and Psychotherapy



XSL•FO
RenderX

(Department of Psychology and Psychotherapy, University Witten/Herdecke).

Primary and secondary outcomes will be gathered via link to web-based self-report questionnaires based on Qualtrics software [44] at baseline and 6 and 12 weeks after baseline.

All participants will be required to give their informed consent before enrollment in the study. The written consent will be obtained by trained psychotherapists at the outpatient centers. Furthermore, all participants are given the option to contact a study member during the intervention ("guidance on demand") either via email (REMOTION) or chat (Res-Up!) but are not actively contacted by the team (except for reminders to complete the interventions or questionnaires and a welcome message). Figure 1 displays the flow of patients through the study.

Figure 1. Flow of participants. CAU: care as usual.

Sample Size Calculation

Sample size was calculated with the software G*Power [45]. We aim to detect small effect sizes of Cohen *d*=0.20 regarding the Time×Group interaction for the 2 active conditions at an error level of .05. A power analysis revealed that a sample size of 80 participants in each of the active study arms is required to detect a statistically significant difference with a power ($1 - \beta$) of .80. The sample size was further estimated based on a dropout rate of approximately 25%. We finally decided to randomize 100 participants to each of the conditions (3 arms, 100 per arm; CAU, Res-Up!, and REMOTION). The second goal of the study is exploratory, and thus no assumptions about differential effects can be made.

Eligibility Criteria

The inclusion criteria are as follows: (1) current diagnosis of a mental disorder according to *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* or *International Classification of Diseases, 10th Revision*; (2) recruitment at one of the participating outpatient clinics listed above; (3) interest to receive psychotherapy at one of the centers but not currently enrolled; (4) at least 18 years of age; and (5) reliable web access. The exclusion criteria are as follows: (1) current severe episode of major depression, (2) current psychotic disorder, (3) acute suicidal tendency, (4) other severe mental disorders (eg, bipolar disorder), and (5) insufficient German language skills. These diagnoses were ruled out because of their severity, as they impair the ability to concentrate on web-based interventions and stay committed for several weeks of programs and measurements. Access to face-to-face psychotherapy after enrollment is not restricted while participants are working with the web-based programs in order to approximate naturalistic conditions.

Recruitment and Randomization

Recruiting training centers for psychological psychotherapists in Germany are located in Bielefeld, Dortmund, Muenster (training centers of DGVT) and in Witten, Germany (Center of Mental Health and Psychotherapy, Witten/Herdecke University). Trained psychotherapists at all centers will inform interested individuals coming to the institution for a face-to-face consultation session. As waiting lists for psychotherapy are

XSL•FO
RenderX

quite long in Germany, the consultation generally does not mark the beginning of psychotherapy but is scheduled to evaluate whether the person has a clinically relevant psychiatric disorder with a structured clinical interview. Interviewers gather written consent to participate in the study, which is forwarded to the study team members. After study eligibility is proven, participants receive an email with a personalized code to the baseline questionnaires. Once participants have filled out the baseline questionnaires, they are randomized via Qualtrics software [44].

Ethics Approval

The study will be conducted according to local regulations and the Declaration of Helsinki. The study was approved by the ethics committee of the University Witten/Herdecke (221/2019). Written informed consent regarding the gathered data and following analyses as well as scientific publications in an anonymous form will be obtained from all patients by the recruiting therapists in outpatient centers. The trial is registered with ClinicalTrials.gov (NCT04352010). Data will only be analyzed in an anonymous form and will be deidentified by a specific member of the research team.

Interventions

Res-Up!

Res-Up! is a web-based intervention focusing on patients' strengths and positive experiences developed at the University Witten/Herdecke. The intervention is based on the PMR [27], which is a positive cognitive intervention that uses patients' strengths to overcome problems. The PMR activates resilient emotions, thoughts, metaphors, images, and behaviors in 4 steps structured into 5 modules. A variety of psychotherapy elements (cognitive behavioral therapy, emotion-focused therapy, positive therapy, etc) are integrated in the program. Participants are asked to work on 1 of 5 consecutive modules per week; completing a module takes about 1-2 hours. Res-Up! is conducted on the web platform Minddistrict [46], which has been approved by the privacy policy office of Witten/Herdecke University before the start of the study. The intervention can be administered as a stand-alone or add-on treatment to psychotherapy. The basic assumption of the PMR is that every individual has a repertoire of resilience strategies that can be used in everyday life or in situations of crisis. Res-Up! aims to identify these strategies and improve, support, and implement them in problematic situations where they were not used before. In the first module, participants are educated on the concept of resilience. In the second session, individual resilience areas of the participant are elaborated. The goal of the third module is to construct the individual's current PMR. The PMR is further developed in the fourth module in which resilient strategies from the model are used and adapted for still problematic areas. At the end of this module, a behavioral experiment is planned. The experiment is evaluated in the last module. To further increase participants' motivation to use their model and resilience strategies, the individual's experiences with the PMR are summarized.

Training and intervention elements are presented as informational texts as well as interactive modules, individualized questions, videos, and audio files. Throughout the whole intervention, participants can ask for guidance (via chat or email) by a member of the study team who is trained in the program and has at least a master's degree in psychology. To increase adherence, reminder messages to complete the modules in time are sent via chat. With continuous participation, participants should complete the intervention within 6 weeks.

REMOTION

The web-based intervention REMOTION is aimed at reducing symptom severity and improving emotion regulation of individuals with different mental health disorders [43]. The theoretical background and exact structure of REMOTION have been described in detail elsewhere [43]. REMOTION includes an introduction and 5 further modules, and individuals are asked to work on 1 module per week, ideally for around 1-2 hours per week. Intervention elements are presented in different formats including video, text, and audio along with different types of exercises throughout the program. The intervention is accessed via a platform provided by the University of Berne, and the access is password protected. Textbox 1 shows the content of the intervention.

For this study described in this protocol, and to allow comparability with the Res-Up! intervention, REMOTION is administered as a stand-alone or an add-on treatment to psychotherapy. If individuals do not work with the program for an entire week, they are then reminded to work with the program, but no other active guidance components (like weekly emails) are added. Individuals are, however, able to contact the study team via email if they have any questions. Like Res-Up!, completion of the REMOTION program should take around 6 weeks.

XSL•FO
RenderX

Textbox 1. The content of REMOTION shown in detail.

Introduction

- Information about the structure of the intervention and about the theoretical background, and a user guide are provided in this module

Psychoeducation

- Information is provided as to what emotions are, what their functions are, and what types of emotional experiences there are
- The concept of emotion regulation is introduced and the relationship between emotion regulation and mental illness is explored

Identification

- Emotional awareness, which is identified as key to the perception substep of the identification stage of emotion regulation [42], is explored in this module
- If and when to regulate emotions, along with information on the value of emotion regulation, is introduced in this module

Selection

- This module shows patients what types of emotion-regulation strategies are available
- The focus is on the selection of an emotion-regulation strategy [42]
- The strategies situation selection or modification, attentional deployment, cognitive change, and response modulation are introduced in this module [47]
- Furthermore, strategies specific to over- and under-regulated states are also introduced [48-50]

Implementation

- This module shows patients how the previously introduced strategies can be implemented, for example, translated to different tactics [42]
- Exercises are introduced for every emotion-regulation strategy, and advice is provided as to how these exercises can be implemented into daily life

Modification and flexibility

- The importance of the flexible use of strategies (being able to modify strategies and being able to apply them flexibly) [42,51] is discussed in this module
- Patients are encouraged to flexibly use strategies, to apply them to different contexts, to practice, and to also attempt sequences or blends of strategies that work for them as individuals

Note: The textbox is adapted from Bielinski et al [43] which is published under Creative Commons Attribution 4.0 International License [52].

CAU Group

Participants in the CAU group will not get access to the web-based interventions for 12 weeks after baseline. They will answer the questionnaires before randomization as well as 6 (respectively 12) weeks later. They get access to the web-based interventions of their choice after completing the follow-up assessment. During the waiting time, participants are allowed to stay on the wait list or start psychotherapy as they would usually.

Trial Organization

Participants are being recruited during their registration to regular psychotherapy in the outpatient centers in Germany mentioned above. Recruiting outpatient centers received information about the study from a member of the study team via a short instruction manual, an instruction video, and a personal introduction for psychotherapists in associated centers. Information on the study and the interventions (Res-Up! and REMOTION) is given to interested patients face to face with additional written information by trained psychotherapists. Written consent to participate is solicited by the respective practitioner. Written consent and necessary information (name, birth date, diagnoses, date of recruitment, and email) is given to a member of the study team. Participants then receive an email from the study team with an individualized code to the baseline measure via Qualtrics [44]. Answering individual questionnaires will take approximately 30 minutes at every assessment point. After completing the baseline, participants are randomly assigned by a randomized computer generator (in Qualtrics [44]) to 1 of the 3 treatment arms. As the interventions are planned for 6 weeks, posttreatment measures are provided 6 weeks after baseline. Twelve weeks after baseline, participants are invited to fill out the follow-up measures in order to reach participants with minimal overlap with face-to-face psychotherapy.

Participants in the CAU group are informed that they will have to complete the following two assessments and will get access to the program of their choice after completing the follow-up. In the experimental conditions, participants receive an email with their web access to either (1) Res-Up! (focusing on resilience) or (2) REMOTION (focusing on emotion regulation).

Measures

Overview

Items recording demographic information of patients will be presented at baseline and a reduced battery at 6 and 12 weeks. Patient diagnostic status will be obtained during the initial interview by conducting a Structured Clinical Interview I (German version) for Diagnostic and Statistical Manual of Mental Disorders (respectively a clinical assessment) by an experienced psychotherapist [53,54]. A full description of all outcomes in the study is provided in Table 1. All measures will be provided via a web platform. Data collection will be supported by email reminders.

Table 1. Assessments listed by time points.

Variable and outcome	Instrument	Time point		
		Baseline	6 weeks	12 weeks
Demographics		✓	✓	✓
Structured clinical interview or clinical assessment		✓		
Primary outcome				
Symptom severity	BSI-18[a]	✓	✓	✓
Secondary outcomes				
Resilience	WIRF[b]; CD-RISC-10[c]	✓	✓	✓
Emotion regulation	SEK-27[d]; FrAGe[e]	✓	✓	✓
Other outcomes

Working alliance	WAI-I[i]		✓	✓

[a]BSI-18: Brief Symptom Inventory [55,56].

[b]WIRF: Witten Resource Questionnaire [57].

[c]CD-RISC-10: Connor-Davidson Resilience Scale [58].

[d]SEK-27: Self-assessment of Emotion Regulation Skills [59].

[e]FrAGe: Questionnaire Assessing the Acceptance of Unpleasant and Pleasant Emotions [60].

[f]PHQ-9: Patient Health Questionnaire-9 [61].

[g]RSES: Rosenberg-Self-Esteem Scale [62].

[h]SCS-D: Self-Compassion Scale—German [63].

[i]WAI-I: Working Alliance Inventory I (adapted for web-based interventions) [64].

Primary Outcome Measure

The primary outcome measure in this study is general symptom severity measured with the Brief Symptom Inventory—a short form (BSI-18; German version) [55] of the Symptom-Checklist-90-Revised (SCL-90R) [65]. The BSI-18 has 18 items and is a frequently used questionnaire to measure general symptom severity (Cronbach α=.85-.89) with good psychometric properties [56], comparable to those of the SCL-90R [65].

Secondary Outcome Measures

Resilience will be assessed by two instruments: (1) the Witten Resource Questionnaire [57], a 37-item self-report of personal and external resources with high reliability (Cronbach α=.72-.85), and (2) the Connor-Davidson Resilience Scale-10 [58], an internationally used 10-item self-report of individual resilience with high reliability (Cronbach α=.81-.90).

Emotion regulation will be assessed via the following two instruments: (1) Self-assessment of Emotion Regulation Skills-27 (Selbsteinschätzung emotionaler Kompetenzen) [59], a 27-item self-report measure of emotion-regulation skills with high reliability and validity (Cronbach α=.90), and (2) the Questionnaire Assessing the Acceptance of Unpleasant and Pleasant Emotions (Fragebogen zur Akzeptanz von Gefühlen) [60], a 32-item self-report of the acceptance and suppression of pleasant and unpleasant emotions with good reliability and validity.

Other Outcome Measures

Severity of depression will be assessed with the German version of the Patient Health Questionnaire-9 (PHQ-9) [61]. The PHQ-9 is an internationally used 9-item self-report for screening, diagnosing, monitoring, and measuring the severity of depression with a high retest reliability and validity (Cronbach α>.86).

XSL•FO
RenderX

Self-esteem will be assessed with the Rosenberg-Self-Esteem Scale [62], an internationally used 10-item self-report of general self-esteem with high reliability and validity (Cronbach α=.72-.85).

Self-compassion will be assessed with the Self-Compassion Scale [63], an internationally used 26-item self-report of self-compassion with high reliability and validity (Cronbach α>.90).

In accordance with meta-analytic results [66], the *therapeutic alliance* between participants and the web-based intervention or study team will be measured with an adapted version of the Working Alliance Inventory for guided Internet Interventions (WAI-I) at the end of the intervention [64]. The WAI-I showed good internal consistency at total and subscale level (Cronbach α between .92 and .94). For the purpose of this study, the term "psychologist" was substituted with the term "study team" in the questionnaire.

Information about whether patients started psychotherapy while working with the web-based interventions will be gathered at 6 weeks and 12 weeks. An overview of the assessments and the measures is provided in Textbox 1. Participants receive up to a maximum of 3 weekly reminders via email if they do not answer the questionnaires in time.

Planned Analysis

Data will be analyzed using an intention-to-treat (ITT) approach, including all randomized patients in the outcome analyses, and handling missing data accordingly. Participants will be defined as dropouts if no baseline measurement is given. The primary outcome measure, general symptom severity, will initially be analyzed descriptively. The effects of the interventions on the primary and secondary outcome measures will be analyzed with linear mixed-effect models (LMMs). LMMs are recommended for ITT analyses with missing data because of the possibility to accommodate for missing data without having to exclude or impute data and do not depend on limited assumptions about the variance-covariance matrix. Sensitivity analysis will be conducted to analyze the impact of dropouts, psychotherapy, and medication on results. The effect sizes of all within groups for pre- to follow-up changes will be computed as Cohen *d*. In addition, clinical significance of changes will be analyzed (reliable change index) [67].

For categorical data, amount, or percentage will be reported. Significance testing of dichotomous data will be conducted with chi-square tests. Results will be reported in accordance with CONSORT (Consolidated Standards of Reporting Trials) [68] and CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklists [69].

Results

Participant recruitment and data collection started in April 2020 and completed in July 2022. Results for the study are expected in 2023. Regarding our research questions, we expect participants of our study to benefit more from the interventions than participants in the CAU control on the dimensions of resilience and emotion regulation, respectively. To accomplish the initial status of resilience and emotion-regulation competencies, they will be assessed and related to intervention effects in the intervention groups. Furthermore, we expect to find possible differences between CAP and COMP when the intervention is delivered via a web platform.

Discussion

Principal Findings

This study aims to compare a CAU control with 2 transdiagnostic web-based intervention programs, focusing either on resilience (as an example of capitalization strategies) or on emotion regulation (as an example of compensation strategies).

In accordance with previous research [11], we hypothesize that both interventions will be more efficacious than no additional treatment (CAU). According to Fuhr et al [12], web-based interventions that focus on individual parts of psychotherapy—preferably in a blended approach—might be more effective than all elements of a disorder-specific therapy when implemented in a routine setting. Because of the dearth of studies comparing CAP versus COMP interventions directly, no directed hypothesis can be formulated in this context. While the primary outcome targets symptom severity, secondary outcomes assess resilience and emotion regulation as the specific target areas of the individual interventions.

The study will be conducted in Germany in 4 outpatient centers in a clinical sample of approximately 300 participants, 100 in each of the 3 study arms. Matching the transdiagnostic approach of the interventions, participants in the sample will have a variety of different mental disorders and varying symptom severity.

Results from this study will be valuable for practitioners, patients, and mental health services in all fields, due to the transdiagnostic approach. Furthermore, it will contribute to the knowledge and efficacy of evidence-based web-based intervention programs and possibilities of implementation in outpatient routine care. In particular, it will create new knowledge for web-based interventions focusing on resilience and emotion regulation and thus shine light on possible differences of capitalization- and compensation-oriented interventions in web settings.

Limitations

There could be several *limitations* that can be considered. First, our results might not be generalizable to the general population of outpatient psychotherapy patients because we will apply exclusion and inclusion criteria and recruit a self-selected sample. Clinical practitioners in outpatient clinics recruit participants and inform in advance to ensure a clinical sample. Second, dropout rates from web assessments due to nonadherence to the interventions are a frequently known problem of web-based interventions [11]. Third, there might be an influence on the results due to Res-Up! and REMOTION being distributed through 2 different platforms, as usability rates might vary. Furthermore, participants have the possibility to contact the study team via email or chat throughout the whole

XSL•FO
RenderX

intervention, which should increase adherence to the web-based programs and support motivation [13]. However, it must be taken into consideration that participants were able to reach out to the study team via 2 different methods (chat and email), which might influence adherence. Starting a psychotherapy during participation will be controlled in the study and the analyses. Whether such a combination of web-based interventions and psychotherapy not coordinated with the web-based interventions is regarded as BT or not is a matter of debate in the field [9]. This debate will be addressed in the study publications.

Conclusions

Therapy Online Plus is a multicenter randomized controlled trial, comparing for the first time in a clinical sample a CAU group with 2 transdiagnostic interventions: Res-Up! and REMOTION. To explore the comparison of the 2 transdiagnostic web-based intervention programs, it will assess the transdiagnostic effectiveness of the above interventions, considering different mental disorders. Furthermore, results will extend existing knowledge about the possibilities of implementing web-based interventions in routine psychotherapy settings.

Acknowledgments

We would like to thank Natalie Fromme-Schwarzhöfer for her contribution to the Res-Up! videos, Marijke Kley and Gwen Wälchli for their support with the sending of reminders for the study questionnaires, and all recruiting institutions for their support. Funding for the study is provided by the Academy of Psychiatry and Psychotherapy e.V. Bielefeld (Germany) and the Department of Clinical Psychology and Psychotherapy, University of Bern (Switzerland) as well as the Centers for Psychotherapy Dortmund and Münster (DGVT and the Center for Mental Health and Psychotherapy [Department Psychology and Psychotherapy, University Witten/Herdecke]).

Data Availability

The data sets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

LFT wrote the initial version of the manuscript. All authors contributed to further drafts of the manuscript. UW and TB are the principal investigators of the study.

Abstract

Background: The recovery of scapular and humeral physiological kinematic parameters, as well as the sensorimotor control of movement, plays a primary role in the rehabilitation process after arthroscopic rotator cuff repair. A highly customized rehabilitation approach is required to achieve this aim. Biofeedback can be a useful tool, but there is poor evidence of its application in the rehabilitation after arthroscopic rotator cuff tear repair.

Objective: The aim of this paper is to outline an innovative exercise-based rehabilitation program exploiting visual biofeedback for the recovery of patients arthroscopically treated for rotator cuff repair.

Methods: For establishment of the innovative program, a multidisciplinary team involving experts in shoulder surgery, rehabilitation medicine, physical therapy, and biomedical and clinical engineering was formed. Starting from a conventional rehabilitation program, the team selected a set of exercises to be integrated with a biofeedback tool, named the INAIL (National Institute for Insurance against Accidents at Work) Shoulder and Elbow Outpatient program (ISEO program). ISEO is a motion analysis system based on inertial wearable sensors positioned over the thorax, scapula, humerus, and forearm. ISEO can return a visual biofeedback of humerus and scapula angles over time or of the scapula-humeral coordination, with possible overlap of patient-specific or asymptomatic reference values. A set of 12 progressive exercises was defined, divided into four groups based on humerus and scapula movements. Each group comprises 2-4 of the 12 exercises with an increasing level of complexity. Exercises can require the use of a ball, stick, rubber band, and/or towel. For each exercise, we present the starting position of the patient, the modality of execution, and the target position, together with notes about the critical factors to observe. The type of visual biofeedback to adopt is specified, such as the coordination between angles or the variation of a single angle over time. To guide the therapist in customizing the patient's rehabilitation program, a list of operative guidelines is provided.

Results: We describe various applications of the ISEO exercise program in terms of frequency and intensity.

Conclusions: An innovative rehabilitation program to restore scapular and humeral kinematics after rotator cuff repair based on kinematic biofeedback is presented. Biofeedback is expected to increase patient awareness and self-correction under therapist supervision. Randomized controlled trials are needed to investigate the potential effect of the exercise-based biofeedback in comparison with conventional rehabilitation programs.

Introduction

Scapular dyskinesis is a common condition in a variety of shoulder disorders, including rotator cuff tears [1-5], with the medio-lateral and anterior-posterior scapular rotations most commonly affected [6]. The evaluation and treatment of scapular dyskinesis are challenging; in particular, finding accurate and repeatable measures to define "how much" scapular movement is dyskinetic and if it is a cause or effect of the rotator cuff tear is objectively difficult [7,8].

An exercise-based, manual, and proprioceptive treatment of scapular dyskinesis should be included in an individualized rehabilitation program following arthroscopic rotator cuff tear repair, with the purpose to restore pain-free physiological function of the shoulder [9]. Current rehabilitation programs should always refer to the time of tendon healing, surgical technique, evidence-based guidelines, literature, biomechanics, and kinesiology foundations, and should avoid a generic approach or a too-strict protocol [10-12]. However, the current literature lacks tools to specifically support therapists in the difficult challenge to tackle shoulder dyskinesis.

To address this aim, biofeedback systems might support patients in improving their own body function by receiving additional information about its status. This is typically achieved by sensing the target function though a wearable technology and returning this information to the patient through an alternative intrinsic sensory feedback (eg, audio, tactile, visual) [13].

Evidence about the use of biofeedback in rehabilitation of shoulder disorders remains limited in terms of both quantity and quality [14,15]. Some preliminary evidence suggests that biofeedback can improve scapular control in patients with adhesive capsulitis [16] and subacromial impingement syndrome, either based on electromyography (EMG) or simple video qualitative biofeedback [17-19]. However, there is poor evidence about the impacts of biofeedback based on quantitative kinematic data. In 2018, Hotta et al [20] reported a study on 26 subjects with impingement syndrome who were assessed during arm elevation before and after completion of a scapula training protocol based on kinematic biofeedback. No substantial differences were found for the range of motion (ROM) of the three scapular rotations, whereas the segmental coordination between the scapula and humerus showed significant differences with respect to scapular tilt in the lowering of the arm and with respect to internal rotation in the elevation and lowering of the arm. Opposite conclusions can be gathered from the study of Antunes et al [21], who completed a randomized controlled trial involving 30 healthy subjects divided into two groups. They tested the effectiveness of kinematic biofeedback on motor relearning transfer during shoulder flexion and a daily activity (drinking from a glass). All subjects were tested before and after the training. The training comprised scapular-focused exercises, performed with a real-time kinematic biofeedback tool consisting of 2D visual information of the scapulo-thoracic orientation. The results demonstrated that real-time kinematic biofeedback introduced relevant differences on scapula control and performance. These studies [20,21] refer to the immediate effect of a single-session biofeedback protocol based on few exercises. However, to our knowledge, there are no studies about the application of kinematic biofeedback for the recovery from rotator cuff tear surgical repair.

To fill this gap, we here propose a newly developed innovative exercise-based program, named the INAIL (National Institute for Insurance against Accidents at Work) Shoulder and Elbow Outpatient program (ISEO program), for the recovery of patients arthroscopically treated for rotator cuff repair. This program integrates the conventional rehabilitation program developed at the Service of Functional Recovery and Rehabilitation of the Azienda Unità Sanitaria Locale (AUSL) Romagna (Ceccarini Hospital, Riccione, Italy), with use of a kinematic visual biofeedback tool that provides a real-time objective and accurate evaluation of the upper arm kinematics [22].

Methods

Conventional Rehabilitation Program

The conventional rehabilitation program is based on a biomechanical foundation, the literature, clinical experience, time of tendon healing, and surgical instructions [10,23-25], providing therapists a timeline scheme with restrictions and objectives for each phase.

In phase 1 (day 1 to day 21), immobilization is established with use of an antirotation sling for 21 days. The sling can be removed for personal care or for active mobilization of the elbow, hand, and only sliding movements in elevation/depression and protraction/retraction of the scapula, keeping the gleno-humeral joint in resting position. Patients are instructed about how to wear and correctly remove the sling and about movement restrictions. Individual outpatient rehabilitation sessions start from day 15 and occur twice per week.

In phase 2 (day 21 to day 35), passive gleno-humeral mobilization on the scapular plane under a 90° angle is allowed (no rotational movements), as well as mobilization of the scapula. The sling is gradually removed from day 21 and passive ROM can be gradually increased over 90°. In this phase, basic exercises to activate scapular stabilizers and humeral head depressors are recommended, as well as improving postural alignment. It is crucial to avoid overstress of the repaired tendon. Two individual outpatient sessions per week are performed.

In phase 3 (day 35 to day 60), the aim is to restore full passive ROM, achieve good control of the kinematics, and correct the timing of muscles activation. From day 35, the patient can start performing gleno-humeral extra rotations and active humerus elevation exercises. Restoration of full passive ROM continues.

XSL•FO
RenderX

In this phase, water exercises are integrated in the recovery program [26]. Four sessions per week are performed: two individual outpatient sessions and two sessions of aquatic therapy in a small group.

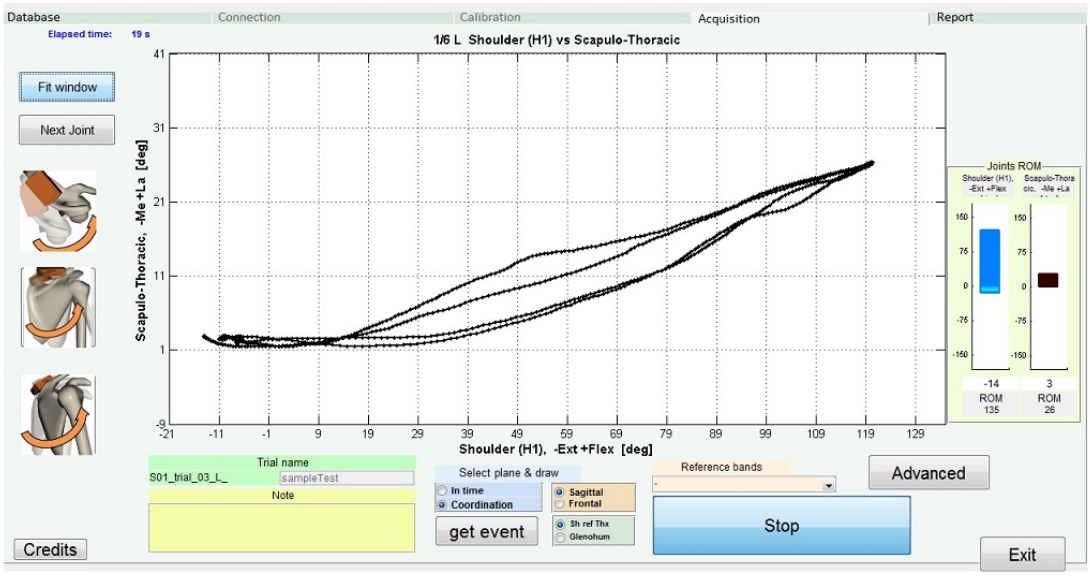
The final phase, phase 4 (from day 60 until return to work), occurs 2 months after surgery, in which dynamic strengthening exercises gradually advance using weights and rubber bands, with an increasing load on the repaired tendon. Functional exercises are integrated in the recovery program. In this phase, two individual outpatient sessions and, if still needed, two aquatic sessions per week are performed.

ISEO Program

Overview

The ISEO program integrates use of instrumental kinematic biofeedback in the conventional rehabilitation program, focusing on the improvement of scapular control of patients recovering from arthroscopic rotator cuff tear repair. The ISEO program is based on recent literature about rotator cuff diseases [27,28], EMG and kinematic studies [29-34], shoulder biomechanical foundations [35], exercises described in other randomized controlled trials without biofeedback [36-40], and clinical experience. The ISEO program was developed following Consensus on Exercise Reporting Template (CERT) guidelines [41].

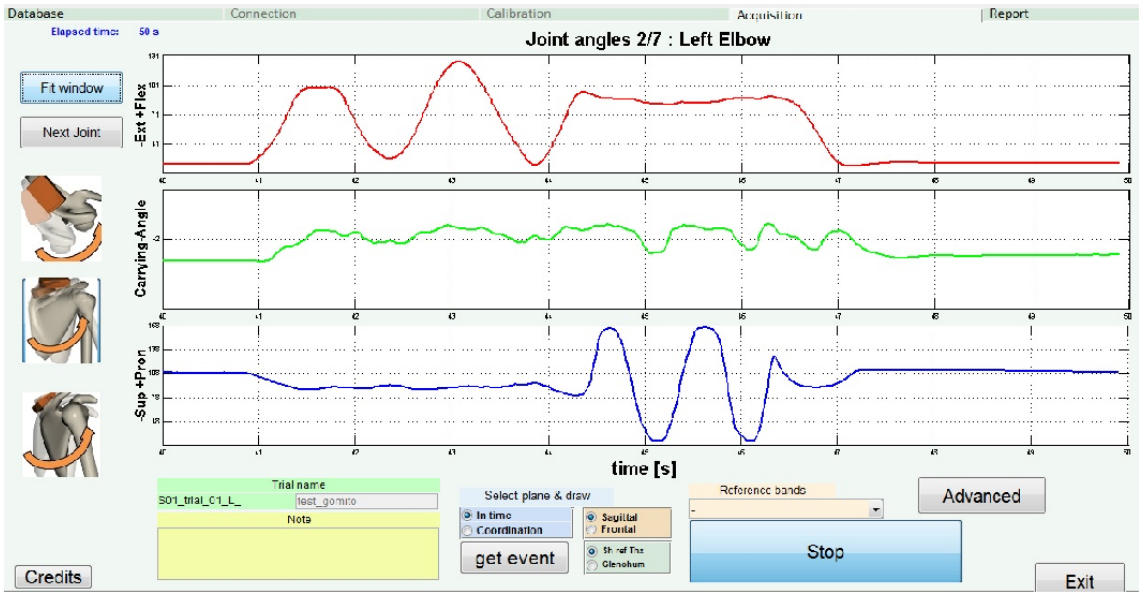
Device



The ISEO program is based on the previously described ISEO protocol application [22]. ISEO was validated against an optoelectronic system [22], and the agreement with respect to the "Scapula-Tracker" method was tested [42]. The reliability of ISEO was assessed, investigating the agreement both within and between testers [43], and age-dependent prediction bands of asymptomatic subjects were estimated [44]. To collect kinematic data, ISEO exploits an inertial and magnetic measurement system (Xsens Technologies, NL). This system is portable, small, easy to use, and comprises four wireless sensors that are placed over the thorax, scapula, humerus, and forearm.

Owing to a dedicated sensor-to-segment calibration and biomechanical model, ISEO provides a quantitative real-time evaluation of humerus and scapula rotations over time with respect to the thorax, as well as the scapulo-humeral coordination by measuring the three scapular rotations with respect to humerus elevation. Specifically, the scapulo-thoracic joint is described by means of three rotations: protraction-retraction, medio-lateral rotation, and posterior-anterior tilting [45]. The humerus orientation is described in terms of elevation with respect to the thorax in the sagittal (flexion-extension) and scapular (abduction-adduction) planes and in the axial rotation (external rotation [ER]/internal rotation [IR]). The scapular plane is intended to be 30°-40° anterior to the frontal plane.

The system provides two types of real-time kinematic data plots, which are reported on a computer screen visible to both the therapist and the patient. The first is the scapulo-humeral coordination plot (Figure 1), which is an angle-angle plot representing humeral elevation on the X-axis (flexion-extension or abduction-adduction) and scapula rotations on the Y-axis (one plot for each scapula rotation). The patient can see how the scapula is moving while performing humerus flexion-extension or abduction-adduction. Preset reference bands [44], based on values obtained from asymptomatic subjects, can be used as targets during the exercises. Furthermore, a custom reference target can be created: the patient performs a reference movement with the help of the therapist, which can serve as the target for all subsequent exercises.



The second is the time plot in which kinematic data are plotted with respect to time (Figure 2), representing humerus-thoracic and scapulo-thoracic rotations changes over time. The relative ROM is also updated in real time.

Figure 1. Scapulo-humeral coordination plot. Example of an angle-angle plot representing humeral flexion on the X-axis and scapula medio-lateral rotation on the Y-axis. L: left; H1: humerus [22]; Me-La: Medio-Lateral rotation; deg: degree; ROM: Range of Motion; Ext: extension; Flex: flexion; Sh ref Thx: shoulder referred to the thorax [22].

Biofeedback Program Development

A multidisciplinary team was established for development of the ISEO program with the professionals typically involved in postoperative rehabilitation, patient assessment, and technology management. Specifically, the team comprised three experts in shoulder surgery and specific experience in shoulder rotator cuff arthroscopy (687 cumulative cases per year), two in rehabilitation medicine, two in physical therapy, and three in biomedical and clinical engineering (two with a PhD in shoulder biomechanics), each with more than 15 years of experience in the field.

After learning the ISEO motion analysis protocol, the team selected exercises from the conventional rehabilitation program as a starting point for integrating the biofeedback technology. In selecting and adapting the exercises, the team assumed the following constraints: (1) ISEO sensors shall not interfere with exercise execution and vice versa (eg, avoiding supine position or sensor contact with any physiotherapy equipment); (2) the therapist must not touch ISEO sensors during a possible manual interaction with the patient (eg, touching the shoulder); (3) the use of aids such as a ball, stick, and elastic band shall be preserved; (4) the visual biofeedback shall be clearly defined to facilitate the patient's engagement and therapist interpretation; (5) exercises shall be performed while watching the visual interface on a screen in a comfortable position for both the patient and the therapist; (6) every exercise shall be monitored and directed by manual and/or verbal inputs by the therapist [46]; (7) to facilitate instructions to the patients, exercises shall only consider humerus movements in one of the main motion planes (sagittal, frontal, and transverse); and (8) exercises shall span all levels of skills, from early to end-phase rehabilitation.

Specifically, the multidisciplinary team selected 12 exercises. The two physical therapists and the two engineers then met during four 3-hour sessions to practice with the ISEO systems while performing the exercises. The two physical therapists, in turns, served as the test subject and therapist. This allowed them to have direct experience in exploiting the system from both the clinician and the patient perspective. Each exercise was checked in terms of respecting the selection constraints. During the practical sessions, engineers supported the physical therapists in identifying the best visual biofeedback to exploit, following the principles reported in the next section. At the end of the four practical sessions, the multidisciplinary team reconvened for a conclusive internal consensus meeting, to (1) review and confirm that all constraints were met, (2) group exercises based on the plane of moment, (3) define their progression, (4) define the physical therapy equipment, and (5) agree on the modality of visual biofeedback. Moreover, the modality of the intervention was set, together with a set of guidelines for therapists.

Biofeedback Graphical Interface and Interpretation

The choice of the graphical interface to be used during the execution of a specific exercise is determined by the objective of the exercise itself.

If the main objective of an exercise is to work on a single joint angle (eg, ER/IR of the humerus with the scapula in a fixed position or scapular protraction/retraction with the humerus in a fixed position), a time plot of the angle of interest should be used. In this case, the main objective of an exercise is usually to obtain variation of the ROM (ie, ROM maximization for physiologic movements or ROM minimization for compensatory movements). The patient and therapist can monitor the trend and the ROM of the specific angle in real time.

If the main objective of an exercise is to work on a multisegmental coordination (eg, scapula medial rotation vs humerus sagittal elevation), then a scapulo-humeral plot should be used. This type of graph is particularly relevant for modulation of the scapulo-humeral coordination, which is usually altered in dyskinetic shoulders. The therapist can ask the patient to minimize or maximize the specific scapula movement during elevation of the humerus. Reference bands [44] can be used as the target (if indicated), and both the patient and the therapist can monitor the performance of the coordination in real time.

XSL•FO
RenderX

It should be considered that use of a time plot graph during an assessment and correction of a coordinated movement can lead to substantial loss of information, and therefore to a partial and potentially misleading feedback. By contrast, the use of a scapulo-humeral plot graph during a single joint movement can unnecessarily complicate the biofeedback graph and may not clearly highlight the kinematic trend of interest.

Figures 1 and 2 are examples of the graphs provided to both the therapist and the patient during execution of the exercises. During the first session, the therapist should instruct the patient with an extensive description of the graphs, and then a brief refresh session should be provided at the beginning of each exercise. Even if the patient is not capable of appreciating the biomechanical details of the graphs, they will be able to associate their movement variations to the curves plotted, and, with therapist assistance, understand the association between segmental movements and graph variations.

Exercises

Overview

The ISEO program includes four groups of exercises (Table 1). The grouping is based on the plane of movement of the humerus (Groups 1 to 3) or of the scapula (Group 4). Each group includes a set of exercises, with a progression in difficulty and/or in load.

Table 1. List of the exercises included in the ISEO program.[a]

Exercise[b]	Physiotherapy equipment	Biofeedback
Group 1		
A: Active assisted flexion/extension with a Bobath ball	Bobath ball	Coordination plots for the humerus elevation in the sagittal plane; time plot for ER/IR[c] of the humerus with respect to the thorax
B: Active assisted flexion/extension with a stick	Stick	Coordination plots for the humerus elevation in the sagittal plane; time plot for ER/IR of the humerus with respect to the thorax
C: Active flexion/extension by stretching a rubber band	Rubber band	Coordination plots for the humerus elevation in the sagittal plane; time plot for ER/IR of the humerus with respect to the thorax
D: Active flexion/extension open chain	Optional: weight and/or rubber band	Coordination plots for the humerus elevation in the sagittal plane; time plot for ER/IR of the humerus with respect to the thorax
Group 2		
A: Active assisted abduction/adduction with a Bobath ball	Bobath ball	Coordination plots for the humerus elevation in the scapular plane; time plot for ER/IR of the humerus with respect to the thorax
B: Active abduction/adduction by stretching a rubber band	Rubber band	Coordination plots for the humerus elevation in the scapular plane; time plot for ER/IR of the humerus with respect to the thorax
C: Active abduction/adduction open chain without/with load	Optional: weight and/or rubber band	Coordination plots for the humerus elevation in the scapular plane; time plot for ER/IR of the humerus with respect to the thorax
Group 3		
A: Active ER/IR arm in adduction	Soft ball, towel, or pillow	Time plots for the three scapula rotations; time plot for ER/IR of the humerus with respect to the thorax
B: Active ER/IR at 90° flexion	Optional: weight and/or rubber band	Time plots for the three scapula rotations; time plot for ER/IR of the humerus with respect to the thorax
C: Active ER/IR at 90° abduction	Optional: weight and/or rubber band	Time plots for the three scapula rotations; time plot for ER/IR of the humerus with respect to the thorax
Group 4		
A: Push-up	None	Time plots for the three scapula rotations
B: Protraction-retraction at 90° and 120° of shoulder flexion	Optional: weight	Time plots for the three scapula rotations

[a] INAIL (National Institute for Insurance against Accidents at Work) Shoulder and Elbow Outpatient program.

[b]Grouping is based on the plane of movement of the humerus or of the scapula: Group 1=sagittal plane; Group 2=scapular plane; Group 3=external-internal rotation; Group 4=scapulo-thoracic.

[c]ER/IR: external rotation/internal rotation.

XSL•FO
RenderX

Group 1: Sagittal Plane

This group comprises four exercises characterized by movements of the humerus in the sagittal plane. The principal aim of the motor tasks is to achieve good scapular kinematic control while performing flexion and return. Coordination plots for the humerus elevation in the sagittal plane are used as visual biofeedback for monitoring the three scapula rotations.

The secondary aim is to check the associated ER of the humerus during elevation. For this purpose, the therapist selects the time plot as visual biofeedback to show the patient the active ROM in the ER/IR of the humerus with respect to the thorax.

The focus is on dynamic scapula stabilizer, infraspinatus, teres minor, and core stability (Textbox 1).

In this group, to ease trunk symmetry and stability, and avoid mistakes in scapulo-thoracic movement due to lateral tilt and/or rotation of the spine, all exercises are performed bilaterally, except exercise D that can be performed with one arm only. The progression from exercise C and D can be switched according to patient skills.

XSL•FO
RenderX

Textbox 1. Description of the exercises in Group 1 (sagittal plane).

- **Exercise A: Active assisted flexion/extension with a Bobath ball**

Starting position: standing with the Bobath ball on a bench, both hands over the ball at shoulder level, and the elbow flexed (Figure 3a).

Figure 3. Group 1 (sagittal plane), exercise A: active assisted flexion/extension with a Bobath ball. (a) Initial position; (b) arrival position at maximum humerus flexion.

Execution: to push the ball ahead using both arms.

Target position: standing position, humerus 90° flexed or more, elbows extended (Figure 3b).

Notes: as soon as the patient gains a wider gleno-humeral range of motion (ROM), they add flexion of the hips and lower back, with a stabilized trunk, to reach a humeral elevation of 120° or more. This exercise allows unloading the supraspinatus and deltoid. For this reason, it is the first to be performed.

- **Exercise B: Active assisted flexion/extension with a stick**

Starting position: standing or sitting position, hands hold the stick (the distance between the hands corresponds to the distance between the shoulders) (Figure 4a).

Figure 4. Group 1 (sagittal plane), exercise B: active assisted flexion/extension with a stick. (a) Initial position; (b) arrival position at maximum humerus flexion.

Execution: with the help of the other arm, the patient performs humerus elevation with the elbow extended.

Target position: standing or sitting position, humerus at 90° of flexion or more, elbows extended (Figure 4b).

Notes: it is important to check the trunk alignment and avoid hyperextension of the spine. If this happens, the exercise must be performed in sitting position and/or the target ROM must be reduced. If pain or inability to perform effective correction of scapular pattern occurs, the exercise can be performed with more distance between the hands, more assistance by the other arm, and/or changing the starting position of the hands (supinated, pronated, neutral).

- **Exercise C: Active flexion/extension by stretching a rubber band**

Starting position: standing or sitting position, elbow extended or at 90° of flexion, with a rubber band slightly stretched by both hands (Figure 5a).

XSL•FO
RenderX

Figure 5. Group 1 (sagittal plane), exercise C: active flexion/extension by stretching a rubber band. (a) Initial position; (b) arrival position at maximum humerus flexion.

Execution: the patient performs a small external rotation (reaching neutral position, with thumbs up) by stretching the rubber band, lifting up the arms with extended elbows while keeping the rubber band stretched and the humerus extra-rotated.

Target position: standing or sitting position, humerus at 90° flexion or more, elbows extended (Figure 5b). *Notes*: it is important to check trunk alignment and avoid hyperextension of the spine. The use of a rubber band provides greater activation of the infraspinatus and teres minor in comparison to the exercise performed without resistance.

- **Exercise D: Active flexion/extension open chain without/with load**

Starting position: standing or sitting position, extended elbow (Figure 6a).

Figure 6. Group 1 (sagittal plane), exercise D: active flexion/elevation open chain without/with load. (a) Initial position; (b) arrival position at maximum humerus flexion.

Execution: the patient lifts up the arms keeping both elbows extended.

Target position: standing or sitting position, humerus at 90° flexion or more, elbows extended (Figure 6b).

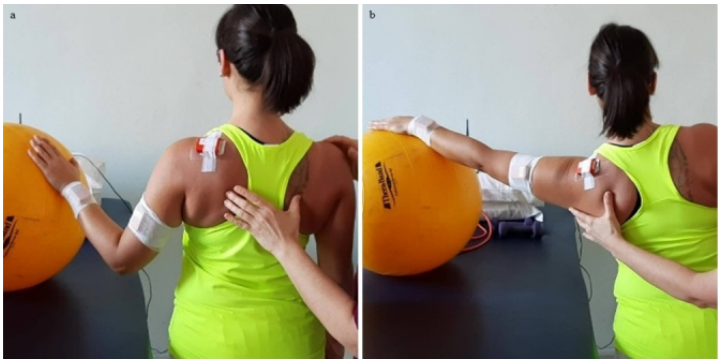
Notes: it is important to check the trunk alignment and avoid hyperextension of the spine; if performing with one arm, lateral flexion or rotation of the spine should be avoided. The exercise can be performed starting with 90° elbow flexion. Starting without a load is recommended as a first step; a weight or a rubber band can be progressively added later.

Group 2: Scapular Plane

This group comprises three exercises characterized by movements of the humerus in the scapular plane. The principal aim of the motor tasks is to achieve good scapular kinematic control during gleno-humeral abduction/adduction. Coordination plots in the scapular plane are used as visual biofeedback for monitoring the three scapula rotations during humeral elevation. The secondary aim is to check the associated ER of the humerus during elevation. For this purpose, the therapist selects the time plot as visual biofeedback to show the patient the active ROM in the ER/IR of the humerus with respect to the thorax.

The focus is on dynamic scapula stabilizer, infraspinatus, teres minor, and core stability (Textbox 2).

It is important to note that elevation on the sagittal and scapular plane is a functional motion (eg, reaching), and therefore needs to be trained as soon as possible and with accuracy. There is high activation of the serratus anterior and lower trapezius, resulting in lateral rotation of the scapula [32]. The lower trapezius maintains the instantaneous center of rotation of the scapula and helps the serratus anterior maintain the scapula close to the thorax, even if each muscle inserted in the scapula contributes to dynamic stabilization [3].



XSL•FO
RenderX

Textbox 2. Description of the exercises in Group 2 (scapular plane).

- **Exercise A: Active assisted abduction/adduction with a Bobath ball**

Starting position: standing position, Bobath ball on a bench or on the physiotherapy bed, hand over the ball at shoulder level, elbow in flexion (Figure 7a).

Figure 7. Group 2 (scapular plane), exercise A: active assisted abduction/adduction with a Bobath ball. (a) Initial position; (b) arrival position at maximum humerus abduction.

Execution: the patient pushes the ball sideways on the scapular plane.

Target position: standing position, shoulders at 90° flexion, elbow extended (Figure 7b).

Notes: as soon as the patient gains a wider gleno-humeral range of motion (ROM), they add low back lateral flexion to reach a humerus abduction of 120° or more.

- **Exercise B: Active abduction/adduction by stretching a rubber band**

Starting position: standing or sitting position with extended elbows and a rubber band slightly stretched by both hands (Figure 8a).

Figure 8. Group 2 (scapular plane), exercise B: active abduction/adduction by stretching a rubber band. (a) Initial position; (b) arrival position at maximum humerus abduction.

Execution: the patient performs a small external rotation by stretching the rubber band, keeping both thumbs up, and then lifts up the arms on the scapular plane while keeping the rubber band stretched, the elbows extended, and the thumbs up.

Target position: standing or sitting position, humerus at 90° abduction on the scapular plane or more, elbows extended (Figure 8b).

Notes: it is important to check the trunk alignment and avoid hyperextension of the spine. The use of a rubber band provides greater activation of the infraspinatus and teres minor in comparison to the exercise performed without resistance.

- **Exercise C: Active abduction/adduction open chain without/with load**

Starting position: standing or sitting position with extended elbows (Figure 9a).

XSL•FO
RenderX

Figure 9. Group 2 (scapular plane), exercise C: active abduction/adduction open chain without/with load band. (a) Initial position; (b) arrival position at maximum humerus abduction.

Execution: the patient lifts both arms upward.

Target position: standing or sitting position, humerus at 90° abduction on the scapular plane or more, elbows extended (Figure 9b).

Notes: it is important to check the trunk alignment and avoid hyperextension of the spine; if performing with one arm, the lateral flexion or rotation of the spine should be avoided. Starting without a load is recommended as the first step; a weight or a rubber band can be progressively introduced.

Group 3: External-Internal Rotation

This group comprises three exercises characterized by axial rotational movements of the humerus. The principal aim of this session is to achieve good scapular kinematic control during gleno-humeral ER and IR considering different humeral elevation positions. Time plots of the scapula are used as visual biofeedback to monitor the variation of the three scapula rotations during the execution of the exercise (eg, the patient must keep the line as flat as possible). The secondary aim is to achieve good active rotational ROM of the humerus and restore the strength of the rotator cuff muscles; time plots of the humerus with respect to the thorax are used as visual biofeedback for this purpose.

The focus is on dynamic scapula stabilizers, rotator cuff muscles, and core stability (Textbox 3).

Note that the progression for every exercise starts without a load, which can then be increased by using a rubber band or weights. Exercises B and C start with the arm laying on a horizontal support and progress without support (the patient keeps their arm lifted on their own). All exercises can be performed with both arms at the same time. The execution of the exercises in standing position requires higher core stability. In the case of poor postural core stability, the exercises can be performed with the back against the wall.

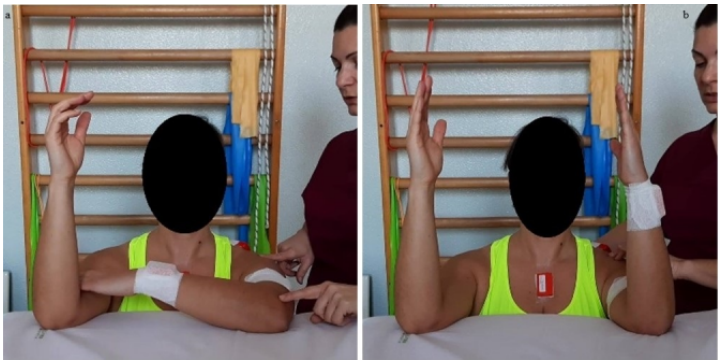
XSL•FO
RenderX

Textbox 3. Description of the exercises in Group 3 (external/internal rotation).

- **Exercise A: Active external/internal rotation arm in adduction**

Starting position: standing or sitting position, arm adducted, hand on the belly, thumbs up, elbow 90° flexed, a small soft ball (or a towel or small pillow) between the elbow and trunk (Figure 10a).

Figure 10. Group 3 (external-internal rotation), exercise A: active external/internal rotation arm in adduction. (a) Initial position; (b) arrival position at maximum humerus external rotation.



Execution: the patient performs an external rotation of the humerus, keeping the ball fixed.

Target position: standing or sitting position, arm adducted, humerus externally rotated, elbow 90° flexed, thumbs up (Figure 10b).

- **Exercise B: Active external/internal rotation at 90° flexion**

Starting position: sitting or standing position, with the humerus at 90° flexion and internally rotated, elbow at 90° flexion, and forearm in horizontal position (Figure 11a).

Figure 11. Group 3 (external-internal rotation), exercise B: active external/internal rotation at 90° flexion. (a) Initial position; (b) arrival position at maximum humerus external rotation.

Execution: the patient performs an external rotation of the humerus.

Target position: humerus at 90° flexion and externally rotated, elbow at 90° flexion, and forearm in vertical position (Figure 11b).

- **Exercise C: Active external/internal rotation at 90° abduction**

Starting position: sitting or standing position, with the humerus at 90° abduction in the scapular plane and internally rotated, elbow at 90° flexion, and forearm in horizontal position (Figure 12a).

XSL•FO
RenderX

Figure 12. Group 3 (external-internal rotation), exercise C: active external/internal rotation at 90° abduction. (a) Initial position; (b) arrival position at maximum humerus external rotation.

Execution: the patient performs an external rotation of the humerus.

Target position: humerus at 90° abduction and externally rotated, elbow at 90° flexion, and forearm in vertical position (Figure 12b).

Group 4: Scapulo-Thoracic

This group comprises two exercises characterized by movements of the scapula with respect to the thorax, while keeping the humerus in a predefined fixed elevation position. The principal aim of this session is to achieve strengthening of the serratus anterior together with the lower and medium trapezius and rhomboids. Scapula time plots are used as visual biofeedback to monitor the variation of the three scapula rotations during the execution of the exercises.

The focus is on the serratus anterior, trapezius, rhomboids, and core stability (Textbox 4).

XSL•FO
RenderX

Textbox 4. Description of the exercises in Group 4 (scapulo-thoracic).

- **Exercise A: Push-up**

Starting position: feet on the ground, hands on a bench or on a physiotherapy bed (more height means less load), and humerus at 90° flexion (Figure 13a).

Figure 13. Group 4 (scapulo-thoracic), exercise A: push-up. (a) Initial position; (b) arrival position.

Execution: while keeping core stability, the patient performs elbow flexion/extension, nearing the body to the bench and back.

Target position: during the nearing, the elbows must stop before passing the line of the trunk (Figure 13b).

Notes: the therapist guides the patient to obtain good postural alignment and to stabilize the scapula. In this exercise, the scapula time plots have to be as flat as possible.

Weight-bearing exercises in a close kinetic chain show significantly greater muscle activation (mainly on the serratus anterior and infraspinatus) while increasing the load on the shoulder [29,34]. The progression of the exercise is from a standing, weight-bearing position to full weight-bearing (if possible).

- **Exercise B: Protraction-retraction at 90° and 120° shoulder flexion**

Starting position: sitting position, humerus in flexion (between 90° and 120°), and elbows extended (Figure 14a).

Figure 14. Group 4 (scapulo-thoracic), exercise B: protraction-retraction at 90° and 120° shoulder flexion. (a) Initial position; (b) arrival position.

Execution: while keeping core stability, the patient performs protraction and retraction of the shoulder girdle.

Target position: sitting position, humerus in flexion (between 90° and 120°), elbows extended, and shoulder girdle in maximum protraction (Figure 14b).

Notes: the exercise should be performed with both arms at the same time. In this exercise, the scapula time plots are used to check the variation of protraction-retraction and medio-lateral rotations. Progression starts with support of the elbow and forearm and then free (with or without holding a weight).

This exercise is specific for the serratus anterior and can be performed in standing position, but this requires higher core stability. In case of poor postural core stability, the exercises can be performed with the back against the wall.

Guidelines for the Therapist

Textbox 5 provides operative guidelines to guide the therapist in customizing the patient's rehabilitation program.

XSL•FO
RenderX

Textbox 5. Operative guidelines for therapists during execution of the program.

- **Assessment**

To choose the appropriate exercise and its starting level, the therapist first assesses the patient's passive and active range of motion (ROM), the presence of pain at rest and during active movements, and the capability to maintain good postural control during active elevation.

- **Exercise presentation**

The therapist must provide a description and demonstration of the exercise to the patient, explaining what is shown on the screen and the visual goal to achieve.

- **Performance evaluation**

For every exercise, the aim is to achieve satisfactory neuromuscular control, without pain or compensatory strategies, with good postural alignment and core stability.

- **Intervention**

If an exercise is performed incorrectly and/or with compensation or pain, the therapist intervenes, giving physical and/or verbal guidance. The exercise can be modified (eg, decreasing the load, changing the starting position) or changed to an easier one.

- **Progression and load**

Any increase in difficulty and load must be gradual, individually adjusted, and with respect of the patient's pain. Exercise progression can be achieved by increasing the ROM, the load, and changing the dosage and the starting position. All active exercises start with no weight other than the arm weight, and progress in 0.5-kg increments. Exercises with a rubber band (Rep band) start with light resistance (Level 1, yellow band) and progress with greater resistance (Level 2, orange band; Level 3, green band; Level 4, blue band). The progression of load occurs when the patient is able to perform a series of 10 repetitions for the specific exercise with no pain and any compensate. The assessment of scapula compensations can be performed using reference bands [44] provided for the scapulo-humeral coordination movements (while executing the specific movement, patient kinematic values should be within bands). If the time plot graph is used, the ROM of the specific angles should be observed and assessed: ROM maximization for physiologic movements and ROM minimization for compensatory movements.

Results

We foresee the application of the exercise program twice a week, during individual physiotherapeutic sessions. Each session shall include 10 minutes for system preparation and calibration on the subject: sensors can be fixed over body segments (thorax, scapula, humerus, and forearm) by means of elastic bands and tape, following the previously detailed protocol [43]. The screen displaying the biofeedback graphs should be positioned to ensure a comfortable view for the patient and then 30 minutes of effective treatment will be conducted. Application of the ISEO program should start from the 45th day after surgery (or the timeline specified by surgeons) until the end of the rehabilitative treatment (ie, time of return to work).

Discussion

Strengths of the ISEO Program

We developed an innovative exercise-based program (ISEO program) for the recovery of patients arthroscopically treated for rotator cuff repair, which incorporates a kinematic visual biofeedback tool providing a real-time objective and accurate evaluation of the upper arm. We expect the biofeedback tool to support therapists and patients in the difficult challenge to tackle shoulder dyskinesis.

Specifically, with a multidisciplinary team of shoulder surgeons, physiatrists, physical therapists, and engineers, we defined a set of 12 progressive exercises divided in four groups based on the plane of movement of the humerus (Groups 1 to 3) or of the scapula (Group 4). Exercises can require the use of balls, sticks, rubber bands, and towels. For each exercise, the neuromotor goal and type of visual biofeedback is specified. Lastly, a detailed description of the method of administration of the protocol and a complete list of guidelines for therapists are provided for correct application and patient-specific customization (eg, administration of the progression and load for a single patient). To our knowledge, this is the first presentation of such a comprehensive rehabilitation program incorporating kinematics biofeedback; therefore, no direct comparisons to the literature are possible.

The ISEO rehabilitation program exploits quantitative motion analysis measures collected in real time by ISEO, owing to the use of wearable inertial and magnetic sensors. The ISEO protocol is extensively documented in the literature, with full details provided allowing its implementation on a wide range of possible hardware platforms. The documentation includes the availability of quantitative prediction bands for patient classification based on bootstrap statistical parameters. Reference bands were provided in Excel files as annexes of the main publication [44] for prompt availability. Commercial solutions are available by companies unrelated to the authors.

The description of the ISEO rehabilitation program is the first step toward randomized controlled trials investigating its potential efficacy and effectiveness in improving patients' functional outcomes, activity level, and quality of life in comparison with conventional programs not incorporating kinematics biofeedback. In particular, it can be hypothesized that the ISEO program can be more effective than a conventional, nonvisual biofeedback protocol in increasing patient function in the short-term (90 days) and mid-term (1 year).

XSL•FO
RenderX

In this context, we believe that among many possible outcome measures, the following three would allow forming a global picture of the patients and might serve as primary outcome measures depending on the study aims.

Outcome Measures

Functional Outcomes

The Scapula-Weighted Constant-Murley score [47], which is a modified version of the well-established Constant-Murley score for shoulder disorders, incorporating a specific assessment of scapula dyskinesis, was applied for the assessment of 32 patients arthroscopically treated for rotator cuff tear undergoing postoperative rehabilitation. The study showed that when scapula dyskinesis is accounted for, the number of patients with "good results" at 90 days postsurgery decreased from 31% to 9.5%, and at follow-up (after at least 6 months), the percentage dropped from 87.5% to 50%. This highlights the impact of scapula dyskinesis on the overall shoulder function and reinforces the common agreement that rehabilitation protocols should specifically address scapula dyskinesis [1,48].

Activities

The Disabilities of the Arm, Shoulder and Hand (DASH) score [49], exploring the impact of impairment on activities of the daily living, including work and recreational tasks, can be used as an outcome measure of activity. Psychometric properties specific for rotator cuff disease have been established supporting its use [50].

Health-Related Quality of Life

the EuroQuol-5D (EQ-5D) [51] instrument is an established measure of quality of life, which is recommended in cost economics and heath technology assessment studies, including interventions at the shoulder such as rotator cuff repair [52].

Limitations

The ISEO program has limitations. A complete description of shoulder kinematics would also comprise sternoclavicular and acromioclavicular motion. Due to the size of the wearable sensors and the impossibility to reliably track segment position, the direct measure of sternoclavicular and acromioclavicular motion is not part of the current ISEO protocol. Therefore, their contribution to shoulder movement was not considered. The ISEO program does not have an age-range limitation, but requires patients to construct an intuitive understanding of the graphs and plots used for the visual feedback and link them to their own body motion. In the initial phase of the program, this requires some extra communication effort by the therapist to introduce the visual biofeedback to the patient. We might hypothesize that patients with a higher degree of confidence with digital systems can benefit the most or more quickly from the biofeedback system. In addition, the ISEO program was developed primarily for patients who underwent an anatomical rotator cuff repair and reconstruction. Finally, the ISEO program requires additional time for therapists to set up the system, and to troubleshoot hardware and software warnings, which can potentially slow down the active part of the therapy.

Conclusions

We believe that the major strength of the ISEO program is providing a comprehensive tool that might effectively and quantitatively support rehabilitation professionals in tackling scapula dyskinesis, as recommended in the literature, by enhancing patient body awareness. Furthermore, the ISEO program can provide the opportunity to undertake a more engaging rehabilitation process, leveraging on the ludic aspect of the "digital feedback" and its novelty. The ISEO protocol provides quantitative parameters that can improve therapist-patient communication (as well as intra- and interprofessional communication), who can refer to objective enhancement or worsening of the kinematics over several sessions.

Abstract

Background: The misuse and overuse of antibiotics contribute to the acceleration of antimicrobial resistance (AMR), but public knowledge on appropriate antibiotic use and AMR remained low despite ongoing health promotion efforts. App gamification has gained traction in recent years for health promotion and to affect change in health behaviors. Hence, we developed an evidence-based serious game app "SteWARdS Antibiotic Defence" to educate the public on appropriate antibiotic use and AMR and address knowledge gaps.

Objective: We aim to evaluate the effectiveness of the "SteWARdS Antibiotic Defence" app in improving the knowledge of, attitude toward, and perception (KAP) of appropriate antibiotic use and AMR among the public. The primary objective is to assess the changes in KAP of antibiotic use and AMR in our participants, while the secondary objectives are to assess the extent of user engagement with the app and the level of user satisfaction in using the app.

Methods: Our study is a parallel 2-armed randomized controlled trial with a 1:1 allocation. We plan to recruit 400 participants (patients or their caregivers) aged 18-65 years from government-funded primary care clinics in Singapore. Participants are randomized in blocks of 4 and into the intervention or control group. Participants in the intervention group are required to download the "SteWARdS Antibiotic Defence" app on their smartphones and complete a game quest within 2 weeks. Users will learn about appropriate antibiotic use and effective methods to recover from uncomplicated upper respiratory tract infections by interacting with the nonplayer characters and playing 3 minigames in the app. The control group will not receive any intervention.

Results: The primary study outcome is the change in participants' KAP toward antibiotic use and AMR 6-10 weeks post intervention or 6-10 weeks from baseline for the control group (web-based survey). We will also assess the knowledge level of participants immediately after the participant completes the game quest (in the app). The secondary study outcomes are the user engagement level (tracked by the app) and satisfaction level of playing the game (via the immediate postgame survey). The satisfaction survey will also collect participants' feedback on the game app.

Conclusions: Our proposed study provides a unique opportunity to assess the effectiveness of a serious game app in public health education. We anticipate possible ceiling effects and selection bias in our study and have planned to perform subgroup

XSL•FO

analyses to adjust for confounding factors. The app intervention will benefit a larger population if it is proven to be effective and acceptable to users.

Introduction

Background

Antimicrobial resistance (AMR) has been a long-standing public health threat since the 1940s [1]. The widespread use of antibiotics has accelerated the growth of antibiotic-resistant bacteria, which can cause infections that are fatal and resistant to treatment [1]. In 2019, 4.95 million and 1.29 million global deaths were associated with and attributable to bacterial AMR [2]. It is estimated that 10 million global deaths will be attributable to AMR annually if no action is taken to tackle the problem [3].

AMR infections are often costly to health systems due to the excess length of hospital stays, more outpatient visits, and increased use of intensive care and isolation units [4]. For example, a methicillin-resistant *Staphylococcus aureus* infection could result in an additional US $31,338 (~SGD $42,620) hospitalization cost per patient [5]. AMR infections can also incur societal costs in terms of loss in work productivity and the risk of further infections [6,7].

The misuse and overuse of antibiotics are major drivers of AMR [8]. One pertinent factor contributing to the misuse of antibiotics is the public's knowledge deficit of the indication for and proper use of antibiotics [9]. This knowledge deficit often leads to unnecessary patient demand for antibiotics and subsequent misuse of antibiotics [10,11]. Knowledge deficit in antibiotic use and AMR was consistently present among populations worldwide [12]. A nationally representative survey conducted in 2021 on adult Singaporeans demonstrated the association between poor knowledge of antibiotics and inappropriate use [9]. The study also showed that younger adults with poor knowledge had a higher likelihood of misusing antibiotics when compared with older adults, highlighting the need to address knowledge deficits on antibiotic use among the younger population in Singapore to mitigate the problem of AMR in the community [9].

Rationale for the Study

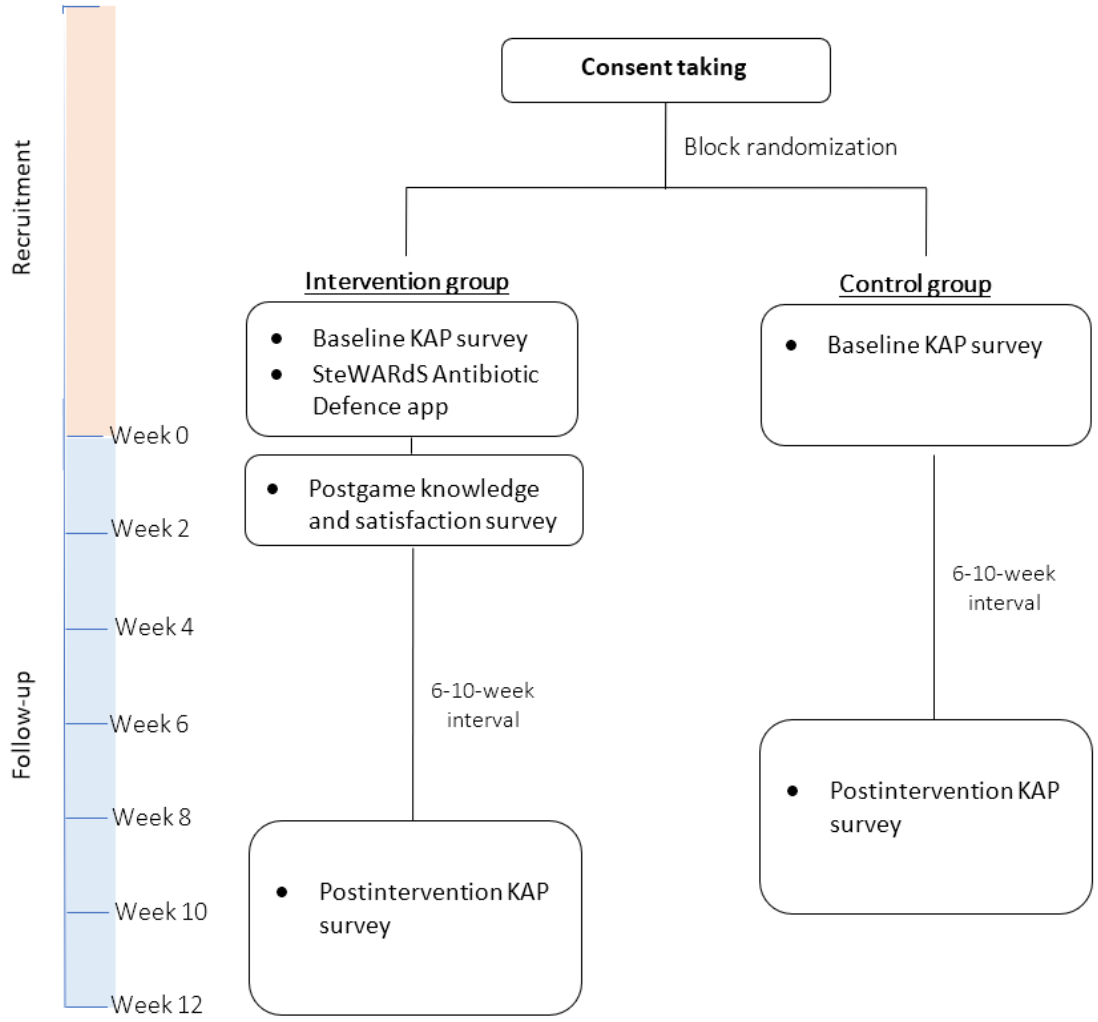
Traditional mass public educational efforts using brochures, posters, and advertisements are extensive in outreach but questionable in improving the general public's knowledge on appropriate antibiotic use and AMR [13,14]. In recent years, gamification—the use of game-playing elements to encourage the use of services—has gained attention as a novel strategy to affect change in health behaviors [15,16]. Increased user engagement can potentially lead to higher knowledge gains and retention for sustained behavioral change. Gamification was found to improve the knowledge of AMR. For example, a study found that the E-bug student website significantly increased the knowledge of appropriate antibiotic use among schoolchildren in the United Kingdom [17]. Another study using an web-based board game also found significant improvement in medical students' knowledge of AMR immediately and 1 month post intervention [16]. These proof-of-concept studies support the effectiveness of gamification in increasing knowledge on appropriate antibiotic use among young people, which should be strengthened with randomized controlled trials along with other segments of the population and age groups.

Hypothesis and Objectives

The public has low awareness of the gravity of AMR as many people perceive AMR as a nonimminent life-threatening problem for themselves [18]. We expect serious games to increase user engagement in learning, which leads to short- and long-term improvements in knowledge of, attitude toward, and perception (KAP) of the appropriate use of antibiotics. Leveraging digital technology to increase the awareness of AMR and the knowledge of appropriate antibiotic use is timely as Singapore develops into a digitalized nation. Hence, we have developed an evidence-based serious game app, "SteWARdS Antibiotic Defence," to educate the public on appropriate antibiotic use and AMR. Users will learn about antibiotic use and AMR through the minigames and the bite-sized information released from the app.

We aim to evaluate the effectiveness of the "SteWARdS Antibiotic Defence" app in improving the KAP of appropriate antibiotic use and AMR among the public in Singapore. The primary objective is to compare the changes in KAP of antibiotic use and AMR among the app users with the control group. The secondary objectives are to assess (1) the extent of user engagement with the app by evaluating the users' average screen time per day and (2) the level of user satisfaction in using the app for learning through a user satisfaction survey.

Methods



Study Design

Our study is a parallel 2-armed randomized controlled trial (RCT) assessing the effectiveness of a serious game app in increasing the knowledge and changing the attitudes and perceptions about appropriate antibiotic use and AMR among the public. Participants randomized to the intervention group will be asked to download and complete the quest in the

"SteWARdS Antibiotic Defence" app within 2 weeks on their smartphones. "SteWARdS Antibiotic Defence" is an evidence-based serious game app developed by the study team. The app will deliver bite-sized information on (1) the management of upper respiratory tract infections (URTIs), (2) appropriate antibiotic use, and (3) development of AMR to users as they complete the game quest (refer to the section on "Serious Game App Intervention"). Participants randomized to the control group will not be required to download the app. All participants will be followed up for 6-10 weeks to assess the effects of short-term knowledge retention. The design of the trial is presented in Figure 1.

Figure 1. Trial schedule. KAP: knowledge of, attitude toward, and perception.

Recruitment

Study Setting

We will recruit patients or their caregivers from government-funded primary care clinics (ie, polyclinics) in Singapore. These polyclinics manage 20% of Singapore's primary health care needs by providing subsidized services such as medical treatment for acute and chronic conditions, vaccinations, and health education [19]. The conditions seen at the polyclinics are acute and are managed outside the health care setting (eg, at home) after consultation with a health care provider. Hence, the intervention will occur outside the health care setting.

Inclusion and Exclusion Criteria

Participants must be older than 18 years, be a visitor of National Healthcare Group (NHG) polyclinic, have access to an Android smartphone, and be able to comprehend the English language to be eligible for the study. Those who are unable to install Android app, not proficient with smartphone apps, and have visual or cognitive impairment will be excluded from the study.

Randomization and Blinding

Participants will be block randomized into the intervention or control group (4 participants per block) by drawing lots from a box. They will not be blinded from the randomization as the study team has to explain the study to them. Only participants assigned to the intervention group have access to the serious game app.

Serious Game App Intervention

App Development

The "SteWARdS Antibiotic Defence" app was developed in collaboration with Temasek Polytechnic, a public tertiary institution in Singapore. The study intervention involves the completion of a quest in the "SteWARdS Antibiotic Defence" app. Participants are required to respond to 11 baseline knowledge items before they can begin the game quest. The game quest involves passing all levels of 2 minigames (ie, Tower Defence and Match3), while the third game (ie, Endless Runner) allows participants unfamiliar with the game mechanics to earn extra coins to complete the intervention within the stipulated time frame.

Completing the baseline knowledge items is a prerequisite to proceed to the minigames, while completing the postgame knowledge items will fulfill the app intervention. The app will release bite-sized messages to reinforce concepts on the prevention and management of URTI and the appropriate use of antibiotics and AMR through gameplay and interaction with the nonplayer characters in the app. Participants are given only 3 "lives" daily to complete the Tower Defence and Match3 levels. Hence, the game completion may take slightly longer if the participant fails the levels more than 3 times in a day.

Evidence-Based Content

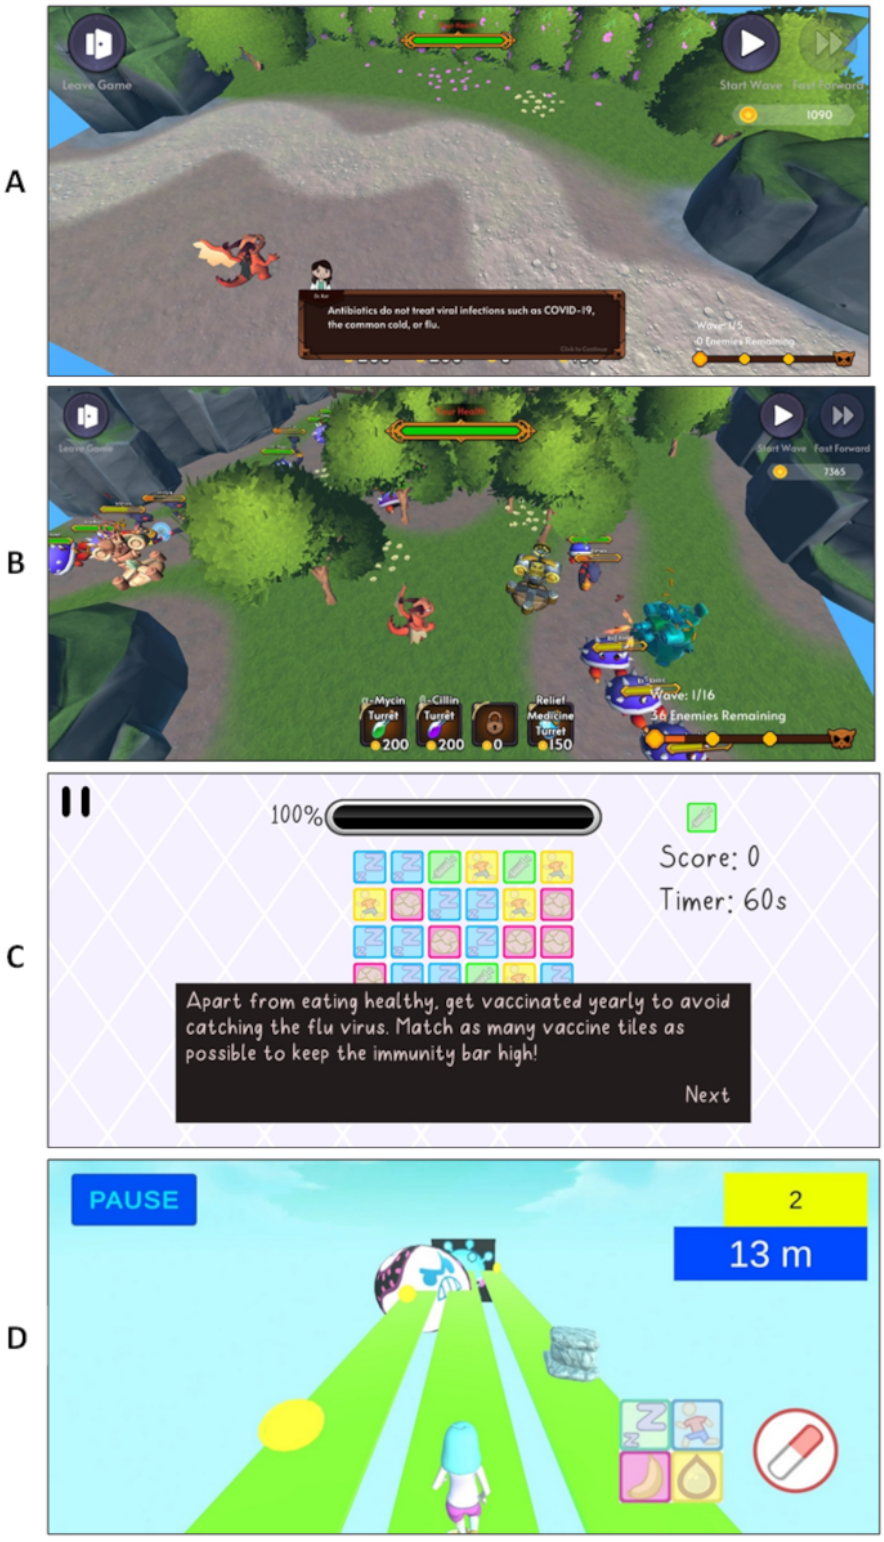
Many serious game apps intended for improving user knowledge failed to consider the cognitive process of learning, which limited the effectiveness of the intended outcome of the app. Therefore, we used Bloom's revised taxonomy [20] as a guide to design the game mechanics. Concepts such as "antibiotics are effective for bacteria and not viruses" are reinforced repeatedly in the minigames to enhance memory. Users have to apply the concepts they learn to advance the game levels. For example, users must eliminate bacteria with the antibiotic turret and viruses with the symptomatic relief medication turret in the Tower Defence game and use the correct weapon to shoot the correct organism in the Endless Runner game. Users will also experience the "cost" of AMR by realizing that "misusing" antibiotic turrets in the earlier levels will drain their resources for tackling the superbug in the final level. Feedback (whether users respond to the items correctly or not) will be provided for the postgame knowledge survey to help users evaluate the concepts they learn from the game quest.

We derived the educational content in the app from a rigorous review of knowledge gaps [9,12,21], antibiotic guidance [22], and inputs from health care professionals. The in-app messages were also adapted to the local context to ensure their relevance to users.

Game Components

Overview

The app was designed with gamification elements to enhance user engagement and the learning process [23]. Gamification was achieved through clear rules, goal-oriented challenges, and rapid feedback. Users learn about appropriate antibiotic use and effective methods to recover from uncomplicated URTIs by interacting with the nonplayer characters and playing the minigames in the app. The 3 minigames are as follows.



Tower Defence

Players are required to build turrets (types of medication) to defend their fort (immunity bar) against enemies (bacteria or viruses) and have to cross 9 levels to complete this game. Players have to choose the appropriate turrets and strategically place them at appropriate locations to effectively target their enemies.

The first 2 levels teach players that antibiotics are effective against bacteria. Players are encouraged to buy and build antibiotic turrets to survive the onslaught of bacteria enemies (Figure 2A). The next 2 levels build on this knowledge by introducing the concept that antibiotics are bacteria specific. There will be 2 different types of bacteria (α-bac and β-bac), and players must build antibiotic turrets (α-mycin and β-cillin) specific to each bacteria enemy to clear the level (Figure 2B).

XSL•FO
RenderX

Figure 2. (A) Scene in the Tower Defence game with bite-sized educational messages. (B) Scene in the Tower Defence game with α-bac, β-bac, and viruses. (C) Scene in the Match3 game with messages for healthy living. (D) Scene in the Endless Runner game. The round icon represents a bacterium.

Levels 5 and 6 educate users that antibiotics are not effective against viruses. New enemies (viruses) are introduced, and players must buy immunity turrets to attack the viruses. To further instill this concept within players, bacteria and virus enemies attack simultaneously in levels 7 and 8, and players need to select the appropriate antibiotic and immunity turrets to complete the levels.

The last level educates players on antibiotic resistance by introducing multidrug-resistant organisms. Players have to invest in an expensive antibiotic turret effective against the multidrug-resistant organisms to complete this level.

The game difficulty increases with the levels, while players must be mindful of the coins they spend when purchasing and upgrading the necessary turrets. The immunity levels of the

XSL•FO
RenderX

players are affected when too many enemies reach the end point. Players lose the level when their immunity bar falls to 0.

Match3

Match3 attempts to educate players on good health habits. Level 1 encourages participants to get a healthy amount of sleep. Level 2 focuses on the importance of a nutritious diet. The third level emphasizes on immunization, and the last level urges participants to care for their health in a holistic manner. Users are required to match 3 or more tiles within a specific time limit to successfully clear each level (Figure 2C).

Endless Runner

This game aims to reinforce the message that antibiotics are only effective against bacteria and not viruses. The player has to dodge obstacles and collect coins while running. An antibiotic gun is effective in shooting away bacteria obstacles, while an immunity gun can be used to shoot virus obstacles. This game also allows players to collect coins for use in the Tower Defence game in an engaging manner (Figure 2D).

Study Procedures

We will randomize participants who are eligible for the study into the control or intervention group and collect their personal details in a password-protected file. Their demographic information will be collected on FormSG, a trusted web-based form manager developed by the Singapore government to collect survey data securely. We will require all participants to complete a 10-minute baseline KAP survey. For participants randomized into the intervention group, a study team member will assist participants in installing the "SteWARdS Antibiotic Defence" app on their mobile phones and provide further instructions regarding the game quest. Participants will need to complete the game quest in the app within 2 weeks, after which they will need to complete the postgame knowledge and an app satisfaction survey to complete the intervention. Participants will be contacted 6-10 weeks after completing the game quest and be asked to complete a 10-minute postintervention KAP survey.

Control group participants will complete a 10-minute baseline KAP survey and be contacted 6-10 weeks after recruitment to complete another 10-minute KAP survey. Participants will receive personalized messages via WhatsApp with a FormSG survey link and instructions to complete the postintervention survey during the study follow-up. We will provide reimbursement to all participants for their participation in the study. Reimbursement is structured according to behavioral economics principles to motivate participants to complete the intervention [24]. For example, reimbursement is divided over smaller amounts and is tiered to a higher value as the participant completes tasks toward the completion of the study. If the participant withdraws from the study, he or she will be asked to uninstall the app and will not be further contacted other than for reimbursement. The data collected prior to study withdrawal will be used for intention-to-treat analysis.

Outcome Measures

Primary Outcomes

The primary outcome is the change in participants' KAP toward antibiotics use and AMR 6-10 weeks post intervention from the baseline, measured by the KAP survey. We developed the KAP survey by assessing the literature [9,21,25] and adapting questions from the World Health Organization's multicountry public awareness survey on antibiotic resistance [12]. Our KAP survey comprises 11 knowledge items with binary responses and 14 three-point Likert-scale items assessing participants' attitudes and perceptions on antibiotics use and AMR (Table 1). We reverse-scored a few knowledge items in the postgame and postintervention surveys to reduce memory effects on knowledge gains.

XSL•FO
RenderX

Table 1. Knowledge, attitudes, and perception survey items.

Item number	Items	Response options
Knowledge items		True and false
1	If bacteria are resistant to antibiotics, it can be very difficult or impossible to treat the infections they cause.	
2	It is okay to buy the same antibiotics or request for them from a doctor, if they had helped you get better previously when you had the same symptoms.	
3	It is okay to use antibiotics that were given to a friend or family member, as long as they were used to treat the same illness.	
4	I can stop my antibiotics course when I start feeling better.	
5	Antibiotic resistance is an issue that could affect me or my family.	
6	Antibiotic resistance is only a problem for people who take antibiotics regularly.	
7	Many infections are becoming increasingly resistant to antibiotics treatment.	
8	Antibiotic resistance is an issue in other countries and in Singapore.	
9	Antibiotic resistance occurs when your body becomes resistant to antibiotics and antibiotics no longer work as well.	
10	Bacteria which are resistant to antibiotics can spread from person to person.	
11	Antibiotic-resistant infections could make medical procedures like surgery, organ transplant, and cancer treatment much more dangerous.	
Statements on attitudes and perceptions		Agree, disagree, and unsure
12	I feel that there is no harm in taking antibiotics.	
13	I need antibiotics to help me to recover faster from the common cold and flu.	
14	I need antibiotics to help me to recover from serious symptoms of the common cold and flu.	
15	I need antibiotics if I continue to have flu symptoms after 2 weeks.	
16	I will keep leftover antibiotics for future use if I have similar symptoms.	
17	I would stop my course of antibiotics if I am concurrently using alternative remedy (eg, Traditional Chinese Medicine, Ayurveda medicine, Jamu).	
18	I am scared of getting antibiotic resistance infections.	
19	I will see another doctor if my doctor does not give me antibiotics.	
20	How I use antibiotics does not affect my chances of getting antibiotic resistance infections.	
21	How I use antibiotics does not affect other people's chance of getting antibiotic resistance infections.	
22	I normally keep antibiotic stocks at home in case of emergency.	
23	If my family member is sick, I will usually give my antibiotics to them.	
24	I normally stop taking antibiotics when I start feeling better.	
25	I will take leftover antibiotics when I think I need them.	

Secondary Outcomes

The secondary outcomes are the assessment of the user engagement level (tracked by time spent on the app) and satisfaction level of playing the game (via the immediate postintervention survey). The satisfaction survey will also collect participants' feedback on the game app.

Sample Size

Based on 2 meta-analyses, the effect size of serious games on improving the knowledge of chronic disease management among young people is 0.361 (95% CI 0.098-0.624) [26] and healthy lifestyle promotion in general is 0.334 (95% CI 0.260-0.407) [27]. Using the smaller 2-tailed effect size of 0.334 with a 1:1 allocation ratio, a minimum sample size of 142 per group is required to detect significant changes in knowledge at a power of 80% and an α level of .05. Assuming an attrition rate of 30%, we will require a sample size of 200 participants per group for the study.

Statistical Analysis

We will analyze the changes in the KAP scores with multivariable linear regression models and app satisfaction levels among intervention group participants with descriptive analyses. We will also conduct a post hoc power analysis to

XSL•FO
RenderX

ensure that the sample size used in our study is adequately powered to detect a significant change.

Ethical Considerations

This study was approved by the NHG Domain Specific Review Board in Singapore (National Healthcare Group Domain Specific Review Board Ref: 2022/00479).

Results

We plan to recruit 400 participants for the study by April 2023. Results are expected to be achieved by June 2023. The data analysis and manuscript are expected to be completed by September 2023.

Discussion

Overview

Our protocol describes an upcoming RCT to evaluate the effectiveness of an evidence-based serious game app in changing the KAP of antibiotic use and AMR among the public. There is currently a paucity of RCTs on the effect of serious game apps on health promotion and health behavior change due to the complexity of evaluating such studies in the population. Many clinical teams have developed stand-alone apps to solve clinical problems, but these apps are often not evidence-based or validated with population-based studies. The myriad of stand-alone apps causes app fatigue and is often unsustainable and limited in its outreach.

The few serious game app studies are targeted at improving physicians' antibiotic prescribing habits [28]. These studies had limited success in changing physicians' prescribing habits and antibiotic use in the community, as patients can influence physicians' prescribing decisions. Since antibiotic prescribing is multifactorial [29,30], it is imperative to concurrently target public awareness of appropriate antibiotic use to slow the progression of AMR. To our knowledge, this is the first RCT that assesses the effect of a serious game app for public education on antibiotic use and AMR. We developed the app with a rigorous review of evidence from the literature and inputs from clinicians, game design specialists, allied health professionals, academics, computer engineers, and members of the public. Therefore, this study will provide us with a rare opportunity to assess the effectiveness of serious game apps in public education to address the threats of AMR.

Potential Limitations

Health promotion efforts to improve the public's knowledge of antibiotics use are ongoing in Singapore via traditional mass media such as posters, advertisements, and billboards. These advertisements may contaminate and dilute the effects of our intervention but should not have a measurable impact on our study as the study period falls outside the national "antibiotic awareness week" campaign. Participants with good baseline knowledge may not see knowledge improvement due to the ceiling effect. We anticipate this problem to be minor, as a recent national study found that knowledge of good antibiotic use and AMR is poor among the population.

We will also ensure that only 1 adult from each household can participate in the study to minimize the possibility of contamination due to randomization (ie, 1 member is randomized into the control group and another into the intervention group). However, we would not be able to ensure that the recruited participant is the person completing the quest in the app, as family members (ie, children) may help to complete the game quest.

Older adults who are not technologically astute may also be excluded from our study or face difficulty in completing the game quest even if they meet the inclusion criteria. We will report problems with recruitment and follow-up and conduct subgroup analyses to assess outcomes between older and younger participants.

Conclusions

Our proposed study provides a unique opportunity to assess the effectiveness of a serious game app in public health education. We may incorporate the "SteWARdS Antibiotic Defence" app as a minigame in an institutional health app platform to provide a sustainable learning resource for a larger population if the intervention is effective and acceptable to users. The findings of this study will also provide a reference for funders, researchers, policymakers, and organizations considering app-based educational interventions for the general population.

Acknowledgments

The app development is supported by the ALIVE (gAmes for heaLthInnoVationscEntre) Serious Games grant SGG19/SN09. The trial is supported by funds under the NCID (National Centre for Infectious Diseases) Catalyst grant and administered by the National Centre for Infectious Diseases. Please email rco_grants@ncid.sg should you have any queries regarding the Catalyst grant. The study team would like to acknowledge Temasek Polytechnic's School of Engineering and School of Informatics & IT, Jeanette Yeo, and Alexis Matthias Soh for their contribution in the development of the "SteWARdS (Steering towards the wise use of antimicrobials through understanding and addressing the determinants in Singapore) antibiotic Defence" app.

Abstract

Background: Williams syndrome (WS-OMIM 194050, orphaned number: Orpha 904) is a rare condition mostly associated with intellectual disability. People with Williams syndrome are 8 times more likely to have anxiety disorders than the general population. Therapeutic solutions to treat the anxiety remain limited, particularly nonpharmacological therapy. However, cognitive behavioral therapy (CBT) has been found efficacious in managing anxiety disorders and can be used for people with intellectual disability.

Objective: This paper describes a protocol to assess the efficiency of a CBT program based on digital support for people with Williams syndrome and anxiety based on a research methodology designed for rare diseases.

Methods: We will recruit 5 individuals with Williams syndrome and anxiety. They will participate in 9 CBT sessions. Participants will perform daily self-assessments of anxiety using a digital app, which will allow for ecological and repeated evaluation of their anxiety. This digital app will provide support for each therapy session. Anxiety and quality of life will be externally assessed before and after the program and at a 3-month follow-up. This is a single-case intervention research design with multiple baselines implying repeated measures of judgment criteria. The present protocol ensures high internal validity and will help identify encouraging contributions for later clinical trials.

Results: Participant recruitment and data collection began in September 2019, and we project that the study findings will be available for dissemination by spring 2023.

Conclusions: This study will allow the assessment of the efficiency of a CBT program based on digital support to treat anxiety in people with Williams syndrome. Finally, the program could be used as an example of nonpharmacological therapy for rare diseases.

Introduction

Williams syndrome (WS) is a rare neurodevelopmental disorder caused by a 7q11.23 deletion encompassing about 25 genes on chromosome 7 [1]. The estimated prevalence is 1 in 7500 live births [2]. Most individuals present with intellectual disability and peculiarities in neuropsychological functioning. The cognitive profile is heterogeneous in terms of strengths and weaknesses and in global functioning [3]. Language skills are generally good, often with deficits in certain executive functions (especially inhibition) [4].

The prevalence of anxiety disorders in WS is high, varying from 16% to 82% [5]. With an anxiety rate 8 times higher than in the general population and 4 times higher than in other individuals with intellectual disability [6], it is the most prevalent mental health problem for individuals with WS. The available drug treatments have been found effective in reducing the level of anxiety in individuals with WS. However, they have side effects [7]. Despite the consequences on quality of life (QoL), there is a lack of research on therapeutic protocols for anxiety for people with WS.

Cognitive behavioral therapy (CBT) belongs to a class of scientifically validated therapeutic interventions. It aims to modify dysfunctional ways of thinking, as well as behavioral patterns, to reduce psychological problems. CBT interventions for anxiety share a focus of changing dysfunctional beliefs and anxious anticipation by using different cognitive, behavioral, and emotional techniques [8]. A meta-analysis [9] showed that CBT provided greater clinical benefit than other forms of psychotherapy in treating several psychological disorders in individuals with intellectual disability. However, in the context of intellectual disability, the number of participants recruited in these studies remains low, and the methodologies used have numerous limitations (eg, no controlled manipulation of the treatment delivered, studies with only 1 patient [10-12], studies evaluating the impact of therapy during 1 week of hospitalization, studies do not allow for patient empowerment [13]). Many of the results tend to show that CBT is a promising therapy for treating the anxiety of patients with intellectual disability [14], but the few studies available and their methodological limitations make further research necessary [15].

A pilot study carried out in 2013 highlighted a mindfulness-based intervention for individuals with WS [13]. The practice of mindfulness is frequently used in CBT interventions. It teaches one to pay attention and to have moment-to-moment awareness [16]. This CBT treatment approach has been found efficacious in treating emotional disorders in individuals with WS. This pilot research took place in a 5-day institutional setting, and the long-term effects of the treatment were not evaluated. In addition, the application of treatment in a context of institutionalization raises the question of the generalization of the results and the autonomy of individuals with WS.

Another study was conducted in 2022, in which a group of 4 adults with WS were virtually delivered an adapted CBT intervention [17]. In this study, a CBT program was adapted for people with intellectual disability. Participants and caregivers in this study reported a high level of satisfaction and a reduction in their anxiety. This study provided support for the acceptability and feasibility of group-based CBT treatment for anxiety in WS. However, the sample size was small, and the methodology used did not have strong scientific reliability.

The objective of our study is to propose and discuss clinical interest in CBT with digital support for anxiety in people with WS, taking into account intellectual disability. Because of the rarity of WS, the single-case methodology seems appropriate. In addition, this methodology allows for analyzing the effects of the intervention at an individual level. The development of digital support will allow participants to perform the therapy exercises at home. This could be particularly interesting for people with intellectual disabilities who need to be assisted with the realization of a number of daily tasks. The objective of the digital support is to empower them. Furthermore, this application makes it possible for the patient to evaluate himself or herself from home on a daily basis, allowing an ecological repeated assessment. We hypothesize that patients with WS will be able to engage in an adapted CBT protocol. We hypothesize that individuals' anxiety will decrease over the course of therapy. We also hypothesize that other factors such as QoL will be improved with this therapy protocol.

Methods

Study Design

We will use a multiple baseline AB single-case experimental design across participants to evaluate the efficacy of the intervention. This method allows for manipulating the intervention in an experimentally controlled manner and testing causal relations among variables of interest in a small group of participants. The multiple baseline design is well-suited for interventions that are irreversible due to learning effects, and it enables testing of whether the improvement in mental health is due to therapy or random factors changing with time [18]. For this purpose, we will use a multiple baseline across subjects and across behaviors design, as our patients will complete a daily self-assessment of 6 items related to their emotions. We will recruit only 5 patients because WS is a rare disease and a minimum of 3 replications of the effect is recommended to increase the reliability of our findings [19]. For each participant, we will first obtain repeated measures during the baseline phase (A) when no treatment is provided. Patients will be assigned to different lengths of the baseline phase to ensure at least 3 replications of the treatment effect [20]. The possible duration of the baseline phase ranges from 14 days to 30 days before treatment onset, as a minimum of 5 measurement points is required [21]. These repeated measures during the baseline phase serve as control conditions to evaluate what changes can be expected without the treatment [9,22]. The duration of the baseline will be randomly assigned by the experimenter. Following that, repeated measures are obtained during a 9-week treatment phase (B) and during 3 months after the treatment to ensure that our measures did not return to the baseline level after the treatment has been withdrawn. Patients will also

XSL•FO
RenderX

complete a range of nomothetic outcome measures 3 times: (1) baseline, (2) intervention, and (3) follow-up termination.

Participants

We will recruit 5 participants for this study. The inclusion criteria are age >18 years, molecular confirmation of WS, sufficient level of language assessed by a score >7 on the Clinical Evaluation of Language Fundamentals 4 test [23], and complaints of anxiety. The complaints of anxiety can be expressed by the individual or the individual's representative. For the inclusion criteria in this study, we chose to evaluate this complaint with the following Likert scale completed by the participant: "This week I have been anxious" or "This week the individual has been anxious." To be included in the protocol, the participant will need to score at least 1 on this self-rated Likert scale. We chose to include people with low anxiety as well as high anxiety, even if an anxiety disorder is not characterized, because anxiety is generally underestimated in WS, with one longitudinal study finding co-occurring anxiety in approximately 82% of patients with WS [24].

Exclusion criteria are uncorrected visual disturbance, uncorrected deafness, or being already treated for anxiety. Because of the intellectual disability, individuals with WS will be accompanied by a caregiver during visits requiring signing consent or a hetero-evaluation.

Individuals will be recruited from patient associations and among individuals followed in the medical genetics department of Montpellier University Hospital. Interested individuals will receive information about the study, first with a letter; then, they will be in contact with a doctor involved in the study to ask questions. Because of the rarity of WS, individuals recruited could live far from the hospital where the study is taking place. Financial support for travel costs will be offered to each individual taking part in this study. Individuals with WS who wish to be involved and a legal representative will sign written informed consent; then, the individual will be prescreened for inclusion and exclusion criteria.

Ethical Approval

The study has been registered with the committee of protection of people (CPP) Sud-Ouest et Outre-Mer 1 (approval number CPP 1-18-86/SI:1752 (2° HPS)).

Procedures

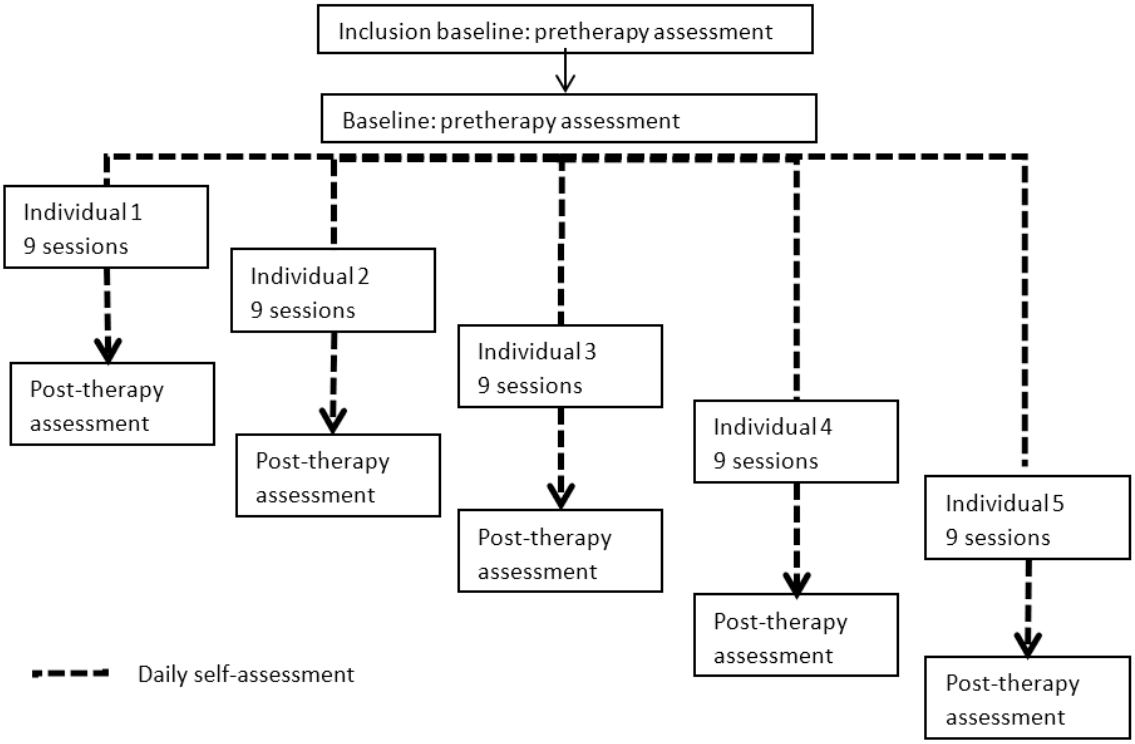
Baseline

We will recruit 5 individuals with WS. Each participant will have a different length of the baseline period (A). The participants will be allocated to a baseline lasting from 2 weeks to 5 weeks. The baseline phase will begin at the same time for each participant. This multiple baseline design allows for the multiple assessments to serve as control conditions to evaluate what changes can be expected without the treatment [22]. During this baseline period, no therapeutic intervention will take place. The participants will continue their daily life without changing their habits. They will complete a daily self-assessment of 6 items related to their emotions.

Intervention

After the baseline period, each individual will undergo a psychotherapeutic intervention with digital support. This intervention will extend over 9 sessions, spaced 1 week to 2 weeks apart depending on the individual's availability. Each session will last from 45 minutes to 90 minutes and will be carried out with the same clinical psychologist. Participants will use a smartphone app daily as support for the therapy. The app will include relaxation exercises and mindfulness audio. Individuals will continue their daily self-assessment during this intervention period.

Follow-up



After the 9 intervention sessions, individuals will be invited to continue to apply tools delivered during the intervention in their daily life. They will continue their daily self-assessment for 3 months after the intervention.

During the research (baseline, intervention, follow-up), the individual's representative will complete daily evaluations.

Hetero-evaluations will be carried out during the inclusion visit (baseline), the visit at the start of the intervention (T1), the visit at the end of the intervention (T9), and the follow-up visit 3 months after the end of intervention (Figure 1).

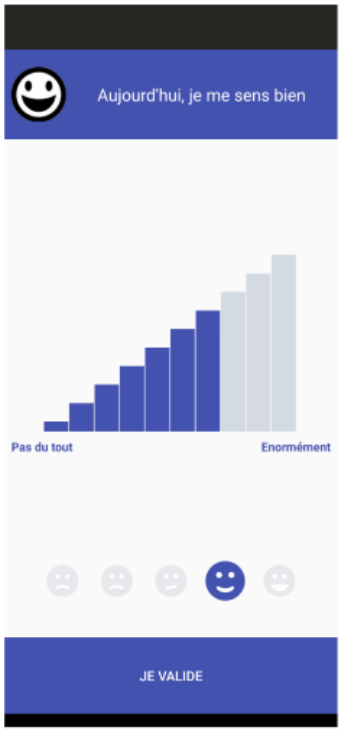
Measures

Repeated Measures: Real-Time Monitoring Technology



There is no validated tool to assess anxiety repeatedly in our target population, to our knowledge [25]. To take into account the specificity of a population with intellectual disability, a smartphone tool has been developed to allow for repeated self-assessment. It is an app named WillCope. Screenshots of this app are presented in Figures 2 and 3. This app includes 6 questions, each related to anxiety manifestations that are usually used to assess anxiety. The items evaluated were initially chosen by a working committee of 10 people including doctors, psychologists, patients, and caregivers. The choice of these items was based on the Hamilton Rating Scale for Anxiety (HAM-A) [26-28]. Items and questions were tested in a study of >300 persons with intellectual disability.

Figure 2. Screenshot of the WillCope app.

XSL•FO
RenderX

Figure 3. Screenshot of the WillCope app.

We will use a single item to measure each targeted behavior because it can be more easily included in an experiment in which patients have to perform daily self-assessments for several months. In addition, single items have been shown to be as reliable as assessments using longer scales [29]. In this study, 6 questions will be presented to the 5 individuals, who will evaluate the intensity of each of the items on a daily basis using a Likert scale from 1 to 10. These 6 questions make it possible to evaluate the principal components encountered in anxiety disorders in people with intellectual disability, taking into account the somatic dimension. The wording of the questions is in easy-to-understand language and is associated with a pictogram as well as an audio reading. The questions are formulated in French and are related to anxiety, pain, sleep, motor agitation, well-being, and motivation.

Regarding anxiety, Williams et al [30] demonstrated the scientific validity of a single-item scale for assessing anxiety: “Today, I am anxious.”

Pain is included because of the importance of somatic symptoms associated with anxiety: “Today, I have pain in my body.”

Sleep is included because of the impact of anxiety on sleep: “Today, I slept well.”

Motor agitation is part of the manifestations of anxiety, especially with intellectual disability: “Today, I need to move around.”

Well-being is directly affected by anxiety: “Today, I am happy.”

Motivation can also be affected by anxiety: “Today, I feel like doing things.”

The primary outcome will be the score obtained for the first question related to anxiety.

The neuropsychologist will check that the questions are correctly understood during the first evaluation. A support person may also accompany the individual in the daily evaluation for guidance, without answering for the individual.

A repeated assessment questionnaire will also be provided to the support person or the caregiver accompanying the individual, to obtain a repeated hetero-assessment of the individual's anxiety. The questions will be the same as in the self-evaluation but will be formulated in the third person.

The smartphone support allows for real-time monitoring of the emotional state of individuals in an ecological environment in their daily life. Patients with intellectual disability might have difficulties self-assessing using classical CBT tools like charts to complete or notebook-based assessments completed with paper and pencil. The app was developed in easy-to-read and understand language, with pictograms and audio support, which makes it accessible to people who cannot read or write. An alarm is integrated into the app to remind the participants to complete the exercises. A backup of each of the patient’s self-assessment is encrypted and stored in the app. It can then be shared by email but requires decryption software to be opened. This backup allows visibility on the frequency of use of the app for self-assessment.

Nomothetic Quantitative Measures

Nomothetic quantitative measures will be completed at the assessment, termination, and follow-up visits.

A hetero-assessment of anxiety will be performed by a clinical psychologist using the HAM-A [26,27]. This scale is the most widely used test to assess the intensity of anxiety symptoms. It is applicable to all adults and consists of 14 questions rated according to the severity of symptoms: anxious mood (worry, apprehension, irritability); feelings of tension, fatigability,

XSL•FO
RenderX

inability to relax, startled reactions, crying, tremors, fears; sleeping troubles; difficulty concentrating and memory problems; depressed mood; somatic symptoms; and behavior during the interview. Symptoms are rated using 5 degrees of severity, from absence to disabling intensity. The overall score ranges from 0 to 56: the higher the score, the more severe the anxiety. This scale will be administered by a clinical psychologist.

This scale does not constitute our main criterion of analysis and will be used in addition to the single-item repeated measures of anxiety-related behaviors and manifestations. It seems to us interesting to allow a descriptive analysis of the evolution of anxiety before and after treatment, and this scale presents several advantages for evaluating anxiety in a population with intellectual disability. Indeed, it allows a hetero-evaluation of anxiety by a psychologist. It also allows the somatic dimension of anxiety, as well as the patient's behavior with its anxious manifestations, to be taken into account. QoL will be assessed with the Abbreviated World Health Organization Quality of Life (WHOQOL-BREF) questionnaire [31]. This scale consists of 26 items, each rated from 0 to 5. The scale will be completed by the representative and by the individual with WS assisted by a clinical psychologist who can explain the items that would be difficult to understand.

Ideographic Qualitative Measures

Individuals will undergo a semidirected interview with a psychologist at each session to identify any significant events in the patient's life. This interview can last from 5 minutes to 30 minutes. The objective will be to observe the presence of factors that cannot be measured by quantitative analyses. The main themes addressed will be the following: the occurrence of a significant event in the participant's life, daily activities, relationships and social situation, autonomy. We will also observe the perception of the impact of the therapy on daily life and elements of daily life modified thanks to the therapy.

In addition, a questionnaire will be completed by the patient at the end of the research and at 3 months after the therapy to evaluate the benefit of and satisfaction with the therapy. The semistructured interviews will be transcribed verbatim. We will determine the presence or absence of the aforementioned factors. The data will be extracted and combined with the data from the questionnaire completed at the end of the therapy and at the follow-up, to evaluate the effectiveness of the intervention.

Intervention

In our study, the intervention will consist of a CBT program based on a process-based approach targeting the processes underlying emotional disorders [32]. This protocol has the advantage of targeting cognitive processes common to different forms of anxiety disorders. Anxiety disorders can have different manifestations in WS, and the rarity of this disease does not allow us to recruit a sufficient number of patients with the same clinical picture. Thus, this protocol is particularly suitable to target the cognitive anxiety processes common to all our patients despite their differences in expression. We will build on the unified protocol designed for children and first developed in 2011 [33]. This protocol has been adapted for WS based on existent literature [30]. It has been found that people with intellectual disability can perform better when linking situations directly to emotions than they do when attempting to link the triad of beliefs, emotions, and situation [34]. It has been shown that the identification of behavior and feelings is associated with verbal ability and the identification of thoughts is linked to IQ [35]. Language ability is very developed in people with WS, but their ability to understand some abstract situations is more limited. It has been shown that the behavioral elements are more consistently effective than the cognitive elements and the behavioral elements are more amenable to short-term intervention [36], which is the case in our study. For these reasons, we decided to not emphasize cognitive restructuration in our protocol but to focus on emotion identification, exposure, and meaningful actions.

During the entire protocol, the psychologist will speak slowly and repeat information. He will give the participant time. He will only emphasize the essential points and give concrete examples. The content of each module is simplified and adapted in easy-to-read and understand language in a way that empowers individuals with WS. Nonverbal communication is emphasized.

People with intellectual disability often have poor self-image, so the following points, which are important in any psychotherapy work, are particularly so with this population. The therapeutic alliance is very important. The patient must be involved in the choice of exercises to be done at home. The objectives must be simple and achievable. Throughout the work, positive reinforcement and appreciation of the participant are essential.

A clinical psychologist specializing in CBT will perform the intervention during the 9-session therapy protocol. Each session will last about 1.5 hours and will be organized as described in Table 1.

First, mindfulness, which has been found effective in individuals with WS, will be integrated into each session [37]. Mindfulness is our innate capacity to pay conscious and full attention to something in the moment. It is often defined as "the awareness that emerges through paying attention on purpose, in the present moment, and nonjudgmentally to the unfolding of experience" [16]. Usually, anxiety therapy is based on mindfulness-based stress reduction. In this protocol, we adapted mindfulness exercises with some exercises used with children [38-40]. The main exercises are mindfulness of the body, of the breath, and of the senses. Mindfulness exercises are integrated into the app so that the participant can repeat them from home on a daily basis. The protocol will target increasing awareness of the emotions present as well as tolerance to emotional sensations. It will also aim to increase cognitive flexibility and will identify and prevent emotional avoidance behaviors as well as exposure.

The intervention will require the daily use of the WillCope app. In addition to allowing daily assessment by the patient, the WillCope app will provide therapy support through relaxation and mindfulness tools. The presence of a single support to allow self-assessments, as well as the realization of mindfulness and relaxation exercises, is facilitating for patients.

XSL•FO
RenderX

Table 1. Main stages of therapy.

Stage of therapy	Description
Retrospective	Each session begins with a look back at the past week and a return to the exercises performed at home.
Mindfulness and relaxation	
Overall	In every session, individuals with WS[a] will be taught how to perceive their body, thoughts, and emotions objectively, in the present moment, without judging them. Mindfulness helps to stay with difficult feelings without analyzing, suppressing, or encouraging them. Individuals with WS often report that their emotions are out of their control, suddenly invading them in a confusing, disturbing way. This module will help individuals recognize the interaction between thoughts, feelings, and behaviors during the emotional experience. The therapist will help identify primary reactions, or early emotional responses to a situation or memory, and reactions to these primary emotions, which tend to be negative and not focused on the present moment. These concepts are taught during the sessions using concrete emotional situations, activating experiences adapted to each individual. Specifically, reactions to emotions tend to be subjective, judgmental, and negative. An example is a concern that anxiety could hinder the smooth running of an activity in the future. To the extent that these reactions are not based on actual information in the present moment, they may block positive information about the nature of emotional responses.
Unit 1: functional analysis (3 sessions)	
Problem identification	What are the triggers, in what context, what are the associated behaviors and thoughts; intensity of emotions; duration of emotions; consequences of associated behaviors
Identification of motivational elements	What are the individual's values, what are the things that make him happy, and what does he want to develop in his life?
Realization	A schematic illustrating the preceding points is reviewed with the individual.
Unit 2: psychoeducation (3 sessions)	This module consists of a psychoeducation session on emotions in general and anxiety in particular. Emotions such as anger, sadness, and fear are described. During this module, the therapist explains the cognitive, physiological, and behavioral components of emotions and their interactions. Individuals should then begin to understand that their emotions have an adaptive and functional role, providing information about the environment and motivating certain actions. The therapist can describe how avoidance during the emotional event (consequence) leads to maintenance of the anxiety and distress associated with the emotional experience. Schematics are built to illustrate the components of the different emotions of the individual, based on experience in daily life
Unit 3: exposure and engagement in meaningful actions (3 sessions)	Previous sessions allowed the individual to become familiar with feelings related to emotions. One of the difficulties with anxiety is a limitation of the individual's activities and autonomy due to avoidance. Therefore, the last sessions of the therapy are devoted to setting up exposure and actions that allow the individual to maintain autonomy and engage in actions that count, even if unpleasant emotions are present. In each session, examples are applied to the individual's daily life. Tools are provided to deal with some difficult emotions. For example, squeezing a frozen lemon in the hands can defocus the attention of anxiety or anger and defer an impulsive response.
Representative	At the end of each session, the tools presented during the session are described to the individual’s representative.
At home	Exercises to be carried out daily in connection with the current module. Every day, the individual with WS must continue to perform self-evaluation as well as a relaxation or mindfulness exercise available on the WillCope app.

[a]WS: Williams syndrome.

Data Analysis

Our primary outcome will be the changes in the level of anxiety evaluated with a repeated scale. We will graph and analyze data for each participant and each target behavior. We will first visually inspect the analyses as per the guidelines for visual analysis in single-case studies [23]. Within-condition analysis (baseline and intervention phases) will include the evaluation of the stability of the level of data by condition by calculating means, medians, ranges, and stability envelopes. The absolute level of change will be evaluated by calculating the difference between the first and last values in each condition. Between-condition analysis of data will allow for comparisons of adjacent data in the study. The change in the trend direction between phases A and B will be evaluated by identifying the trend as accelerating, decelerating, or zero-celerating. The therapeutic or contra-therapeutic direction will also be reported. The level of change between conditions will be evaluated by calculating the median level of change.

A comparative table of data will be edited for each repeated measure, patient, and step of the protocol. The means, medians, range, stability envelope, and absolute level of change will be presented in this table.

We will use the Tau-*U* to examine the within-phase trend and between-phase difference to estimate the treatment effect both within and between phases. We prefer the Tau-*U* to alternative statistics (ie, proportion of nonoverlapping data) because it provides a baseline trend–corrected estimation of trends in treatment and follow-up phases by combining nonoverlap between phases and trends within phases. The following 3 Tau-*U* indices will be calculated: (1) Tau-*U* A-to-A compares

XSL•FO
RenderX

a phase-A score with another phase-A score, (2) Tau-*U* B-to-B compares a phase-B score with another phase-B score, and (3) Tau-*U* A-to-B compares a phase-A score with a phase-B score. The Tau-*U* A-to-B is similar to the Mann-Whitney *U* test for group independence, and a *P* value is produced in addition to an estimate of effect size. These Tau-*U* indices estimate the effect of the treatment on both within phase trends and between-phase differences. We will use the following 2 forms of the Tau-*U* indices: the uncorrected and corrected Tau-*U*. The corrected Tau-*U* estimates the degree of the baseline trend and adjusts baseline and treatment phase observations to remove the effect of the baseline trend. We will use the corrected Tau-*U* to estimate an effect size from the corrected data when the Tau-*U* A-to-A is significant [41]. We will use the Tau-*U* calculator web-based application [42].

We will estimate the reliability of change for our nomothetic outcomes using the reliable change index (RCI) [43]. The RCI measures in which direction an individual has changed and estimates whether this change is reliable and clinically significant. We will calculate the RCI statistic for the 3 dimensions of the French WHOQOL-BREF (physical health, psychological health, and social relationships) for which reliability coefficients are available [31]. For each of these 3 WHOQOL-BREF dimensions, we will calculate the value of the standard using our patients' scores at baseline. A reliable change in both treatment and follow-up compared with baseline measures will be achieved with values ≥1.96.

Concerning the HAM-A, there is no fidelity index validated in French, which does not allow the calculation of an RCI value. The results obtained from this evaluation will therefore be used in a descriptive manner, in order to relate them to the repeated evaluations of anxiety that constitute our main evaluation criterion.

A comparative table data will also be edited with the nomothetic outcome measures.

Results

As of spring 2019, the app was fully developed. Participant recruitment and data collection began in September 2019. Due to the COVID-19 crisis, data processing was postponed in 2022-2023, and it is projected that the study findings will be available for dissemination by summer 2023.

Discussion

In this manuscript, we describe the research protocol for evaluating an anxiety therapy program for individuals with WS. WS is a rare genetic disease in which individuals present with intellectual disability of variable intensity but, in general, have good language skills. Most individuals with WS present with anxiety. Because of the rarity of WS, there is a lack of validated studies on the psychotherapy of anxiety in these individuals. Therefore, their anxiety is usually treated with medication, and the side effects are more severe than in the general population. However, some therapies have been found effective in individuals with intellectual disability. Because of their good language skills, such individuals could particularly benefit from psychotherapy.

This manuscript describes the research protocol to test the effectiveness of CBT for anxiety in individuals with WS. This protocol is based on the single-case and multiple baseline research methodology. This methodology is particularly interesting for 2 aspects. First, it is a scientific research method that applies to small samples (as few as 3 people), so it is a particularly interesting methodology for rare diseases. Second, this methodology enables consideration of interindividual variations by observing the results of each individual individually. It enables evaluation of the fluctuations of anxiety in the daily life of individuals. For this protocol, a smartphone app was developed. This app allows daily self-assessment of anxiety by the patients and can be a support mechanism for the therapy protocol. This app can be particularly helpful for a population with an intellectual disability, for whom the appropriation of certain CBT tools may be difficult.

However, this work has some limitations. First, regarding the app, some improvements might be possible. The developed app has not yet been validated from a psychometric point of view. It can only be used to assess the evolution of anxiety for each patient but cannot be used as a diagnostic tool.

In addition, this app makes it possible to store the participant's evaluation data and thus to know when the patient evaluated his or her anxiety, but there are no data to know how the participant used the other tools in the app (the therapy support tools). It would be interesting to integrate a module to know how often the participant uses the app for therapeutic purposes.

Finally, this protocol only includes a small sample of patients with WS. Depending on the results, it would be interesting to evaluate this protocol with patients with other pathologies.

Abstract

Background: Perinatal mood disorders such as depression and anxiety are common, with subclinical symptomology manifesting as perinatal mood disturbances being even more prevalent. These could potentially affect breastfeeding practices and infant development. Pregnant and lactating women usually limit their exposure to medications, including those for psychological symptoms. Interestingly, the naturally occurring probiotic *Bifidobacterium longum* (BL) NCC3001 has been shown to reduce anxious behavior in preclinical models and feelings of low mood in nonpregnant human adults. During the COVID-19 pandemic, mental health issues increased, and conventionally conducted clinical trials were restricted by social distancing regulations.

Objective: This study, Probiotics on Mothers' Mood and Stress (PROMOTE), aimed to use a decentralized clinical trial design to test whether BL NCC3001 can reduce symptoms of depression, anxiety, and stress over the perinatal period.

Methods: This double-blind, placebo-controlled, randomized, and 3-parallel-arm study aimed to recruit 180 women to evaluate the efficacy of the probiotic taken either during pregnancy and post partum (from 28-32 weeks' gestation until 12 weeks after delivery; n=60, 33.3%) or post partum only (from birth until 12 weeks after delivery; n=60, 33.3%) in comparison with a placebo control group (n=60, 33.3%). Participants consumed the probiotic or matched placebo in a drink once daily. Mood outcomes were measured using the State-Trait Anxiety Inventory and Edinburgh Postnatal Depression Scale questionnaires, captured electronically at baseline (28-32 weeks' gestation) and during e-study sessions over 5 further time points (36 weeks' gestation; 9 days post partum; and 4, 8, and 12 weeks post partum). Saliva and stool samples were collected longitudinally at home to provide mechanistic insights.

Results: In total, 520 women registered their interest on our website, of whom 184 (35.4%) were eligible and randomized. Of these 184 participants, 5 (2.7%) withdrew after randomization, leaving 179 (97.3%) who completed the study. Recruitment occurred between November 7, 2020, and August 20, 2021. Advertising on social media brought in 46.9% (244/520) of the prospective participants, followed by parenting-specific websites (116/520, 22.3%). Nationwide recruitment was achieved. Data processing is ongoing, and there are no outcomes to report yet.

Conclusions: Multiple converging factors contributed to speedy recruitment and retention of participants despite COVID-19–related restrictions. This decentralized trial design sets a precedent for similar studies, in addition to potentially

XSL•FO
RenderX

providing novel evidence on the impact of BL NCC3001 on symptoms of perinatal mood disturbances. This study was ideal for remote conduct: because of the high digital literacy and public trust in digital security in Singapore, the intervention could be self-administered without regular clinical monitoring, and the eligibility criteria and outcomes were measured using electronic questionnaires and self-collected biological samples. This design was particularly suited for a group considered vulnerable—pregnant women—during the challenging times of COVID-19–related social restrictions.

Introduction

Background

Anxiety and depression during pregnancy and post partum are referred to as perinatal mood disorders [1-3]. Subclinical symptomatology, including low mood and stress, that does not reach thresholds for clinically diagnosable pre- and postpartum depression and anxiety is also becoming an area of concern. Collectively, such symptoms of varying severity in the perinatal period will be referred to as perinatal mood disturbances (PMD) in this paper. Depressive symptoms are relatively common in the perinatal period, and many women experience mild forms of such negative feelings, typically called *baby blues*, owing to many factors, including physiological hormonal changes [1-5]. It is estimated that as many as 70% of women experience “baby blues” during the postpartum period [4], and approximately 24% of women in their third trimester of pregnancy and 15% of postpartum women experience anxiety [6-8]. Furthermore, low mood and stress often coexist in the postpartum period [4]. The consequences of PMD, even within normal variation of mood and stress, can also have a downstream impact on the infant’s development and behavior owing to alterations in the in utero environment [1-3,8] and in postnatal mother-infant interactions [9,10]. In addition, postpartum mood disorders are reported to be negatively associated with the initiation and duration of breastfeeding [1-4,10,11], which are known to have multiple short- and long-term consequences on maternal and infant health [11,12].

Many women opt to avoid taking pharmacological treatments to address feelings of low mood and stress during the perinatal period [1,13], often to prevent the potential risk of drugs being transferred to the baby through the placenta or breast milk. Thus, there is a specific need for alternative solutions for pregnant and breastfeeding mothers [14]. Currently, many pregnant women are open to consuming naturally occurring probiotics, which are emerging as a potential solution to modulate mood. The concept of a gut-brain axis linking differences in gut microbiome with central nervous system function via endocrine factors, inflammatory mediators, neurotransmitters, and autonomic nervous signaling is becoming more compelling and could explain how probiotics may affect emotions and mood [15].

A randomized controlled trial of the probiotic *Lactobacillus rhamnosus* HN001, whose primary outcome was infant eczema, showed its potential role in reducing PMD as a secondary outcome [16]. However, the strength of the conclusions was limited by the lack of baseline mood scores, mood evaluation at a single time point, and the retrospective collection of mood data 4 to 11 months post partum potentially contributing to recall bias. A more recent study, which assessed the effect of a multiple probiotic strain combination of *Lactobacillus rhamnosus* GG and *Bifidobacterium lactis* BB12 administered to pregnant women with obesity between 12 and 36 weeks of pregnancy, showed no difference between the intervention and placebo groups in improving prenatal depression or anxiety [17]. Other probiotic trials in pregnancy also found no statistically significant effects on PMD [18,19]. Such mixed findings suggest variation in the impact of different probiotics on PMD, consistent with findings of strain-specific effects of probiotics on other health outcomes [20].

Outside of the perinatal setting, the naturally occurring probiotic *Bifidobacterium longum* (BL) NCC3001 normalized anxiety-like behavior in different preclinical models [21,22] and reduced feelings of low mood and emotional reactions to fearful stimuli in human adults with irritable bowel syndrome [23]. However, a possible effect of this probiotic during the perinatal period has not yet been tested.

This study was designed to test the efficacy of the probiotic BL NCC3001 as a nonpharmacological intervention in reducing PMD. In addition, we are investigating the optimal time window for commencement of probiotic intake to obtain a protective effect: whether there is a need to start the intervention prenatally or whether there would still be a beneficial effect if it is started only after delivery. We hypothesize that daily ingestion of the probiotic BL NCC3001 in the perinatal period will lower time-trend scores of mood and stress as measured by the validated State-Trait Anxiety Inventory (STAI) [24] and Edinburgh Postnatal Depression Scale (EPDS) [25] questionnaires.

Decentralized Study

With the unprecedented advent of the COVID-19 pandemic at the start of 2020, the conduct of many clinical trials was hampered by government-imposed restrictions on face-to-face contact. It was particularly challenging to set up new trials to evaluate interventions unrelated to COVID-19 infections,

XSL•FO
RenderX

especially in populations considered vulnerable, such as pregnant women. Clinical trials that could be designed for remote conduct using digital tools were at an advantage [26]. Given that our intervention could be self-administered without clinical monitoring and that the primary outcome was measurable using electronic questionnaires, the design allowed for decentralized remote conduct. This approach was thought to be also well suited to the advanced, high-resource setting of Singapore where participants have easy access to the technology needed for remote contact with study teams. Here, we present the protocol of an entirely decentralized study in Singapore, the Probiotics on Mothers' Mood and Stress (PROMOTE) study, which could serve as a basis for the design of similar studies in the future.

Methods

Design

Study aspects as well as the technical means used for each aspect are presented in Textbox 1.

Textbox 1. Study aspect and technical means used for each aspect of this decentralized study.

Recruitment

- Digital advertising (social media, parenting websites, and workplace website)
- Physical posters in public places (public transport and stores)
- Paper brochure dissemination in mailboxes and partner locations
- Word of mouth

Registration of interest

- Secured online form; participant-initiated self-referral

Screening and study sessions

- Video call with screen-sharing capabilities

Signing of the informed consent form

- REDCap (Research Electronic Data Capture; Vanderbilt University) electronic database

Delivery of intervention product and study materials, as well as biological sample collection

- Trained and licensed courier service

Self-reported questionnaires

- Medidata Patient Cloud (Medidata Solutions Inc) mobile app in which participants can complete questionnaires (automatically syncs to iMedidata; Medidata Solutions Inc)

Product compliance and all non–self-reported data

- iMedidata electronic patient-reported outcome database entry completed by study team

Recruitment and Remote Study Conduct

This trial was set up and conducted in Singapore, where the smartphone penetration rate in the population is 98% and where 42.5% of the population, including 34.3% of women of reproductive age, use social media predominantly to research brands [27]. There is also a high level of trust in digital security systems associated with governmental organizations such as the Agency for Science, Technology and Research (A*STAR).

Recruitment in the community at large in Singapore was carried out via self-referral by interested women who heard about the study through the following channels: (1) social media advertising; (2) parenting websites as well as internet forums, platforms, and group chats; (3) physical posters on public transport; (4) brochures in mailboxes and partner locations; and (5) word of mouth. Relevant groups were approached through strategies such as targeted advertising to female users of reproductive age and specific estimated due date groups on various social media and messaging platforms, sending out electronic direct mail messages to members of the parenting websites engaged for the study, and placing physical posters in maternity stores or electronic posters on relevant websites such as the A*STAR Singapore Institute for Clinical Sciences web page.

All advertisements included the distinctive, easily recognizable PROMOTE logo. Electronic advertisements contained a convenient web link, and public posters incorporated a QR code to allow potential participants to scan and be directly taken to the website of an official government organization with a secure address to view the eligibility criteria and register their interest. Once they had submitted the forms on the website, the research coordinators would call them to confirm their interest, explain the study, and arrange a screening session via video chat to confirm their eligibility.

The study was designed to be conducted completely remotely, with all interaction between study team members and

XSL•FO
RenderX

participants taking place via video chat sessions and with collection of biological samples by a licensed courier service.

Online Screening Session

The screening session involved 3 parties (the potential participant, the study coordinator, and a witness who may be another member of the study team or a participant's spouse, relative, or friend) engaged in a video call when the participant was at approximately 27 (range 24-30) weeks' gestation. If the woman was agreeable to taking part after a detailed explanation of the study, a remote electronic signing of the informed consent form was then undertaken by all 3 parties within the same sitting. The eligibility of the potential participant was confirmed according to the inclusion and exclusion criteria (Textbox 2) and immediately recorded on the electronic research database with each participant assigned a unique participant identification code.

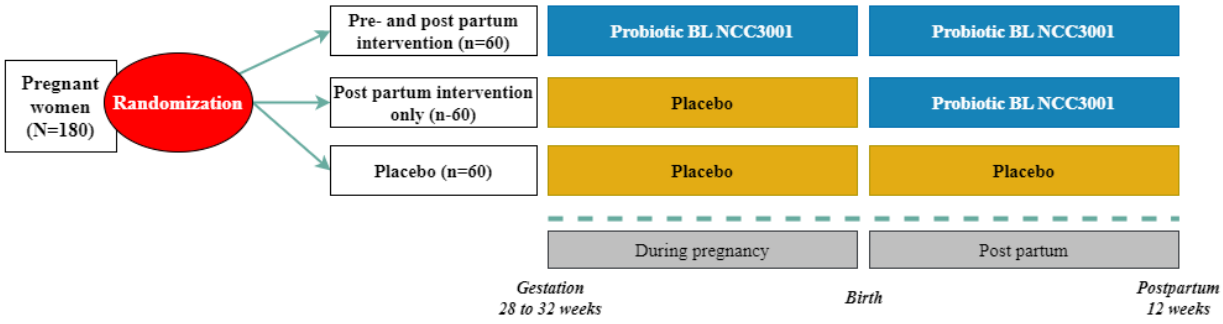
Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Pregnant women aged ≥21 years at recruitment
- Willing and able to provide written informed consent
- Gestation of 28 to 32 weeks at randomization
- Singleton pregnancy at recruitment
- Able to complete questionnaires in English
- Hospital Anxiety and Depression Scale [28] score of ≥5 (out of 21) for either depression or anxiety subscale to indicate some general feelings of low mood or stress; each participant to fill out the questionnaire using a secured app with the scores programmed to be computed instantly and automatically upon submission
- Intention to breastfeed

Exclusion criteria

- Not willing or unable to comply with the study procedures and requirements
- Diagnosed food allergy
- Has taken probiotic supplements in the 4 weeks before screening
- Has received pharmacological treatment for anxiety or depression in the 12 weeks before recruitment
- Major complications during pregnancy (eg, pre-eclampsia, gestational diabetes requiring insulin intervention, severe intrauterine growth restriction, and fetal anomalies)
- Preexisting medical conditions (eg, hypertension, diabetes mellitus, thyroid diseases, autoimmune diseases such as systemic lupus erythematosus, antiphospholipid syndrome, and other major chronic illness)
- Active participation in another clinical trial or ongoing observational study



Randomization Procedure and Study Arms

This is a double-blind, placebo-controlled, randomized, and 3-parallel-arm study aimed at assessing time trends in perinatal mood and stress with ingestion of the probiotic BL NCC3001, starting from either the third trimester (28-32 weeks' gestation) or immediately after birth until 12 weeks post partum, compared with placebo. The 3 arms are (1) prepartum + postpartum probiotic, (2) prepartum placebo + postpartum probiotic, or (3) prepartum + postpartum placebo in a 1:1:1 ratio (Figure 1). Participants were randomly allocated via an electronic database to 1 of these 3 arms at the first virtual study session when the participant was at 30 (allowed window 28-32) weeks' gestation.

Until the database lock of the primary outcome, neither the investigator nor the participant nor the site team nor the independent monitor managing the study will know to which investigational product each participant was allocated, with the exception of specified delegated regulatory staff within Nestlé, the product manufacturing site, and the supply and quality managers at the sponsor's clinical research unit.

XSL•FO
RenderX

Figure 1. Graphical representation of the 3-parallel-arm study design. Participants are randomly allocated to 1 of the 3 different arms of the trial in a 1:1:1 ratio, with the probiotic intervention taken either (1) during pregnancy and post partum (n=60) or (2) post partum only (n=60) compared with (3) a placebo control group (n=60). BL: Bifidobacterium longum.

Intervention

The daily intervention comprised a dry powder stick pack containing 1.0×10^{10} colony-forming units of the probiotic strain BL NCC3001 (8.25%) premixed with a maltodextrin (91.75%) carrier. It is being compared against a placebo of similar sensory characteristics, packaged in a dry powder stick pack containing maltodextrin (84%), yeast extract (12%), pea flour (2%), and cysteine (2%). Both products need to be stored refrigerated and were couriered to participants by designated services trained to maintain the cold chain. The participants were instructed to first dissolve the probiotic in an approved liquid medium (eg, plain water or milk) at room temperature or cooler, then consume it within an hour, in the evening with a meal on a daily basis.

The dosage and schedule were identical to those of a previous study [23], and this approach has been shown to induce an immunologic or microbiota host response to the probiotic in healthy human adults [29]. BL NCC3001 has also been administered at a similar dose to pregnant and lactating women [30,31] as well as infants [32] in studies unrelated to PMD, with no major adverse effects reported.

Adherence was assessed by participant recall at each study session. Good adherence was predefined as at least 80% over the study period. Upon the resupply or return of unused products, product consumption was additionally verified.

Usual consumption of foods containing probiotics was recorded at baseline (screening session) and again at the end of the study. Participants were requested not to increase the intake of probiotic foods across the duration of the study. In any case, the intake of particular diets, treatments, medications, or concomitant therapies such as probiotic supplements and antibiotics that may interfere with the intervention, as well as medications known to affect mood and stress, during the trial period were captured.

Study Outcomes and Other Assessments

The primary outcome is change in time trends of mood and stress scores as measured by the STAI [24] and EPDS [25] evaluated across 6 study sessions between baseline at 28 to 32 weeks' gestation and 12 weeks post partum.

The secondary outcomes will be derived from validated self-reported questionnaires, including probable depression requiring follow-up (defined as an EPDS score of ≥13) at each time point; change in Hospital Anxiety and Depression Scale score [28] (anxiety and depression subscales) from baseline to post partum; Parenting Stress Index [33] score at 12 weeks post partum; Pittsburgh Sleep Quality Index [34] at 36 weeks' gestation and 12 weeks post partum; a longitudinal assessment of the Gastrointestinal Symptom Rating Scale score (explores any experience of bloating, rumbling, flatulence, and abdominal pain, as well as stool frequency and consistency) [35]; and a longitudinal assessment of the duration, initiation, and exclusivity of breastfeeding as well as breastfeeding practices using the Early Feeding Questionnaire. Other secondary outcomes will be derived from digital measures and biological sample analyses, including longitudinal changes in stress biomarkers (assessed using a digital app linked to the central electronic database and morning salivary cortisol measures) and in maternal gut microbiota (composition and probiotic strain colonization to generate mechanistic insights). The digital stress app is designed to use transdermal optical imaging of the face to measure heart rate variability and blood flow, which is then extracted and used to generate a *stress index* score on a scale ranging from 1 to 5, where higher scores reflect greater stress levels [36]. Interviewer-administered questionnaires specifically designed for this study were used to (1) capture sociodemographic and medical history, (2) record probiotic food and medication intake, and (3) record pregnancy complications and birth outcomes. Scores from a validated self-administered Childbirth Experience Questionnaire [37] were also captured because this could potentially influence postnatal mood. The timing and activities at each of the 6 study sessions are listed in Table 1.

[g]CEQ: Childbirth Experience Questionnaire.

[h]GSRS: Gastrointestinal Symptom Rating Scale.

All sessions were conducted virtually (e-sessions) using video or voice calls accessed via a secure link that maintains data privacy. Participants filled out self-administered questionnaires on their own devices through Medidata Patient Cloud (Medidata Solutions Inc), an electronic patient-reported outcome app that was automatically integrated with the web-based research database (iMedidata; Medidata Solutions Inc). Each study participant was provided with a deidentified personal username and password to access the electronic patient-reported outcome system. For interviewer-administered questionnaires, the study team entered the answers directly into iMedidata. Each participant was assigned a clinical research coordinator for the entire duration of her participation to help build rapport and increase participant retention; regular contact included reminders for upcoming study sessions and the accompanying activities. If a participant became noncommunicative, attempted follow-up was carried out via SMS text messaging or email, and the case was only classed as lost to follow-up or withdrawn after the window period for her final study session had passed.

Ethics Approval, Study Conduct and Registration, and Participation

Ethics approval was granted by the A*STAR institutional research board (2020-065), and all women provided signed informed consent. This study is being conducted in line with Good Clinical Practice [38] and the Declaration of Helsinki [39]. The study has been registered on ClinicalTrials.gov (NCT04685252). The clinical data management systems developed for this study complied with Good Clinical Practice [38], predicate rule requirements, and laws and regulations (personal data protection), and they allow an audit of actions by users. Participants were reimbursed for their participation in the form of electronic vouchers that could be redeemed at a local chain of malls. Reimbursement was prorated based on the number of study sessions and tasks completed, with a maximum possible value of SGD $330 (approximately US $240) for the entire trial duration for participants who completed all activities.

Biological Sample Collection

Saliva and stool samples were self-collected at participants' residences and couriered back to the study site by a designated, reliable, and licensed courier trained to respect the *cold chain* to maintain sample integrity. Biological samples are being stored at –80 °C at an appropriately regulated tissue repository until the planned batch analyses at the end of the study. This strategy required comprehensive collection kits to be sent to participants, which included a clear, illustrated, and concise manual, as well as items to alleviate any concerns about needing to store the biological samples in their freezer between the time of collection and courier pickup. These items included laboratory-grade biohazard bags and additional containers to contain the biohazard bags to have multiple degrees of separation between the collected biological sample and the food items in the freezer.

Monitoring and Safety Reporting

Monitoring was carried out periodically by an external, independent monitor. This allowed the evaluation of the trial progress, verification of the accuracy and completeness of electronic case report forms, and resolution of any inconsistencies in the trial records, as well as ensured that all protocol requirements, applicable local laws, International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use [38] guidelines, and investigator obligations were fulfilled.

Safety reporting was conducted in accordance with a preagreed study safety monitoring plan. All adverse and serious adverse events were recorded in the study database.

Statistics

This is an exploratory study of the effect of BL NCC3001 on mood in pregnant and postpartum women; therefore, effect sizes are unknown. However, illustrative power calculations are shown in Table 2. Once completed, this trial will allow a potential follow-up trial to be designed and powered properly, where observations could be confirmed.

XSL•FO
RenderX

Table 2. Illustration of error rates and statistical power for the Edinburgh Postnatal Depression Scale (EPDS) and State-Trait Anxiety Inventory (STAI) over 1000 simulations.

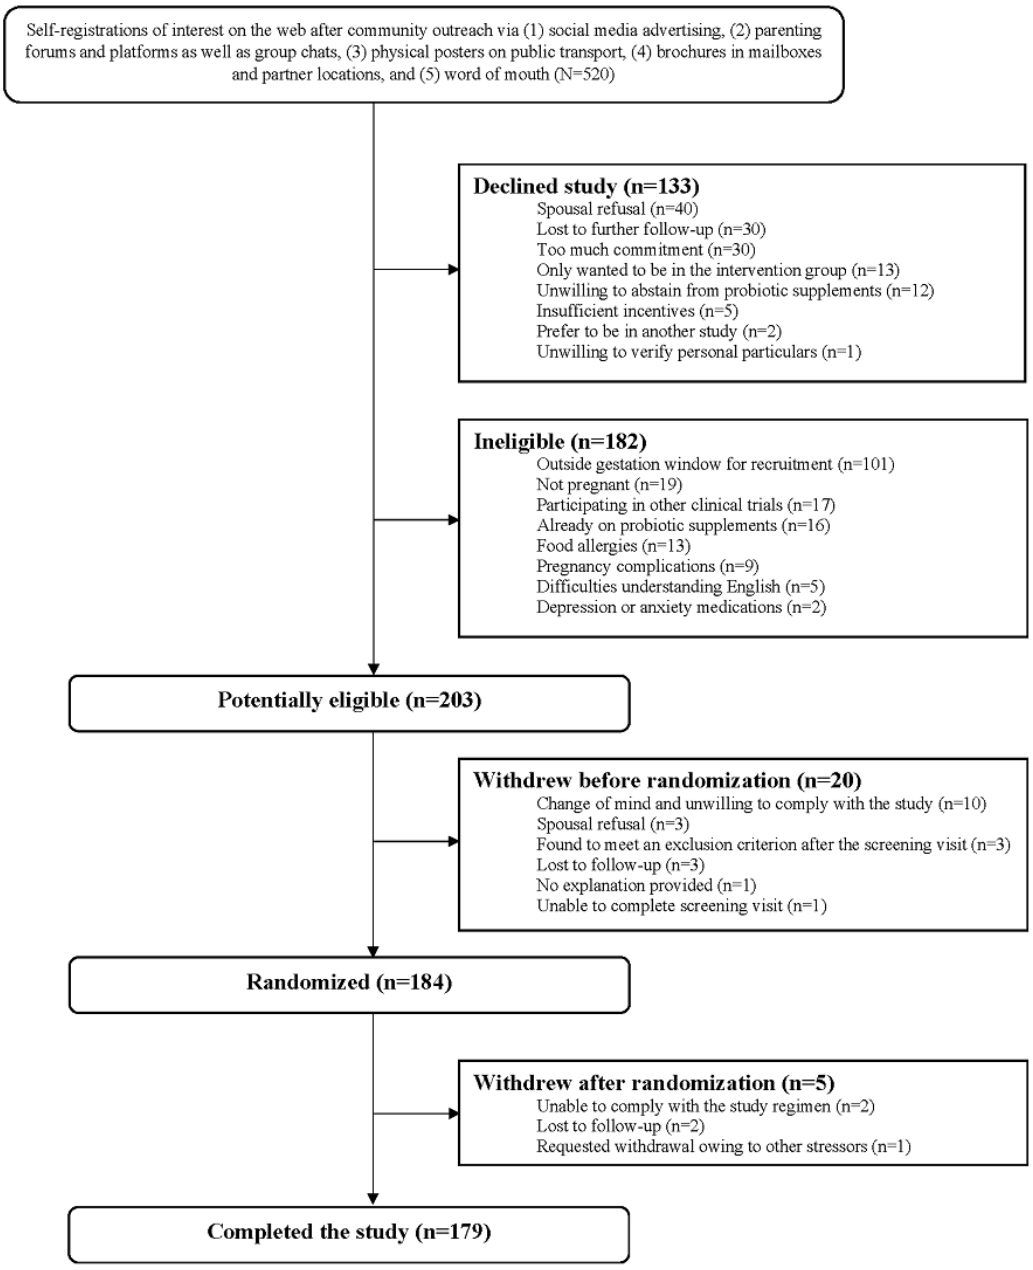
Outcome and hypothesis	Comparison	Max-*t* test[a], %
EPDS		
Null	Prepartum + postpartum probiotic vs placebo control	1.70
Null	Postpartum-only probiotic vs placebo control	1.60
25% difference	Prepartum + postpartum probiotic vs placebo control	72.00
25% difference	Postpartum-only probiotic vs placebo control	48.10
STAI		
Null	Prepartum + postpartum probiotic vs placebo control	2.20
Null	Postpartum-only probiotic vs placebo control	1.30
25% difference	Prepartum + postpartum probiotic vs placebo control	69.20
25% difference	Postpartum-only probiotic vs placebo control	50.30

[a]Rows where the hypothesis is null display the error rate, whereas the ones where the hypothesis is 25% difference in time trends display the power of the test. For the control group, the means and SDs of mood scores were based on previous perinatal studies of longitudinal Edinburgh Postnatal Depression Scale scores [40] and assumed to be normally distributed. For the prepartum + postpartum intervention group, the test scores are assumed to be gradually decreasing over time with a maximal difference of 25% with respect to the controls. For the postpartum probiotic intervention group, the effect was assumed to have the same kinetics but with onset at birth. The correlation between study sessions was assumed to be 0.5.

The trial has 2 primary outcome variables (EPDS and STAI scores) and 2 primary group comparisons (prepartum + postpartum intervention vs placebo control and postpartum-only intervention vs placebo control). Thus, the false positive rate controlled at 5% level is as follows: $\alpha / 4 = 0.0125$ (for each combination of a primary outcome variable and a group comparison). The time trends for comparing prepartum + postpartum intervention versus control (session 2-session 6; Table 1) and for comparing postpartum-only intervention versus control (session 3-session 6; Table 1) are modeled by 2 separate mixed models where baseline scores (session 1; Table 1), time point (considered a categorical variable), treatment, and the interactions between the time point and treatment were fixed effects, and participant was included as a random effect (random intercept). A history of previous pregnancy complications will be added as a binary covariate to the model. The global test for time-trend differences between groups is a max-*t* test. For each group comparison, the multiplicity coming from comparison at multiple time points is dealt with by performing inference based on the joint distribution of the test statistics from the appropriate set of linear contrasts of the linear mixed model parameters (using the R library *multcomp*).

A simulation using R statistical software (version 3.6.1; R Foundation for Statistical Computing) showed a power of 50% to 70% for observing statistically different time trends when considering recruiting 60 individuals per group, after accounting for an expected dropout rate of 20%, representing 48 participants per group completing the study (Table 2).

With the substantially lower observed dropout rate of 2.7% compared with the initially anticipated 20%, more participants than expected have completed the study, and the power therefore is increased from this initial illustration. Although every effort has been made to obtain complete data sets, the mixed model used for analysis is robust against missing values and valid under missing at random. Outliers will be detected before unblinding, with appropriate action taken considering the medical context. The primary analysis will be an intention-to-treat analysis (considering all randomized participants who took at least 1 dose of the assigned product and provided postrandomization data) with a secondary per-protocol analysis planned. No interim analysis was performed for this trial.



Results

Recruitment and Retention

Recruitment for the trial commenced on November 7, 2020, and was completed in the following 10 months, with the last participant recruited on August 20, 2021. A total of 520 women expressed interest in the trial through online registration, of whom 205 (39.4%) were agreeable and potentially eligible to participate. Of these 205 participants, 21 (10.2%) withdrew or were found to be ineligible after the screening session, leaving 184 (89.8%) women who were randomized. Of these 184 women, 5 (2.7%) withdrew after randomization, and 179 (97.3%) completed the study (Figure 2). Therefore, we exceeded our target of at least 48 participants per group completing the study (the original target for the 3 groups was $48 \times 3 = 144$ in total) because the final attrition rate was 2.7% instead of the anticipated 20%.

Recruitment Strategies

Of all the recruitment strategies used (Table 3), advertisements on major general social media platforms were the avenues that most women expressing interest claimed were their first knowledge of the trial (244/520, 46.9%), followed by other parenting-specific web-based platforms (116/520, 22.3%). None of them claimed to have been attracted via advertisements on the main popular search engines despite efforts to target female users of reproductive age. The recruitment avenue with the next highest success rate was via physical posters on public transport (64/520, 12.3%). The local metro train system, known as Mass Rapid Transit (MRT), is used daily by 2.2 million passengers [41], which is equivalent to approximately 41% of the population of Singapore [42].

The geodemographic data of Singapore were considered so that resources could be focused on the MRT routes most used by our target population. We first targeted the North-East Line, which services District 19, a catchment area that includes an area with the highest number of residents aged <5 years, an indicator of young families. Almost a quarter (122/520, 23.5%) of the prospective participants reported residing in District 19 [43,44]. The strategy was then extended to other major lines, including the Downtown Line, North-South Line, and East-West Line, that serve other districts with young families [43]. Of the 28 Singapore districts, 7 (25%) are known to have the highest proportions of residents aged <5 years; of these 7 districts, 5 (71%) contributed nearly half (233/520, 44.9%) of the potentially eligible participants, whereas the other 2 (29%; Districts 17 and 24) did not contribute any participants and were incidentally not covered by an MRT line (Figure 3).

RenderX

Table 3. Source of recruitment advertisement reported by potential participants during self-registrations of interest on the web (N=520).

Source of recruitment advertisement or study recruitment strategy	Potential participants, n (%)
Social media	244 (46.9)
Parenting-specific online platforms	116 (22.3)
Public transport (Mass Rapid Transit trains)	64 (12.3)
Word of mouth	42 (8.1)
Physical poster or brochure	26 (5)
Internal A*STAR[a] electronic outreach and email blast	28 (5.4)
Advertisements on search engines	0 (0)

[a]A*STAR: Agency for Science, Technology and Research.

Figure 3. Distribution of participants' area of residence with Mass Rapid Transit (MRT) route map of Singapore (map data: Google, 2022). Each blue drop represents 1 potentially eligible participant. Participants were recruited from across the country, particularly from districts with the highest density of residents aged <5 years (dotted circles: districts 4, 9, 19, 23, and 27) and along targeted MRT lines (purple: North-East Line, blue: Downtown Line, red: North-South Line, and green: East-West Line). Two of the 7 districts with the highest number of residents aged <5 years (districts 17 and 24) contributed no participants; in addition, they were not served by an MRT line.

Discussion

Overview

This double-blind, placebo-controlled, and randomized controlled trial will be the first to examine the efficacy of the naturally occurring probiotic BL NCC3001 in alleviating or suppressing symptoms of PMD when taken either from the third trimester or immediately after birth until 12 weeks post partum. It was designed to be conducted entirely remotely in Singapore and was successfully carried out during the height of the COVID-19–related restrictions, using digital technology in all aspects of the conduct of the study while complying fully with research governance and regulations.

Although other probiotic interventions have been tested in pregnant women for their impact on PMD with inconsistent results [16-19], it is important to note that these studies differed in one or more methodological aspects from our study. Aside from different probiotic strains or multiple probiotic strain combinations used, there were variations in probiotic concentrations; combinations with other nutritional supplements; study populations with specific comorbidities in addition to being pregnant or post partum; and different timelines for intervention intake, such as commencement in the first half of the pregnancy [17-19].

The COVID-19 era has posed many challenges globally. The first challenge concerned the need for social distancing and the associated unpredictable restrictions on in-person activities,

XSL•FO
RenderX

including participation in conventional clinical trials. The second challenge concerned the fact that pregnant women are considered a vulnerable group with compromised immunity—in the early stages of the pandemic, very little was known about the detrimental effects of the virus on pregnant women and their unborn child; hence, more precautionary steps were taken to promote their isolation. Therefore, designing a research study that could overcome these hurdles and decrease barriers to participation was crucial to ensure feasibility, continuity, and the eventual successful completion of the study in the face of unpredictable governmental regulations. This study was designed to maintain robust operating procedures that would be resilient to the constant changes in COVID-19–related mandates in Singapore. This was possible because of several reasons, many novel to the local research arena. The remote approach contributed to minimizing inconvenience, reducing exposure risk to COVID-19 infection, and complying with local social distancing regulations. This included all study sessions being conducted virtually (e-visits), which comprised using digital apps to answer self-reported questionnaires and web-based databases that securely synced with these apps, and the intervention products being delivered by courier services, with self-collection of biological samples by participants conducted at their own residences and trained couriers engaged to transport the samples back, with a contactless pickup provided as an option for the participants as well. Despite the apparent success in the recruitment phase, there were some initial challenges before the study could begin. In particular, the ethics board had to be convinced of the reliability and feasibility of remote consenting procedures and approve of the entirely remote conduct of the trial, especially for a population considered vulnerable, such as pregnant women. We also had to design a new secure, acceptable, and legally valid remote e-consenting process to allow consecutive instantaneous signing by a participant, researcher, and witness located at different places, which could be completed rapidly.

The widespread ownership and use of personal mobile phone and computerized devices, high availability of internet (both cellular and home internet), trust in digital security systems associated with established local institutions, and greater IT savviness among the target age group [27], coupled with high health and research literacy, likely increased participant comfort with engaging digitally for research purposes. The established consumer trend of women of reproductive age using social media as a main avenue to research new brands, obtain information, and establish connections is another aspect that may have made the use of online channels for recruitment and conducting research in the study plausible and successful. The study team was able to achieve a much wider community reach, passively capturing a more diverse pool of participants attending different institutions for maternity care and including those mostly confined to their own home owing to COVID-19–related restrictions. The strategy of using social media proved the most effective recruitment tool because it resulted in the highest traffic of potential participants, especially during the recruitment phase that occurred from late 2020 to mid-2021 at the height of the COVID-19 pandemic when restrictions were at their most stringent in Singapore and before widespread vaccination of the pregnant population. This is in contrast to recruitment from particular health facilities (eg, a university hospital's maternity department), which is often restrained by a geographical catchment area and the need for physical accessibility to the location to view a poster, receive a brochure, or be approached by staff to introduce the study. The same reasons that explain the success of an entirely remotely conducted clinical trial could also be used to explain the particular success of our social media recruitment strategy, despite the various other recruitment strategies being afforded similar resources in terms of time, finances, and workforce hours.

Although most of the participants (244/520, 46.9%) claimed that social media platforms gave them their first knowledge of the trial, recruitment efforts were strengthened when different avenues of recruitment were used simultaneously. Most notably, when we were targeting recruitment from a geographical perspective, interest from a particular district with a high density of young families peaked when brochures were dropped into residential letter boxes at a similar time to a physical poster advertisement campaign running on the main MRT line servicing that area. We speculate that these different forms of advertisements provided multiple reminders that increased the likelihood of expression of interest. The effectiveness of our nationwide community recruitment strategies is reflected by our data indicating that participants come from all parts of the country.

Another aspect integral to the success of the study was the at-point-of-residence self-collection of biological samples. Extensive thought and planning were required to design a biological sample collection workflow that was easy to follow, convenient, and acceptable to participants. Good coordination among the study team, participants, and the licensed courier tasked for pickup was essential. The courier had to follow a robust workflow, maintain the cold chain in tropical Singaporean weather, and demonstrate flexibility in response to constant changes in local COVID-19–related restrictions. Additional benefits that likely attracted participation include increased convenience, attributable in part to no traveling time required to attend sessions. Similarly, this also increased overall time and cost saved for the study team.

The actual subject matter of mood disorders also likely resonated more with pregnant women during the COVID-19 pandemic, which helped with study recruitment. Generally increased stress levels across the population have been widely reported worldwide during the pandemic, with pregnant women highlighted as a particularly affected group [45,46]. We aimed to recruit women who already had some symptoms of low mood or anxiety, as determined by the Hospital Anxiety and Depression Scale, to allow for the possibility of improvement with intake of the intervention product. Our data showed that none of the women who consented to join the study were excluded specifically because they did not fulfill this criterion; this means that all who were interested in participating already had some PMD symptoms. These women may have been motivated to reduce their PMD to avoid negative impacts on the health of both mother and baby and were open to exploring probiotics as a solution that is thought to have few or no unwanted effects.

XSL•FO
RenderX

As many women try to avoid taking pharmacological treatments during pregnancy and lactation [4,13], there is a potential opportunity for natural and nutrition-based solutions to provide mood benefits in this population [47]. However, a systematic review of nutritional interventions concluded that current evidence is inconsistent and inconclusive on whether nutritional factors influence the risk of PMD [48,49]. As there is some evidence suggesting that probiotics could help fill this gap [50], this study of the probiotic BL NCC3001 was designed to help inform that possibility. As the intervention had been classed by the Health Sciences Authority of Singapore as a nutrition product and not a pharmaceutical drug, it meant that the study design did not need to include the usually extensive in-person monitoring that drug trials would normally require. This, therefore, decreased the barriers to participation and study retention.

Conclusions

Multiple converging factors contributed to the study being able to recruit at speed and retain the required number of participants despite COVID-19–related restrictions. In addition to providing novel evidence for the potential benefit of the probiotic BL NCC3001 in reducing the symptoms of PMD, this entirely remote research study design sets a precedent for similar studies. Such studies could be highly suitable if (1) the intended study population has a high rate of digital device penetration and internet access, (2) systems allow secure data exchange and capture, (3) the intervention can be self-administered without clinical monitoring, and (4) eligibility criteria and outcome measures can be reliably assessed remotely either by digital capture or self-collected biological samples. We have described here such a study that has been successfully conducted in a group considered vulnerable, pregnant women, despite the presence of challenges and barriers presented by the COVID-19 pandemic.

Acknowledgments

The authors thank the whole Probiotics on Mothers' Mood and Stress (PROMOTE) study team that contributed to the design and execution of this study, including Sabeera Ali, Dominik Grathwohl, Carmine d'Urzo, Chiara Nembrini, Leslie Tan, Florence Rochat, Pamela Sun, Farouk Chughlay, Sagar Thakkar, Julia Mauger, Sophie Moille, and Fanny Membrez. This study is a collaboration between Singapore Institute for Clinical Sciences, an institute within the Agency for Science, Technology and Research (A*STAR), a governmental body of Singapore, and Société des Produits Nestlé, Switzerland. It is jointly funded by the A*STAR and Nestlé through the Industry Alignment Fund–Industry Collaboration Project funding stream (Innovation and Enterprise Domain, project I1901E0G15). The intervention product was designed and manufactured by Société des Produits Nestlé, Switzerland.

Conflicts of Interest

At the time of writing, all authors were employees of Singapore Institute for Clinical Sciences, an institute within the Agency for Science, Technology and Research (A*STAR), a governmental body of Singapore, and Société des Produits Nestlé, Switzerland.

Abstract

Background: Virtual reality (VR) is an innovative tool that can facilitate exposure to either stressful or relaxing stimuli and enables individuals who have difficulties visualizing scenes to be involved in a more realistic sensorimotor experience. It also facilitates multisensory stimulation, a sense of presence, and achievement of relaxation. VR scenarios representing visual and auditory elements of natural relaxing environments can facilitate the learning of relaxation techniques such as the progressive muscle relaxation technique (PMRT). A complementary standardized technique deployed to reduce anxiety symptoms is the integration of PMRT and guided imagery (GI). Exposure to a pleasant imaginary environment helps the establishment of an association between a relaxing scenario and the relaxation technique, consequently promoting relaxation. Empirical evidence has shown that VR scenarios can increase the effects of relaxation techniques by enabling people to experience emotional conditions in more vivid settings.

Objective: The main aim of this pilot study protocol is to investigate the impact on state anxiety of PMRT, associated with a personalized relaxing scenario in VR, and the role of VR scenarios in facilitating the recall of relaxing images and a sense of presence. A secondary aim is to understand if relaxing sessions administered via Zoom are more effective for managing anxiety and stress than a procedural setting based on audio-track guidance.

Methods: Based on a longitudinal, between-subject design, 108 university students will be randomly exposed to one of three experimental conditions: (1) PMRT via Zoom and GI exposure, (2) PMRT via Zoom and personalized VR exposure, and (3) PMRT based on audio-track guidance and personalized VR exposure. Individuals are assessed before and after 7 training sessions based on self-report questionnaires investigating anxiety, depression, quality of life, coping strategies, sense of presence, engagement, and side effects related to VR exposure. Heart rate data are also detected by an Mi Band 2 sensor.

Results: The experimental procedure is ongoing. In this paper, preliminary data from a sample of 40 participants will be illustrated. The experimental phase is expected to conclude in May 2023, and the final results of the research will be presented in June 2023.

Conclusions: The results of this study will help shape the experimental design to apply it on a subsequent randomized controlled trial, also considering clinical samples. This work is expected to measure whether VR is a more engaging and helpful technique in promoting relaxation and decreasing anxiety levels than GI, by making the visualization process easier and by helping people to face more realistic sensory experiences. Assessing the efficacy of the PMRT in alternative delivery modes may extend its

XSL•FO
RenderX

applications, especially in situations where the standard procedure is more challenging to be administered. To our knowledge, no equivalent study has been published so far on this matter.

Introduction

Background

Virtual reality (VR) is widely used to treat various mental diseases [1], also in association with different types of relaxation training (eg, progressive muscle relaxation training), and it facilitates multisensory stimulation, sense of presence, and achievement of relaxation [2,3]. VR can facilitate the learning of relaxation techniques through exposure to scenarios in which natural environments, which are commonly considered relaxing, are shown [2]. VR also has several advantages such as follows: easy to use, user-friendly, promotes engagement, and allows a full multisensory immersion in the virtual experience facilitating the control of external disturbing stimuli [4,5].

It was also highlighted that the customization of VR environments is an element that promotes relaxation. This latter type of user-centered approach [6] allows individuals to experience more realistic emotional conditions, like those experienced in everyday life, and it enhances relaxation, sense of presence, and perception of security in the virtual context (eg, [7]).

Standard relaxation programs usually include more directive techniques that imply larger involvement of the cognitive functioning system (eg, hypnosis) or the physiological response system (eg, progressive muscle relaxation technique [PMRT]), as well as fewer directive procedures that may be based on the cognitive functioning control (eg, meditation) or the physiological feedback (eg, autogenic training), respectively [8]. All these protocols are effective in promoting relaxation.

Jacobson [9] developed the PMRT protocol in 1938, suggesting that the overactivation of the sympathetic nervous system is primarily responsible for excessive skeletal muscle activity. Thus, interference in the skeletal muscle activity based on progressive relaxation reduces the activation. This process also positively affects other physiological parameters (eg, heart rate frequency) [10,11].

On these grounds, the training consists in learning how to tense and release several muscle groups.

Evidence suggests that stress-competing relaxation techniques are among the most effective training programs for enhancing psychological resources and reducing psychological distress [12].

PMRT is based on “top-down” and “bottom-up” neuronal processing. The “top-down” pathway is turned on by higher cognitive activities, such as focused attention, related to the cerebral cortex and the cerebellum, which send commands to peripheral areas by controlling muscle tension and gradual release. The holding and releasing activities allow proprioceptive stimulation from peripheral sensory afferents to the higher nervous system regions via the spinal cord and the brainstem as a “bottom-up” pathway [13-15]. Also, based on these processes, PMRT is considered one of the most effective and adaptable techniques for relaxation, anxiety management, stress, and depression reduction considering different kinds of target populations (eg, nonclinical individuals, patients with cancer, chronic pain, osteoarthritis, heart disease, chronic headache, anxiety, and depression) [16-20].

Still, the administration of combined methods appears very useful in reducing anxiety and the perception of pain in patients with medical conditions or during pregnancy [19-21]. Indeed, complementary methods that imply the administration of integrated cognitive and behavioral procedures are studied to manage anxiety, stress, depression, and pain, particularly in populations such as patients with cancer. Notably, the integration of PMRT and guided imagery (GI) enhances and facilitates the effect of relaxation, reducing anxiety and depression symptoms [19,22].

The application of GI, or VR, and PMRT is based on classical conditioning theory that involves learning relaxation techniques and exposure to relaxing mental images as conditioned stimuli useful for overcoming stress and specific fear [23,24].

The integration of PMRT and GI has been highlighted in the literature as an effective complementary method for reducing pain and anxiety symptoms (eg, [19,21]). GI is useful in creating mental imagery and refocusing attention on positive and relaxing imagined visual, auditory, tactile, or olfactory sensations, resulting in specific psychological and physiological responses, such as relaxation [25]. GI may also increase the reduction of the autonomic nervous system responses [19,25,26]. This combination can promote a higher sense of relaxation during training sessions, but it should also play a role in recalling a state of relaxation during everyday activities.

The combined methods introduced by Baird and Sands [19] implement eight steps [27-31]:

1. Setting a comfortable and protected real environment in which to relax
2. Recreating an imagined scene involving different senses
3. Guiding the user in focusing on breathing
4. Using passive progressive relaxation techniques

XSL•FO
RenderX

5. Recalling the imagined scene to direct the attention to pleasant stimuli
6. Feeling a release from pain and activation (eg, imagining a decrease in painful sensations)
7. Imagining moving into the scene by continuing to use focused breathing and relaxation
8. Ending the session ("Breathe deeply. When you are ready, allow the image to fade. Stretch and open your eyes" [19]).

Considering the positive impact on relaxation of GI associated with PMRT, exposure to a more vivid, closer-to-reality virtual experience should be a useful technique in further improving the relaxation learning promoted by the PMRT.

Furthermore, it is well known that before delivering PMRT with GI, some sessions of PMRTs, focused on learning to recognize and relax the muscle areas of our body, are needed. Usually, these training sessions are administered face-to-face in the therapist's presence. Finally, to investigate the effectiveness of web-based psychotherapy interventions, there are controversial results regarding a PMRT procedure administered in vivo or via audio-tracks [32-34]. To our knowledge, no recent study exists addressing the comparison among training sessions administered in vivo, in a remote modality, or via audio-tracks. In light of the pandemic due to SARS-CoV-2, we intend to explore PMRT's efficacy in a remote situation via both Zoom and audio-tracks.

In general, it is essential to point out that remote treatments have been increased. They promote users' independence in managing some psychotherapy techniques, leaving time for other face-to-face psychotherapy activities that require the active involvement of both the patient and the therapist. Assessing the efficacy of PMRT in alternative settings may facilitate the administration of treatment where it is impossible to implement the standard procedure. It may also increase the positive impact of abbreviated relaxation session and combining relaxation methods with patients who have chronic pain or must be exposed to invasive medical treatments (eg, chemotherapy) [35,36].

Study Overview and Objectives

The purposes of the present research project are as follows:

1. Investigating if PMRT associated with a personalized relaxing scenario in VR can facilitate relaxation and lower state anxiety
2. Understanding if the VR scenario helps recall the relaxing image assessed during the follow-up session
3. Investigating if VR is more effective in promoting the association between the relaxing scenario and PMRT than the standard procedure, consisting of PMRT associated with the imagery-induced exposure to a subjective relaxing environment
4. Analyzing if the relaxing sessions administered via Zoom are more effective in managing anxiety and stress than a procedure administered via audio-tracks.

We hypothesize that VR would be more effective than GI in promoting relaxation and decreasing state anxiety because it would facilitate the visualization process, allowing individuals to have more realistic sensory experiences than imagery-induced exposure.

Methods

Ethics Approval

This study protocol involving human participants was General Data Protection Regulation compliant and developed following the Declaration of Helsinki (Italian law 196/2003, European Union General Data Protection Regulation 679/2016). The institutional review board of the Interdepartmental Ethical Committee of Psychology (17 Area) of the University of Padova (Italy) approved the study protocol on May 28, 2021 (approval number 4213). In February 2022, the trial was tested based on a convenience sample of 5 individual volunteers from the general population. Then, it was decided to introduce the following questionnaires: the Coping Orientation to the Problems Experienced-New Italian Version (COPE-NVI), the ITC-Sense of Presence Inventory (ITC-SOPI), the Vividness of Visual Imagery Questionnaire [37,38], and the Test of Visual Imagery Control [37,38]. The amendments and supplementations have been accepted, and the protocol received the final approval of the institutional review board of the Interdepartmental Ethical Committee of Psychology (17 Area) of the University of Padova, Italy (approval number 4701; April 29, 2022). Before their study enrollment, the participants signed a written informed consent form based on a paper-and-pencil form, agreeing to participate in all the study sessions.

They were informed that (1) their data would be confidential, (2) they could omit any information they did not wish to give, and (3) they could withdraw from the study without providing any explanation.

Eligibility, Recruitment of Study Participants, and Randomization

The recruitment phase started in May 2022. Study participants were recruited in Northeast Italy via social networking websites (eg, Facebook groups) and by providing information on the research during university lectures. Those interested in participating were asked to make an appointment with the investigators to participate in the first assessment phase (T0) in which the inclusion and exclusion criteria were evaluated, written informed consent was obtained, and a baseline evaluation was made.

Eligible participants were adults from the general population (18 years or older), native Italian speakers, owning a PC, and able to use a PC and smartphone.

Participants were excluded from the study if they had been diagnosed with a severe mental disorder or medical conditions that could hinder their participation in the study (eg, neuromuscular disorders, severe psychiatric or neurological disorders, and assumption of drugs that could interfere with heart rate assessment and the subjective relaxation state), or if a psychotherapeutic treatment was ongoing.

Eligible participants were randomly allocated to 1 of 3 experimental conditions based on a simple blinded randomization via an Excel (Microsoft Inc) file.

Two experimenters, trained in cognitive and behavioral psychotherapy, conducted the relaxation sessions, each

XSL•FO
RenderX

administering to 50% of the sample of each group to control for possible biases related to the therapist's personality and competence. The 2 therapists who administered the experimental procedure received the same PMRT training and were supervised by a senior researcher and psychotherapist supervisors.

The Integrated PMRT and Virtual Environment Design

The virtual environment design and the hardware and software equipment are described in the paper by Pardini et al [39], in which the aim was to investigate the user experience, preferences, and engagement of the exposure to personalized, natural, and realistic VR scenarios.

Specifically, we adapted the procedure that Baird and Sands [19] introduced to propose an integrated intervention using different new technologies.

The protocol concerns the learning of the adapted abbreviated PMRT [33] in 5 sessions 2 times a week, as follows:

- Four sessions of active progressive muscle relaxation, in which participants are required perceptively learn the differences between the tension and relaxation of different muscle sections of the body. Each session has a duration of approximately 25 minutes. The first session is dedicated to the hands, forearms, arms, neck, shoulders, and back; the second to the facial muscles; the third to the diaphragmatic breathing; and the fourth to the abdomen, buttocks, and lower limbs. These sessions take place via the Zoom platform and are conducted by a cognitive-behavioral psychotherapist. Each Zoom session consisted of filling out 2 measures for the state anxiety and relaxation state based on the Moodle e-learning platform, sharing general standardized instructions for conducting relaxation and the rationale of the PMRT, guided relaxation aimed at relaxation of a dedicated body site, and filling out the same measures administered at the beginning of the session. A profile was created for each participant to access the Moodle platform. For the participants in condition "intervention B" (described in the following section) who participated in the first 4 PMRT sessions through the audio-track, all sessions were self-managed within the Moodle platform. Various activities have been scheduled based on the beginning of the training and the end of the activities planned in previous sessions.
- The fifth VR session is administered at the University of Padova Laboratory. All participants are asked to wear a smartwatch for heart rate detection. A total of 5 measurements (1 per minute) are made before the VR experience, 12 during the entire exposure in the virtual environment, and 5 after the experience in the virtual context. A duration of approximately 12 minutes has been established to avoid potential cybersickness symptoms during the virtual experience. This brief relaxation session is practiced by inexperienced individuals allowing for a decrease in anxiety and negative mood [40,41].

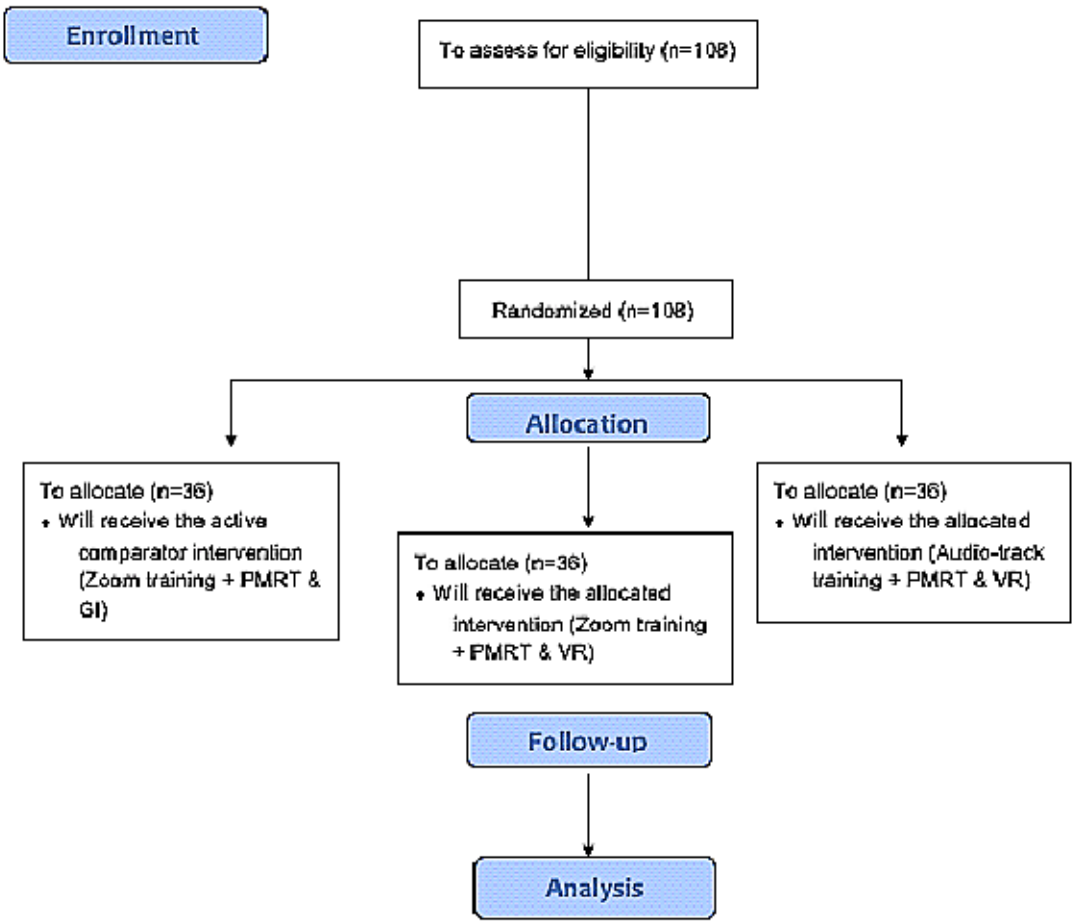
Study Design

The present protocol of the proof-of-concept study is a longitudinal, between-subjects, 3-armed randomized controlled trial aiming to compare three treatment conditions (Figure 1):

1. Active Comparator condition, consisting of the deployment of the PMRT training via Zoom and GI exposure. It consists of a standard behavioral intervention based on 4 individual PMRT sessions via Zoom (t1-t4), an in vivo PMRT relaxing session and GI conducted by a psychotherapist (T1) after a week from the baseline assessment (T0), and a follow-up phase (T2) after 2 weeks consisting in recovering the GI relaxing scenario and PMRT session (see Multimedia Appendix 1 and Figure 2).
2. Intervention A is an experimental condition in which the complementary intervention is composed of the PMRT administered via Zoom integrated with a personalized VR exposure deployed by a head-mounted display (Oculus Quest 2). It comprises 4 individual PMRT sessions via Zoom (t1-t4), an in vivo PMRT relaxing session and VR exposure (T1) after a week from T0, and a follow-up phase that consists of the same activities as the Active Comparator condition (see Multimedia Appendix 1 and Figure 3).
3. Intervention B is an experimental condition in which the complementary intervention is composed of progressive muscle relaxation training administered through an audio-track integrated with the same personalized VR exposure setup in Intervention A. It is composed of 4 individual PMRT sessions via an audio-track delivered on the Moodle platform (t1-t4), an in vivo PMRT relaxing session and VR exposure (T1) after a week from T0, and a follow-up phase that consists of the same activities as the Active Comparator and the Intervention A conditions (see Multimedia Appendix 1 and Figure 4).

The assessment phases take place at baseline (T0), before and after the 4 PMRT sessions (via Zoom or audio-track), at the fifth in-presence session (T1), and a week later (T2).

The T0 (baseline) assessment phase has a duration of approximately 37 minutes, is the same for all participants, and is administered at the Virtual Reality Laboratory (A10-A11), Department of General Psychology, University of Padova (Italy). In this phase, the following measures are administered: (1) a demographic schedule (addressing age, gender, nationality, mother tongue, marital status, years of school attendance, employment status, psychological problems or disorders, ongoing psychological treatment, drug use, medical conditions, neuromuscular issues, previous injures, previous experiences in relaxation practice or anxiety management training, or with Oculus), and also, refraining from smoking, intense physical exercise, consuming caffeine for at least 1 hour before testing, and consuming alcohol for at least 6 hours before testing [42]; (2) a series of self-report questionnaires investigating depression, anxiety, stress, quality of life, and distress coping strategies (State Trait Anxiety Inventory-Y [STAI-Y], Depression Anxiety Stress Scales-21 [DASS-21], Psychological General Well-Being Index [PGWBI], and COPE-NVI); and (3) resting heart rate detection with an Mi Band 2 sensor.



XSL•FO
RenderX

Before and after each relaxation session (t1-t4), in approximately 20 minutes, the personal level of tension is assessed by using a visual analog scale from 0 (no tension) to 10 (extreme tension level). The state-anxiety level is evaluated based on the STAI-Y1. The 4 relaxation sessions are administered 2 to 3 days apart from each other for all 3 groups. The assessment phase is administered through Moodle, an e-learning platform used for data collection.

The T1 phase (day 7) required approximately 60 minutes. Before and after the relaxation session, states of tension and anxiety are assessed by using a 0 (no tension) to 10 (extreme tension level) scale, and the state-anxiety level is evaluated based on the STAI-Y1. Then, participants are exposed to a PMRT session merged with a VR or a GI procedure. Before the GI or the VR experience, all the participants fill out the Vividness of Visual Imagery Questionnaire and the Test of Visual Imagery Control. After the PMRT session, users compile a series of self-report questionnaires investigating depression, anxiety, stress, and quality of life (STAI-Y, DASS-21, PGWBI), and the VR group only fill out the Virtual Reality Sickness Questionnaire to monitor VR-related side effects (eg, sickness) and the ITC-SOPI to assess the sense of presence at the end of the T1 phase. The Mi Band 2 sensor is used during the entire T1 phase administration to detect resting heart rate activity. This assessment phase is administered through the Moodle e-learning platform.

The T2 phase (follow-up) is deployed for approximately 45 minutes. Before and after the relaxation session, states of tension and anxiety are assessed using a visual analog scale from 0 (no tension) to 10 (extreme tension level). The state-anxiety level is evaluated based on the STAI-Y1. All the users are exposed to a self-GI experience in which those who were part of the VR group are asked to recall the personalized VR scenario experienced during the T1 phase (day 7). Instead, the GI group retrieve the image participants had used in association with the PMRT during the T1 phase (day 7). After the session, participants fill out a series of self-report questionnaires investigating depression, anxiety, stress, quality of life (STAI-Y, DASS-21, PGWBI), and an ad hoc version based on the ITC-SOPI to assess the sense of presence experienced during the imagery experience. This assessment phase is administered based on the Moodle e-learning platform. The Mi Band 2 sensor is used during the entire T1 phase administration (day 7) to detect resting heart rate activity.

Power Calculation

Sample size estimation was computed with G*Power 3.1 software (Heinrich Heine Universität Düsseldorf) [43]. As a statistical test, the repeated-measures ANOVAs between factors have been considered. The effect size was set as 0.25, the α as .05, and the Power (1β error probability) as 0.80. We have 3 separate groups and 3 measurements. On the basis of these parameters, we estimated having to recruit at least 36 participants for each of the 3 groups.

Data Collection, Storage, and Security

Based on informed consent, participants are informed about the experimental procedure; how data are collected, transmitted, and stored; and who has access to the data. Any digital data, such as responses to web-based questionnaires, are uploaded and saved to a secure server. Any hard copy documents are stored in a locked cabinet. Both digital data and hard copy documents are retained for 10 years after the end of the study and then securely destroyed.

Measures-Screening and Primary Outcomes

In Table 1, all the assessment and primary outcome measures are described.

XSL•FO
RenderX

Table 1. Evaluation tools and methods by outcome of interest.

Primary objective	Description	Evaluation tool
1. Number of participants with virtual reality (VR)–related side effects as assessed by the Virtual Reality Sickness Questionnaire (VRSQ) and the investigators' observations[a]	Participants in the 2 VR experimental arms (Interventions A and B) are asked to refer to whether the VR head-mounted display was painful, too heavy, or uncomfortable. Participants are asked if they have experienced negative side effects during the VR exposure based on the VRSQ, administered at the end of the VR exposure. This questionnaire is based on a dichotomous answer (Yes/No). During the VR experience, the investigator observes participant reactions and records the behaviors and signs that suggest an unpleasant experience.	VRSQ [44,45]
2. Changes between and within subjects in depression scores[b]	Differences between groups and change from baseline to the T1 and T2 phases in depression scores are assessed based on the Depressive Anxiety Stress Scale-21 (DASS-21-Depression Subscale). Items are answered using a 4-point Likert scale (0-3). Scores range from 0 to 42 (the scores will need to be multiplied by 2 to calculate the final score). Higher scores indicate more severe depression.	DASS-21-Depression Subscale [46-48]
3. Change is being assessed between and within subjects in trait-anxiety scores[b]	Differences between groups and change from baseline to the T1 and T2 phases in trait-anxiety scores are assessed based on the State-Trait Anxiety Inventory-Y2 (STAI-Y2, Trait Anxiety). The measure is a self-report questionnaire investigating trait anxiety based on a 4-point Likert scale (1-4). Scores range from 20 to 80. Higher scores indicate higher trait-anxiety severity.	STAI-Y2 [49-51]
4. Changes between and within subjects in state-anxiety scores[b]	Differences between groups and change from baseline to the T1 and T2 phases in state-anxiety scores are assessed based on the State-Trait Anxiety Inventory-Y1 (STAI-Y1, State Anxiety) before and after each session. The STAI-Y1 is a self-report questionnaire investigating the state anxiety based on a 4-point Likert scale (1-4). Scores range from 20 to 80. Higher scores indicate greater state-anxiety severity.	STAI-Y1 [49-51]
5. Change is being assessed between and within subjects in autonomic arousal, skeletal muscle effects, situational anxiety, and subjective experience of anxious affect[b]	Differences between groups and change from baseline to the T1 and T2 phases in anxiety scores are assessed by the "DASS-21-Anxiety Subscale" based on a 4-point Likert scale (0-3). Scores range from 0 to 42 (the scores will need to be multiplied by 2 to calculate the final score). Higher scores indicate more anxiety severity.	DASS-21-Anxiety Subscale [46-48]
6. Change is being assessed between and within subjects in bodily anxiety sensations[b]	Differences between groups and change from baseline to the T1 and T2 phases in bodily anxiety sensations scores are assessed based on the Self-Assessment Manikin (SAM). The SAM is a nonverbal imagery-based assessment technique used to assess bodily anxiety sensations that directly measure the pleasure, arousal, and dominance associated with a person's affective reaction to a wide variety of stimuli. Each sensation is assessed on 5 different images distributed in order of size. Participants can tick either of the 5 pictures or 4 spaces in between, making it a 9-point Likert scale. The SAM varies from a minimum score of 3 to a maximum score of 27.	SAM [52]
7. Change is being assessed between and within subjects in levels of chronic nonspecific arousal (stress)[b]	Differences between groups and change from baseline to the T1 and T2 phases in levels of chronic nonspecific arousal (stress) scores are assessed by the "DASS-21-Stress Subscale" based on a 4-point Likert scale (0-3). Scores range from 0 to 42 (the score will need to be multiplied by 2 to calculate the final score). Higher scores indicate a higher level of stress.	DASS-21-Stress Subscale [46-48]
8. Change is being assessed between and within subjects in relaxation levels[b]	Differences between groups and change from baseline to the T1 and T2 phases in relaxation levels are assessed based on the visual analog scale administered before and after each session. This measure assesses relaxation levels before and after each VR experience. Participants had to express how relaxed they felt (0 =not at all relaxed; 10=completely relaxed; 0 =absent; 10=complete). Higher scores indicate higher relaxation levels.	Visual analog scale-relaxation level

XSL•FO
RenderX

Primary objective	Description	Evaluation tool
9. Change is being assessed between and within subjects in quality-of-life scores[c]	Change from baseline to the T1 and T2 phases in quality-of-life scores on the Psychological General Well-Being Index (PGWBI) is assessed at 3 different assessment times. The measure consists of 22 self-administered items, rated on a 6-point scale (0-5), which assesses psychological and general well-being. Scores range from 0 to 110. Higher scores indicate greater well-being.	PGWBI [53-55]
10. Change is being assessed between and within subjects in coping strategies scores[b]	Change from baseline to the T1 and T2 phases in coping strategies is assessed at 3 different assessment times. The Coping Orientation to the Problems Experienced-New Italian Version (COPE-NVI) is a self-report questionnaire developed to assess the different coping strategies people use in response to stress; it is based on 60 items rated on a 4-point scale (1-4). Total scores range from 60 to 240. Higher scores indicate that a certain coping strategy is frequently used by the person.	COPE-NVI [56]
11. Change is being assessed between and within subjects in sense of presence scores related to the VR and guided imagery experiences[c]	Differences between groups and change from the T1 and T2 phases in sense of presence related to the VR or guided imagery experience are assessed at 2 different assessment times based on a visual analog scale and the ITC-Sense of Presence Inventory (ITC-SOPI). The ITC-SOPI is a self-report questionnaire assessing the sense of presence. Items are rated on a 5-point Likert scale (1-5). Scores range from 36 to 180. To obtain the scores for each of the scales, the average of the items is calculated. Higher scores indicate a higher sense of presence.	ITC-SOPI [57]; Visual analog scale-sense of presence
12. Change is being assessed between and within subjects in heart rate[b]	Differences between groups and change from baseline to the T1 and T2 phases in heart rate are assessed based on the Xiaomi Mi Band 2 sensor. It is used in 3 different assessment times (T0, T1, T2). During T1 and T2 heart rate is measured before, during, and after the in-presence relaxation session.	Xiaomi Mi Band 2 tool [58,59]

[a]T1 (day 7) phase.

[b]T0 (baseline), T1 (day 7), and T2 (day 14) phases.

[c]T1 (day 7) and T2 (day 14) phases.

Statistical Procedure and Data Analysis

Quantitative statistical analyses will be performed using SPSS (versions 27.0 and 28.0; IBM Corp) [60,61] and R package [62]. To investigate the normal data distributions of the dependent variables, ranges of skewness and kurtosis will be determined. The Kolmogorov-Smirnov and the Shapiro-Wilk tests will also be performed to evaluate the statistical significance (mean, 95% CI) and normality of the distributions. In addition, Cronbach α will be assessed for each self-report questionnaire's subscales. To explore sociodemographic features, frequencies, means, and SDs will be measured.

To examine differences between and within subjects, the 3 groups will be evaluated by a repeated-measures ANOVA for mixed designs, where individuals will be the random effect, while the type of intervention and time (T0/T1/T2/before and after each session) will be the fixed effects. The Akaike information criterion and binary logistic regression will be performed to explore significant influence factors.

Spearman rank correlation coefficient will be used to investigate the relationship between the self-reported measures and heart rate.

Results

As of July 2022, a total of 45 individuals have been assessed as eligible for study enrollment (Multimedia Appendix 2).

Preliminary data showed adequate Cronbach α for all the T0 self-report questionnaire scores (ranging from .66 to .83). No differences emerged between the GI and VR groups at the baseline (T0) for all the sociodemographics and psychological features investigated (gender, marital status, school attendance, employment, participation in relaxation training in the past, use of VR in the past, anxiety, depressive and stress symptomatology, and the ability to imagine in a vividness way mental images) except for age ($F_{1,39}$=12.32; P<.001) and years of education ($F_{1,39}$=4.81; P=.04), factors that have been controlled for in the following group comparisons. To preliminarily investigate the differences between the VR and GI groups in experiencing state anxiety before and after the relaxation session (T1) and at T2, repeated-measures multivariate ANOVAs have been computed. At T1, our preliminary analysis showed a significant difference of the state-anxiety symptoms ($F_{1,39}$=22.48;P<.001) between groups with lower scores in state anxiety (VR group: mean 30.10, SD 4.35; GI group: mean 39.35, SD 4.71; $t_{1,39}$=5.92;P<.001) for the VR group after the relaxation session. Moreover, the VR group perceived a higher sense of physical presence ($F_{1,39}$=7.38;P<.01). The study's experimental phase is expected to conclude in May 2023, and the results of the research will be presented in June 2023. The results obtained from this work will be published in an open-access scientific paper and in the form of posters and conference papers to be presented at national and international conferences.

Discussion

This study aims to evaluate the impact of exposure to customized natural and realistic VR-based scenarios as a factor that may enhance relaxation when administered with PMRT. To our knowledge, few studies have addressed this topic [63].

Furthermore, in light of the COVID-19 pandemic, innovative VR treatment protocols are increasingly requested and helpful in managing relaxation, also due to the possibility to be administered with larger flexibility in several different contexts and partially independent from the presence of the therapist [64].

Moreover, delivering an entire PMRT protocol with a psychotherapist present may require a considerable amount of time and higher costs. The introduction of VR may positively reduce intervention costs, as it allows partial self-management of the treatment. Furthermore, in the case of patients with medical problems (eg, cancer), the integration of VR may facilitate the administration of the relaxation intervention during specific invasive treatments (eg, chemotherapy sessions).

Assessing the efficacy of PMRT in alternative ways could extend the treatment administration, especially in situations where the standard delivery procedure is more difficult to implement.

With the aim to preliminarily investigate this study's main objective, initial analyses showed that VR with PMRT facilitates a greater decrease of state anxiety than GI. Based on our knowledge, no studies have investigated VR with PMRT as an alternative complementary technique instead of GI. The current findings are promising and will be extensively investigated at the end of the recruitment phase.

This study is characterized by a series of limitations that should be considered and solved in the implementation of future studies. First of all, it is essential to consider the prominent role that psychophysiological parameters have in measuring relaxation, defined as the ability of the human body to reduce physiological arousal, and which can be assessed by measuring a decrease in muscular tension, heart rate, respiration rate, and sweating rate [3,65]. Although our project is targeted at investigating a self-reported sense of presence, engagement, and relaxation feeling, it should be important to also investigate psychophysiological measures other than heart rate, such as breathing rate, heart rate variability, galvanic skin response, cortical levels, and changes in brain wave activities. Research conducted so far investigated these parameters to understand the impact of distinct VR-based relaxation techniques different from progressive muscle relaxation, showing promising results [3]. Moreover, it would be important to thoroughly investigate psychophysiological activity also when VR is merged with PMRT both with clinical and nonclinical samples.

Data Availability

The data set generated and analyzed during the current study is available from the corresponding author on reasonable request.

Authors' Contributions

SP, CN, SG, and SF contributed to the conceptualization of the protocol; SP, CN, and SG contributed to the methodology; MD worked on the hardware and software components; SP and SO contributed to the curation and formal analysis, and wrote the original manuscript; CN and SG revised the analysis and the original manuscript; and SP, FF, SG, CN, SO, and CL contributed to the manuscript's editing and revision. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: In the last few years, new noninvasive strategies have emerged as rehabilitative treatments for patients with stroke. Action observation treatment (AOT) is a rehabilitation approach based on the properties of the mirror neuron system with a positive impact on modifying cortical activation patterns and improving the upper limb kinematics. AOT involves the dynamic process of observing purposeful actions with the intention of imitating and then practicing those actions. In recent years, several clinical studies suggested the effectiveness of AOT in patients with stroke to improve motor recovery and autonomy in activities of daily living. However, a deeper knowledge of the behavior of the sensorimotor cortex during AOT seems to be essential.

Objective: The aim of this clinical trial, conducted in 2 neurorehabilitation centers and in patients' homes, is to investigate the effectiveness of AOT in patients with stroke, confirming the translational power of a tailored treatment. Particular emphasis will be placed on the predictive value of neurophysiological biomarkers. In addition, the feasibility and impact of a home-based AOT program will be investigated.

Methods: A 3-arm, assessor-blinded, randomized controlled trial will be performed by enrolling patients with stroke in the chronic stage. A total of 60 participants will be randomly allocated to receive 15 sessions of AOT with different protocols (AOT at the hospital, AOT at home, and sham AOT), 3 sessions per week. The primary outcome will be assessed using the Fugl-Meyer Assessment-Upper Extremity scores. Secondary outcomes will be clinical, biomechanical, and neurophysiological assessment.

Results: The study protocol is part of a project (project code GR-2016–02361678) approved and funded by the Italian Ministry of Health. The study began with the recruitment phase in January 2022, and enrollment was expected to end in October 2022. Recruitment is now closed (December 2022). The results of this study are expected to be published in spring 2023. Upon completion of the analyses, we will examine the preliminary effectiveness of the intervention and neurophysiological outcomes.

Conclusions: This study will be used to evaluate the effectiveness of 2 different AOT scenarios (ie, AOT at the hospital and AOT at home) in patients with chronic stroke and to assess the predictive value of neurophysiological biomarkers. Specifically, we will attempt to induce the functional modification of the cortical components by exploiting the features of the mirror neuron system, demonstrating relevant clinical, kinematic, and neurophysiological changes after AOT. With our study, we also want to provide, for the first time in Italy, the AOT home-based program while assessing its feasibility and impact.

Introduction

Background

Stroke is a leading cause of death and one of the most common causes of long-term disability that interferes with good quality of life [1]. Currently, one of the major components of rehabilitation interventions is focused on disability reduction to achieve the functional motor goal [2]. In the last few years, to improve activities of daily living (ADL), new noninvasive strategies that have emerged as rehabilitative treatments have been added to conventional motor rehabilitation programs [3,4].

One such noninvasive strategy is the action observation treatment (AOT), supported by results collected through randomized controlled trials [5-10]. This new rehabilitation approach is based on the network properties of the mirror neuron system (MNS) [11-13]. AOT involves the dynamic process of observing purposeful actions with the intention of imitating and then practicing those actions.

Extensive research over the last 20 years on human MNS [14-16] showed its importance not only in action recognition [17] but also in understanding action intentions and other important social cognitive aspects [14,16]. Moreover, higher activation of temporoparietal networks was found when a goal-directed action was observed [18]. Enabling the patients to acquire new skills and potentially relearn movement patterns, AOT is involved in the motor learning process and could be a helpful adjunctive treatment to conventional therapy in upper limb motor rehabilitation. Indeed, AOT seems to be a useful rehabilitation strategy in addition to physical therapy for improving upper limb functions, especially in daily activities after stroke [19,20], alone or in association with motor imagery [21]. Finally, because it is also recruited in the damaged brain [22,23], the MNS is demonstrated to provide remarkable rehabilitative outcomes [7,24-27].

On the basis of the MNS properties able to activate the sensory-motor system through the observation of actions as well as the execution of the same actions, the AOT is proving to be an innovative rehabilitative approach for recovery of patients with stroke in chronic stage with upper limb impairment; several findings are present in scientific literature [5,23,27-31].

On the basis of these results, several clinical studies have been published in recent years, suggesting the effectiveness of AOT in improving motor recovery and autonomy in ADL [19,20,24,32]. However, a deeper knowledge of the behavior of the sensorimotor cortex during AOT seems to be essential. Recent studies have investigated cortical responses during the visualization of standardized actions by using 4 biomarkers primarily: related desynchronization and synchronization of alpha and beta rhythms (event-related desynchronization [ERD] and event-related synchronization [ERS]), beta brain coherence, and mu rhythm suppression [33-36].

In our previous work, we administered AOT treatment to a group of patients with stroke and observed the predictive value of ERD of electroencephalography (EEG) alpha rhythm (ie, 8-13 Hz) during rehabilitation tasks and at the end of the treatment, as a sign of neural plasticity. In addition, increased functional dexterity was found in patients with stroke in the subacute stage that had AOT compared with their peers who underwent a control treatment [8].

Recently, our research group conducted a pilot study to assess which type of ADL visual stimulus was the most effective in inducing motor excitability during action observation. EEG signals were recorded in 20 patients with stroke in chronic stage during the observation of task-oriented upper limb tasks (including self-care and feeding actions) and nonfinalized actions. The comparison of EEG rhythms between the 2 groups of motor actions (ie, task-oriented and non–task-oriented) revealed that an increased suppression of mu and beta bands occurred during the observation of the former category [37].

The procedures described in this protocol, including recruitment, assessments, and visual stimuli for motor action, have been tested in a single-group uncontrolled feasibility study. Preliminary analysis from a qualitative observation of a few collected data by using the proposed protocol showed desynchronization effects of all cerebral rhythms (especially of the beta rhythm) after the AOT treatment (ie, pretest vs posttest assessment). In addition, a few patients had alpha and beta rhythm desynchronization compared with a group of healthy participants.

The encouraging results obtained from clinical outcomes were confirmed by studies that included instrumental assessments, among others: AOT has an additional positive impact on modifying cortical activation patterns [9,26,38] and in improving upper limb kinematics [39].

Furthermore, in Italy, to the best of our knowledge, no evidence has been found related to the effectiveness of home-based AOT programs compared with the same AOT performed in the hospital.

According to the inspiring results reported in the literature, AOT rehabilitative treatment exemplifies a translational step from neuroscience to clinical rehabilitation applications.

Aims

The project aims to achieve the following objectives: (1) induce functional modification of the cortical components underpinning the action organization, exploiting the peculiar features of the

XSL•FO
RenderX

MNS and demonstrating the relevant clinical, kinematic, and neurophysiological changes after AOT—in particular, the analysis of the AOT effectiveness will also consider the predictive value of neurophysiological biomarkers; and (2) provide the home-based AOT program, to the best of our knowledge, for the first time in Italy, thereby rendering evidence-based considerations regarding the feasibility and impact of our home-based AOT program for future systematic application of the approach.

Methods

Overview

A randomized, parallel-arm, controlled, outcome measurer–blinded, and multicenter clinical trial conducted in 2 neurorehabilitation centers in Italy aims to investigate the effectiveness of AOT in patients with chronic stroke (ie, >6 months from the first event) using quantitative EEG biomarkers, confirming the translational power of a tailored treatment.

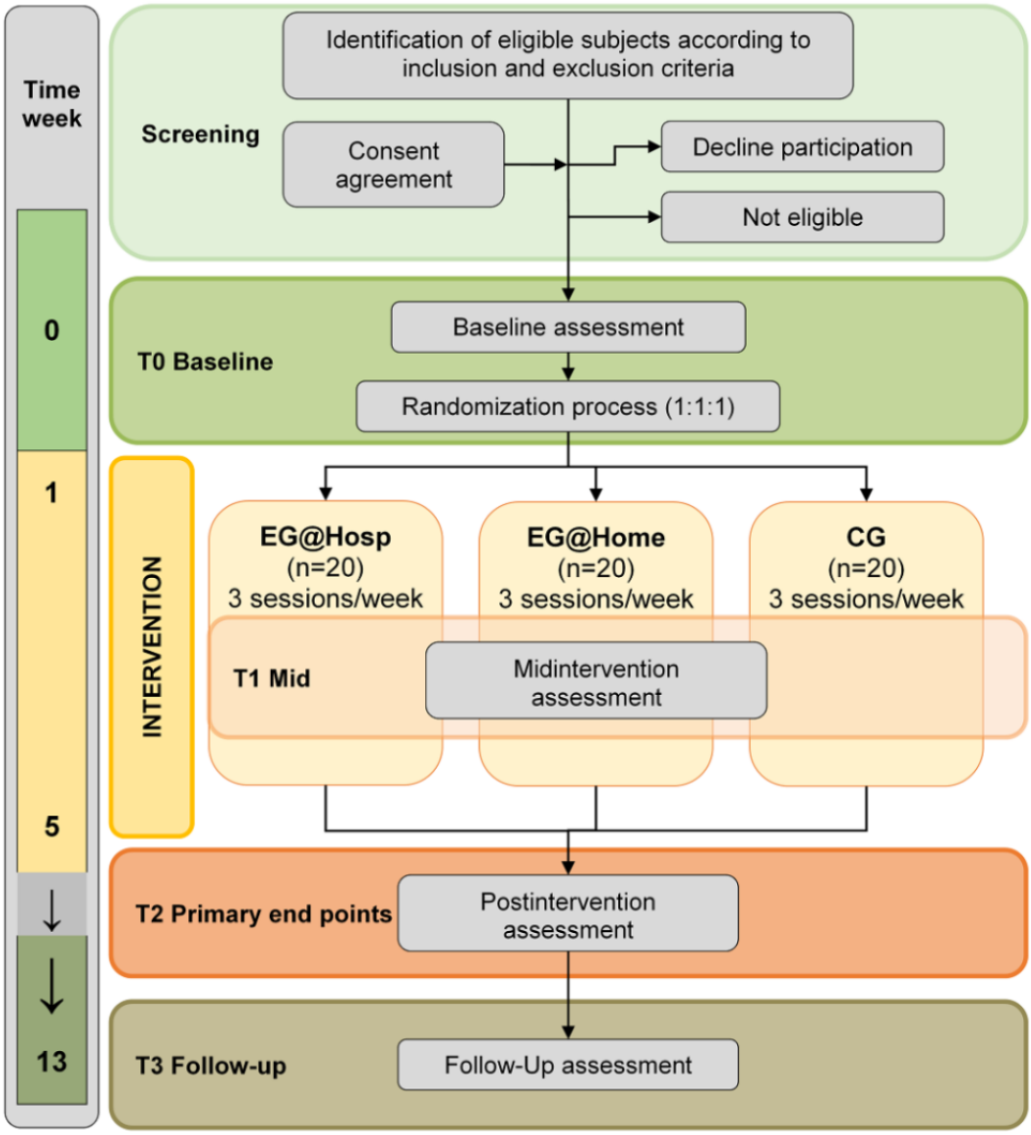
A total of 60 individuals who have been enrolled will be randomized to the experimental group in hospital (EG@Hosp), experimental group at home (EG@Home), or control group (CG) in a 1:1:1 ratio.

The EG@Hosp will observe and execute ADL that are task-oriented actions (AOT protocol); the EG@Home will observe and perform the same ADL at home (AOT protocol at home); and the CG will not observe any motor task videos (but will watch video only on landscapes and historical issues), and after verbal instructions, they will perform the same actions observed by the other 2 groups.

After completing the patient screening, randomization will be performed before the first treatment session (T0). At baseline (T0), midintervention (after the 7th session; T1), and after the intervention (15th session or 5th week; T2), outcomes (ie, clinical scales, EEG and electromyography [EMG] signals, and kinematic parameters) will be assessed to evaluate impairment and functional abilities.

For each group, the total duration of the intervention will be 5 weeks (3 times a week) for a total of 15 sessions. After the end of the intervention, a 2-month follow-up assessment period (T3) will be scheduled to assess the maintenance and long-term effects.

The primary outcome assessed at T2 will be assessed by the Fugl-Meyer Assessment-Upper Extremity (FMA-UE) scores.



The trials will be performed at 2 neurorehabilitation centers in Italy: IRCCS San Raffaele Roma Hospital in Rome and at Casa di Cura del Policlinico Hospital in Milan.

All the data will be recorded in electronic case report forms through the REDCap (Research Electronic Data Capture; Vanderbilt University) system, accessed on the web via the internet for data collection and management.

A specific route diagram is presented in Figure 1. The protocol for this study was developed in accordance with the Standard Protocol Items: Interventional Trial Recommendations guidelines (SPIRIT) [40].

XSL•FO
RenderX

Figure 1. Flowchart of the proposed randomized controlled trial according to the Consolidated Standards of Reporting Trials. CG: control group; EG@Home: experimental group at home; EG@Hosp: experimental group in hospital.

Study Population, Setting, and Recruitment

This study will be conducted in patients with chronic stroke. Between January 2022 and October 2022, a total of 60 outpatients or inpatients were recruited from the 2 centers mentioned earlier. The intervention will be provided in 2 different settings: rehabilitation centers (EG@Hosp and CG) and the patient's home (EG@Home).

Patients will be included after signing a written informed consent form, provided the inclusion and exclusion criteria are met.

The schedule of enrollment, interventions, and assessments are presented in Figure 2.

Selection Criteria

The inclusion and exclusion criteria of participants is shown in Textbox 1.

Patients with intellectual disability or other serious pathological conditions (eg, aphasia and hemianopsia) that affect their ability to watch or understand the proposed video were excluded.

XSL•FO
RenderX

Textbox 1. Participant inclusion and exclusion criteria.

Inclusion criteria

- First ever unilateral ischemic stroke in the chronic stage (ie, the time elapsed from the event>6 months) provoked a clinically evident upper limb or hand deficit that affects the daily activities
- Diagnosis verified by brain imaging (magnetic resonance imaging)
- Aged 18-85 years
- Cognitive function sufficient to understand the experimental instructions (Mini-Mental State Examination Score of≥24)
- Chedoke-McMaster Stroke Assessment Scale—arm-hand section score of>1

Exclusion criteria

- Bilateral impairment
- Severe sensory deficits in the paretic upper limb
- Cognitive impairment or behavioral dysfunction
- Any other neurological or orthopedic deficit that affects arm function
- Any severe cardiovascular disease that can preclude intervention
- Any other current severe medical problems
- Refusal or inability to provide informed consent

Randomization

On the enrollment day, by using the electronic data capture system software (ie, REDCap) and the method of central stratified regional group randomization, the enrolled patients will be randomly allotted to one of the 3 groups (ie, EG@Hosp, EG@Home, and CG).

Blinding

Participants and intervention delivery facilitators cannot be blinded to group allocation. Evaluators conducting the clinical, neurophysiological (EEG and EMG), and physical (kinematics) assessments will be blinded to group allocation.

Interventions

Overview

For all groups of participants (ie, EG@Hosp, EG@Home, and CG), the intervention will include 15 sessions spanning 5 weeks (3 sessions per week) in addition to the conventional motor rehabilitation program expected for each patient's condition. Motor rehabilitation will be based on the relevant ADL that include at least one of the following: feeding, self-care, or external actions on the affected side. A total of 5 different videos (with the same motor task) will be presented in each session, beginning with the easiest action and ending with the most complex action. Each session will last approximately 15 minutes and will be repeated twice a day, at least 60 minutes apart.

AOT Protocol for EG@Hosp

Participants will be asked to carefully observe the videos showing different daily actions. Each motor act will be presented for 2 minutes. At the end of each motor act presentation, participants will execute the observed motor sequence for 1 minute (without any verbal instructions) with the affected upper limb.

Participants enrolled in EG@Hosp will perform rehabilitation treatment in the hospitals' premises.

The video will be played on a 15-inch monitor at a distance from the participant such that there will be sufficient space to perform the required movements. During the repetition of the motor action, a black screen will appear on the monitor.

AOT Protocol for EG@Home

After appropriate training of patients and caregivers, the use of tablets will allow home-based treatment. In particular, a tablet will be enabled with a web-based program that will be used to train the patients (and receive feedback on their progress).

Participants enrolled in EG@Home will be asked to carefully observe the videos showing different daily actions on the tablet. The web-based program will present each motor act for 2 minutes. At the end of each motor act presentation, the web-based program will ask the participants to execute the observed motor sequence for 1 minute (by audio or video message) with the affected upper limb.

Participants enrolled in EG@Home will perform rehabilitation treatment at their homes.

A 7-inch tablet with Android software 11.0 will be used for the experimentation. Before handing the tablet to the patient, the researcher will schedule the AOT program via the web, defining the days when the patients should perform the treatment independently at home. Patients can check the days on which treatment will be performed by consulting the web-based application, specifically the section where the scheduling of sessions is provided, on the tablet. The research teams will be remotely monitoring the progress of the EG@Home sessions using a dedicated web platform.

The web-based application was developed by a specialist following the researchers' specification.

XSL•FO
RenderX

CG Protocol

The participants will be asked to observe video clips with no content on human motor activities. Videos will concern scientific, geographical, and historical issues.

For EG@Hosp and EG@Home, 5 different video clips (each 2 minute long) will be presented during each session. At the end of each video, and after the therapist's verbal instructions, participants will execute the motor task actions for 1 minute with the affected upper limb.

In this way, both the groups and controls will undergo the same amount of motor practice and receive the same amount of visual stimulation, with the only difference being the visual stimulus content.

Participants enrolled in the CG will perform rehabilitation treatment in the hospitals' premises.

The video will be played on a 15-inch monitor at a distance from the participant such that there will be sufficient space to perform the required movements. During the repetition of the motor action, a black screen will appear on the monitor.

Assessment: Instrumental Setup

The assessment setup and protocol will be the same as those used in similar studies [33,41] for the evaluation of impaired upper extremity functionality. The participant will sit in front of a target panel (eg, a 24-inch touch screen monitor) to perform the pointing task evaluation test.

The panel will have 9 targets; 8 of these, arranged in a circle, will be positioned 20 cm from its center, that is, the ninth target. The center of the target panel will be aligned with the shoulder acromion of the impaired upper limb. The distance between the participant and the center of the panel will be set according to each participant's arm length measured with the fist closed. During the pointing task trials, the participants will be instructed to reach, at their self-selected speed, one of the 9 targets on the board.

All the participants enrolled in this study will perform assessment tasks in the hospitals' premises.

Assessment: Primary and Secondary End Points

Overview

A thorough assessment of the clinical improvement in the functionality of the affected upper extremity will be performed using the FMA-UE (primary outcome), which will be combined with other clinical scales (secondary clinical outcomes).

In addition, the secondary instrumental outcomes (ie, EEG, EMG, and kinematics) will be included to verify neural plasticity and motor recovery using neurophysiological and kinematic parameters.

In addition, only for home-based treatment (EG@Home) group, the usability of the platform and the participants' satisfaction with the services will be evaluated using a specific questionnaire (Technology Acceptance Model [TAM]) and a nonstructured interview.

The variables related to the secondary instrumental outcomes (ie, EEG, EMG, and kinematics) will be evaluated during the standardized pointing task described earlier.

All the data will be analyzed using MATLAB software (MathWorks Inc). Specifically, the EEG recordings will be preprocessed offline using the MATLAB's toolbox called *EEGLAB* for artifact removal.

The Functionality of the Affected Upper Extremity

To perform a thorough assessment, different motor components of the affected upper extremity will be evaluated using the FMA-UE combined with 6 other scales.

1. The FMA-UE [34,35] (primary outcome) is a stroke-specific, performance-based impairment index. It is designed to assess motor function, balance, sensation, and joint function in patients with poststroke hemiplegia.
2. The Frenchay Arm Test [36] is a measure of upper extremity proximal motor control and dexterity during ADL performance in patients with impairments resulting from neurological conditions. The Frenchay arm test is an upper extremity–specific measure of activity limitation.
3. The Box and Block Test [42] assesses the unilateral gross dexterity of the hand. It requires participants to move as many blocks as possible from one side to the other in 1 minute.
4. The Modified Ashworth Scale [43] measures resistance during passive soft tissue stretching and is used as a simple measure of spasticity of all movements of the different joints of the upper extremity.
5. The Modified Barthel Index [44] is an ordinal scale used to measure ADL performance. Each performance item is rated on this scale, with a given number of points assigned to each level or ranking. It uses 10 variables to describe ADL and mobility.
6. The Motor Activity Log [45] assesses the quantity (*amount* subscale) and quality (*how well* subscale) of the use of the upper limb during ADL performance.
7. The Nine Hole Peg Test [46] measures hand dexterity. This requires participants to repeatedly place and then remove 9 pegs into 9 holes, one at a time, as quickly as possible.

Neurophysiological Biomarkers

The following biomarkers will be used in the study:

1. The EEG signal will be recorded (0.01-100 Hz band pass; sampling frequency: 1024 Hz) using 64 to 128 electrodes (high-density EEG, system 10-10 increased) during the pointing task (described earlier). Alpha (8-13 Hz), beta (14-30 Hz), and mu (8-13 Hz) bandwidths will be registered. EEG biomarkers will be ERD and ERS of alpha and beta rhythms, beta brain coherence, and mu rhythm suppression [47-50].
2. Surface EMG signals from the activation of 2 pairs of agonist and antagonist muscles from 4 upper arm and shoulder muscles (brachial biceps, brachial triceps, anterior deltoid, and posterior deltoid) will be recorded. Dual Ag-AgCl snap electrodes with an interelectrode spacing of 2 cm will be used during the acquisitions. A standard procedure, in accordance with Surface ElectroMyoGraphy

XSL•FO
RenderX

for the Noninvasive Assessment of Muscles recommendations [51], will be used for skin preparation and electrode placement. The reference electrode will be placed over the electrically neutral lateral wrist epicondyle. The outcome of this analysis will be the cocontraction index calculated during the initial portion (epoch) of the single pointing movement (forward and return movement will be analyzed separately), which is identified as the acceleration phase of the hand kinematics.

Kinematics

Kinematic parameters of the pointing motor task will be acquired at 100 Hz by using a 7-camera motion capture system (Vicon, Oxford Metrics Ltd). Spherical reflective markers for motion tracking will be placed on specific body landmarks. In addition, an inertial measurement unit will be placed over the metacarpophalangeal joint of the middle finger.

The data acquired during the assessment trial with respect to the hand trajectory (ie, metacarpophalangeal joint of the middle finger) will be evaluated using the following metrics, related to the entire turn [52]:

1. Number of peaks of the speed profile: If a point-to-point reaching movement has a low number of peaks, it means that few acceleration and deceleration periods are present [53].
2. The smoothness described by Teulings's index is the rate of change of the acceleration in a movement [54]; a lower value of Teulings's index indicates a smoother movement.
3. Movement accuracy will be evaluated using the normalized path length parameter, as described by Colombo et al [55]; essentially, it is the line obtained by normalizing the effective length path with the ideal path; when this parameter approximates 1, the movement accuracy is very high.
4. The absolute hand path error, as computed by Franklin et al [56], is the area between the actual movement path and the straight line; this is considered an index of learning, and a reduction of this metric indicates a better adaptation to the required task.

Usability of the Platform (Only for Home-Based Treatment)

The feasibility of the home-based treatment and the usability of the platform, as well as the participants' satisfaction with the services, will be assessed by patients at the end of the intervention (T2) with the following scales:

1. TAM [57] includes 3 criteria (perceived ease of use, perceived usefulness, and behavioral intention to use). A Likert scale has been developed in which the user will rate from 1 to 7 whether they agree with a series of statements.
2. Nonstructured interviews (adapted from the TAM) to investigate patients' feelings.

Sample Size

As the changes in the effects of upper limb AOT in patients with stroke on EEG biomarkers have not been previously investigated, we have estimated the sample size based on previously published studies [58,59], comparing AOT and conventional therapy. We estimated the sample size required to detect differences in the effects of "group"×"time" interactions on primary clinical outcome (FMA-UE).

For this outcome, an effect size of 0.495 [60,61] is expected based on previous studies. Given the expected effect size, a total sample size of 54 will be required for repeated ANOVA with a power of 0.8 and a 2-sided type-I error of 0.05 (number of groups=3 [ie, EG@Hosp, EG@Home, and CG]; number of measurements=3 [ie, T1, T2, and T3]). Therefore, when considering a dropout rate of 10%, we plan to recruit 20 participants for each group (a total of 60 participants) for this study.

Statistical Analysis

Baseline Comparability Analysis

The baseline characteristics of the participants will be summarized and compared. These include the descriptions of demographic data, symptoms, and general conditions. The 2-tailed *t* test or nonparametric statistical method will be used for quantitative data. Categorical data will be analyzed using chi-square or Fisher exact tests and the Wilcoxon test.

Analysis of the Effectiveness

Analysis of the primary outcome (ie, functionality of the affected upper extremity) will be performed using the per-protocol principle. Treatment effects will be compared using a 2-way repeated ANOVA for clinical measurements, considering "time" (3 levels: T0, T1, and T2) as a within-subject factor and "group" (3 levels: EG@Hosp, EG@Home, and CG) as a between-subject factor.

In addition, the percentage of participants who passed the minimal clinically important differences of the FMA-UE will be compared using chi-square tests between the 3 groups.

The mean power across the assessment "time" (ie, T0 and T2) related to the action observation condition will be implemented in a mixed-design ANOVA to evaluate significant changes. A separate ANOVA will be performed to assess power changes in the stimuli selection data, using "treatment" (ie, EG@Hosp vs EG@Home vs CG) as the between-subjects factor and action as the within-subjects factor. To assess the predictive value of biomarkers for AOT effectiveness, an analysis of covariance (ANCOVA) will be performed considering the clinical data as the dependent variable, the "group" as a fixed factor, and the biomarkers as covariates.

Subsequently, to evaluate kinematic parameters recovery, a mixed design ANOVA will be implemented with "time" and "treatment" as within- and between-subjects factors, respectively.

The level of significance will be set at $P<.05$. For post hoc comparisons, the level of significance will be set at $P<.017$ after Bonferroni adjustment (.05/n; the number of comparisons, n=3) for the comparison of interaction effects. Cohen *d* will be calculated to determine the effect size of the change in scores for the behavioral motor outcomes between the groups. Immediate training effects (data from T0-T2) and the durability

XSL•FO
RenderX

of training effects (data from T2-T3) will be separately investigated using mixed effect models.

Clinical-neurophysiological correlations will also be analyzed: the correlation between the ERD and factors such as the clinical scale score will be studied. To evaluate the differences in trends related to the clinical evolution of the patients, we will define a new variable to group the participants according to the presence or absence of relevant clinical improvements. The relevant clinical improvement will be defined by a clinical specialist for this purpose.

Data Collection and Management

The study data will be collected and managed using REDCap electronic data capture tools hosted at the IRCCS San Raffaele Roma Hospital and Casa di Cura del Policlinico Hospital [62,63]. REDCap is a secure web-based software platform designed to support data capture for research studies, providing (1) an intuitive interface for validated data capture, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for data integration and interoperability with external sources.

Ethics Approval

The ethics committees of both involved centers (ie, IRCCS San Raffaele Roma Hospital and Casa di Cura del Policlinico Hospital) reviewed and approved the study protocol (Ethics Committee IRCCS San Raffaele Roma: protocol code RP05/2018; Ethics Committee Milano Area 2: protocol 705_2018bis).

The institutional review boards of both centers approved the study and will receive study reports at the middle and end of the study and monitor the study implementation and data collection.

Any deviations from the protocol will be promptly notified to the ethics committees and will be applied only after approval.

This study will be conducted in accordance with the principles of the Declaration of Helsinki. Written informed consent forms will be obtained from each participant before the start of the study. Only those participants who provided informed written consent before starting will be included. During the study, written data will be stored in a closed cabinet; all data, after anonymization, will be entered into a REDCap electronic data capture repository. The input data will be double-checked by another research assistant. Personal data will be discarded after 5 years.

The results of this study will be disseminated through peer-reviewed journals and national and international academic conferences only by the professionals directly involved in the clinical trial.

Patient Withdrawal Criteria

Patients will be informed of the possibility of interrupting the study at any time they deem appropriate. Any interruption will be fully documented in the case report form by the investigators. The investigators shall make all reasonable efforts to maintain the patients who express a willingness to interrupt the participation in the study protocol.

Patients may prematurely discontinue the study if any of the following conditions occur:

1. Request from the patient, even if not motivated
2. Withdrawal of consent by the patient to participate in the study
3. Modification of the psychophysical state of the patient, significantly altering at least one of the variables considered in the inclusion or exclusion criteria
4. The occurrence of serious adverse reactions, which in the opinion of the investigator, make the continuation of the study impossible
5. Absence from >3 consecutive experimental session
6. Inability of the patient to continue the study for organizational and personal reasons

Results

Participants will be identified from hospital records or among those who show interest in participating by seeing the initiative through the communication channels of the hospitals, posters, and networks; all of them will be contacted by phone. After obtaining permission, the physicians will visit and explain the study. If they agree, the research assistants will manage their recruitment. This will be performed every week to identify participants.

The results of the evaluations will be released to the participants upon request. The results of this study will be presented at national and international patient organizations and to the general public.

The study protocol is part of a project (project code GR-2016–02361678) approved and funded by the Italian Ministry of Health.

Discussion

Rationale

The rationale of this study protocol is based on the AOT in patients with chronic stroke for upper limb rehabilitation. AOT relies on the MNS network to boost motor functions in patients affected by motor impairments, engaging the brain networks active during action execution. The imitation of observed gestures may increase the reorganization of the primary motor cortex, contributing to the formation of motor memories of the observed action, thus improving the physiological processes underlying motor learning [28,30].

It is well known that the MNS plays an essential role in considering the actions of others and in our ability to learn by imitation [64]. Furthermore, the activation of motor areas by AOT seems to be reinforced by the subsequent active execution of observed actions [9]. Indeed, as a motor representation technique, AOT has become an emerging motor learning training strategy to improve motor recovery in different healthy and pathological populations. Moreover, AOT preactivates specific areas of the brain, reinforcing intact cortical networks and facilitating the activation of the damaged ones [65]. Recently,

XSL•FO
RenderX

a systematic review on this topic highlighted how AOT is an effective method for improving upper limb motor functions after stroke and that task-based AOT (based on goal-oriented activities, eg, a reaching task) might be superior to movement-based AOT (eg, a pure movement of elbow extension without any functional goals), as mirror neurons are more receptive to object-related actions [24]. The authors concluded that the optimal dosage, substantiality of effects, and underlying neural mechanisms of AOT in improving upper limb motor functions in patients with stroke should be considered in further investigations [24]. According to previous findings, we believe that increasing evidence supporting the effectiveness of observation-based inventions to assist traditional therapeutic practice in the rehabilitation of motor disorders [66] must be explored.

On the basis of these findings, the proposed study protocol aims to identify the effects of AOT and motor rehabilitative treatment on the clinical and functional status of patients with stroke through an advanced multidomain assessment and to infer the effects on brain plasticity.

This study will be a starting point for the evaluation of the effectiveness of the 2 AOT scenarios proposed (ie, AOT in the hospital and AOT at home) in patients with chronic stroke (ie, the time elapsed from the event is >6 months), as well as for the assessment of the predictive value of neurophysiological biomarkers.

Specifically, we will attempt to induce functional modification of the cortical components by exploiting the features of the MNS, demonstrating relevant clinical, kinematic, and neurophysiological changes after AOT.

The added value of a multidomain assessment that includes test and clinical scales and kinematic and neurophysiological (ie, EEG and EMG) outcomes aims to identify neurophysiological biomarkers capable of evaluating the effectiveness of AOT and confirming the translational power of a tailored rehabilitation treatment for chronic stroke.

Moreover, as AOT is involved in the motor learning process and could be a useful addition to conventional therapy, an innovative home-based AOT program will be implemented in the framework of this protocol study. Indeed, the continuity of care and personalized rehabilitation for people who are affected by chronic diseases is often interrupted after transitioning from the hospital to the home environment [67].

Future Implications

As a result of the COVID-19 pandemic, telerehabilitation and home care are growing rapidly, offering opportunities for integrating digital health interventions into community-based aging services. The COVID-19 pandemic has accelerated the adoption of technology and virtual care in patients' homes, and this trend likely to stay after the pandemic. Although notable age differences in technology use remain, the adoption of key technologies by older adults is the new challenge. With this purpose, this study protocol will permit the investigation of whether a home-based program could be effective, especially in terms of exercise capacity and perceived ease of use, offering comparable benefits to hospital-based programs.

The translational research results will ensure advances in the optimization and personalization of the rehabilitative process, both in hospitals and at home, thus improving upper limb motor functions and the quality of life of patients with chronic stroke.

Acknowledgments

This work was supported by the Italian Ministry of Health grant GR-2016-02361678.

Data Availability

The data sets generated and analyzed during this study will be available from the corresponding author upon reasonable request.

Authors' Contributions

FI, IS, and PT conceived the study design. PT wrote the drafts of the protocol with significant contributions from MC, MP, and AS at all stages. MO, PA, PR, MP, MG, RR, and SP participated in the conception and design of the trial, planned the data analysis, and drafted the manuscript. Neurological review was performed by MF and MC.
All authors contributed, read, and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Globally, suicide is among the leading causes of death, with men being more at risk to die from suicide than women. Research suggests that people with suicidal ideation often struggle to find adequate help. Every month, around 4000 people fill in the anonymous self-test for suicidal thoughts on the website of the Dutch suicide prevention helpline. This self-test includes the Suicidal Ideation Attributes Scale (SIDAS), which educates users about the severity of their suicidal thoughts. The vast majority (70%) of people who complete the self-test score higher than the cutoff point (≥21) for severe suicidal thoughts. Unfortunately, despite this, less than 10% of test-takers navigate to the web page about contacting the helpline.

Objective: This protocol presents the design of a web-based randomized controlled trial that aims to reduce barriers to contacting the suicide prevention helpline. The aim of this study is 2-fold: (1) to measure the effectiveness of a brief barrier reduction intervention (BRI) provided in the self-test motivating people with severe suicidal thoughts to contact the Dutch suicide prevention helpline and (2) to specifically evaluate the effectiveness of the BRI in increasing service use by high-risk groups for suicide such as men and middle-aged people.

Methods: People visiting the self-test for suicidal thoughts on the website of the suicide prevention helpline will be asked to participate in a study to improve the self-test. Individuals with severe suicidal thoughts and little motivation to contact the helpline will be randomly allocated either to a brief BRI, in which they will receive a short tailored message based on their self-reported barrier to the helpline (n=388) or care as usual (general advisory text, n=388). The primary outcome measure is the use of a direct link to contact the helpline after receiving the intervention or control condition. Secondary outcomes are the self-reported likelihood of contacting the helpline (on a 5-point scale) and satisfaction with the self-test. In the BRI, participants receive tailored information to address underlying concerns and misconceptions of barriers to the helpline. A pilot study was conducted among current test-takers to identify these specific barriers.

Results: The pilot study (N=1083) revealed multiple barriers to contacting the helpline. The most prominent were the belief that a conversation with a counselor would not be effective, fear of the conversation itself, and emotional concerns about talking about suicidal thoughts.

Conclusions: Our study will provide insight into the effectiveness of a brief BRI designed to increase the use of a suicide prevention helpline provided in a self-test on suicidal thoughts. If successful, this intervention has the potential to be a low-cost, easily scalable, and feasible method to increase service use for helplines across the world.

KEYWORDS

barrier reduction intervention; suicidal ideation; self-help; suicide prevention helpline; randomized controlled trial; help-seeking

Introduction

According to the World Health Organization, suicide is among the leading causes of death worldwide, with more lives taken by suicide than by malaria, HIV/AIDS, breast cancer, or war and homicide. Globally, men are more likely to die from suicide than women, with a 2.3 times higher age-standardized suicide rate among males than females [1]. Unfortunately, research suggests that people with suicidal thoughts often do not seek help, making them invisible for preventive measures and targeted support [2-4]. Connecting individuals with suicidal ideation to appropriate mental health care services is, therefore, a key preventive effort.

A recently conducted systematic review by Tang et al [5] examined the factors associated with not using formal mental health services among individuals who died by suicide. They found the following key factors: male sex, both younger and older age, and living in a rural location. A subsequent systematic review by the same authors identified predictors of not receiving formal mental health services among people at risk of suicide. The findings of this review indicated that among people experiencing suicidality, minority ethnicity, better perceived general health, lower psychological distress, lower severity of suicidality, no mental health diagnosis, a lower perceived need for treatment, and lower use of medical services are all associated with nonreceipt of formal mental health services [6].

It is also assumed that a considerable percentage of people with suicidal ideation do not disclose their ideation. Studies among the general public in France and the Netherlands indicate that almost half of the adults with suicidal ideation do not disclose their thoughts about suicide to others [7,8]. And even when people are engaged in mental health care, disclosure of suicidality is not self-evident. A recent study among young Australians (aged 16-25 years) who had experienced suicidal ideation and were engaged with a mental health professional, revealed that 39% had never disclosed their suicidality to their clinician, with concerns about confidentiality as the most common reason [9].

In order to increase help-seeking behavior, it is important to have insight into the barriers that people experience when seeking help for suicidal thoughts. Known barriers to care are a lack of perceived need for services, the preference for self-management, fear of hospitalization, structural factors like time and finances, and stigmatizing attitudes toward suicide, mental health problems, and toward seeking professional treatment [3,10]. Another important issue is that of unmet mental health needs. Individuals may not receive the help they need because there are insufficient services available, they are unable to afford the cost of care, or they feel their treatment is not meeting their needs [11,12].

Previous studies that compared web-based and offline help-seeking among people with suicidal ideation found that people who sought help on the internet reported higher levels of suicidal ideation, indicating that individuals may choose to go on the internet when their suicidality becomes more severe [13,14]. Anonymous digital help can be a low-threshold first step toward professional face-to-face help. In their innovative study, Jaroszewski et al [15] provide evidence that a brief, risk assessment and intervention platform increased crisis service use among those on the internet and in current mental health crisis. Due to their accessible, affordable, and often anonymous nature, digital innovations have the potential to reduce structural barriers to help-seeking. But as Jaroszweski et al [15] state, attitudinal barriers like the preference for informal help remain. It is, therefore, important to develop and evaluate interventions that address those barriers, particularly on digital platforms. However, robust research on reducing barriers to help-seeking in a web-based environment is scarce.

In the Netherlands, the suicide prevention organization “113 Suicide Prevention” provides around-the-clock anonymous support by phone and chat, as well as a web-based self-help course, self-assessment tests, and brief web-based coaching and therapy. Since its opening in 2009, the organization has seen an annual increase in brand awareness and service users, with almost 140,000 chat and phone call conversations and 1.3 million website visits in 2021 [16]. Apart from the homepage, the “test yourself” page is the most visited section of the helpline’s website. Every month, around 4000 people fill in the anonymous self-test for suicidal thoughts. This self-test includes the Suicidal Ideation Attributes Scale (SIDAS) and informs the test-taker of the severity of their suicidal thoughts [17]. Although the vast majority (70%) of people who complete the test score higher than the cutoff point (≥21) for severe suicidal thoughts, only approximately 10% of test-takers go on to navigate to the web page about contacting the helpline. And although due to the anonymity of the helpline’s services, it is not possible to know if people follow up on the advice of contacting the helpline, the difference in demographic distributions between the users of the self-test and the crisis helpline confirms the assumption that a substantial group does not continue using helpline service. While the percentage of men among the self-test users is 40%, it is only around 25% among the users of the helpline [18].

This paper presents the design of a web-based randomized controlled trial (RCT) that aims to reduce barriers to a suicide prevention helpline. The trial is inspired by Jaroszewski et al’s [15] study in which they evaluated a brief, automated barrier reduction intervention (BRI) designed to increase the use of crisis service referrals provided in the mental health app, Koko [19]. Although help-seeking behavior and barriers have been studied in traditional mental health care, guiding reluctant high-risk individuals in web-based environments toward professional help is still relatively uncharted territory. To the best of our knowledge, this study will be the first web-based RCT among people with severe suicidal ideation aimed to reduce

XSL•FO
RenderX

the barriers to a helpline. The aim of this study is 2-fold: (1) to measure the effectiveness of a brief barrier reduction intervention (BRI) provided in the self-test motivating people with severe suicidal thoughts to contact the Dutch suicide prevention helpline and (2) to specifically evaluate the effectiveness of the BRI in increasing service use by high-risk groups for suicide such as men and middle-aged people [20].

Methods

Study Design

The study is designed as a web-based randomized controlled trial for the anonymous users of a web-based self-test for suicidal thoughts in which individuals with severe suicidal thoughts and no interest in contacting the helpline will be randomly allocated either to a short BRI or receive a general advisory text (care as usual). To minimize the burden on our high-risk and sensitive study population, we aim that it is feasible to complete the intervention within 10 minutes.

Participants

The participants of the trial will be recruited among the anonymous visitors to the helpline's website. People who would like to participate will be directed to a web-based information letter and consent form. If they give their consent to the processing of their data for research purposes, the participants will be transferred to the web-based RCT on the survey platform Qualtrics. To assure strict anonymity, no identifying information or IP addresses will be collected.

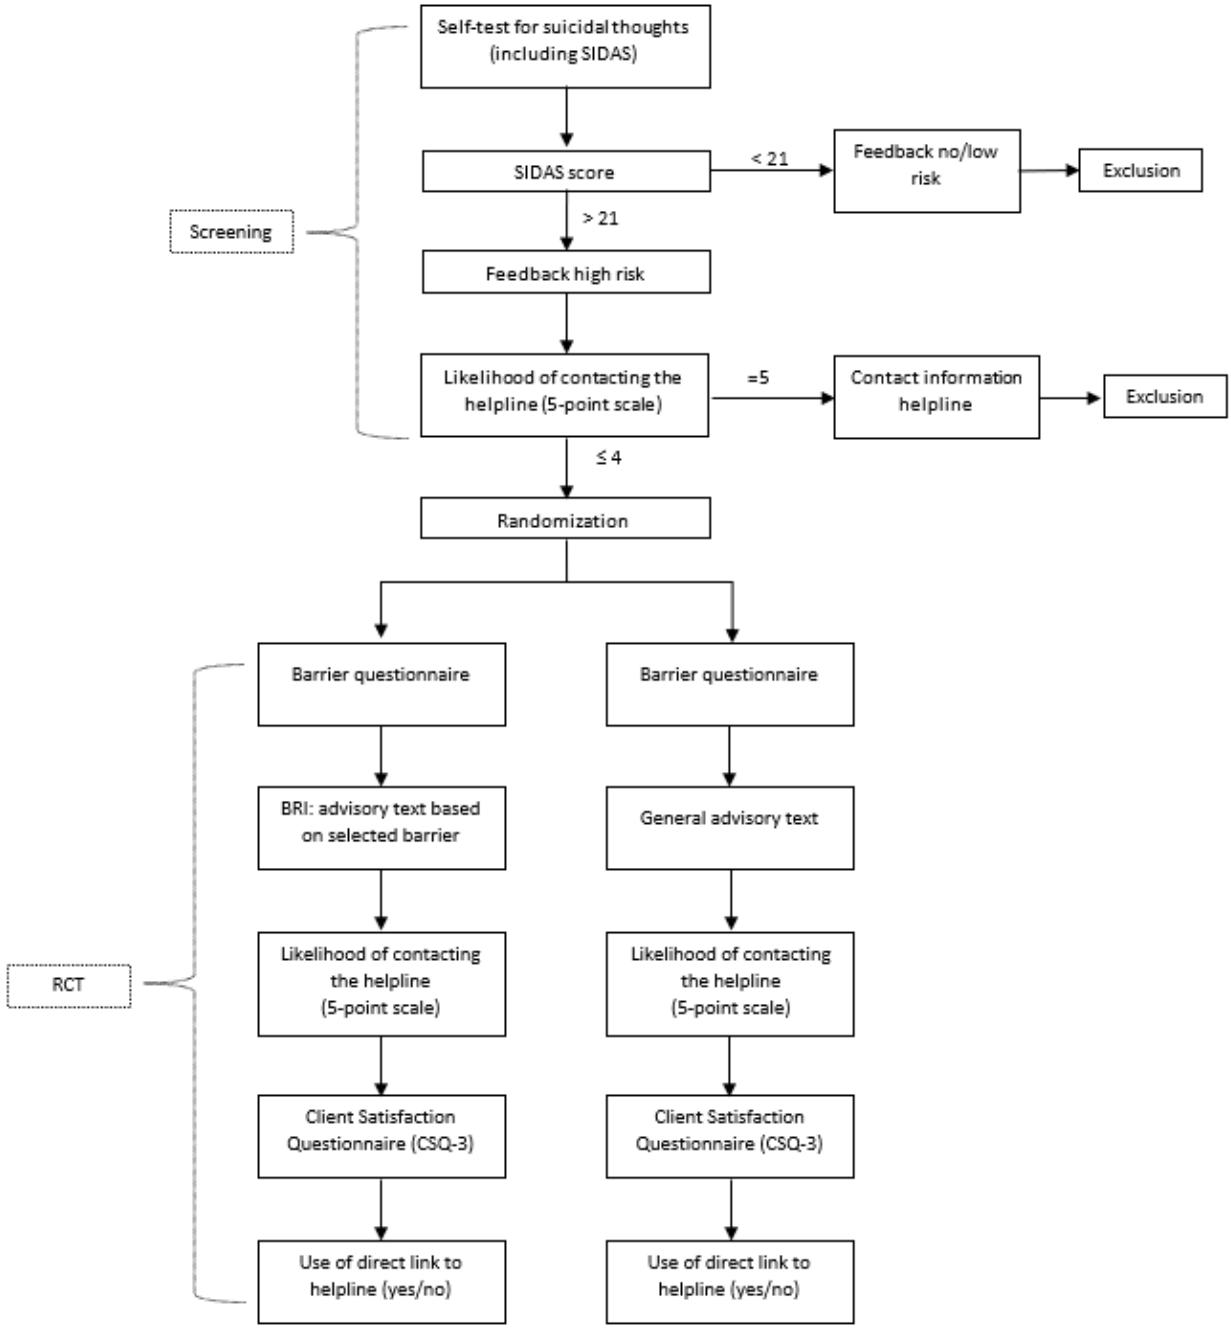
Exclusion Criteria

Participants will be excluded from the study if (1) they are younger than 16 years old, (2) they score below the cutoff point for severe suicidal thoughts (SIDAS score <21), (3) they score above the cutoff point for severe suicidal thoughts (SIDAS score ≥21) and report being likely to contact the suicide prevention helpline. They will be directly transferred to the contact details of the helpline.

People who do not meet the inclusion criteria will be directed to a web page thanking them for their time and encouraging them to contact the helpline if they feel distressed.

Sample Size

When assuming probabilities of 0.49 and 0.39 for contacting the helpline for the intervention group and the control group, respectively (based on Jaroszweski et al [15]), a power of .8 and alpha of .05, a sample size calculation for logistical regression analysis (2-tailed) indicates a total sample size of 775 participants [21]. We estimate that about 10% of participants drop out during the intervention; therefore, at least 853 participants have to be included. Furthermore, we estimate that approximately 30% of respondents score below the cutoff point for high risk of suicidal behavior, and based on Jaroszewski et al [15], we expect that 20% of respondents will indicate a high probability of contacting the helpline [15]. We, therefore, estimate that a minimum of 1706 respondents need to be recruited. We will continue to recruit participants until there are enough participants per condition.



Procedure

After giving their informed consent and stating that they are 16 years or older, participants will be transferred from the helpline's website to the Qualtrics platform. Figure 1 displays the study's flowchart. During the screening phase, respondents start with the self-test. The self-test includes the SIDAS, which consists of 5 items on a 10-point scale measuring the frequency of suicidal thoughts, controllability, closeness to an attempt, distress, and interference with daily activities [17]. The self-test also contains questions regarding gender, age, and if the test-taker is currently in treatment for mental health problems. As mentioned in the exclusion criteria, if respondents score below the cutoff point for severe suicidal thoughts or score above the cutoff point but report that they are likely to contact the helpline, they will be excluded from the RCT.

After inclusion, participants will be randomly assigned to either the intervention or control condition. In both conditions, participants receive a barrier questionnaire to identify the reason why their self-reported likelihood of contacting the helpline in the screening phase was not very likely. After the barrier questionnaire, they receive a general advisory text (control) or an advisory text based on their selected barrier.

XSL•FO
RenderX

Figure 1. Flowchart. BRI: barrier reduction intervention; RCT: randomized controlled trial; SIDAS: Suicidal Ideation Attributes Scale.

Measures

The primary outcome measure is the use of a direct link to the helpline after completing the intervention or the control condition. Due to the anonymous nature of the helpline, it is not possible to measure if people who do not directly use the link to the helpline, contact the helpline at a later point in time. Therefore, the self-reported likelihood of contacting the helpline will be included as a proxy measurement. This will be measured by the question “How likely are you to contact 113's helpline via chat or phone?” with answering options ranging from “not likely” to “very likely” on a 5-point scale. Other measures include gender, age group, SIDAS score, being in treatment for mental health problems (yes, no, and on a waiting list), and satisfaction with the self-test (Dutch CSQ-3) [22].

Persuasive System Design Model

Preceding research and literature on the design of persuasive eHealth technologies often cover software or applications intended for continuous use, whereas our study entails a single-session intervention. With this in mind, the BRI has been designed with the use of the persuasive system design (PSD) model [23,24]. The PSD model is a framework for the development and evaluation of persuasive behavior change technologies and offers 28 design principles [23]. Table 1 gives an overview of the applicable and relevant principles for our intervention, the corresponding requirements, and the implementation goals for the BRI.

XSL•FO
RenderX

Table 1. Design principles originating from the persuasive system design model applied to the intervention.

Principle [24]	Requirement	Implementation goals
Primary task support		
Reduction ("A system that reduces complex behavior into simple tasks")	The system should lower the barrier toward help-seeking; breaking it down into small steps.	• Guiding toward the first small step in the help-seeking process: emphasis on different low-threshold methods of contact (24/7 chat and telephone) and the anonymous nature of the helpline
Tunneling ("Using the system to guide users through a process or experience provides opportunities to persuade along the way")	The system should guide users in the attitude change process by providing means for action.	• Self-test offers the test-taker information about the severity of their suicidal thoughts.
Tailoring ("Information provided by the system will be more persuasive if it is tailored to the potential needs, interests, personality, usage context, or other factors relevant to a user group")	The system should provide tailored information based on the user's level of suicidality and barriers toward the helpline.	• User receives feedback on their level of suicidality. BRI[a] provides different information based on the selected barrier.
Simulation ("Systems that provide simulations can persuade by enabling users to observe immediately the link between cause and effect")	The system should persuade users to contact the helpline with experiences from others.	• BRI provides statements of people with lived experiences of suicidality.
Dialogue support		
Similarity ("People are more readily persuaded through systems that remind them of themselves in some meaningful way")	The system should be designed in such a way that users can identify with the stories.	• BRI includes photos from people with lived experience and counselors of the helpline of different ages and gender.
Liking ("A system that is visually attractive for its users is likely more persuasive")	The system should appeal to the target group.	• Self-test and BRI use the same design and tone of voice as the helpline's website.
System credibility support		
Trustworthiness ("A system that is viewed as trustworthy will have increased powers of persuasion")	The system should provide information that is truthful, genuine, and unbiased.	• Feedback after the self-test score and information offered in BRI are written in a noncoercive style and leave all autonomy to the user, for example, "We respect your decision, of course, but would encourage you to talk about your feelings, either with us or with someone close to you."
Expertise ("A system that is viewed as incorporating expertise will have increased powers of persuasion")	The system should provide information that conveys knowledge, experience, and competence.	• The BRI was built on the results of a pilot study conducted among the users of the current self-test. • The information or feedback provided has been developed by the professionals of 113 (psychologists, communication advisors, and researchers).
Real-world feel ("A system that highlights people or organizations behind its content or services will have more credibility")	The system should provide information about the organization and the people behind it.	• BRI includes photos and experiences from counselors telling about their work in the helpline.
Authority ("A system that leverages roles of authority will have enhanced powers of persuasion")	The system should convey authority.	• Self-test and BRI are in the same style and tone of voice as the helpline's website and include the helpline's logo. • BRI includes persuasive messages about the many help seekers that contact the helpline. • BRI includes persuasive messages about the expertise of the helpline and its counselors.

[a]BRI: barrier reduction intervention.

Tailored Information

After selecting a barrier in the barrier survey, participants receive tailored information with the purpose of addressing common concerns and misconceptions about the helpline. Tailored information is useful for giving people the right information and suitable feedback and helps with selecting the most effective persuasive strategies. To persuade people to overcome their barriers to the helpline, the principles of the PSD model as well as the principles of consistency, social proof, likability, and authority derived from Cialdini's [24] principles of influence will be used [23].

Statistical Analysis

The analyses will be carried out with an intention-to-treat analysis. Missing values will be imputed using the MICE package in R (v4.2.2; R Core Team 2022) [25]. In order to verify the randomization process and inspect drop-outs, independent

XSL•FO
RenderX

t tests and chi-square tests will be used to determine whether the control group and the intervention group, as well as the completers and noncompleters, are comparable on baseline factors (ie, gender, age, SIDAS score, and in treatment or not). Chi-square analysis will also be used to test the hypothesis that participants who receive the brief BRI are more motivated to contact the suicide prevention helpline (using the direct link yes/no) than participants in the control condition. To evaluate the effectivity of the BRI in increasing service use by men and middle-aged people, and to examine potential moderators, logistic regression analysis will be used.

Ethics Approval

This study protocol is designed in accordance with the relevant guidelines. This research is not subject to the Research Involving Human Subjects Act (Wet medisch-wetenschappelijk onderzoek met mensen) because participants are not subject to procedures and are not required to follow rules of behavior. All participants of the trial will be directed to a web-based information letter and consent form. After giving consent and stating to be 16 years or older, respondents will be transferred to the web-based RCT. No identifying information or IP addresses will be gathered to ensure strict anonymity. This study was reviewed and approved by the Medical Ethics Committee of the Vrije Universiteit Medical Centre (registration number 2021.0443) and is registered at ClinicalTrials.gov (NCT05458830).

Results

Overview

The BRI has been designed with the use of the PSD model, the expertise of the professionals at the helpline, and relevant literature. For the design of the barrier questionnaire, a pilot study was carried out among the users of the current self-test.

Pilot Study

To gain insight into the specific barriers to the helpline of people who fill in the self-test, a pilot study has been carried out. Between August 5 and October 14, 2021, people who took the self-test were asked the following additional questions; “What is the likelihood of you contacting the helpline to talk to our counsellors about your thoughts about suicide?” (5-point scale) and “If this likelihood is small, would you please indicate the main reason why you do not want to talk to one of our counsellors at the moment?” (open text field). During the pilot study, 7252 people filled in the self-test, of which 72% (n=5200) scored higher than the cutoff point (≥21) for severe suicidal thoughts. Almost 20% (n=1441) of all test-takers completed the open question, with 82% (n=1175) of them scoring above the cutoff point for severe suicidal thoughts. Cleaning the data led to a data set containing the answers of 1083 people in the high-risk category. Their answers revealed multiple barriers to contacting the helpline. The most prominent of them was mentioned 259 times and was the belief that a conversation with a counselor would not be effective (eg, “nobody can help me,” “it has no point anyway,” “I don’t see any possibility that my situation will change for the better,” “I already had professional help before and nothing helps,” “they would not believe me and think I exaggerate”). The second most mentioned barrier (151 times) concerned the fear of the conversation itself (eg, “I’m afraid to call,” “I’m too nervous and scared,” “I’m afraid to talk to people I don’t know,” “I don’t know what to expect”). The third most mentioned barrier (148 times) can be described as emotional concerns regarding talking about suicidal ideation (eg, “I’m not ready to talk about it yet,” “I’m afraid to talk about those feelings,” “I’m afraid that when I talk about it out loud it will get worse,” “I would not know what to say,” “I cannot articulate my feelings”). The fourth most frequently observed barrier concerned shame, stigma, and the fear that someone finds out about their contact with the helpline (eg, “I’m ashamed of my feelings,” “I’m afraid my parents will find out,” “I don’t want my spouse to know”). Other barriers concerned the topics of not wanting to be helped, being afraid to be a burden to someone, believing their problems were not bad enough, precious negative experiences with the helpline, wanting to solve their problem themselves, being already in treatment, having no energy or motivation, being afraid of the consequences (eg, having to go to a facility/crisis help or police involvement), or practical reasons such as not being in the right environment or having time restrictions.

Assessment of Barrier

To be able to provide customized information and advice, a barrier survey is included in the BRI. To not overwhelm the test-takers or expose them to more barriers than they have thought of themselves, the barrier questionnaire lists a limited number of options. As described earlier, previous studies identified the following key barriers to care: lack of perceived need for services; the preference for self-management; the fear of hospitalization; structural factors (eg, time and finances); and stigmatizing attitudes toward suicide, mental health problems, and seeking professional treatment [3,10]. Although these barriers were reflected among the users of the self-test, the pilot study revealed other, more frequently mentioned, barriers among our target population. We, therefore, chose to include the following barriers in the BRI: (1) “I don’t think that 113 can help me,” (2) “I’m scared to talk about my feelings,” (3) “I don’t think that my problems are serious enough for 113,” (4) “I’m scared that people will find out,” (5) “I would rather solve it myself,” and the remaining option (6) “I have other reasons.”

Testing of Prototypes

During the testing phase of the prototype, which included the names and photos of some counselors, the staff raised concerns regarding the anonymity and privacy of the counselors. We, therefore, decided to design the brief BRI with text-based feedback only and to anonymize the participating counselors (see Figure 2).

Discussion

Principal Findings

This paper describes the study protocol for a web-based RCT of a brief barrier reduction intervention. The aim of the trial is 2-fold: (1) to measure the effectiveness of a brief BRI provided in the self-test motivating people with severe suicidal thoughts to contact the Dutch suicide prevention helpline and (2) to specifically evaluate the effectivity of the BRI in increasing service use by high-risk groups such as men and middle-aged people. The goal of the intervention is to reduce self-stigma, provide information, and clear up misconceptions on which barriers to the helpline are based. To identify these barriers specific to self-test users, a pilot study was conducted. The open-ended answers of 1083 current self-test users in the high-risk category revealed multiple barriers to the helpline, of which the most common were the belief that a conversation with a counselor would not be effective, fear of the conversation itself, and emotional concerns about talking about suicidal thoughts. These identified barriers were used to design the barrier questionnaire.

Limitations

To our best knowledge, our study will be the first web-based RCT among people with severe suicidal ideation aimed to reduce the barriers to a suicide prevention helpline. One of the strengths of the study that should not be underestimated is the fact that it will take place among the actual service users of 113 Suicide Prevention, a difficult-to-reach and high-risk population. Moreover, by measuring the intended outcome measure, contacting the helpline, behavioral as well as attitudinal, we increase the measure's reliability and validity. Furthermore, we expect to achieve a substantial sample size and will, therefore, be able to provide a reliable estimate of the intervention's effectiveness. However, our study is not without limitations. First, although the study takes place among the target population, it is still possible that some form of selection bias will occur as it is less likely that users in severe distress will participate in the study. Second, as mentioned before, due to the helpline's anonymous nature it is not possible to have a follow-up measurement to determine if those who will not use the link directly after the intervention will contact the helpline at a later moment in time. For that reason, a respondent's self-reported likelihood of contacting the helpline will be measured as well as the use of a direct link to the helpline. Third, the BRI is only text-based, it would also be valuable to examine the effects of different components (eg, video material) in a BRI.

Conclusions

The short barrier reduction intervention built in a self-test for suicidal thoughts aims to motivate people with severe suicidal thoughts to contact the Dutch suicide prevention helpline. Guiding people with suicidal ideation to appropriate resources is a key aspect of suicide prevention. Our study will add to a growing body of research on web-based mental health interventions and provide a better understanding of the effect of tailored information and dispelling misconceptions in a high-risk group. Furthermore, if it proves to be effective, this intervention has the potential to be a low-cost, highly scalable, and easily implementable method to increase service use for mental health and crisis helplines worldwide.

Acknowledgments

We would like to thank all respondents of the pilot study for their valuable contribution. We would also extend our special thanks to Scarlet Hemkes for her insightful content, Salim Salmi for his help with the barrier reduction intervention prototype, and Siyu Chen, whose thesis has been a great inspiration for our study [26]. This research was funded by 113 Suicide Prevention, which is in itself mainly funded by the Ministry of Health, Welfare & Sports of the Netherlands.

Data Availability

The data set generated and analyzed during this study will not be publicly available due to company policies regarding help-seekers' data but are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: The number of elective outpatient surgeries in Canada has increased markedly in the last 10 years. However, unanticipated cancellations on the day of surgery and adverse postoperative events are frequent. Modern technologies have been shown to be of great help in the medical field in improving patient care. Thus, it is likely that dedicated technologies could also significantly improve surgical outpatients' pathways. Therefore, the department of anesthesiology at the University of Montreal Medical Center, in collaboration with LeoMed, a telemedicine platform, has developed a telehealth solution to offer more efficient perioperative support and follow-up for patients undergoing ambulatory surgery.

Objective: The objective is to evaluate the medicoeconomic benefit of a dedicated perioperative telehealth platform for patients undergoing day surgery. Our hypothesis is that this dedicated telecare solution will allow more efficient patient care, which will reduce all types of medical costs related to day surgery pathways.

Methods: This study is a single-center, single-blinded, 2-group randomized controlled trial. One thousand patients aged over 18 years with internet access who are scheduled to undergo ambulatory surgery will be enrolled and randomized either to follow a perioperative path that includes a patient-tailored perioperative digital app via the LeoMed telecare platform for 1 month or to follow the standard of care, which does not offer personalized digital support. The primary outcome will be to evaluate the cost-effectiveness of the telecare platform, assessing direct costs from factors such as unanticipated cancellations on the day of surgery due to preoperative instructions not being followed, calls to the local health information line, calls to the provincial health information line, emergency department consultations, unplanned readmissions, or medical visits for problems related to the surgical procedure within the first 30 days after the intervention. The secondary outcome will be to evaluate cost utility using a questionnaire assessing quality-adjusted life years. A blinded independent research team will analyze outcomes. All data will be analyzed according to the intention-to-treat principle. A sample size of 500 subjects in each group was calculated to detect a 21% reduction in postoperative complications with a power of 90%. This study has been approved by the ethics board of Centre hospitalier de l'Université de Montréal (University of Montreal Health Centre). No employee of LeoMed was involved in the study conception, and none will be involved in either data collection or analysis.

Results: Results of this trial will be useful to determine the economic benefit of a telecare platform specifically developed for surgical outpatient pathways.

XSL•FO
RenderX

Conclusions: We believe that the deployment of a dedicated perioperative telehealth app will lead to better patient care and fewer postoperative complications, which will lower all types of costs related to surgical outpatient care.

Introduction

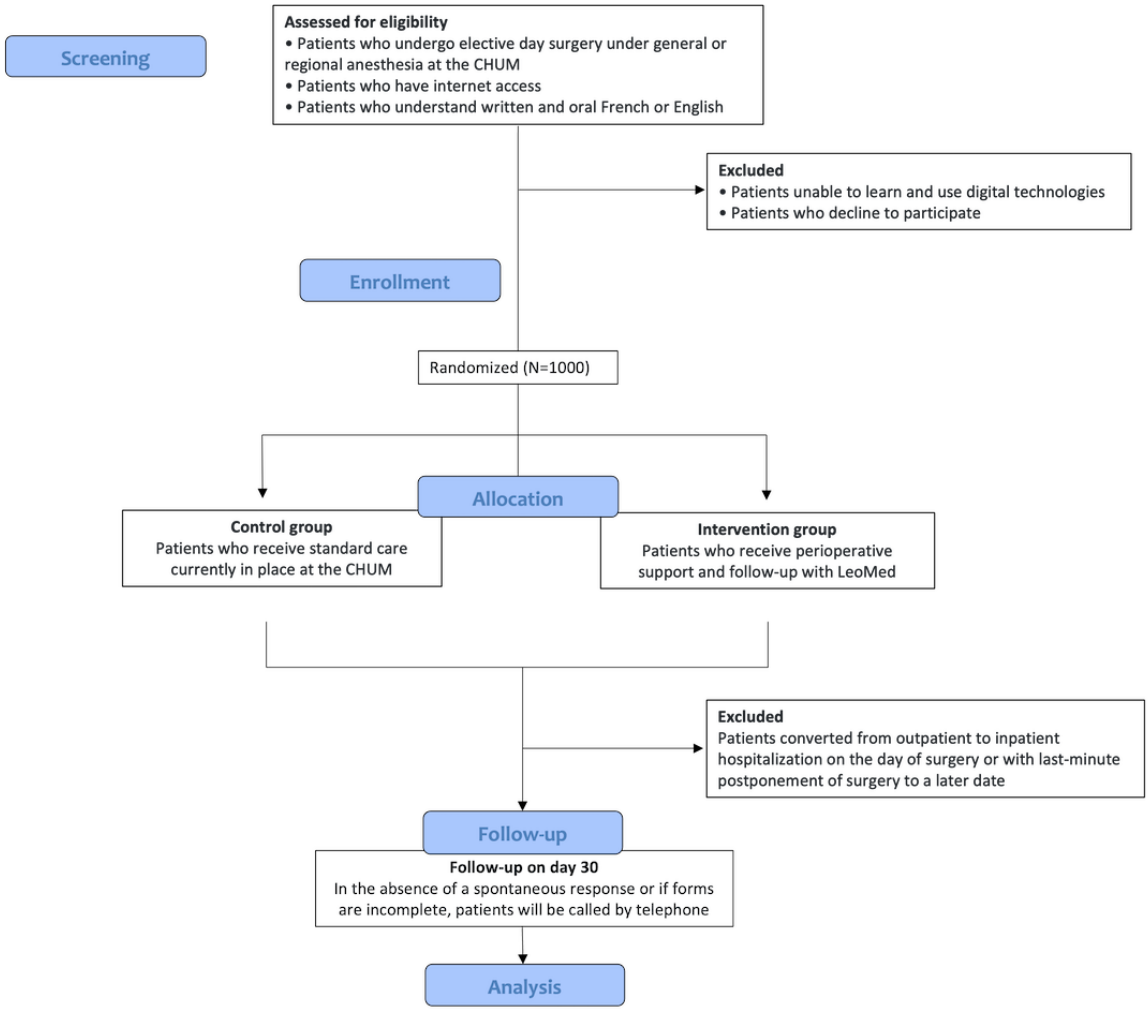
Outpatient surgeries have increased significantly in the last 3 decades [1]. In Canada, there was an overall 30% increase in outpatient surgeries between the fiscal years 1995-1996 and 2005-2006 [2]. In some countries, day surgeries account for more than 70% of all elective procedures [3]. Nowadays, it is common to perform day surgeries for both higher-risk patients and procedures [4]. However, postoperative measures currently in place to support and follow patients undergoing day surgeries are suboptimal. Indeed, a recent Canadian study has shown that the same-day cancellation rate for outpatient surgeries ranges from 8% to 10% [5,6]. The authors of that study also mentioned that 60% of these cancellations could have been avoided with better preoperative support [7]. Despite current recommendations, adverse postoperative events are very rarely searched for or detected by health care institutions [8-10]. The most common reasons for readmission, emergency department consultation, or unplanned medical visits are postoperative pain, nausea, and vomiting [10]. In addition, the prevalence of moderate-to-severe postoperative pain after ambulatory surgery ranges from 21% to 30% at 24 hours, and as much as 24% to 43% at 7 days [11,12]. This could lead to inappropriate postoperative use of opioids [13]. Inadequate pain relief is also one of the main risk factors for impairment of patients' overall quality of life after surgery [14]. A recent report by the Canadian Institute for Health Information showed that patients scheduled for day surgery in Canadian teaching hospitals return to the emergency department or are readmitted within 30 days postoperatively at incidence rates of 9.4% and 7.3%, respectively [15]. The additional costs associated with these cancellations and unplanned readmissions amount to several billion dollars every year [15].

In efforts to ensure better perioperative support and follow-up for patients undergoing day surgeries, many tools have been developed [16]. With recent technological advances and with the widespread use of smartphones and tablets, digital solutions have been suggested to guide and follow these patients [17].

The department of anesthesiology at the Centre hospitalier de l'Université de Montréal (CHUM; University of Montreal Medical Center in English), in collaboration with LeoMed, has developed a dedicated digital smart solution specifically designed to offer personalized perioperative support and follow-up via a telecare platform that can easily be installed on any smartphone. We hypothesize that the implementation of this telehealth platform at CHUM will (1) reduce the rate of unanticipated cancellations of elective surgeries through better preoperative information and communication, (2) improve quality of life 30 days after surgery due to faster and better recognition of postoperative complications, and (3) reduce the rate of emergency department or unplanned medical visits and unnecessary calls to the health information line, as well as reduce unplanned hospital readmissions, through more personalized health support. Our overall conjecture is that including the LeoMed patient-tailored telecare platform in the perioperative day-surgery pathways of patients will improve the medicoeconomic impact of care services compared with standard care. The main objective of this study is to assess the cost-effectiveness of the LeoMed platform, and our secondary objective is to perform a cost-utility analysis.

Methods

Design



In order to achieve the abovementioned objectives, we propose to conduct a single-center, single-blinded, 2-group randomized controlled trial. A group of patients who use the LeoMed patient-tailored telecare platform will be compared to a group of patients who have access to usual care. As mentioned earlier, the study will be conducted at CHUM.

Population

All patients aged over 18 years who undergo elective day surgery under general or regional anesthesia at CHUM will be eligible. All included patients must (1) have internet access and (2) understand written and oral French or English. Patients were possibly excluded at two stages: (1) before randomization, if they were unable to learn and use the digital technologies or if they refused to participate, and (2) after randomization, in cases of conversions from outpatient to inpatient hospitalization on the day of surgery or in cases of last-minute postponement of the surgery to a later date. Figure 1 shows the trial flowchart.

XSL•FO
RenderX

Figure 1. Flowchart of study participation. CHUM: Centre hospitalier de l'Université de Montréal.

Blinding and Allocation Concealment

Eligible patients will first be approached by telephone by a member of the research team when the preoperative clinical appointment is booked. During the preoperative clinical assessment, patients will receive both oral and written information on the study by a research nurse not involved in patient care. Patients will be included in the trial only after a research nurse has obtained written informed consent.

All included patients will be electronically randomized into the intervention group or the control group. Randomization will be performed by one of the investigators using the MedSharing Randomizer for Clinical Trial web application. The 2 groups will be balanced at a 1:1 ratio. Patients who are recruited but do not receive surgery within the study time frame will be secondarily excluded.

The study will be single-blinded. Statisticians will assess the primary and secondary outcomes, blinded to the randomization group. However, due to the nature of the intervention, neither the patients nor the care providers will be blinded to the randomization.

Recruitment and Intervention

During the recruited patients' visits to the preoperative clinic, they will benefit from safe and restricted web access to the LeoMed telehealth platform. After confirmation of the date of surgery, patients will be allocated according to the randomization list to the intervention group or the control group.

Intervention Group

The day before their surgery, patients will receive an email or SMS notification encouraging them to access the LeoMed platform. The platform prompts patients to click on links that direct them to the digital portal of the CHUM website, where all health sheets describing the perioperative pathway are published and grouped together, and preoperative psychological empowerment video resources are available that have been specifically created with the help of the CHUM communications service.

Postoperatively, notifications will be sent to the participants every day during the first 4 days. These notifications will direct patients to online forms assessing their medical condition. The questionnaires used are derived from the Brief Pain Inventory [18] and the Institut national de santé publique du Québec (INSPQ; Quebec Public Health Expertise and Reference Center in English) [19], which suggests using a simple questionnaire with 4 items for identification of surgical site infections. The items include redness at the surgical site, presence of pus at the surgical site, fever, and wound pain.

XSL•FO
RenderX

The LeoMed platform will automatically classify patients' responses using an artificial intelligence algorithm and generate alerts on the home page. The home page is displayed on a giant screen on CHUM's telehealth service, which will offer tailored support according to patients' clinical need.

Health support will be provided by CHUM's telehealth service, which comprises a team of 50 nurses. This department is a 24/7 call center that manages many telecare platforms dedicated to remote patient support for various medical specialties. All the staff of this service are trained in new technologies. Their mission is to provide health care remotely and to coordinate the interventions of different medical and paramedical personnel within the hospital. Specifically for this project, patient responses appear on a giant screen in the main open space where the CHUM telehealth service nurses work. In the event of an alert, a nurse will contact the patient within a maximum of 8 hours and provide appropriate care.

On postoperative day (POD) 15 and 30, the LeoMed platform will send a follow-up form that aims to evaluate all indicators considered in the medicoeconomic analysis. All the indicators are detailed in Table 1.

Table 1. Schedule of enrollment, interventions, and assessments.

Timepoint	Preoperative consultation	At the confirmation of the date of surgery	Preoperative day 1	POD[a] 1	POD 4	POD 7	POD 15 and POD 30

Calls to CHUM[b] online support							✓
Calls to the Quebec health information line							✓
Assessments from the electronic medical record system							
Same-day cancellations				✓			
Calls to CHUM online support							✓

[a]POD: postoperative day.

[b]CHUM: Centre hospitalier de l'Université de Montréal.

Control Group

Participants assigned to the control group will be followed up according to usual care, which consists of a telephone call the day before the procedure as a reminder of safety instructions. Postoperative follow-up is not standardized and remains specific to each surgical specialty. Access to a limited version of the LeoMed platform will also be given to these participants during the preoperative clinic visit. This version includes a preoperative questionnaire and follow-up forms at POD 15 and POD 30 that are identical to those received by the intervention group and collect the indicators considered in the primary analysis (Table 1). Like the patients in the intervention group, the control patients will have 24/7 access to the provincial or CHUM health information lines, if needed.

Primary Outcome

The primary outcome will be the cost-effectiveness of the LeoMed telecare platform deployment assessed by its direct costs, including unanticipated cancellations on the day of surgery due to preoperative instructions not being followed, calls to the local CHUM health information line, calls to the Quebec health information line (ie, 811), visits to the emergency department, and unplanned readmissions or medical visits (to family doctors or outpatient clinics) for problems related to the procedure within the first 30 days after the procedure.

Secondary Outcome

The secondary outcome considered for the cost-utility analysis will be quality-adjusted life years (QALYs). According to a recent update of the guide for economic evaluation published

XSL•FO
RenderX

by the French National Authority for Health [20], the EQ-5D-5L visual analog scale (VAS) is the preferred measure used to assess quality of life and to derive utility values for use in health technology appraisals. It will be assessed at POD 30 and compared with the preoperative baseline [21]. The EQ-5D-5L VAS is a questionnaire that is well validated. It includes 5 dimensions, each describing a different aspect of health: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression. Patient satisfaction with care services will also be assessed.

Data Collection

Data for primary and some secondary outcome measures will be collected from the LeoMed platform until POD 30, with the exception of same-day cancellations. These data will be collected on POD 1 from the electronic medical record (EMR) system by 1 member of the research team (Table 1). In the absence of spontaneous responses from patients at POD 30 or if the forms are incomplete, patients will be called by one of the research assistants to assess the indicators included in the cost-effectiveness and cost-utility analyses. If a postoperative event is reported via the form, the patient will also be contacted personally by telephone.

For each patient, data will be systematically registered and archived on a local secure server. Patients will be identified using a unique numeric code, and all patient data will be anonymized to ensure confidentiality. All data will be extracted and cross-referenced with Oacis (Telus Health), the EMR system used at CHUM.

Data Analysis

Data analysis will be performed by a team of researchers at the École des Hautes Études Commerciales in Montreal, Quebec, using SPSS (version 28; IBM Corp). All data will be analyzed according to the intention-to-treat principle. Descriptive statistics will be reported as frequencies and proportions for categorical data and means and standard deviations for continuous variables. Demographic data for the 2 groups of patients will be compared using the Mann-Whitney *U* test (for ordinal data), the chi-square test (for nominal data), and a 2-tailed *t* test (for continuous data).

Considering the Canadian guidelines for the economic evaluation of health technologies [22], the perspective of the health care system will be privileged in this study. Specifically, 2 main types of analyses will be carried out. First, all interventions in both groups related to surgery (calls to the provincial or CHUM information lines, visits to the ambulatory unit, hospital readmissions, and visits to the emergency department) will be recorded during the study to perform the cost-effectiveness analysis. Second, a cost-utility analysis will be conducted to quality-weight each effectiveness outcome measured in QALYs. QALYs will be calculated as life with the health state under study multiplied by the utility associated with that health state. CHUM's internal data will be used to determine the cost of health care staff and the average cost of an emergency room visit for the clientele concerned in fiscal year 2019-2020. For hospitalizations, we will use the average costs calculated according to the American diagnosis-related groups method, which was applied at CHUM in 2019-2020. Technology costs will be estimated based on license prices in effect at the time of the study and amortized on a straight-line basis over a 5-year period. All calculations will be in Canadian dollars. Last, patient satisfaction with care services will be measured in both groups at the end of the trial using Likert scales adapted from Sicotte et al [23]. This protocol follows the SPIRIT (Standard Protocol Items: Recommendation for Interventional Trials) 2013 Statement for trial protocols [24].

Sample Size

There are very few studies that have examined the effects of digital solutions for personalized support and follow-up for patients undergoing day surgery. We based our sample size calculations on Jaensson et al [25], assuming that a better postoperative recovery (ie, decreased symptoms and complications) should reduce the number of postoperative calls to the health information line, visits to the emergency department, unplanned readmissions and medical visits, and the associated costs (our primary outcome). Jaensson et al [25] reported better recovery (based on the global Swedish Web Version of the Quality of Recovery [SwQoR] score) in an intervention group (ie, day surgery patients using a recovery assessment mobile phone app) compared with a control group (standard care) on POD 7 (effect size 0.21; $P<.001$). With a significance level of .05 and a statistical power of .90, G*Power (Heinrich Heine University) generated a group size of 357. To allow for a 20% rate of loss to follow-up and protocol deviations, we thus aim to recruit 500 patients per arm. In the third quarter of 2019, CHUM provided nearly 630 outpatient surgical stays per month on average. Considering 70% of patients should be eligible for the study [26], it will take about 12 months to recruit 1000 patients.

Ethics Approval

The study conforms to the principles outlined in the Helsinki Declaration. The project has been approved by the institutional review board and research ethics committee at CHUM (21.110). The trial was registered at the ClinicalTrials.gov (NCT04948632). If any protocol amendments are needed, research committees and the institutional review board at CHUM will be asked to approve them. Participant recruitment began in August 2022.

Results

The platform was launched in January 2022. A patient-as-partner approach was chosen in the initial phase, where 12 patients who had undergone day surgery in the last 6 months were recruited to test the platform. Another 12 patients scheduled for outpatient surgery tested the optimized support and follow-up platform. Their feedback helped to correct and improve the platform before beginning study recruitment. The inclusion of the first patients began in August 2022. As of October 31, 2022, we enrolled 142 patients.

Discussion

Principal Findings

Outpatient surgeries have been significantly increasing in the last decade in Canada, with more than 1.8 million interventions being performed annually [2]. These surgeries were historically restricted to low-risk interventions, but recent improvements in anesthesia care and the development of minimally invasive surgical techniques have resulted in moving some higher-risk interventions to day-surgery pathways. Limitations in the number of hospital beds due to the COVID-19 pandemic have probably accelerated the transition toward outpatient surgery. Nowadays, major procedures, including intra-abdominal, intrathoracic, orthopedic, and endovascular surgeries, are commonly performed as ambulatory surgeries [27-29].

In addition, the number of elderly patients undergoing same-day surgery is set to increase. In 2010, the American Ambulatory Surgery survey showed that among patients who underwent day surgery, 35% and 15% were aged 65 years or older and 75 years or older, respectively [30]. The burden of comorbidities in patients undergoing day surgery also has changed. Nowadays, patients with American Society of Anesthesiologists Physical Status III and IV are commonly eligible. These older patients with more comorbidities are sent home on the day of surgery, raising questions about quality of recovery and prognosis.

To resolve these issues, digital health solutions represent an attractive option. They have been highlighted by the World Health Organization as a potential lever to increase quality of health, enhance equality of care, and reach more patients, including those in rural areas [31]. As mentioned earlier, LeoMed's telehealth platform is specifically designed to offer perioperative support and follow-up for outpatient care. The platform was developed by the LeoMed company in partnership with members of the anesthesia department at CHUM to meet the challenges of patients' perioperative day-surgery pathways.

One challenge is ensuring optimal communication of the measures that should be followed preoperatively to promote rapid postoperative recovery. In our institution, patients are informed of these preoperative measures during their visit at the preoperative clinic. The average time between this preoperative visit and the surgery is often one to several weeks. In the intervention group, we again provide all the documents containing the useful preoperative information in a text message sent the day before the intervention. Ideally, we would have liked to provide this information 48 to 72 hours in advance to give patients more time to read and assimilate it. Unfortunately, the operating program is confirmed only on the day before surgery due to institutional COVID-19 policy.

In the postoperative context, several studies have shown that telehealth reduces the use of opioids and improves quality of recovery [25,32,33]. We previously showed that the prevalence of moderate to severe postoperative pain after ambulatory surgery ranges from 21% to 30% at 24 hours, and as much as 24% to 43% at 7 days [12]. Inadequate pain relief is one of the main risk factors for impairment of patients' overall quality of life after surgery [14] and can lead to inappropriate postoperative use of opioids [13]. Yet, to our knowledge, no study has demonstrated solid economic effects at the health-system level [34,35]. Hence, the lack of medicoeconomic data does not encourage government institutions and public medical insurance to recognize and promote the use of mobile technologies for outpatient surgeries. This trial aims to fill this gap.

Limitations

We propose to conduct a randomized controlled trial that is single-center, which represents the main limitation of our study protocol. Indeed, we will not be able to generalize our findings to ambulatory centers that perform other types of surgical procedures, specifically minor procedures. This limitation must be balanced with the difficulty of developing and implementing the same telehealth solution in many hospitals. Moreover, technical challenges, costs, and data security issues might represent barriers to the successful implementation of similar telehealth solutions in other settings.

Conclusions

This trial will help determine the cost-effectiveness of telehealth when used in the perioperative context. The trial is also necessary because it will improve knowledge about postoperative pain and adverse effects after day surgery. Outpatient surgery will not remain at low risk of complications for long. Nowadays, many procedures previously requiring hospitalization are evolving toward day-surgery pathways, and monitoring of potential adverse events is mandatory to control associated costs. This study will provide a clearer view of patient-reported outcome measures after outpatient surgery.

Acknowledgments

This project received CAD $240,000 (US $173,856) in funding as part of the Fonds de soutien à l'innovation en santé et en services sociaux from Medteq. The sponsor had no role in the trial design, trial conduct, data handling, data analysis, writing, or publication of the manuscript.

Data Availability

The data sets generated during and/or analyzed during this study will be made available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Protocol

Combining Behavioral Economics–Based Incentives With the Anchoring Strategy: Protocol for a Randomized Controlled Trial

Abstract

Background: Chronic (ie, long-term) elevated stress is associated with a number of mental and physical health conditions. Mindfulness meditation mobile apps are a promising tool for stress self-management that can overcome several barriers associated with in-person interventions; however, to date, poor app-based intervention adherence has limited the efficacy of these mobile health tools. Anchoring, or pairing, a new behavior with an existing routine has been shown to effectively establish habits that are maintained over time, but this strategy typically only works for those with high initial motivation and has yet to be tested for maintaining meditation with a mobile app.

Objective: This study will test novel combinations of behavioral economics–based incentives with the anchoring strategy for establishing and maintaining adherence to an effective dose of meditation with a mobile app.

Methods: This 16-week study will use a 5-arm, parallel, partially blinded (participants only), randomized controlled design. We will implement a fractional factorial study design that varies the use of self-monitoring messages and financial incentives to support participants' use of their personalized anchoring strategy for maintaining adherence to a ≥10 minute-per-day meditation prescription during an 8-week intervention period, followed by an 8-week postintervention observation period. Specifically, we will vary the use of self-monitoring messages of either the target behavior (ie, meditation tracking) or the outcome associated with the target behavior (ie, mood symptom tracking). We will also vary the use of financial incentives conditional on either meditation at any time of day or meditation performed at approximately the same time of day as participants' personalized anchors.

Results: Continuous meditation app use data will be used to measure weekly meditation adherence over the 16-week study period as a binary variable equal to 1 if participants complete ≥10 minutes of meditation for ≥4 days per week and 0 otherwise. We will measure weekly anchoring plan adherence as a binary variable equal to 1 if participants complete ≥10 minutes of meditation within +1 or −1 hour of the timing of their chosen anchor on ≥4 days per week and 0 otherwise. In addition to these primary measures of meditation and anchoring plan adherence, we will also assess the secondary measures of stress, anxiety, posttraumatic stress disorder, sleep disturbance, and meditation app habit strength at baseline, week 8, and week 16.

Conclusions: This study will fill an important gap in the mobile health literature by testing novel intervention approaches for establishing and maintaining adherence to app-based mindfulness meditation. If successful, this study will identify an accessible and scalable stress self-management intervention that can help combat stress in the United States.

Introduction

Problem Statement

The prevalence of stress in the United States is at an all-time high, with >75% of US adults reporting elevated levels of stress in 2021 [1,2]. Chronic (ie, long-term) elevated stress is associated with a number of mental and physical health conditions, such as depression, anxiety, cardiovascular disease, and reduced cognitive functioning [3-5]. The COVID-19 pandemic exacerbated stress levels, with 78% of Americans reporting that the pandemic was a significant stressor in their lives and 67% of Americans experiencing significantly increased stress over the course of the pandemic [6]. Recent reports by the American Psychological Association have documented the cumulative negative effects of increased stress during the pandemic on mental and physical health, where 84% of Americans in 2021 reported feeling at least 1 emotion associated with prolonged stress, such as anxiety, sadness, or anger [2,7]. In addition, the reported physical health consequences of chronic elevated stress during the pandemic include undesired weight changes, sleep problems, and increased alcohol consumption [2,7].

These findings demonstrate the significant consequences that chronic elevated stress can have on health outcomes, and existing research has shown that these negative health effects also impose a large economic burden. Recent reports suggest that stress is associated with annual costs of >US $300 billion owing to workplace absenteeism, accidents, reduced productivity, and employee turnover, in addition to direct medical, legal, and insurance costs [8]. Despite the clear need for stress management resources, only 54% of Americans reported seeking help for their mental health in 2020 [9], and nearly half of Americans delayed or canceled health care service appointments after the beginning of the pandemic [7]. Thus, there is an urgent need for novel stress self-management solutions that are more accessible and that can provide alternative approaches for stress reduction than those currently offered by conventional mental health care in the United States.

The rapid development and widespread availability of mobile health (mHealth) apps for treating mental health conditions may be a key self-care solution to address the ongoing stress epidemic. Mindfulness meditation apps are a particularly promising tool for stress self-management, as they can overcome several barriers associated with in-person interventions, such as cost, stigma, and accessibility [10]. Importantly, previous research has demonstrated the efficacy of app-based mindfulness meditation interventions for improving mental health outcomes, such as depression, anxiety, and sadness, compared with both control groups and traditional in-person interventions [10]. In addition, our own work with the Calm meditation app, one of the most popular commercially available mindfulness meditation apps [11], has shown that meditation with Calm can improve a wide range of mental health outcomes and reduce stress [12-14].

Despite these promising findings, many mHealth app–based studies have reported significant dropout rates and poor intervention adherence (intervention adherence rates ranging from 39% to 92%), which ultimately limit the efficacy of app-based meditation interventions for stress management [15,16]. In general, user retention rates for mHealth apps are low, with one systematic review finding median 15- and 30-day mental health app retention rates of 4.9% and 4.7%, respectively [17]. This pattern of declining user engagement with apps has been frequently observed in the mHealth literature [18-20] and mirrors the decline in treatment adherence documented in other behavioral interventions and clinical settings [21-23]. Although a growing field of research has started to examine the issue of maintaining adherence to app-based interventions and other behavioral and medical treatments [19,24], little is known about the strategies that can successfully maintain adherence in these settings. Thus, there exists a critical need for researchers to identify and implement novel, effective, and accessible strategies for maintaining adherence to health apps, particularly meditation apps, that can help combat the alarming rates of elevated stress in the United States.

Study Aims

This study will test novel combinations of behavioral economics–based incentives with a habit formation intervention from the psychology literature for establishing and maintaining adherence to an effective dose of meditation with a mobile app. In a 5-arm randomized controlled trial, we will implement a fractional factorial study design that varies the use of self-monitoring messages and financial rewards to support participants' use of the anchoring strategy for maintaining adherence to a ≥10 minute-per-day meditation prescription during an 8-week intervention period, followed by an 8-week postintervention observation period. The study is designed to examine 3 specific study aims. First, we will assess the study group differences in adherence to daily meditation prescriptions during the 8-week intervention. Second, we will estimate the study group differences in meditation adherence maintenance over the 8-week postintervention observation period. Third, we will investigate the role of anchoring performance during the intervention on participants' ability to maintain their meditation app adherence during the postintervention observation period. In this paper, we will outline previous research on mobile meditation apps, the background and rationale behind the adherence strategies we developed, our research methodology, and our hypotheses.

App-Based Mindfulness Meditation: Strengths and Weaknesses

Previous research has demonstrated the effectiveness of mindfulness meditation interventions in improving a wide range of health outcomes in both clinical and nonclinical populations, including stress, anxiety and depressive symptoms, well-being, and sleep [15,16,25]. While traditional mindfulness meditation interventions have been delivered via in-person sessions,

XSL•FO
RenderX

app-based interventions have become increasingly popular in recent years because they are less costly and more accessible than face-to-face interventions [15,16]. In addition, a growing body of research has established the feasibility and acceptability of app-based mindfulness meditation interventions [26,27], suggesting that they are scalable and acceptable alternatives to traditional in-person interventions [12,13,16,28]. Several randomized controlled trials and meta-analyses have also documented the efficacy of app-based interventions on various mental health outcomes, including stress reduction, finding similar effects when compared with in-person interventions and when compared with control groups [12,16,29]. Many of these effects have also been observed during the COVID-19 pandemic [29], suggesting that meditation apps may be a useful self-management tool for reducing stress during a prolonged period of stress, such as the pandemic.

Despite these promising findings, the efficacy and generalizability of app-based interventions are limited by their substantial attrition and poor adherence. Previous meta-analyses have estimated app-based intervention study attrition rates to range from 31% to 42% and intervention adherence rates (ie, the number of sessions actually completed compared with the prescribed amount) to range from 39% to 92% [15,16,30]. Baumel et al [17] examined objective user adherence with various mental health Android apps, including those specifically for mindfulness meditation, and found that only a small portion of users actually used the apps for an extended period, with open rates declining >80% between days 1 and 30 across all mental health apps. For mindfulness meditation apps specifically, median 15- and 30-day retention rates were 4.9% and 4.7%, respectively [17], greatly limiting the efficacy of these mHealth tools. Similar patterns of declining adherence have been observed in our research with the Calm meditation app, in which adherence rates to the daily prescription of ≥10 minutes of meditation with Calm fell by approximately 68% over the course of a 16-week study period [31]. This pattern of rapidly declining meditation app use limits the impact of these mental health solutions. The next step in the mHealth research is therefore to find effective interventions to keep mobile app users engaged, that is, to maintain meditation app adherence.

In general, study attrition and adherence are critical issues in mHealth interventions that must be addressed to improve the efficacy of these therapeutic tools. Health behavior models such as the transtheoretical model [32,33] outline several key stages of behavior adoption that should be considered when developing interventions: precontemplation, contemplation, preparation, action, and maintenance stages. Individuals who download a health app and purchase a subscription are likely to be in the preparation or action stage because they have taken steps to initiate behavior change. However, common app-based mHealth issues, such as poor adherence, suggest that significant barriers exist when moving from the preparation and action stages to the maintenance stage. The proposed socio-cognitive intervention strategies have focused on bolstering self-efficacy for dealing with obstacles, increasing motivation, and reiterating the long-term benefits of performing a behavior; however, to date, these strategies have largely been unsuccessful in maintaining health behavior changes [34-38]. Thus, in this study, we synthesized theory- and evidence-based intervention approaches from psychology and behavioral economics to test novel combined strategies for maintaining adherence to meditation using the accessible and scalable Calm app.

Habits as a Key Strategy to Maintain Adherence

Psychological research suggests that developing a habit may be a successful behavioral strategy for maintaining behaviors over time [39]. Habits have been shown to underlie many long-term healthy behaviors [40] and may be a key strategy for maintaining adherence to a mindfulness meditation app [31,41]. Existing research has shown that habits are formed gradually over time as an individual repeatedly and consistently performs a behavior in response to the same stimulus or contextual cue, to the point where it can be performed automatically with little or no cognitive effort [23,41,42]. Through such "context-dependent repetition," [43] exposure to the cue reflexively, or nonconsciously, triggers the initiation of the behavior [44]. In this way, behavioral control is delegated to external cues, thereby reducing the demand on an individual's attention and memory processes [42,45,46]. Importantly, habits have been shown to persist long term despite declining motivation or willpower [47-49] and even when participants were distracted [50]. In addition, habit formation strategies have been used to successfully maintain various health behaviors, such as dietary habits [51,52], physical activity [53-56], medication adherence [57-60], and dental hygiene [61,62], among others [63,64].

One common intervention strategy for promoting habit formation is anchoring, which is when a new behavior is paired, or "anchored," to an existing routine (ie, the contextual cue) [23]. Anchoring has successfully established health habits, such as increased physical activity [65], improved diet [51,66-68], smoking cessation [69], and medication adherence [70,71]. However, it takes approximately 3 months of adherence to an anchoring plan to form a habit [43,72-74], and many participants fail to adhere to their anchoring plan for this entire habit formation period [23,75,76]. Common barriers to anchoring plan adherence include lack of motivation [77,78] and self-efficacy [79,80] and forgetfulness [81]; on average, only 55% of anchoring intervention participants stick with anchoring long enough to form a habit. In a recent study, using the anchoring plan alone did not lead to meditating for more days per week over a 3-month intervention [82], which further suggests that additional strategies may be needed to increase anchoring plan adherence for establishing a new meditation habit.

Other common behavioral intervention strategies include reminder messages, personalization, and self-monitoring. Text message reminders are increasingly being used in health promotion interventions as a simple and cost-effective way to enhance healthy behaviors [83]. Several meta-analyses have demonstrated the efficacy of text message reminders across a wide range of populations and behaviors, with personalized messages being the most efficacious compared with generic messages or no messages at all [83,84]. Our previous work also suggests that using anchoring plan text message reminders in addition to the anchoring plan can lead to small, but significant,

XSL•FO
RenderX

increases in meditation practice over an 8-week period [31]. Although the evidence to support the long-term effectiveness of text message reminders has been inconsistent [85], using personalized anchoring plan text message reminders may be a feasible, acceptable, and effective way to increase anchoring plan adherence [31,84].

Different types of self-monitoring messages may also influence anchoring plan adherence [86-88]. Self-monitoring has been cited as an important facilitator of behavior change and habit formation [74], and many existing mHealth apps have incorporated self-monitoring features to improve and sustain user engagement [89-91]. In addition, existing interventions have successfully used prompts either alone or in combination with other strategies to support health behavior change [92,93]. According to Michie et al [94], there are 2 types of self-monitoring: self-monitoring of behavior and self-monitoring of behavior outcomes. Messages that focus on self-monitoring of a target behavior (eg, number of completed meditation sessions during the past week and changes in the number of completed meditation sessions over time) may increase self-efficacy for a behavior by helping individuals visualize their effort investment and compliance with their behavioral goals [74]. Self-monitoring of behavior also helps individuals build self-regulatory skills [95], which may be particularly useful during the "learning phase" of the habit formation process [46]. Alternatively, messages that focus on self-monitoring of the outcomes associated with the meditation practice may increase the salience of both the immediate and long-term benefits of meditation practice, which may not be as clear from meditation practice alone [96,97]. In fact, our previous work on the Calm app's self-monitoring mood check-in feature (ie, assessing and documenting mood before or after meditation practice) found that using mood check-ins was associated with increased meditation engagement, particularly among inactive subscribers [96]. As the mental health benefits of meditation are not immediately observable, messages that focus on the self-monitoring of outcomes of behaviors (ie, mood check-ins) may be a more effective way to reinforce participants' adherence to the ≥10 minute-per-day meditation prescription than messages that focus on self-monitoring of behavior, which can only provide an indirect signal of participants' mental health benefits. By varying the type of self-monitoring messages (ie, behavior or outcomes of behavior) between intervention study groups, we will be able to test the following hypothesis:

- *Hypothesis 1*: the study groups receiving messages that focus on self-monitoring of outcomes of meditation behavior will have greater adherence to the ≥10 minute-per-day meditation prescription during the 8-week intervention and during the 8-week postintervention observation periods than the study groups receiving messages that focus on self-monitoring of meditation behavior.

In addition to self-monitoring messages, offering financial or in-kind incentives may be a successful strategy to further increase anchoring plan adherence [98]. Research from the behavioral economics literature suggests that traditional external rewards are often successful in *initiating* a wide range of health behaviors [99-101]. While the effects of these behavioral economics–based incentives often disappear once the incentives are withdrawn [21,23], it is possible that combining incentives with the anchoring strategy may leverage the short-term effectiveness of incentives to increase anchoring plan adherence and establish long-term habits [24]. One way in which this combined approach could be implemented is by using "time-contingent" incentives that are conditional on performing the target behavior at approximately the same time that the planned anchor (ie, existing routine) is expected to occur. Such time-contingent incentives (TCIs) may direct participants' focus and attention to the use of their anchors, which may help to better maintain meditation after the incentives are withdrawn. To test this approach and compare these strategies with the previous behavioral economics literature, the intervention study groups will receive either TCIs or non-TCIs (NTCIs) during the 8-week intervention period. This variation in intervention approaches will allow us to evaluate the following hypothesis:

- *Hypothesis 2*: The study groups receiving TCIs will have greater adherence to their anchoring plans and to the ≥10 minute-per-day meditation prescription during the 8-week intervention and during the 8-week postintervention observation periods than the study groups receiving NTCIs.

Combining anchoring, a well-studied habit formation strategy, with additional intervention strategies (ie, self-monitoring messages and incentives) is a novel behavioral intervention that may overcome adherence barriers and develop strong meditation habits. Therefore, our study will test anchoring in combination with varying forms of these 2 additional strategies to determine the optimal combined approach for establishing and maintaining meditation with a mindfulness meditation app. Importantly, our findings will test the following hypothesis regarding the success of the anchoring plan for maintaining the behavior change:

- *Hypothesis 3*: The study groups that display the greatest anchoring plan adherence during the 8-week intervention will be the most successful in maintaining meditation adherence during the 8-week postintervention observation period.

Methods

Study Setting

This study will be conducted using a nationwide sample of new, self-initiated Calm subscribers who purchased 1-year-long membership. There is no specified location for this study, as all study procedures can be completed remotely through our web-based surveys and the meditation app, and participants will not be required to complete any in-person laboratory procedures.

Study Design

This study will use a 5-arm, parallel, partially blinded (participants only) randomized controlled design. After completing a web-based eligibility survey, the participants will be randomized into 1 of the 5 study groups. Stratified randomization methods will be used to ensure that race and ethnicity (ie, Hispanic) are equally represented across study groups. The 5 study groups include a control group that will use the anchoring plan to form a meditation habit with Calm and then receive no additional intervention supports, while the

XSL•FO
RenderX

4 intervention groups will also use the anchoring plan in combination with 1 of the 2 different types of self-monitoring messages and 1 of the 2 different forms of incentives. Participants in the 4 intervention groups will also be eligible for an in-kind reward (eg, Calm t-shirt, Calm tote bag, or Calm water bottle; all gifts have a retail value of roughly US $25 but a wholesale cost of US $5) conditional on either completing ≥10 minutes of meditation at any time of day on at least 8 days over a 2-week period (NTCIs) or completing ≥10 minutes of meditation within a 2-hour window around the time their chosen anchor typically occurs during the day (ie, anchor time1 hour) on at least 8 days over a 2-week period (TCIs). All additional interventions to support adherence to the anchoring plan will be delivered for 8 weeks; thus, participants are eligible to win up to 4 in-kind incentives during the intervention period. Participants within the intervention groups will also be randomly assigned to receive either messages that focus on self-monitoring of behavior (eg, "You completed a meditation session using your Calm app on at least 8 days during the past 2 weeks") or messages that focus on self-monitoring of outcomes of behavior (eg, "We encourage you to continue using the 'How Are You Feeling?' check-in feature after completing your meditation sessions"). The "How Are You Feeling?" check-in feature is an existing feature available to all users of the Calm app that allows users to record their current mood state (eg, happy, sad, or anxious). The fractional factorial study design is shown in Table 1.

After randomization, all participants will complete a baseline survey that includes self-report questionnaires, a study introduction video (described below under *Introductory Video*), a comprehension quiz, and a web-based worksheet that will guide the participants on how to develop their meditation anchoring plan. At weeks 8 and 16, participants will complete a follow-up survey to assess changes in our secondary outcome measures as well as satisfaction with the Calm app, their anchoring plan, and the intervention. Figure 1 outlines the timeline of all study activities.

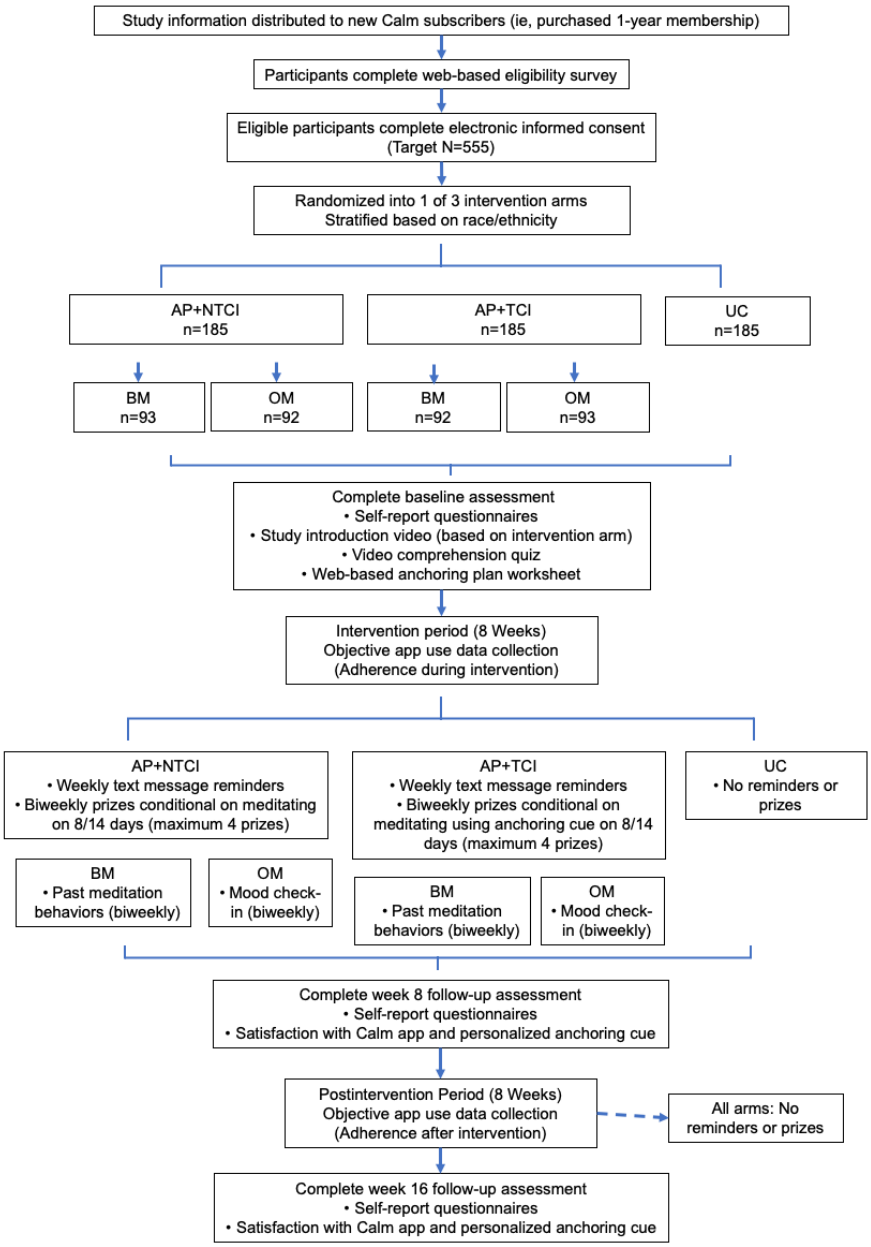
Table 1. Fractional factorial study design[a].

Study group	AP[b]	BM[c]	OM[d]	NTCI[e]	TCI[f]
Control	1	0	0	0	0
Treatment 1	1	1	0	1	0
Treatment 2	1	0	1	1	0
Treatment 3	1	1	0	0	1
Treatment 4	1	0	1	0	1

[a]This table shows which of the intervention strategies are received by each of the 5 study groups, where the column headers list each strategy and 1 indicates that the strategy is received by the study group listed in the row label.

[b]AP: anchoring plan.

[c]BM: self-monitoring of behavior messages.



[d]OM: self-monitoring of outcomes of behavior messages.

[e]NTCI: non–time-contingent incentive.

[f]TCI: time-contingent incentive (conditional on meditation within a 2-hour window around anchor timing).

Sample Size

The target recruitment sample size for this study is 555 participants, with 111 participants per study group. On the basis of our existing studies using the Calm app, we anticipate a 20% study attrition, which will yield an effective study group sample size of 88. Our primary measure of meditation app adherence is a binary indicator variable for performing ≥10 minutes of meditation on at least 4 days of the week. This measure of adherence is based on the concept of behavioral regularity, which was proposed by Cheung et al [102] as a standardized measure of treatment adherence. In addition, researchers have recommended that practicing mindfulness for 3 to 4 days per week is the sufficient level of adherence (or regularity) for attaining the mental health benefits associated with meditation, such as stress reductions [103], and this recommendation is theoretically consistent with the notion that a mindful mind is the product of frequent, effortful, and persistent training [104,105]. Thus, we determined our sample size to detect study group differences in meditation regularity at the end of the study (week 16). Using data from our previous studies with Calm, we know that approximately 15% of new Calm users regularly meditate (ie, complete ≥10 minutes of meditation for at least 4 days of the week) 8 weeks after first subscribing to the app and fewer than 10% regularly meditate with Calm 16 weeks after subscribing. An effective study group sample size of 88 provides adequate statistical power (1–β=.82) for detecting study group differences of 18 percentage points in the likelihood of regular mediation in week 16 (Cohen h=0.43, which is a small to medium effect size).

Eligibility

Participants will be eligible and included in our sample if they are aged at least 18 years, are new Calm subscribers (ie, have purchased at least 1-year of membership within the past week), are able to read and understand English, have access to a

XSL•FO
RenderX

smartphone daily, reside in the United States or a US territory, and have a Perceived Stress Scale (PSS; PSS-4) score ≥6. Participants will be excluded if they are new Calm subscribers but have used Calm for ≥2 days in the last week, have practiced meditation (including meditative movement, ie, yoga or tai chi) for >60 minutes a month in the past 6 months, or are unable to provide consent or understand study procedures owing to mental illness or cognitive limitations.

Recruitment and Enrollment Procedures

Potential participants will be invited to participate in the study via weekly recruitment emails sent by Calm to all new subscribers. The recruitment email will contain a link to complete an eligibility survey using the survey software Qualtrics (Qualtrics International Inc). Recruitment emails will be sent every week for 6 consecutive weeks or until the target sample size has been met. Participation will be voluntary, and participants may withdraw from the study at any time.

The eligibility survey will contain a brief overview of the study along with a series of questions based on the eligibility criteria listed in the previous section. If eligible, the participants will be asked to read an electronic consent form and provide their consent via electronic signatures. The electronic consent form also contains 2 comprehension questions to ensure that participants understand the study procedures. Once consented and enrolled, participants will be told that they will receive additional study instructions (ie, the baseline survey) via email in the coming weeks. During this time, eligible participants will be randomized based on the stratification dimensions described in the *Study Design* section.

Data Collection Tools and Procedures

Overview

Data will be collected at 3 time points: baseline, week 8 (following completion of the intervention), and week 16 (following the 8-week postintervention observation period). Objective app use data will be collected via the Calm app, which will record the day and time of every app session; the duration of sessions; the type of session (eg, meditation, sleep story, and breathing exercise); and title of sessions (eg, Daily Calm and Daily Move) performed during the study period. Table 2 shows the primary and secondary outcome measures collected at each administration time point.

Table 2. Primary and secondary outcome measures at each administration time point.

Measure	Assessment	Baseline	8-week follow-up	16-week follow-up	Continuous data collection
Primary outcomes					
Meditation adherence	Objective app use data	N/A[a]	N/A	N/A	Yes
Anchoring plan adherence	Objective app use data	N/A	N/A	N/A	Yes
Secondary outcomes					
Stress	Perceived Stress Scale	Yes	Yes	Yes	N/A
Anxiety	Hospital Anxiety and Depression Scale	Yes	Yes	Yes	N/A
PTSD[b]	Impact of Events Scale—Revised	Yes	Yes	Yes	N/A
Sleep disturbances	Insomnia Severity Index	Yes	Yes	Yes	N/A
Habit strength	Self-report Behavioral Automaticity Index	Yes	Yes	Yes	N/A

[a]N/A: not applicable.

[b]PTSD: posttraumatic stress disorder.

Primary Outcomes: Adherence Maintenance (Objective App Use Data)

The primary outcomes for this study measure participants' ability to maintain adherence to the ≥10 minute-per-day meditation prescription over the 16-week study period. Specifically, we will measure meditation adherence as a binary variable equal to 1 if participants complete ≥10 minutes of meditation for ≥4 days per week and 0 otherwise. This meditation adherence outcome will be defined weekly during both the 8-week intervention and the 8-week postintervention observation periods. We will also measure objective meditation app use using the number of days with ≥10 minutes of meditation per week and the total number of meditation minutes per week, both of which will allow us to investigate the behavioral frequency of app-based meditation and improve the statistical power of our analyses. We will also augment these objective app-based meditation measures with a self-reported measure of days with any meditation (ie, either using the app or meditation outside the app) over the past week that is assessed at baseline, week 8, and week 16 time points. We will measure anchoring plan adherence as a binary variable equal to 1 if participants complete ≥10 minutes of meditation within 1 hour of the timing of their chosen anchor for ≥4 days per week and 0 otherwise. Similar to overall meditation, we will also measure anchoring plan adherence as the number of days completing ≥10 minutes of meditation within 1 hour of the timing of their chosen anchor per week.

XSL•FO
RenderX

Secondary Outcomes: Stress, Anxiety, and Posttraumatic Stress Disorder

We will assess stress at baseline, week 8, and week 16 using the PSS-10. The PSS is a 10-item self-report inventory that assesses the degree to which individuals have felt stressed during the past month [106]. The PSS is a widely used measure of self-reported stress that has demonstrated acceptable validity and reliability in previous research [107]. We will also assess anxiety symptoms at baseline, week 8, and week 16 using the Hospital Anxiety and Depression Scale. The Hospital Anxiety and Depression Scale is a 14-item self-report inventory that assesses the severity of anxiety and depressive symptoms during the past week [108]. For our purposes, we will only be focusing on the anxiety subscale. Finally, we will assess posttraumatic stress disorder (PTSD) symptoms at baseline, week 8, and week 16 using the Impact of Events Scale—Revised. The Impact of Events Scale—Revised is a 22-item self-report inventory that assesses the severity of PTSD symptoms (eg, trouble sleeping, irritability, and jumpiness) over the past 7 days [109]. The instructions were modified to include PTSD symptoms resulting from specific trauma or from the ongoing COVID-19 pandemic.

Secondary Outcome: Sleep Disturbances

We will assess sleep disturbances at baseline, week 8, and week 16 using the Insomnia Severity Index (ISI). The ISI is a 7-item self-report inventory that assesses the severity of sleep problems, noticeability of sleep problems, stress resulting from sleep problems, and the perceived impact of these problems on daily functioning and quality of life [110]. The ISI is a valid and reliable measure that has demonstrated excellent internal consistency in previous research [111].

Secondary Outcome: Habit Strength

We will assess habit strength at baseline, week 8, and week 16 using the Self-Report Habit Index (SRHI). The SRHI is a brief self-report inventory that assesses the perceived habit strength (ie, automaticity) of a specific behavior, such as meditation [112]. The SRHI has been used to assess habit strength in a wide range of behaviors and has demonstrated adequate reliability in previous research [112].

Demographic Information

The following demographic information will also be collected from participants at baseline assessment: age; gender; race; Hispanic status; employment information (ie, status, hours, and work from home); annual household income; number of adults and children in the household (if any); marital status; education level; past mental health diagnosis (ie, PTSD and depression); current mental health medications (if any); self-rated physical health (5-point Likert scale); and any current chronic medical condition diagnosis (eg, high blood pressure, diabetes, and asthma).

Satisfaction

Participant satisfaction will be assessed at weeks 8 and 16. All participants will be asked to rate their overall enjoyment and satisfaction with the Calm app and the study itself, as well as their intent to continue using the app along with the app features (eg, mood tracking and session tracking) and app content (eg, daily meditations, sleep meditations, and soundscapes) that they found most helpful for maintaining their daily meditation practice. Then, participants will be asked specific questions regarding their chosen meditation anchor, such as how easy it was to select and use their chosen anchor during the intervention, their intent to continue using their meditation anchor, and the helpfulness of the anchoring plan in maintaining their meditation practice. Participants in the intervention groups will also be asked questions related to the incentives, including how easy it was to understand the incentive process; how easy it was to earn incentives; if they liked the incentive options, how motivated they were by the incentives; and if there was anything that would have motivated them more. This information will provide helpful qualitative data that can be used to improve future adherence studies, including the types of anchoring strategies that are most successful in establishing a meditation habit and what motivates people to establish and maintain an app-based meditation habit.

Attrition will be assessed at all stages of the study: (1) enrolled but did not complete the baseline assessment, (2) completed baseline assessment but lost to follow-up during the 8-week intervention period (ie, did not complete week 8 assessment), and (3) completed the 8-week assessment but lost to follow-up during the 8-week postintervention observation period (ie, did not complete the week 16 assessment).

Intervention

Randomization and Baseline

This randomized controlled trial aims to test the effectiveness of different strategies on adherence to the daily ≥10-minute meditation prescription via a mindfulness meditation app. Note that the meditation prescription and the anchoring plan are not interventions; rather, the interventions are the additional supports that are provided for the anchoring plan to establish an app-based meditation habit. After randomization, all participants will complete a web-based baseline survey to collect additional demographic information and to assess the baseline levels of the secondary outcome measures listed in the previous sections.

Introductory Video

Immediately following the web-based surveys, participants will then watch 1 of 3 brief 5-minute introductory videos that will vary slightly based on their experimental conditions. All 3 videos will contain background information on the benefits of mindfulness meditation and habit formation (eg, previous research and theory); a sample anchoring plan (eg, “After [insert behavior here], I will meditate for 10 minutes”); a study timeline (ie, baseline assessment, 8-week intervention period, follow-up assessment, 8-week postintervention period, and second follow-up assessment); and compensation information for completing the 3 web-based surveys (US $20 gift card). In addition to these foundation elements, participants in the NTCI and TCI groups will be told in the video that they are eligible for incentives every 2 weeks during the 8-week intervention period conditional on either meditating at any time (NTCIs) or meditating using their anchoring plan (TCIs). The video for the usual Calm condition will only include the foundation elements mentioned previously, with no mention of incentives or personalized feedback messages. Information in all 3 videos

XSL•FO
RenderX

will be presented by a member of the study team using both written and spoken texts. Participants in the NTCI and TCI groups will also receive instructions regarding prize eligibility as detailed in the *Study Design* section.

Anchoring Plan Worksheet

After watching the introductory video, participants will complete a video comprehension quiz to ensure that they understand the study timeline and requirements. Participants must score 100% on the quiz to move on with the study. Then, all participants will be asked to complete a web-based worksheet to help them develop a meditation anchoring plan. This worksheet will first ask participants to fill out a basic implementation intention plan (ie, "After _____, I will meditate for 10 minutes") based around a routine behavior (ie, their anchor) they perform in the morning, given that previous research suggests the morning habits are easiest to form [31]. Next, participants will be instructed to add additional details to their anchoring plan to make it more specific (eg, anchor timing and anchor location), as generic plans may not be as effective as plans that specifically outline when and where this behavior will occur. After finalizing their anchoring plan, the participants will be emailed a copy of their anchoring plan for their records.

Intervention, Postintervention, and Follow-up Surveys

The 8-week intervention period will begin once the participants complete the baseline assessment and anchoring plan worksheet. All the participants will be asked to meditate for ≥10 minutes every day during the intervention period. Every 2 weeks, participant use data will be checked to determine incentive eligibility for participants in the NTCI and TCI groups. Every week, all the participants will also receive a text message from the study team as a reminder to continue meditating using their chosen anchor. In addition, participants in the BM group will receive a message focused on self-monitoring of their meditation behavior every 2 weeks that informs participants of the number of ≥10-minute meditations they completed during the past 2 weeks. Participants in the self-monitoring of outcomes of behavior messages groups will receive a message focused on self-monitoring of outcomes of their meditation behavior (ie, mood tracking) every 2 weeks that encourages the participants to keep track of their mood using the "How Are You Feeling?" feature in the Calm app. After 8 weeks, participants will be emailed a link to complete the first of the 2 follow-up surveys. These surveys will assess any improvements in the secondary outcome measures assessed at baseline, as well as their satisfaction with both the Calm app itself and the interventions. Following the completion of the 8-week intervention period and the week-8 follow-up survey, participants will be asked to continue using their anchors to strengthen their meditation habits during the 8-week postintervention observation period. However, unlike in the intervention period, participants in all intervention groups will no longer receive weekly reminders, biweekly self-monitoring messages, or incentives during the postintervention period. Participants will then be contacted at week 16 to complete the second follow-up survey to assess changes in the secondary outcome measures at week 16.

Data Analysis Plan

To examine our specific aims, statistical analyses comparing group-level differences in the primary and secondary outcome measures will be performed. First, an analysis of covariance framework will be used to test for group-level differences in each primary and secondary outcome, controlling for participant characteristics that are found to significantly differ between study groups at baseline. For analyses of dichotomous outcomes, such as meditation regularity at weeks 8 and 16, a nonparametric McNemar test and multiple logistic regression that controls for additional participant-level covariates will be used to assess study group differences. In addition to static comparisons of group means for each outcome, the longitudinal nature of the app use data will be leveraged by using repeated measures and time-series techniques. Specifically, a linear mixed model with repeated observations will be fitted using maximum likelihood through "xtmixed" in the software package Stata (StataCorp) to study group-level temporal dynamics in the primary and secondary outcomes.

To estimate the impact of our intervention on our static primary outcomes of meditation regularity and anchoring plan regularity at weeks 8 and 16, we will use logistic regressions with the following specifications.

Our main unadjusted model will have the following form:

$$\Pr(y_i) = \exp(\beta_0 + \beta_1 T + \beta_2 T2 + \beta_3 T3 + \beta_4 T4 + \varepsilon_i) \quad \textbf{(1)}$$

Our main adjusted model has the following form:

$$\Pr(y_i) = \exp(\beta_0 + \beta_1 T + \beta_2 T2 + \beta_3 T3 + \beta_4 T4 + X_i\beta_5 + \varepsilon_i) \quad \textbf{(2)}$$

where y_i is a binary variable equal to 1 if individual i completed ≥10 minutes of meditation for ≥4 days during week 8 of the study; T1 is an indicator for treatment group 1 (that receives self-monitoring behavior messages and NTCIs); T2 is an indicator for treatment group 2 (that receives self-monitoring outcome messages and NTCIs); T3 is an indicator for treatment group 3 (that receives self-monitoring behavior messages and TCIs); T4 is an indicator for treatment group 4 (that receives self-monitoring outcome messages and TCIs); and $_i$ is the idiosyncratic error. The coefficients of interest are β_1 through β_2. Equation 2 has the term $X_i\beta_5$, which includes a vector of the following observable participant characteristics (X_i): age, education, sex, race, ethnicity, household income, self-reported mental and physical health, baseline meditation habit strength, intrinsic motivation for meditation, and measures of time and risk preferences and the respective coefficients (β_5). For more information on our data analysis plan, please see Multimedia Appendix 1.

In addition, we will investigate potential intervention moderators and mediators. Specifically, we will use the same regression models specified earlier in this section and include additional interaction terms between each study group indicator variable and a single moderating variable measured at baseline. Significant coefficients estimated for these interaction terms will be used to identify the moderating effects of participants' baseline characteristics, such as age, gender, race, and

XSL•FO
RenderX

employment information. In addition, we will separately examine the mediating effects of anchoring plan adherence and habit strength at the end of the intervention on the maintenance of mediation following the procedures outlined by Judd and Kenny [113]. We will first regress meditation measured in week 16 on indicator variables for each study group and then regress meditation in week 16 on indicator variables for each study group as well as anchoring plan adherence measured over the first 8 weeks (ie, during the intervention). The mediating effect of anchoring plan adherence (our third hypothesis) will be calculated by subtracting the coefficients estimated in the first regression from those in the second regression. We will also use these procedures to investigate the mediating effect of habit strength measured at week 8 (ie, immediately after the intervention). We will also use a modern mediation analysis technique that allows for additional covariates when estimating the direct and indirect treatment effects in the equations described earlier [114].

Ethics Approval

This research was reviewed and approved by the Arizona State University Institutional Review Board (STUDY00014710) on 11/9/2021. This study has also been registered at ClinicalTrials.gov NCT05217602. Participants will provide consent electronically and will be emailed a copy of the consent form for their records. Participants can withdraw from the study at any time without penalty and request that their data be removed from the analysis. The data collected by the research team will be stored on a password-protected cloud-based secure server. All data retrieved from the questionnaires will be deidentified (kept separate from any personal identifying information, including consent forms). The questionnaire data will only be linked to individual participants via the assigned study ID numbers. Only anonymous aggregated data regarding app use during the 8-week study and an additional 8-week postintervention observation period will be retrieved from the Calm informatics team. All the participants will be compensated US $20 in electronic gift cards for completing the 3 web-based surveys (ie, baseline, postintervention, and follow-up surveys). Participants in either the NTCI or TCI groups will also be eligible to win up to 4 incentives during the intervention period, in addition to a US $20 gift card as compensation for completing all 3 web-based surveys.

Results

Recruitment for this study was expected to occur between March 2022 and May 2022. Data collection is expected to be completed by October 2022. The results from this study will be available within 12 months of the final data collection date, which will be sometime between late 2022 and early 2023. The findings of this research will be disseminated using various methods, including peer-reviewed journals, academic conferences, and other verbal and digital communication platforms.

Discussion

Overview

Mobile meditation apps can be an effective and feasible way to deliver mindfulness meditation interventions. However, low intervention adherence over time limits the long-term potential of these apps. This study aims to address this critical issue by testing a combination of behavioral intervention strategies to determine the optimal combined strategy for establishing and maintaining meditation habits with a mobile app. To accomplish this, we have three specific aims: (1) assess study group differences in adherence to the daily meditation prescription during the 8-week intervention, (2) estimate study group differences in adherence maintenance over the 8-week postintervention observation period, and (3) investigate the role of anchoring performance during the intervention on the participants' ability to maintain their meditation app adherence during the postintervention observation period.

This study will make important contributions to mHealth and behavior change research. First, the results of this study will improve future app-based interventions by identifying the most effective strategies for establishing and maintaining adherence to a mobile app, adding to the sparse body of literature on adherence to app-based interventions, particularly those for mindfulness meditation. Current research on app-based interventions is limited by poor adherence, and improving adherence is necessary to understand the full potential of app-based interventions for promoting health behavior change as well as the associated benefits from these health apps. This is particularly important for health behaviors such as mindfulness meditation, which requires maintaining a long-term practice to experience the maximum physical and mental health benefits. Second, this study will assess adherence by using objective app use data. Previous studies examining adherence in app-based interventions have found significant discrepancies between self-reported (eg, retrospective, daily diaries) and objective measures of adherence, as self-report measures are subject to more biases such as recall or response bias [115]. Testing strategies for maintaining objective measures of app-based intervention adherence will provide more rigorous evidence that will help to better understand the habit formation process in this setting. Finally, this research will make important contributions to the behavior change literature, in which existing interventions in the psychology and behavioral economics literature have largely been unsuccessful in maintaining behavior changes after interventions. By combining the anchoring habit formation strategy from psychology with behavioral economics–based incentives (ie, in-kind prizes awarded for short-term behaviors), this study will provide important evidence for a novel combined approach that may be more successful in maintaining behavior changes and will help improve our understanding of the habit formation process.

Several potential limitations of this study must also be addressed. First, the 8-week intervention period may not be sufficient to develop a strong and long-lasting meditation habit. Similarly, the 8-week intervention and 8-week postintervention periods may not be long enough to adequately assess our

XSL•FO
RenderX

primary and secondary outcomes. Future research should plan to assess adherence and our secondary outcomes over longer periods to better understand the long-term effectiveness of these strategies. Another limitation to consider is the likely demographic characteristics of the recruited sample. Previous studies using Calm have reported samples that consisted of predominantly individuals who are White, female, and have bachelor's degrees or higher qualification [116,117]. As a result, we anticipate having difficulty recruiting a diverse sample, which will limit the generalizability of our findings. In addition, studying the meditation app behavior of paid subscribers to a meditation app may not be generalizable to the general population. We plan to address this limitation by using a stratified randomization method to ensure that each study group has equal representation across racial and ethnic groups. Finally, it is possible that the incentives (ie, Calm prizes) provided to the NTCI and TCI groups during the intervention period may not be incentivizing to participants. We will test this by comparing the NTCI and TCI groups with the control group and by examining which items were most commonly chosen by eligible participants, and we will publish the results of these analyses to help determine the magnitude of incentives in future incentive-based meditation studies.

Conclusions

This study will contribute to an important gap in the literature by testing novel intervention approaches for establishing and maintaining adherence to app-based mindfulness meditation. We are using unique combinations of previously established intervention strategies from the psychology and behavioral economics literature to help participants better maintain adherence to an effective dose of meditation that can reduce stress. If successful, this study will identify an accessible and scalable stress self-management intervention to combat the ongoing stress epidemic in the United States.

Conflicts of Interest

CS was a member of the Scientific Advisory Board at Calm during the implementation of the survey but no longer receives any financial or nonfinancial compensation from Calm. At the time this research was completed, JH conducted investigator-initiated research and used the Calm app to deliver mindfulness meditation interventions. Calm financially supported her research with a postdoctoral scholar and 2 research coordinators (contractors). The roles of these persons were to help JH with her investigator-initiated research using the Calm app. JH consulted for Calm as the Director of Science and Director of the Scientific Advisory Board at Calm. Her role was to ensure the quality of Calm's science and she had no specific obligations to the company. JH is no longer working with Calm.

Abstract

Background: Maintaining a sufficiently high systolic blood pressure is essential for free flap perfusion after microsurgical breast reconstruction. Yet, many women undergoing these procedures have low postoperative systolic blood pressure. Intravenous volume administration or vasopressors may be needed to maintain systolic blood pressure above a predefined threshold. However, excessive volume administration may lead to volume overload and flap stasis, and the postoperative use of vasopressors may be limited depending on institutional standards. Additional nonpharmacological measures to raise blood pressure might be beneficial. Evidence suggests that the Red Bull energy drink could raise blood pressure. It has been shown to increase systolic and diastolic blood pressure in healthy volunteers and athletes.

Objective: The primary objective of this study is to determine the difference in systolic blood pressure between an intervention group receiving Red Bull and a control group receiving still water after microsurgical breast reconstruction. Secondary objectives include postoperative heart rate, 24-hour fluid balance, pain level, or necessity for revision surgery due to flap complications.

Methods: The Red Bull study is a prospective, multicenter randomized controlled trial comparing the effect of postoperative ingestion of Red Bull energy drink against still water in female patients undergoing unilateral microsurgical breast reconstruction. A total of 250 mL of Red Bull (intervention group) or 250 mL of still water (control group) will be administered to the study participants 2 hours postoperatively as well as for breakfast and lunch on postoperative day 1, amounting to a total volume of 750 mL per 24 hours. Female patients between 18 and 70 years of age undergoing unilateral microsurgical breast reconstruction will be included. Exclusion criteria are a history of arterial hypertension, cardiac rhythm disorder, diabetes mellitus, gastric or duodenal ulcer, thyroid disease, and current use of antihypertensive or antiarrhythmic drugs or thyroid hormones, as well as intolerance to Red Bull.

Results: Recruitment for the study started in June 2020 and was completed in December 2022. There is evidence that the Red Bull energy drink increases blood pressure in healthy volunteers and athletes. We hypothesize that postoperative ingestion of Red Bull will increase systolic blood pressure in women after microsurgical breast reconstruction. Red Bull could hence be used as a nonpharmacological adjunct to vasopressors or volume administration in women with hypotensive blood pressure after microsurgical breast reconstruction.

Conclusions: This paper describes the Red Bull study trial protocol and analysis plan. The information will increase the transparency of the data analysis for the Red Bull study.

Introduction

Overview

Maintaining a sufficiently high systolic blood pressure is vital for free flap perfusion after microsurgical breast reconstruction. However, many women undergoing microsurgical breast reconstruction have low systolic blood pressure postoperatively. Often, intravenous volume administration or vasopressors are needed to maintain systolic blood pressure above 100 mm Hg. Yet, intravenous volume administration may lead to volume overload and flap stasis, and the use of vasopressors in the postoperative setting may be limited depending on institutional policies. Additional nonpharmacological measures to guarantee adequate postoperative perfusion pressure would be beneficial.

Clinical Evidence for Red Bull Energy Drink

Red Bull energy drink has shown varying effects on the hemodynamic profile and pain perception in clinical studies performed on healthy participants and athletes [1-3]. A randomized crossover study showed a negative hemodynamic profile in response to Red Bull [2]. Participants who ingested 355 mL of Red Bull showed increased systolic and diastolic blood pressure, increased heart rate, and cardiac output without significantly reduced endothelial function compared with a control group who received 355 mL of tap water. This was reproduced in another randomized crossover study that further explored the combined effect of Red Bull and mental stress on cardiovascular parameters [1]. The combination of Red Bull and mental stress leads to an additional increase in systolic and diastolic blood pressure and heart rate, suggesting a cumulative effect.

Energy drinks have shown varying effects on endothelial function [4,5]. In a case report, a reduced reactive hyperemia index was observed after ingestion of Monster energy drink, suggesting worsened endothelial function [4]. In contrast, Red Bull improved endothelial function in a prospective study involving 6 volunteers [5]. Ingestion of 250 mL of Red Bull significantly increased endothelial function as measured by the reactive hyperemia index. In the same study, coffee containing comparable amounts of caffeine did not affect endothelial function. These results suggest that ingredients other than caffeine account for the vasodilatory effect.

Considering the mild diuretic effect of caffeine, Red Bull energy drink may increase urine formation rate and decrease urine specific gravity. Although urinary output increased with caffeine and Red Bull energy drink in 1 study [6], this trend could not be observed elsewhere [7].

Red Bull energy drink may furthermore increase pain tolerance [7]. Levels of pain after a cold pressor test were measured in participants before and after consumption of 250 mL of Red Bull. All participants reported a decreased perception of pain directly following Red Bull consumption.

Interventional Product

Red Bull energy drink was first introduced in Austria in 1987 and launched in Switzerland in 1994. It is among the most popular energy drinks with over 6 billion cans being sold annually worldwide [8]. A can of 250 mL Red Bull energy drink contains 80 mg caffeine, 1 g taurine, 240 mg glucuronolactone, 27 g carbohydrates as well as water, sodium citrate, vitamins (B3, B5, B6, and B12), flavoring, and coloring agents [9]. This corresponds to total calorie content of 194 kJ (46 kcal) per 100 mL [8].

Despite anecdotal reports that linked Red Bull consumption with ventricular tachycardia and symptoms of cardiovascular disease, limited daily consumption of 500 mL of Red Bull appears safe [7,9]. When investigated in clinical studies no deleterious effects of Red Bull energy drink on cardiovascular function have been found [10]. Any adverse effects after excessive consumption are most likely due to the accumulation of caffeine, which is known to cause nervousness, anxiety, tremor, insomnia, tachycardia, arrhythmia, and nausea with ingestion exceeding 200 mg/day [11,12]. The amounts of taurine contained in Red Bull are far below the threshold to cause adverse effects [11].

Caffeine is an adenosine receptor antagonist with stimulating properties on the central nervous system It is known to increase blood pressure and peripheral vascular resistance through sympathetic stimulation [13]. Taurine is a sulfur-containing amino acid that constitutes the most abundant intracellular amino acid in humans [14]. Taurine seems to modulate skeletal muscle contractile function and possesses antiarrhythmic, inotropic, and chronotropic properties [15]. Glucuronolactone occurs naturally in small amounts within the body. Little data exists on its function in humans [9]. The amount of sugar provided in a can of 250 mL Red Bull energy drink is 27 g, which corresponds to 6.5 teaspoons of sugar [9]. Consuming moderately concentrated carbohydrate solutions (5%-8%) has been shown to promote prolonged exercise performance without causing adverse effects [15].

XSL•FO
RenderX

Dose Rationale

The authors selected a daily administration of 250-500 mL of Red Bull in the study. Most investigators studied the effect of Red Bull after ingestion of 250, 355, or 500 mL. When ingested in standard amounts, Red Bull energy drink is a safe beverage without notable side effects [7,9].

Risks

Daily oral administration of 500 mL of Red Bull has proven safe, and any side effects after consumption exceeding 500 mL daily have been linked to caffeine [9]. These include nervousness, anxiety, tremor, insomnia, tachycardia, arrhythmia, and nausea. To minimize adverse events, participants with allergies or intolerance to any component of Red Bull will be excluded from the study.

Study Aim

The authors prospectively study the effect of postoperative ingestion of Red Bull energy drink on perfusion-related variables and patient recovery after microsurgical breast reconstruction. To our knowledge, there are no competing trials.

Objectives

This study aims to assess perfusion-related variables, postoperative levels of pain, type of postoperative complications, operative reexploration rate due to complications, and total duration of hospital stay in patients undergoing autologous microsurgical breast reconstruction with postoperative ingestion of Red Bull Energy drink.

Primary Objective

The primary objective is to assess the difference in systolic blood pressure (mm Hg) between the intervention group and the control group at 15, 30, 45, 60, 75, 90, 105, and 120 minutes after each of 3 Red Bull (intervention group) or water (control group) applications.

Secondary Objective

The secondary objective is to document and assess the following variables in the intervention group and the control group:

1. Diastolic and mean arterial blood pressure (mm Hg) at 15, 30, 45, 60, 75, 90, 105, and 120 minutes after each of 3 Red Bull (intervention group) or water (control group) applications.
2. Postoperative heart rate (1/min) at 15, 30, 45, 60, 75, 90, 105, and 120 minutes after each of 3 Red Bull (intervention group) or water (control group) applications.
3. Postoperative urinary output (mL) during the first postoperative 24 hours.
4. Intraoperative and postoperative fluid administration (mL) until 24 hours after surgery.
5. Intraoperative and postoperative administration of vasoactive drugs (mg) until 24 hours after surgery.
6. Postoperative pain (numeric rating scale [NRS]) during the first postoperative 24 hours.
7. Postoperative administration of opioid analgesics (analgesic in mg).
8. Postoperative administration of nonopioid analgesics (analgesic in mg).
9. Postoperative administration of benzodiazepines (mg).
10. Rate of operative reexplorations during the first hospitalization (%).
11. Flap loss (%).
12. Duration of hospital stay (number of nights spent at hospital).
13. Wound healing 4 weeks after surgery (photo documentation).

Safety Objective

Notable adverse events of Red Bull energy drink in this population are as follows: nervousness, nausea, anxiety, tremor, insomnia, arrhythmia, need for revision surgery, and flap loss.

Methods

Overview

This is an open-label, multicenter, prospective, and randomized controlled trial comprising a cohort of 100 patients. Patient selection and inclusion as well as the anesthetic visit will occur preoperatively in an outpatient clinic. During hospitalization, microsurgical breast reconstruction will be performed under general anesthesia by JF, AML, or DB. Additionally, oral ingestion of Red Bull energy drink (intervention group) or still water (control group) will occur 2 hours after surgery and on a postoperative day 1 for breakfast and for lunch. Finally, wound healing and scarring will be assessed at the 4-week follow-up in our clinic using photo documentation.

Participants are expected to participate from the signing of the informed consent form until the 4-week follow-up visit. All patients enrolled prospectively in the trial will receive a Red Bull energy drink or still water. Blinding or masking is not feasible.

Study Population

The study population will be women between 18 and 70 years of age undergoing unilateral microsurgical breast reconstruction by JF, AML, or DB at 2 institutions.

Inclusion and Exclusion Criteria

Textbox 1 shows the inclusion and exclusion criteria.

As a standard of care, all patients are asked to perform a check-up by their general practitioner (GP) within 2-4 weeks before the microsurgical procedure. Their GP fills in a standardized form provided by the Institute of Anesthesiology, from which all inclusion and exclusion criteria can be drawn. Additionally, the GP performs an electrocardiogram and a blood test (complete blood count, electrolytes, creatinine, and international normalized ratio or Quick) for the patient and sends the result to the institute of anesthesiology at the respective clinic.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Female patients between 18 and 70 years of age.
- Ability to give written informed consent before participation in the study.
- Ability to comply with the requirements and restrictions listed in the consent form.

Exclusion criteria

- History of arterial hypertension.
- History of cardiac rhythm disorder.
- History of diabetes mellitus.
- History of gastric or duodenal ulcer.
- History of hyperthyroidism or hypothyroidism.
- Current use of antihypertensive drugs, antiarrhythmic drugs, and thyroid hormones.
- Allergy or intolerance to the component of Red Bull energy drink.
- Not fulfilling inclusion criteria.

Intervention

All consecutive female patients receiving unilateral autologous microsurgical breast reconstruction will be administered a total of either 750 mL Red Bull energy drink (intervention group) or 750 mL of still water (control group) at predefined intervals. The first dose of 250 mL of Red Bull energy drink or still water will be given 2 hours after surgery in the postanesthesia care unit. The following doses will be given on postoperative day 1 at 8 AM for breakfast (250 mL) and at 12 PM for lunch (250 mL). Full consumption of the study drink will be verified by a nurse. The study will be carried out at the 2 centers where JF, AML, and DB have been accredited: Klinik Pyramide am See, Zurich, Switzerland and Klinik Hirslanden, Zurich, Switzerland. The perioperative protocols have been standardized at both institutions and standard operating procedures have been implemented.

The systolic and diastolic blood pressure as well as pulse will be measured noninvasively using a 24-hour ambulatory blood pressure monitor (Tonoport VI, Anandic Medical Systems AG) during the first postoperative 24 hours. The device will be applied to the participant's arm upon their arrival in the postanesthesia care unit and remain in place for 24 hours. Upon completion of these 24 hours, the readings will be downloaded on the study computer by the study personnel, using the software provided by Anandic Medical Systems AG.

Total fluid administered intraoperatively and postoperatively as well as intraoperative and postoperative administration of vasoactive drugs will be recorded. The daily urinary output will be measured 24 hours after surgery. Pain levels will be measured on NRS with values ranging from 0 to 10. The rate of operative reexplorations, flap loss, and total length of primary hospital stay will be recorded. Wound healing and scarring will be assessed 1 month after surgery in our clinic and documented photographically.

The variables obtained from the intervention group receiving Red Bull energy drink postoperatively will be compared with the corresponding variables of patients in the control group receiving the same amount of still water.

Randomization and Blinding

Randomization is undertaken with equal allocation to each study group (Red Bull:still water=1:1) using a computed code. Blinding or masking is not feasible.

Other Measures of Minimizing Bias

We will measure the systolic and diastolic blood pressure using ambulatory 24-hour blood pressure monitors (Tonoport VI, Anandic Medical Systems AG) to ensure comparable measurements (same side of arm and same cuff) and reduce intermeasurer variability. All patients will remain in bed during the first 12 hours postoperatively and will have a urinary catheter during this period. This further reduces changes in blood pressure not related to the study intervention. Additionally, all patients entering hospital preoperatively will have fasted for 6 hours (solids) and 2 hours (liquids). Also, oral fluid and food intake during the first 24 hours after a microsurgical procedure is typically low among all patients to ensure that patients could be taken back to theater in a timely manner should flap complications occur. The preoperative regular consumption of caffeinated products and the consumption of additional caffeinated products during the hospital stay will be recorded and incorporated in the final analysis. If a patient requires additional vasopressors postoperatively, this will be documented and incorporated in the final analysis.

Outcomes

Primary Outcome

Difference in systolic blood pressure between the intervention group and control group at 15, 30, 45, 60, 75, 90, 105, and 120 minutes after each of 3 Red Bull (intervention group) or water (control group) ingestions as measured by the ambulatory blood pressure monitoring device.

XSL•FO
RenderX

Secondary Outcomes

Difference in the following postoperative variables between participants with or without postoperative intake of Red Bull energy drink:

- Diastolic and mean arterial blood pressure at 15, 30, 45, 60, 75, 90, 105, and 120 minutes after each of 3 Red Bull (intervention group) or water (control group) ingestions as measured by the ambulatory blood pressure monitoring device.
- Postoperative heart rate (1/min) at 15, 30, 45, 60, 75, 90, 105, and 120 minutes after each of 3 Red Bull (intervention group) or water (control group) applications.
- Postoperative urinary output (mL) during the first postoperative 24 hours.
- Intraoperative and postoperative fluid administration (mL) until 24 hours after surgery.
- Intraoperative and postoperative administration of vasoactive drugs (mL) until 24 hours after surgery.
- Postoperative pain (NRS) during the first postoperative 24 hours.
- Rate of operative reexplorations during the first hospitalization (%): flap complications (%) and flap loss (%); total duration of hospital stay (number of nights spent at hospital); wound healing 4 weeks after surgery (photo documentation).

Other Outcomes of Interest

Patient- and tumor-related data, such as age, BMI (size and weight), tobacco use; diabetes mellitus, indication for surgery (oncologic or prophylactic), neoadjuvant chemotherapy, previous irradiation, side and type of flap, flap weight, and ischemia time will be assessed perioperatively or collected from the medical history.

Harm Outcomes

Differences in the incidence of notable adverse events between both groups. Adverse events include nervousness, nausea, anxiety, tremor, insomnia, arrhythmia, need for revision surgery, and flap loss.

Frequency and Duration of Follow-up

The schedule of trial enrolment, interventions, and assessments are presented in Table 1. Following surgery, the study intervention will take place in the recovery room and on the ward of the 2 study sites. The follow-up ends 4 weeks post operation in clinic.

[d]NRS: numeric rating scale.

Recruitment

Participants are recruited for the study in outpatient clinic. All patients undergoing elective microsurgical breast reconstruction will be screened. Patients who consent to participate in the study are randomized at the moment of surgery planning. No compensation or payment is given to the study participants.

Data Collection

Data are collected from clinical proformas, clinical notes, and study-specific forms and then entered onto a Excel (Microsoft Corp) file. The data collection form is provided in the Multimedia Appendix 1. The database has been programed by NES and MM. No identifiable data will be entered into the database. Participants will be identified using a unique code and initials. To avoid unauthorized people accidentally or deliberately perform changes, copies, or deletions of the analyzed data in Microsoft Excel, the following precautions are planned: after each relevant processing step, the new data version is saved and is not allowed to be changed. Such a new

XSL•FO
RenderX

data version will be converted into a secured document (PDF file).

Sample Size

The following assumptions estimated from literature and clinical experience:

- Mean systolic blood pressure (mm Hg): We assume the same SDs (ie, 15) for both groups and the correlation coefficient among repeated measures to be 0.7. If we assume no differences in time in the control group (mean 115 mm Hg) and assume the difference between the intervention group and the control group to be about 10 mm Hg, the required sample size would be 27 per group.
- Heart rate (1/min): We assume the same SDs (10) for both groups and the correlation among repeated measures to be 0.7. If we assume no differences in time in the control group (mean 80/min) and assume the difference between the intervention group and the control group to be 5/min, the required sample size would be 46 per group.
- Vasoactive drug Ephedrine (mg): We assume the mean drug dose in the control group to be 63 and the mean drug dose in the intervention group to be 48. Assuming equal SDs (ie, 25) we get 45 per group.

The predefined parameters include a significance level (α level) of .05 and power (1-β) of 0.8.

We calculated the patients needed to be included using the application STATA (version 15.1; StataCorp, 2017; Stata Statistical Software: Release 15) and G*Power (version 3.1.9.4—a program written by Franz Faul, Universität Kiel). Considering the different calculations and accounting for potential missing data or dropouts, 50 patients per group will be included, leading to a total of 100 patients.

Statistical Methods

We are planning to measure mean systolic blood pressure at 8 time points. For this, the right statistical model is a mixed ANOVA where the group is an independent (unpaired) factor, and the time is a dependent (paired) factor. The comparison of drug intake between the Red Bull group and the control group will be performed by student *t* test for independent data (assuming data will follow a normal distribution). In case data will not follow a normal distribution, an alternative nonparametric test will be used (Mann-Whitney *U* test).

Analysis Plan

As the null hypothesis (H0), we assume that mean systolic blood pressure from baseline to 120 minutes post drinking does not differ between the 2 groups. The analysis will be conducted by a senior statistician (MM) in accordance with the above mentioned statistical methods.

Analysis of Harm Outcomes

The frequency of adverse events and the number of patients experiencing events will be tabulated by relation to the study intervention (ie, as adverse reaction, serious adverse event, or serious adverse reaction) and by study group. Nonserious adverse events unrelated to the intervention are recorded in the medical notes only.

Handling of Missing Data and Dropouts

If vital data relevant for the calculation of the primary and secondary end point are missing (ie, blood pressure recordings) patients will be excluded from the participant list. Dropouts will be replaced by consecutive patients.

Ethics Approval

Ethics approval was granted from the Cantonal Research Committee, Switzerland (KEK-ZH 2020-00493). Patients receive an information sheet and provide informed consent before screening to participate in study-specific procedures. The study will be carried out in accordance with the protocol and with principles enunciated in the current version of the Declaration of Helsinki, the guidelines of Good Clinical Practice issued by ICH, the Swiss Law and Swiss regulatory authority's requirements.

Compensation

Participants will not be compensated for their participation in this scientific research project.

Publication and Dissemination Policy

After the statistical analysis of this trial, the principal investigator will make every endeavor to publish the data in a medical journal. Participants will be informed about the outcome of the study once the trial results have been published.

Results

Recruitment of the study participants started in June 2020 and was completed in December 2022. As described previously, there is evidence that Red Bull energy drink increases blood pressure in healthy volunteers and athletes [1,2]. We hypothesize that systolic blood pressure will be higher after each drink ingestion in the intervention group receiving Red Bull compared with the control group receiving still water. Red Bull could hence be used as a nonpharmacological adjunct to vasopressors or volume administration after microsurgical breast reconstruction. It could be particularly useful in settings where the postoperative use of vasopressors is limited.

Discussion

The Red Bull study is a multicenter randomized controlled trial that will explore the effect of Red Bull energy drink intake on perfusion-related variables and flap outcome after microsurgical breast reconstruction. This paper describes the study protocol and statistical analysis plan. The trial sponsor is Plastic Surgery Group. Recruitment started on June 1, 2020, and completed in December 2022. Database lock and data extraction for analysis were carried out in February 2023 when all randomized patients completed the surgical procedure and follow-up period.

There is evidence that the Red Bull energy drink increases blood pressure in healthy volunteers and athletes [1,2]. We hypothesize that Red Bull will increase systolic blood pressure in women after microsurgical breast reconstruction. Red Bull could hence be used as a nonpharmacological adjunct to vasopressors or volume administration in women with hypotension after microsurgical breast reconstruction.

XSL•FO
RenderX

Strengths and Limitations

This trial has some strengths. This is the first trial assessing the influence of Red Bull on perfusion-related variables after surgery. To minimize adverse events and limit premature dropout from the study, participants with allergies or intolerance to any component of Red Bull will be excluded from the study. Also, diabetes mellitus is considered an exclusion criterion. Red Bull contains 27.5 g of sugar per 250 mL. Patients with diabetes mellitus might require the intake of sugar-free Red Bull, which could, however, be associated with a different hemodynamic pathway [16]. Furthermore, patients with thyroid disease or patients requiring the intake of thyroid hormones will be excluded from this study as the intake of Red Bull was associated with an increased heart rate in a previous study [2]. This trial also has some limitations. Blood pressure is measured noninvasively, which might not be as precise as arterial blood pressure monitoring.

After the statistical analysis of this trial, the principal investigator will make every endeavor to publish the data in a medical journal. Participants will be informed about the outcome of the study once the trial results have been published. The reporting of results from the outlined statistical analysis will comply with the consolidated standards of reporting trials protocol.

Acknowledgments

The authors would like to thank Noël M Speck, BSc for designing the randomization code. This study will be entirely financed by Plastic Surgery Group.

Data Availability

The protocol and statistical analysis plan can be obtained by contacting the corresponding author. The data will be the property of the principal investigator. The study team will retain the exclusive use of the trial data until publication of major outputs has been completed.

Authors' Contributions

NES contributed to the study design, is responsible for acquisition of the data and drafted the manuscript. MM developed the statistical analysis plan. KD contributed to the study design and designed the perioperative anesthetic regimen. DB assists with the acquisition of data. AML contributed to the study design and assists with the acquisition of data. JF is the principal investigator; he conceived the study and contributed to the study design. All authors contributed to the writeup of the protocol and statistical analysis plan for publication, approved the final version to be published and agreed to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: Many patients experience pain in the intensive care unit (ICU) despite receiving pain medication. Research has shown that music can help reduce pain. Music interventions studied so far have not used music streaming to generate playlists based on patient preferences while incorporating recommended tempo and duration. Previous research has focused on postoperative ICU patients able to self-report, which is underrepresentative of the ICU population that might benefit from a music intervention for pain management. We developed a new patient-oriented music intervention (POMI) that incorporates features based on theoretical, empirical, and experiential data intended to be used in the ICU. Such a music intervention should consider the expertise of ICU patients, family members, and nursing staff, as well as the practicality of the intervention when used in practice.

Objective: The primary objectives of this study are to (1) evaluate the acceptability and feasibility of the POMI to reduce pain in ICU patients and (2) evaluate the feasibility of conducting a crossover pilot randomized controlled trial (RCT) for intervention testing in the ICU. A secondary objective is to examine the preliminary efficacy of the POMI to reduce pain in ICU patients.

Methods: A single-blind 2×2 crossover pilot RCT will be conducted. Patients will undergo 1 sequence of 2 interventions: the POMI which delivers music based on patients' preferences via headphones or music pillow for 20-30 minutes and the control intervention (headphones or pillow without music). The sequence of the interventions will be inverted with a 4-hour washout period. Timing of the interventions will be before a planned bed turning procedure. Each patient will undergo 1 session of music. Twenty-four patients will be recruited. Patients able to self-report (n=12), family members of patients unable to self-report (n=12), and nursing staff (n=12) involved in the bed turning procedure will be invited to complete a short questionnaire on the POMI acceptability. Data will be collected on the feasibility of the intervention delivery (ie, time spent creating a playlist, any issue related to headphones/pillow or music delivery, environmental noises, and intervention interruptions) and research methods (ie, number of patients screened, recruited, randomized, and included in the analysis). Pain scores will be obtained before and after intervention delivery.

Results: Recruitment and data collection began in March 2022. As of July 5, 2022, in total, 22 patients, 12 family members, and 11 nurses were recruited.

Conclusions: Methodological limitations and strengths are discussed. Study limitations include the lack of blinding for patients able to self-report. Strengths include collecting data from various sources, getting a comprehensive evaluation of the intervention, and using a crossover pilot RCT design, where participants act as their own control, thus reducing confounding factors.

Introduction

Background and Rationale

Pain is a common symptom in critically ill adults, both in patients able and unable to self-report [1]. Guidelines recommend the use of a multimodal approach to pain management to reduce opioid use and optimize pain relief [1]. Music has been suggested as a nonpharmacologic intervention in acute and chronic care settings, but little is known about its efficacy and feasibility in the intensive care unit (ICU) [2-8]. We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) to establish the efficacy of music in the adult ICU. Music interventions of 20 to 30 minutes were effective to reduce pain by almost 2 points on a 0-10 numeric rating scale (NRS) in ICU patients able to self-report [9]. However, the effect of music on pain in ICU patients unable to self-report remains unknown. In a previous review, some studies reported that family members of ICU patients expressed their interest in participating in the music selection process and in the pain management of their loved ones [10]. Therefore, music interventions for patients unable to self-report could involve the participation of family members based on their intimate knowledge of the patient and their music preferences.

Current recommendations for music interventions in postoperative patients are to provide music in the range of 60-80 beats per minute (bpm) [11]. However, most ICUs do not have access to music therapists, who have the expertise to provide personalized music within this range. Thus, there is a need to develop an easy-to-use music intervention that produces individualized music playlists with a tempo of 60-80 bpm for ICU patients. Music streaming services allow for the music selection of specific tempo ranges and should be explored as a simple means to provide a more accessible music intervention in the adult ICU.

Studies conducted thus far have mainly focused on postsurgical patients, mechanically ventilated, and able to communicate despite the fact that many patients are likely to be unable to communicate during their ICU stay [9,12,13]. Therefore, RCTs conducted until now on the effect of music to reduce pain in critically ill adults have limited generalizability to the entirety of the ICU population, despite the knowledge that all patients can experience pain and could benefit from this nonpharmacological pain management intervention.

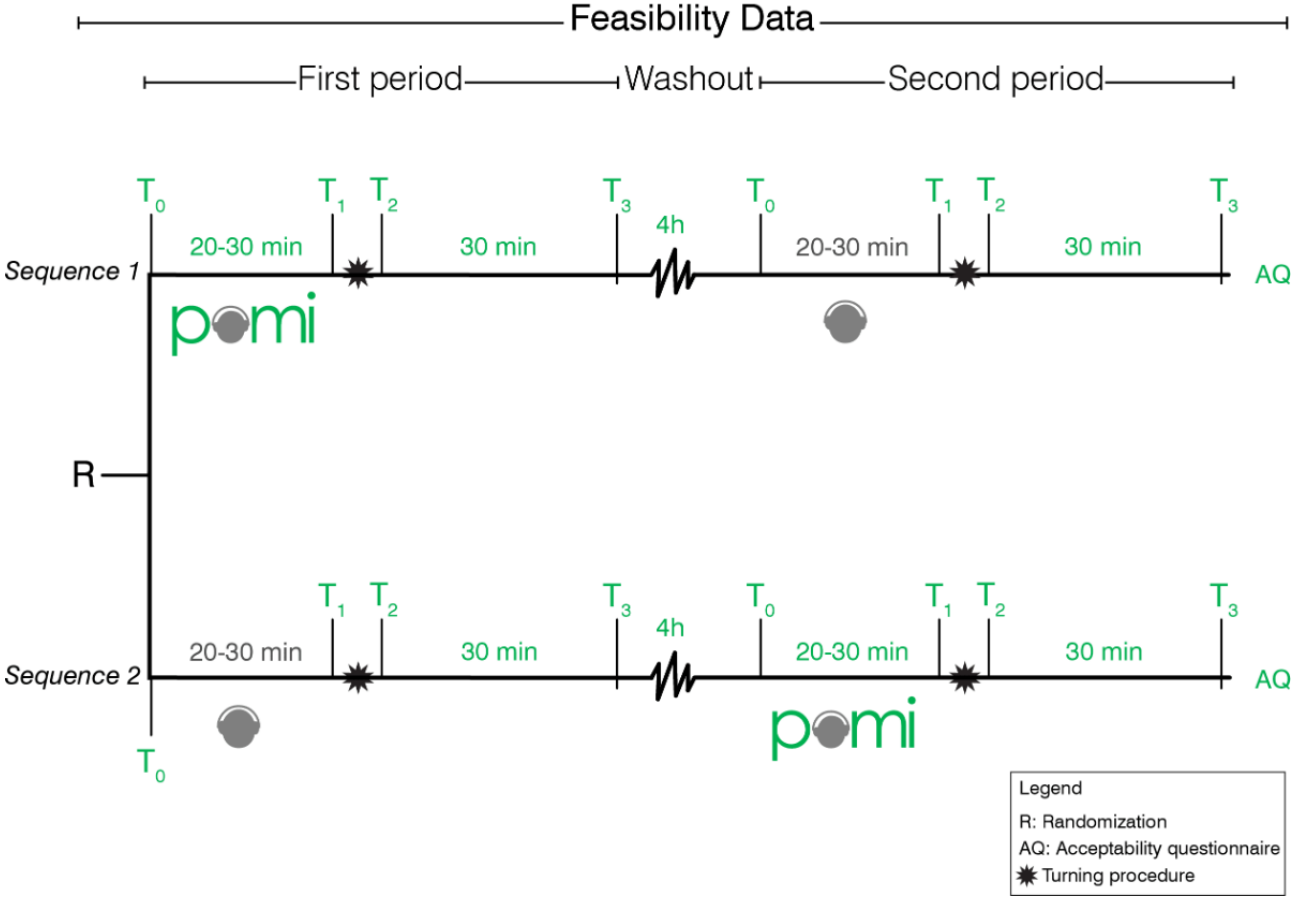
Another limitation in previous RCTs analyzed in the systematic review relates to sample size [9]. In 4 RCTs, no sample size calculation was reported [14-17]. In 3 RCTs, the sample size was calculated based on outcomes other than pain [18-20]. In another 3 studies, the calculated sample size required was not attained for various feasibility issues attributed to “slow” or “difficult” recruitment (due to time limit, refusal rate due to randomization or family visits, and narrow inclusion criteria), or withdrawal of ICU adult patient participants who did not like the music chosen for them [21-23]. In 1 study, it was unclear whether the sample size represented the number of ICU adult patient participants or the number of observations [24]. Inadequate power may explain why 11 of the 18 RCTs found a significant pain reduction while 7 did not. Therefore, there is a need to evaluate the feasibility of research methods by conducting a pilot RCT prior to evaluating the efficacy of any new music intervention in the adult ICU.

Objectives

This study aims to (1) evaluate the acceptability and feasibility of a new patient-oriented music intervention (POMI) to reduce pain in ICU patients (primary objective); (2) evaluate the feasibility of conducting a crossover pilot RCT for intervention testing in the adult ICU (primary objective); and (3) examine the preliminary efficacy of the POMI (secondary objective).

Trial Design

A single-blind 2×2 crossover pilot RCT was selected for this study protocol, where patients undergo a sequence of 2 intervention periods: the POMI and the control intervention (CTL: headphones or pillow without music), with an allocation ratio of 1:1.



Methods

Design

A single-blind 2×2 crossover pilot RCT is being conducted to evaluate the acceptability, feasibility, and preliminary efficacy of the POMI. Recruitment is planned to occur over a period of 6 months during which we aim to enroll a total of 24 patient participants. As shown in Figure 1, each participating patient is randomly assigned to 1 sequence (sequence 1 or 2) of 2 intervention periods: the POMI and the CTL (headphones or pillow without music). Patients in sequence 1 receive the POMI during the first intervention period, followed by the CTL in the second intervention period; and patients in sequence 2 receive the CTL first, followed by the POMI. Each 20-30–minute intervention period is provided before a bed turning procedure that is planned as part of the participating patient’s usual care by the nursing staff. There is a 4-hour minimum washout period between both intervention periods, with data collected during the day and evening. Data collection begins as soon as possible following recruitment, always in coordination with patient care. Therefore, the first period of data collection may occur in the daytime or in the evening.

Figure 2. Example of web-based tool screenshots for the patient-oriented music intervention.

Recruitment

Recruitment is conducted by the first author (MRL), who is introduced to the eligible patient and family member by the nurse caring for the eligible patient. If the eligible candidate is interested in hearing about the study, the student researcher meets with them at the ICU bedside to present the study, provides a copy of the informed consent form, and answers any question. The eligible candidate is then given time to think about whether they are interested in the study. ICU nursing staff (ie, nurses and orderlies) involved in the turning procedure during the study are invited individually prior to the scheduled bed turning procedure. Eligible nursing staff are given the informed consent form and can choose to participate at their convenience. Eligible criteria are detailed in Table 1.

	Type of participant			
	Patient able to self-report	Patient unable to self-report	Family member	Nursing staff
Inclusion criteria				
Is ≥18 years old	✓	✓	✓	✓
Is admitted to ICU[a]	✓	✓		
Has a loved one admitted to the ICU			✓	
Works in the ICU				✓
Is able to self-report	✓		✓	✓
Is able to listen to music as per patient or a family member for patients unable to self-report	✓	✓		
A family member is present at the bedside		✓		
Considers self to have knowledge of the patient's music preferences			✓	
Is qualified to consent to any care required by the state of health for the incapable ICU adult patient			✓	
Is present during the turning procedure at the time of the POMI[b] project data collection				✓
Exclusion criteria				
Cannot be turned	✓	✓		
Does not speak or understand French or English	✓	✓	✓	✓
Is unarousable, as defined by a score of −5 on the Richmond Agitation Sedation Scale (RASS)	✓	✓		
Is under the effects of neuromuscular blocking agent	✓	✓		

[a]ICU: intensive care unit.

[b]POMI: patient-oriented music intervention.

Participants

Sample Size

A minimal sample size of 10 participants per group is recommended in pilot studies [25,26]. Because studies with repeated measures (such as crossover designs) require more time commitment from participants (ie, multiple measurements over time), an attrition rate of approximately 15% (n=2 per group) can be anticipated, which is consistent with what has been reported in previous studies conducted in the targeted population [27,28]. To account for this, the recruited sample size was estimated to be 12 participants per group.

Patients

A sample size of 24 patients is targeted, with 12 being able to self-report and 12 unable to self-report. Patients able to self-report will be asked about their music preferences, levels of pain intensity, distress, and acceptability of the POMI.

Family Members

Family members are defined by the patient or, in the case of those unable to self-report, by their surrogates. In such cases, the family may be related or unrelated to the patient. Family members are the individuals who provide support and with whom the patient has a significant relationship [29]. A sample size of 12 family members is targeted: 1 for each patient unable to self-report. Family members will be responsible for providing information on the music preferences of their loved one unable to self-report, as well as answering questions on the POMI acceptability.

Nursing Staff

A total of 12 members of nursing staff involved in a participating patient's bed turning procedure will be recruited to answer questions on the acceptability of the POMI from their perspective.

Randomization

For the equal allocation of both groups, 24 opaque envelopes were prepared in advance by an independent member of the research team, with the use of a digitally generated list [30]. Once patients or their representatives consent to participate and agree to randomization, patient participants are categorized as either able to self-report or unable to self-report, producing 2 strata. Within each stratum, patients are randomized to either sequence 1 or sequence 2, following a permuted block randomization to ensure balance within each stratum. A block size of 4 was used (3 blocks per stratum) for a sample size of 24 ICU adult patient participants (in each block, 2 patient participants will be assigned to sequence 1 and 2 patient participants will be assigned to sequence 2, and the ordering will be random).

Patient-Oriented Music Intervention

Overview

The brief name given to this intervention is POMI (patient-oriented music intervention). In POMI, music is delivered to adult patients either via headphones (Bose, QuietComfort 35) or by a music pillow (MusiCure, hospital grade). Adult patients admitted to the ICU and able to self-report can choose the mode of delivery based on their personal preference. Adult patients admitted to the ICU and unable to self-report are given the music pillow. For patients able to self-report, individualized music playlists are created based on the patient's music preferences. For patients unable to self-report, a family member is asked about the patient's music preferences. Questions about music preferences include music genre, track title, artist name, instrumentalness, acousticness, energy, and valence, as defined by the streaming service Spotify.

Playlist Creation

The personalized music playlist is generated prior to the POMI period for each patient participant. To determine the participant's music preferences, the following questions are asked, based on possible recommendations through the Spotify Application Programming Interface [31]:

1. Is there any music genre that you would like to listen to?
2. Is there any specific song title that you would like to listen to?
3. Is there any music artist that you would like to listen to?
4. Would you like to hear music that is more instrumental, more vocal, or do you have no preference?
5. Would you like to hear music that is more acoustic, more electric, or do you have no preference?
6. Would you like to hear music that is more calming, more energetic, or do you have no preference?
7. Would you like to hear music that is more cheerful, more melancholic, or do you have no preference?
8. Would you like to hear music that is more popular, less popular, or do you have no preference?
9. Would you like to hear music that is recorded in studio, do you prefer live recordings of music, or do you have no preference?

Any or all the questions can be skipped as preferred if at least 1 answer is given to questions 1, 2, or 3. Definitions of any of the music attributes (eg, electric and energetic) are provided if necessary and are available on the web-based tool.

The reported preferences are entered into a POMI web-based tool (Figure 2) to generate a personalized music playlist on Spotify, with a tempo restriction of 60-80 bpm as recommended [11]. Music is then played for 20 to 30 minutes via a smart device (iPad, 8th generation).

At all times, patients can control the music (eg, skip a song or stop the music, either briefly or permanently) by accessing the iPad themselves or communicating with the student researcher. Patients unable to self-report are continually monitored by the student researcher while the music is playing so that any nonverbal reaction to the music, indicating such dislike of the music, would lead the student researcher to stop the music immediately.

Control Intervention

The CTL consists of providing a 20-30–minute period without music either while wearing headphones (Bose, QuietComfort 35) or with the head resting on a music pillow (MusiCure, hospital-grade), which is consistent with the mode of delivery for the POMI. Adult patients admitted to the ICU and able to self-report can choose 1 of the 2 modes of delivery. Patients unable to self-report are given the music pillow.

Washout Period

To allow for any pain-reducing effect of the POMI to dissipate before the CTL, a washout period of at least 4 hours is scheduled between both intervention periods, based on previous data on the duration of the analgesic effect of music on pain [32].

Video Recordings

Video will be recorded for the duration of the intervention period and at each pain assessment time point. These video recordings will be used to have an independent member of the research team evaluate: (1) the Critical-Care Pain Observation Tool (CPOT) scores for each patient participant (to ensure blinding of the research team member interrater to sequence allocation) and (2) the intervention fidelity.

Outcomes

Acceptability

The acceptability questionnaire is adapted from the treatment acceptability and preferences (TAP) validated measure [33]. The TAP is comprised of 4 items: suitability, appropriateness, effectiveness, and willingness to comply, each of which is rated on a 5-point scale ranging from 0 (not at all) to 4 (very much) with higher scores indicating greater acceptability [33]. The total scale score is then obtained by calculating the mean of all the items' scores. The TAP was shown to have a Cronbach α coefficient greater than .75, supporting good internal consistency [34], and it has been used to evaluate a variety of interventions in different acute and postsurgical care settings [35-37]. The TAP can capture "the complex nature of [participants'] preferences" and yet being simple enough for use in the ICU setting [33]. As recommended [38], 1 item has been added to the questionnaire to determine the risks of side effects of the POMI, an additional important aspect in assessing the acceptability of the intervention.

Feasibility of Intervention

The items for the assessment of intervention feasibility include (1) time spent (in minutes) creating the individualized playlist; (2) the presence or absence of any issue with headphone or pillow use; (3) the presence or absence of any issue with music delivery; (4) the presence or absence of skipping one or more songs from the generated playlist; (5) the presence or absence of any environmental noise (eg, alarms and voices) during intervention delivery; (6) the presence or absence of any POMI interruptions; (7) whether the patient participant received the full duration of the POMI; (8) the dose (duration in minutes) of

XSL•FO
RenderX

the music delivered; (9) the characteristics of the music delivered (eg, music genres).

Additionally, as part of the feasibility of the intervention, the fidelity of the intervention will be assessed based on specific criteria [39] and will include meeting with participants to discuss music preferences, producing a personalized playlist, and playing music once at least for 20 minutes. Any issues with the delivery of the POMI will also be recorded.

Feasibility of Research Methods

The items for the assessment of the feasibility of research methods, based on the CONSORT guidelines for pilot and feasibility RCTs [40,41], include the number of patients screened, number of eligible patients, number of participants recruited, number of participants randomized, and number of participants included in the analysis.

Preliminary Efficacy of POMI on Acute Pain

Pain will be assessed at 4 different timepoints for each intervention period: before the intervention, immediately after the intervention, during the bed turning procedure, and 30 minutes after the bed turning procedure (Figure 1, T_0-T_3). Pain assessments will be performed using validated tools as recommended in ICU clinical practice guidelines [1]. For all patient participants, the CPOT will be used because it is one of the most valid behavioral scales for assessing pain in critically ill adults [42]. In addition to the CPOT, patient participants able to self-report will be asked to rate their pain intensity using the 0-10 Faces Pain Thermometer [43] and their pain distress on a 0-10 NRS [44,45].

Data Analysis

Overview

A data bank will be created with the SPSS software (version 27.0; IBM Corp) [46], where the collected data on acceptability, feasibility, and preliminary efficacy will be entered. All the statistical analyses described below will be performed using SPSS.

Acceptability of the Intervention

The acceptability of the POMI will be determined using the TAP questionnaire. The frequencies, medians, and IQRs will be calculated for each item as well as for the total score, which will be calculated by taking the median, out of 4, of all items. The first 4 items (suitability, appropriateness, perceived effectiveness, and willingness to comply) will be scored in sequence (with 0 being the least favorable and 4 being the most favorable), whereas the last item (risks or side effects) will be scored in reverse (with 4 being the least favorable and 0 being the most favorable), as it is a negatively worded question. Any notes or comments added to the ratings will be compiled by category and presented descriptively to accompany the numerical ratings. A median above 2 out of 4 for the total score will be considered as an acceptable intervention, overall. An item median score above 2 out of 4 will be considered an acceptable attribute of the POMI. A median below 2 out of 4 will indicate the need to look more closely at the comments accompanying the ratings and modify the intervention to improve the acceptability of the POMI (eg, mode of delivery and dose). The acceptability of the POMI will be established via data triangulation from all study participants: patients, family members, and nursing staff [47].

Feasibility and Fidelity of Intervention

Descriptive statistics will be obtained to compute the frequencies for each of the intervention feasibility items. The POMI will be considered a feasible intervention if there are no issues in over 50% of the items for the assessment of the intervention feasibility (as listed above) for at least 80% of the patient participants in each group [48]. Regarding the fidelity of the intervention, descriptive data will be computed on the amount of time spent creating the music playlists (≤10 minutes), delivery of the overall POMI (use of headphones or pillow), as well as the amount of time the music will be listened to (once, for at least 20 minutes). The percentage of items completed on the fidelity checklist will also be computed in order to ensure that at least 80% of the intervention fidelity items will be delivered as planned, yet to allow for a certain amount of flexibility, if needed [48,49].

Feasibility of Research Methods

Descriptive statistics will be generated for each of the feasibility of research methods items. The screening and recruitment procedures will be described and include the number of patients screened, the proportion of eligible patients as well as the number of enrolled participants. If less than 50% of the potential patient participants are found to be eligible, considerations will be made to broaden the inclusion criteria in an eventual full-scale RCT [39]. Time to recruit will be considered adequate if 24 patient participants are enrolled within 6 months. All issues related to recruitment will be described and grouped into categories by the student researcher.

The retention rates will be calculated and expected to be above 80%. Reasons for participant withdrawal will be described, when known, and if retention rates are below 80%, strategies will be recommended to reduce attrition, based on the reasons for study withdrawal. If more than 10% of the participants (in each group) are found to have missing data, reasons for missing data will be described to inform how to reduce the amount of missing data in future research.

Preliminary Efficacy

Descriptive statistics will be computed for all outcomes (CPOT, pain intensity, and pain distress scores). The 95% CIs will be computed for each dependent variable at each time point.

Considering the small sample size for a pilot study, the potential efficacy of the POMI will be analyzed using nonparametric tests. For the dependent variables (CPOT, pain intensity, and pain distress scores), the Friedman test will be used to compare the scores at individual time points in each group separately. If the Friedman test is found to tend toward significant (P<.10), the Wilcoxon signed rank test will be used to compare 2 timepoints in pairs with a Bonferroni correction (.05 per number of tests) to locate the differences.

The preliminary efficacy findings will not be used to inform the decision to pursue a full-scale RCT. However, any tendency

XSL•FO
RenderX

toward statistical significance (P<.10) or significant lower pain scores in the music period versus the control period will support that the intervention group might decrease pain over time, compared to the control group. A formal hypothesis of efficacy will need to be tested in a full-scale RCT, which will only be recommended if the POMI is deemed acceptable and feasible.

Ethics Approval

Ethics approval was submitted in July 2021 and approved in December 2021 (Project #2022-3005). Participation in this research project is voluntary and ongoing for all participants. Participants are free to refuse to participate and may withdraw from this research study at any time, without having to give a reason, and without any consequence to them now or in the future. The participant's decision not to participate in the study, or to withdraw from it, will have no impact on the quality of care and services to which they are otherwise entitled. Participants are free to refuse to answer any question and remain in the study. Participants are free to refuse to be video recorded.

For a patient who is unable to consent to participate in the study, a family member representative will provide the written consent on behalf of the patient. From this time and until the patient participant is discharged from the ICU, the student researcher will follow up on the ICU adult patients who were unable to consent to determine if they regain the ability to consent for themselves. In the case where a patient participant who was previously unable to consent regains the ability to consent at any time, before or after the intervention, the student researcher will present the research project and the information and consent form to allow the ICU adult patient to make an informed decision regarding their participation in the study.

The data collected from a participant as part of this study, excluding the video recordings, could be used for future research projects related to this study only with the participant's explicit permission. The results of the research study, excluding video recordings, may be presented at conferences, published in specialized journals or be the subject of scientific discussions, or be used for teaching purposes. No identifying information will be published in any way.

At any time, participants have the right to consult their study file in order to verify the information gathered and to have it corrected if necessary. All study data will be stored safely for 10 years, after which time they will be permanently destroyed by being either shredded or permanently deleted from the server.

Patients and families will be offered the hyperlink to their playlist as well as a paper version of the list of songs played as part of the study. Nursing staff participants will be offered a US $20 gift certificate to compensate for their time spent participating in the study.

Results

This study was registered to ClinicalTrials.gov (NCT05320224) in March 2022. Recruitment and data collection began in March 2022.

Discussion

Methodological Strengths

One strength of this study is the evaluation of the intervention acceptability from multiple sources: ICU patients, families, and nursing staff. This will allow us to gain access to the different perspectives of the various stakeholders and acquire a more comprehensive understanding of the overall acceptability of the intervention. The crossover design is another strength as it allows each patient participant to be their own control, thus reducing confounding factors that are usually present in between-subject designs [50,51]. Moreover, the crossover design will allow for patient participants able to self-report to share their preference between the POMI and the CTL because they will experience both interventions. Information about participant preference will add rich qualitative data beyond the quantitative comparison of preliminary efficacy [41,51]. The crossover design is relevant to use during procedures that are planned within a short period of time (eg, molar extractions at 2 different times) [50]. In addition to intervention comparisons and patient participant preferences, we will be able to determine the pain and distress differences individually (numerically) and compute the proportion of patient participants for whom the treatment was effective in reducing pain by more than 1 point on a 0-10 NRS, for example [51]. The crossover design will also enable us to describe whether any reduction in pain or distress was qualified as meaningful by the patient participant (for those able to self-report). These data could later contribute to the understanding of the minimally clinically significant difference in procedural pain in the adult ICU population [51]. Knowing that patient participants will receive both interventions as part of the crossover design may allow them to think more objectively about pain levels in each intervention period (thus minimizing the placebo effect) compared to if they participated in a parallel-group trial, in which the patient participants' hope to receive the intervention may influence their pain rating [50]. Finally, blinding patient participants unable to self-report will reduce the risk of bias based on these participants' expectations of music efficacy to reduce pain.

Methodological Limitations and Mitigation Strategies

The Initiative on Methods, Measurement, and Pain Assessment in Clinical Trials recommendations state that the use of a crossover trial at an earlier stage study, followed by confirmation of the results in a larger parallel-group study, is an efficient approach, as long as a washout period is carefully planned to minimize or avoid carryover effects [50]. To allow for any pain-reducing effect of the POMI to dissipate before the CTL, there will be a washout period of at least 4 hours between both intervention periods, based on previous data on the duration of the analgesic effect of music on pain [32]. Due to the sample size and to evaluate the time effect, the Friedman and Wilcoxon rank sum tests will be used when analyzing pain-related data for each subgroup [51]. To avoid response shifts due to the crossover design, baseline pain intensity will be measured for each intervention period (T_0 in Figure 1). Because blinding will be difficult with patient participants receiving both the POMI and the CTL, there is a risk of ascertainment bias for patient

XSL•FO
RenderX

participants. To address this, patient participants able to self-report will be asked about their perception of how effective they think the music is compared to the CTL. To minimize possible interruptions and noise during intervention periods, the nurse responsible for the patient will be met to discuss and plan for the best time to start the intervention period, prior to a scheduled bed turn.

Due to the current context of the pandemic and this study being conducted in an ICU setting, it is possible that limited family visits and nursing staff shortages will impact recruitment from these populations. To mitigate these possible limitations, meeting families at the bedside will be coordinated with the nursing staff.

Acknowledgments

The authors would like to thank the ICU care team and participants for making this study possible. The study materials (music pillow, headphones, and iPads) were funded as part of a previous study by a small operating grant from the McGill Nursing Collaborative for Education and Innovation in Patient- and Family-Centered Care. Additional funding that contributed to the production of this manuscript were provided by: FRQS (Fonds de Recherche du Québec – Santé), MES-Universités (Ministère de l'Enseignement Supérieur-McGill University), and RRISIQ (Réseau de Recherche en Interventions en Sciences Infirmières du Québec).

Data Availability

The data sets generated during and analyzed during the current study are available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Exposures to “traumatic” events are widespread and can cause posttraumatic stress disorder (PTSD). Cognitive behavioral therapy and eye movement desensitization and reprocessing (EMDR) are frequently used and validated behavioral PTSD treatments. Despite demonstrated effectiveness, highly upsetting memory reactions can be evoked, resulting in extensive distress and, sometimes, treatment dropout. In recent years, multiple treatment approaches have aimed at reducing such upsetting memory reactions to traumatic memories while therapeutic progress proceeds. One of these methods, the flash technique (FT), a modification of standard EMDR (S-EMDR), appears effective in distressing memory reduction. This study will examine FT-EMDR and S-EMDR efficacies when both methods are delivered via web-based video.

Objective: This study aims to assess the relative efficacy of (web-based) FT-EMDR versus S-EMDR in reducing the PTSD symptoms, anxieties, and depression associated with traumatic memories at postintervention and 1-month follow-up.

Methods: This double-blinded, web-based, 2-arm randomized controlled trial will employ self-report outcomes. A total of 90 participants will be identified from the web-based CloudResearch platform and randomly allocated to the experimental or comparison group. Inclusion criteria are as follows: (1) approved for engagement by the CloudResearch platform; (2) 25-60 years of age; (3) residing in Canada or the United States; (4) a recalled disturbing memory of an event >2 years ago that has not repeated and was moderately or more upsetting during occurrence; (5) memory moderately or more upsetting at baseline and not linked to an earlier memory that is equally or more than equally disturbing. Exclusion criteria are bipolar disorder, borderline personality disorder, obsessive-compulsive disorder, schizophrenia, substance abuse or addiction in the past 3 months, suicidal ideation, and suicide attempt in the past 6 months. Interventions include guided video instruction of full FT or guided video of EMDR. Outcome measures are as follows: Primary outcome is PTSD symptoms that are measured by the PTSD Checklist for DSM-5 (Diagnostic and Statistical Manual of Mental Disorders-5) at 1-month follow-up. Secondary outcomes are State Anxiety subscale of State-Trait Anxiety Inventory at baseline, postintervention, and 1-month follow-up; Trait Anxiety subscale of State-Trait Anxiety Inventory; depression (Patient Health Questionnaire-9); and Positive and Negative Affect Schedule measured at 1-month follow-up.

Results: If, at 1-month follow-up, the web-based FT-EMDR intervention is more effective in reducing PTSD symptoms (as measured by the PTSD Checklist for DSM-5) than EMDR, it may help reduce traumatic memory distress in multiple contexts.

Conclusions: This randomized controlled trial will advance current understandings of PTSD symptoms and interventions that target traumatic memory–related distress.

KEYWORDS

EMDR variants; eye movement desensitization reprocessing; flash technique-EMDR; posttraumatic stress disorder

Introduction

Posttraumatic stress disorder (PTSD) can occur after direct or indirect exposure to traumatic events with frequent symptoms of reexperiencing, avoidance, cognitive-mood alterations, and heightened arousal or reactivity [1]. Traumatic exposures are widespread [2-4], and a study of 2991 Canadian adults indicated that 76% of participants reported one or more traumatic exposures of the type that can lead to diagnosed PTSD [5]. The prevalence of diagnosed PTSD is ~3.9% worldwide and 10% in Canada (~3.7 million people) [5-7]. Disturbing memory retention can lead to diagnosable PTSD, while adversely impacting psychological and physiological well-being [8-10]. Innovative interventions that reduce memory-based disturbance can prevent PTSD diagnoses and improve current status.

Pharmacological PTSD treatments include antidepressants, sympatholytic drugs, antipsychotics, anticonvulsants, and benzodiazepines [11-13]. Despite the availability of these agents, their limited efficacy has motivated adjunctive behavioral interventions [14,15]. A meta-analysis of PTSD treatment indicated that psychological therapies were generally more effective than drug therapies in symptom reduction [14].

Several of the most prominent methods addressing "traumatic" memories are trauma-focused cognitive behavioral therapy, cognitive processing therapy, prolonged exposure, and eye movement desensitization and reprocessing (EMDR) [16-18]. Other exposure-based treatments designed for PTSD are narrative exposure therapy and written exposure therapy [19]. In traditional EMDR, patients follow the horizontal movement of the therapist's index finger while recalling details of the traumatic memory [20]. The attention devoted to finger movement during recall has been proposed to reduce the intensity and intrusiveness of memory disturbance [20-24]. EMDR is now widely supported as a treatment for PTSD and is being tested for other mental health conditions (eg, generalized anxiety disorders, addiction, and depression) [25,26].

The mechanisms by which EMDR delivers benefits are controversial [27-29] and differ substantially from those proposed for other psychological therapies [30-32]. The divergence maps onto a frequent limitation acknowledged in exposure approaches, namely, traumatic memory confrontation, can generate high arousal levels, emotional distress, dissociation, and treatment dropout [33,34]. The novel variant of EMDR for PTSD investigated in the proposed study, the flash technique-EMDR (FT-EMDR) [35,36], emphasizes, in combination with standard EMDR (S-EMDR) procedures, the use of a positive engaging focus (PEF), which is recalled and imagined while a right-hand-left-hand alternate knee tapping proceeds [35-38]. Although several explanations for the mechanisms mobilized by this method are proposed, their identification is secondary to our goal of assessing efficacy within a double-blinded randomized controlled trial (RCT) that compares S-EMDR with FT-EMDR. If the FT variant demonstrates greater efficacy, mechanism identification and measurement may proceed more clearly.

As FT is a novel EMDR variant, the related research is in its early stages. Nonetheless, our study will follow prior findings that suggest FT efficacy in reducing the distress associated with disturbing memories [35-38]. If efficacy is indicated, one or both approaches could be used in geographic areas that require more immediate treatment needs, such as when warfare or natural disasters evoke traumatic reactions that are more prevalent.

This study has following three objectives: (1) to evaluate whether web-based delivery of FT is more effective in reducing PTSD symptoms than web-based S-EMDR at 1-month follow-up measured by the PTSD Checklist for DSM-5 (Diagnostic and Statistical Manual of Mental Disorders-5) (PCL-5); (2) to assess whether web-based delivery of FT-EMDR is more effective in reducing state anxiety symptoms than S-EMDR at postintervention and 1-month follow-up; and (3) to evaluate whether web-based delivery of FT-EMDR is more effective in reducing depressive symptoms than S-EMDR at postintervention and 1-month follow-up.

Methods

Overview

Previous studies of FT-EMDR have indicated that guided in-person FT effectively reduces subjective units of distress caused by distressing memories. These studies were limited due to a lack of randomization and adequate control comparison. This study will be an assessor-blinded, 2-arm (experimental and control) randomized controlled trial, which minimizes placebo effects and implements an adequate sample size and psychometric measurement. This study is expected to have an overall duration of 3 months. The length of study for each participant will be 4 weeks. The recruitment period is estimated to last for 2 months.

Ethical Considerations

The study was approved by the Research and Ethics Board at York University (087/2020) and is registered with ClinicalTrials.gov (NCT05262127).

Informed Consent

After eligibility is confirmed by the investigator, web-based informed consent will be obtained from participants. Each participant will review approved informed consent documents where guaranteed privacy and confidentiality protections are specified, along with assurances that all study data will be anonymized and deidentified. Each participant is compensated US $17 for participation. Participants will be informed about the scientific benefits of the study; however, they are informed that their participation is voluntary, and they have the right to terminate their participation at any time. The signed form will be retained as part of the study records.

RenderX

Sample Size

Overview

With the assistance of the Institute for Social Research at York University, the sample size was calculated for a 3-way repeated measures ANOVA. Sample size calculation was conducted using G*Power 3.1.9.4. The options in G*Power 3.1.9.2 were as follows: (1) test family: "*F* test"; (2) statistical test: "ANOVA: Repeated measures, between factor interaction"; and (3) type of power analysis: "A priori: Compute required sample size–given α, power, and effect size." An a priori power analysis was completed using a moderate effect size (F=0.25), 0.8 power (1β error probability), and an α error probability at P<.05. G*Power 3.1.9.4 determined that a minimum sample size of 37 participants per group provides ample testing power. Considering a 20% (n=7.4) oversampling to account for potential participant dropout and experimental error, a proposed minimum sample size of 44 per group is deemed adequate to detect within-group and between-group differences based on a repeated measures design.

Inclusion Criteria

Participants must pass the CloudResearch platform's standardized assessment of *attention*, *engagement*, and *language comprehension* for study participation [39]. Language comprehension and engagement are assessed by identifying synonyms, reading articles, and answering comprehension questions. Additional attentional competencies are assessed by evaluating factual correctness in answers to demographic questions (eg, "I work 28 hours in a typical workday"). In addition, the CloudResearch platform screening is based on a recorded history of providing high-quality data in prior study participation.

In the investigator-based criteria, participants must (1) be between 25 and 60 years of age and maintain residence in the United States or Canada; (2) be able to identify a memory regarding an event that occurred more than 2 years ago and has not been since repeated; (3) identify the memory as moderately upsetting, or more than moderately upsetting, when it occurred; (4) clearly recall the identified memory; (5) find the memory to be still moderately upsetting, or more than moderately upsetting, when recalled; and (6) identify the memory as not tied to an earlier memory that is equally or more disturbing.

Since participants are exposed to only 1 brief session, processing a series of upsetting memories is unreasonable and potentially harmful. Hence, the inclusion of only a single distressing memory, which should be distant from the participation date, was carefully implemented to minimize emotional arousal.

Exclusion Criteria

Exclusion criteria are as follows: (1) individuals who disclose a past or present self-reported diagnosis of bipolar disorder, borderline personality disorder, obsessive-compulsive disorder, schizophrenia, or a substance abuse or addiction in the past 3 months; and (2) individuals who disclose having suicidal ideation or who have attempted suicide in the past 6 months prior to the study.

Recruitment Plan

Participants will be recruited from a web-based platform (CloudResearch) [40]. Potentially eligible participants will be prescreened and eligibility assessed. After eligibility screening, they will be invited to a Zoom meeting where the study investigator further explains the study procedures. If the participant is interested, written consent will be obtained prior to randomization. The investigator will perform electronic randomization, with study IDs blindly assigned to experimental and control group participants. Study ID information will be recorded on an excel sheet as well as on the SurveyMonkey platform. After a participant completes baseline questionnaires, blinded research assistants will play a taped version of the video assigned to the participant in accordance with the randomization plan.

The randomly assigned participants will proceed to watch a 15-minute guided video of either FT-EMDR (experimental condition) or S-EMDR (comparison condition) in a quiet environment. Assessments will take place at pre- and postintervention and 1-month follow-up.

A streaming recruitment method will be employed where the study description is made available on the internet (CloudResearch platform) for a duration of 15 minutes prior to a participation-designated interview time slot. This will enable potential participants to enter the study description link, read a description of the study format, and pass the eligibility criteria before proceeding further if interested in study participation.

The additional steps to "streaming recruitment" require specifying how many participants can access the experiment's Zoom link at a given time, up to a maximum of 15. When more than one subject uses the link to enter the Zoom waiting room, the researcher will allow the first participant to enter the Zoom study meeting, while the remaining waiting room occupants are thanked for their interest and prompted to sign off. Once 1 eligible participant enters the video interview, the Zoom meeting will be locked, and no additional participants can access or join.

Procedure

This study will require 2 contact commitments from participants during a 4-week period. The first interaction will include gaining consent, completing preintervention psychometric questionnaires, and then watching and engaging in the 15-minute either intervention or control video. Subsequently, participants will complete postintervention measures and are provided with a debriefing statement.

The second interaction will be a follow-up of intervention outcomes 1 month after the initial interaction. A SurveyMonkey link will be sent out to participants via the CloudResearch platform, which will include all primary and secondary outcome measures. Both participants and research assistants will be blinded to experimental and control conditions throughout the trial.

XSL•FO
RenderX

Interventions

Experimental Group

After a participant consents and completes demographic and baseline psychometric questionnaires, a "blinded" research assistant will share the computer screen and play a taped video of FT-EMDR containing vocalized and viewable instructions by licensed EMDR practitioners. Participants will be asked to follow the instructions with their full attention in a distraction-free environment. Participants assigned to the experimental condition will be invited by the video instructor to perform the following additional tasks: (1) identify a traumatic memory and rate its disturbance on a numerical scale that extends from 0 (no disturbance at all) to 10 (most disturbing)—This is often referred to as the Subjective Units of Distress Scale (SUDS) [41]; (2) identify a PEF, which can include a person, vacation, pet, favorite activity, or favorite music that is immediately gratifying when recalled or is a reminder of a past gratifying experience; (3) rhythmically tap knees while thinking of the selected PEF; periodically, the video instructor will say the word "flash," prompting 4-6 rapid blinks of the eyes, simultaneously establishing the blink rhythm and duration; (4) continuously envision the proposed PEF after blinking; and (5) respond to periodic check-ins concerning changes in the memory experience.

At the end of the video, the instructor will ask participants to rate their target memory once again on the SUDS. The assigned research assistant will collect SUDS reports at baseline and postintervention.

The PEF is considered essential to the FT-EMDR approach component. Participants will be instructed to immerse themselves into their PEF while rhythmically tapping their knees; however, they will not be instructed to avoid and suppress their target memory. Conversely, participants will be encouraged to bring their attention back to their PEF once distracted by the target memory.

Comparison Group

Members of the comparison group will be exposed to a pretaped video following similar instructions by the same licensed EMDR practitioners as the experimental group. In a procedure that is identical to the experimental group, participants will be instructed to identify a traumatic event as a target memory. The concept of PEF, however, will not be mentioned, precluding any engagement with or use of it. Instructions will specify that participants should only focus on their traumatic memory and recall as many details as possible. The duration and rhythm of tapping and blinking are identical to what is done with the experimental group, and SUDS measurements are taken in a similar manner. The comparison group protocol will closely follow the S-EMDR format, where clients generate back-and-forth eye movements while focusing on vivid recalls of the traumatic event.

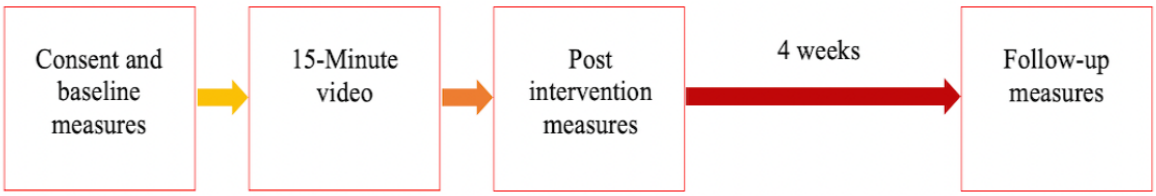
Outcome Measures

Primary Outcome

The primary outcome measure will be the PCL-5 [42]. It is a 20-item self-report instrument measuring the presence and severity of PTSD symptoms. Each item is rated on a 5-point Likert scale ranging from 0 (not at all) to 4 (extremely), indicating how much each symptom has bothered the respondent in the past month. Higher scores indicate more severe PTSD-like symptoms, and a score higher than 31-33 alerts to a possible PTSD diagnosis.

Secondary Outcomes

Four self-reported secondary outcome measures will be employed only at baseline and 1-month follow-up. All outcome measures will be carried out on the internet via SurveyMonkey links.



The State-Trait Anxiety Inventory (STAI) Form Y-1 (S-STAI, where S is state subscale) [43] is a 20-item self-report scale that measures subjective tensions, apprehension, nervousness, worries, and physiological arousal. The customary cutoff score for probable clinical levels of anxiety is 40 and above. Trait anxiety is measured by STAI Form Y-2 (T-STAI; trait subscale) [43], which is a 20-item self-report scale. The trait scale measures how people generally feel and it is the most widely used measures for assessing anxiety in clinical and experimental settings [44].

Patient Health Questionnaire-9 (PHQ-9) [45] is used to assess depression levels. This questionnaire has 9 items rated on a 5-point Likert scale from 0 (not at all) to 4 (nearly every day). Similarly, expected ranges for nonminimal, mild, moderate, moderately severe, and severe depression are 0-4, 5-9, 10-14, 15-19, and 20-27.

Positive and Negative Affect Schedule (PANAS) [46] is a 20-item questionnaire that measures positive (10 items) and negative (10 items) affects. Each item is scored with a 5-point Likert scale ranging from 1 (not at all) to 5 (very much). Higher scores on a positive scale translate to higher levels of positive affect, whereas lower scores on negative affect suggest low levels of negative affect. This reliable and valid self-report scale is brief, easily administered, highly internally consistent, and stable at appropriate levels over about as long as a 2-month time period [46]. Visual representation of the study procedures is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Visual representation of study procedure. Baseline measures: State Subscale-State-Trait Anxiety Inventory (S-STAI), Trait Subscale-STAI (T-STAI), Subjective Units of Distress Scale (SUDS), Posttraumatic Stress Disorder Checklist for DSM-5 (PCL-5), Patient Health Questionnaire-9 (PHQ-9), and Positive and Negative Affect Schedule (PANAS). Postintervention measures: S-STAI and SUDS. Follow-up outcome measures: S-STAI, T-STAI, PCL-5, PHQ-9, and PANAS.

Hypotheses

FT-EMDR (the experimental condition) will be significantly more effective than S-EMDR in reducing self-report scores on the PCL-5 at 1-month follow-up to the intervention than traditional EMDR.

FT-EMDR (the experimental condition) will be significantly more effective than S-EMDR in reducing self-report scores on the S-STAI at postintervention and 4-week follow-up than traditional EMDR.

FT-EMDR will be significantly more effective than S-EMDR in decreasing self-report scores on the PHQ-9 at 1-month follow-up.

Statistical Analyses

Statistical analysis will include the calculation of descriptive statistics for demographic and psychological characteristics at baseline, postintervention, and the follow-up period. Study outcomes will be presented as means and SDs for numeric variables and frequencies and percentages for categorical variables. In addition, potential between-group differences at baseline will be evaluated using *t* tests for numeric variables and chi-square tests of independence for categorical variables. Significance will be set at $P \leq .05$ and will be presented with *r* values for each questionnaire.

To evaluate the effects of the intervention on primary study outcome (PCL-5) and secondary outcomes (PHQ-9, S-STAI, Trait Subscale-State-Trait Anxiety Inventory, PANAS-Positive, and PANAS-Negative), linear mixed models (LMM) will be employed with an AR (1) covariance structure and random intercepts for each study participant to allow for both fixed and random effects. The LMM assumes that the outcome measure is normally distributed. All models will include adjustments for age and sex (among other psychological characteristics). Statistically significant group×time interactions, indicating between-group changes in outcomes, will be followed by simple main effect evaluation. Cohen d effect sizes for between-group and within-group comparisons will also be calculated according to procedures outlined in Lakens [47]. All analyses will be conducted using RStudio [48] and associated statistical packages, including nlme [49], psych [50], and ggplot2 [51].

Missing Data

Missing data in the context of this study occurs if study participants miss an assessment at the immediate postintervention or drop out prematurely before the 1-month follow-up assessment. Missing observations, in addition to specific reasons for dropout, will be monitored and presented as part of the associated study flow diagram. The LMM does not require imputations and uses a restricted maximum likelihood strategy to estimate study parameters. Restricted maximum likelihood produces unbiased estimates of variance and covariance variables.

Results

Our findings are scheduled for a full analysis, with expectations that analyses will be completed by July, 2023. Our intention is to publish results in peer-reviewed journals.

Discussion

In this study, 2 videotaped EMDR variants are compared for efficacy within a double-blinded RCT. They are conveyed by registered EMDR therapists in a web-based format and compared for efficacy using standard psychometric scales at postintervention and 1-month follow-up. The innovations addressed are (1) use of videotaped approaches conveyed through web-based contacts; and (2) different EMDR approaches, varying by insertion of a PEF (in FT-EMDR) and its absence (in S-EMDR). Aside from the inclusion or omission of the PEF, the approaches to EMDR employed in this study are nearly identical. It is important to note that a qualified clinical psychologist will be available while participants undergo either one of these interventions in case of psychological disturbance.

If study findings reveal the efficacy of these interventions, one or both innovations could be potentially useful when individuals with disturbing memories are distant geographically from areas where face-to-face encounters with EMDR therapists can be arranged. Some individuals may also find the typical professional fees too expensive. The web-based alternative is likely to be considerably less expensive. Given the divergences from routine EMDR services, these interventions might be considered stop-gap measures. Nonetheless, this trial provides an initial evaluation of these alternative (web-based) treatments.

Other investigators interested in PTSD treatment have been experimenting with web-based and video-based tools [52,53]. For example, an actuator- and web-based system based on EMDR principles was tested to reduce anxiety, distress, and negative cognitions [52]. This autonomous system used video, tactile, and audio *actuators* and an artificial intelligence "chatbot." In a pilot single-arm study of 31 subjects selected for moderate baseline scores on the Impact of Events Scale-Revised [54] and the STAI [43], subjects demonstrated significant reductions on the Impact of Events Scale-Revised

XSL•FO
RenderX

and STAI following a single session of intervention. The system directed by the investigators recruited 24 participants and exposed them to a 1-session intervention, using a "Blind 2 Therapist" EMDR protocol as a videoconference psychotherapy format that included nondisclosure of the traumatic target memory [53]. This group also reported significant reductions on several self-report scales, notably a SUDS and Validity of Cognition Scale [21], designed to evaluate cognitive structure on emotional and somatic levels. Significant reductions in several self-report instruments were found at postintervention, 1-month, and 6-month follow-up.

The limitations of both studies are the nonblinded, posttreatment assessments that are invariably susceptible to placebo responding. In our study, the double-blinded RCT design aims to limit the placebo response. The data we derive must be regarded as preliminary and preparatory to follow-up studies that, optimally, would include several additional components: (1) a larger group of EMDR-trained therapists to convey interventions (so as to compare results across varying backgrounds, training, and gender); (2) comparisons between participants recruited using the internet (in a similar manner) versus participants recruited through clinics (to compare results regarding initial contact mode). Other acknowledged study limitations include the sole employment of self-report measures and the use of only postintervention and 1-month follow-up, rather than a more extensive series of longitudinal measures.

In conclusion, the study represents a step forward in evaluating web-based, video-taped interventions, which may prove useful where large populations are traumatically exposed (ie, through environmental disasters and warfare) and routine psychological therapy is difficult to deliver. Once widely available, a combination of EMDR variants with other technological tools could possibly broaden the opportunity for more accessible therapy.

Acknowledgments

This study will be a part of a master's thesis in Kinesiology and Health Sciences at York University. No specific funding was obtained for this investigation.

Data Availability

Following analysis, an anonymized data set will be made available to interested fellow investigators by the corresponding author upon reasonable request.

Abstract

Background: Exercise is crucial for individuals with paraplegia to reduce the risk of secondary diseases and improve independence and quality of life. However, numerous barriers such as inadequate accessibility restrict their participation in exercise programs. Digital exercise apps can help overcome these barriers. Personalization is considered a crucial feature of mobile exercise apps, as people with paraplegia have individual requirements regarding exercise programs depending on their level of impairment. Despite the increasing popularity of mobile exercise apps, there are none available that target the individual needs of this cohort. The ParaGym mobile exercise app prototype was designed to automatically tailor exercise sessions to the individual needs of users with paraplegia.

Objective: This study aims to evaluate the feasibility, usability, safety, and preliminary effectiveness of the ParaGym mobile exercise app prototype.

Methods: This pilot block-randomized controlled feasibility trial will include 45 adult participants with paraplegia. Eligible participants will be block randomized to either the intervention or waitlist control group. The intervention group will perform a 6-week exercise program using the ParaGym mobile exercise app, comprising three 35-minute exercise sessions per week. The waitlist control group will continue their usual care and receive access to the app after study completion. Participants will record all exercise sessions conducted with the app as well as additional exercise sessions conducted during the study period using exercise diaries. The primary outcomes include feasibility, usability, and safety. Feasibility will be assessed through semistructured interviews, study adherence, and retention rates. Usability will be measured using the System Usability Scale. Safety will be determined by the occurrence of adverse events. Secondary outcomes include the effects of the intervention on peak exercise capacity (VO_2 peak); handgrip strength; independence, which will be measured using the Spinal Cord Independence Measure III (SCIM III); and health-related quality of life, which will be measured using the Short Form–36 Health Survey (SF-36).

Results: Recruitment commenced in November 2022. Overall, 12 participants were enrolled at the time of submission. Data collection commenced in January 2023, with completion expected in April 2023.

Conclusions: To the best of our knowledge, this is the first study to assess the feasibility, usability, and safety of an intelligent mobile exercise app for individuals with paraplegia. Thereafter, the app should be adapted according to the findings of this trial. Future trials with an updated version of the app should aim for a larger sample size, longer intervention duration, and more diverse target group. In the long term, a fully marketable version of the ParaGym app should be implemented. This would increase the

access to personalized, independent, and evidence-based exercise training for this cohort and, in the future, other people who use wheelchairs.

Introduction

Background

A high level of sedentary behavior is associated with an increased risk of noncommunicable diseases, such as type 2 diabetes, cardiovascular diseases, and cancer [1]. This especially affects people who depend on a wheelchair for mobility, such as those with a spinal cord injury (SCI) [2,3]. Individuals with SCI show lower physical activity levels than able-bodied individuals and individuals with other chronic diseases [3,4]. This results in a 2- to 4-fold increased risk of obesity, diabetes, and cardiovascular diseases [5]. To prevent comorbidities and secondary diseases resulting from a sedentary lifestyle, exercise is of fundamental importance for this cohort [2,6,7]. Regular exercise increases muscle strength and cardiovascular fitness [8-13], leading to greater independence [10,14], improved mobility [8,14], and higher quality of life [11,15]. Furthermore, individuals with SCI who are engaged in sports show substantially higher social integration [15-17] and fewer depressive symptoms [10,17] than those in the inactive comparison group.

For individuals with SCI, engaging in sports is complicated by multiple infrastructural (eg, inadequate accessibility to buildings), internal (eg, not knowing how to exercise), and monetary barriers [18-20]. Digital exercise platforms have the potential to overcome these barriers and promote exercise participation because they do not require transportation, offer a guided program addressing the needs of individuals with SCI, and may be cheaper than a gym membership or personal training [21]. Using a digital exercise platform has been shown to promote adherence to exercise guidelines in able-bodied individuals during the COVID-19 pandemic, when access to sports facilities was restricted [22]. It can be assumed that this is also applicable to individuals with SCI. However, despite the wide variety [23] and recent increasing popularity of mobile fitness apps [24-26], a mobile exercise app targeting the needs of people with paraplegia does not exist.

Only 2 studies have assessed the feasibility of exercise apps for individuals with SCI, the WHEELS mobile health app [27] and the Fisiofriend app [28], although neither of these is available on the mobile app market. People with SCI have individual requirements regarding exercise programs depending on the level of impairment of their trunk stability and leg function [2,29]. Therefore, the exercise programs provided by apps must be personalized [30]. The exercise programs delivered by these 2 apps can be individualized by the users themselves [27] or by a clinician [28], but untrained individuals may not have the expertise to create and tailor their own exercise programs. In addition, the requirement of support from a health care professional further restricts the user's independence.

To our knowledge, there is no mobile fitness app available that provides an exercise program for individuals with paraplegia that is automatically tailored to the user's requirements while the user is completely independent of health care professionals. A prototype of the ParaGym mobile exercise app was developed to enable people with paraplegia to have their own virtual personal fitness coach in addition to their usual care. The app uses an intelligent algorithm that automatically personalizes its exercise program to the user's needs, considering their physical capacity, fitness level, and exercise equipment.

Bizzarini et al [28] and Hoevenaars et al [27] showed that using a mobile app to promote physical activity in this cohort was feasible. However, there are no instances of conducting an exercise program tailored by an algorithm in this cohort. Therefore, a pilot study is needed to assess whether exercise using the new ParaGym mobile exercise app is feasible and safe for people with thoracic or lumbar SCI.

Aims of the Study

The primary aims of this trial are as follows:

- To qualitatively assess the feasibility of an app-based exercise program (ParaGym) tailored by an algorithm to the needs of people with paraplegia
- To investigate the usability of the ParaGym app prototype in terms of the app's design, information provided by the app, app's ease of use, satisfaction with the app, and app's functionality using the System Usability Scale (SUS)
- To assess the safety of this program by considering adverse events (AEs) and serious AEs (SAEs)

The secondary aim is to analyze the effects of a 6-week training intervention using the ParaGym mobile exercise app on peak exercise capacity, handgrip strength, independence, and health-related quality of life.

Methods

Study Schedule

The SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 statement was used to develop the content, quality, and completeness of this protocol [31]. A SPIRIT study schedule (Table 1) and checklist (Multimedia Appendix 1) are provided.

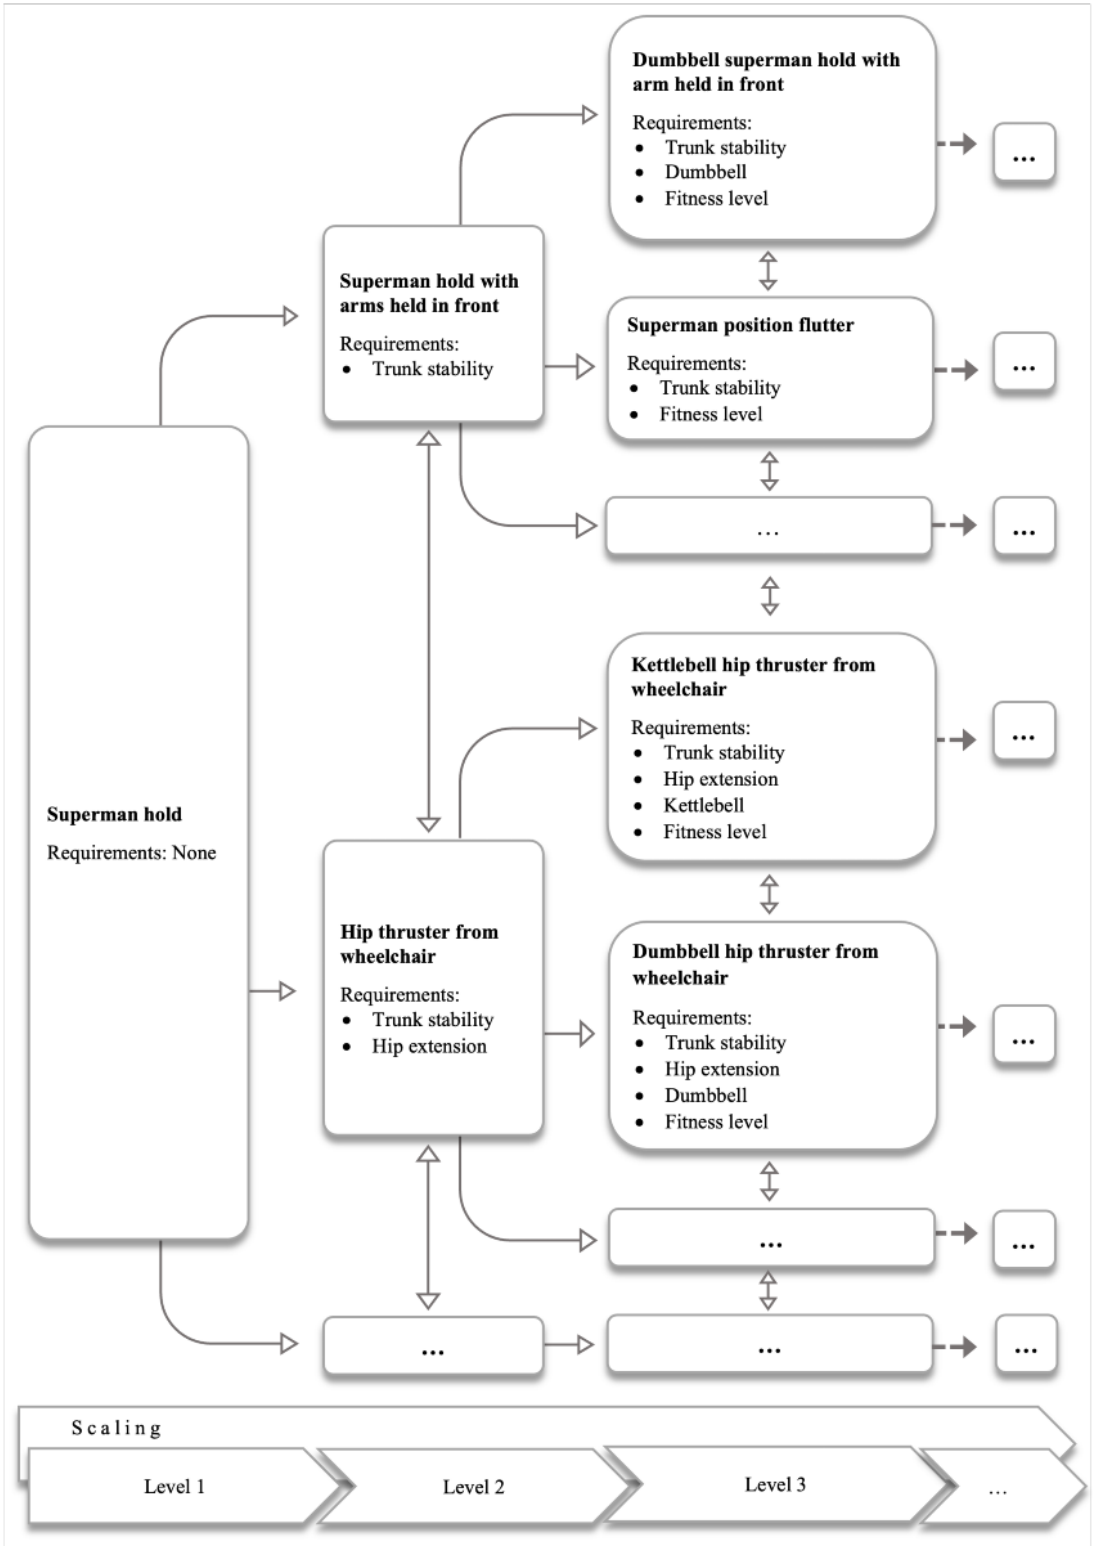
Development of the ParaGym Mobile Exercise App Prototype

The development of the ParaGym mobile exercise app prototype is based on the Kernwerk mobile exercise app (Kernwerk GmbH), which was designed to improve general fitness in able-bodied individuals. The Kernwerk app offers daily functional training sessions created by exercise scientists and uses an intelligent algorithm to individualize these sessions to the user's needs. The goal of the ParaGym project is to develop a prototype of an intelligent mobile exercise app for individuals with paraplegia.

The ParaGym mobile exercise app uses the same algorithm to provide an automatically individualized training program for people with paraplegia. The steps taken to develop the app are as follows. A user-centered approach was adopted to create the ParaGym exercise app for people with paraplegia. This included a survey among the target group and an extensive review of the literature [32] to identify both health-related and disability-related demands for an exercise program and a mobile fitness app. The results of the survey and the literature review revealed the following: (1) there is an urgent need for accessible and personalized exercise programs; (2) exercises with free weights are preferred over exercises with machines; (3) the exercise pool should contain stretching exercises and exercises to improve scapula coordination; (4) workouts should focus on the dorsal rather than the ventral shoulder musculature to avoid overuse injuries; and (5) users should be provided with comprehensive information about the potential risks of exercising (eg, increased risk of autonomic dysreflexia) and, if required, be cleared by a physician.



On the basis of the results of the survey and literature review, in cooperation with physiotherapists and sports scientists from different spinal cord centers, we developed a pool of 56 exercises to strengthen the core, upper, and lower body musculature; increase aerobic capacity; and improve wheelchair mobility and flexibility. Exercise videos and step-by-step descriptions were added for each exercise. Before integrating the exercises into the app, all exercises, including exercise videos and descriptions, were tested and evaluated in terms of feasibility, usability, and comprehensibility by 10 workshop participants with paraplegia [33]. Adjustments to all 3 components were made based on the feedback of the workshop participants and 3 physiotherapists. This resulted in a total of 67 exercises.

In the next step, further attributes were added for each exercise, specifying the required equipment (eg, dumbbells), required environmental conditions (eg, sufficient space for wheeling), difficulty level ranging from 1 (very easy, no specific requirements) to 150 (very difficult), and required physical capacity (eg, the extent of core stability and articular movements, such as "hip flexion" or knee extension). In addition, similar exercises were linked to each other. The linkage of the exercises and attributes results in an exercise scaling tree (Figure 1). All these factors are considered by the algorithm so that if 1 attribute does not apply, a similar but more appropriate exercise will be suggested automatically. Whereas information on available training equipment and environmental conditions is provided by the users, the appropriate difficulty level is assessed by rating each exercise on a scale from 1 (too easy) to 7 (too hard) after each training session (Figure 2D). If an exercise is rated "too easy," a more advanced version of this exercise will be suggested to the user in the following training sessions. Thus, the intelligent algorithm can adjust the exercise level to the current fitness level of the user.

Training sessions focusing on different training goals (eg, improvement of wheelchair mobility or increase in strength) were created based on the exercise pool. The exercises and training sessions were then integrated into the mobile app.

(C) Screen during workout mode showing the first exercise. (D) Difficulty level rating. (E) Exercise equipment settings. (F) Physical capacity settings.

Description and Content of the ParaGym Mobile Exercise App Prototype

The ParaGym mobile exercise app prototype offers a daily training session that is automatically tailored to the individual requirements of people with paraplegia. Users must input information on their height, weight, age, gender, available exercise equipment (eg, dumbbells), and physical capacity (eg, impaired trunk stability and ability to extend the knee) when registering. The home screen of the app summarizes the daily training session (Figure 2A). Users can choose between different workouts by selecting another date on the timeline above the workout summary. Upon selecting one of the exercises within this summary, the exercise video and description will be displayed (Figure 2B). If one of the exercises selected for the workout is not appropriate, it can be excluded through the settings as described in the subsequent paragraph. To start a workout, users press “play.” Before starting the first exercise,

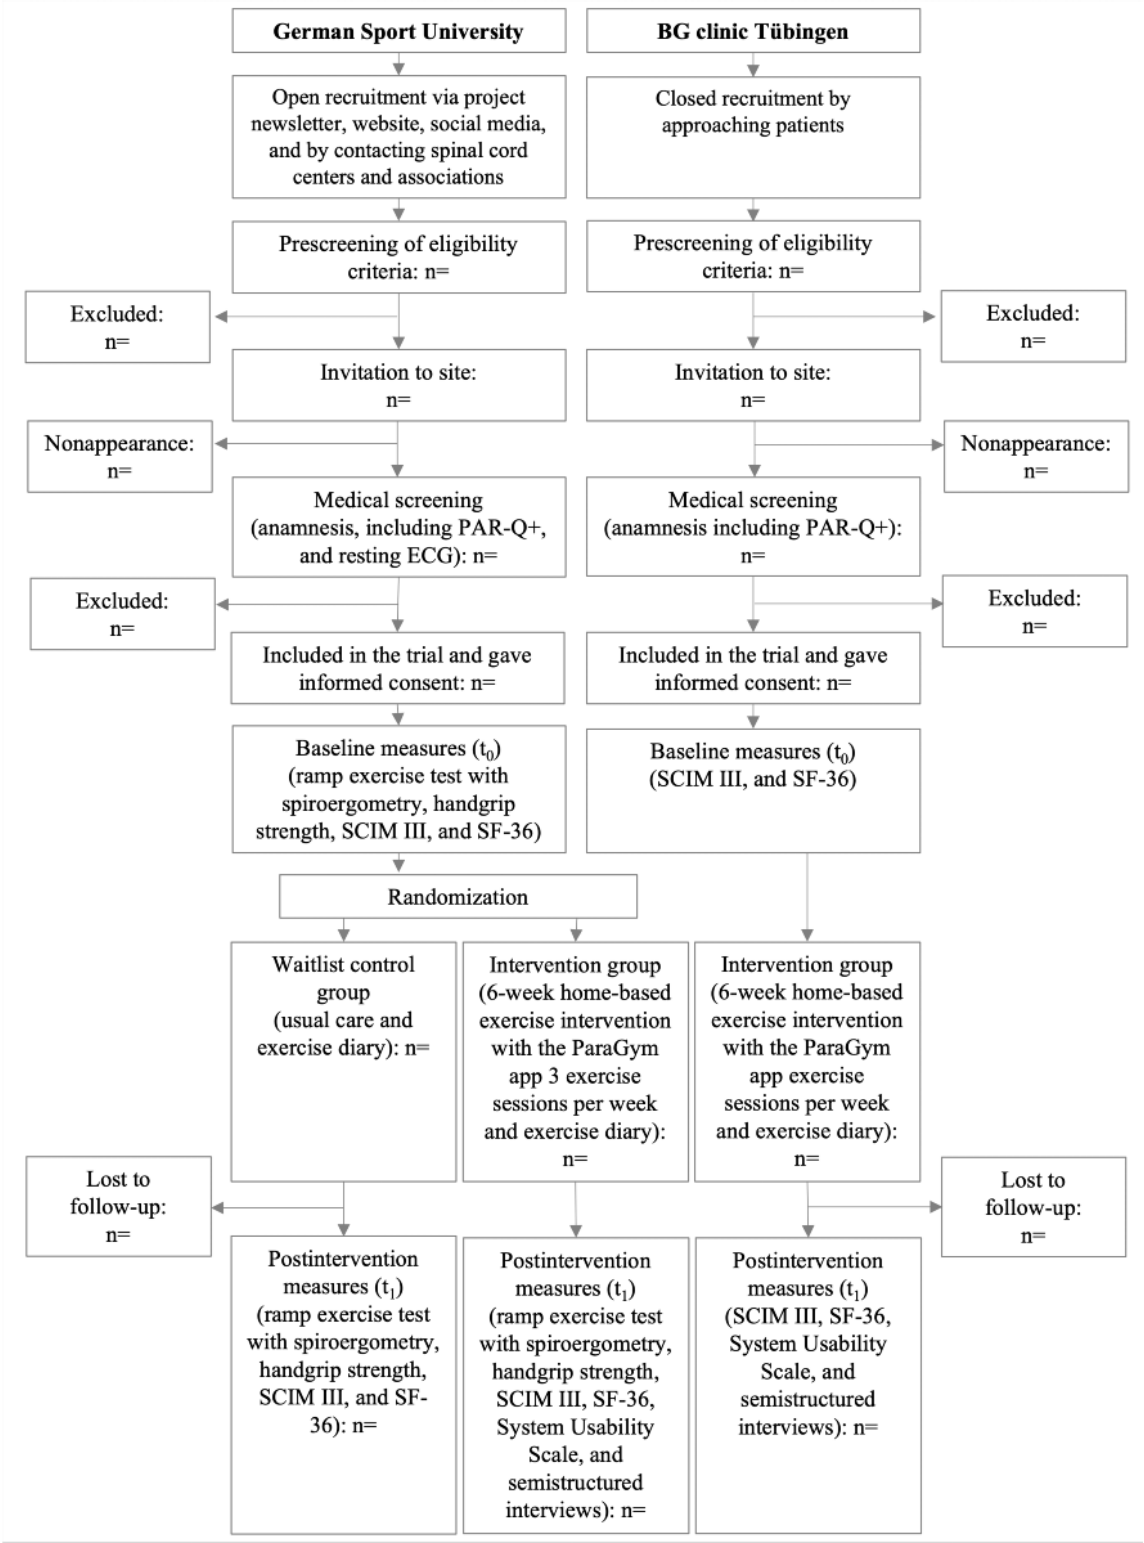
XSL•FO
RenderX

users must confirm that they have read the general safety advice (eg, regarding bowel and bladder management) and specific advice regarding the execution of the exercise (eg, "sit up straight"). When starting the workout, a 10-second countdown will be shown before the first exercise appears on the display (Figure 2C). Users can skip to the next exercise by touching the screen. They can pause or discontinue the workout at any time.

On the home screen, users can tap on the hexagon symbol in the upper right corner to navigate to settings, where they can find a list of all exercises included. Upon selecting one of the exercises within the list, the users are given the option to block the exercise from being included in the workouts or view the exercise video and description. In addition, they can find a link to the project website, receive comprehensive safety information for exercising, and obtain contact information.

Users can make changes to their personal profile by selecting their name in the top row to access the profile settings. Within the section "Sportliches" (English: sporty), users can edit the information on their available exercise equipment (Figure 2E) and physical capacity (Figure 2F). Changes made to this information influence the exercise selection within the workouts.

Study Design



This pilot mixed methods block-randomized controlled feasibility trial with an allocation ratio of 1:1 for the intervention and waitlist control groups is conducted at the German Sport University Cologne (GSU), Germany. The trial was registered with the German Clinical Trials Register (DRKS00030370).

Participants will be recruited at the GSU and the SCI center at the BG (*Berufsgenossenschaft*; English: occupational insurance association) clinic Tübingen, Germany. Participants will be recruited at the GSU via the project newsletter, the project website, social media, and by contacting rehabilitation centers and spinal cord associations. The BG clinic in Tübingen will recruit among their patients.

Measurements will be conducted at baseline (t_0) and after the intervention (t_1; Table 1). The primary outcomes (feasibility, usability, and safety) will be assessed during the intervention and at t_1. The secondary outcomes (peak exercise capacity, handgrip strength, independence, and quality of life) will be assessed at t_0 and t_1. As data collection at the BG clinic Tübingen will focus on the primary outcomes and owing to limited capacity, the ramp exercise test for evaluating peak exercise capacity and handgrip strength test will be conducted only at the GSU and not at the BG clinic Tübingen. After randomization and group allocation, participants in the intervention group will be provided with the ParaGym mobile exercise app and uptake a 6-week home-based training intervention. The participants will be instructed to complete 3 training sessions per week. For this cohort, resistance training for at least 2 days a week is recommended [2,6]. As the training sessions delivered by the app comprise not only strength but also aerobic and flexibility exercises, we decided to provide training sessions for 3 days instead of 2. Eitivipart et al [34] recommend 3 sessions for a minimum duration of 20 minutes per week over at least 6 weeks to achieve substantial outcomes. The waitlist control group will proceed with their usual care and receive access to the mobile app once they have completed the trial. After the 6-week intervention, participants in the intervention group will be interviewed over the phone to assess feasibility and usability. Subsequently, both groups will return to the study site (t_1) for the SUS questionnaire and secondary outcome measures. The study design and planned participant flow are presented in Figure 3.

XSL•FO
RenderX

Figure 3. Study design and planned participant flowchart. BG: Berufsgenossenschaft; ECG: electrocardiogram; PAR-Q+: The Physical Activity Readiness Questionnaire for Everyone; SCIM III: Spinal Cord Independence Measure III; SF-36: Short Form–36 Health Survey.

Participants

Eligibility Criteria

Participants are eligible for the study if they meet the following inclusion criteria: (1) chronic paraplegia (time since injury >1 year), (2) age between 18 and 67 years, (3) sufficient German language skills, (4) ability to provide informed consent, and (5) access to a smartphone. Participants will be excluded from the trial if they have any of the following conditions or diseases: (1) acute infection or inflammation (eg, urinary tract infection or pressure ulcers), (2) uncontrolled hypertension or diabetes, (3) manifest cardiovascular diseases, (4) psychiatric or mental conditions that compromise informed consent or may interfere with the study results (eg, major depression and psychotic disorders), (5) ongoing alcohol or substance abuse, and (6) other

XSL•FO
RenderX

medical contraindications. In addition, they will be excluded if they are high-performance athletes (in the national team).

Potential participants will be enrolled based on the results of the medical screening using their medical records, a resting electrocardiogram, and the Physical Activity Readiness Questionnaire for Everyone (PAR-Q+) [35]. Because participants recruited by the BG clinic Tübingen will not perform exercise tests, a resting electrocardiogram is not required.

Randomization

Only the 30 participants recruited at the GSU will be block randomized, stratified by the level (high vs low paraplegia) and completeness (complete vs incomplete paraplegia) of the SCI with a block size of 4. This will be done using Excel (Microsoft Corp). The randomization code will be released after the participant has completed all baseline measures. The randomization list will be password protected. Only JB and AL, who conduct the randomization and allocation, will have access to the list. No randomization is required at the BG clinic Tübingen, as data collection at that site focuses on the primary outcomes.

Intervention

Following baseline measures, the intervention group will receive an introduction to the downloading process and a demonstration of the app [28,36-39]. They will also be provided with a user's manual and 2 resistance bands with a resistance of their choice (TheraBand, The Hygenic Corporation), one of which is for backup. The intervention group will perform a 6-week home-based exercise program delivered by the ParaGym mobile exercise app, comprising three 35-minute exercise sessions per week. The app offers a different workout every day, and participants get to choose the days on which they want to exercise. An exercise session consists of 4 parts: warm-up, 2 exercise parts, and cooldown. The first exercise part focuses on the correct execution of the exercises at a moderate intensity and prepares the musculature for the high-intensity second part. Exercise sessions aim at various training goals, such as stabilization of the shoulder girdle and improvement of wheelchair mobility. The waitlist control group will only maintain usual care and receive access to the mobile app after postintervention measurements.

Measures

Primary Outcomes

Overview

The primary outcomes are feasibility, usability, and safety. Six weeks after commencing the intervention, semistructured interviews will be conducted via phone to investigate feasibility and usability. An interview guide was conceptualized based on interview domains and topics in similar studies [27,36,39-43]. The following topics will be addressed: (1) overall experience, (2) ease of use, (3) app functionality, (4) perceived safety, (5) technical functionality, (6) communication, (7) perceived effects and usefulness, (8) adherence and motivation, and (9) recommendation. The interviews will be audio recorded with the consent of the participants.

Feasibility

During their first site visit, participants in both the intervention and waitlist control groups will be provided with an exercise diary (Multimedia Appendix 2). They will be asked to record the following: (1) any physical activities, including app exercise sessions, additional exercise sessions (eg, hand biking), and physical therapy; (2) the time spent performing the exercise; (3) the intensity of the exercise; and (4) any annotations concerning the exercise sessions as needed (eg, whether the session adapted by the algorithm was appropriate in terms of the choice of exercise and intensity). This will help obtain more information about the feasibility of the app in addition to the information provided in the retrospective interviews and help assess adherence to the program. Adherence rates in terms of completed sessions will also be measured based on app use data. Furthermore, retention rates will be measured by assessing dropout rates and reasons. As both adherence and retention are study outcomes, they should not be influenced by the investigators. Therefore, no measures will be taken to promote either of them. All outcome measures will be obtained regardless of adherence.

Usability

The SUS [44] is a 10-item Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree") and is a common tool for investigating the usability of health-related mobile apps [27,36,38,39,41-43,45,46]. The score will be converted according to Brooke [44], so the total score will range from 0 to 100. The app will be considered usable if the overall SUS score is at least 70 [47].

Safety

The safety of the app-based exercise program will be determined based on the occurrence of intervention-related AEs and SAEs. Participants will be instructed to report any AEs or health-related interruption of the intervention within 24 hours. AEs and SAEs will be classified by the grade of severity based on the Spinal Adverse Events Severity System version 2 (SAVES-V2) scale [48] (Table 2) and expectance. The following AEs and SAEs can occur because of physical strain or are common complications after SCI and are, therefore, classified as expected AEs or SAEs: (1) autonomic dysreflexia, (2) pressure ulcers, and (3) shoulder pain [49].

XSL•FO
RenderX

Table 2. Classification of adverse events (AEs) and serious adverse events (SAEs) based on the Spinal Adverse Events Severity System version 2 scale.

Severity of AE or SAE	Clinical impact
1	AE—no treatment
2	AE—outpatient treatment
3	SAE—inpatient treatment
4	SAE—life-threatening injury
5	SAE—death

Secondary Outcomes

Overview

The secondary outcome is the effect of the intervention on peak exercise capacity, handgrip strength, independence, and quality of life. Peak exercise capacity and strength parameters were chosen because they are important factors for improving quality of life [11,15] and independence [10,14]. Quality of life and independence were chosen because these parameters are integral to the overall rehabilitation goal of people with SCI [50]. Furthermore, the guidelines for the conduct of clinical trials for SCI [51] suggest using the Spinal Cord Independence Measure III (SCIM III) for functional assessments and the Short Form–36 Health Survey (SF-36) for quality-of-life assessments.

Ramp Exercise Test

Participants will perform a ramp exercise test on an arm crank ergometer (ergo-metrics 800s, Ergoline). The rotational axis of the ergometer will be set at shoulder level. The distance between the wheelchair and ergometer will be set such that there is a slight flexion in the elbow joint when the participant extends their arm. A 3-minute warm-up will be conducted at a cadence of 60 to 70 revolutions per minute and a resistance of 0 W. After the warm-up, the workload will be increased by 10 W per minute (1 W every 6 seconds) until volitional exertion is reached [52]. Volitional exertion is reached when the cadence drops below 50 revolutions per minute [52] or rate of perceived exertion exceeds 18 on the Borg scale ranging from 6 to 20 [53]. Heart rate (Polar H7 chest belt, Polar Electro Oy), workload, and respiratory gas exchange parameters (MetaMax 3B, Cortex) will be monitored throughout the exercise test [52]. Participants will be asked to rate their level of perceived exertion on the Borg Rate of Perceived Exertion scale upon the termination of the exercise test.

Handgrip Strength

The determination of handgrip strength using a handgrip dynamometer is a widely applied, simple, and reliable method for evaluating the efficacy of a treatment [54] and predicts functional independence [55]. An electronic hand dynamometer (Trailite TL-LSC1000, LiteXpress GmbH) will be used to determine maximal handgrip strength. Participants will be asked to grip the handle with maximal effort [56]. As warm-up trials decrease the variability of strength measurements [54], participants will be given 1 warm-up trial for each hand. A total of 3 attempts will be made for each hand for a duration of 3 seconds each at a 90-degrees elbow flexion and neutral wrist position [54,55,57]. A rest period of 60 seconds will be provided in between. The sum of the highest values for the right and left hands will be used to determine handgrip strength [55].

Independence

The SCIM III was developed to sensitively detect changes in function (eg, concerning respiration) in individuals with SCI [58] and changes in various activities of daily living (eg, bed-wheelchair transfers) [59]. It shows a very high interrater reliability (r=0.98; P<.001). The SCIM III is subdivided into 3 categories: (1) self-care, (2) respiration and sphincter management, and (3) mobility. The score ranges from 0 to 100. A higher score indicates greater independence. In this study, the German version of the SCIM III will be used [60].

Quality of Life

The SF-36 is the most commonly used questionnaire to assess quality of life in people with SCI and has been shown to be valid and reliable for this population [61]. The survey comprises 36 items across 8 domains. The score ranges from 0 to 100, with a higher score indicating a better quality of life [62]. As previously recommended [11,63,64], 2 items referring to "climbing stairs" were replaced with "going up stairs" (German: *Stufen überwinden*), and 3 items referring to "walking" were replaced with "going" (German: *fortbewegen*).

Data Management and Analyses

Data Management

Data will be entered into Microsoft Excel (version 2018) by one researcher and double-checked by another researcher before being analyzed using SPSS Statistics (version 29, IBM Corp). To ensure confidentiality, data will be recorded using the participants' study ID instead of their names. All data forms will be stored electronically and protected by a password in addition to being stored in paper form and secured in a locker in a room with restricted access. Only the authors of this manuscript will have access to the full data set. The principal investigator (JB) will monitor AEs. The data will be deleted upon participants' request.

Sample Size

The aim is to recruit a total of 45 participants between November 2022 and January 2023: 30 participants at the GSU and 15 participants at the BG clinic Tübingen. As this is a pilot trial, the sample size was based on previous studies with similar aims and methods [27,28] and recommendations for usability testing [65].

XSL•FO
RenderX

Qualitative Analysis

The interview audio recordings will be transcribed verbatim and analyzed using a qualitative content analysis approach according to Mayring [66] using MAXQDA (version 22, VERBI). Categories arising from the interview guide will be determined a priori. Two researchers will identify codes for the first 3 interviews and assign them to a category deductively. An inductive approach will be used to create additional categories and subcategories. Disagreements between researchers during the categorization process will be discussed until a consensus is reached. The interviews will be revised upon considering possible changes in the category system. More interviews will be analyzed until data saturation is achieved [40,45].

Quantitative Analysis

Quantitative data analysis will be performed using SPSS. All data will be tested for normal distribution using the Shapiro-Wilk test. Study participant characteristics will be presented descriptively by calculating means and SDs for normally distributed variables. Median values and IQR will be calculated for skewed continuous variables, and absolute and relative frequencies will be calculated for nominal variables. Group differences at baseline will be calculated for independent samples using a 2-tailed *t* test, Mann-Whitney *U* test, or chi-square test depending on the distribution and level of measurement. At t_1, normally distributed continuous variables will be analyzed using a mixed analysis of variance model to test for significant effects for group and time. For skewed continuous variables, Wilcoxon and Mann-Whitney *U* tests will be conducted to test the differences between the groups and between t_0 and t_1. The significance level will be set at $P<.05$. Absolute and relative frequencies will be reported for adherence and retention.

Feasibility will be assumed if (1) at least 66% of the training sessions (equivalent to 2 out of 3 sessions per week) are completed [43] and (2) the retention rate is at least 75% [67]. Exercise diaries will be analyzed in terms of the frequency, duration, and intensity of the training sessions. Safety will be assessed by comparing the number of study-related AEs or SAEs in the intervention group with that in the waitlist control group [68].

Spearman correlations will be used to assess the association between performance and strength outcomes and SCIM III and SF-36 outcomes. Subgroup analyses might be conducted for lesion level (high vs low paraplegia) and age. Missing data will not be imputed.

Ethics Approval

The conduct of the trial was approved by the ethics committee of the GSU (ethics committee number 180/2021). Comprehensive study information is sent to potential study participants before their first site visit to allow sufficient time to fully read and understand all the information. Study information includes details on the following: (1) general information and background; (2) eligibility criteria; (3) study aims and procedures; (4) participants' rights, duties, and benefits; (5) potential risks; (6) data protection and management; (7) insurance; (8) funding; and (9) contact persons.

Participants will confirm that they have read, understood, and agreed to the terms of study participation by providing written informed consent before inclusion in the trial.

Precautions that will be taken to minimize the risk of cardiovascular events and AEs include the application of exclusion criteria, the conduct of a medical screening before enrollment, the distribution of a safety advice sheet, and integration of safety advice into the app.

To ensure confidentiality, we pseudonymized all participants' data (refer to the *Data Management* section). Participants will receive compensation for travel expenses and the interpretation of their test results upon study completion. Any amendments to the protocol will be documented, and substantial changes will need to be approved by the ethics committee.

Results

This trial is part of the FIT-IN^3 (ParaGym) project, which is funded by the German Federal Ministry of Education and Research in September 2020 (funding number 16SV8572). The project started in September 2020 and is expected to be completed by August 2023. Recruitment for the trial began on November 1, 2022. A total of 12 participants were enrolled in the trial at the time of the submission of this manuscript (Table 3). Data collection will begin in January 2023 and is expected to be completed by April 2023. The results will be published in accordance with the CONSORT (Consolidated Standards of Reporting Trials) 2010 statement for randomized pilot and feasibility trials [69] as well as the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) statement [70].

Table 3. Characteristics of the participants (n=12) enrolled in the study at the time of submission.

Characteristics	Intervention group (n=8)	Control group (n=4)
Gender, n (%)		
Women	4 (50)	2 (50)
Men	4 (50)	2 (50)
Age (years), median (IQR)	55 (37-62.5)	34 (18.5-56)
Lesion level, n (%)		
T1-T6[a]	3 (38)	0 (0)
T7-S5[b]	5 (62)	4 (100)
Lesion completeness, n (%)		
Motor complete (AIS[c] A-B)	6 (75)	2 (50)
Motor incomplete (AIS C-D)	2 (25)	2 (50)
Time since injury (years), median (IQR)	11 (4.5-26.5)	17 (8-24.5)
Experience with exercise apps, n (%)		
Yes	4 (50)	0 (0)
No	4 (50)	4 (100)

[a]T: thoracic vertebra.

[b]S: sacral vertebra.

[c]AIS: American Spinal Injury Association Impairment Scale.

Discussion

Principal Findings

To the best of our knowledge, this is the first trial to investigate the feasibility, usability, and safety of a 6-week exercise program delivered by an intelligent mobile exercise app for individuals with paraplegia using qualitative and quantitative measures. As secondary outcomes, the preliminary effects of this program on peak exercise capacity, handgrip strength, independence, and quality of life will be assessed. As the app is currently at a prototype stage, technical issues compromising feasibility and usability might occur. Both the semistructured interviews and exercise diaries will provide detailed insights into the users' experience with the app. This will help identify various aspects regarding the feasibility and usability of the exercise sessions, app's interface, and app's technical functionality, including intelligent personalization. Furthermore, users' practical suggestions for improvement will contribute to drawing practical implications. These could include the following: (1) further adapting the app to meet the needs of the target group; (2) fixing technical issues; (3) improving the ease of use, (4) improving the design, intensity, and duration of the exercise sessions; and (5) improving the overall satisfaction with the app. Before integrating the exercises into the app, all exercises, including the exercise videos and descriptions, were tested and evaluated in terms of feasibility, usability, and comprehensibility by 10 workshop participants with paraplegia. Therefore, we expect these exercises to be feasible and usable. The program is expected to be safe, as a very low incidence of AEs has been reported during exercise trials with this cohort [49,71].

Similar mobile apps for promoting a healthy lifestyle in people with SCI have been shown to be feasible [27,28]. However, these apps were not declared to be at a prototype stage. In contrast to these already existing mobile apps, the ParaGym mobile exercise app delivers individualized training sessions without the need for exercise selection by the users or health care professionals. Thus, training sessions can be performed independently by people without specific knowledge of training and exercise. In fact, the most frequently mentioned suggestion for improvement of the WHEELS app [27] was related to personalization and better tailoring to the user's needs and functional capabilities.

This trial will provide preliminary insights into the potential effects of the intervention on peak exercise capacity, handgrip strength, independence, and quality of life. Integrated exercises were designed to be appropriate for a beginner's fitness level, so they will be feasible for most participants.

Strengths and Limitations

Using the SPIRIT 13 Guidelines [31,72] for reporting the planned trial and the SCI trial guidelines [51,73] for designing as well as randomizing and controlling the trial improves its strength. In addition, the GSU cooperates with the BG clinic Tübingen to reach a larger sample size. Another strength is the compatibility of the app with various operating systems such as iOS (Apple Inc) and Android. However, smartphones should not be older than approximately 5 years to guarantee absolute functionality.

The ParaGym mobile app is currently at a prototype stage. Therefore, only basic functions and features are currently included. This could impact the variety of exercises, especially for users with severe impairments, which may decrease their motivation to use the app. The conclusiveness and generalizability of the results will be limited owing to the small

XSL•FO
RenderX

sample size. In addition, only healthy adults with paraplegia were included in the study. Therefore, many individuals will be excluded from the study. Generalizability is also limited because the prevalence of cardiovascular diseases is high in individuals with SCI [74,75]. In addition, not restricting additional sports activities may have a major impact on the postintervention measurement results. Moreover, selecting exercises that are mainly suitable for beginners may compromise the effectiveness for intermediate users. Finally, all exercises will be performed using body weight or a resistance band, which will limit the user's opportunity to increase intensity compared with using additional weights.

Conclusions and Implications

By using both qualitative and quantitative measures, the results of this trial will generate a comprehensive understanding of the limitations and strengths of the ParaGym mobile exercise app as well as possible solutions to address the limitations. In the next step, in addition to fixing technical issues, the app should be adapted according to the findings of this study. This could include the expansion of the exercise pool and the addition of more equipment to increase variability and meet the needs of more advanced users. Hence, this could lead to an increased intensity of exercise sessions, which might result in greater effectiveness. Furthermore, the app interface might need to be adjusted to improve the ease of use. Finally, users may desire more features, such as the opportunity to design individual workouts or the integration of gamification to visualize the training process and promote adherence.

This pilot study will provide important results that need to be considered in the planning of future trials with an updated version of the app, which would aim for a larger sample size, longer intervention duration, and more diverse target group. As other individuals who use wheelchairs may also benefit from using the app, a requirement analysis addressing a broader target group should be conducted. Subsequently, a full-scale multicenter trial [73] including a broader target group, for example, people with acute SCI, tetraplegia, or other impairments, should be undertaken. In addition, by solely including healthy adults with SCI, a large proportion of the population was excluded. The prevalence of secondary diseases, such as cardiovascular diseases, is higher in individuals with SCI than in able-bodied people [74,75]. Therefore, investigators of future trials should consider including individuals with secondary diseases to assess the safety of the intervention for this group as well. Finally, future trials should include follow-up measures to investigate long-term motivation and adherence. In the long term, a fully marketable version of the ParaGym app should be implemented to make it publicly accessible.

An additional application of the ParaGym app could be its incorporation into workplace health programs, offering an exercise program for individuals who use wheelchairs and individuals with high levels of sedentary time at work.

A feasible, usable, and safe intelligent exercise app would increase access to personalized, independent, and evidence-based exercise training for this cohort and, in the future, for other individuals who use wheelchairs.

Acknowledgments

This trial is part of the FIT-IN^3 (ParaGym) project, which is funded by the German Federal Ministry of Education and Research in September 2020 (funding number 16SV8572). The trial design and conduct are entirely independent of the funding party.

Data Availability

The results of the trial will be published with open access in international journals after study completion. Additional anonymized information is available from the corresponding author upon request.

Authors' Contributions

JB is acting as a trial sponsor, taking responsibility for the conception and implementation of the trial; data management, analysis, interpretation; and reporting of results. The sponsor's contact information is consistent with that of the corresponding author. JB, AL, HGP, and CP conceived the study design and methodology. JB, AL, RM, and AB are responsible for recruitment and will implement the study. Data will be collected and assembled by JB, AL, and RM. Statistical analysis and data interpretation will be conducted by JB and AL with support from CP. JB drafted the first manuscript. All authors contributed to editing and critically revising the study protocol and approved the final version. All authors agree to be accountable for all aspects of this work.

Conflicts of Interest

None declared.

Abstract

Background: One-third or more of breast cancer survivors report stress and other psychological and physical complaints that can negatively impact their quality of life. Psychosocial stress management interventions, shown to mitigate the negative impact of these complaints, can now be delivered as accessible and convenient (for the patient and provider) eHealth interventions. In this randomized controlled trial (RCT), Coping After Breast Cancer (CABC), 2 modified versions of the stress management eHealth intervention program StressProffen were created: one with predominantly cognitive behavioral stress management content (StressProffen-cognitive behavioral therapy intervention [StressProffen-CBI]) and another with predominantly mindfulness-based stress management content (StressProffen-mindfulness-based intervention [StressProffen-MBI]).

Objective: This study aims to investigate the effects in breast cancer survivors of using StressProffen-CBI and StressProffen-MBI compared with a control group (treatment as usual).

XSL•FO
RenderX

Methods: Women diagnosed with breast cancer (stage I-III, unequivocally human epidermal growth factor receptor 2–positive or estrogen receptor-negative tumors) or ductal carcinoma in situ (DCIS) aged 21-69 years who completed the Cancer Registry of Norway–initiated health survey on quality of life are invited to the CABC trial about 7 months after diagnosis. Women who give consent to participate are randomized (1:1:1) to either the StressProffen-CBI, StressProffen-MBI, or control group. Both StressProffen interventions consist of 10 modules of stress management content delivered through text, sound, video, and images. The primary outcome is between-group changes in perceived stress at 6 months, assessed with Cohen 10-item Perceived Stress Scale. The secondary outcomes comprise changes in quality of life, anxiety, depression, fatigue, sleep, neuropathy, coping, mindfulness, and work-related outcomes approximately 1, 2, and 3 years after diagnosis. Long-term effects of the interventions on work participation, comorbidities, relapse or new cancers, and mortality will be assessed using data from national health registries.

Results: Recruitment is scheduled from January 2021 to May 2023. The goal is to recruit 430 participants (100 in each group). As of April 14 2023, 428 participants have been enrolled.

Conclusions: The CABC trial is possibly the largest ongoing psychosocial eHealth RCT in patients with breast cancer. If 1 or both interventions prove to be effective in reducing stress and improving psychosocial and physical complains, the StressProffen eHealth interventions could be beneficial, inexpensive, and easily implementable tools for breast cancer survivors when coping with late effects after cancer and cancer treatments.

Introduction

Breast Cancer Treatment and Long-Term Complaints

Breast cancer survival rates largely depend on cancer subtype, stage, treatment, and age. The 5-year relative survival rate for individuals with early breast cancer is firmly increasing and has exceeded 90% in most Western countries due to advances in diagnostics and treatment [1,2]. In Norway, nationwide mammography screening programs combined with high breast cancer awareness have contributed to most patients being diagnosed with stage I with 100% 5-year survival rate [2].

Supportive therapies have improved and thus reduced the immediate side effects of adjuvant systemic therapies. Nonetheless, breast cancer diagnosis and treatment may still cause substantial psychosocial complaints (stress, distress, anxiety and depression), pain, fatigue [3,4], and several physical complaints that usually emerge during treatment and often persist over a longer term [5,6].

These complaints can affect the ability to manage thoughts, feelings, and behavior [7,8] and negatively impact the individual's perceived physical, mental, and social well-being, often assessed through measures of health-related quality of life [9-11]. A breast cancer diagnosis and therapy may also have persistent negative effects on work and increase the risk of both short-term sick leave [12-14] and long-term disability pension [15-24], thus resulting in a lower workforce participation years following the diagnosis [25]. With an increasing prevalence of cancer worldwide [26], interventions to improve quality of life for cancer survivors are therefore important [27].

Psychosocial Stress Management Interventions

Psychosocial stress management interventions have been shown to mitigate short- and long-term complaints following a cancer diagnosis and treatment [9,28,29]. This includes improvement of negative psychosocial impacts of breast cancer [30-32], reduction of stress and stress-related symptoms [31,33,34], anxiety [31], depression [10,31,35], fatigue [31,35-37], insomnia [37-39], and pain [34], as well as improvement in quality of life [9,37,40,41]. The prevalence of distress and the potential negative impact of unrecognized and untreated distress in patients with cancer are widely recognized [42], and so is the potential effectiveness of psychosocial interventions for stress and distress management [43].

Psychosocial stress management interventions typically include components of cognitive behavioral therapy (CBT) and mindfulness techniques, designed to teach patients strategies for managing stress [27,44]. The basis of CBT is understanding that cognitions mediate the relationship between life events and emotional reactions [45]. CBT strategies target unhelpful or maladaptive cognitions with various techniques and behavioral strategies to moderate emotional responses and unhelpful coping behavior [45]. CBT-based interventions (CBIs) often combine aspects such as cognitive restructuring, coping effectiveness training, assertiveness, and anger management skills with relaxation (eg, muscle relaxation and imagery) [46].

Mindfulness-based interventions (MBIs) aim to cultivate present-moment awareness coupled with attitudes of acceptance, nonjudging, and nonattachment, through both formal (eg, awareness of breathing, sitting, walking, body scan) and informal (eg, mindfulness in everyday life) mindfulness practices. MBIs are typically adapted from the Mindfulness-Based Stress Reduction program of Kabat-Zinn

XSL•FO
RenderX

[31,47]. One such adaptation, mindfulness-based cancer recovery [29], is specifically designed for patients and survivors of cancer [48].

Although often used in combination, there are distinct theoretical and methodological differences between CBIs and MBIs for stress management. Although one of the core components in CBIs is to help modify "unhelpful" ways of thinking, MBIs fall within a group of "acceptance-based therapies" and focus on adopting a state of nonjudgmental awareness and acceptance of the present moment, without a specific intent to modify thoughts or behavior [49]. CBIs such as cognitive behavioral stress management interventions have been used extensively in studies with breast cancer survivors [9,10] with positive effects in both short and long term [9,10]. This includes a reduction in psychosocial and physical complaints and improvement of physical and mental quality of life [9], up to 15 years after the intervention [50]. MBIs have shown positive short-term effects on psychosocial and physical complaints and improvement in measures of quality of life [51-54], but the long-term effects are either inconclusive or have not been studied [37]. Furthermore, whether the effects of CBIs and MBIs on stress management are comparable is unknown, as no known direct comparison between the intervention types has been conducted.

The optimal window for when to deliver stress management interventions has not been established [55]. Many psychosocial interventions have been conducted short term following a breast cancer diagnosis as this represents an acute period of stress that may influence treatment response and relevant clinical outcomes. There have also been successful psychological interventions implemented after surgery, although not as frequently as after other types of treatment for breast cancer survivors [55].

e-Health Interventions

Although in-person face-to-face delivery of psychosocial stress management interventions has been the most common, technical innovations that have accelerated due to the COVID-19 pandemic have resulted in increased use of eHealth interventions in clinical practice [55]. There are advantages to developing eHealth versions of established stress management interventions that extend beyond an adaptation to the restrictions imposed by the pandemic. eHealth interventions are often less expensive to implement after the initial production costs, and are more accessible for people living in remote areas. These can also be more convenient for persons with movement restrictions or other reasons for not being able to see health care providers face-to-face [56]. Studies testing eHealth psychosocial stress management interventions have been considered acceptable and feasible for breast cancer survivors [56,57], with positive effects on quality of life in patients with cancer following diagnosis [58]. However, more research is needed [55], as the effects of psychosocial eHealth interventions, in general in cancer survivors, have been mixed and inconclusive [59-63]. Furthermore, there is a need for studies testing stress management eHealth interventions in larger samples, after the initial phase of medical treatment, and with longer follow-up than previous research [64].

The Coping After Breast Cancer (CABC) trial was designed to test the effect of 2 eHealth-based stress management interventions (CBI and MBI groups), in comparison to a treatment as usual (TAU) control condition, on improving psychosocial factors, physical complaints, and work-related outcomes in breast cancer survivors. With long-term follow-up on work participation, comorbidities, relapse or new cancers, and mortality, the trial addresses the overall aim of validating eHealth stress management interventions to facilitate future implementation.

Methods

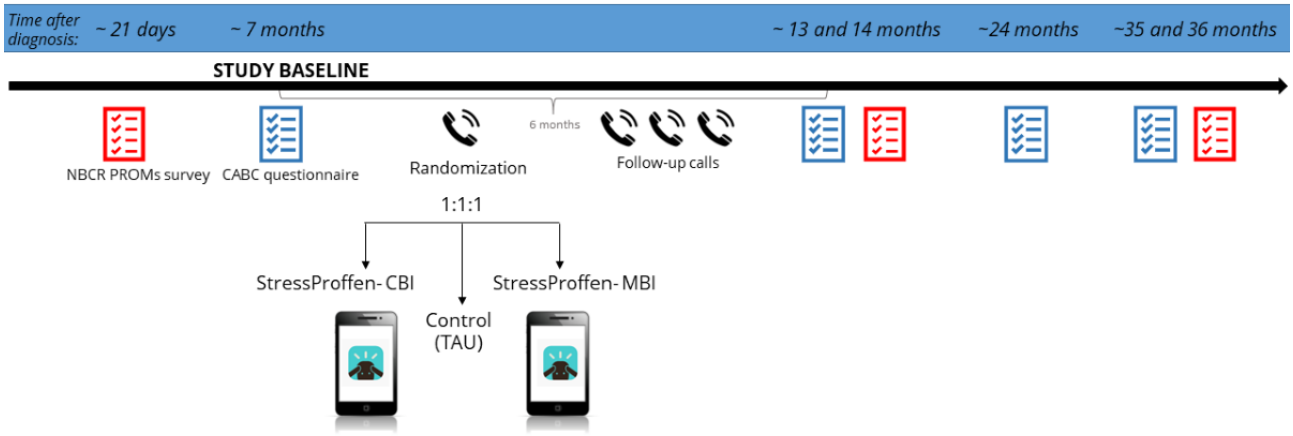
Objective and Hypotheses

The overall objective of the CABC trial is to investigate the effects of using eHealth interventions with cognitive behavioral stress management content (CBI group) or mindfulness-based stress management content (MBI group) in breast cancer survivors compared with a TAU control group (TAU group).

Specific Hypotheses

- The CBI and MBI groups will achieve a statistically significant larger reduction in perceived stress after 6 months of access to the interventions (13 months after diagnosis) compared with the TAU control group (*primary outcome*).
- The CBI and MBI groups will achieve a significantly larger reduction in perceived stress, distress, fatigue, peripheral neuropathy, vaginal symptoms, and arthralgia and a significantly larger improvement in quality of life, mindfulness, sleep, coping, and work-related outcomes 13, 24, 35, and 36 months after diagnosis compared with the TAU control group (*secondary outcomes*).
- Additionally, exploratory analyses will be conducted to investigate the following:
  - characteristics of study responders and intervention completers versus nonresponders and noncompleters;
  - predictors of intervention effects;
  - potential differences in intervention effects between the CBI and MBI groups;
  - long-term consequences of the interventions related to work participation; and
  - long-term effects of the interventions on comorbidities, relapse or new cancers, and mortality.

Study Design and Setting



The CABC trial is a randomized controlled trial (RCT; ClinicalTrials.gov identifier NCT04480203) assessing the effects of 2 stress management eHealth interventions compared with TAU in breast cancer survivors. The trial is conducted at the Cancer Registry of Norway (CRN) at Oslo University Hospital. The eHealth interventions are delivered through the mobile app StressProffen [65], which was developed, and is managed, by a team led by 2 of the coauthors (LSN and EB) at the Department of Digital Health Research at Oslo University Hospital.

The study protocol of the CABC trial is presented according to the SPIRIT (Standard Protocol Items: Recommendations for

XSL•FO
RenderX

Interventional Trials) initiative [66] (Multimedia Appendix 1). The study outline is shown in Figure 1 and described in further detail in the following sections.

Figure 1. Overview of milestones in the CABC RCT. Study baseline is approximately 7 months after breast cancer diagnosis. Eligible participants who have completed the CRN PROMs survey, consented to the CABC study, and completed baseline questionnaires are randomized to either the StressProffen-CBI, StressProffen-MBI or a control group (TAU). Recruitment is scheduled from January 2020 to May 2023. Pictures from colourbox.com and StressProffen. CRN PROMs survey: The Cancer Registry of Norway Patient Reported Outcome Measures; CABC: Coping After Breast Cancer; CBI: cognitive behavioral intervention; MBI: mindfulness-based intervention; NBCR: Norwegian Breast Cancer Registry; RCT: randomized controlled trial; TAU: treatment as usual.

Participants and Eligibility

The Cancer Registry of Norway

Study participants with incident breast cancer are identified and included from the CRN. The CRN has recorded incident cancer cases in Norway since 1952 with accurate and almost complete ascertainment of cases (99% complete on a minimum of diagnostic information on solid tumors [2]). The CRN hosts the Norwegian Breast Cancer Registry that has detailed information on breast cancer diagnoses extracted from pathology reports, and details on treatment including the type of breast and axillary surgery, radiotherapy, and systemic therapy. Nonetheless, as of 2020, the CRN also collects and stores data on patient-reported outcome measures (PROMs). The CRN PROMs survey is an ongoing, digital survey sent through the official Norwegian health portal Helsenorge [67] or an official digital mailbox (Digipost/eBox) to patients with breast cancer and age-matched controls approximately 21 days, 14 months, and 36 months following diagnosis. Currently, 88% of eligible patients with breast cancer are invited to this survey, and the response rates were 52% in 2020 and 49% in 2021 [68]. Specific data from the CRN PROMs survey will be included as outcomes in this study, and the survey content is therefore described further below.

CABC Trial Eligibility

Women who are aged between 21 and 69 years when diagnosed with subtypes of invasive breast cancer, International Classification of Diseases, 10th revision (ICD-10) code C50, or ductal carcinoma in situ (DCIS), ICD-10 code D05.9, in the period from 2020 to 2023, and who have completed the initial CRN PROMs survey are eligible for inclusion in the CABC trial, at about 7 months (6-9 months) after diagnosis. The timing was chosen to ensure that most patients have completed the first part of their treatment, and that details about the breast cancer subtype have been coded in the CRN.

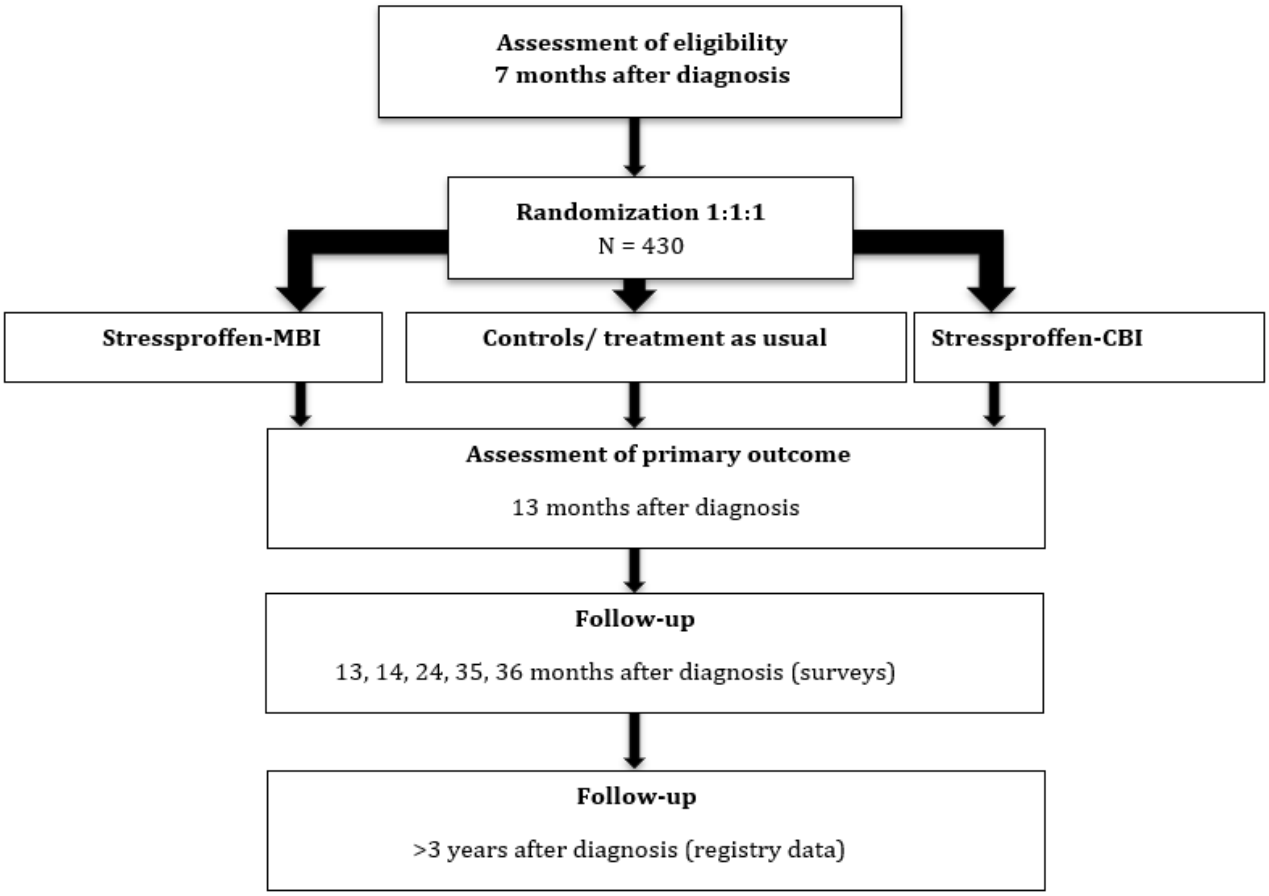
See Textbox 1 for an overview of the inclusion criteria. Participants in the intervention groups must also have access to, and be able to use, a smartphone or a tablet. There are no restrictions regarding types of treatment, nor any geographical restrictions, given the digital nature of the intervention.

The upper age limit of 69 years was chosen to correspond with the upper age limit of the participants in the Norwegian breast screening program. To avoid overlap with 2 ongoing clinical trials in Norwegian patients with breast cancer (EMIT, ClinicalTrials.gov Identifier: NCT03904173 and OPTIMA [no registration number]), recruitment of the invasive cases in the CABC trial is restricted to those with stage I-III estrogen receptor (ER)–negative or human epidermal growth factor receptor 2 (HER2)–positive tumors, or a combination of ER+ and HER2–. This is typically about 15% of all breast cancer cases (unpublished data from the CRN during 2020-2021).

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for the Coping after Breast Cancer trial.

Inclusion criteria



- Women;
- Incident: ductal carcinoma in situ or breast cancer stage I-III, unequivocally human epidermal growth factor receptor 2–positive or estrogen receptor–negative tumor(s);
- Age 21-69 years;
- Residing in Norway;
- Submitted the initial Cancer Registry of Norway patient-reported outcome measures (CRN PROMs) survey, which is sent 21 days after diagnosis. This also implies that they are fluent in Norwegian and are active users of the digital portal: Helsenorge [67] or have a digital mailbox.
- Submitted the initial Coping after Breast Cancer (CABC) survey, which is also sent 21 days after diagnosis. This also implies that they are fluent in Norwegian and are active users of the digital portal: Helsenorge or have a digital mailbox (that imply consent to participation).

CABC Trial Enrollment

Study recruitment is scheduled from January 2021 to May 2023 with patients diagnosed over the previous year. Participants are continually recruited at approximately 7 months after their breast cancer diagnosis.

Invitations are sent every week (except during holiday periods) along with the study-specific CABC survey. In total, 430 participants will be enrolled in the trial (Figure 2).

Figure 2. Flowchart of inclusion of study participants invited ≈7 months after diagnosis. CBI: cognitive behavioral intervention. MBI: mindfulness-based intervention.

Randomization

Once an eligible participant has submitted the CABC survey at baseline (that also implies consent to participate), the participant is allocated to 1 of the intervention groups or the control group in the ratio 1:1:1 (Figure 1). The randomization algorithm uses a variant of block randomization, with no stratification, where block sizes vary between 12, 18, 21, and 27. The output of the randomization algorithm for each participant is a string representing an access code to 1 of the 2 interventions (each intervention has a unique access code), or a string indicating that the participant was randomized to the control group. The access code is used to download the StressProffen program (an

XSL•FO
RenderX

app). The randomization is performed in R studio version 1.2.1335 (The R Foundation for Statistical Computing).

Intervention identification is not possible from the access code, and participants in the 2 intervention groups are not informed to which of the intervention they have been assigned to. However, an informed participant may detect which group they are in by identifying content when using the assigned app. Hence the trial is single blinded.

After randomization, participants randomized to 1 of the intervention groups receive a letter containing information about the scheduled time for the first phone call. For participants randomized to the control group, the letter contains information about the timing of further follow-up surveys.

StressProffen Interventions

The interventions used in this trial are 2 modified versions of an evidence-based stress management eHealth intervention program (StressProffen) developed for cancer survivors [65,69-71]. For privacy reasons, there is, however, no mention of the word "cancer" in either intervention.

The original StressProffen program includes both CBT and mindfulness. It contains psychoeducational materials (eg, about stress, coping, social support, anger management, assertiveness, and health behaviors) and a variety of exercises, including exercises related to how to cope with challenging thoughts, feelings, and bodily states (eg, positive self-talk, diaphragmatic breathing, progressive muscle relaxation, guided imagery, mindfulness, and meditation) [65].

For the CABC trial, the project team modified the StressProffen program and developed 2 distinct stress management interventions: a CBI (StressProffen-CBI) and an MBI (StressProffen-MBI) (E. Børøsund et al, unpublished data, 2022).

Both interventions contain 10 modules of stress management education material and exercises delivered through text, sound, video, and images/pictures [65]. After 1 module is completed, there is a 3-day delay before the next module is available. The purpose of this delay is to encourage the participant to spend time reflecting and practicing previous content and exercises. The program has several features that make it easy to use, such as the ability to mark exercises as favorites, offline mode, and the possibility to set reminders [65].

Modification of the content/content development was conducted by 4 subject matter experts (AM, HRE, LSN, and EB), an epidemiologist (GU), and a content editor (CMR). As in the original StressProffen intervention program, the StressProffen app was used for both interventions. General information (ie, text unrelated to CBI and MBI) was retained from the original StressProffen program and reused for both interventions, and the team strived to balance the number and length of the other modules and subsections, exercises, figures, and models between the 2 interventions.

The content of the final interventions relied on the original StressProffen program, with most of the original content being retained in the CBI version, but with some adjustments, including minor therapeutic language adjustments. More content adjustments and revisions were made for the MBI version, with new developed content from the project team experts, as well as inclusion of adapted content (ie, translation and modifications to fit the language and structure) from the Mindfulness-Based Cancer recovery manual [29]. The adaptation included translation and modifications to fit the language and structure used in the current intervention (E. Børøsund et al, unpublished data, 2022).

All participants in the intervention groups have access to the assigned StressProffen interventions for the entire study period and in the future for as long as Oslo University Hospital manages the app. The control group receives access to StressProffen upon request when their participation in the trial is finished.

Potential Intervention Harms

The CBI and MBI interventions have no known harms. A feeling of disappointment might arise if the participant does not feel that their stress level has been reduced during the study period. Although the vast majority of literature says otherwise, it cannot be completely ruled out that meditation-based therapies may lead to distress [72].

As the participants do not have access to individual therapy through the study, participants in both intervention groups are encouraged to seek professional help from their primary caregiver, should they wish/feel a need to do so.

Follow-up

The initial phone call to participants in the intervention groups is scheduled shortly after randomization and consists of a structured introduction to the StressProffen program lasting 15-20 minutes (Figure 1). During this phone call, participants download the StressProffen app, obtain, and enter their access code, and consequently receive access to download 1 of the 2 interventions. Participants are encouraged to start using the app immediately after the phone call.

After the initial phone call, there are 3 additional follow-up phone calls (approximately 1, 3, and 6 weeks following the initial phone call) to increase adherence to the protocol, especially to support motivation and prevent dropouts by checking how participants are doing with the intervention and resolving any technical issues. For the follow-up phone calls, 3 weekly attempts to reach the participants are undertaken. During the final phone call at 6 weeks, participants are informed that further follow-up in the CABC trial will consist of annual surveys over the next 3 years (Figure 1).

Communication

In addition to the scheduled follow-up calls, participants are encouraged to call the study telephone number with any questions they may have. The cancer advisory unit at the patient advocate organization, the Norwegian Cancer Society [73], and the Breast Cancer Oncology Group (Norwegian Breast Cancer Group) [74] also have basic information about the CABC trial, in case the participants call them for support. Furthermore, the CRN and the Norwegian Breast Cancer Society share information about the trial occasionally through their social media platforms and newsletters. These channels will also be

XSL•FO
RenderX

used to inform people about published results. In addition to scientific publications and presentations of results at scientific conferences, results will be communicated to the public through various media outlets after the study end. Any changes to the protocol will be recorded simultaneously at the ClinicalTrials.gov registry [75].

Outcome Measures

Surveys

Outcomes are assessed with 2 digital surveys: the ongoing CRN PROMs survey and the study-specific CABC survey (Table 1).

Table 1. Detailed information on outcome measures that will be obtained from the CABC[a] survey and the CRN PROMs[b] survey.

Outcome(s)	Assessed with	Number of items, n
CABC survey: ≥7, 13, 24, and 35 months after diagnosis		
Primary outcome (from 7 to 13 months after diagnosis)		
Perceived stress	Cohen 10-item Perceived Stress Scale [76]	10
Secondary outcomes (all time points)		
Perceived stress	Cohen 10-item Perceived Stress Scale [76]	10
Health and health-related quality of life	RAND Corporation 36-Item Short Form Health Survey [11]	36
Coping	Theoretically Originated Measure of the Cognitive Activation Theory of Stress [77]	7
Fatigue[c]	Chalder's Fatigue Scale [78]	11+2[d]
Awareness/mindfulness	Baer's Mindfulness Questionnaire [49,79]	15
Distress	Patient Health Questionnaire [80]	4
Sleep	The Survey of Shift Work, Sleep and Health [81]	10
Work and use of social services[e]	Work, use of social services, and Ability Index [82] and single-item question [83]	3
CRN PROMs survey: ≥21 days and 14 and 36 months after diagnosis		
Secondary outcomes (all time points)		
Cancer-related quality of life	European Organization of Research and Treatment of Cancer-Core Quality of Life Questionnaire [84]	30
Breast cancer–related quality of life	European Organization of Research and Treatment of Cancer-Core Quality of Life Questionnaire: Breast Cancer–Specific Module [85]	23
Neuropathy/neuropathic pain, vaginal symptoms, arthralgia	Functional Assessment of Cancer Therapy: Gynecologic Oncology Group—Neurotoxicity and Endocrine Symptoms [86]	8
Fatigue	Chalder's Fatigue Scale [78]	11+2[d]
Workability and use of social services	Work Ability Index [82] and single-item question [83]	3
Stress[f]	Stress Experience Scale [87]	1
Background questions	Educational level, living with children <18 years (yes/no), household income, living situation, income, physical activity level (light and high intensity), smoking and alcohol habits, and height and weight	11

[a]CABC: Coping After Breast Cancer.

[b]CRN PROMs survey: Cancer Registry of Norway patient-reported outcome measures survey.

[c]Chalder's Fatigue Scale is only included at baseline and at month 24 by the CABC survey because it is assessed with the CRN PROMs survey at 13 and 36 months after diagnosis.

[d]The survey sent to participants diagnosed in 2020 included the 11-item Chalder's Fatigue Scale, whereas questions on duration and extent of fatigue symptoms [88,89] were added to the survey sent to participants enrolled and followed up after 2021.

[e]Only included at 24 months of follow-up in the CABC survey.

[f]Stress assessed as 1 item is not defined as a secondary outcome but can be used in exploratory analysis.

The CRN PROMs Survey

The CRN PROMs survey is sent to all patients with breast cancer 21 days and 14 and 36 months following diagnosis. Several measures from the CRN PROMs survey are included as secondary outcomes in this study as outlined in Table 1.

Fatigue is assessed using variants of Chalder's Fatigue Scale rating subjective physical and mental features of fatigue [78,88,89]. Peripheral neuropathy, vaginal symptoms, and arthralgia are measured by the Functional Assessment of Cancer Therapy/Gynecologic Oncology Group—Neurotoxicity and Endocrine Symptoms questionnaire [86] (only available for

XSL•FO
RenderX

patients diagnosed from 2021). Quality of life is assessed by the 30-item European Organization of Research and Treatment of Cancer-Core Quality of Life Questionnaire (EORTC QLQ-C30) [84] and its Breast Cancer–Specific Module (EORTC QLQ-BR23) [85]. Report on work-related outcomes including use of social services is assessed with the Work Ability Index [82] and single-item question [83].

The CRN PROMs survey also contains self-reported information on background data including educational level, living situation, number of children less than 18 years, income, physical activity level, smoking and alcohol habits, height, and weight (Table 1).

Coping After Breast Cancer Questionnaire

Participants receive the baseline CABC survey at approximately 7 months after diagnosis and the follow-up CABC surveys 13, 24, and 35 months after diagnosis (Figure 1). The follow-up surveys were sent about 1 month after the CRN PROMs surveys, in order for participants not to confuse the 2 data collections.

The Cohen 10-item Perceived Stress Scale [76] in the CABC survey will be used to assess the primary outcome: 6-month change in perceived stress (from 7 to 13 months following diagnosis) between each of the intervention groups and TAU (Table 1).

The following secondary outcomes are also obtained from the CABC survey: distress ranging from sadness and worry to anxiety and depression, as measured by the Brief Version of the Patient Health Questionnaire for Depression and Anxiety [80]. (Health-related) quality of life is measured by the RAND Corporation 36-Item Short Form Health Survey (RAND-36). RAND-36 assesses 8 health concepts: physical functioning, role limitations caused by physical health problems, role limitations caused by emotional problems, social functioning, emotional well-being, energy/fatigue, pain, and general health perceptions [11]. Mindfulness is assessed using the 15 items from Baer's 5 Facet Mindfulness Questionnaire [49]. Sleep (duration and quality) is measured by items from the Norwegian Shift Work, Sleep and Health survey [81]. Coping, defined as 3 dimensions of response outcome expectancies related to an individual's ability to handle stressors and challenges in everyday life related to coping, hopelessness, and helplessness, is measured by the Theoretically Originated Measure of the Cognitive Activation Theory of Stress [77].

As there is no CRN PROMs survey 24 months after diagnosis, the work-related outcomes are included in the CABC survey after 24 months, whereas Chalder's Fatigue Scale is included at baseline and at month 24 (Table 1).

Other Outcomes

The study will further explore characteristics of those who respond to the CABC trial (responders versus nonresponders) and those who complete the interventions (at least 7 out of 10 modules of StressProffen-CBI or StressProffen-MBI) and their counterparts. Data from the CRN PROMs survey 21 days prior to diagnosis will be used to assess differences in CABC trial invitation responders and nonresponders. Differences in intervention effects (primary and secondary outcomes) between StressProffen-CBI and StressProffen-MBI will also be explored.

Participant data will be linked to the Norwegian Labor and Welfare Administration database, Statistics Norway, the CRN, the Norwegian Patient Registry, the Norwegian Prescription database, and the Norwegian Cause of Death Registry. In addition to data from the surveys, data from the registries will be used for exploratory analysis, including predictors of intervention effects and long-term effects of study participation on comorbidities, relapse and new cancers, and mortality. Detailed and objective information on work participation including sick leave, disability pension, and use of social services will also be obtained. These linkages will enable long-term follow-up of participants in the CABC trial until study end (currently 2035).

Monitoring Compliance

Those who have not completed the CRN PROMs survey and the CABC survey automatically receive 1-2 reminders (unless they have opted out of receiving reminders) during a 30-day period. To ensure as high participation rate as possible, the CABC survey sent 13 months after diagnosis is available for 45 days and includes 2 additional reminders: 1 by phone and 1 by a standard motivational letter. There is no manual review or monitoring of survey responses during the trial. Survey data and participant data (ie, name, phone number, randomization string, scheduled and actual phone calls, and participant dropouts) are stored in CRN databases protected with 2-factor authentication. Access to survey data is limited to selected employees from the CRN, while participant data are further restricted to employees involved in the CABC study.

In addition to using survey data for monitoring compliance, system usage data (eg, the number of modules completed and time spent on each module and between modules) are logged and stored at the Services for Sensitive Data at the University of Oslo. Only approved study personnel have access to this information prior to study end.

Pilot Study

Before study implementation in 2021, a pilot study with 23 women (of 59 invited) was conducted to inform the need for adjustments prior to the RCT. Adjustments included minor rewordings of the informed consent, scheduling additional follow-up calls, and reducing the number of items in the CABC survey (eg, the 24-item version of Baer's Mindfulness Questionnaire [90] was replaced with the 15-item version [49,79]).

Ethical Considerations

Data collection in the CRN PROMs survey is based on informed consent—Article 6 (1) (a) and Article 9 (2) (a) of the European Union's General Data Protection Regulation. The Regulations on Population-Based Health Surveys give additional conditions for data collection and processing and what data can be accessed in this study.

All participants are asked to provide informed consent by responding to the CABC survey. Participants are informed that consent also implies consent to have their data linked to several

XSL•FO
RenderX

national registries. This includes the CRN; the Norwegian Breast Cancer Registry, where cancer subtypes are recorded; the Norwegian Patient Registry; the Norwegian Cause of Death Registry; and the Norwegian Prescription Database (for comorbidity, morbidity, mortality, and prescription data). Data are also linked with the Norwegian Labor and Welfare Administration Database and Statistics Norway to obtain information on work participation including sick leave and disability. Registry linkages can currently be performed until the end of the study (ie, up to December 31, 2035).

As the intervention is digital, including digitally completed outcome measures, no methods to identify adverse effects have been identified. Further, there is no monitoring committee and hence no stopping guidelines have been implemented. Participants can withdraw from the study at any time and without stating their reasons for doing so. This will not have any consequences for their further treatment. Participants are also free to stop using the app whenever they wish to do so.

The study is approved by Regional Committee for Medical Research Ethics Southeast Norway (reference number 32637 "Stressmestring etter brystkreft" [CABC] and registered at ClinicalTrials.gov, NCT04480203 [CABC]).

Sample Size Calculations

Power calculation in the CABC trial was conducted on the primary outcome (ie, 6-month between-group difference in perceived stress) using independent sample *t* tests. The α level was adjusted for multiple comparisons (comparing 2 intervention groups with 1 control group for each outcome) by setting the significance level to 2.5%. Estimates of effect sizes and SDs were retrieved from previous StressProffen interventions on multiple groups of patients with cancer, which found a mean difference in perceived stress of 2.8 and SDs of 6.6 and 8.3 in the case and control groups, respectively [70]. As the CABC trial includes a more homogenous population (only female patients with breast cancer), the effect size was set to 3 and the SD to 6.

With an estimated 80% power to detect a difference between 1 of the intervention groups and the control group, a sample size of 235 participants is needed. With an assumed completion rate of 70%, a total of 335 participants will need to be enrolled, 70 in each group.

Statistical Analysis

Between-group differences in primary and secondary outcomes will be analyzed using intention-to-treat and per-protocol analyses. Continuous outcomes will be analyzed using standard *t* tests (2-tailed and unpaired) and multivariable linear and mixed regression models to adjust for potential differences between groups occurring by chance. Categorical outcomes will be analyzed with chi-square tests and multivariate logistic regression analyses. When analyzing longitudinal data, multivariate regressions with clustered standard errors, multilevel models, or generalized estimating equations may be used to account for the correlation between repeated measurements.

Potential interaction effects between the interventions and relevant covariates such as age at diagnosis, disease characteristics (triple negative, HER2+, or DCIS), and primary treatment will also be explored, either by stratification or by estimating multivariate models including interaction effects.

Missing data will be handled using multiple imputation techniques, primarily if the proportion of participants with missing information exceeds 15%. A detailed description of statistical analysis will be developed. All statistical analyses will be performed using STATA statistical software version 15 or later (StataCorp LLC).

Results

During inclusion there were signs that the completion rate among participants was lower than expected. By contrast, during the pandemic, a higher than expected percentage of newly diagnosed patients with breast cancer were digitally active (88% in 2022), which resulted in an increase in the percentage of eligible patients with breast cancer that were invited to the CRN PROMs survey in 2022. This provided an opportunity to account for the lower completion rate by recruiting more participants. The target number was therefore increased from 335 to 430 participants (about 100 in each group; enrollment end date May 31, 2023). As of April 14, the total number recruited is 428.

The project has received funding from the Norwegian Breast Cancer Society's "Pink Ribbon" charity funding (principal investigator: GU).

Discussion

Impact of Stress Management

Psychosocial and physical long-term complaints after breast cancer treatment remain a major public health challenge with substantial social and personal costs [9]. Psychosocial stress can be associated with inflammation, tumor progression, and disease prognosis [55,91,92], as well as increased risk and prognosis of other chronic diseases [93,94]. Stress management interventions have been effective in reducing stress and other long-term complaints following a cancer diagnosis [64]. Cancer survivors using the original StressProffen intervention (ie, with a combination of CBT and MBI) over a 12-month study period reported significantly greater reduction in perceived stress, depression, and anxiety compared with controls (ie, TAU). The intervention also showed significantly improved health-related quality of life for cancer survivors receiving StressProffen compared with controls [71].

The CABC trial will study similar outcomes as in the original StressProffen intervention, but solely in breast cancer survivors and with additional long-term follow-up. If any or both of the current interventions have effects that are superior to findings from the TAU control group, implementation of the convenient eHealth intervention StressProffen should be considered in clinical practice, perhaps as a future extension to precision oncology care [55].

The original StressProffen program (ie, the app) targeting cancer survivors is in the process of being made commercially available

XSL•FO
RenderX

in English and Norwegian versions, whereas the StressProffen-CBI and MBI versions are only available for study participants. Future distribution will depend on study findings.

Strengths

The CABC trial is, to our knowledge, currently the largest psychosocial eHealth intervention (RCT) in patients with breast cancer. The trial has a long-term follow-up with an assessment of intervention effects 1, 2, and 3 years after a breast cancer diagnosis, corresponding to up to 29 months after baseline. Furthermore, study participants can be prospectively followed up with respect to comorbidity, relapse and new cancers, and mortality until the end of the study (ie, currently, December 31, 2035) through linkage with national health registries using personal identification numbers (mandatory for all Norwegians). The feasibility of the StressProffen app was assessed initially by Børøsund and colleagues [71] and the CABC trial has further extended the StressProffen research line through developing the StressProffen-CBI and StressProffen-MBI interventions, pilot tested these, and implemented necessary adjustments. Another strength of the trial is the ongoing systematic collection of CRN PROMs survey data. This enables us to compare study participants with all CRN PROMs survey data.

Development of the 2 interventions strived to balance design and content presentation to enhance the chance of any effect differences arising due to theoretical content (ie, CBI/MBI). However, due to statistical power limitations, direct comparisons of the 2 interventions will solely be conducted on an exploratory basis. The flexibility of the intervention can be beneficial for patients with cancer undergoing treatment while coping with everyday activities [64]. Given the high percentage of the population that has access to digital platforms within Norway [68], the study has a unique possibility to recruit participants across different socioeconomic statuses and geographical locations. Digital intervention delivery also demands less resources than face-to-face interventions [56]. Thus, if found to be effective, the StressProffen eHealth intervention may have a better chance of being integrated as part of clinical practice than costly face-to-face interventions.

Limitations

The CABC trial has some limitations. First, outcome measures are primarily self-reported. Second, data related to outcomes prior to breast cancer diagnosis are not available. Third, the study only includes a subsample of patients with breast cancer with either noninvasive disease (DCIS) or severe (triple-negative or HER2 positive) breast cancer. Participants are therefore likely to be a heterogenous group of patients with breast cancer with varying treatment according to stage and subtype (eg, in addition to surgery, patients with DCIS may only receive radiation therapy, whereas patients with triple-negative or HER2-positive cancer are advised chemotherapy for several months) [95]. Selection bias may be present as participation depends on the use or access to the digital mailbox and willingness to participate in the CRN PROMs survey (ie, about 50%) [68]. These factors could also limit the generalizability of the study results. However, an eHealth intervention requires the use of digital resources and access to digital tools as requirements.

Conclusions

The CABC trial is possibly the largest ongoing psychosocial eHealth RCT in patients with breast cancer. If 1 or both interventions prove to be effective in reducing stress and improving psychosocial and physical complains, the StressProffen eHealth interventions could be beneficial, inexpensive, and easily implementable tools for breast cancer survivors when coping with late effects after cancer and cancer treatments.

Acknowledgments

The authors thank Kjersti Østby, Ingunn Aune, and Tanja Nygård for their contributions in planning and implementing the study. We also thank Stine Nygård Sætrang for her diligent proofreading and feedback on the StressProffen-CBI and StressProffen-MBI interventions. The group also sincerely thanks Birte Helene Moen for her contribution to the study as a user representative from the Norwegian Breast Cancer Society. The project is funded by the Norwegian Breast Cancer Society's "Pink Ribbon" charity funding (PI: GU). The funder had no influence on any parts of the study including, but not limited to, writing of this protocol paper.

Availability of Data and Materials

The informed consent as well as the General Data Protection Regulation will limit the extent to which individual-level data can be shared with other researchers.

Authors' Contributions

AM, HRE, and GU conceptualized the study and design. KS, LSN, AM, IML, YMG, EB, CMR, TÅM, CEK, HS, KVR, MHA, TC, IM, LEC, HRE, and GU contributed to the planning or implementation of the study. KS, LSN, AM, IML, EB, CMR, YMG, HRE, and GU handle the ongoing data collection and management of the Coping After Breast Cancer (CABC) trial. KS, EB, LSN, AM, TÅM, HRE, and GU will have the overall responsibility of data analysis and all authors will contribute to interpretation of the data. KS, GU, and HRE wrote the initial draft of the protocol. All authors contributed by editing the manuscript for content. All authors consent to publication and have read and approved the final manuscript and agreed both to be personally accountable for their own contributions and to ensure that questions related to the accuracy or integrity of any part of the work, even ones in

XSL•FO
RenderX

which the author was not personally involved, are appropriately investigated, resolved, and the resolution documented in the literature.

Conflicts of Interest

KS, AM, IML, EB, CMR, YMG, TÅM, HS, KVR, IM, CEK, and GU declare no conflicts of interest. LSN is an unpaid board member of dHealth AS, a company aiming to commercialize the original StressProffen program. TC is Co-chief investigator on a National Institute for Health and Care Research (NIHR) program grant in the UK testing a modified acceptance and commitment therapy intervention to improve quality of life for people with a range of cancers in the posttreatment phase. MHA is a consultant for Blue Note Therapeutics and Atlantis Healthcare, both digital health software companies. LEC receives royalties for 2 mindfulness book titles, and from eMindful for an online mindfulness-based cancer recovery program. HRE is a co-founder and a shareholder of a company offering lectures, education, and supervision about stress and coping (Stressprofessorene AS). HRE has no commercial interest in the StressProffen program.

Abstract

Background: Emotion dysregulation is key to the development and maintenance of chronic pain, feeding into a cycle of worsening pain and disability. Dialectical behavioral therapy (DBT), an evidence-based treatment for complex transdiagnostic conditions presenting with high emotion dysregulation, may be beneficial to manage and mitigate the emotional and sensory aspects of chronic pain. Increasingly, DBT skills training as a key component of standard DBT is being delivered as a stand-alone intervention without concurrent therapy to help develop skills for effective emotion regulation. A previous repeated-measure single-case trial investigating a novel technologically driven DBT skills training, internet-delivered DBT skills training for chronic pain (iDBT-Pain), revealed promising findings to improve both emotion dysregulation and pain intensity.

Objective: This randomized controlled trial aims to examine the efficacy of iDBT-Pain in comparison with treatment as usual to reduce emotion dysregulation (primary outcome) for individuals with chronic pain after 9 weeks and at the 21-week follow-up. The secondary outcomes include pain intensity, pain interference, anxiety symptoms, depressive symptoms, perceived stress, posttraumatic stress, harm avoidance, social cognition, sleep quality, life satisfaction, and well-being. The trial also examines the acceptability of the iDBT-Pain intervention for future development and testing.

Methods: A total of 48 people with chronic pain will be randomly assigned to 1 of 2 conditions: treatment and treatment as usual. Participants in the treatment condition will receive iDBT-Pain, consisting of 6 live web-based group sessions led by a DBT skills trainer and supervised by a registered psychologist and the iDBT-Pain app. Participants in the treatment-as-usual condition will not receive iDBT-Pain but will still access their usual medication and health interventions. We predict that iDBT-Pain will improve the primary outcome of emotion dysregulation and the secondary outcomes of pain intensity, pain interference, anxiety symptoms, depressive symptoms, perceived stress, harm avoidance, social cognition, sleep quality, life satisfaction, and well-being. A linear mixed model with random effects of individuals will be conducted to investigate the differences between the baseline, 9-week (primary end point), and 21-week (follow-up) assessments as a function of experimental condition.

XSL•FO
RenderX

Results: Recruitment started in February 2023, and the clinical trial started in March 2023. Data collection for the final assessment is planned to be completed by July 2024.

Conclusions: If our hypothesis is confirmed, our findings will contribute to the evidence for the efficacy and acceptability of a viable intervention that may be used by health care professionals for people with chronic pain. The results will add to the chronic pain literature to inform about the potential benefits of DBT skills training for chronic pain and will contribute evidence about technologically driven interventions.

Introduction

Background and Rationale

Chronic pain, defined as any pain condition that persists continuously or intermittently beyond 3 months [1], is a substantial and costly burden on individuals and society [2,3]. Regardless of the condition (eg, arthritis, musculoskeletal pain, back pain, and fibromyalgia), chronic pain is a multidimensional construct incorporating both unpleasant sensory (eg, pain intensity) and psychological (eg, emotional) components [1]. Evidence corroborates the detrimental effect of chronic pain on emotions [4-7], demonstrating a cyclical association between negative emotional states, such as fear, anger, worry, and low mood, and worsening pain intensity and disability [8-10]. Beyond negative emotional states, co-occurring anxiety and depressive disorders present in up to 80% of people with chronic pain [11-14]. Other related issues include reduced sleep quality (up to 70%) and lower quality of life and well-being [15].

Increasingly, emotion dysregulation is regarded as a mechanism that underpins negative emotional states in people with chronic pain [16-18]. Emotion dysregulation is defined as an extreme sensitivity to emotional events and a reduced capacity to identify and moderate emotions [19]. The modal model of emotions helps make sense of the association between chronic pain and emotion dysregulation. According to this model, when a stimulus is experienced, it gives rise to an emotion that is then cognitively appraised before determining physiological arousal and a behavioral response [10,20]. For people with chronic pain, this process may be disrupted because emotion regulation capabilities are fatigued by persistent negative emotions that are likely a result of the debilitating and distressing symptoms of chronic pain and the experience of missing out because of episodes of escalating pain (eg, on career, social, and educational opportunities) [8-10]. Over time, emotion dysregulation appears to lead to a greater focus on pain, reports of heightened levels of pain intensity, and increasing negative emotions [21].

The development of emotion dysregulation may be further explained by previous experiences and neurobiological changes in people with chronic pain. The persistent presence of pain has been related to neurotransmitter dysregulation—specifically, a reduction in key neurochemicals (γ-aminobutyric acid and glutamate) in the medial prefrontal cortex—which is thought to affect social cognition, including the integration of emotions for decision-making, culminating in emotion dysregulation [22]. In addition, a recent mini review connects hyperactivity in emotion-regulating brain pathways with trauma, posttraumatic stress disorder (PTSD), and the presence and severity of chronic pain [23]. Trauma has been extensively reported as a risk factor for the development of chronic pain [21]. Emotion dysregulation may also be an antecedent to chronic pain, whereby certain personality traits manifest in emotion dysregulation, thereby increasing the risk of developing chronic pain [24,25]. Notably, chronic pain is a condition that is unpredictable in how it transpires over time, but regardless, psychological factors, specifically emotion dysregulation, appear to be a key factor in its development and maintenance [21].

Although a definitive explanation of how and why people with chronic pain present with emotion dysregulation remains elusive, the role of effective emotion regulation in reducing pain intensity and emotional distress is increasingly evident [26,27]. Successful emotion regulation includes emotional awareness, understanding and accepting emotions, and an ability to modify emotions or emotional expression consistent with social norms [19]. Existing psychological interventions for chronic pain, such as cognitive behavioral therapy, mindfulness-based stress reduction, and acceptance and commitment therapy, include few strategies for effective emotion regulation and have shown at best minimal improvement in mood and pain severity [28-30]. Including specific strategies to develop effective emotion regulation skills may mean that psychological interventions for chronic pain are more beneficial [16].

Owing to this promising evidence, psychological interventions for chronic pain that focus on improving emotion regulation are increasingly being investigated. Examples include interventions that incorporate emotion regulation training into cognitive behavioral therapy [31] and emotion awareness and expression therapy [32] and the integration of emotion regulation methods from dialectical behavioral therapy (DBT) [33]. A recent systematic review of randomized controlled trials (RCTs) summarized that emotion-regulation focused interventions, defined as studies that target emotion regulation as a mechanism of chronic pain, have a substantial clinical benefit in reducing

XSL•FO
RenderX

pain; however, findings about psychological outcomes (eg, emotion dysregulation, depression, and anxiety) are uncertain owing to a lack of data [34]. Several pilot studies have begun to explore the effect of DBT on psychological outcomes, finding that DBT may improve anxiety and depression (in a study of 6 patients with chronic gastrointestinal pain [35]); depressive symptoms and emotion dysregulation (in a case study with a patient with chronic pain [36]); and negative emotion, fear, depression, and anxiety (seen in 5 out of 6 study participants with chronic lower back pain [37]). However, as these are all small pilot trials, further evidence is needed to understand the effects of psychological factors related to chronic pain in addition to pain intensity. Understanding how these types of interventions affect emotion dysregulation may be particularly important considering its potential role in the development and maintenance of chronic pain (as discussed previously).

Building on previous evidence of DBT for chronic pain, our group used one mode of DBT, DBT skills training, to develop a 6-session internet-delivered intervention focused on improving emotion dysregulation in people with chronic pain. Standard DBT is an evidence-based treatment for clients with multiple diagnoses presenting with high emotion dysregulation [38]. Standard DBT encompasses a comprehensive treatment plan using 4 modes delivered over 12 months: group skills training, individual therapy, phone coaching, and a therapist consultation team. However, increasingly, DBT skills training as a key mode of standard DBT is delivered as a stand-alone intervention without the 3 other modes [39]. An advantage of stand-alone DBT skills training is that the resources and time to deliver it are substantially reduced, whereas a real-world study found that improvements in emotion dysregulation are comparable with those of standard DBT (ie, all modes) [40]. In addition, DBT skills training does not necessarily require a psychologist; it can be delivered by DBT trainers, who can be anyone well trained on the principles of the training and skills (eg, teachers, professional trainers, volunteers, therapists, physiotherapists, and nurse practitioners) [39,41].

The DBT skills training developed for this trial is the internet-delivered DBT skills training for chronic pain (iDBT-Pain), a guided intervention designed to enhance emotion regulation through learning key skills from DBT in mindfulness, emotion regulation, and distress tolerance. These modules are first taught by a DBT skills trainer and a supervising psychologist in weekly sessions and then reinforced and practiced by accessing an app. As an intervention that is optimized for mobile use (eg, on a smartphone or tablet), iDBT-Pain is functional for anyone with a mobile device and an internet connection. To our knowledge, iDBT-Pain is the first guided internet-delivered DBT intervention for people with chronic pain even though technologically supported interventions have been encouraged since a Cochrane report in 2014 [42]. Importantly, internet-delivered psychological interventions increase accessibility for remote communities, where it can be difficult to access mental health services, and enable access for people with restricted mobility because of chronic pain [42].

A previous trial using a repeated single-case experimental design (SCED) explored the efficacy of iDBT-Pain, showing promising findings to improve both emotion dysregulation and pain intensity with effect sizes of −0.88 and −0.81, respectively [43]. However, although the findings of this previous trial are encouraging, further evidence is necessary to compare iDBT-Pain to usual modes of treatment in a larger sample to generalize the findings more broadly. This protocol details the methods to be used in an RCT to investigate the efficacy of iDBT-Pain. This trial will test a group-based version of iDBT-Pain that builds on the individualized treatment previously investigated in the SCED trial. Group treatment has advantages over individualized treatment, including enabling individuals to interact with others like themselves, resulting in validation that can in itself be therapeutic [39].

Overall, this trial builds on the literature on interventions that focus on improving emotion regulation as a key mechanism related to chronic pain. This trial will add evidence to the current literature on the efficacy and acceptability of a potentially viable emotionally focused intervention that may be administered by health care professionals for people with chronic pain.

Choice of Comparators

To investigate the efficacy of iDBT-Pain, we chose treatment as usual (TAU) as a comparator, with the open-ended definition of TAU as any treatment received for chronic pain that an individual accesses from their usual health care provider. The rationale for this comparator is that we consider it necessary to compare the efficacy of iDBT-Pain with those treatment options that would be available in the absence of the intervention. In addition, TAU as a comparator assists with the feasibility of the study as there is no need to recruit expert clinicians on a specific comparator therapy method. Therefore, the chosen trial design enables a feasible comparison of the efficacy of iDBT-Pain with the general practice in chronic pain treatment and enables the investigation of whether iDBT-Pain can come close to the effects of the multifaceted, individually adjusted chronic pain treatment currently delivered by health care services in the community.

Objectives

Primary Objective

Our primary objective is to evaluate the efficacy of iDBT-Pain in reducing emotion dysregulation (primary outcome) in individuals with chronic pain. The 9-week iDBT-Pain intervention is hypothesized to improve emotion dysregulation compared with TAU.

Secondary Objectives

First, we will investigate the efficacy of iDBT-Pain in improving the secondary outcomes of pain intensity, pain interference, anxiety symptoms, depressive symptoms, perceived stress, posttraumatic stress, social cognition, sleep quality, life satisfaction, and well-being. It is hypothesized that the group administered the 9-week iDBT-Pain intervention will improve in the secondary outcomes compared with the TAU control group.

Second, we will investigate the efficacy of the iDBT-Pain intervention at the 21-week follow-up on the primary and secondary outcomes. It is hypothesized that the iDBT-Pain

XSL•FO
RenderX

intervention group will significantly improve in both the primary and secondary outcomes compared with the TAU control group.

Finally, we will investigate the acceptability of the iDBT-Pain intervention at the 9- and 21-week follow-ups. It is anticipated that these findings will help determine participants' affective and cognitive responses to the intervention as well as indicate the most useful aspects of the intervention for future development and testing.

Trial Design

In a 2-arm randomized controlled superiority trial, participants with chronic pain will be allocated at a ratio of 1:1 to either receive iDBT-Pain (in addition to TAU) or continue with TAU only. Assessments will take place at baseline and the 9-week (primary end point) and 21-week follow-ups. The efficacy of iDBT-Pain will be determined by comparing treatment with TAU for the primary and secondary outcomes. The acceptability of iDBT-Pain will be investigated using a mixed methods approach whereby quantitative and qualitative data (semistructured interviews) will be collected, separately analyzed, and then collectively interpreted [44]. Reporting of this protocol is in accordance with the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines [45] (Multimedia Appendix 1).

Methods

Study Setting

This study will be conducted by researchers in Australia at the University of New South Wales (UNSW). The iDBT-Pain intervention will be administered by researchers using videoconferencing and an app, meaning that it will be accessed entirely on the web by participants in their everyday life. Assessments, including participant screening for eligibility, will be conducted remotely via telephone and links to web-based questionnaires.

Eligibility Criteria

Participants will be eligible for this trial if they fulfill the inclusion and exclusion criteria outlined in Table 1.

Table 1. Inclusion and exclusion criteria.

	Inclusion criteria	Exclusion criteria
Age	Adults aged >18 years	Individuals aged <18 years
Chronic pain	Average pain rating of ≥3 for the past 7 days (Numeric Rating Scale)	Average pain rating of <3 for the past 7 days (Numeric Rating Scale)
Technology	Access and capability to use the internet to participate in the iDBT-Pain[a] sessions and access to a smartphone or tablet device capable of running the iDBT-Pain app	No access or capability to use the internet or no access to an internet-enabled device (eg, smartphone or tablet)
Commitment	Ability to commit to the expectations of the trial (eg, weekly sessions lasting 90 minutes and daily practice)	Inability to commit to the expectations of the trial
Psychiatric disorders	No diagnosed psychotic or personality disorders	Diagnosed psychotic (eg, schizophrenia) or personality (eg, borderline personality disorder or bipolar disorder) disorders; uncontrolled mental health disorder
Dementia or Alzheimer disease	No presence of dementia or Alzheimer disease	Diagnosis of dementia or Alzheimer disease
Language	Reasonable level of written and spoken English	Poor level of written and spoken English
Country of residence	Located in Australia	Located outside Australia

[a]iDBT-Pain: internet-delivered dialectical behavioral therapy skills training for chronic pain.

Informed Consent Process

Informed consent will be obtained after potential participants have been screened as eligible (see the *Recruitment* section) and stated their interest in participating in the trial and before they complete the baseline questionnaires. A trained research assistant or a member of the research team will contact the potential participant by email to arrange a time for a call to discuss informed consent. Before the call, the potential participant will be sent a link to the participant information statement and consent form to ensure that they have the full details about the trial and consent process ahead of the call. During the call, the opportunity to ask questions about the trial and consent will be emphasized, and the procedure and opportunity to withdraw from the trial will be fully explained. To ensure understanding and that the questions have been addressed adequately, a teach-back method of informed consent will be used whereby the researcher will ask the potential participant to restate information back in their own words. Consent will be obtained only from individuals with the capacity to make an informed decision regarding their participation. Potential participants who wish to consent to participate will be sent a link to sign the consent form in a secure web-based application (Qualtrics [Qualtrics International Inc]). This form will then be countersigned by the principal investigator, and a copy will be emailed to the participant for their records.

Additional Consent Provisions

On the consent form, participants can optionally consent to (1) their anonymized data being used in future research, (2) being contacted about future research studies for which they might be suitable, (3) being contacted about potential participation in media events, (4) allowing video recording of the iDBT-Pain Zoom (Zoom Video Communications) sessions, (5) being

XSL•FO
RenderX

entered into a prize draw if they complete the study, and (6) using the iDBT-Pain app after the study. For more details, copies of the participant information statement and consent form are available upon request from the corresponding author. This trial does not involve collecting biological specimens.

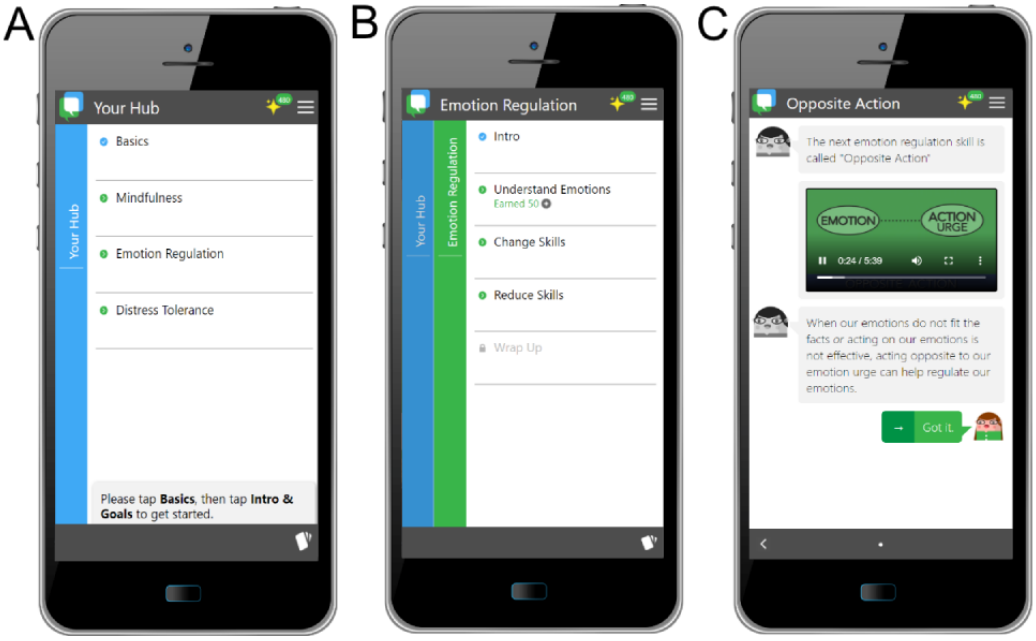
Interventions

Treatment Group

Participants in the treatment group will receive the iDBT-Pain intervention (Table 2), consisting of two key elements: (1) the iDBT-Pain sessions, involving six 60- to 90-minute iDBT-Pain sessions delivered via Zoom to groups of 8 to 12 participants, and (2) the iDBT-Pain app, accessed by participants on their own smart devices (eg, smartphone) to watch videos and complete tasks (Figure 1). In addition to the iDBT-Pain sessions and app, there will be an introductory session to explain the trial and a concluding session. To develop iDBT-Pain [46], evidence-based protocols for DBT skills training according to the DBT Skills Training Manual [39] were used. Participants in the treatment group may continue to receive their usual care (eg, medication and physiotherapy) while in the trial; any such treatment will be monitored (see the *Medication and Health Intervention Measures* section).

The intervention will be delivered by a DBT skills trainer who is a psychology graduate, PhD candidate, and qualified in DBT skills from the Linehan Institute [41]. An Australian Health Practitioner Regulation Agency–registered psychologist will supervise the DBT trainer. Both the trainer and supervisor are familiar with the iDBT-Pain intervention, having delivered it in the previous trial [43], and will adhere to the intervention manual. To ensure treatment fidelity and manual adherence, with the participants' permission, Zoom sessions will be recorded.

Table 2. Internet-delivered dialectical behavioral therapy skills training for chronic pain (iDBT-Pain) intervention protocol.



Week	iDBT-Pain session content (via Zoom [Zoom Video Communications])	iDBT-Pain app content
1	Introductory session: meet the skills trainers and the group; intervention overview; and association between chronic pain, the brain, and emotions	N/A[a]
2	Session 1—mindfulness 1: rationale for mindfulness for chronic pain and skills of *wise mind* and mindfulness *whats*	Introduction to mindfulness; *Wise mind*; 3 mindfulness *whats* skills (observe, describe, and participate); and watching the video about the association between chronic pain, emotions, and the brain
3	Session 2—mindfulness 2: mindfulness *how* skills to practice mindfulness with skillful effectiveness	Mindfulness *how* skills (nonjudgmentally, one mindfully and effectively)
4	Session 3—emotion regulation 1: how to identify and label emotions as a function for emotion regulation	Introduction to emotion regulation and understanding and naming emotions
5	Session 4—emotion regulation 2: skills to reduce the frequency and quantity of unwanted emotions	Handling unwanted emotions
6	Session 5—emotion regulation 3: skills to build future resilience against intense emotion	Building mastery and coping ahead
7	Session 6—distress tolerance: skills that help weather crises and intense negative emotions	Distress tolerance skills: TIP[b] and distract
8	Concluding session: recap the skills learned and the association between chronic pain and difficulties with emotions	Train daily in all skills for mindfulness, emotion regulation, and distress tolerance
9	No session	Train daily in all skills for mindfulness, emotion regulation, and distress tolerance

[a]N/A: not applicable.

[b]TIP: temperature of face, intense exercise, and paced breathing.

XSL•FO
RenderX

Figure 1. Screenshots of the key sections within the internet-delivered dialectical behavioral therapy skills training for chronic pain (iDBT-Pain) app. (A) iDBT-Pain app home page; (B) the 3 emotion regulation modules; and (C) learning the skill of opposite action.

Control Group

Participants in the control group will receive TAU, meaning that they may receive treatment options offered by their usual health care provider (eg, general practitioner). Treatment received outside the trial will be monitored and described [47].

Criteria for Discontinuing or Modifying the Allocated Interventions

Dropout from the study will be recorded, including the reasons. Participants will be free to withdraw at any point. Withdrawn participants will not be replaced. If a participant chooses to withdraw, the research team will only contact them to ascertain reasons for not wishing to take part or continue and ask if they would still be willing to take part in the assessments to enable the intention-to-treat (ITT) analysis.

In the case of an adverse event, an evaluation form will be completed by the research team for the principal investigator in accordance with the UNSW Safety Monitoring Register Template. The form will include a description of the event; a classification of seriousness; an assessment of the potential relationship to the intervention; and, if considered serious, an assessment of the need for change in the consent or the study activities, a summary of known previous health issues, and the event outcome. This process will inform whether the adverse event warrants a trial or treatment modification or discontinuation by a participant.

Strategies to Improve Adherence

To improve adherence to the intervention, at the outset of the trial, all participants in the treatment group will be emailed a calendar invite to book the time for the weekly Zoom sessions in their diary and provide them with the Zoom link. Participants will then be contacted (eg, by email) with a reminder the day before the weekly Zoom session. Participants will be asked to attend all Zoom sessions live unless there are circumstances where they are unable to do so (eg, they have an urgent appointment to attend). On occasions in which a participant cannot attend the live session, after the Zoom session has finished, they will be contacted by the DBT skills trainer, emailed a link to a secure password-protected web page that will contain a recording of the Zoom session, and asked to watch the video before the next weekly Zoom session. To ensure adherence to using the app daily, all participants will be sent detailed instructions to set up the app on their smartphone at the outset of the trial and will be reminded in each of the weekly Zoom sessions to continue to practice in the app for homework. Participants allocated to TAU will receive access to the app after completing the questionnaires in the study. Participants in the TAU group will also be reminded of the importance of their contribution to the research to try to avoid resentment.

Relevant Concomitant Care Permitted or Prohibited During the Trial

Participants who are currently taking medication (eg, pain-relieving analgesics) and receiving therapeutic interventions (eg, physiotherapy) will be eligible for the trial. Medication and intervention use will be documented (see the *Secondary Outcome Measures* section) at the 3 assessment time points (baseline, 9-week follow-up, and 21-week follow-up). All patients will be encouraged to continue their usual treatments that they access for their pain.

Ancillary Provisions and Posttrial Care

The clinical trial insurance held by the trial sponsor (UNSW) provides indemnity against personal injury claims from trial participants arising from their involvement in a UNSW-sponsored human clinical trial.

Outcome Measures

Overview

In addition to clinical and demographic data assessed at baseline (eg, age, sex, education, marital status, pain condition, and pain location), outcomes, measures, and their assessment time points

XSL•FO
RenderX

are presented in Table 3. All measures used for the primary and secondary outcomes have demonstrated validity and reliability. Measures to monitor participants' ongoing medication and health interventions accessed during the trial are also listed. All measures, including demographic data, will be self-reported by the participants on the web. Links to the questionnaires will be emailed to participants at 3 time points: baseline, 9-week follow-up, and 21 week follow-up.

[a]Primary outcome.

[b]Secondary outcome.

[c]PROMIS: Patient-Reported Outcomes Measurement Information System.

[d]NIH: National Institutes of Health.

[e]PTSD: posttraumatic stress disorder.

[f]COMPAS-W: Composure, Own-worth, Mastery, Positivity, Achievement, Satisfaction with Life–Well-being.

[g]Using the listed quantitative and qualitative measures, seven domains of acceptability will be assessed according to the theoretical framework of acceptability [48]: (1) affective attitude, (2) burden, (3) ethicality, (4) intervention coherence, (5) opportunity costs, (6) perceived effectiveness, and (7) self-efficacy.

[h]DBT: dialectical behavioral therapy.

Primary Outcome Measure

The primary outcome of emotion dysregulation will be measured using the Difficulties in Emotion Regulation Scale [49], an 18-item Likert-type scale ranging from 1 (*almost never*) to 5 (*almost always*) with some reverse-coded items. Total scores will be used for this study, with higher scores indicating a higher level of emotion dysregulation.

Secondary Outcome Measures

Numeric Rating Scale

Pain intensity will be measured using the Numeric Rating Scale [50], a rating scale ranging from 0 to 10, with 0 representing one extreme (*no pain*) and 10 representing the other extreme (*pain as bad as it could be*) over the last 7 days.

XSL•FO
RenderX

Patient-Reported Outcomes Measurement Information System Pain Interference Instrument

Pain interference will be measured with the Patient-Reported Outcomes Measurement Information System Pain Interference instrument [51], an 8-item Likert-type scale ranging from 1 (*not at all*) to 5 (*very much*), to assess how much pain has interfered with life in the last 7 days. Total raw scores will be converted to a standardized score, with higher scores representing higher pain interference.

State-Trait Anxiety Inventory

State anxiety will be measured using the state anxiety subscale of the State-Trait Anxiety Inventory [52], a 20-item Likert-type scale ranging from 1 (*not at all*) to 4 ("very much so"), to measure current anxiety. Higher scores denote higher anxiety.

Beck Depression Inventory

Depressive symptoms will be measured using the Beck Depression Inventory [53], a scale where participants select the best-fitting statement from 4 options ranging from 0 to 3 to measure depressive symptoms experienced in the last 7 days. Higher scores reflect greater depressive symptoms.

National Institutes of Health Toolbox Perceived Stress Scale

Perceived stress will be measured using the National Institutes of Health Toolbox Perceived Stress Scale [54], a 10-item Likert-type scale with scores ranging from 1 (*never*) to 5 (*very often*), to assess the levels of stress experienced in the past month. Total raw scores will be converted to a standardized score, with higher scores representing higher stress.

PTSD Checklist–Civilian Version

Posttraumatic stress symptoms will be measured using the PTSD Checklist–Civilian Version [55], a 17-item Likert-type scale with scores ranging from 1 (*not at all*) to 5 (*extremely*), to assess how much participants have been bothered by problems regarding past traumatic events over the last month. Total scores will be used, with higher scores indicating a higher level of posttraumatic stress symptoms (re-experiencing, avoidance, and hyperarousal).

The Awareness of Social Inference Test–Short

Social cognition will be measured using a web-based version of the Awareness of Social Inference Test–Short [56]. The Awareness of Social Inference Test–Short uses audiovisual vignettes separated into three parts: (1) The Emotion Evaluation Test, in which participants identify emotions (happy, neutral, sad, anxious, angry, and disgusted); (2) the Social Inference–Minimal; and (3) the Social Inference–Enriched. For parts 2 and 3, participants are asked to answer *Yes*, *No* or *Don't Know* to 4 probe questions about thoughts, intentions, and feelings. The 3 parts are scored, and there is an overall score (sum of the 3 parts), with higher scores indicating higher social cognition.

Medical Outcomes Study Sleep Scale

Sleep quality will be measured using the Sleep Problems Index II from the Medical Outcomes Study Sleep Scale [57], a 9-item Likert-type scale ranging from 1 (*all of the time*) to 6 (*none of the time*), to measure sleep quality over the last 4 weeks. Higher scores indicate greater sleep problems over the last 4 weeks.

Temperament and Character Inventory–Harm Avoidance Scale

The personality trait of harm avoidance will be measured using the Temperament and Character Inventory–Harm Avoidance Scale [58], a 35-item scale that uses alternate-response questions (true or false) to measure how individuals usually feel. Total scores are converted to percentile scores (84%-100%=very high; 67%-83.3%=high; 34%-66.7%=average; 17%-33%=low; 0%-16.7%=very low).

Satisfaction With Life Scale

Overall life satisfaction will be measured using the Satisfaction with Life Scale [59], a 5-item Likert-type scale ranging from 1 (*strongly disagree*) to 7 (*strongly agree*). Scores are summed to obtain a total, with higher scores indicating higher life satisfaction.

The Composure, Own-Worth, Mastery, Positivity, Achievement, Satisfaction With Life–Well-being Scale

Well-being will be measured using the Composure, Own-worth, Mastery, Positivity, Achievement, Satisfaction with Life–Well-being Scale [60], a 26-item Likert-type scale ranging from 1 ("strongly disagree") to 5 (*strongly agree*) with 5 items reverse-coded (items 5, 7, 14, 21, and 26). Participants' scores are summed and compared with standardized cutoffs: languishing (<88), moderate (89-108), and flourishing (>109).

Acceptability Measures

A mixed methods (qualitative and quantitative) approach will be used to measure acceptability in accordance with the theoretical framework for acceptability (TFA) [48]. The TFA encompasses seven domains to measure cognitive and emotional responses to a health care intervention: (1) affective attitude, (2) burden, (3) ethicality, (4) intervention coherence, (5) opportunity costs, (6) perceived effectiveness, and (7) self-efficacy [48].

Semistructured Interview

A semistructured interview will be administered via video conference at 9 weeks to participants one-on-one in the treatment group. The question topics in the semistructured interview will be guided by the TFA [48]. Specifically, questions will provide insights into affective attitude (eg, "what are your thoughts about the program?"), burden (eg, "Has the effort required to participate in the intervention outweighed the burden of participating?"), ethicality (eg, "How likely would you be to recommend the program?"), intervention coherence (eg, "What's been your experience of using the web app?"), self-efficacy (eg, "How confident are you in your abilities to use the intervention?"), opportunity costs (eg, Have you had to give up anything that is of benefit to you to do the intervention?), and perceived effectiveness (eg, "How does this approach compare to other treatments? Has it had more effect/less?").

Usefulness, Satisfaction, and Ease of Use Questionnaire

The Usefulness, Satisfaction, and Ease of Use Questionnaire [61] is a 30-item Likert-type scale ranging from 1 (*strongly*

XSL•FO
RenderX

disagree) to 7 (*strongly agree*) whereby average scores are calculated for 4 dimensions of usability (usefulness, ease of use, ease of learning, and satisfaction). A higher mean reflects a greater presence of the dimension, with a suggested threshold score of 5 denoting a positive rating [62]. The TFA constructs of burden, self-efficacy, intervention coherence, and ethicality will be assessed using the Usefulness, Satisfaction, and Ease of Use Questionnaire subscales of usefulness, ease of use, ease of learning, and satisfaction, respectively.

DBT Ways of Coping Checklist–DBT Skills Subscale

The DBT skills subscale of the DBT Ways of Coping Checklist [63], which evaluates DBT skills use, will be used to help evaluate intervention coherence. An average score across the subscale items will be calculated, with higher average scores indicating greater intervention compliance.

Patient Global Impression of Change Scale

Perceived effectiveness will be measured using the Patient Global Impression of Change Scale [64], a 7-point scale depicting overall improvement related to activity limitations, symptoms, emotions, and overall quality of life, and a scale of 0 (*much better*) to 10 (*much worse*) points to identify the degree of change since the start of treatment.

Treatment Adherence

The burden of the intervention will be evaluated according to session attendance (eg, iDBT-Pain sessions attended) and time spent using the app, recorded by the DBT skills trainer and on the app server. A higher attendance and greater amount of time spent on the app will indicate a lower burden.

Medication and Health Intervention Measures

Although participants will be asked to refrain from making changes to their current medication (eg, pain analgesics) and health care treatment (eg, physiotherapy) during the trial, it is realistic that the treatment that participants access from their regular health care providers may change. To capture information about medication and health care changes, participants will be asked to complete two measures: (1) the Chronic Pain Medication and Health Intervention Questionnaire and (2) the Healthcare Utilization Questionnaire.

Participant Timeline

Interested participants will undergo a structured screening process that includes a web-based screening survey and, for those eligible after their survey responses, a phone call with a study investigator. Phone screening will be conducted as soon as possible after the web-based screening. After obtaining informed consent, baseline questionnaires will be administered within a window of 3 weeks before randomization. Participants will be randomly allocated and will learn about group assignment at least 1 week before the first Zoom session. After the 9-week intervention delivery period, participants will be assessed again at 9 and 21 weeks after randomization. Participants will be asked to complete the assessment within 1 week and will be prompted by phone, SMS text message, and email a maximum of 3 times for up to 4 weeks if they are not responsive. See Table 4 for a schematic showing the schedule of enrollment, interventions, and assessments.

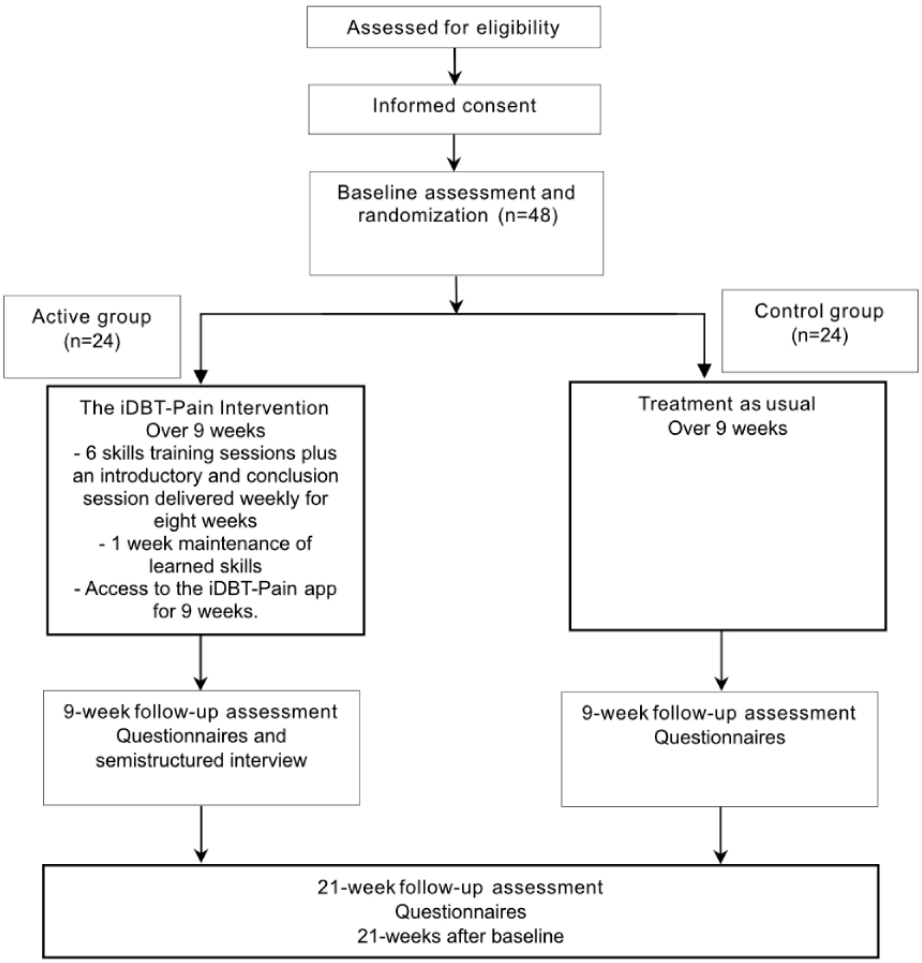
Sample Size

The sample size for this trial was calculated using the SAS software (version 9.4; SAS Institute) of the SAS system (SAS and all other SAS Institute Inc product or service names are registered trademarks or trademarks of SAS Institute Inc in the United States and other countries) and is based on the large effect size (pain intensity; effect size=0.81) obtained from our previous trial [46]. The power analysis is based on the effect size of the secondary outcome from the previous trial rather than the primary outcome effect size of 0.88 for emotion dysregulation to obtain a more cautious sample size estimate given that the previous trial was conducted with a small population using a single-case design. To detect a large mean difference (η^2=0.14) between the treatment groups in this trial, a total of 40 people (20 in each group) will be required. This assumes 80% power, a Cronbach α of .05, and a within-subject correlation of 0.5. Attrition rates for studies investigating cognitive behavioral treatments for chronic pain vary between 0% and 30%, with a mean attrition of 13% (SD 10%); thus, we have set expectations for attrition at 20%, resulting in a total sample size of 48 [65]. We expect this estimate to be transferable to the web-based delivery of psychological interventions as research suggests that trials using remote delivery generally show comparable or even lower rates of attrition [66]. Rates of attrition will be monitored by the research team at regular milestones during the trial (eg, at the point where 50% of the participants have reached their scheduled 21-week follow-up time), and we will consider taking steps to increase sample size if this is required.

Recruitment



Individuals with chronic pain who had previously contacted our group (n=300) and requested information about participating in studies on chronic pain will receive by email the study details, including the participant information statement, and a link to the study web page. Recruitment will also use ethically approved web-based community advertising on Facebook. There is growing evidence that Facebook is a useful recruitment tool for research, particularly to access hard-to-reach populations [67] such as the chronic pain population. The Facebook advertisement will include a link to the study web page.

From the study web page, interested participants can click through to a web-based screening survey that will ask questions about age and demographics, chronic pain condition, existing and previous psychological and neurological diagnoses, internet accessibility, fluency in reading and speaking English, contact details, and location. Potential participants who are positive on their web-based screening will be contacted to arrange a phone call with a study investigator. The purpose of the phone call is to ask further questions to determine eligibility. Questions will ascertain chronic pain diagnosis, injury, current medications, therapy, and interventions being received, along with plans for any upcoming medication or treatment changes or surgery. An important part of the screening phone call is to determine whether there is a previous or current diagnosis of any psychological or neurological disorder that may exclude the participant from the study. The researcher will ask the potential participant if there is any current or previous diagnosis of schizophrenia, borderline personality disorder, or bipolar disorder and whether there is a current diagnosis of a psychological disorder that is uncontrolled (eg, depression that is not being treated with psychotherapy or antidepressants). Those who do not meet the eligibility criteria will be informed of this sensitively and asked if they wish to remain on our secure database to be contacted about future trials.

Participants that are eligible will be emailed after the phone call to complete the informed consent process, whereby they will have the opportunity to discuss the Participant Information Statement and consent process with a researcher before electronically signing the consent form. Eligible, fully informed, and consenting participants will then be entered into the study for baseline assessment and randomization (Figure 2).

XSL•FO
RenderX

Figure 2. Flowchart of the study design. iDBT-Pain: internet-delivered dialectical behavioral therapy skills training for chronic pain.

Allocation

Sequence Generation

Following informed consent, participants will be randomly allocated to groups (treatment or TAU) at a ratio of 1:1. A block randomization schedule will be used with a block size of 2 generated by a statistician blinded to study recruitment, treatment, and data collection. Opaque sealed envelopes will ensure concealment from the DBT trainer and psychologist administering the intervention until the interventions are assigned. An independent research assistant will prepare the envelopes. Once the participant has consented to the trial and completed the baseline assessment, the independent research assistant will open the envelope to assign the participant. Owing to the nature of this intervention, the participants and DBT skills trainer delivering the intervention will not be blinded to group allocation. The skills trainer will be made aware of the group allocation by the research assistant and will then advise the participants of their group after completion of the baseline assessment. The statistician conducting the primary data analysis will be blinded to group allocation.

Concealment Mechanism

Opaque sealed envelopes will ensure concealment until interventions are assigned.

Implementation

A statistician blinded to study recruitment, treatment, and data collection will generate the allocation sequence. Participants will be enrolled in the study by the researchers, who will be blinded until after intervention assignment. An independent research assistant will assign participants to the interventions.

Blinding

Owing to the nature of this intervention, the participants and those delivering the intervention (DBT skills trainer and psychologist) will not be blinded to group allocation after the baseline assessment. However, the baseline assessment is conducted before randomization, meaning that there is no risk of disclosure of treatment allocation to the assessor or participant at the time. All assessments will be distributed remotely via automated email with a web link to complete the assessment on the web, thereby ruling out any potential effects of assessors on assessments of outcomes at the 9- and 21-week follow-ups. The statistician analyzing the outcome data will remain blind to treatment allocation throughout the analysis.

Data Collection and Management

Plans for Assessment and Collection of Outcomes

Data will be collected sequentially using web-based questionnaires administered through the Qualtrics survey platform at 3 time points: baseline and 9- and 21-week follow-ups. The measures for the primary and secondary

XSL•FO
RenderX

outcomes are validated and commonly used instruments (see the *Outcome Measures* section). Web-based data collection is an appropriate way of collecting data for our study as questionnaires can be answered and delivered remotely, consistent with the web-based nature of the trial. Participants will self-report data about their pain, emotions, and psychological states and traits.

Plans to Promote Participant Retention and Complete Follow-up

To aid retention, participants in both groups who complete the trial may enter a prize draw to receive 1 of 2 Aus $200 (US $133.72) gift cards. To further aid retention, participants (treatment and TAU) who complete the study (ie, following the 21-week follow-up assessment) will be asked if they would like to retain or obtain access to the iDBT-Pain app. In addition, the use of web-based assessments will reduce the burden on participants to promote retention. Dropout from the study will be recorded, including the reasons. Participants will be free to withdraw at any point. Withdrawn participants will not be replaced. Upon conclusion of the study (ie, following the 21-week follow-up assessment), all participants (treatment and TAU) will be asked if they would like to retain or obtain access to the iDBT-Pain app.

Data Management

The research team will treat all participant information ethically and with confidentiality in accordance with the UNSW data governance policy. Data will be anonymized and stored on a secure data platform at UNSW protected via username and password. Personal and identifiable information will be stored separately from the anonymized trial data, and data will be anonymized wherever possible. For analysis, the qualitative and statistical data will be downloaded onto password-protected computers accessible by the trial investigators. Data from the web-based questionnaires will be quality checked by the research team before analysis.

Confidentiality

Information collected as part of the trial will be kept strictly confidential within the research team. Participants' names and contact details will be stored in password-protected files on secure servers and separately to linked anonymized data. To ensure skills trainer adherence and competency, the sessions will be recorded with the consent of all participants appearing in the recording. With the consent of the participants, recordings will be made available to participants who need to catch up on missed content on a password-protected web link to view the video on the web. Participants will have the option to keep their camera off during the session. Access to these recordings is restricted to those with the link and password.

Access to Data

All investigators will be able to access the full trial data set. To ensure confidentiality, data dispersed to the project team members and the statistician conducting the analysis will not contain any identifying participant information.

Data Analysis Methods

Statistical Methods

Overview

For all primary and secondary outcomes that are normally distributed and measured over time, a linear mixed model with random effects of individuals will be specified. The fixed effects of time, treatment group, and their interaction will be included. Treatment differences at 9 and 21 weeks and change from baseline to 9 and 21 weeks within each group will be estimated. If the distributional assumption of normality is not tenable, an appropriate transformation of the outcome will be conducted. Alternatively, a generalized linear mixed model with appropriate distribution will be used.

The data will be analyzed on an ITT basis. Unadjusted and adjusted analyses will be conducted. The adjusted analyses will include age at baseline and sex. P values of $<.05$ will be considered significant. Effect sizes will be expressed in terms of pooled baseline SD units, as described by Feingold [68].

Qualitative Methods

Qualitative data from the semistructured interviews will be transcribed, coded, and then summarized according to the TFA framework [48]. Specifically, under the headings of the TFA constructs (affective attitude, burden, perceived effectiveness, ethicality, intervention coherence, opportunity costs, and self-efficacy), a thematic analysis will be used to code responses according to key emerging themes [69]. Quantitative data from measures that assess domains of acceptability along with treatment adherence data will be descriptively summarized according to the individual measures. A collective summary of both quantitative and qualitative data will be reported to provide a comprehensive understanding of the acceptability of the iDBT-Pain intervention.

Methods for Additional Analyses

There is no a priori plan to conduct subgroup analyses.

Methods in Analysis to Handle Protocol Nonadherence and Any Statistical Methods to Handle Missing Data

Although linear mixed models do allow for unbiased estimates of the treatment effect with missing data assuming data that are missing at random [70], we will also use multiple imputation to estimate the treatment effect in the primary outcome as a sensitivity analysis. Supposing that the missing-at-random assumption is tenable, we will use multiple imputation using chained equations, include variables of baseline pain intensity and psychological factors in the imputation model, and then estimate the treatment effect in the imputed data.

As a sensitivity analysis, a modified ITT analysis will be performed. As detailed in the *Allocation* section, participants are randomized into a treatment group, but they will be included in the final data set only if they have completed the 6 iDBT-Pain skills training sessions delivered via Zoom in weeks 2 through 7 either by attending the session or by watching a video of the session.

XSL•FO
RenderX

Data Monitoring

An independent data monitoring committee has not been arranged as the intervention occurs over a short period, the protocol will not be modified irrespective of data collected during the intervention, and there are minimal risks to participants. No interim analyses are planned.

Trial Management Group

The Trial Management Group (TMG) will oversee the day-to-day conduct of the trial and will be responsible for reviewing the safety information to identify any serious emerging safety concerns. Any major amendments required to the study or changes to the protocol will first be agreed upon by the TMG and then communicated to participants as soon as possible by one of the researchers. The TMG will be responsible for seeking the advice of the ethics committee and the trial sponsor. The TMG is a board of elected individuals comprising the principal investigator, researchers, DBT skills trainers, trial managers, and research assistants.

Adverse Event Reporting and Harms

DBT skills training is an evidence-based protocol for emotion dysregulation [39,71] and a standardized approach with no known side effects [35,36]. Thus, although we will measure safety, we do not anticipate any intervention- or study-related adverse events or reactions and consider the potential risks to be mild and of minimal likelihood to occur. Potential risks include experiencing temporary and transient increases in distress during the skills training, discomfort in terms of fatigue from attending up to 9 hours of Zoom sessions over the course of the intervention, and upset or discomfort when answering the questionnaires. To identify risk issues, participants will have the ability to communicate with the research staff throughout the study via email and phone, with concerns then raised to the TMG. Where necessary, participants will be provided with details of support services or advised to contact their regular health care professional (eg, general practitioner). To mitigate fatigue during the Zoom sessions, the sessions will be spaced evenly throughout the intervention period, 1 per week over 8 weeks, with sufficient time between sessions and breaks as necessary. Participants will also be asked to have a glass or bottle of water during the Zoom sessions to stay hydrated. If participants find the questionnaires distressing, they will be advised that they can skip to the next question or stop immediately.

Safety will be measured according to adverse events (untoward medical occurrence) or reactions (unintended response to treatment) related to iDBT-Pain, with data collected about the incidents by the research team in trial-related Safety Monitoring and Adverse Events forms.

Frequency and Plans for Auditing Trial Conduct

The TMG will be responsible for periodic auditing to evaluate trial conduct and compliance with the protocol, good clinical practice, standard operating procedures, and UNSW sponsor and ethics requirements.

Protocol Amendments

In the instance that amendments to the protocol are needed, the TMG will seek sponsor approval, after which trial registrations and the published protocol will be amended accordingly. A member of the TMG will communicate any resulting changes in the protocol to the participants.

Dissemination Plans

To enable effective dissemination, the results will be considered for submission to appropriately selected peer-reviewed journals, summarized in a press release for the media, and included in presentations at conferences. This will ensure the dissemination of this research and data to other researchers and interested parties. Anonymized data sets and associated material may be available upon reasonable request from the corresponding author. Participants will be sent a summary of the research findings if they consent to this.

Ethics Approval and Consent to Participate

Ethics approval was obtained from the University of New South Wales Human Ethics Committee (HC220078). Written informed consent to participate will be obtained from all participants.

Results

Recruitment started in February 2023, and the clinical trial started in March 2023. Data collection for the final assessment is planned to be completed by July 2024.

Discussion

Potential Clinical Implications

Emotion dysregulation is key to the development and maintenance of chronic pain, leading to a cycle of worsening pain intensity, disability, and emotional difficulties [16-18]. Evidence is arising that DBT may be a viable intervention to target emotion dysregulation in people with chronic pain, helping reverse this cycle of pain and emotional distress and leading to improved physical and psychological function [35-37]. Specifically, iDBT-Pain, a guided internet-delivered approach encompassing live web-based sessions and access to an app, has been found in a previous SCED trial to reduce symptoms of emotion dysregulation and pain intensity [46].

In this protocol, we described an RCT to test iDBT-Pain compared with a control group. We plan to investigate the efficacy of iDBT-Pain in improving the primary outcome of emotion dysregulation and the secondary outcomes of pain intensity, pain interference, anxiety symptoms, depressive symptoms, perceived stress, posttraumatic stress, harm avoidance, social cognition, sleep quality, life satisfaction, and well-being. The RCT will test the acceptability of a group-based version of iDBT-Pain that builds on the individualized treatment previously investigated in the SCED trial.

To our knowledge, iDBT-Pain is the first guided internet-delivered DBT intervention for people with chronic pain. As an internet-delivered approach, iDBT-Pain offers an accessible option for those with restricted mobility and remote communities where there are often limited psychological

XSL•FO
RenderX

services for people with chronic pain. If our hypotheses are confirmed, our findings will contribute to the evidence for the efficacy and acceptability of a viable intervention that may be used by health care professionals for people with chronic pain. Similarly, the results will add to the chronic pain literature to inform about the potential benefits of DBT and technologically driven interventions. More broadly, the findings will contribute to the evidence on whether interventions that target emotion dysregulation in people with chronic pain can lead to improved emotions and less pain.

Limitations

The limitations of this study include the potential for participants to access other interventions and pain analgesics while in the trial. However, we will ask participants to disclose their pain medication and treatments and advise us of any changes in their dosages that occur during the trial period. Thus, the results can be considered in the context of any confounding factors related to treatment outside the trial. A further limitation is that therapist blinding is not possible because of the nature of the intervention. In addition, the sample size may limit the ability to generalize the findings to a larger population and detect more subtle effects.

Acknowledgments

The authors gratefully acknowledge the work of Pauline Zahara for providing feedback and advice regarding the development of the clinical trial protocol. They also thank Jeremy Norman-Nott and Kevin Yi Chen for their software development work on the app. This work was supported by a Rebecca Cooper Fellowship from the Rebecca L. Cooper Medical Research Foundation awarded to SMG. NNN was supported by the Australian Government Research Training Program Scholarship (administered by the University of New South Wales), a supplementary scholarship administered by Neuroscience Research Australia, and funding from the Neuroscience Research Australia PhD Pearl Program. NHS was supported by a postdoctoral fellowship from the Craig H. Neilsen Foundation. The funding bodies had no role in the decision to publish this protocol. Funder and grant numbers are not applicable in these instances. The trial was sponsored by the University of New South Wales (contact: Dr Ted Rohr, Director of Research Ethics Compliance Support; ted.rohr@unsw.edu.au). The sponsor of the trial was involved in the design of the study and will not be involved in the collection, analysis, or interpretation of the data or writing of the study report.

Data Availability

Anonymized data sets and associated material will be available upon reasonable request from the corresponding author.

Authors' Contributions

NNN and SMG conceptualized the idea for this trial. CRW, J Schroeder, and J Suh were responsible for the original development of the app, with updates by NNN and SMG. The trial and analysis plan were developed by NNN, SMG, CRW, NEB, YQ, NHS, and JHM. NNN prepared the first draft of the manuscript. Successive drafts received substantial contributions from all authors to revise and critically review all content and plans for the analysis. The final version of the manuscript was approved by all authors.

Conflicts of Interest

CRW receives consulting fees from Mindstrong Health, Behavioral Tech, and Lyra Health. All other authors declare no conflicts of interest.

Abstract

Background: Obesity is common in individuals with severe mental illness (SMI), contributing to a significantly shortened lifespan when compared to the general population. Available weight loss treatments have attenuated efficacy in this population, underscoring the importance of prevention and early intervention.

Objective: Here, we describe a type 1 hybrid study design for adapting and pilot-testing an existing mobile health intervention for obesity prevention in individuals with early SMI and Class I or early-stage obesity, defined as a BMI of 30-35.

Methods: An existing, evidence-based interactive obesity treatment approach using low-cost, semiautomated SMS text messaging was selected for adaptation. Community mental health clinics and Clubhouse settings in Eastern Missouri and South Florida were identified to participate. This study has the following 3 aims. First, using the Enhanced Framework for Reporting Adaptations and Modifications to Evidence-based interventions, contextual aspects of the clinical and digital treatment environments are identified for adaptation, considering 5 main stakeholder groups (clinical administrators, prescribing clinicians, case managers, nurses, and patients). Following a 2-week trial of unadapted SMS text messaging, Innovation Corps methods are used to discover needed intervention adaptations by stakeholder group and clinical setting. Second, adaptations to digital functionality and intervention content will be made based on themes identified in aim 1, followed by rapid usability testing with key stakeholders. A process for iterative treatment adaptation will be developed for making unplanned modifications during the aim 3 implementation pilot study. Individuals working in partner community mental health clinics and Clubhouse settings will be trained in intervention delivery. Third, in a randomized pilot and feasibility trial, adults with 5 years or less of treatment for an SMI diagnosis will be randomized 2:1 to 6 months of an adapted interactive obesity treatment approach or to an attentional control condition, followed by a 3-month extension phase of SMS text messages only. Changes in weight, BMI, and behavioral outcomes, as well as implementation challenges, will be evaluated at 6 and 9 months.

XSL•FO
RenderX

Results: Institutional review board approval for aims 1 and 2 was granted on August 12, 2018, with 72 focus group participants enrolled; institutional review board approval for aim 3 was granted on May 6, 2020. To date, 52 participants have been enrolled in the study protocol.

Conclusions: In this type 1 hybrid study design, we apply an evidence-based treatment adaptation framework to plan, adapt, and feasibility test a mobile health intervention in real-world treatment settings. Resting at the intersection of community mental health treatment and physical health promotion, this study aims to advance the use of simple technology for obesity prevention in individuals with early-stage mental illness.

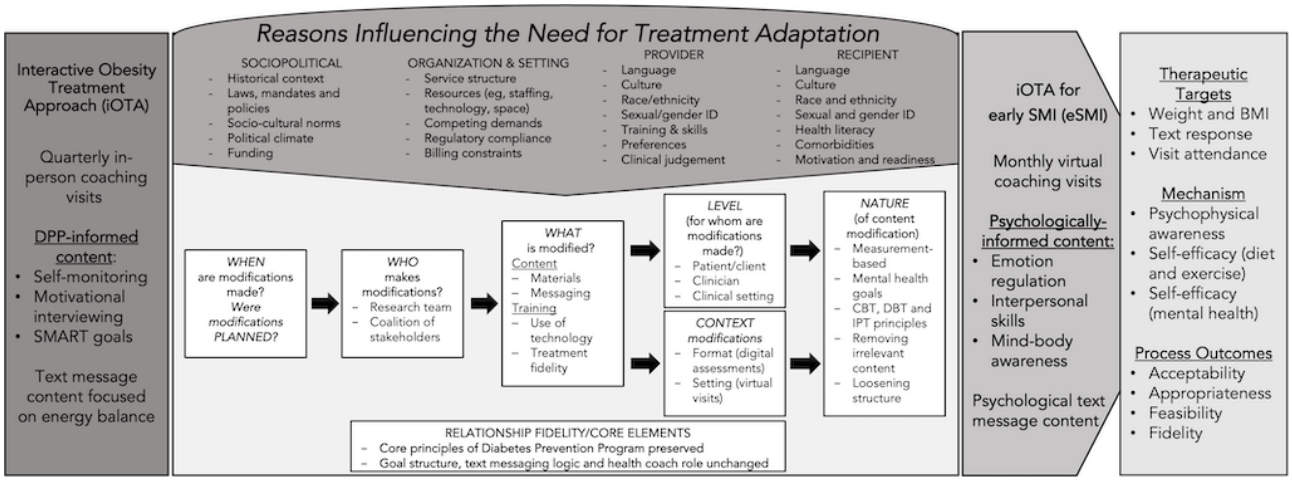
Introduction



Background and Rationale

Younger and treatment-naïve individuals with early severe mental illness (eSMI) experience adverse health effects associated with medications, including significant weight gain, metabolic dysregulation, and early onset cardiovascular disease [1,2]. eSMI patients are at high risk for treatment nonadherence, and benefit from behavioral programming that recognizes their unique engagement needs, which include psychological support to shore up healthy coping strategies and reduce cognitive load [3-5]. Successful health behavior change requires promotion of self-determination and cognitive control [6,7] as well as development of psychophysical self-knowledge through accurate interpretation of interoceptive cues (eg, hunger and satiety) [8,9]. These target mechanisms map onto the National Institute of Mental Health Research Domain Criteria [10] constructs for cognitive systems, cognitive control, and social processes (social awareness, self-awareness), offering a constructive pathway to achieve self-determination for health behaviors [11], cognitive control, and interoceptive awareness.

Digital or mobile health (mHealth) interventions show promise for enhancing engagement in lifestyle interventions among adolescents and young adults with chronic medical conditions [12-14]. Nonetheless, digital interventions to prevent or attenuate weight gain occurring early in the course of treatment remain understudied [15,16]. We have modified an existing interactive obesity treatment approach (iOTA) [17,18] involving collaborative goal setting with a health coach and interactive SMS text messaging to provide ongoing support and self-monitoring of behavior change goals in adults with severe mental illness (SMI) (iOTA-SMI) [19,20]. Adaptation of iOTA-SMI for a prevention focus in eSMI, however, requires unique target mechanism engagement, due to the cognitive and functional characteristics of patients with eSMI, who are still coming to terms with the brain system dysfunction caused by their illness.

Adaptation of effective interventions for new populations and settings (eg, eSMI and prevention) necessitates a formal evaluation process and implementation science framework. Stirman's Framework for Reporting Adaptation and Modifications-Enhanced (FRAME, Figure 1) [21], offers an evidence-based approach for identifying adaptation needs based on contextual information that will inform adaptations specific to underrepresented racial, ethnic, socioeconomic and gender groups. Using FRAME, this study will further adapt the existing iOTA for obesity prevention in people with eSMI, hypothesizing treatment-related change in body weight will be inversely related to psychophysical awareness and self-efficacy for managing physical and mental health.

The mixed methods approach for this project involves the following three research aims to be conducted over 3 years: (1) identify adaptation targets to optimize iOTA for use by younger patients with eSMI treated in community mental health clinics (CMHCs) settings, incorporating perspectives from underrepresented groups; (2) adapt the existing iOTA, including modifications to key messaging to facilitate engagement and understanding in racial, ethnic socioeconomic, and gender-diverse groups in addition to adaptations relevant to eSMI in younger adults; and (3) conduct a randomized pilot test of the adapted iOTA in eSMI patients, evaluating both treatment effectiveness (change in body weight) and implementation effectiveness (feasibility, acceptability, and appropriateness) over 24 weeks.

Trial Design

Employing the FRAME model, we will apply Innovation Corps (I-Corps) methods [22,23] to identify perceived barriers and challenges to implementing an iOTA in CMHC settings. Attention will be given to challenges related to the patient population (eg, early illness, cognitive impairment, and negative symptom effects on the ability to engage), care setting, case manager burden, lack of time and human resources, limited training, and supervision or accountability) and to the collection of multilevel (eg, patient, family, clinical staff, and administrator) and multimethod (eg, focus groups, semistructured interviews) data that can inform adaptations to increase the likelihood of success. Finally, key process outcomes will be measured (eg, acceptability, feasibility, fidelity, and appropriateness) during adaptation and pilot testing [24].

Methods

Aim 1: Identify iOTA Adaptation Needs for eSMI Using I-Corps Methods

This aim will determine how to best facilitate health behavior change in eSMI patients through interventions at the level of the individual, the health care provider, and the broader health care organization.

Study Settings

To achieve diversity in the participant samples, treatment settings, and social determinants, the proposed project will be conducted in CMHC and community Clubhouse settings in Missouri and Florida. Locations were chosen for the long-term collaboration between research teams and the representative racial and ethnic diversity of client and clinician populations and marked diversity of health care environments.

Study Procedures

I-Corps Methods

Starting with a list of hypotheses about barriers or challenges to implementation in CMHC settings, the study team identifies individuals who represent consumers or customers at multiple levels within the organization. Interviews and focus groups are conducted to test the hypotheses. Once facts have been obtained, the team reviews data looking for emergent themes that inform an overall “value proposition” for the customer or key stakeholder, identifying potential “pain” and “gain” areas. The team can then determine actions needed to change or adapt iOTA to best fit the CMHC environment. Purposive sampling methods will be applied to avoid bias in focus group responses, working with community partners to ensure group composition represents a broad range of perspectives from underrepresented populations.

Focus Groups

Once the focus group participants are identified, they will be asked to participate in one in-person or phone visit to set up health goals and related SMS text messages. They will then participate in 1-2 weeks of iOTA SMS text messaging to facilitate optimal feedback on intervention adaptations. Focus groups will be scheduled within 1 week of completing the 2-week iOTA trial. Groups will be conducted at the CMHC site during a time that is convenient for participants and will be facilitated by a research assistant facilitator and CMHC staff member taking additional notes.

Eligibility Criteria

We will conduct 8 focus groups of 5 participants each at each CMHC site, for a total of 16 focus groups (Table 1). Focus group composition will be monitored to balance groups with respect to age, race, and gender, taking care to include outlier perspectives on mHealth technology and obesity treatment. Participants will include administrators, prescribers, nursing staff, case workers, clients, and client social support.

XSL•FO
RenderX

Table 1. Focus group composition and questions.

Group type	Participant type	Areas of interest
Directors and Supervisors	Medical director, clinical supervisor	• What should the qualifications and characteristics of the health coach be? • Is it reasonable for the health coach to be an existing staff member?
Prescribing clinicians	Psychiatrists, advanced practice nurses	• What type of training should health coaches receive? • How often should face-to-face health coaching meetings be?
Nursing staff	Nursing staff, nurse care managers	• What should the content of health coaching meetings be? • How frequent should text messages be?
Community support workers	Community and peer support specialists	• What should the content of the messages be? • Is it helpful to have secure, 2-way texting capability?
Administrative staff	Supervisors and clinic managers	• How much time could existing staff devote to intervention delivery? • What would the optimal amount of time be for intervention effectiveness?
Members or clients	Adult clients (18-45 years of age)	• What would make the intervention acceptable to younger adults? • Are there modifications needed to address social determinants of health?

Data Management and Analytic Plan

Recorded groups will be transcribed, and text data will be entered into NVivo, coded by 2 independent raters. We will use inductive coding methods based on pragmatic-variant grounded theory to develop a coding tree based on the focus group question framework and new themes identified in the focus group transcripts. Precoding data exploration will identify the most used words and phrases by focus group, which are then explored for meaning and context to establish content themes.

Aim 2: Adapt the Parent iOTA for Use in Younger Adults With eSMI

Contextual, content, and training aspects of the treatment will be adapted based on qualitative data collected using the I-Corps methods within the FRAME treatment adaptation model in aim 1. Adaptations will be tested for feasibility by members of the focus groups queried in aim 1.

Eligibility Criteria

Individuals who participated in aim 1 focus groups will be queried with individual semistructured interviews to obtain feedback on treatment adaptations.

Study Procedures

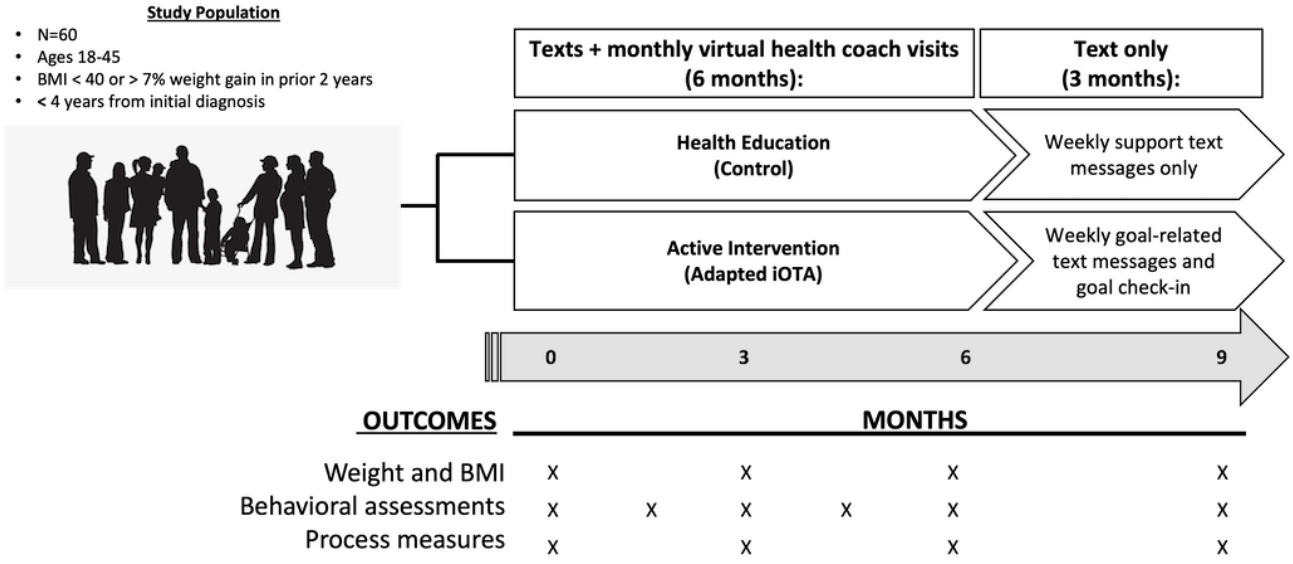
iOTA Adaptation

Existing libraries of SMS text messages will be tested for usability and cultural appropriateness among members of our target population of eSMI patients. We will conduct key informant interviews using the I-Corps methodology following this testing and adapt the messages and risk assessment platform as needed based on this information.

Key Informant Interviews

Using a standardized interview guide developed using I-Corps methods, we will conduct semistructured, in-person key informant interviews with 1-2 members from each focus group at each study site to obtain impressions about adaptations made based on focus group results. Interviewing will be curtailed when saturation occurs (ie, when the same themes repeatedly emerge) [25,26].

Data Management and Analytic Plan



Interviews will be digitally recorded and transcribed verbatim. Data will be analyzed using standard content analysis strategies listed in aim 1.

Aim 3: Randomized Controlled Pilot Test of the Adapted Intervention

In this aim, we will conduct a randomized 24-week pilot study of the adapted iOTA-eSMI intervention, followed by 12 weeks of SMS text messaging intervention alone in 60 participants (30 at each study site), evaluating both intervention and implementation effectiveness (Figure 2).

XSL•FO
RenderX

Figure 2. Study overview. iOTA: interactive obesity treatment approach.

Eligibility Criteria

To capture "early" phase mental illness, we will use the length of illness requirement commonly used in Food and Drug Administration Phase III clinical trials testing treatment efficacy in early mental illness (eg, less than 5 years from diagnosis). "At risk" weight is categorized using the Food and Drug Administration definition of clinically significant weight gain (eg, more than 7%) or overweight or early Class 1 obesity by BMI.

Study Procedures

Screening Assessments

To ensure minimal cognitive capacity to understand treatment materials and engage in SMS text messaging, we will use the Rapid Estimate of Adult Literacy in Medicine-Short Form (REALM-SF) minimal score of 5 (consistent with 7th grade reading level) and the University of California San Diego Brief Assessment of Capacity to Consent score of 15 or higher (consistent with the capacity to consent). To ensure minimal psychiatric symptom stability, we will use the Clinical Global Impression-Severity scale minimal score of 4 (consistent with moderate illness severity) or lower. The schedule of study visits and assessments is presented in Table 2.

[a]Ability to provide Informed Consent assessed via the Rapid Evaluation of Adult Literacy in Medicine-Short Form and University of California, San Diego Brief Assessment of Capacity to Consent.

[b]CEI: credibility and expectations for improvement.

[c]CGI: clinical global impression scale.

[d]Assessments done as needed based on clinician judgment.

[e]PASS: psychophysical awareness and skills scale.

[f]Self-efficacy: self-efficacy for mental health, diet and physical activity.

Primary and Secondary Outcomes

The overall goals of this study are to establish the feasibility and acceptability of iOTA-eSMI as well as to inform sample size calculations for future randomized studies. Thus, the primary outcome will be a change in body weight (lbs) during 24 weeks of randomized treatment. Secondary outcomes will include changes in BMI, psychophysical awareness and skills, and self-efficacy for mental and physical health [27-29]. An increase in self-efficacy and psychophysical awareness are the proposed mechanisms of action for active iOTA intervention.

Psychophysical Awareness and Skills Scale

This composite measure draws from research domain criteria domains of cognitive systems and social processes, including cognitive control, perception, and understanding of self,

XSL•FO
RenderX

self-awareness, self-monitoring, and self-knowledge. The composite measure includes 10 items that assess cognitive control [30], self-determination [31,32], and interoceptive awareness [33].

Self-Efficacy for Eating and Exercise Habits

For this study, we will use abbreviated surveys developed by Sallis et al [11] to measure self-efficacy in health behaviors involving eating and physical activity. Self-efficacy for diet and exercise will be measured at each study visit.

Mental Health Self-Efficacy Scale

The Mental Health Self-Efficacy Scale assesses belief in one's capability to perform behaviors related to mental health self-care and has been shown to predict response to mHealth interventions for mental health [27]. The Mental Health Self-Efficacy Scale will be completed at each in-person health coaching visit [28].

Exploratory Outcomes

We will characterize intervention feasibility, engagement, and implementation challenges as measured by enrollment, retention, and visit adherence; intervention acceptability [5,34]; engagement as measured by visit attendance and SMS text messaging response rates; health coach self-assessment of competence and fidelity to the intervention [5,35]; and intervention appropriateness and acceptability [36,37] as rated by clients and staff. Finally, participants will be provided a Fitbit Flex to be worn for 1 week before study visits 1 (baseline) and 7 (24 weeks) to assess for change in physical activity through step counts. Data will be downloaded upon return of the device.

Study Interventions

Parent iOTA

The individual-level iOTA intervention for adults with an SMI [20,38] is based on assessment of individual behavior risks, collaborative goal setting with a health coach, and use of an interactive SMS text messaging system that prompts participants to report their weight and their progress on achieving their goals with a "check-in" day each week, and sends immediate, tailored feedback about their progress. Weekly and monthly health tip messages are customized to the participant's selected health goals. If a participant is making progress on their goal, the SMS text messaging system provides an opportunity to increase goal difficulty between health coaching sessions.

iOTA-eSMI Active Intervention

Monthly in-person visits consist of assessing current health behaviors, working collaboratively with the client to identify desired behavior changes, then using a list of existing goals with a stepped level of difficulty based on the participant's current behaviors, the client and health coach collaboratively select up to 3 goals for the next month. These goals have prescribed SMS text messaging tailored to the level of difficulty to support the participant daily with health behavior change [20].

Health Education

The Health Education attentional control condition matches iOTA in time and number of sessions. Participants randomized to the control conditions will receive monthly in-person health coaching visits and a weekly SMS general "Health Tip" text message. Visits will be structured according to the current US Preventive Services Task Force recommendations to counsel participants on energy balance, physical activity, and nutrition [39,40], but will not involve formal goal setting.

Ensuring Rigor and Reproducibility

Treatment Fidelity

Health coach adherence to the intervention protocol is determined by structured, direct observation of individuals carrying out the behavioral intervention, evaluating for evidence of (1) adherence to the treatment protocol and (2) competence in the treatment delivery. Health coaches will self-monitor treatment fidelity as noted above, and implementation challenges will be discussed during weekly study teleconferences.

Outcomes

Both clinical and implementation-related outcomes will be measured, with the primary endpoint being 24 weeks. Clinical outcomes of interest are related to obesity either directly (weight, BMI), or indirectly (self-efficacy, psychophysical awareness). Implementation outcomes include engagement, acceptability, appropriateness, and fidelity.

Recruitment

Targeted educational and recruitment in-services will be conducted at clinical sites in Missouri and Florida. The goal of the in-service will be to make clinicians and clinical administrators aware of this project and to assist in identifying eligible participants. Recruitment and retention tracking across sites will be reviewed on weekly study team conference calls between the sites to identify recruitment shortfalls and broaden recruitment efforts.

Randomization Strategy

As it is anticipated that participants in the health education group will either continue to gain weight or at least maintain their current weight, participants will be randomized 2:1 to either the iOTA-eSMI intervention or to the health education control condition. Groups will be balanced to reflect the age, gender, racial, and ethnic distribution of the client base at each site.

Data Collection, Management, and Analysis

Data Collection Methods

All data will be entered into the Research Electronic Database Capture (REDCap) database through a secure web portal and stored on secure servers. Databases are built with multiple layers of security, following best practices and institutional requirements for securing sensitive data. All automatic system-generated messages in the iOTA program will be sent directly to participants' mobile phones through a web-based app developed and supported by a Health Insurance Portability and Accountability Act–compliant digital platform that has been approved by the institutional review board (IRB) [19].

Planned Primary and Secondary Analyses

The primary outcome for this study will be mean change in body weight (lbs) after 24 weeks of iOTA-eSMI or Health

XSL•FO
RenderX

Education. Secondary outcomes include a change in BMI, psychophysical awareness and skills, and health-related self-efficacy. We will use a repeated measure mixed model to look at trajectory over the study course with a time × treatment interaction estimating treatment effect. Structural equation growth models will be used to estimate the correlation between the trajectory of psychophysical skills and related self-efficacy and that of weight or BMI.

Exploratory Analyses

Additional analyses will focus on characterizing feasibility, engagement, and implementation challenges as measured by enrollment and retention; visit adherence and text response rates; client expectations for improvement [41]; fidelity of treatment delivery; client and staff-rated feasibility, appropriateness, and acceptability. Exploratory analyses will also evaluate the relationship between mental health self-efficacy and psychotropic medication compliance and iOTA treatment compliance or engagement.

Monitoring

Data Monitoring

All electronic files (eg, database, spreadsheet, etc) containing identifiable participant information are password protected. Databases that contain private health and identifiable information are behind firewalls and require a password or username for access. All data will be entered into the REDCap [42] through a secure web portal. Databases are built with multiple layers of security, following best practice requirements for securing sensitive data. Conditional mean imputation will be used to account for missing data.

Harms

Potential Risks

All participants will be informed of potential risks before enrollment. Participation is voluntary, and the participant may choose not to participate in the research study or to withdraw at any time.

Prevention of Risk

All data collected from participants participating in the intervention will only be used for research purposes. Only members of the research team will have access to the data collected as part of this proposed study. No individual's data will be shared outside of the research team. Participants will be advised that their participation in the research study is completely voluntary, that they may choose not to participate in the study, and that they may withdraw their participation in the research study at any time without impacting their ongoing psychiatric or medical care.

Auditing

Before study enrollment, all current and ongoing health issues and medications will be identified and documented. Over the course of the study, participants will be asked to report any health events, changes in medication, and hospitalizations, and a determination will be made as to whether these may be related to their participation in the study protocol and/or intervention. Follow-up surveys will contain questions on potential adverse events (AEs), and interactions with the health coach will include specific inquiries about potential AEs. We will track the dates of each event, intervention needed (if applicable), severity, and the likelihood that the event is related to the study.

AE Definitions

An AE is defined as any untoward medical occurrence in a participant that is temporally associated with participation in the clinical study, whether it is attributed to the study. Unanticipated AEs are those occurrences not noted in the study consent form. A severe adverse event (SAE) will be defined as an AE that is life-threatening, requires inpatient hospitalization, and/or results in death or severe disability.

AE Reporting

All AEs and SAEs will be reviewed within 72 and 24 hours, respectively. Reports will be generated for each event and will include a description of the event, when and how it was reported, as well as any official chart records or documentation to corroborate the event, and determination of attribution. AE and SAE reports will then be sent to the IRB and the National Institutes of Health (NIH) program official.

Reporting Timeframes

Any "related" or "possibly related" deaths will be reported within 1 day of when we become aware of the event. Unanticipated AEs will be reported to the IRB within 10 working days. Any study-related SAE will be reported to the NIH within 2 weeks; all others will be included in the annual report to NIH. Anticipated AEs will be reported to the IRB at the time of continuing review. Any action resulting in temporary or permanent suspension of study conduct will be immediately reported to the appropriate NIH program official.

Safety and Study Progress Reviews

Oversight of data collection, management and intervention development, and delivery will be provided during weekly supervisory teleconferences with the study team delivering the intervention during the pilot study.

Ethics Approval

Research Ethics Approval

The Washington University Institutional Review Board (IRB) approved the focus groups (IRB ID: 201907136) and the randomized pilot study (IRB ID: 201911123).

Protocol Amendments

Protocol versions and related changes are listed in Table 3.

XSL•FO
RenderX

Table 3. Protocol version, date, and description of amendment content.

Version	Approval date	Protocol modifications
1.0	December 9, 2019	Initial protocol approval
1.1	December 16, 2019	Updated recruitment materials, modification of total planned enrollment
1.2	May 6, 2020	Added and removed research staff; added a clinical site in Missouri; added option for doing "in-person" study visits virtually or by phone; added verbal consent by phone and waiver of written consent if no access to a computer; rationale for no power calculation (pilot and feasibility study) added to the analysis plan
1.3	June 5, 2020	Updated consent language
1.4	December 16, 2020	Added and removed research staff; updated inclusion and exclusion criteria–increased upper age limit to 60 years from 45 years; removed the REALM-SF[a] from consent process; removed exclusion for stable or well-managed type 2 diabetes; added recruitment from EPIC
1.5	March 17, 2021	Added research staff
1.6	November 5, 2021	Added and removed research staff; added a clinical site in Florida
1.7	November 27, 2021	Added research staff
1.8	March 4, 2022	Added research staff; added methods for sending test and secure, encrypted emails as well as option for participants to opt out of encrypted email communication with study staff (eg, can authorize emails to be sent without encryption)
1.9	June 9, 2022	Added research staff

[a]REALM-SF: Rapid Estimate of Adult Literacy in Medicine-Short Form.

Consent and Assent

Each participant will be administered the REALM-SF to estimate literacy and the University of California, San Diego Brief Assessment of Capacity to Consent to establish understanding of the study and active treatment. Prior to randomization, all participants will undergo 1 week of SMS text messaging to ensure that they are able to receive and appropriately respond to SMS text messages.

Confidentiality

The potential risk to privacy and/or confidentiality is that protected health information may be accidentally disclosed outside of the study. To avoid sending messages to the wrong number, the research team will first send a test message to ensure that messages are being sent to correct number. Participants will also be encouraged to use passcode protection to keep information on their phones private.

Access to Data

All data collected as part of the study will be coded with a unique study identification number. Only research study staff trained in the Health Insurance Portability and Accountability Act, Collaborative Institutional Training Initiative, and Good Clinical Practice training will have access to the data collected. At each site, data collected for this study will be stored in locked files in locked offices and only designated members of the research team will have access to the files.

Ancillary and Posttrial Care

Participants will continue to receive primary medical and psychiatric care as usual from their existing treatment teams during study participation, and health coaches will communicate any relevant information on their medical and psychiatric progress to treatment teams as authorized by the participant to coordinate care. At the conclusion of the study, participants will remain in the care of their existing treatment teams.

Dissemination Policy

The sharing of information created by this project will follow the NIH's requirement for sharing raw, descriptive, and analyzed data (positive and negative) with the National Institute of Mental Health (NIMH) Data Archive via the National Database for Clinical Trials Related to Mental Illness. The data generated by NIH funding and other support will be presented at national or international scientific conferences and published in peer-reviewed journals. All publications will abide by the NIH Public Access policy, and any unique research resources or tools resulting from the project will be made readily available for research purposes to qualified individuals within the scientific community after publication and upon request.

Results

The characteristics of focus group participants from aim 1 are outlined in Table 4. The Community Support Specialist group included Peer Specialists (6/16, 38% of the overall support specialist group). The "Prescriber" group included psychiatrists (7/9, 78% of the prescriber group) and psychiatric nurse practitioners (2/9, 22%).

At the time of publication, a total of 52 participants have been enrolled in aim 3. The baseline characteristics are reported in Table 5.

[a]iOTA: interactive obesity treatment approach.

Discussion

Early-onset obesity and premature mortality due to cardiovascular disease are more prevalent in mentally ill persons, who experience many barriers to engaging in healthy lifestyle behaviors. Furthermore, communities of color, and those who live with chronic medical conditions like SMI and obesity are disproportionately affected, and particularly those living in underserved areas, may not have access to high-quality health promotion programs. Here, we describe the design of a hybrid pilot and feasibility study evaluating both the effects of a

XSL•FO
RenderX

mHealth obesity prevention program on body weight and the implementation of an intervention in real-world clinical settings.

The study design and baseline characteristics of the enrolled participant population for aims 1 and 3 largely reflect what has been reported in other studies of individuals with SMI. Participants who reported ethnicity as Hispanic or Latino (12/72, 17%) is similar to the 19% reporting any mental illness in the 2020 Census Bureau but lower than the number of individuals of Hispanic or Latino ethnicity reporting any mental health disorder in 2020 (27%) [43]. The proportion of focus group participants who reported race as Black or African American (22/72, 31%) was higher than in the overall US population (12%) [44] but is similar to the proportion of Black Americans reporting any mental health disorder (28%) in the 2020 National Survey on Drug Use and Health [43]. The proportion of individuals enrolled and randomized in aim 3 who were assigned as female at birth (29/52, 58%) and those of Hispanic ancestry (24/52, 24%) are consistent with what has been reported in large population-based studies [43,45,46]. However, the proportion of African American participants represented in the overall study sample (24/52, 48%) is higher than what has been reported in larger studies of both the prevalence of SMI [43,47] and the prevalence of obesity in the general population [48]. Finally, the mean age of 38.2 (SD 11.2) years and BMI of 40.8 (SD 11.8) at baseline were both on the higher end of the range allowable by inclusion criteria.

This study is subject to important limitations. First, although not completed, the sample size for the study is small, and therefore, subgroup analyses are unlikely to yield interpretable results. Second, the results may not be generally applicable in all contexts. That the enrolled population in this study is predominantly Black and, in general, physically and psychiatrically more symptomatic at baseline than expected could be explained in part by timing. Enrollment began at the height of the COVID-19 pandemic when community clinics across the country were shut down to new admissions and in-person visits [49]. Thus, the higher than expected physical and psychiatric comorbidities at baseline, a greater proportion of Black participants, and higher mean age than expected likely reflect the now well-described disproportionate impact the pandemic had on individuals with SMI from underrepresented communities [49].

Obesity prevention programs that use technology as the primary intervention delivery method may increase patient engagement with health promotion programs in general, in addition to reducing care delivery costs and increasing accessibility. This is especially relevant in the era of COVID-19 infection control precautions, which favor remote health care delivery. By pilot-testing this intervention in real-world clinical settings, we aim to adapt the intervention in real-time based on the prominent challenges and barriers that arise in the CMHC context. The results of this study will inform not only how such interventions may need to be modified for optimal effectiveness in eSMI, but also help us to understand how digital and mHealth interventions can be adapted for use in the unique ecosystems of clinical care delivery in community mental health settings, where implementation of digital interventions has been limited.

Acknowledgments

This work was supported by the National Institute of Mental Health grant MH118395, the Healthy Mind Lab and the Center for Brain Research in Mood Disorders in the Washington University Department of Psychiatry, the Washington University Center for Diabetes Translational Research funded by a grant from the National Institute of Diabetes and Digestive and Kidney Disorders, (P30DK092950), and the Washington University Institute for Public Health and the Mobile Health Research Core in the Institute of Clinical and Translational Sciences funded by grant UL1TR002345 from the National Center for Advancing Translational Sciences of the National Institutes of Health. The content is solely the responsibility of the authors and does not necessarily represent the official view of the National Institutes of Health.

Data Availability

Dissemination (ie, sharing) of all data created by this study is an explicit goal of the overall project. Thus, raw, descriptive, and analyzed data (positive and negative) will be uploaded to the National Institute of Mental Health Data Archive via the National Database for Clinical Trials Related to Mental Illness. This process is part of our data safety and management plan for the study. All publications will abide by the National Institutes of Health Public Access policy, and any unique research resources and tools will be made readily available for research purposes to qualified individuals within the scientific community after publication and upon request.

Authors' Contributions

GEN contributed in conceptualization, funding acquisition, project administration, investigation, supervision, data curation, writing (original draft, review, and editing), and visualization. MJ was involved in writing (original draft, review, and editing). AR was responsible for conceptualization, funding acquisition, investigation, and writing (review and editing). JAS was involved in project administration, supervision, investigation, and writing (review and editing). MDY was responsible for data curation, formal analysis, and writing (review and editing). KK was responsible for software, validation, resources, project administration, and writing (review and editing). ZG contributed in data management and primary analysis. BE was involved in software, resources, investigation, and writing (review and editing). JWN was responsible for conceptualization, funding acquisition, investigation, supervision, data curation, and writing (original draft, review and editing).

Abstract

Background: Psychosocial interventions delivered by nonspecialists can be effective at reducing common adolescent mental health problems in low-resource settings. However, there is a lack of evidence on resource-efficient methods for building capacity to deliver these interventions.

Objective: The objective of this study is to evaluate the effects of a digital training (DT) course, delivered in a self-guided format or with coaching, on nonspecialists' competency to deliver a problem-solving intervention intended for adolescents with common mental health problems in India.

Methods: We will conduct a pre-post study with a nested parallel, 2-arm, individually randomized controlled trial. The study aims to recruit 262 participants, randomized 1:1 to receive either a self-guided DT course or a DT course with weekly individualized coaching provided remotely by telephone. In both arms, the DT will be accessed over 4 to 6 weeks. Participants will be nonspecialists (ie, without prior practice-based training in psychological therapies) recruited from among university students and affiliates of nongovernmental organizations in Delhi and Mumbai, India.

Results: Outcomes will be assessed at baseline and 6 weeks post randomization using a knowledge-based competency measure that incorporates a multiple-choice quiz format. The primary hypothesis is that self-guided DT will lead to increased competency scores among novices with no prior experience of delivering psychotherapies. The secondary hypothesis is that digital training with coaching will have an incremental effect on competency scores compared with DT alone. The first participant was enrolled on April 4, 2022.

XSL•FO
RenderX

Conclusions: The study will address an evidence gap on the effectiveness of training methods for nonspecialist providers of adolescent mental health interventions in low-resource settings. The findings from this study will be used to support wider efforts to scale up evidence-based mental health interventions for young people.

KEYWORDS

adolescent mental health; capacity building; digital training; India; problem-solving intervention; randomized controlled trial

Introduction

Task-sharing is increasingly used to address unmet mental health needs in low-resource settings. Task-sharing approaches deploy trained community and voluntary sector workers in service delivery roles that are traditionally held by specialized professionals [1]. Trials have demonstrated the effectiveness of resource-efficient "low-intensity" psychological interventions delivered by nonspecialists [2,3], but there is a lack of evidence on how to make these solutions work sustainably.

Training capacity has been a major supply-side barrier, with traditional face-to-face methods requiring a critical mass of expert trainers and physical infrastructure [4]. The growing use of web-based educational materials, which accelerated during the COVID-19 pandemic, presents significant opportunities for building workforce capacity at scale [5,6]. The supporting evidence from the global mental health literature suggests benefits of digital training (DT) in terms of time, efficiency, flexibility, and reduced economic costs [7]. However, differences in training approaches and evaluation measures limit comparability of findings across studies. Moreover, key engagement challenges identified for digital learning from the wider pedagogical literature leading to relatively high rates of dropout [8-10] have not been systematically addressed or studied in relation to nonspecialist providers of mental health care.

This study addresses the lack of evidence on workforce development strategies for scaling up evidence-based adolescent mental health interventions in low-resource settings. The aim is to evaluate 2 versions of DT for nonspecialists, recruited from a variety of contexts in India, and compare their effects on knowledge-based competency needed to deliver a brief evidence-based problem-solving intervention for common adolescent mental health problems. The effects of the problem-solving intervention on adolescent mental health have been previously evaluated in a randomized controlled trial in Indian secondary schools where lay counselors were trained using face-to-face methods [3]. In this study, we are interested in assessing the effects of DT on competency in a nonspecialist workforce that could deliver the problem-solving intervention more widely.

We are particularly interested in the potential incremental effects of providing personalized coaching for learners on a DT course. A recent pilot study involving nonspecialist primary care workers in Madhya Pradesh, India, demonstrated that the addition of remote telephone coaching improved training completion rates for a digital program [11], for training frontline community health workers on a brief psychological treatment for adults with depression [12]. We wished to test whether a similar coaching approach may enhance engagement with, and competencies attained, with a DT package related to an adolescent mental health intervention.

Our specific objectives are to (1) evaluate the effects of DT on knowledge-based competency of trained nonspecialists to deliver an evidence-based problem-solving intervention for common adolescent mental health problems; (2) evaluate the incremental effect of digital training with coaching (DT-C) in comparison with self-guided DT on nonspecialists' competency to deliver the problem-solving intervention; and (3) investigate the implementation of the training intervention in both arms.

Methods

Design

This protocol adheres to the Standard Protocol Items: Recommendations for Interventional Trials guidelines [13,14]. A parallel, 2-arm, individually randomized controlled trial design will be nested within a pre-post intervention study. Outcomes will be assessed at baseline and 6 weeks post randomization.

Setting

This study will be conducted in partnership with 4 universities (2 coeducational colleges in the National Capital Territory of Delhi, 1 coeducational college in Bangalore, Karnataka, and 1 girls-only college in Mumbai, Maharashtra), and 5 nongovernmental organizations (NGOs) working in the fields of adolescent health and education. The sampling frame comprises approximately 2500 university students and 2500 staff and volunteers associated with NGOs.

Participants

Participants will be sampled from two broad groups: (1) university students currently enrolled in a bachelor's-level degree program in psychology, education, or allied fields; and (2) NGO employees who are working as teachers, social workers, or mental health advocates. Eligible participants in both groups will be aged 18 years or older; be fluent in written and spoken Hindi or English; and have regular access to a web-enabled smartphone or computer that can be used to participate in the digital course. Potential participants will be excluded from the study if they have prior practice-based training in psychological therapies.

XSL•FO

Interventions

Self-guided DT Arm: Digital Content

The DT course comprises 16 modules organized into 2 sections: nonspecific counseling skills and skills that are specific to problem-solving counseling. The course content is based on an existing manual for the Premium for Adolescents (PRIDE) problem-solving intervention [2], which was designed in India as a first-line treatment within a transdiagnostic stepped care architecture for adolescents with elevated mental health concerns of varying types. A previous randomized controlled trial in India showed that the problem-solving intervention effectively reduces adolescents' self-rated psychosocial problems and mental health symptoms when implemented by relatively inexperienced lay counselors in four or five 20- to 30-minute sessions held across 3 weeks [3,15]. The manual was translated into a DT course in 5 steps as described in Textbox 1, following a structured process established in previous research [16].

Textbox 1. Intervention development process.

Create curriculum outline

- A course outline was developed to ensure alignment between the learning objectives and the core content of the Premium for Adolescents (PRIDE) problem-solving intervention manual
- Three members of the current study team (SM, TS, and RM) drafted the course blueprint, which was reviewed by 3 of the original PRIDE manual developers (DM, CF, and VP) to ensure that all key competencies were represented

Develop training content

- Written content from the PRIDE manual was adapted into multimodal content including videos, text, and PowerPoint for the training course
- Draft materials were reviewed again by the original PRIDE manual developers to ensure faithful translation of concepts and procedures

Digitize training content

- Materials were produced in digital formats that could be accessed from both a smartphone app and website
- These included video-based lectures, role plays, animated summary slide shows, and quizzes
- Materials were checked for accuracy and visual appeal by members of the study team

Adding content to a learning management system (LMS)

- Digital content was published on an open-source web-based LMS
- The platform included learner performance tracking and metrics, a customizable interface available in multiple languages, and a user-friendly dashboard

Conduct user testing

- User testing was carried out in a group format with 20 undergraduate psychology students
- On the basis of feedback received, the app was further optimized for viewing video content, a message repository was prepared to send automated notifications to motivate learners
- The numbering of videos was made simpler, the glossary was expanded, and a recruitment video was prepared

The course will be hosted on a learning management system (LMS) hosted by Sangath, the implementing organization in India, which can be accessed through a smartphone app and website in either Hindi or English, based on the user's preference. The content will be delivered through a variety of instructional methods including video-based lectures, role-play videos, animated summary slide shows, quizzes, and brief readings adapted from the source problem-solving manual. The training requires approximately 20 hours to complete, accounting for the time needed to engage with the various content areas. This can be spaced out over 4 weeks, with 4 modules being unlocked every week to facilitate sequential learning. Participants who are unable to complete the course within 4 weeks will be offered an extension for up to 2 weeks during the trial, after which their access to the course will be locked for the duration of endline assessment.

Automated support features include weekly emails and text notifications on the LMS platform that serve as reminders and motivators to engage with the digital content. In addition, participants will be able to send technical queries (eg, related to accessing and navigating the digital platform) to a dedicated WhatsApp number. This account will be monitored during regular working hours by a research assistant who will provide support accordingly, while declining to answer any course content-related queries.

DT-C Arm

Coaching

In addition to the DT program, participants in the DT-C arm will receive personalized remote coaching for the duration of the course. The main functions of the coach are to (1) review core concepts from the course content, (2) respond to specific content-related queries, and (3) reinforce progress toward completing the course in the allocated time frame. There will be 4 coaches, each of whom will be bilingual and possess an undergraduate degree. Coaches will have completed training in

XSL•FO
RenderX

the PRIDE problem-solving intervention, as well as receiving 5 days of office-based training in the coaching protocol that was designed specifically for the current study. The coaching protocol (see the outline in Table 1) has been adapted from 2 existing psychotherapy coaching protocols intended for nonspecialists [11,17].

Table 1. Outline of the coaching protocol.

Content sections (activities done by the coach)	Description
Build rapport	Engage the learner and create a collaborative space for coaching
Orient learner	Introduce learner to the course and coaching and set expectations
Plan for course completion	Discuss timetable over the intended 4-week course duration, including time required for each module and schedule for weekly coaching calls
Review progress	Assess progress on a weekly basis and troubleshoot challenges to completion
Resolve queries	Answer any queries from the learner about course content
Provide motivation	Encourage the learner by verbally reinforcing progress
Set learning goals	Collaboratively set learning goals for week ahead
Wrapping up	Recap material and discuss potential for skills practice and application

Coaching will be delivered through voice-based telephone calls and SMS text messages. The coach will call participants once per week over the 4-week duration, which may be extended by up to 2 weeks. Each coaching call is intended to last for approximately 30 minutes and follow a structured agenda. Prior to the call, the coach will review key performance metrics (modules completed and scores on formative quizzes) collected from the LMS dashboard. During each call, the coach will check if the participant has experienced progress-related challenges, clarify any difficulties with course concepts, reinforce continued participation, and collaboratively set learning goals for the week ahead. Participants will also have the option to ask queries via SMS text messages to their coach between calls. Depending upon the nature of the query, a coach may respond over text or address the query during the next scheduled phone-based coaching session. Additionally, coaches will send a reminder message to learners 1 day prior to scheduled coaching calls.

Throughout the trial, coaches will participate in weekly peer group supervision meetings lasting 2 to 3 hours. Group supervision will include quality ratings of audio-recorded coaching sessions and trouble-shooting around logistical/technical issues, which will be moderated by a supervising masters- or doctoral-level clinical or counseling psychologist. The coaches will be able to make ad hoc calls to a supervising psychologist in case of any pressing concerns outside the group supervision sessions.

Coaches will not supervise learners in the applied use of the problem-solving intervention for treating adolescent mental health problems. The study recruitment materials will emphasize that a suitably experienced and qualified clinician should be engaged in supervising any such clinical activity with appropriate quality assurance and safeguarding arrangements in place. An outline of the coaching components is given in Table 1.

Procedure

The study schedule is summarized in Table 2 and set out in further detail below.

XSL•FO
RenderX

Table 2. Schedule for enrolment, interventions, and assessments.

Time point	Baseline (week 0)	Intervention (weeks 0-24, with a 2-week allowance)	Follow-up (week 6, with a 2-week allowance)

[b]KOPS: knowledge of problem solving scale.

[c]MUSIC: eMpowerment, usefulness, success, interest, and caring scale.

[d]LMS: learning management system.

Recruitment and Consent

Participants will be recruited through sensitization webinars that will raise awareness about the study and opportunities to participate in the DT course. The webinars will be coordinated with the 9 partner organizations (NGOs and universities) using existing communication channels such as email lists and WhatsApp groups. Sessions will be conducted throughout the recruitment period to maintain a consistent flow of referrals until our target sample is achieved. Webinars will be facilitated by a member of the intervention team using a PowerPoint presentation, video demonstration, and Q&A. A telephone number and REDCap platform URL [18] will be provided to individuals who wish to begin the enrollment process. Where possible, physical posters, with information about the study and associated training opportunities, will also be displayed in preselected locations on the premises of the collaborating organizations.

Following sensitization activities, interested individuals will be able to initiate a referral by directly visiting the study website, or by contacting a dedicated centralized number (via call or SMS text message) to request further information and leave their preferred contact details. A research assistant will respond by emailing and, if required, by texting a link to the study website (hosted on the REDCap platform). When accessing the REDCap platform, they will be able to read information about the study before completing a series of eligibility questions on the web. The questions will ask about age, current occupation, device access, preferred language for training, and prior training or other experience in delivering psychological therapies. Individuals who require assistance to complete the eligibility form will be able to contact the study helpline and speak to a research assistant. Details of the helpline contact will be shared through the recruitment posters and messages shared via WhatsApp and email. If an individual leaves the eligibility screening form incomplete for 2 days, a research assistant will contact the participant to identify and clarify any difficulties they are facing. If the participant is ineligible for the study, then they will not be followed up by the research team and instead redirected to the Sangath website to view other information about alternative courses. Once eligibility is confirmed, a prospective participant will be emailed a weblink to the study information sheet and consent form. Each consenting participant will be asked to complete a demographic proforma (see "measures" below).

Baseline Assessment

Consenting individuals will be directed to complete the baseline assessment measure (see "measures" below) via a weblink contained within a further email. Each participant will also have the option to contact the study helpline if they face technical difficulties during the assessment. If the baseline assessment has not been completed within 2 days after enrollment, a research assistant will make contact by telephone to remind the participant. If needed, research assistants will make up to 4 more attempts to contact the individual over the subsequent 2 weeks.

Randomization and Allocation Concealment

Participants will be randomized in a 1:1 allocation ratio to 1 of the 2 trial arms. Randomization will be stratified by the type of organization, using randomly sized blocks of 4 or 6. The randomization sequence for each stratum will be generated by an independent statistician and deployed on REDCap by the data manager on site. The trial principal investigator, trial

XSL•FO
RenderX

coordinator, trial statisticians, and members of the Trial Steering Committee will remain blinded to allocation arms throughout the trial and until the final analysis is complete. It will not be possible to blind the participants or coaches to the allocation because of the nature of the intervention. The data manager will also not be blinded. A separate Data Monitoring Committee was not established, since this is not clinical trial and there is no risk to the safety or participants.

An onboarding email will be sent to the participant informing them of their allocation status within 24 hours of randomization. This email will also contain details of the course and study structure, login details to access the DT platform, and a link to a tutorial video explaining participants how to access and navigate the training platform. Participants in the DT-C arm will additionally receive an introductory onboarding call from their coach to orient them toward coaching within 24 hours of randomization. A daily check will be performed by the data manager to evaluate if allocations are consistent with the allocation code.

Follow-Up Assessment

A link to the follow-up assessment materials will be shared with participants using their registered email address at 42 days (ie, 6 weeks) post randomization. The course has been structured in such a way that each week, 4 modules are unlocked for the learners. This would ensure that the learners can comfortably complete the course within 4 weeks. However, we have given the provision of additional 2 weeks for the learners to complete the course. Research assistants will make up to 4 more attempts to contact the participant over the subsequent 2 weeks or until the follow-up assessment is completed on the study website. Participants will be given a maximum allowance of 2 weeks to complete the follow-up assessment.

Measures

Participant Characteristics

Sociodemographic data will be collected at baseline on age, gender, education level, occupation, years of experience (if employed), year and course of study (if currently a student), and preferred language for receiving the course (English or Hindi).

Primary Outcome

Self-completed outcome data will be collected remotely through the REDCap platform at baseline and 6 weeks after randomization into the study. The primary outcome will be a knowledge-based competency measure, the knowledge of problem-solving (KOPS) scale. This was developed specifically for the current study and contains 17 multiple-choice questions organized around 5 session vignettes. The measure produces a score ranging from 0 to 17, where higher scores indicate higher levels of competency. The vignette-based format was informed by previous research on competency assessments for nonspecialists [19-21]. Twelve questions assess knowledge of specific problem-solving competencies (eg, problem identification) and 5 questions assess nonspecific competencies of relevance to psychotherapies generally (eg, rapport building). To enhance external validity, question domains were cross-referenced with problem-solving items from an established CBT competency framework implemented widely in the United Kingdom [22] and nonspecific counseling items from 2 existing competency measures used in previous studies with nonspecialist providers in South Asia [23-25]. The wording of questions and details of the case vignettes were refined through piloting with a reference sample that included both experienced counselors and novices. The process of developing the KOPS measure is described in detail elsewhere (S Mathur et al., unpublished data).

Parallel forms of the case vignette and quiz will be used at baseline and end line assessments (ie, respondents will be assessed on the same domains but with different cases and alternative question formulations at each time point). In each form, participants will be presented with a written case description followed by 5 session vignettes in a logical sequence. The participant will be required to respond sequentially to a set of multiple-choice questions after each of these vignettes (3 to 4 questions per set). The sequencing of the 2 forms will be determined at random. Participants will have up to 90 minutes to complete the quiz once they begin answering, after which the assessment link will expire. The remaining time available will be visible as a countdown clock on the assessment screen.

Secondary Outcomes

User satisfaction data will be obtained from participants in both trial arms using the MUSIC (eMpowerment, Usefulness, Success, Interest, and Caring) questionnaire. We will use a version of the MUSIC scale that has been adapted in previous DT trials in India [11,26]. The scale will include 26 items, each rated on a 6-point scale, covering domains of feasibility, acceptability, adoption, and appropriateness. The questionnaire provides a score on each of the 5 scales (empowerment, usefulness, success, interest, and caring), each based on 4 to 6 items. Two supplementary free-text items will be used to obtain written qualitative feedback from participants about what they enjoyed the most in the course, as well as suggestions for improvement.

Process Evaluation

Data on enrolment, randomization, and completion of assessment procedures will be obtained from the REDCap platform. This will include numbers and proportions of study referrals that are assessed, eligible, consented, and randomized (by host organization, age, and gender); and reasons for missed assessments, ineligibility, declined consent, and missed randomization. Session record forms and automated data captured from the LMS will be used to assess frequency of log-ins, number of modules completed, and time spent logged into the LMS. Additional process variables in the DT-C arm will include number and duration of attended coaching sessions (and number of missed coaching sessions and reasons for nonattendance). Fidelity of coaching will be assessed using independent ratings of audio-recorded coaching calls (based on 10% of recorded calls). Coaches will also document the frequency and duration of calls (and reasons for missed calls), as well as frequency of SMS text messages received and sent in response.

XSL•FO
RenderX

Study Size

For the primary hypothesis that the DT intervention improves competency score, a sample size of 262 participants will provide 80% power to detect an effect size of 0.19 (ie, a standardized mean difference [SMD] of post vs pretraining scores), assuming 20% loss-to-follow-up, and a 5% 2-sided significance level. This indicative effect size (SMD=0.19) was informed by a systematic review and meta-analysis of web-based learning evaluations which compared analogous learning conditions [27]. For the second hypothesis that the DT-C intervention is superior to the DT intervention, this sample size will provide 80% power to detect an effect size (standardized mean difference) of 0.39 between the DT and DT-C arms with a 1:1 allocation ratio between randomized arms. With the 20% loss-to-follow-up, we anticipate that 210 (80%) participants will complete follow-up and contribute to the endline analysis (105 per arm).

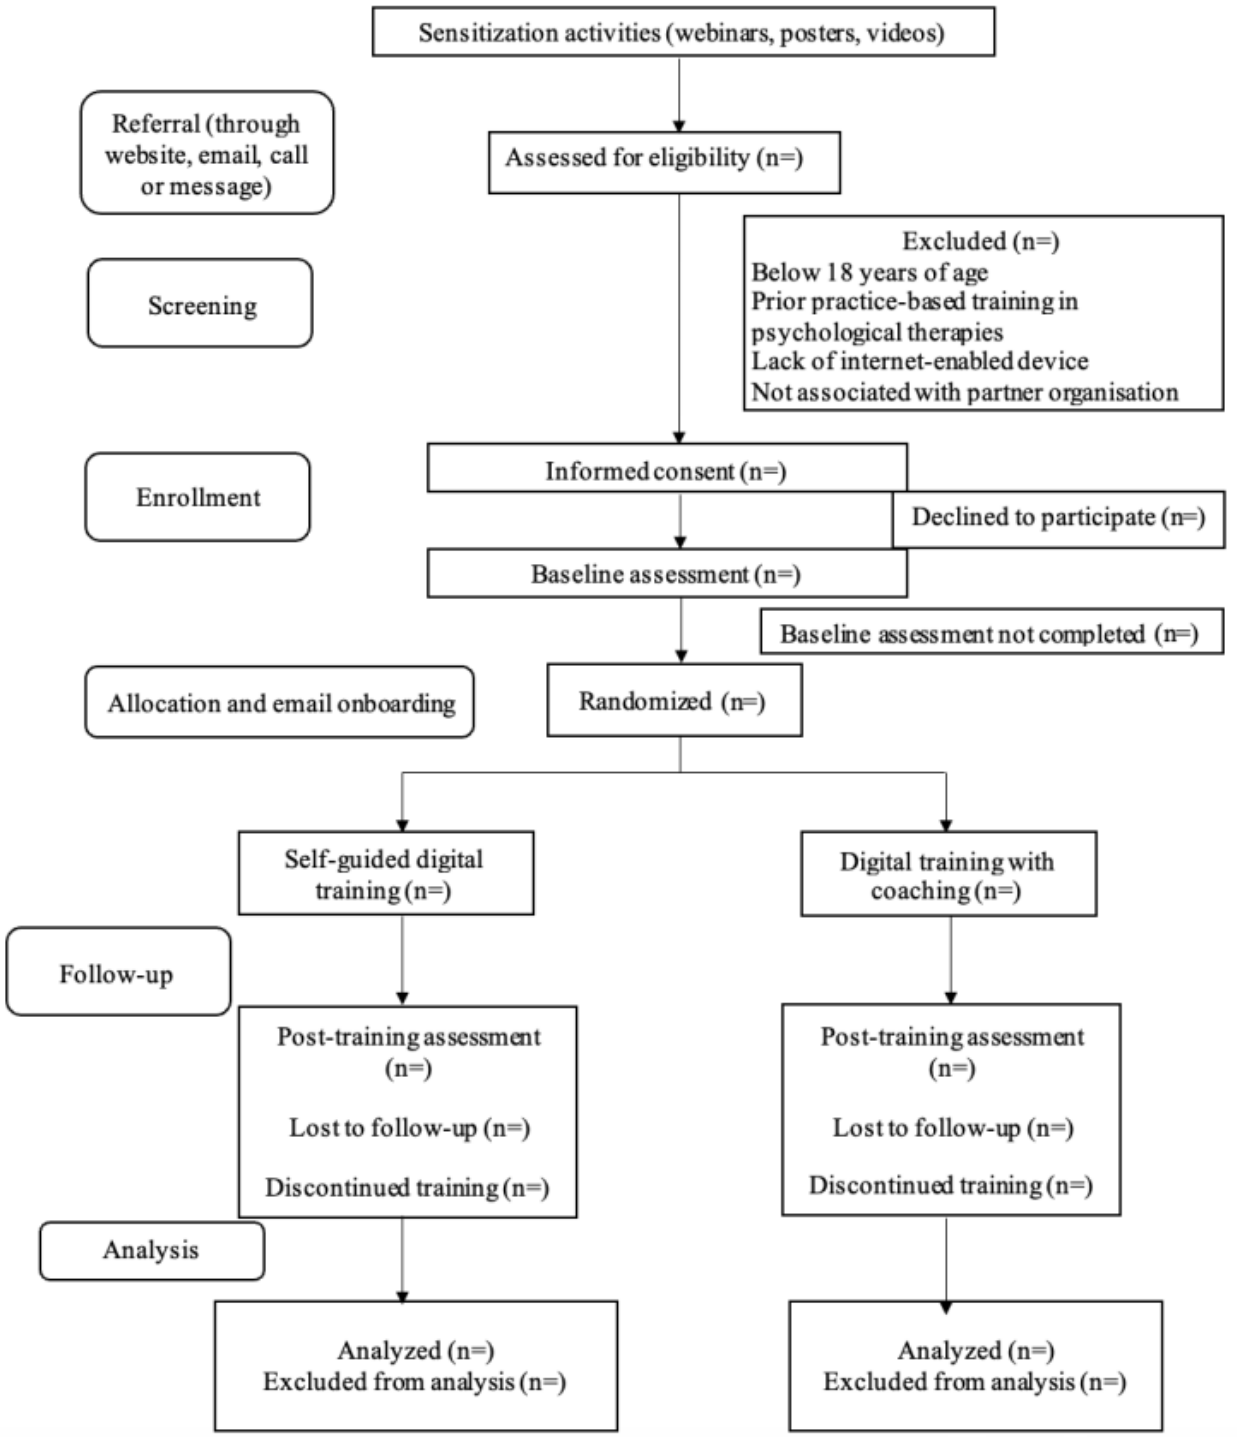
Data Security and Management

The principal investigator (VP) will act as custodian of the data in accordance with regulations of the research sponsor (Harvard Medical School) and funder (Wellcome Trust, United Kingdom). Each participant will be assigned a unique ID and password to access both the DT course and secure REDCap platform for outcome assessments. Data will be stored on a secure and backed-up server operated by a trusted third party (Sangath) in a managed environment that protects against data loss and corruption, unauthorized access, and modification. To mitigate the risk of identifying participants from the data collected in the study, we will not record direct identifiers on study data. Data in its original form will be retained on the server and will be accessible only to core research team members who are directly involved in the study.

Participant information sheets (and instructions for completing the outcome measures) will clearly explain that scores will remain confidential and will not be shared with university authorities, employers, or any other third parties. Participants will be informed through the information sheet that they can withdraw from the study at any time and their data will be removed up to the point when the primary analysis is completed. Anonymized participant data and a data dictionary will be made available 12 months after study completion. Data will be shared after approval by the PRIDE principal investigator, following a reasonable submitted request.

Statistical Analysis

General Principles



Except otherwise specified, analysis will be conducted according to the arm participants were randomized to, regardless of intervention effectively received (“intention to treat” principle), CIs will be reported at the 95% level, and significance considered at a 2-sided 5% α.

Descriptive Statistics

We will describe participants’ baseline characteristics overall and by arm. A CONSORT flow diagram (Figure 1) will be used to summarize trial processes. Adherence to the intervention will be reported descriptively, including the number of modules and number of coaching calls completed.

XSL•FO
RenderX

Figure 1. Consolidated standards of reporting trials (CONSORT) flow diagram.

Psychometric Analysis

We will use the baseline data of outcome scores obtained from all participants to establish the psychometric properties of the multiple-choice KOPS competency measure. Prior to unblinding the trial data set, a 2-parameter Rasch model will be fitted to estimate the item characteristic curves, discrimination, and difficulty parameter for each item on both forms of the competency measure. In addition, the test information function will be estimated to look at the overall characteristics of the forms. Based on this analysis, items may be removed, and the primary outcome analysis will be conducted using retained items. Items that have poor discrimination or are at the very extremes of difficulty may be removed in the interests of a test information function that suggests that the scale as a whole provides information across a range of abilities. If any items are removed, a sensitivity analysis will be conducted in which the original 17-item version is used as the outcome for the model that tests the main trial hypothesis.

XSL•FO
RenderX

Missing Data

We will compare baseline characteristics of study completers versus noncompleters. The main analyses (hypotheses 1 and 2) will use multiple imputation under the missing at random assumption, by chained equations, and including the main predictors of missing data in the imputation model. Sensitivity analysis will include complete case analysis, adjusting for factors associated with missing data, and under missing not-at-random assumptions.

Analysis of Pre-Post Differences

The analysis of pre-post differences will be conducted by doing a linear regression of the change in competency score between baseline and 6 weeks. The null hypothesis will be that there is no change in score.

Randomized Controlled Trial Analysis

The second hypothesis will be analyzed by a linear regression of the change in competency score between baseline and 6 weeks, testing for a difference between the 2 arms. The analysis will be adjusted for strata, and baseline competency score.

Analysis of Effect Modification

To assess on whom the DT and additional coaching may work best, we will assess effect-modification on the primary and secondary outcomes by *a priori* defined modifier (age, gender, language, and type of organization [NGO vs university]), by including these factors as predictors (pre-post analysis), or as interaction terms (trial analysis) testing for heterogeneity of treatment effects in the regression models specified above.

Secondary Outcomes Analysis

The effect of coaching on the secondary outcomes (MUSIC 5 subscales and DT course completion) will be conducted similarly to the trial analysis model described above, but without adjusting for baseline score. The MUSIC subscales will be analyzed as continuous variables using linear regression (or a suitable transformation). Course completion as a binary variable will be analyzed using logistic regression.

Compliance Analysis

We will report descriptively adherence to the intervention (number of training modules and coach sessions completed). Change in competency score will be reported descriptively by level of intervention received, in a dose-response type analysis.

Process Evaluation

Process data will be used to facilitate interpretation of the main trial results. Findings from the various data sources will be triangulated and used to develop explanatory hypotheses about potential differences in training delivery and participation across arms, subgroups of participants and coaches. We may conduct further analyses to test hypotheses generated from the integration of the process evaluation and trial outcome data (eg, on whether the duration of time taken to complete the training influences outcomes).

Ethics Approval

Institutional review board approvals have been obtained from Sangath (the implementing organization in India; VP_2015_017); Harvard Medical School (IRB21-1197), United States (the sponsor; IRB21-1197); and the London School of Hygiene and Tropical Medicine, United Kingdom (a collaborating organization; 26565).

Dissemination Plan

A multimodal dissemination strategy will share findings with diverse stakeholders. Strategies will include scientific publications, training manuals and videos, and web-based dissemination. All publications will be in an open access format and authorship will be determined according to the International Committee of Medical Journal Editors' guidelines [28]. Targeted stakeholders will include practitioners, academics, NGOs, authorities involved in education and health, policy makers, and donors at state and national levels.

Results

Participant sensitization sessions began on March 31, 2022. The first participant was enrolled on April 4, 2022, and their 6-week assessment was completed on May 18, 2022.

Discussion

Although India has been an incubator for some of the most widely cited task-sharing innovations in mental health care, the lack of implementation of these interventions at scale is a major challenge. The current trial will address this critical implementation gap by evaluating DT for nonspecialists, recruited from a range of contexts in India. This research expands on prior workforce development studies by evaluating 2 approaches to implementing DT, 1 self-guided and the other supported by remote individualized coaching, with a specific focus on competencies needed to treat adolescent mental health problems [8,17,29]. The evaluation design will enable a primary analysis of the effects of DT on knowledge required to deliver a brief evidence-based problem-solving intervention. A secondary analysis will compare outcomes for the DT package when delivered with and without coaching.

The coaching protocol has been designed in part to address motivational challenges highlighted in previous research on DT [30,31]. Research has recommended blended methods that combine e-learning with face-to-face or remote human support to increase engagement [11,31,32]. We have also included provision for a technical helpline, distinct from coaching, which can be used by participants in both arms of the trial.

The strengths of this trial are including participants from varied contexts across India and assessing their competency through counseling vignettes that approximate real-life situations, thus adding to their ecological validity. However, we recognize the limitation that the study does not directly assess the applicability of the acquired knowledge in counseling settings. The latter is a future research priority.

The results from the study will provide important insights into how competencies in youth-focused psychotherapies can be developed at scale outside specialist mental health settings. Related evidence will also be produced about how to motivate and support nonspecialists in settings where expert trainers and supervisors are scarce. Such evidence can be used to shape the

XSL•FO
RenderX

wider dissemination of the PRIDE problem-solving intervention, and similar low-intensity psychotherapies, to address the mental health treatment gap for adolescents in India and globally.

Acknowledgments

The authors offer particular thanks to members of the PRIDE Scientific Advisory Group and colleagues who contributed to intervention and research activities across the various phases of the study, including Shreyas Kamat, Abhija Teli, Keshav Shakya, Niket Agarwal, Rukhsar Akram, Sai Priya Kumar Chodankar, Mamta, Aarohi Sharma, Manogya Sahay, Meenakshi Pandey, Sarita Rao, Shouaib Ahmed, and Himanshu Gupta. The authors also gratefully acknowledge the contributions made by the Population Foundation of India in designing the digital training course. This study was supported by a Principal Research Fellowship awarded to VP by the Wellcome Trust (grant 106919/A/15/Z). The funders had no role in the design of the study, data collection, or the writing of the manuscript. For open access, the author has applied a CC BY public copyright license to any author accepted manuscript version arising from this submission.

Data Availability

The data sets that will be generated during this study will be available from the corresponding author on reasonable request.

Authors' Contributions

SM, DM, and VP conceptualized the study. SM led on drafting the protocol, with critical inputs from DM and VP. HAW, MN, BL, and APF contributed to the statistical analysis plan. SM, TS, JEJ, PN, and RM contributed to the coordination and implementation of the trial. KM contributed to the refinement of the protocol. All authors read and approved the final manuscript. DM and VP contributed equally as senior authors.

Conflicts of Interest

None declared.

Abstract

XSL•FO
RenderX

Background: Nonmuscle invasive bladder cancer (NMIBC) accounts for 75% of bladder cancers. It is common and costly. Cost and detriment to patient outcomes and quality of life are driven by high recurrence rates and the need for regular invasive surveillance and repeat treatments. There is evidence that the quality of the initial surgical procedure (transurethral resection of bladder tumor [TURBT]) and administration of postoperative bladder chemotherapy significantly reduce cancer recurrence rates and improve outcomes (cancer progression and mortality). There is surgeon-reported evidence that TURBT practice varies significantly across surgeons and sites. There is limited evidence from clinical trials of intravesical chemotherapy that NMIBC recurrence rate varies significantly between sites and that this cannot be accounted for by differences in patient, tumor, or adjuvant treatment factors, suggesting that how the surgery is performed may be a reason for the variation.

Objective: This study primarily aims to determine if feedback on and education about surgical quality indicators can improve performance and secondarily if this can reduce cancer recurrence rates. Planned secondary analyses aim to determine what surgeon, operative, perioperative, institutional, and patient factors are associated with better achievement of TURBT quality indicators and NMIBC recurrence rates.

Methods: This is an observational, international, multicenter study with an embedded cluster randomized trial of audit, feedback, and education. Sites will be included if they perform TURBT for NMIBC. The study has four phases: (1) site registration and usual practice survey; (2) retrospective audit; (3) randomization to audit, feedback, and education intervention or to no intervention; and (4) prospective audit. Local and national ethical and institutional approvals or exemptions will be obtained at each participating site.

Results: The study has 4 coprimary outcomes, which are 4 evidence-based TURBT quality indicators: a surgical performance factor (detrusor muscle resection); an adjuvant treatment factor (intravesical chemotherapy administration); and 2 documentation factors (resection completeness and tumor features). A key secondary outcome is the early cancer recurrence rate. The intervention is a web-based surgical performance feedback dashboard with educational and practical resources for TURBT quality improvement. It will include anonymous site and surgeon-level peer comparison, a performance summary, and targets. The coprimary outcomes will be analyzed at the site level while recurrence rate will be analyzed at the patient level. The study was funded in October 2020 and began data collection in April 2021. As of January 2023, there were 220 hospitals participating and over 15,000 patient records. Projected data collection end date is June 30, 2023.

Conclusions: This study aims to use a distributed collaborative model to deliver a site-level web-based performance feedback intervention to improve the quality of endoscopic bladder cancer surgery. The study is funded and projects to complete data collection in June 2023.

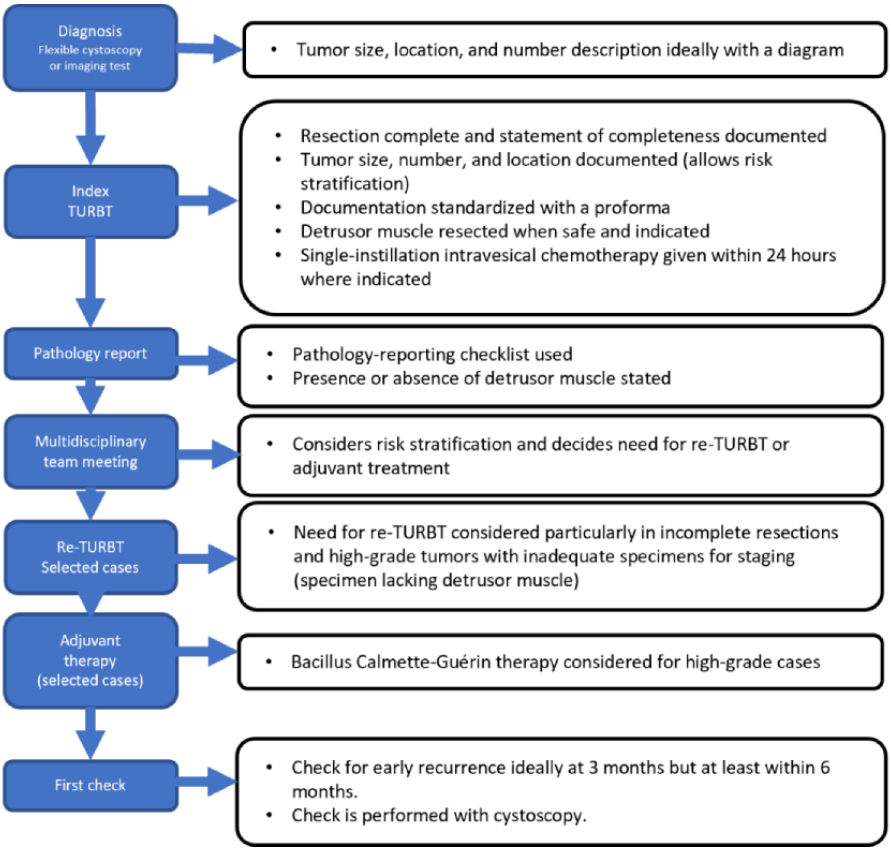
Introduction



Background

Nonmuscle invasive bladder cancer (NMIBC) is a common disease with an incidence of 19.1 and 4.0 cases (men and women, respectively) per 100,000 person-years in the European Union [1]. Three-quarters of all new bladder cancer diagnoses are that of NMIBC [2]. This disease is the most expensive to manage, per patient, from diagnosis to death [3,4].

The standard of care management for all suspected NMIBC is surgical transurethral resection of bladder tumor (TURBT). Evidence guides how the initial TURBT should be performed and perioperative practice, including the use of single-instillation intravesical chemotherapy (SI-IVC) to reduce recurrence rates of cancer [5]. It has been proposed that achieving “good-quality” NMIBC surgery and perioperative practice results in reduced recurrence rates [6]. This evidence forms the basis for the recommendations made in guidelines including those by the European Association of Urology (EAU) [5], the American Urological Association (AUA) [7], and the National Institute for Health and Care Excellence (NICE) [8] in England and Wales. The usual NMIBC diagnosis and treatment pathway is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Nonmuscle invasive bladder cancer diagnosis and treatment pathway. TURBT: transurethral resection of bladder tumor.

The Problem

Compliance with best practice for TURBT surgery and perioperative guidelines varies widely [9], which may impact oncological outcomes [10-12]. There is a significant variation in early tumor recurrence rates between different sites that cannot be accounted for by patient, tumor, or adjuvant treatment factors [10], suggesting surgical factors may be the cause. In a survey of practice in 9 European countries published in 2019, significant deviation from guidelines was identified even for interventions with high certainty of evidence, such as SI-IVC administration [9]. There has recently been a proposed set of "quality indicators" for TURBT but the published review acknowledged that there was a lack of evidence that implementing these quality indicators resulted in improved outcomes [13]. A long-running study on quality standards in TURBT surgery in Scotland demonstrated that being involved in a national audit and feedback program of TURBT quality performance indicators did lead to a trend in improvement of quality indicator achievement over time, but a critical limitation was that there was no control group or comparison to baseline performance [14,15]. This work also established the utility and measurability of certain TURBT quality indicators in the real world.

The Intervention: Electronic Audit, Feedback, and Education

Audit and feedback have the potential to improve professional practice and impact patient outcomes. Meta-analyses of the effects of audit and feedback in health care demonstrate wide variation in effect size [16]. The median baseline performance–adjusted improvement in compliance with desired practice was 4.3% but varied from 0.5% to 16%. Further, there is theory and evidence that education on addressing deficiencies highlighted by audit may enhance the effectiveness of audit and feedback [17,18].

A systematic review concluded that feedback can improve surgical performance, but the strength of the conclusions was tempered by the heterogeneity, the lack of randomization, and the lack of controls in the included studies [15,19,20]. A systematic review of electronic audit and feedback interventions concluded that effects were variable and only 2 of 7 identified studies used theory to guide interventions [21].

For bladder cancer surgery, there are professional practice behaviors under the control of the surgeon that have proven to be associated with patient outcomes after TURBT surgery [6,22-25]. Given that audit, feedback, and education is a cost-effective and simple intervention and has demonstrated efficacy in other settings, we would hypothesize that this intervention also improves perioperative indicators of surgical quality. Furthermore, there is evidence that targeting "process measures" as the unit for change is more effective than targeting patient outcomes [26]. Therefore, we chose to target professional practice behaviors (or quality indicators) as the primary outcomes rather than a disease outcome such as recurrence rates.

Objectives

Main Objective

The primary objective is to determine whether "audit, feedback, and education" improves achievement of TURBT quality indicators.

XSL•FO
RenderX

Other Objectives

The other objectives are to determine (1) if audit, feedback, and education improves the early recurrence rate of NMIBC after first TURBT; (2) if achievement of TURBT quality indicators is associated with early recurrence rate of NMIBC after the first TURBT; (3) the average and variation in achievement of TURBT surgery quality indicators and early recurrence rate across surgeons, sites, countries, and health care settings (site type and operating list type); and (4) associations among site, surgeon, and surgical factors and achievement of TURBT quality indicators and early recurrence rate.

Methods

Study Design

This is an international, observational, multicenter study with an embedded prospective cluster–cluster randomized, parallel-arm, superiority trial of audit, feedback, and education. A cluster randomized trial was chosen because intrasite contamination would be expected if randomization was at the clinician level. A cluster is defined as one or more hospitals within the same health care organization where the same surgeons perform TURBT surgery. Sites will be informed of any updates to the protocol or standard operating procedures with the latest trial documents available on the BURST RESECT study website (protocol version 4.0 November 11, 2020).

Data Collection, Management, and Privacy

Data will be entered into a web-based secure database hosted at University College London (Research Electronic Data Capture [REDCap]). Collected data are anonymous. Case report forms were developed with peer review and national and international testing (tested in the United Kingdom, France, and the United States). Data range checks, data sense rules, and essential required variable alerts will be programed at outset to improve accuracy and completeness. In total, 10% of all records will be manually checked for sense and completeness. Manually identified errors will be coded as automated rules, and the whole database scanned or audited for errors. Identified errors will be alerted to sites for correction before database lock. Data errors and incomplete or missing follow-up data will be queried with sites on a patient-by-patient basis through a web-based data auditing app. The resection and single-instillation intravesical chemotherapy for nonmuscle invasive bladder cancer treatment study data analysis group comprising statisticians based at the University of Aberdeen will have access to the final data set.

Ethical Considerations

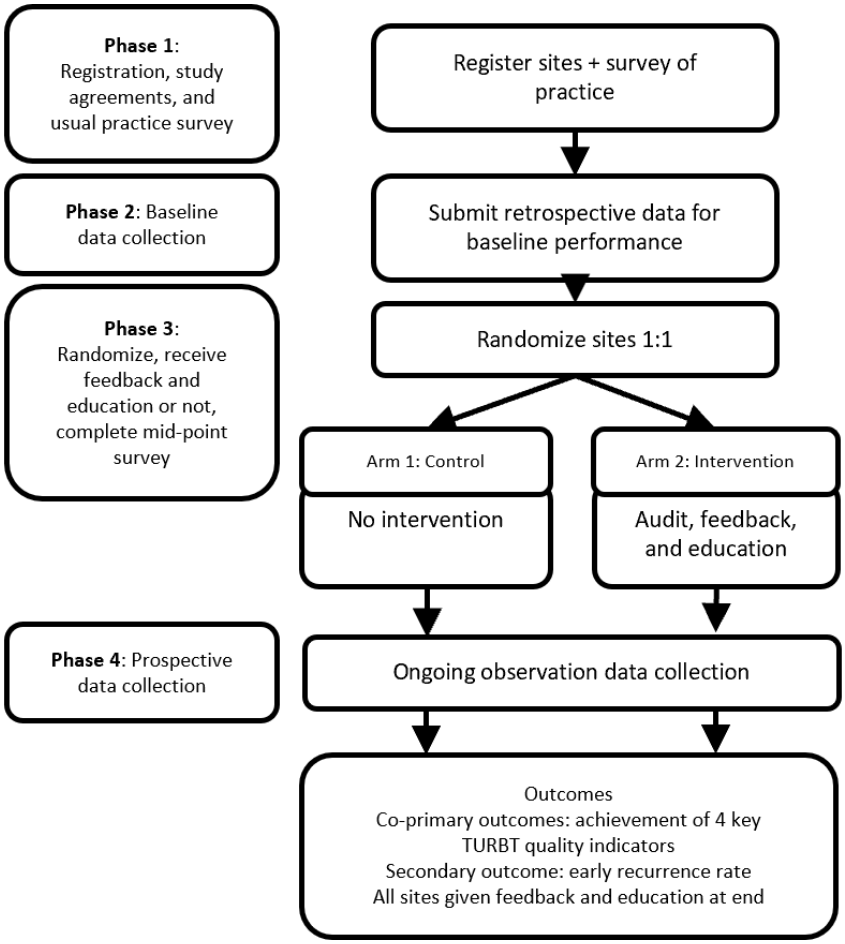
Local and national ethical and institutional approval or exemption will be obtained at each participating site. In the United Kingdom, the University of Aberdeen deemed this study exempt from research ethical approval in line with health research authority guidelines. There is no compensation to sites associated with this study. The study will be published in peer-reviewed journals and presented at national and international scientific congresses. Individual sites or surgeons will not be identified in study reports or performance feedback.

Inclusion and Exclusion Criteria

Site Inclusion and Exclusion Criteria

Sites anywhere in the world will be included if they perform TURBT for NMIBC and could include at least 20 consecutive eligible cases in a period of 12 months. Sites will be excluded if they fail to include 20 cases with a minimum required data set to determine baseline performance. Where a site requests removal from the study, data collected to date will be maintained for reporting purposes unless the site requests deletion.

TURBT Case Inclusion and Exclusion Criteria



Sites will include consecutive cases of first, curative intent, elective transurethral surgery for a new diagnosis of urothelial carcinoma, thought to be nonmuscle invasive at the time of surgery, across all surgeons at their site. Cases with known concurrent upper tract urothelial carcinoma will be excluded.

Study Design

The study will have four phases, which are summarized in Figure 2: (1) phase 1: site registration, study agreements, and usual practice surveys; (2) phase 2: retrospective baseline data collection; (3) phase 3: randomization to either arm of “no intervention,” or “audit, feedback, and education”; and (4) phase 4: prospective data collection.

XSL•FO
RenderX

Figure 2. Study phases and design. TURBT: transurethral resection of bladder tumor.

Site Registration, Study Agreements, Surgeon Registration, and Usual Practice Surveys

Sites will complete a survey about their location, hospital type, and their usual practice. An agreement will be signed by the site principal investigator including consent to randomization. Each surgeon performing TURBT at the site will be registered along with details about their surgical experience including their grade, number of TURBTs performed per month, and years of experience.

Baseline Data Collection

Sites will be asked to enter data about consecutive eligible TURBT cases performed at their site counting backward from the date of site registration. The rationale is to sample cases from before a site had awareness of the study to obtain a cohort free from the Hawthorne effect [27].

Randomization

Sites will be randomized 1:1 in parallel arms when the submission of the minimum required retrospective data is complete. Sites will be randomized to either (1) no intervention (the site continues to submit data on consecutive eligible cases but without performance feedback and education during the study). Once the study is complete, these sites will be provided with performance and education feedback or (2) audit, feedback, and education (performance feedback and education provided before beginning further prospective phase of study).

Sites will be randomized using the randomization app at the Centre for Healthcare Randomised Trials (CHaRT), University of Aberdeen, which developed the randomization sequence. This randomization app is available 24 hours a day, 7 days a week as a web-based app. Randomization will be minimized for site-level variables that are thought to significantly impact achievement of TURBT quality indicators. There is no blocking. These are baseline performance from the baseline audit, geographical region (continent, except that the United Kingdom is considered alone, Australia will be combined with mainland Europe), and the presence of an existing TURBT audit at that site before the study. In addition, a random component is used in the minimization algorithm to ensure concealment of the allocation.

The study administrator will access the web-based system. They will enter the minimization variables into the web-based system, which returns the allocation status. The chief investigator of the site will be informed of their allocation following randomization. There is no blinding. To prevent contamination following randomization, sites randomized to no intervention will not be granted access to the dedicated personalized feedback and education resources, which are username and password protected.

Data Management

Local data will be routinely collected health care data accessed by members of the clinical team. Nonidentifiable data will be manually entered into the secure, password-protected study

XSL•FO
RenderX

database (hosted at University College London) after appropriate local approvals have been obtained. Only the study management and statistical team will have access to the full data set.

Results

Audit, Feedback, and Education Design

The audit, feedback, and education intervention was designed using evidence-based theories about interventions that cause behavior change. These theories were both general [16,18,28-31] and specific to TURBT surgery based on our previous work [12,32].

The intervention is delivered at the site level with recommendations about how to engage with, disseminate, and use the feedback and education. There is no mandated change to clinician behavior or patient care, all patient treatment and professional practice decisions are at the discretion of the clinician. Sites can request to leave the study at any time, and all withdrawals will be reported. It will not be permitted for a site allocated to "no intervention" to receive the intervention during the study period.
