This study was reviewed and approved by the Johns Hopkins Bloomberg School of Health Institutional Review Board, Baltimore, United States (IRB No. 9177/MOD1879), the Human Development Research Foundation Ethics Committee, Islamabad, Pakistan (IRB/001/2017), the RMU Institutional Research Forum, Rawalpindi, Pakistan (IRB/RMU-20/12/20190), the National Bioethics Committee of Pakistan, Islamabad, Pakistan (IRB No.4-87/NBC-536/20/881), and the National Institute of Mental Health (NIMH)–appointed Global Mental Health Data Safety and Monitoring Board from the United States.

Consent Procedures

Following WHO guidelines [64], full study information is provided in Urdu before any study participant is asked to provide written informed consent. In cases of illiteracy, information is read aloud in the presence of a witness (not affiliated with HMHB), and oral consent is witnessed. These procedures as alternatives to written informed consent are routine and culturally acceptable in Pakistan.

Care and Referrals

Detailed ethical procedures have been established for the main trial. These procedures are the same for the extra 60 healthy (nonanxious) controls added for this substudy. Any woman showing severe depression or suicidality at any point during the study will be referred directly for psychiatric or psychological care. For non–life-threatening but high-symptom levels of anxiety or depression, the obstetrician or primary care provider will be alerted to undertake further assessment and to make appropriate referrals. Based on any report of intimate partner violence (IPV), during assessments, or reports of IPV in answer to a screener asked (at baseline and the third trimester) or on questions about emotional and physical violence taken from the Pakistan Demographic Health Surveys asked at 6 weeks post partum, women who report IPV will be referred to the Institute of Psychiatry, Rawalpindi Medical College, for social services.

Dissemination

The HMHB intervention is designed to reduce symptoms of anxiety during pregnancy, which has the potential to affect the development of common maternal postpartum perinatal mental disorders, including postnatal depression and anxiety, as well as intrauterine growth, as reflected in SGA, LBW, and PTB. The findings from this study will describe the biological mechanisms through which antenatal anxiety may be linked to future maternal psychiatric risk as well as how these biological markers may relate to birth and child development outcomes. The principal investigator and coinvestigators, both in the United States and the host country, will be given access to the cleaned data sets. The deidentified project data from the study will be posted on ClinicalTrials.gov and the NIMH data archive. The study results will be disseminated through peer-reviewed journals and conferences.

Results

Recruitment started on October 20, 2020, and data collection was completed on August 31, 2022. The start date for recruitment for this biological supplement study was delayed by approximately half a year due to the COVID-19 pandemic. The trial was registered at ClinicalTrials.gov (NCT03880032) on September 22, 2020. The last shipment of blood samples was shipped to the United States on September 24, 2022, where they will be processed for analysis. At the time of this submission on November 27, 2022, data had been collected but biological and data analysis had not yet begun.

Discussion

This study is an important addition to the HMHB randomized controlled trial of an intervention for antenatal anxiety. The intervention itself makes use of nonspecialist providers and, if effective, will represent an important new tool for the treatment of antenatal anxiety in LMICs. Our biological substudy is one of the first attempts to link biological mechanisms to antenatal

XSL•FO
RenderX

anxiety in an LMIC in the context of a psychosocial intervention, and our findings have the potential to significantly advance our knowledge of the biological pathways of perinatal mental illness and treatment efficacy.

Expected Principal Findings

We hypothesize that anxious women will exhibit increased innate immune activity in late pregnancy compared to healthy controls. We further hypothesize that pregnancy ALLO levels will be negatively correlated with anxiety and that low ALLO in early- and midpregnancy will predict increased immune activation in late pregnancy. Lastly, we hypothesize that adverse birth outcomes will be positively correlated with immune activation and negatively correlated with pregnancy ALLO and that the neurobehavioral functioning of babies born to women with anxiety will be correlated with biological indicators when compared to infants born to healthy controls.

Comparison to Prior Work

These hypotheses are centered on our previous work finding elevations of innate immune cytokines in women with anxiety during pregnancy and early postpartum and our work finding that low ALLO in pregnancy is associated with current and future symptoms of anxiety [1,2,65]. These prior studies were carried out in extremely different populations (both in a high-income country, one with largely low-income Black and Hispanic participants and the other with largely high-income White participants). Should we find alterations in immune and/or neurosteroid activity, we will advance the field's understanding of the biological mechanisms that may underlie perinatal mood and anxiety disorders and pave the way for future research into new methods of treatment to address these potential mechanisms.

Strengths and Limitations

Our study involves research teams on 3 continents and the training of a substantial number of nonspecialist providers. It is complex to begin with. Nevertheless, recruitment for both the main study and the supplement study has been steady. The biggest logistical challenge has been the COVID-19 pandemic (combined in Pakistan with waves of dengue fever). These public health crises delayed the start of the study due to the lockdown and have greatly reduced our ability to recruit during the rest of the study period. Pregnant women in Pakistan have been reluctant to come into the hospital even for standard prenatal care due to the pandemic, and there have been misconceptions and misinformation about the role of public hospitals in COVID-19 [66]. These logistical challenges have resulted in a scaling back of our study design. We had originally planned to recruit larger numbers (N=300) into this substudy, which would have allowed us to examine not only differences between anxious and healthy women but also whether those differences were mitigated by our psychosocial intervention. These latter questions will now await a follow-up study.

Future Directions

Our next step for this research is to analyze the biological samples collected. Future studies may include additional secondary biological analyses and the design of future studies involving other maternal and infant biological systems.

Trial Status

This article reports on the first version of our protocol; recruitment began in October 2020 and ended in January 2022; study visits ended on August 31, 2022.

Acknowledgments

The authors wish to acknowledge all participants involved in the study. They wish to thank members of the Osborne Lab at Johns Hopkins University for their assistance in coordinating sample shipments and study protocols. All work in this manuscript, including design, data collection, analysis, and interpretation, was supported by the NIMH at the US National Institutes of Health grant RO1 MH111859-01. LMO's time was additionally supported by NIH-NIMH K23 MH110607 and MLS' by NIH-NIAID T32 AI007417.

Data Availability

The HMHB intervention is designed to reduce symptoms of anxiety during pregnancy, which has the potential to affect the development of common maternal postpartum perinatal mental disorders, including postnatal depression and anxiety, as well as intrauterine growth, as reflected in SGA, LBW, and PTB. The findings from this study will describe the biological mechanisms through which antenatal anxiety may be linked to future maternal psychiatric risk as well as how these biological markers may relate to birth and child development outcomes. The principal investigator and coinvestigators, both in the United States and the host country, will be given access to the cleaned data sets. The deidentified project data from the study will be posted on ClinicalTrials.gov and the NIMH data archive. The study results will be disseminated through peer-reviewed journals and conferences.

Authors' Contributions

MLS drafted the original manuscript. PJS and LMO are the lead investigators on this project and edited the manuscript. All other authors are involved in the study team and edited the manuscript. All authors approved the final version of the manuscript.

Abstract

Background: Lung cancer is the leading cause of cancer-related death in the United States, with the majority of lung cancer occurrence diagnosed after the disease has already metastasized. Lung cancer screening (LCS) with low-dose computed tomography can diagnose early-stage disease, especially when eligible individuals participate in screening on a yearly basis. Unfortunately, annual adherence has emerged as a challenge for academic and community screening programs, endangering the individual and population health benefits of LCS. Reminder messages have effectively increased adherence rates in breast, colorectal, and cervical cancer screenings but have not been tested with LCS participants who experience unique barriers to screening associated with the stigma of smoking and social determinants of health.

Objective: This research aims to use a theory-informed, multiphase, and mixed methods approach with LCS experts and participants to develop a set of clear and engaging reminder messages to support LCS annual adherence.

Methods: In aim 1, survey data informed by the Cognitive-Social Health Information Processing model will be collected to assess how LCS participants process health information aimed at health protective behavior to develop content for reminder messages and pinpoint options for message targeting and tailoring. Aim 2 focuses on identifying themes for message imagery through a modified photovoice activity that asks participants to identify 3 images that represent LCS and then participate in an interview about the selection, likes, and dislikes of each photo. A pool of candidate messages for multiple delivery platforms will be developed in aim 3, using results from aim 1 for message content and aim 2 for imagery selection. The refinement of message content and imagery combinations will be completed through iterative feedback from LCS experts and participants.

Results: Data collection began in July 2022 and will be completed by May 2023. The final reminder message candidates are expected to be completed by June 2023.

Conclusions: This project proposes a novel approach to facilitate adherence to annual LCS through the development of reminder messages that embrace content and imagery representative of the target population directly in the design process. Developing effective strategies to increase LCS adherence is instrumental in achieving optimal LCS outcomes at individual and population health levels.

Introduction

Background

Lung cancer is the leading cause of cancer-related deaths in both men and women in the United States [1,2] and is expected to account for approximately 21% of all cancer deaths in 2022 [2]. Most lung cancer occurrences are diagnosed at advanced stages, after the cancer has metastasized, directly contributing to the deadliness of the disease [2]. Lung cancer screening (LCS) with low-dose computed tomography (LDCT) can detect lung cancer in the early stages when curative and less-invasive treatment options exist [3,4]. LCS received a B recommendation from the United States Preventive Services Task Force (USPSTF) in late 2013, prompting private insurance companies to cover the cost of the service for high-risk individuals, defined as individuals aged 55 to 80 years, with a minimum tobacco smoking exposure history of 30 pack-years and currently smoking or have quit within the past 15 years [5]. The Centers for Medicare and Medicaid Services (CMS) subsequently approved reimbursement for LCS in 2015 for Medicare beneficiaries, although they recommended stopping screening at 77 years of age [6]. Recently, the LCS eligibility criteria were expanded by lowering the recommended starting age to 50 years and tobacco exposure to 20 pack-years [7,8]. The USPSTF implemented these recommendations in 2021, followed by Medicare in early 2022.

The efficacy evidence for implementing LCS in routine clinical practice is based on the results of 2 large randomized trials: the National Lung Screening Trial [3] and the Dutch-Belgian Lung Cancer Screening Trial [4]. The results from these trials showed that LCS can reduce lung cancer–specific mortality by at least 20% when performed annually. Importantly, both trials diagnosed more early-stage cancers on follow-up rounds of screening than on the first baseline LDCT scan [3,9], highlighting the importance of sustained engagement with LCS programs. Adherence to multiple rounds of screening exceeded 90% in both clinical trials, further demonstrating the importance of annual screening to maximize the effectiveness of LCS [3,9]. Unfortunately, the translation of yearly LCS participation has emerged as one of the core threats to fully achieving the population health benefits of early lung cancer detection, with real-world annual adherence rates as low as 22% [10]. There is an urgent need for individual- and system-level interventions that focus on increasing the annual adherence rates.

The American College of Chest Physicians recommends that LCS programs develop strategies to maximize compliance with annual screening, including mechanisms to communicate with screening participants [11]. Community and academic LCS programs have reported using reminder letters to address adherence [12-14], and the Community Preventive Services Task Force (established by the United States Department of Health and Human Services in 1996) strongly recommends client reminders for breast cancer screening with mammography and colorectal cancer screening with fecal occult blood test [15]. Research supporting this recommendation found that any type of reminder (live telephone call, automated telephone call, letters, and postcards) increased adherence rates over no reminders, and targeted and tailored materials were superior to generic materials for continued screening participation [16,17].

Although research on established cancer screening modalities serves as a starting point for understanding interventions for reminder preferences, modes, and frequency, the needs and context of the LCS-eligible population must be considered during intervention development. For optimal impact, the unique elements of the LCS and the eligible community must be used to inform efforts to build and sustain engagement with the LCS process. At the center of this milieu is the stigma surrounding cigarette smoking and lung cancer, which is deeply embedded in all levels of society and presents as a barrier for some LCS-eligible candidates to participate in screening [18]. In addition, individuals eligible for LCS often face additional health care disparities, as cigarette smoking is linked to indicators of low socioeconomic status such as rural residence, individuals with Medicaid or being uninsured, and racial and ethnic minority groups [19]. Furthermore, health messages that contain pictures are processed more efficiently [20], highlighting another integral component of LCS communication. Understanding the informational needs and imagery considerations of the LCS-eligible population is crucial for messaging in reminder intervention development.

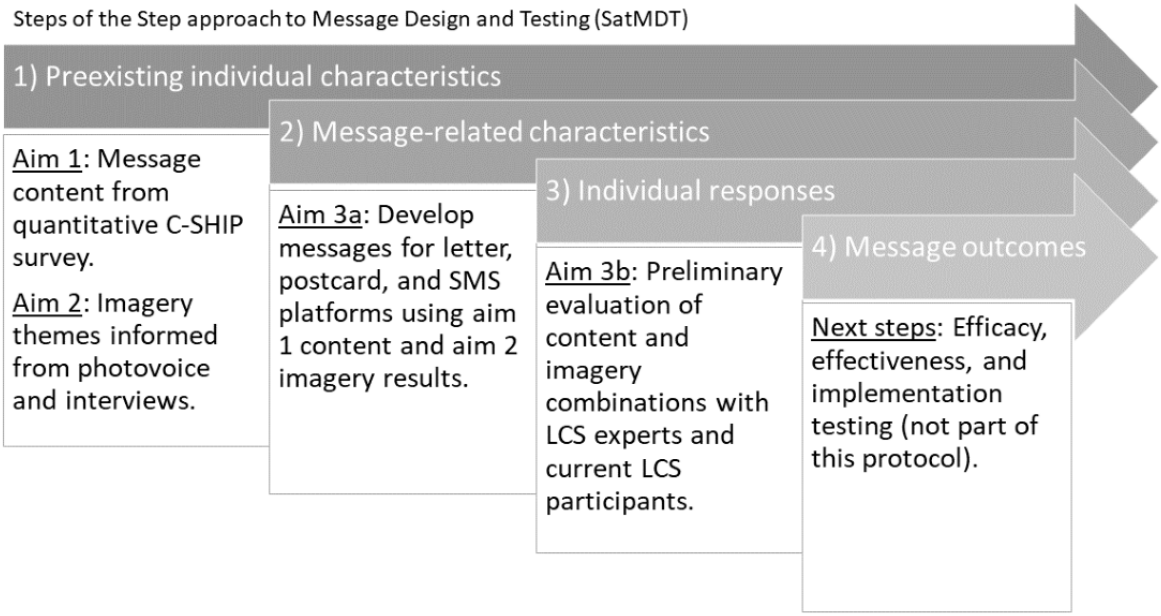
Objectives

This paper describes an iterative, mixed methods study that uses the principles of user-centered design and participatory research methods to develop a reminder message intervention specific to annual LCS. This research study will (1) determine how LCS participants process health information regarding screening to identify possible options for reminder message content targeting and tailoring, (2) pinpoint imagery options that engage LCS participants, and (3) use these data to develop adherence to reminder messages for individuals who participate in LCS. Accordingly, the aims of this study are as follows:

- Aim 1: to determine key reminder preferences and demographic and clinical characteristics associated with LCS-specific health processing, informed and facilitated by Cognitive-Social Health Information Processing (C-SHIP) model constructs to guide reminder message content and options for message targeting and tailoring.
- Aim 2: to identify engaging graphic themes drawn from photos selected by LCS participants to facilitate annual adherence aided by meaning and visual appeal.
- Aim 3: to develop and evaluate a pool of candidate reminder messages for multiple platforms (postcard, letter, and SMS text messaging) integrating visual imagery based on LCS experts and participant feedback using the principles of user-centered design.

XSL•FO
RenderX

Methods



Design Overview

The goal of this research is to use a theory-informed, multiphase, and mixed methods approach with LCS experts and participants to develop a set of clear and engaging reminder messages to support LCS annual adherence. In a 3-step process, survey data (step 1) and themes for imagery informed by LCS participant photovoice and key informant mixed method interviews (step 2) will inform the development of a pool of candidate reminder messages (step 3) for usability evaluation and testing with LCS experts and participants. This research will be guided by methodological, theoretical, and conceptual frameworks and principles to direct the steps needed to design and evaluate reminder message content, provide guidance to measure relevant constructs about how LCS participants process health information, and inform message context and imagery through engagement with LCS participants.

Methodologic Framework

This research study will be guided by the Step approach to Message Design and Testing (SatMDT), a four-step conceptual process—(1) preexisting individual characteristics, (2) message-related characteristics, (3) individual responses, and (4) message outcomes—that will guide the overall reminder message development, from content identification to outcome evaluation [21]. As shown in Figure 1, step 1 of the SatMDT corresponds to study aims 1 and 2, informing the selection of relevant message content identified from quantitative survey data and further guiding reminder message imagery selection through the photovoice and interview activity. Aim 3 operationalizes SatMDT steps 2 and 3 by first using content results from aim 1 and imagery results from aim 2 to develop 10 to 12 reminder messages with varying visual combinations for each reminder type (ie, letter, postcard, and SMS text messaging). Second, it conducts preliminary testing of the message content and imagery combinations with rapid, iterative feedback with LCS experts and participants. SatMDT step 4 is outside the scope of this study. However, future studies will evaluate the efficacy and effectiveness of reminder messages to improve LCS annual adherence rates in clinical trials and real-world settings and on implementation testing to measure the acceptability and feasibility of using the reminder system in busy clinical settings.

Figure 1. Study approach as guided by the Step approach to Message Design and Testing (SatMDT). C-SHIP: Cognitive-Social Health Information Processing Model; LCS: lung cancer screening.

Theoretical Framework

To find informative and appealing content for the reminder messages that can further be targeted and tailored to the intended recipients, the C-SHIP model [22] will be applied to identify, contextualize, and operationalize the content of the reminder messages for the aim 1 quantitative survey. The C-SHIP model draws from several theoretical frameworks within the fields of health, cognitive, clinical, social, and behavioral psychology to identify health information seeking and processing behaviors, with the main premise detailing that health decision-making processes are the result of an interaction between the individual and the environment [22]. Aim 1 survey data informed by C-SHIP will be collected to assess how LCS participants process health information aimed at health protective behavior to develop content for the reminder messages and pinpoint options for message targeting and tailoring.

Conceptual Framework and Guidance

Additional research methodology will be guided by user-centered design and participatory photovoice to identify relevant content and imagery through engagement with LCS-eligible individuals and assessing preliminary usability testing. User-centered design is an intervention design approach that encompasses information about the individuals that will be using the intervention in the development and testing processes [23]. The goal of user-centered design is to maximize the usability of the intervention among the population of interest

XSL•FO
RenderX

in a real-world context [23]. User-centered design will be used to (1) design the reminder intervention based on the characteristics of LCS participants and (2) refine message content and imagery based on rapid testing and feedback from LCS experts and participants. Consideration of the needs and emotions of LCS participants is vital for effective adherence reminder messaging.

Photovoice is a participatory research method that invites participants to take pictures representing an area of research within their community, allowing areas of concern to be documented and contemplated [24]. Traditional photovoice is completed by providing participants with a camera to capture the visual representation of the concern or research question and is then discussed through critical dialog in focus groups [25]. In this research project, photovoice will be used to invite participants to identify images that represent LCS to them and to identify themes for reminder message imagery through mixed methods interviews with the photovoice participants to understand the selection, likes, and dislikes of each photo.

Aim 1—Participant Health Information Processing Survey to Inform Message Content

Participants

The study participants will be recruited from three established LCS programs across the Colorado Front Range: (1) UCHealth University of Colorado Hospital in Aurora, Colorado; (2) UCHealth South in Colorado Springs, Colorado; and (3) UCHealth North in Fort Collins, Colorado. All LCS participants screened at these sites that meet the CMS or USPSTF eligibility guidelines, are English speaking, and have a screening-specific LDCT scan with results recommending 1-year (annual) follow-up (Lung-RADS 1 or 2) will be invited to complete the aim 1 health information processing survey 1 to 2 weeks after their LDCT. LCS participants who do not agree or consent to complete the survey or whose screening LDCT recommends shorter-term follow-up (Lung-RADS 3 or 4) will be excluded.

Procedure

Recruitment

All LCS participants that are screened in the 3 recruitment programs and have LDCT results recommending annual screening follow-up will be identified from clinical databases used to manage each program (Powerscribe Lung Cancer Screening developed by Nuance or Lung Cancer Screening Eon Patient Management developed by Eon Health). Additional variables, including Lung-RADS score, sex, race, ethnicity, smoking status, and pack-year information, will be abstracted from the clinical database to describe the study population and to report any differences between respondents and nonrespondents.

Survey Distribution

Potential study participants will be emailed a link for a REDCap (Research Electronic Data Capture; Vanderbilt University; electronic data capture hosted at University of Colorado Anschutz Medical Campus) web-based survey if an email is available in the electronic health record or a mailed paper version of the survey if only a postage address is available. The Tailored Design Method [26] will be used to maximize the response rate; specifically, enrolled participants will be contacted on multiple attempts if records indicate that the survey has not been completed, and respondents will receive US $40 compensation on the completion of the survey. Potential participants who received the survey by email will be contacted up to 4 times, 3 times by email and once by postal mail. This strategy has been reported to help increase survey response rates for individuals who do not respond to web-based surveys. Potential study participants who receive the survey by postal mail will be contacted up to 3 times.

Interested participants will be asked to acknowledge the contents of the informational consent form before proceeding with the survey. By completing the survey, respondents will agree to participate in the research study.

Sample Size

Using a 2-sample proportion test and assuming a minimum sample size of 125 survey respondents, there will be 80% power to detect a minimum difference of 20% for a χ^2 test with 1 *df* or 28% for a χ^2 test with 2 *df* between C-SHIP constructs (dependent) and survey respondent characteristics (independent) at an α level of .05. Power calculations were performed using PASS 11 (NCSS, LLC) [27]. A minimum of 125 complete surveys will be an achievable goal because the Tailored Design Method [26] will be used to optimize the response rate by offering multiple modes of survey delivery, making multiple contact attempts to nonrespondents, and offering US $40 compensation on the completion of the survey.

Measures

Relevant constructs from each C-SHIP domain have been chosen as a foundation for survey questions based on an extensive LCS literature review and identification of how C-SHIP has been applied to breast, cervical, and prostate cancer research [22,28,29]. Multimedia Appendix 1 [30-43] shows each LCS construct relevant to each C-SHIP domain and the scale or measure that will be used to measure each construct. Standardized scales were chosen wherever possible during the development of the aim 1 quantitative survey (LCS Health Beliefs Scale [30], Health Information National Trends Survey [31], Health Perceptions Questionnaire [32], Self-Regulatory Questionnaire for LCS [33], LCS Knowledge Survey [34], Cataldo Lung Cancer Stigma Scale [35], Revised Powe Fatalism Inventory [36], Health Behavior Scale for Cancer Patients [37], Medical Minimizer Maximizer Scale 1 [38], BRIEF Health Literacy Scale [39], Subjective Numeracy Scale [40], 9-item Shared Decision-Making Questionnaire [41], and radiology results from Woolen et al [42]).

The survey instrument contains all close-ended questions and comprises eight sections: (1) health-relevant encodings, (2) health beliefs and expectancies, (3) affects (emotions), (4) health goals and beliefs, (5) self-regulatory competencies, (6) previous screening LDCT and shared decision-making experience (satisfaction and stigma), (7) reminder preferences (timing, modality, and frequency), and (8) demographic and clinical information. The principles of the Tailored Design Method [26] (using simple words, complete sentences, as few words as

XSL•FO
RenderX

possible, logical question organization, and easily understood concepts) were used to develop the survey to reduce common survey biases. The survey takes approximately 30 minutes to complete.

Analysis

All data from the aim 1 survey will be quantitative, mainly using Likert-type scales. Survey responses that occur more frequently will be prime candidates for reminder message content. Differences in C-SHIP constructs between demographic and clinical characteristics will guide reminder message content, with any statistically significant differences becoming a focus for message targeting and tailoring. To test for differences between C-SHIP constructs and respondent characteristics, the normal distribution of all variables will be evaluated with quantile-quantile plots. Variables with a normal distribution will be treated as continuous, whereas nonnormally distributed data will be categorized or analyzed using nonparametric tests. Univariate differences between the constructs and characteristics will be assessed with a 2-tailed *t* test or ANOVA for continuous variables (or nonparametric tests using ranks) and the chi-square test for categorical variables. The quantitative data collected in aim 1 will directly inform and influence the development of the reminder message content in aim 3.

Aim 2—Participant Photovoice and Interviews to Inform Themes for Message Imagery

Participants

Participants for aim 2 will be recruited from the same LCS programs used for the aim 1 survey. This sampling of participants will be recruited both independently and as a continuation of the aim 1 sample. As the purpose of aim 2 (to inform the imagery that will be selected for reminder messages) is separate from that of aim 1, no bias is expected from involving the same participants for both aims 1 and 2. Participants who completed an LCS LDCT within the past 12 months with results of Lung-RADS 1 or 2 with recommended 1-year (annual) follow-up and are English speaking will be eligible for aim 2. Sampling will be purposive, with emphasis placed on accruing heterogeneous participants (eg, males and females, race and ethnicity, and individuals that currently and formerly smoked cigarettes) for the photovoice activity and subsequent interviews. Participants who do not agree or consent to the photovoice activity and interview or whose screening LDCT recommends shorter-term follow-up (Lung-RADS 3 or 4) will be excluded from aim 2.

Procedure

Recruitment

The recruitment strategies will be similar to those of aim 1. Participants eligible for aim 2 will have completed an LCS LDCT that recommends 1-year (annual) follow-up within the past 12 months. Potential participants who represent a wide range of demographics and demographic characteristics (purposive sampling) will be sent an informational letter about aim 2 with directions to return the response card in the postage paid addressed envelope if only a postal address is available in the electronic health record or respond to the email to receive more information about participation.

The research team will follow-up with interested individuals using the contact information provided on the response card or email with additional information about participation in aim 2. Owing to the ongoing COVID-19 pandemic, enrollment will be limited to individuals who have access to computers with internet and video and audio capabilities. Participants will be asked to agree to an information sheet and consent electronically in REDCap to participate in aim 2.

Participant Photovoice Procedures

After obtaining informed consent, aim 2 participants will be asked to find 3 photos that represent LCS to them and to upload them into a REDCap database to later be used for the interview portion. This approach will use a modified photovoice component for participants to visually capture their idea of LCS by taking photos or finding photos using Google Images. Photovoice is a visual research methodology that traditionally supplies participants with a camera to take a picture that captures the essence of a cultural phenomenon or problem [24]. Photovoice is meant to facilitate community engagement in research and invoke a *voice* for self-perception in a research problem [24]. Using photovoice for LCS adherence will help pinpoint visual imagery that is attractive to a population traditionally stigmatized at individual and societal levels. The photovoice activity instructions will provide prompts about participating in LCS to help them think thoughtfully when choosing photos (Multimedia Appendix 1 [30-43]).

Interview Guide, Procedures, and Measures

Photovoice interviews will be conducted via Zoom and will be guided by a semistructured interview guide and use both open- and close-ended questions. Close-ended questions will yield quantitative data, and the open-ended questions will provide qualitative data. Participants will be shown the images they chose for the photovoice component one at a time on Zoom and asked questions about why they chose the image, what the image means to them, and likes and dislikes about the image. The interview questions were modified from the SHOWeD technique, which is commonly used in photovoice studies to help participants discuss the photos they captured [43] (Multimedia Appendix 1 [30-43]). Interview participants will also be asked to rate the image on a scale of 0 to 10, where 0 is "I don't like this photo" and 10 is "I really like this photo." At the end of the interviews, participants will be shown images commonly used in current LCS communications (cigarettes, lungs, and smoke) and will be asked about their thoughts, likes, dislikes, and ratings of each image on a scale of 0 to 10 (Multimedia Appendix 1 [30-43]). Probing questions will be used when appropriate. Interviews will be audio recorded and transcribed verbatim. Interview participants will receive US $60 as compensation on the completion of the interview.

Sample Size

The participants photovoice aim involves conducting approximately 20 debriefing interviews to reach saturation for photo visual appeal and thematic content. Interviews will be stopped early if saturation is reached before 20 interviews or

XSL•FO
RenderX

will continue beyond 20 if the research team concurs that saturation has not been reached.

Analysis

Aim 2 interviews will use qualitative and quantitative data collected in parallel from the same interview guide, as described earlier. Following a parallel convergent mixed methods design [44], quantitative and qualitative data will be analyzed separately and then merged to make final conclusions about themes for reminder message imagery. Quantitative data from the closed-ended rating questions will be recorded in a matrix in Microsoft Excel (Microsoft Corporation), and similar responses will be categorized and ranked in order of frequency. Qualitative data from open-ended questions will be analyzed using thematic analysis [45]. Coding will be completed by 2 coders for the first 5 interviews to establish intrareader reliability, calculated using Pearson correlation or κ statistics. Coding will be inductive, meaning that the research team will use codes that emerge from the data. Standardized codes from the first 5 interviews will also be used to inform the development of a codebook that will be used to code the remaining interviews. The study team will meet weekly during the coding process to review and categorize themes and to determine when saturation has been reached. Finally, the team will integrate the results from the qualitative and quantitative data to make rich, multiangled inferences for the determination of the final imagery themes. The integration of the 2 data types will be done using a matrix analysis, in which the quantitative imagery ratings are compared with the qualitative themes. It is expected that the data types will corroborate, with higher-rated imagery containing positive and encouraging themes and lower-rated imagery associated with themes about lower-rated pictures. The matrix design will also offer the opportunity for qualitative data to explain the quantitative ratings and highlight the specific aspects the participants did or did not like regarding high- or low-rated imagery.

Aim 3—Development and Preliminary Evaluation of Reminder Messages

The purpose of aim 3 is 2-fold: first, to develop a group of reminder message candidates for 3 platforms (ie, letter, postcard, and SMS text messaging) with differing content and imagery combinations, and second, to conduct preliminary usability testing of the messages with LCS experts and participants. Evaluative testing will consist of rapid, iterative feedback cycles, with the refinement of messages occurring after each cycle of 3 experts or participants.

Development of Reminder Message Candidates

Reminder messages and content will be developed by the principal investigator (EAH), with final message candidates reviewed and finalized by the full research team. Messages will likely focus on conveying the benefit ("gain-framed") of annual LCS adherence [46]. Gain-framed messages have been shown to lead to greater knowledge and message recall [47]. Options for reminder message visual imagery based on themes from aim 2 will be chosen to accompany the message text. Messages that include a combination of verbal and visual cues are processed more efficiently than those with text alone [20]. Message content will be guided by messages that have led to increased adherence to repeat mammography [48,49] and messages developed for LCS awareness campaigns [50]. Overall, 10 to 12 reminder messages with differing visual appeals for each reminder type (postcards, letters, and SMS text messages) will be developed to achieve engagement for LCS-eligible individuals. Differences between health information processing constructs by demographic or clinical characteristics found to be statistically significant from aim 1 will be the focus of message targeting and tailoring.

Preliminary Testing by LCS Experts

Expert review of the reminder message candidate combinations (content and imagery) will be completed by LCS experts to gauge the message content from a clinical and implementation perspective.

LCS Expert Study Participants

Experts will be prespecified by the research team before the survey invitation and will include pulmonologists, radiologists, primary care clinicians, advanced practice providers, medical oncologists, and implementation scientists with expertise in LCS. Experts who agree to complete the evaluative survey will be included in aim 3. LCS experts who do not agree to participate in the rating process will be excluded.

LCS experts will be selected a priori based on the knowledge and contacts of the research team. Experts will be contacted via email to introduce the study and ask about their willingness to participate. Every effort will be made to have a balanced panel of experts (ie, pulmonologists, radiologists, advanced practice coordinators, primary care providers, medical oncologists, and implementation specialists). Informed consent will be obtained electronically using REDCap.

LCS Expert Survey Distribution and Follow-up Procedure

Expert surveys will be closed-ended and administered on the REDCap electronic platform. Respondents will be presented with a mock-up of each message-type and a brief clinical vignette with targeting and tailoring characteristics (if applicable) and asked to rate each message on 6 categories adapted from the Centers for Disease Control and Prevention (CDC) Health Communication Playbook [51] and the National Institutes of Health (NIH) Health Literacy Online [52] guidelines. Message ratings will use a 7-point Likert scale, where 1 is "very poor" and 7 is "very good," to rate the following categories specific to LCS annual adherence: (1) relevance of the message content, (2) readability of the message content, (3) accuracy of the message content, (4) intent of the message content (conveying screening benefit), (5) memorability of the visual appeal, and (6) overall rating of the message content and visual imagery combination (Multimedia Appendix 1 [30-43]). Experts will be asked to evaluate each message candidate, 10 to 12 for each message-type platform (letter, postcard, and SMS text messaging), or 30 to 36 messages in total.

XSL•FO
RenderX

LCS Expert Sample Size

Rapid, iterative feedback and refinement of messages will be completed in cycles comprised of 3 experts. It is expected that usability testing will consist of 3 to 4 iterative cycles, with a total of 9 to 12 LCS experts.

LCS Expert Analysis Plan and Message Refinement

Data from the expert survey will be quantitative. Responses will be entered into a matrix in Microsoft Excel, and similar responses will be categorized and ranked in the order of frequency. Messages with lower ratings will be revised accordingly. Message candidates will be refined based on the feedback of each feedback cycle.

Preliminary Evaluation by LCS-Eligible Participants

In addition to expert review, further evaluative testing of the reminder messages will be performed with LCS participants who are close to their annual screening to determine the usefulness, desirability, and value of the reminder message content and imagery combinations.

LCS-Eligible Study Participants

Message evaluation participants will be recruited solely from the UCHealth University of Colorado Hospital LCS program, with emphasis on participants who are close to their annual screening LDCT (Lung-RADS result of 1 or 2). This sampling of participants will be separate from the aims 1 and 2 samples. The focus for this aim will be on participants within 4 to 6 weeks of their recommended annual screening LDCT. Participants will be eligible for annual screening by CMS or USPSTF guidelines, English speaking, and due for their annual LDCT scan within 4 to 6 weeks. Participants who do not agree or consent to participate in the reminder evaluation interviews or are not eligible for annual screening (aged out of screening age, >15 years since quitting smoking, or competing comorbidities) will be excluded from this study.

LCS-Eligible Participant Recruitment

Participants eligible for aim 3 will be due for their annual screening within 4-6 weeks. These participants will be identified in the database that is used to clinically manage the screening program at the University of Colorado Hospital. Recruitment strategies and informed consent procedures will mirror those used for aim 2.

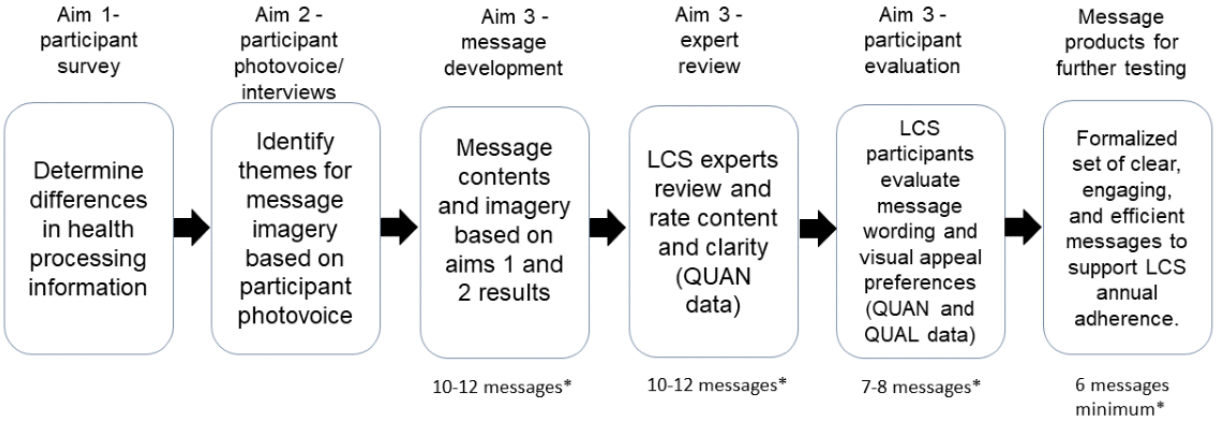
LCS-Eligible Participant Interview Guide and Procedures

Evaluation interviews will be conducted on the Zoom platform, with participants shown each reminder message content and imagery combination during the interview. The interview guide will include both open- and closed-ended questions and is based on prior research work in adherence for mental health appointments [53]. A total of 3 questions will focus on the understanding of the message content, 3 questions will ask about the message appeal (likes and dislikes), and 1 question will ask about how wording or content could be improved (Multimedia Appendix 1 [30-43]). Interview procedures and participant compensation will be parallel to those used in the aim 2 photovoice interviews. Participants will be asked to evaluate approximately 20 to 25 message candidates, 7 to 8 for each message-type platform (letter, postcard, and SMS text messaging). The interviews are expected to last approximately 60 minutes, and participants will receive US $60 as compensation on the completion of the interview.

LCS-Eligible Participant Sample Size

Rapid, iterative feedback and refinement of messages will be completed in cycles comprised of 3 participants. It is expected that usability testing will consist of 3 to 4 iterative cycles, with a total of 9 to 12 LCS participants.

LCS-Eligible Participant Evaluation Analysis Plan



The participant evaluation will use qualitative and quantitative data collected from the same survey instrument and will therefore be completed using the same procedures as in the aim 2 analysis. Quantitative and qualitative data will be analyzed separately and then merged to make final inferences and recommendations for further reminder message refinement. It is expected that the data types will corroborate one another, with higher-rated messages and visuals containing positive and encouraging themes and lower-rated messages associated with themes about confusion or misunderstanding of the message. The matrix design will also offer the opportunity for the qualitative data to explain the quantitative ratings and highlight the specific aspects the participants did or did not like about high- or low-rated messages.

Refinement and Determination of Final Reminder Messages for Further Testing

The determination of the final reminder messages for each reminder type and matched visual picture will be driven by 3 main criteria: understanding, appeal rating, and anticipated impact. Difficulties in understanding the core message or with specific words will be used to refine the wording. Final message determination will consider results from both the usability expert survey and participant interviews by comparing the concordance or discordance between overall message ratings. Study team consensus will determine the final message set. The entire message development process is illustrated in Figure 2. The study team expects to have a minimum of 6 messages per communication type ready for robust testing in busy clinical settings.

XSL•FO
RenderX

Figure 2. Summary of the message development process. *Per message-type (letter, postcard, and SMS text messaging). LCS: lung cancer screening; QUAL: qualitative data; QUAN: quantitative data.

Ethics Approval, Informed Consent, and Participation

This study was approved by the Colorado Multiple Institutional Review Board (COMIRB #21-3881) with full waivers of informed consent and Health Insurance Portability and Accountability Act of 1996 authorization to use LCS clinical databases and electronic health records to identify potential participants. In addition, a waiver of written documents for informed consent was obtained to allow for the ease of the consent process in REDCap. Participants in all aims will agree to the contents of an informational consent form containing details about the study purpose, procedures, confidentiality, and use of data before the initiation of any study procedures.

Results

The estimated milestones for study completion include (1) six months for setup (institutional review board approval, initiating procedures at accrual sites, updating the literature review for survey and interview guide development), which was completed in July 2022; (2) nine months for aim 1 survey recruitment, data collection, and analysis (expected completion: March 2023); (3) four months for aim 2 recruitment, data collection, and analysis (expected completion: March 2023); and (4) three months for aim 3 development of reminder message content and imagery combinations, recruitment, data collection, analysis, and refinement of final message candidates (expected completion: June 2023).

Discussion

Expected Outcomes

This project proposes a novel approach to facilitate adherence to annual LCS through the development of reminder messages that embrace content and imagery representative of the target population directly in the design process. Developing effective strategies to increase LCS adherence is instrumental in achieving optimal LCS outcomes at individual and population health levels. Engaging participants in yearly screening will ultimately increase the number of early-stage lung cancers detected, leading to improved outcomes and quality of life. Interventions aimed at addressing this critical need must be designed with the unique LCS population and context in mind and eliminate stigmatizing and biased content and imagery.

This research will develop message content based on health information processing theory conceptualized with the C-SHIP model, which recognizes health protective behavior decisions are the result of an interaction between the individual and their environment [22]. C-SHIP provides a broad framework to describe the characteristics of LCS-eligible individuals and constructs that may influence decisions to adhere to annual screening and to explore options for message targeting and tailoring. This project also aims to pinpoint imagery that is visually appealing and engaging in the LCS-eligible population. Imagery is often considered a significant component of health messaging and is even more important for individuals with low health literacy [54]. Specific to LCS, previous qualitative research in individuals at high risk for lung cancer found that images with cigarettes and lungs are ineffective in informational campaigns [55], highlighting the importance of identifying appropriate imagery for LCS communication. Finally, the resulting reminder messages will be iteratively tested with both LCS experts and participants to refine the message accuracy, understandability, and value of the content and imagery combinations.

Limitations

Although this approach will leverage the strengths of participatory research and user-centered design methods, there are limitations that must be acknowledged using the available settings and resources. First, we will not be able to assess social cognitive theory for all LCS populations that experience health disparities and could benefit from message targeting and tailoring (eg, lesbian, gay, bisexual, transgender, queer or questioning persons or those with mental and substance disorders). Second, Colorado's population lags the US population with regard to African American representation but exceeds the national average of individuals with Hispanic ancestry [56]. These demographic differences may compromise the generalizability of the initial development and testing of the message combinations. Finally, the efficacy and generalizability of these messages to clinical and health care settings are unknown. Despite these limitations, the design choices are appropriate to stimulate collaborative development of interventions directed specifically at improving LCS annual

XSL•FO
RenderX

adherence and to highlight important areas of the future to strengthen the healthy equity reach and future efficacy, effectiveness, and implementation of the intervention.

Acknowledgments

This work is supported by a National Cancer Institute F99/K00 Predoctoral to Postdoctoral Fellow Transition Award (F99CA264409, principal investigator: EAH; Multimedia Appendix 2). This research was supported by National Institutes of Health (NIH) and National Center for Advancing Translational Sciences Colorado Clinical and Translational Science Awards grant UL1 TR002535.

Conflicts of Interest

JLS has provided consultation with the J&J Lung Cancer Initiative and the Lung Ambition Alliance and serves as the Scientific Advisory Committee for the Go2 Foundation for Lung Cancer and the Steering Committee for the National Lung Cancer Roundtable, which is currently funded by the National Cancer Institute (R01254734), the Bristol-Myers Squibb Foundation, Golfers Against Cancer, and the American Cancer Society. EAH reports grants from the National Institutes of Health (NIH) and National Cancer Institute (F99CA264409) and nonfinancial support from the NIH and National Center for Advancing Translational Sciences (UL1 TR002535).

Abstract

Background: Communication is a critical component of the patient-provider relationship; however, limited research exists on the role of nonverbal communication. Virtual human training is an informatics-based educational strategy that offers various benefits in communication skill training directed at providers. Recent informatics-based interventions aimed at improving communication have mainly focused on verbal communication, yet research is needed to better understand how virtual humans can improve verbal and nonverbal communication and further elucidate the patient-provider dyad.

Objective: The purpose of this study is to enhance a conceptual model that incorporates technology to examine verbal and nonverbal components of communication and develop a nonverbal assessment that will be included in the virtual simulation for further testing.

Methods: This study will consist of a multistage mixed methods design, including convergent and exploratory sequential components. A convergent mixed methods study will be conducted to examine the mediating effects of nonverbal communication. Quantitative (eg, MPathic game scores, Kinect nonverbal data, objective structured clinical examination communication score, and Roter Interaction Analysis System and Facial Action Coding System coding of video) and qualitative data (eg, video recordings of MPathic–virtual reality [VR] interventions and student reflections) will be collected simultaneously. Data will be merged to determine the most crucial components of nonverbal behavior in human-computer interaction. An exploratory sequential design will proceed, consisting of a grounded theory qualitative phase. Using theoretical, purposeful sampling, interviews will be conducted with oncology providers probing intentional nonverbal behaviors. The qualitative findings will aid the development of a nonverbal communication model that will be included in a virtual human. The subsequent quantitative strand will incorporate and validate a new automated nonverbal communication behavior assessment into the virtual human simulation, MPathic-VR, by assessing interrater reliability, code interactions, and dyadic data analysis by comparing Kinect responses (system recorded) to manually scored records for specific nonverbal behaviors. Data will be integrated using building integration to develop the automated nonverbal communication behavior assessment and conduct a quality check of these nonverbal features.

Results: Secondary data from the MPathic-VR randomized controlled trial data set (210 medical students and 840 video recordings of interactions) were analyzed in the first part of this study. Results showed differential experiences by performance

XSL•FO
RenderX

in the intervention group. Following the analysis of the convergent design, participants consisting of medical providers (n=30) will be recruited for the qualitative phase of the subsequent exploratory sequential design. We plan to complete data collection by July 2023 to analyze and integrate these findings.

Conclusions: The results from this study contribute to the improvement of patient-provider communication, both verbal and nonverbal, including the dissemination of health information and health outcomes for patients. Further, this research aims to transfer to various topical areas, including medication safety, informed consent processes, patient instructions, and treatment adherence between patients and providers.

Introduction

Overview

The most important component of the patient-provider encounter is communication [1,2]. This finding has been reinforced by the National Cancer Institute model of patient-centered communication [3]. A recent meta-analysis of randomized controlled trials found a statistically significant effect (Cohen *d*=0.11; *P*=.02) on patient outcomes [4], consistent with other systematic reviews [5,6]. Poor patient-provider communication represents a pressing public health issue associated with increased medical errors and malpractice [1,7-11]. Communication has been shown to be a driver of patient satisfaction and outcomes and is closely connected with patient-centered care [9,10,12]. Collectively, these reports stress the public health importance of health communication and the need for interventions to improve providers' health communication.

Research on verbal health communication has led to important insights into information dissemination in the patient-provider encounter. However, less is known about nonverbal communication despite its equal importance [4]. Mehrabian and Ferris [13] reported that only 7% of emotional communication is conveyed verbally, 38% is conveyed by voice tone and inflections, and 55% is transferred by facial expressions [1,14,15]. Health issues, such as cancer, evoke fear, anxiety, and uncertainty. Patients are keen on subtle cues communicated both verbally and nonverbally [16]. For example, increased direct clinician body orientation is associated with increased patient satisfaction and understanding [17]. Inconsistency between verbal and nonverbal communication is detrimental to patient-centeredness because patients likely perceive these inconsistencies as disingenuous [1]. Henry et al's [18] systematic review of nonverbal communication found an association between nonverbal communication (global affect, warmth, negativity, listening, etc) and patient satisfaction. Connection to patient outcomes was less clear but also less researched, potentially due to the lack of a systematic assessment of nonverbal behavior. The authors called for developing consistent and validated measures of nonverbal communication and urged that "studies of facial expression might analyze patients' and clinicians' expressions at the dyadic rather than the individual level" with dyadic data analysis [18]. Thus, better assessment of nonverbal communication and application of appropriate dyadic statistics are needed.

Communication interventions directed at providers tend to provide communication skills training in a variety of formats, such as courses, workshops, or training videos [6]. One promising informatics-based educational strategy is virtual human training. Technology-based avatars and virtual humans have been developed to address cognitive tasks [19], such as verbal communication [20,21] and reasoning for diagnosis and therapy [22]. However, this body of literature is relatively nascent, particularly related to health communication. Research on virtual humans to enhance health communication has the potential to train medical students and nurses [23,24], as virtual humans offer a unique advantage by providing an authentic, safe simulated environment to learn with the appropriate level of challenge [25]. Users perceive virtual human interactions as real [26], and learners feel a social presence that can enhance learning and engagement [25,27,28]. After receiving feedback, the professional can immediately practice and implement the feedback, which is crucial to developing communication skills [29]. In contrast to human-standardized patients, virtual humans offer needed training without becoming fatigued. As a result, interactive and engaged virtual human informatics–based interventions demonstrate promise in enhancing communication.

Improving communication skills requires a reliable and valid method to assess them. Many communication assessments focus on verbal communication. These methods involve coding recorded interactions, such as the evidence-based Roter Interaction Analysis System (RIAS) [30], which has 41 categories, including a global affect rating (eg, voice tone) and the use of standardized patients instructors (SPIs) in simulated interactions [31] to evaluate performance. A nonverbal assessment is the Facial Action Coding System (FACS), which delineates observable components of facial movement into action units [32,33]. However, these are typically used for summative assessment of interventions or competence. Virtual human and informatics simulations have the potential to use assessment formatively by assessing behavior, providing automated feedback to the user, and giving further opportunities to practice. Educators often distinguish "assessment for learning" (ie, formative) with "assessment of learning" (ie, summative) because strategic use of formative assessment provides a more tailored, engaging experience with better outcomes [34,35]. Unfortunately, with few exceptions

XSL•FO
RenderX

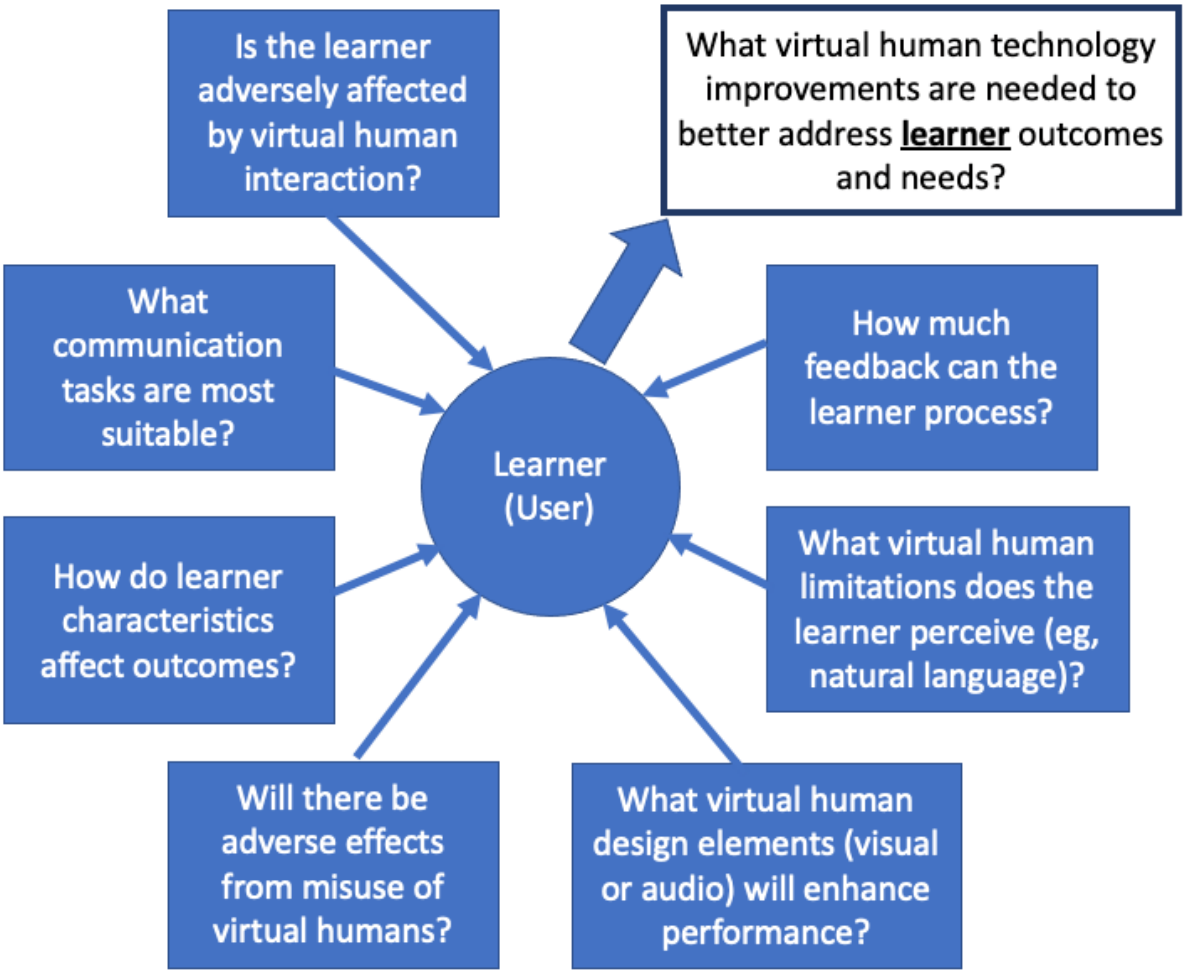
[23,36,37], interventions tend to rely on verbal assessment and standardized patients as a summative assessment only, rather than feeding results into the intervention as a formative assessment.

Standardized patients are widely used but are also costly, fatigue-prone, and have reliability concerns. SPIs have been used in objective structured clinical examinations (OSCEs) to assess verbal and nonverbal communication and provide feedback to learners. SPIs and OSCEs are a gold standard in communication assessment and are used in many interventions, including the MPathic–virtual reality [VR] trial, to assess primary outcomes. Yet, the cost of developing the scenarios, finding and hiring SPIs to conduct 1 OSCE, training to reach interrater reliability, and ongoing maintenance training is high. Published costs were estimated at US $35 per student in the United States in 1994 [38] and more recently in 2011 at US $90 per student in a European study [39]. The personnel time required for 1 OSCE has been reported as 104 hours for supervision, monitoring, logistics, and evaluation [39]. Finally, SPIs are prone to fatigue and excessive mental workload, which limits their ability to correctly identify and report on critical conversational and behavioral cues [40]. Therefore, SPIs are costly and best suited for summative assessment.

These informatics-based interventions to improve communication have primarily focused on verbal aspects. A recent innovation is an automated nonverbal feedback and detection system based on teleconferencing with an SPI, as reported by researchers in an Australian medical school [37]. The researchers demonstrated the utility of automated feedback on nonverbal behavior. In a randomized crossover trial, they found the system useful for enhancing medical communication and a statistically significant improvement over the standard curriculum component based on assessments by an SPI. Mpathic-VR, a virtual human simulation, has also assessed nonverbal communication by providing instructions to the user and by collecting sensor data (unanalyzed to date and a focus of this study) on nonverbal behaviors demonstrated. It also included an assessment of nonverbal behavior as 1 of 4 domains in a follow-up OSCE about 1 week post intervention, which indicates training transfer. It is important to note that communication may vary across in-person and telehealth visits. For example, clinicians tend to display more dominant behaviors, fewer empathy utterances, and portray an increased sense of urgency in telehealth visits [41].

One area that remains unclear is how nonverbal behavior is a mediating factor in communication competence, the accuracy of this nonverbal assessment, and whether the assessment is patient-centered. As a mediating factor, a potential path is that the system provides instruction on nonverbal communication (ie, stimulus), which prompts the learners to follow those instructions, leading to improved nonverbal communication as assessed by the Mpathic-VR and the follow-up OSCE. A path model is needed to test these assumptions, beginning with the extent to which the learner followed instructions. Although the data exist in this data set to test that path model, it has not yet been investigated. Understanding the mediating influence of nonverbal communication is essential to fully integrate nonverbal aspects into virtual human technology.

Conceptual Frameworks



This study is guided by several conceptual frameworks, including frameworks for analysis of human factors and virtual human intervention.

Conceptual Framework for Analysis of Human Factors

Two models help guide the analysis of the human-computer interaction with the virtual human and the understanding of the mediation of nonverbal behavior. Stanney et al's [42] human factors in virtual environments (Figure 1) provide a model for systematic informatics research to harness the potential of virtual environments [42]. Second, the Activity Theory–based Model of Serious Games posits 3 interrelated activities contribute—instructional (what MPathic intrinsically teaches), learning (communication outcomes), and gaming (interacting with MPathic) [43]. This model is a framework for analyzing the relationship between the virtual human and educational goals. Teaching communication principles is not enough, and MPathic incorporates audit and feedback principles to reinforce lessons and promote sustained change [44]. A major outcome of this study is to better understand computer-human interaction to ensure a realistic experience that drives behavior change.

XSL•FO
RenderX

Figure 1. Human factors in virtual human environment. Adapted from Stanney et al [42].

Conceptual Framework for the Virtual Human Intervention

Previous work has developed broad models of patient-centered communication (Figure 2) that guide the virtual human's instructional tasks. The National Cancer Institute's model of Patient-Centered Communication in Cancer Care [3] posits that patient-centered care and clinicians skilled in communication lead to improved health communication, which leads to improved health outcomes. Effective communication requires that patients and clinicians have "knowledge, understanding, and self-awareness of what is required to communicate effectively" and the skills to do so. In the Patient-Centered Communication model and consistent with educational theory [45], motivation of all parties is necessary to enhance communication skills. Additionally, health outcomes improve with attention to 6 core communication functions: (1) responding to emotions, (2) exchanging information, (3) making decisions, (4) fostering healing relationships, (5) enabling patient self-management, and (6) managing uncertainty. Nonverbal behavior can be mapped onto these core functions. An intervention that targets these core functions—both verbal and nonverbal aspects—to develop skills and attend to motivation through an engaging learning experience may overcome the limitations of these training models.

XSL•FO

Figure 2. Conceptual model of core functions of patient-clinician communication. Adapted from Epstein and Street [3].

Study Aims

This research aims to improve providers' dissemination of health information and related health outcomes for patients through an enhanced conceptual model of patient-centered communication that not only describes core communication functions but also presents a directional model of the interrelationships between those components. That conceptual model will be critical to incorporate into the technology to address verbal and nonverbal communication more comprehensively. Finally, this research will build the nonverbal assessment and automated feedback directly into the virtual human simulation for testing. This research has implications for a wide range of disease areas and broad applicability to medication safety, informed consent processes, patient instructions, and treatment adherence.

Methods

Overview

This research will use a multistage mixed methods design that includes convergent and exploratory sequential components (Table 1). The first phase will use a convergent design that merges [47] qualitative and quantitative MPathic-VR data to better understand the mediating influence of nonverbal communication (aim 1). Next, an exploratory sequential design will follow that begins with a qualitative grounded theory exploration through patient interviews. This information will be used to build [47] an automated nonverbal communication behavior assessment (aim 2). These findings will be used to develop the virtual human software's nonverbal assessment and conduct a quality control check as a small pilot of the enhanced system (aim 3).

XSL•FO
RenderX

Table 1. Summary of research design: data sources, analysis, and outcomes of each phase.

Aim	Data collection procedures	Data analysis procedures	Product or outcome
(1) Mediating effects nonverbal communication	• Quantitative: MPathic game scores, Kinect nonverbal data, OSCE[a] communication score, RIAS[b] and FACS[c] coding of video • Qualitative: video recording of MPathic-VR interactions, student reflections	• Dyadic data analysis, path modeling • Thematic analysis of video data, followed by data transformation to quantify it	Understand what elements of the nonverbal behavior construct are most important in the human-computer interaction
(2) Develop model of nonverbal communication	• Interviews with oncology providers about intentional nonverbal behaviors (eg, mirroring, silence, and nodding)	• Grounded theory qualitative analysis: open coding and relating components to develop the model	Model of nonverbal communication; function to include in virtual human
(3) Add and validate a new automated nonverbal communication behavior assessment in MPathic-VR	• Qualitative findings inform development of assessment along with FACS and RIAS models; Providers use MPathic-VR and assess if the system detects nonverbal behavior	• Mixed methods to build assessment: codes → variables, quotes → item language, interrater reliability analysis; code interactions, dyadic data analysis	Updated virtual human with new automated nonverbal communication behavior assessment; initial quality control data

[a]OSCE: objective structured clinical examination.

[b]RIAS: Roter Interaction Analysis System.

[c]FACS: Facial Action Coding System.

Convergent Mixed Methods Design

Overview

A mixed methods convergent design [48] will be used that integrates qualitative nonverbal assessment and student reflections with quantitative MPathic-VR game data and OSCE communication skill scores. The results generated from the convergent mixed methods design will help identify the mediating influence of nonverbal behavior and what nonverbal elements of the intervention were most important.

Data Collection

Data will be collected from the MPathic-VR to investigate the mediating influence of nonverbal behavior in virtual human intervention. Although results from the trial indicated a positive effect, it is imperative to understand what aspects of nonverbal communication were most predictive of outcomes. To address this, a large amount of data will be gathered from 210 participants in the MPathic-VR intervention arm (that has not yet been previously analyzed) to understand the extent and mechanism by which nonverbal communication influenced outcomes. Data include video recording MP4 files for each of 4 interactions (840 videos), MPathic-VR scores (continuous data) that reflect the path through the system and responses for each participant, a warehouse of nonverbal sensor data (binary data) recorded by the Microsoft Kinect sensor for 4 nonverbal behaviors (eg, nodding, shaking head, smiles, and proximity), OSCE performance scores (5-point rating for 4 domains and a continuous global score), and qualitative written reflections from the medical students.

Data Analysis and Integration

Data will be analyzed using several methods. Specifically, instances of nonverbal behavior displayed by the learner and the virtual human will be coded, and dyadic data analyses will be carried out to examine the extent to which the learner mirrored the behavior of the virtual humans. Then, interactions using the RIAS and FACS will be coded. Another aspect that will be investigated is how participants responded to each virtual human after their action review by using the feedback in their second attempt at the scenario. Thus, it is necessary to test the relationship between the nonverbal behavior the learner demonstrated, and the assessment scores focused on that behavior (ie, if a learner demonstrates nonverbal behavior through the scenario, do the assessments detect it?). These will be tested in a structural equation model that will be compared to the qualitative data.

Importantly, analyzing video and individual-level data will help explain the extent to which participants followed instructions regarding nonverbal behavior and connect it to communication skills outcomes. The R-squared of nonverbal behavior relative to verbal behavior by learners on the OSCE outcome will be calculated to guide virtual human simulations. Data will be integrated by merging the qualitative and quantitative data, which will yield new insight into the particular mechanisms of nonverbal behaviors related to OSCE outcomes. Integration aims to generate meta-inferences, that is, integrated conclusions, beyond what either database alone could determine. The outcomes will provide a better understanding of human-computer interaction with virtual humans, which will inform future informatics interventions and identification of variables to assess nonverbal communication for inclusion in the virtual human.

Exploratory Sequential Design

Overview

To develop a new conceptual model of nonverbal communication to inform virtual human-based training (aim 2) and develop new nonverbal functionality into the MPathic-VR

XSL•FO
RenderX

virtual human simulation by creating an automated nonverbal communication behavior assessment for health care providers (aim 3), an exploratory sequential design will be carried out. First, a qualitative study using grounded theory methods [49] will be conducted to explore patient-provider communication, in addition to drawing from existing models. The follow-up quantitative strand will assess how well the system detects added features of nonverbal behavior through a quality control check.

Data Collection

For the qualitative grounded theory phase of this exploratory sequential design, data sources will include findings and video data from the MPathic-VR trial (aim 1). Interviews will also be conducted with providers focused on understanding intentional nonverbal communication (eg, mirroring, silence, distance, smiling, nodding, and leaning). Specifically, using theoretical, purposeful sampling [49] of providers (eg, physicians, nurse practitioners, and physician assistants) actively seeing oncology patients, 20 providers will be recruited from the University of Michigan health system, seeking variation in terms of cancer specialty, years since training, gender, and other demographics. The ultimate sample size will be determined by data saturation—the point at which the theory is developed, and new information is not emerging [50]. It is necessary to obtain the providers' perspectives firsthand of intentional nonverbal communication to develop a patient-centered model. The quantitative strand will consist of video recordings that will allow for comparisons of nonverbal behaviors from provider participants between the system-recorded (Kinect) responses and manually scored records.

Data Analysis and Integration

Patient-provider interviews will be analyzed following Corbin and Strauss' [49] constant comparative method, including open and focused coding, to develop a theory of the process of patient-provider nonverbal communication. This model will provide a theoretical basis for the subsequent automated nonverbal communication behavior assessment I will develop. The outcomes will be a new model of nonverbal communication that refines models of patient-centered communication and novel nonverbal elements to include in MPathic-VR for testing.

The qualitative data analysis, including coding of nonverbal behavior, provider interviews, and the FACS and RIAS models of communication assessment, will inform the development of a novel automated nonverbal communication behavior assessment that will be tested. Specifically, qualitative findings will be incorporated using building integration to systematically use the qualitative findings to develop the assessment. Themes will inform assessment features, and qualitative codes will inform variables to measure in the automated nonverbal communication behavior assessment [51]. The video recordings will be used to assess the reliability of the assessment by calculating Cronbach α using .8 as a standard for internal consistency and will be compared with OSCE nonverbal behavior ratings to gather initial evidence of construct validity. Finally, the manually coded video data will be compared to the Kinect sensor data, both dichotomously scored for each encounter, to gather further evidence of the validity of the assessment. As described above, this existing nonverbal data recorded whether or not 4 nonverbal behaviors (eg, smiles, nods, body lean, and eyebrow raises) occurred for each participant interaction. The new automated nonverbal communication behavior assessment will be programed into the MPathic-VR intervention for quality testing.

A prospective quality check will be conducted to test and refine the new automated nonverbal communication behavior assessment of the MPathic-VR's ability to capture and assess nonverbal communication using the newly added features. This testing is needed to ensure the virtual human software is assessing clinically meaningful nonverbal behavior. Especially, it will be critical to test whether the system can recognize predefined aspects of nonverbal behavior by comparing system-recorded (Kinect) responses to manually scored records for predefined nonverbal behavior produced by provider test participants (n=30).

All data will be dichotomous (Yes/No) for each nonverbal behavior. Participants will be directed in advance to produce certain behaviors during the scenarios. Then, 2 analysts (principal investigator and research assistant) blinded to the directions will code behavior for each interaction from a video recording using the nonverbal communication behavior assessment, the RIAS, and the FACS. Because the manual recording will be considered the standard, the principal investigator and second independent reader will score manually to account for and investigate variability in manual coding. An interrater reliability analysis of the system-recorded responses with manually scored responses will be conducted. Dyadic data analysis techniques will also be applied to examine recorded nonverbal behaviors.

Based on accepted interrater reliability of SPIs [52,53], κ=0.6 will be considered adequate interrater reliability and κ=0.8 optimal using Cohen statistic [54,55]. Using the most conservative estimate of detecting κ=0.6 and a 2-tailed test of the null hypothesis of 0 agreement, a sample of 30 is needed for 90% power to assess the reliability [55]. If reliability falls below κ=0.6, we have 2 alternative procedures: (1) identify the lowest-performing cue and delete it to improve reliability, or (2) when 1 cue performs poorly, seek new technology, and repeat the analysis with the new technology, and compare to manually-coded assessment data from the MP4 recording. The outcome of this aim will be a refined virtual human software that includes the automated nonverbal communication assessment and initial quality control check data. Aim 3 will be critical to prepare for a subsequent R01 intervention to refine and test the revised virtual human system that contains novel scenarios assessing and automating both nonverbal and verbal communication after action review feedback.

Ethical Considerations

This study has been approved by the University of Michigan's institutional review board (HUM00134766). Informed consent will be requested electronically from each participant interested in participating in the study.

Privacy and Security

Given the large amount of video data that will be used in this study, several steps will be taken to ensure the security of these

XSL•FO
RenderX

documents. For example, all data will be stored on University-approved Box and Dropbox secure storage systems using password-protected security and encrypted computers.

Results

Data collection for this study started in 2019 by accessing secondary data of the MPathic-VR randomized controlled trial data set (210 medical students and 840 video-recordings of interactions) [56]. These data have been analyzed and are expected to be published in 2023. After analyzing these data, recruitment for the qualitative phase of the exploratory sequential design followed in 2021. We expect to complete data analysis for the qualitative phase by July 2023.

Discussion

Principal Findings

This study aims to improve providers' dissemination of health information and related health outcomes for patients through an enhanced conceptual model of patient-centered communication. This study will not only describe core communication functions but also present a directional model of the interrelationships between those components. This conceptual model will be critical to incorporate into the technology to address verbal and nonverbal communication more comprehensively. It is expected that the resulting conceptual model will be able to capture differences in verbal and nonverbal communication behaviors based on the delivery format (eg, in-person or telehealth visits). Finally, the project will build the nonverbal assessment and automated feedback directly into the virtual human simulation for testing. In doing so, we anticipate learners will be able to incorporate the program feedback and improve their nonverbal behaviors.

We expect to find changes across learners interacting with virtual humans on nonverbal behaviors, including those emphasized by the MPathic-VR (eg, eyebrow raise, nodding, and smiling), as well as other facial expressions (eg, furrowed eyebrows, lip corner puller, lower eyelid raise, and oblique eyebrows slight lip press) [57], and head and body orientation (eg, eye gaze toward virtual human, forward lean, and head tilting). Specifically, we would expect to find an increase in the frequency of nonverbal behaviors across learners after repeated interactions with virtual humans. We also anticipate that feedback from the virtual human will contribute to an increased awareness of learners' nonverbal behaviors. Dissemination of research findings will occur through conferences and articles.

Limitations

It is important to consider some limitations of this study. First, a team of researchers will be involved in coding a large number of video recordings to analyze learners' nonverbal behaviors. As a result, coder drift can occur, and discrepancies across coders can arise. To mitigate potential issues of coder drift, the team will meet regularly to discuss any discrepancies throughout the coding process. Second, the role of culture is critical to the assessment of nonverbal behaviors. Nevertheless, a previous study assessing the effectiveness of the MPathic-VR for teaching intercultural and interprofessional communication among medical students demonstrated that the MPathic-VR helped to increase students' scores after repeated exposure, thus leading to increased awareness of cultural components [36]. Moreover, previous research found significantly higher scores on cultural conversational verbal and nonverbal behaviors for participants exposed to a virtual human condition compared to using illustrations as guides [58]. Thus, the use of virtual humans has been shown to enhance cultural awareness across interactions.

Conclusions

This research has implications for a wide range of disease areas and broad applicability to medication safety, informed consent processes, patient instructions, and treatment adherence. One of the main strengths of this study is the potential to advance understanding of key aspects of nonverbal communication that can be used to develop informatics-based interventions and ultimately improve patient-provider communication. Using a multistage mixed methods design consisting of convergent and exploratory sequential components, we will be able to more thoroughly understand the nonverbal elements that lead to skill enhancement, develop a model, and automate nonverbal communication behavior assessment. These results will be needed for further virtual human simulation development and will help advance biomedical informatics.

Acknowledgments

This research was funded by the National Institutes of Health K01: Mentored Research Scientist Career Development grant (1-K01-LM-012739).

Data Availability

Deidentified data will be made available to all appropriate requests from interested researchers at the time of results publications.

Conflicts of Interest

MDF has stock options in Medical Cyberworlds and FWK serves as president of Medical Cyberwords, which develops MPathic-VR. The University of Michigan Conflict of Interest Office considered potential for conflict of interest and concluded that no formal management plan was required.

Abstract

Background: Adolescent alcohol and drug use (ADU) is a significant public health challenge. Uganda, one of the poorest countries in Sub-Saharan Africa (SSA), has the second-highest rate of per capita alcohol consumption in SSA, and over one-third of Ugandan adolescents have used alcohol in their lifetime (over 50% of them engage in heavy episodic drinking). These estimates further increase in fishing villages, a key HIV-vulnerable population, where ADU is normative. However, few studies have assessed ADU among adolescents and youths living with HIV despite their increased risk for ADU and its impact on engagement in HIV care. Moreover, data on risk and resilience factors for ADU are scarce as only few studies evaluating ADU interventions in SSA have reported positive outcomes. The majority have been implemented in school settings, potentially excluding adolescents in fishing communities with high school dropout rates, and none have targeted risk factors including poverty and mental health, which are rampant among adolescents and youths living with HIV and their families, undermine their coping skills and resources, and have been associated with increased risk for ADU among them.

Objective: We propose a mixed methods study with a sample of 200 adolescents and youths living with HIV (aged 18-24 years) seen at 6 HIV clinics in southwestern Uganda's fishing communities to (1) examine the prevalence and consequences of ADU and identify the multilevel risk and resilience factors associated with ADU among them and (2) explore the feasibility and short-term effects of an economic empowerment intervention on ADU among them.

Methods: This study comprises four components: (1) focus group discussions (FGDs) with adolescents and youths living with HIV (n=20) and in-depth qualitative interviews with health providers (n=10) from 2 randomly selected clinics; (2) a cross-sectional survey with 200 adolescents and youths living with HIV; (3) a randomized controlled trial with a subgroup of adolescents and youths living with HIV (n=100); and (4) 2 postintervention FGD with adolescents and youths living with HIV (n=10 per group).

Results: Participant recruitment for the first qualitative phase has completed. As of May 4, 2023, ten health providers from 6 clinics have been recruited, provided written consent to participate, and participated in in-depth qualitative interviews. Two FGDs was conducted with 20 adolescents and youths living with HIV from 2 clinics. Data transcription, translation, and analysis of qualitative data has commenced. The cross-sectional survey will commence shortly after and dissemination of the main study findings is targeted for 2024.

KEYWORDS

adolescents living with HIV; alcohol; Sub-Saharan Africa; substance use; Uganda

Introduction

Overview

Adolescent alcohol and drug use (ADU) is a growing public health concern globally, especially in low-resource settings such as Sub-Saharan Africa (SSA), where the epidemics of ADU and HIV/AIDS are co-occurring. ADU plays a significant role in the epidemiology of HIV among adolescents and young adults in SSA, who accounted for over 40% of new infections globally in 2019 [1]. ADU is associated with higher rates of HIV risk behaviors, such as condomless sex [2] and lower rates of HIV testing [3-5]. Among adolescents and youth living with HIV, ADU is a significant barrier to achieving positive HIV treatment outcomes, including enrollment and retention in HIV care [6], adherence to antiretroviral therapy (ART) [7-9], and viral suppression [8,10]. Among HIV-infected adults, it has been shown that alcohol and drug misuse increase AIDS mortality, even among virally suppressed and medication-adherent persons [11-13]. Uganda, one of the poorest countries in SSA, has high rates of HIV/AIDS (6.2%) [14] and alcohol use [15], and illicit drug use is on the increase [16]. Previous studies have reported high rates of alcohol consumption among adults living with HIV [17-19]. Fishing communities, a key vulnerable population in Uganda [20], have high levels of ADU, including among adolescents and youths [16,21-23], which lead to poor HIV prevention and care outcomes.

ADU onset typically occurs in adolescence as an experimental behavior that may escalate into problematic use and disorders [24,25]. Adolescence is a period characterized by the exploration of new roles, identities, and behaviors, including experimentation with ADU [26]. A multitude of factors influence ADU, and these include individual factors (eg, sensation seeking, impulsivity, and mental health) [27-32], interpersonal factors (eg, peer pressure, parental drug use, and poor parental monitoring) [33-43], and structural factors (eg, availability of alcohol and drugs, exposure to ADU marketing, community drug use attitudes, laws and policies, and structural barriers that contribute to poverty) [33,38]. Adolescents and youths living with HIV also experiment with ADU, which may escalate into problematic ADU.

Adolescents and youths living with HIV face numerous HIV-related psychosocial challenges, including HIV stigma, bereavement, chronic pain, relationship stress, and poverty, which heighten their risk for ADU [44-46]. Indeed, research reports indicate a higher burden of mental health problems among adolescents and youths living with HIV [45,47-50], which may lead to ADU. The co-occurrence of mental health problems and ADU is common, including among adolescents and youths living with HIV [49,51-57]. Both ADU and mental health difficulties are associated with nonadherence to ART [48,58-60] and risky sexual behaviors among adolescents and youths living with HIV [59,61-63], which could lead to secondary transmission of HIV and ART resistance due to nonadherence [64-66]. Poor mental health and poverty, which are rampant in poor countries, are significant risk factors for ADU. Poor mental health [54,67,68] and poverty [69-71] are rampant among HIV-affected households, and both are significant risk factors for acquiring HIV [72] and for poor HIV treatment outcomes [73,74]. Adolescents and youths living with HIV living in poverty-stricken households face greater challenges in accessing and sustaining HIV treatment due to economic factors, such as lack of money preventing access to transportation to clinics [75,76] and insufficient resources to afford food leading to inadequate meals to support medication adherence [77-79], which could lead to psychological distress and consequently, ADU [80]. Poverty adversely affects the quality of family relationships, including parent-child communication, involvement [81-83], and parenting skills [84,85], which increases susceptibility to emotional and behavioral challenges and increases risk for ADU [41,43,82,86-90].

Several studies have examined the risk and resilience factors for ADU [91] but few interventions targeting ADU have been tested in SSA. Efforts to prevent ADU are rooted predominantly in the substance use risk reduction and protection enhancement model [91] and require understanding of the risk and resilience factors for ADU. These interventions largely target individual and interpersonal risk factors for ADU, with a focus on providing participants with information on ADU and its consequences or building life skills. In SSA, only 1 intervention targeted the family [92], an important developmental context for adolescents, with a focus on enhancing parenting skills. Yet, none of these interventions has targeted risk factors, such as poverty and mental health, that are widespread in SSA and may undermine the resources and coping skills of adolescents and youths living with HIV.

Despite our knowledge of the higher risk for ADU among adolescents and youths living with HIV [93-96], there is lack of evidence-based interventions targeting ADU risk among adolescents and youths living with HIV. Only 10 ADU interventions have been evaluated in SSA [27,92,97-104] and only a few have been successful [27,98,99,101,103,104]. Most have been ineffective in preventing or reducing ADU, and none of these interventions have targeted adolescents and youths living with HIV. The majority of these interventions are largely

XSL•FO
RenderX

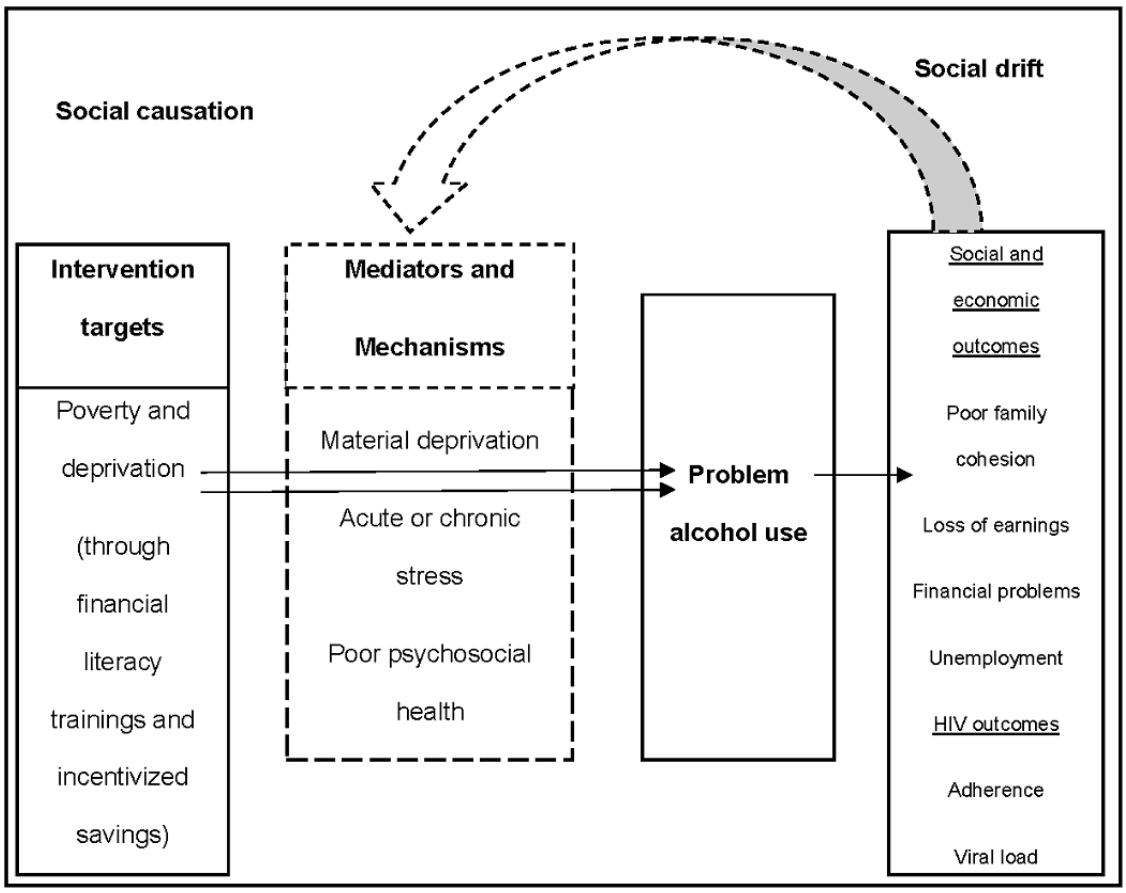
school-based [27,100-104], which may exclude adolescents in fishing communities that have high rates of school dropout. These interventions also focused on individual and intrapersonal risk factors for ADU without paying attention to structural risk and resilience factors for ADU. The few existing studies on ADU among adolescents and youths living with HIV have been conducted in high-income countries. These studies focused on younger adolescents, yet ADU typically emerges and escalates in middle-to-late adolescence. Further, these studies rely on self-reports of ADU, which can be undermined by underreporting of ADU.

Economic empowerment (EE) interventions have the potential to prevent ADU among adolescents and youths living with HIV by reducing poverty and its associated mental impacts and bolster adolescents and youths living with HIV and their families' resources to overcome the challenges associated with HIV. In our previous studies, we have used EE strategies to reduce poverty and improve mental health and HIV care outcomes (eg, medication adherence) among adolescents and youths living with HIV and other AIDS-affected adolescents in Uganda [73,82,105-108]. In this application, we propose to build on this growing evidence by examining the feasibility of using EE to address ADU among adolescents and youths living with HIV.

This study will investigate the epidemiology, underlying risk, and resilience factors for ADU among adolescents and youths living with HIV and evaluate the effects of an EE intervention on ADU among adolescents and youths living with HIV. The specific aims of the study are as follows.

Aim 1a: Examine the prevalence and consequences of ADU in a cohort of 200 adolescents and youths living with HIV (aged 18-24 years) seen at 6 HIV clinics in southwestern Uganda. We will use adolescent self-reports and biological measures of ADU (urine).

Aim 1b: Using a mixed methods approach, identify the multilevel (individual, interpersonal, community, and structural) factors associated with ADU among adolescents and youths living with HIV.



Aim 2: Using a subset of the sample, explore the feasibility and short-term effects of an EE intervention on ADU among adolescents and youths living with HIV.

Theoretical Framework

Our conceptual approach is informed by the socioecological model (SEM) [109], social causation and drift theories [110], and asset theory [111,112]. We have applied the SEM as a basis for investigating the contextually relevant risk and resilience factors for ADU. SEM posits that environmental factors fall into 4 broad domains: micro-, meso-, exo-, and macrosystems, and interactions within and between these domains determine behavior. This model has demonstrated effectiveness in identifying risk and resilience factors for prevention planning and intervention for ADU [113-117]. Social causation and social drift theories suggest that alcohol consumption problem may be both a response to and a driver of poverty [118]. Acute and chronic stress associated with living in a poverty-impacted environment increases the likelihood of ADU, which causes further material and economic deprivation, hence fueling the cycle of alcohol misuse, and contributing to downward social mobility. Our conceptual framework describes the hypothesized relationship among the intervention targets, poverty, poor mental health, and alcohol use. This has been adapted from Jones and Sumnall [119] (Figure 1)**.** Research in Uganda has reported a higher burden of alcohol and drug abuse among poor populations [120], and many poverty-impacted Ugandan households engage in informal alcohol production for income-generating purposes [121]. Impoverished youths are burdened with hopelessness due to lack of opportunities for improvement in their economic well-being [122,123]. As a result, for impoverished adolescents and youths living with HIV, they may be inclined to spend on instant pleasures, such as alcohol and drugs, as a coping mechanism since they are less likely to believe they can afford the costs associated with accessing and maintaining long-term care for HIV. Our proposed EE intervention is based on Asset theory [124] and is intended to improve economic well-being, relieve poverty and its related consequences, such as poor mental health [106,125], and create a more hopeful and optimistic outlook for the future, thus reducing engagement in risk-taking behaviors like ADU by adolescents and youths living with HIV. The proposed EE will be one of the first studies to examine the impact of EE interventions on reducing ADU among adolescents and youths living with HIV in poverty-impacted communities.

Methods

Overall Study Design

This mixed methods study comprises the following four components: (1) focus group discussions (FGDs) with adolescents and youths living with HIV (n=20) and in-depth qualitative interviews (QIs) with health providers (n=10) from 2 randomly selected clinics; (2) a cross-sectional survey (CS) with 200 adolescents and youths living with HIV; (3) a randomized controlled trial (RCT) with a subgroup of adolescents and youths living with HIV (n=100); and (4) 2 postintervention FGDs with adolescents and youths living with HIV (n=10 per study group). Figure 2 depicts the study components and expected number of participants in each component.

Figure 2. Study components and participant flow through the study. RCT: randomized controlled trial.

Study Sites and Participants

The study will be conducted in 6 randomly selected HIV clinics located in fishing districts within the Greater Masaka region of Southwestern Uganda—a region heavily affected by HIV (12% prevalence vs 6.2% national average) [126] with high rates of household poverty and alcohol use [127,128]. The target populations for this study are adolescents and youths living with HIV and health care providers at the selected HIV clinics. We

XSL•FO
RenderX

will specifically target HIV clinics located in fishing districts with known HIV hot spots that are accredited by the Uganda Ministry of Health as a provider of ART and currently have established services for adolescents and youths living with HIV.

Inclusion Criteria

For the overall study, the inclusion criteria for adolescents and youths living with HIV are: (1) male or female adolescents and youths living with HIV aged 18-24 years; (2) medically diagnosed with HIV and aware of their HIV status; and (3) enrolled in care at one of the selected HIV clinics. Additionally, we will recruit 1-2 health care providers (psychosocial counselors, nurses, clinical officers, or doctors) from each of the selected clinics. For the RCT, a subsample of adolescents and youths living with HIV (n=100) with a positive self-report for ADU will be randomly selected and randomly assigned at the clinic level (3 clinics per group) to either the intervention group (n=50) or control group (n=50). A subsample of adolescents and youths living with HIV from both the control (n=10) and intervention groups (n=10) will be selected to participate in 2 FGDs at the end of the intervention. Overall, we will exclude any potential participant with significant cognitive impairments that interfere with their understanding of the informed consent process or who is unable or unwilling to consent. For the RCT and postintervention FGDs, we will exclude any adolescents and youths living with HIV with a negative self-report for ADU. However, given the minimum and maximum detection times for different drugs of abuse in the urine, we will not exclude those with a positive self-report but negative urine test results from being included in the RCT.

Participant Recruitment and Consent

Recruitment strategies will build on Reach the Youth Uganda (local implementing partner) and ICHAD's (International Center for Child Health and Development) long-standing relationships (>15 years) with 39 health clinics in the greater Masaka region. We will capitalize on recruitment procedures tested in previous SUUBI (Luganda word for Hope) studies that involve collaborating with health clinics in the region (namely Suubi+Adherence: 1R01HD074949-01, Suubi+Adherence-R2: R01HD074949-07, and Suubi4Stigma: R21MH121141) [129-131]. All participants will be recruited from the selected HIV clinics. For the CS, 200 adolescents and youths living with HIV will be recruited from across 6 clinics located in the greater Masaka region. The designated study contact at each health clinic will present the project to all eligible adolescents and youths living with HIV aged 18-24 years during their clinic visits. If there is interest, they will provide verbal consent to be contacted by the research study team. The study coordinator will contact interested adolescents and youths living with HIV to inform them about the required extent of participation, the risks and benefits of participating, and to ask any questions. Written informed consent will be obtained from adolescents and youths living with HIV aged 18-24 years and from health care providers aged more than 18 years to participate. The written consent documents will emphasize the following elements: (1) participation in the study is voluntary; (2) responses to study questions are confidential; (3) participants can terminate their participation at any time, and their decision to withdraw from the study will not affect their access to services they are currently receiving in any way; and (4) participants may be contacted to participate in the RCT if eligible. A screening tool will be developed to assess whether participants meet the study inclusion criteria.

Ethics Approval

We have obtained approval for the study procedures from the institutional ethics and institutional review boards at the Washington University in St. Louis (202301145) on January 31, 2023 (with an amendment approved on March 2, 2023); the University of Michigan (HUM00223732) on February 23, 2023 and from the in-country local institutional review boards in Uganda: Uganda Virus Research Institute (GC/127/933) on January 16, 2023, and Uganda National Council of Science and Technology (HS2683ES) on March 2, 2023. The study has been registered with ClinicalTrials.gov (NCT05597865) as of October 28, 2022. The dissemination of the main study findings is targeted for 2024. Participants' data will be protected by a certificate of confidentiality, which protects the privacy of research subjects by prohibiting the disclosure of identifiable, sensitive research information to individuals not involved in the research unless the participant consents.

Data Collection and Assessments

After pilot testing of data collection interview tools, 2 separate FGDs will be conducted with adolescents and youths living with HIV (n=20) and in-depth QIs will be conducted with health providers (n=10). Adolescents and youths living with HIV will be recruited from 2 randomly selected clinics, with 10 participants per FGD. The FGDs and QIs will explore participants' perceptions of the multilevel risk and resilience factors associated with ADU and recommendations for culturally appropriate ADU interventions for adolescents and youths living with HIV. Data from the qualitative phase will inform assessments to be conducted in the CS. For the CS, 200 adolescents and youths living with HIV will complete an interviewer-administered survey comprising questions assessing their alcohol and drug consumption patterns and frequency, as well as exposure to multilevel (individual, interpersonal, community, and societal) factors that may be associated with risky and hazardous drinking and drug use among adolescents and youths living with HIV. To reduce social desirability bias, questions on ADU will be self-administered using audio computer–assisted interviewing. We refer to the social ecological framework [132] to guide data collection on the multiple levels of influence that are associated with harmful alcohol and drug use among adolescents and youths living with HIV (see Table 1 for socioecological framework and additional measures that will be collected at each time point). Questions assessing the presence of common mental disorders and other physical health conditions will be included.

Urine tests for ADU will be conducted for all 200 adolescents and youths living with HIV who participate in the CS and for the 100 who participate in the RCT (at the 2 time points: baseline and postintervention). A trained research assistant will collect and test a urine specimen from each participant. The urine sample will be tested for up to 16 classes of the most commonly abused illicit drugs using the T-Cup 16 panel

XSL•FO
RenderX

Compact Instant Drug Test Cup at the study site. The T-Cup can detect alcohol in the urine from as early as 8 hours to up to 80 hours after consumption. Minimum and maximum detection times for illicit drugs of abuse range from 1 hour to 40 days, depending on the drug.

Table 1. List of measures and time points collected during the study.

Category	Measure	Time point
Individual level of socioecological framework	Sociodemographic: gender, age, orphanhood status, education, income and unemployment, food insecurity [133], experienced homelessness, refugee, day and boarding school, and urban and rural residence. Mental health: depression [134], hopelessness [135], optimism [136], stress [137], pain [138], and history of substance abuse [139].	Cross-sectional survey, qualitative interview, focus group discussion, randomized controlled trial
Interpersonal and relationship levels of socioecological framework	Loneliness [140], number of close friends, bullying, interpersonal violence [141,142], social support [143], family cohesion [144,145], childhood abuse and trauma [146], family history of substance abuse [139], and sexual risk-taking [147]	Cross-sectional survey, qualitative interview, focus group discussion, randomized controlled trial
Community level of socioecological framework	Community norms and access to alcohol and illegal drugs	Cross-sectional survey, qualitative interview, focus group discussion, randomized controlled trial
Society level of socioecological framework	Educational campaigns, price and supply of alcohol, and social stigma [148]	Cross-sectional survey, qualitative interview, focus group discussion, randomized controlled trial
Biomarkers	Urine alcohol and drug tests	Cross-sectional survey, randomized controlled trial
Savings deposits	Savings	Randomized controlled trial
Assessments	Self-reported alcohol and drug use [139], viral load from clinic records, self-reported adherence [149], depressive symptoms [134], hopelessness [135], physical health conditions, and sexual risk-taking [147]	Randomized controlled trial

Randomized Controlled Trial: Intervention Conditions

For the RCT, 100 adolescents and youths living with HIV with a positive self-report or urine ADU test (based on data from the CS) will be randomly recruited from the 6 clinics and randomly assigned at the clinic level (3 clinics per group) to either the control (n=50) or intervention (n=50) group. The intervention will be delivered over a period of 6 months, with assessments at baseline and 6 months (end of intervention). Upon completion of the RCT, adolescents and youths living with HIV will be randomly selected to participate in 2 FGDs (n=10 from control group and n=10 from intervention group). Adolescents and youths living with HIV in the intervention group will share how the intervention affected their alcohol and drug use as well as their recommendations on how to improve the intervention to be more culturally appropriate and effective in reducing ADU among adolescents and youths living with HIV in Uganda, while adolescents and youths living with HIV in the control group will share their experiences with ADU risk reduction sessions and how this influenced their ADU.

Description of the Control Condition

Adolescents and youths living with HIV in the control condition will receive 4 ADU risk reduction sessions tailored for adolescents and youths living with HIV. Working with author JM (consultant), we plan to adapt, expand, and tailor the Program for Appropriate Technology in Health (PATH) Life Planning Skills curriculum (Unit 11 on substance use) [150] to include issues specific to adolescents and youths living with HIV. We will train research assistants, using an adapted facilitator's manual, to deliver the adapted curriculum. As part of the RCT, adolescents and youths living with HIV will complete a questionnaire (at baseline and at the end of the intervention) on their alcohol and drug use behaviors (self-reported and biologically measured) and risk and resilience behaviors.

Description of the Intervention Group

In addition to the adapted ADU training module that the control group will receive, adolescents and youths living with HIV in the intervention arm will receive 4 financial literacy training sessions and a youth development savings account (YDA) for long-term savings. Although akin to conditional cash transfer interventions, which have become increasingly popular in the social development field by enabling individuals to meet basic needs while incentivizing prosocial behaviors [82,107,151-153], EE interventions that apply matched savings accounts go beyond incentivizing behavior. They emphasize long-term investment and promote lifelong financial inclusion by forming savings habits and establishing partnerships between the participants and local financial institutions and the actual intervention program. For the proposed study, the EE intervention will be in the form of a YDA, where savings are housed at a local bank and deposits made by the adolescent are matched by the intervention to encourage savings. YDAs yield positive effects, including creating a greater sense of security, self-confidence, and future orientation for young people [82,107,151-153]. Each adolescent and youth living with HIV in the EE intervention will receive a YDA held in their own name in a bank registered by the Central Bank (Bank of Uganda). We will form partnerships with national banks operating in the study area. The account will then be matched with money from the program.

XSL•FO
RenderX

The maximum adolescent's contribution to be matched by the program will be an equivalent of US $20 per month per adolescent or US $120 for the 6-month intervention period. Our previous studies indicate that the partner financial institutions have multiple and easily accessible deposit locations in the study area and that participants can save these amounts [82,107,151-153]. Therefore, adolescents and youths living with HIV who save the maximum amount will have a total of US $240 at the end of the intervention (US $120 in savings and US $120 from the match: a 1:1 match).

As in the studies that inform this application, each month a bank account statement will be generated for every adolescent and youth living with HIV to note their accumulated savings. The statements are intended to act as "moral boosters" for the enrolled adolescents and youths living with HIV. Unique to this study is our innovative spending model, which empowers participants to make informed financial decisions. During the intervention period, adolescents and youths living with HIV will have direct access to both their personal savings deposited in the accounts as well as the match provided by the study. This is different from our previous studies that required the participants' own savings and the match to be maintained in separate accounts and to get approval by the research team to access the match [82,107,151-153]. This added unconditional component provides adolescents and youths living with HIV with a safety net to address short-term medical needs and financial and consumption emergencies if they arise. Participants will be provided with financial literacy sessions and mentorship tailored specifically to the needs of adolescents and youths living with HIV and ADU. We expect adolescents and youths living with HIV to be equipped with the knowledge to make well-informed consumption and expenditure decisions but also to feel supported in case of immediate medical needs. The research team will monitor, but not restrict, how participants spend their money. Additionally, the study team will have access to and review participants' bank statements to ascertain deposit and withdrawal frequency. Participants will be encouraged to use financial diaries to record their expenditures.

Analysis of CS Data

Frequency distributions and summary statistics for the outcome and all predictor variables will be derived. The prevalence of ADU from both biological tests and self-reports, assessed using the Smoking and Substance Involvement Screening Test (NIDA-Modified ASSIST) [139] among adolescents and youths living with HIV, will be calculated by dividing the number who tested positive for ADU by the total number of participants tested and dividing the number screened to be of moderate or high risk in self-reported data by the total number of participants who completed the survey. To determine which multilevel factors are associated with substance misuse, we will fit logistic regression models comprising the outcome (ADU) and potential risk factors with standard errors adjusted for clustering by clinics.

Analysis of RCT Data

Primary Outcome Measures

Our primary outcomes are feasibility and acceptability of the intervention. Feasibility will be determined by the proportion of participants who enrolled or refused to participate in the intervention. In addition, we will measure the willingness of local partners to assist with recruitment, reasons for refusal, enrollment, and ineligibility. Acceptability will be determined by measuring retention rates at 6 months, the proportion of participants that adhered to study procedures, intervention attendance and engagement, and the extent to which the intervention is acceptable and appealing to study participants.

Secondary Outcome Measures

Changes in ADU and mental health functioning are our secondary outcomes. Our primary hypothesis is that participants in the intervention group will have a lower odds of ADU compared to participants in the control group at the end of the intervention. Our secondary hypothesis is that adolescents and youths living with HIV in the intervention group will have better mental health outcomes, including lower levels of depressive symptoms, less hopelessness, improved adherence, better viral suppression, and improved economic outcomes than adolescents and youths living with HIV in the control group. To test these hypotheses, we will fit 3-level mixed-effects models. Each model will comprise the outcome and fixed categorical effects for study group (intervention vs control), time (baseline and 6-months), and a group-by-time interaction term. Random intercepts will be fitted at the clinic and person levels, with unstructured correlations among subjects' repeated measures. Robust Huber-White standard errors and test statistics will be computed for each model. We will assess the omnibus effects of study group, time, and their interaction. Postestimation analyses will be conducted to assess time within group simple effects and group within time simple effects.

Qualitative Data Analysis

Interviews will be transcribed and uploaded to NVivo 12 (QSR International) [154]. Analytical induction techniques [155] will be used for coding. Ten interview transcripts will be randomly selected, read multiple times, and independently coded by the team using sensitizing concepts to identify emergent themes (open coding) [156]. Broader themes will be broken down into smaller, more specific units until no further subcategory is necessary. Analytic memos will be written to further develop categories, themes, and subthemes and to integrate the ideas that emerge from the data [156,157]. Codes and the inclusion and exclusion criteria for assigning codes will be discussed as a team to create the final codebook in NVivo 12. Each transcript will then be independently coded by 2 investigators using the codebook. Intercoder reliability will be established. A level of agreement ranging from 66% to 97% based on level of coding indicates good reliability [158]. Disagreements will be resolved through team discussions. The secondary analysis will compare and contrast themes and categories within and across groups to identify similarities, differences, and relationships among the findings. Member checking, peer debriefing, and an audit trail will be used to ensure rigor [159].

XSL•FO
RenderX

Results

Recruitment of participants for the first qualitative phase has commenced. As of May 4, 2023, ten health providers from 6 clinics have been recruited, provided written consent to participate, and participated in in-depth QIs. Two FGDs was conducted with 20 adolescents and youths living with HIV from 2 clinics. Data collection for the qualitative phase has completed and transcription, translation, and analysis of qualitative data will commence immediately thereafter. The CS will begin shortly after the qualitative phase. Data collection will continue over the next year, and dissemination of the main study findings is targeted for 2024.

Discussion

This will be one of the first studies to examine the impact of EE interventions on reducing alcohol and drug use among adolescents and youths living with HIV in poverty-impacted communities. This study will advance our understanding of the epidemiology, underlying risk factors, and consequences of ADU among adolescents and youths living with HIV in high-risk environments and evaluate a culturally tailored intervention that could prevent harmful ADU and improve the overall and long-term health and well-being of adolescents and youths living with HIV. We specifically target adolescents and youths living with HIV living in fishing communities—known HIV hot spots that typically have high levels of poverty as well as ADU. Study findings will contribute to our understanding of the epidemiology, risk and resilience factors, and consequences of ADU among adolescents and youths living with HIV in order to inform the development of effective ADU prevention interventions. We envision that the findings will also inform the design of longitudinal studies to evaluate the long-term effects of an EE intervention on ADU among adolescents and youths living with HIV.

There is a scarcity of evidence-based interventions for addressing ADU among youth in resource-limited settings. Only a few ADU interventions evaluated in SSA have targeted the family context [92]. No study has targeted poverty and its attendant impacts (eg, mental health) as a risk factor for ADU. In this proposal, we will examine the feasibility, acceptability, and short-term effects of an EE intervention to reduce and prevent risky and hazardous alcohol and drug use. Our intervention targets the most commonly occurring risk factors for ADU (ie, poverty and mental health problems). This will be one of the first studies to examine the impact of EE interventions on reducing alcohol and drug use among adolescents and youths living with HIV in poverty-impacted communities. The proposed EE intervention is based on Asset theory [124] and is intended to improve economic well-being, create a more hopeful and optimistic outlook for the future, and thus reduce engagement in risk-taking behaviors by adolescents and youths living with HIV, including ADU. However, our findings should be interpreted with some limitations. Given our target population, our findings may not be generalizable to adolescents and youths living with HIV populations in more urban or developed areas, and to younger or older age groups. This is a small feasibility study, so our study is not powered to detect significant changes but will provide preliminary data for a larger-scale study with sufficient power.

Acknowledgments

We would like to thank our staff and volunteers at the International Center for Child Health and Development (ICHAD) Uganda and Reach the Youth Uganda for their respective contributions to study preparation. In addition, we are grateful to the participating health care clinics and participating youth for agreeing to participate in the study. The study outlined in this protocol is supported by the National Institute on Alcohol Abuse and Alcoholism (NIAAA) under award number 1R21AA030225-01 (multiple principal investigators: MM, PhD and RB, PhD). NIAAA has no role in the study design, data collection, analysis, interpretation of findings, and manuscript preparation. The content is solely the responsibility of the authors and does not necessarily represent the official views of NIAAA or the National Institutes of Health.

Data Availability

Data sharing is not applicable to this study as no data sets were generated or analyzed during this study. However, the data sets generated during this study will be available in the National Institute of Mental Health Data Archive.

Conflicts of Interest

None declared.

Abstract

Background: Research and policy demonstrate the value of and need for systematically identifying and preparing care partners for their caregiving responsibilities while their family member or friend living with dementia is hospitalized. The Care Partner Hospital Assessment Tool (CHAT) has undergone content and face validation and has been endorsed as appropriate by clinicians to facilitate the timely identification and preparation of care partners of older adult patients during their hospitalization. However, the CHAT has not yet been adapted or prospectively evaluated for use with care partners of hospitalized people living with dementia. Adapting and testing the CHAT via a pilot study will provide the necessary evidence to optimize feasibility and enable future efficacy trials.

Objective: The purpose of this paper is to describe the study protocol for the adaptation and testing of the CHAT for use among care partners of hospitalized people living with dementia to better prepare them for their caregiving responsibilities after hospital discharge.

Methods: Our protocol is based on the National Institutes of Health Stage Model and consists of 2 sequential phases, including formative research and the main trial. In phase 1, we will use a participatory human-centered design process that incorporates people living with dementia and their care partners, health care administrators, and clinicians to adapt the CHAT for dementia care (ie, the Dementia CHAT [D-CHAT]; stage IA). In phase 2, we will partner with a large academic medical system to complete a pilot randomized controlled trial to examine the feasibility and estimate the size of the effect of the D-CHAT on care partners' preparedness for caregiving (stage IB). We anticipate this study to take approximately 60 months to complete, from study start-up procedures to dissemination. The 2 phases will take place between December 1, 2022, and November 30, 2027.

Results: The study protocol will yield (1) a converged-upon, ready-for-feasibility testing D-CHAT; (2) descriptive and feasibility characteristics of delivering the D-CHAT; and (3) effect size estimates of the D-CHAT on care partner preparedness. We anticipate that the resultant D-CHAT will provide clinicians with guidance on how to identify and better prepare care partners for hospitalized people living with dementia. In turn, care partners will feel equipped to fulfill caregiving roles for their family members or friends living with dementia.

XSL•FO

Conclusions: The expected results of this study are to favorably impact hospital-based care processes and outcomes for people living with dementia and their care partners and to elucidate the essential caregiving role that so many care partners of people living with dementia assume.

dementia; caregiving; health care; systems; co-design; randomized control trial

Introduction

People living with dementia experience frequent and costly hospitalizations, which are associated with poor health outcomes. Compared to other older people, people living with dementia have twice as many hospitalizations and stay nearly a day longer [1]. Moreover, evidence indicates that people living with dementia discharged from hospitals are at higher risk for readmission within 30 days [2,3], urinary tract infections, pressure areas, pneumonia, and delirium [4]. The total costs of these hospital services are more than 3 times greater for people living with dementia than for those without dementia [5]. Further, hospitalizations also hasten the cognitive decline of people living with dementia [6]. Care partners (a traditional family, partner, or other support person designated by the older adult care recipient) have the potential to mitigate these adverse outcomes for people living with dementia when included in care processes during hospitalization.

While more than 11 million care partners of people living with dementia provide nearly 15 billion hours of unpaid care annually [6], many hospitals fail to integrate care partners in the care delivery processes of people living with dementia [7]. Care partners are not included despite our knowledge that frontline approaches to reducing adverse outcomes rely on their unique knowledge of the preferences and functional abilities of people living with dementia [7,8]. In fact, a recent study investigated compliance with the Caregiver Advise, Record, and Enable (CARE) Act, which requires hospitals to (1) provide admitted patients the opportunity to identify and record the name of a care partner; (2) inform the care partner when discharge is to occur; and (3) prepare care partners to fulfill caregiving roles to be performed in the home, like complex medical and nursing tasks [9]. Analyses of more than 200 direct observations and 13,000 patient electronic health records for the first 6 months after implementation of the CARE Act in 1 health care system revealed the following: (1) 53% of patients identified a care partner on admission, 23% declined, and 8% were not asked by a clinician; (2) 97% of care partners identified on hospital admission were not notified of the patient's upcoming discharge; and (3) only 19% of care partners received preparation on tasks to be performed in the home during the patient's hospital stay [10,11].

Further, a systematic review of the needs of care partners of people living with dementia across care settings [12] found limited available evidence for identifying and preparing care partners for their caregiving tasks in settings other than the home and community; no studies focused on acute care settings. These findings highlight missed opportunities to individualize care for people living with dementia and to prepare their care partners to fulfill caregiving tasks post hospital discharge. Despite their essential role, care partners who are poorly integrated into hospitalizations and inadequately prepared to fulfill dementia caregiving tasks are at high risk of experiencing excess burden, chronic stress, and depression [13,14].

Clinical decision-support tools offer a valuable resource for addressing this gap in practice as they enable multidisciplinary teams to navigate complex care processes (eg, care partner identification) using structured yet flexible guidance [15]. Common uses of clinical decision-support tools include timely screening for preventable conditions or medical events and ensuring accurate diagnoses [15]. Yet, a recent systematic review uncovered no clinical decision-support tools to guide the systematic identification and preparation of care partners for hospitalized people living with dementia [16].

In response to this gap, we developed and validated a standardized decision-support tool to facilitate the timely identification and preparation of care partners for cognitively unimpaired adult patients during their hospitalization. The Care Partner Hospital Assessment Tool (CHAT) has strong content and face validity and is endorsed as appropriate by clinicians and care partners in the hospital setting [17,18]. Guided by the widely used and effective decision-support model of Screening, Brief Intervention, and Referral to Treatment [19,20], the CHAT applies a sequential screening and referral pathway that (1) identifies care partners and their preferences for involvement in the patients' hospital care and (2) tailors referrals to address their stated preferences and unmet needs for postdischarge preparedness.

Because there is a great need for a novel decision-support tool in hospital-based dementia care, we will (1) adapt the CHAT for dementia (ie, the Dementia Care Partner Hospital Assessment Tool (D-CHAT)), and then (2) test the feasibility and estimate the size of the effect of the D-CHAT compared to usual care. D-CHAT has the potential to improve hospital-based care processes and outcomes for people living with dementia and their care partners. In addition, findings from this study will further elucidate the essential caregiving role that so many care partners of people living with dementia assume.

Methods

Design and Conceptual Framework

The study is based on the National Institutes of Health Stage Model approach [21] to intervention development, focusing on stage 1, and will be conducted in 2 phases: formative research and the main trial. During the formative research phase, we will use a participatory human-centered design process that incorporates people living with dementia and their care partners, health care administrators, and clinicians to refine and adapt the CHAT for hospital-based dementia care (stage IA). During the main trial phase, we will conduct a pilot randomized controlled trial to examine the feasibility and estimate the size of the effect of the D-CHAT on care partners' preparedness for caregiving tasks (stage IB).

The System Engineering Initiative for Patient Safety 2.0 model (Figure 1) will guide our data collection and analysis to ensure the identification of components influencing the adaptation and delivery of the D-CHAT across all health care system components. This model emphasizes a working system that includes interacting components (ie, people, tasks, tools or technology, organization, and physical environment) that influence health care processes and outcomes [22-24].

Figure 1. System Engineering Initiative for Patient Safety 2.0 model.

Ethics Approval

The study was approved by the institutional review board on April 11, 2023 (2022-0352). All protocol modifications will be reviewed and approved by the institutional review board as needed.

Phase 1—Formative Research

Sample

Based on established relationships with health system and community partners, we will purposefully select interested parties for two groups: (1) health care administrators and frontline clinicians, and (2) people living with dementia and their care partners that meet eligibility criteria (see Table 1). Each group will form a design team and have 5-7 participants, which is within the standard range used in participatory design research [25]. The small number of participants in groups reduces the potential for groupthink (ie, by having products from one group evaluated by the other) and ensures that all participants have ample time to provide their perspectives [26].

XSL•FO
RenderX

Table 1. Sampling plan (N=10-14).

Group	Reason for inclusion	Eligibility criteria
Group 1 (n=5-7)		
Health care administrators	Knowledge and expertise related to the day-to-day operations of hospital, patient eligibility, enrollment, claims, and payment of health services	• Have at least 5 years of professional experience in their respective position • Speak and understand English
Clinicians	Knowledge and expertise related to the delivery of health services	• Have at least 5 years of professional experience in their respective position • Speak and understand English
Group 2 (n=5-7)		
People living with dementia	Knowledge and experience related to receiving hospital care	• Have experienced a hospitalization • Have some form of dementia • Identified a care partner
Care partners of people living with dementia		• Provide unpaid care to a relative or partner living with dementia to help them take care of themselves • Be at least 18 years or older • Speak and understand English

Data Collection

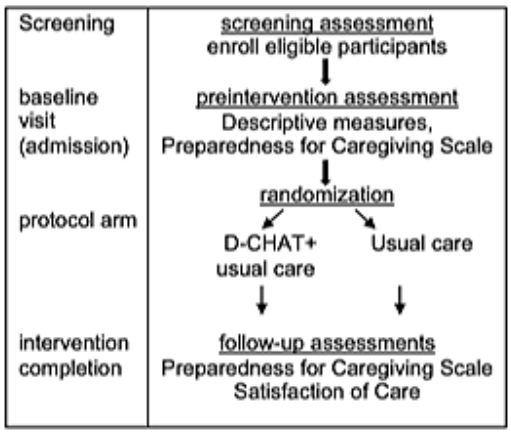
Teams will complete 5 co-design videoconference sessions occurring in parallel across 4 months, with 2-3 weeks between each session. In session one, we will present the original CHAT. We will lead discussion, interpretation, and respectful debate among design team members to begin to generate the needs of dementia care partners and health care system process changes to optimize their involvement in care. We will ensure progress toward solution convergence from session to session. The design teams will conduct sessions independently, but in between sessions, they will swap solutions and provide feedback, which we will summarize and present in subsequent sessions. Each web-based session will last approximately 90 minutes and will be audio recorded for subsequent analysis. The design process can be conceptualized as a funnel in which we start with divergent ideas and then work toward convergence through the sessions. Participants will receive US $20 after completing each session.

Data Analysis

Within the 2-3 weeks between each session, we will review audio recordings as well as any team and participant observation notes, case scenarios, and sketches. Two members of our team will use the Rapid Identification of Themes From Audio Recordings (RITA) method [27] to identify design specifications. The same 2 team members will then combine the themes from the RITA with the synthesized team and participant observation notes, use of case scenarios, and sketches to provide as inputs to participants at the following design session. Following the design session's completion, we will adapt the CHAT for dementia care, applying input from the final design session, and performing member checking by reviewing changes with members from the groups. This process will produce a converged-upon D-CHAT that is ready for stage 1B feasibility testing [21].

Phase 2—Main Trial

Setting and Sample



This single-blind pilot randomized controlled trial [28] will occur on medical and surgical units at a large academic health care system in the Midwest. This system serves more than 700,000 patients each year with approximately 1849 physicians and 21,000 staff at 7 hospitals. Care partners will be asked to participate if they meet the following inclusion criteria: (1) provide unpaid care to a hospitalized adult relative or partner to help them take care of themselves because of a dementia diagnosis, (2) be at least 18 years or older, and (3) speak and understand English. Care partners of hospitalized adult relatives or partners that are observation or same-day stay patients will be excluded. There will be no exclusion based on sex, gender, race, or ethnicity.

Training, Informed Consent, and Screening

Before recruitment begins, we will provide training on the D-CHAT to clinicians in medical and surgical units. To reduce contamination [29], we will instruct trained clinicians to not use the D-CHAT when treating those in the control arm and to not discuss details of the D-CHAT with nontrained clinicians. Once this training is completed, a member of the study team will work with unit coordinators to schedule morning, afternoon, and evening shifts for data screening, consent, and data collection. Institutional review board approval will be obtained to access electronic health records of hospitalized people living with dementia. We will use electronic health records to identify patients who have a documented care partner (or legally authorized representative). Someone who is part of the patient's care team will then approach the patient's present care partners to determine their interest in the study. If a care partner expresses interest in participating, a study team will then share study details, obtain written consent, and complete the baseline visit (see Figure 2). A member of the study team will monitor protocol deviations like unintended crossovers by completing weekly, in-person check-ins with the trained clinicians.

XSL•FO
RenderX

Figure 2. Main trial flow diagram. D-CHAT: Dementia Care Partner Hospital Assessment Tool.

Baseline Visit

The baseline visit will be completed in a designated room in the hospital to limit distractions. After completing consent, participants will complete descriptive measures and the primary clinical outcome measure (see Table 2). All measures will be administered by a trained, blind assessor. Immediately after these procedures, participants will be randomized to either the intervention or control group, and the clinical team will be notified of the assignment. These efforts will minimize bias and increase internal validity [28].

Table 2. Measures.

Study measures	Instrument	Collection method	Time points	
			1[a]	2[b]
Clinical outcomes				
Preparedness for caregiving	The Preparedness for Caregiving Scale	Self-report	✓	✓
Satisfaction of care	Hospital Consumer Assessment of Health care Providers and Systems	Self-report		✓
Burden	Zarit Burden Interview	Self-report	✓	✓
Depression	Patient Health Questionnaire-2	Self-report	✓	✓

[c]D-CHAT: Dementia Care Partner Hospital Assessment Tool.

XSL•FO
RenderX

Intervention

Care partner participants randomized to the intervention group will receive the D-CHAT and usual care delivered through the patient's care team. Aftercare partners complete the D-CHAT, and their responses will be given to the unit coordinator to review and make suggested referrals to specified clinicians. These clinicians then use the responses to develop and complete information and skill preparation with the care partners. For example, the D-CHAT could reveal that a care partner does not have the necessary diabetes knowledge or skill set to help give her husband living with Alzheimer disease and diabetes his insulin injections. Information gleaned from the D-CHAT would trigger a diabetes care and education specialist to address the care partners' caregiving needs.

Usual Care Control

The comparison condition will be the usual care that hospitalized people living with dementia and their care partners receive as part of the large academic health care system. No standardized clinical decision-support tool that facilitates the identification and preparation of care partners is currently used for routine hospital-based dementia care. These care partner participants will complete the same measures as participants in the intervention condition on the same timeline using identical assessment procedures.

Measures

Participants will be assessed on the measures listed in Table 2. Participants will be compensated US $25 after each time point is completed. Baseline measures will be collected in person at the hospital, and follow-up assessments will be administered via phone by a study team member. The primary clinical outcome we will measure is a change in care partner preparedness. The Preparedness for Caregiving Scale [30] is a self-rated measure that consists of 8 items that ask care partners how well prepared they believe they are for multiple domains of caregiving. Preparedness is defined as perceived readiness for multiple domains of the caregiving role, such as providing physical care, providing emotional support, setting up in-home support services, and dealing with the stress of caregiving. Responses are rated on a 5-point scale, with scores ranging from 0 (not at all prepared) to 4 (very well prepared). The scale is scored by calculating the mean of all items answered with a score range of 0 to 4. The higher the score, the more prepared the care partner feels for caregiving. The items have an internal consistency rating of 0.88 to 0.93. We will also collect secondary outcome measures, including satisfaction of care, caregiving burden, and depression, using standardized measures.

Sample Size Justification

An estimated sample size of 128 will be recruited for the main trial based on the 95% CI width around the effect of the D-CHAT on care partner preparedness as measured by the Preparedness for Caregiving Scale [31]. Since this is a novel tool that will be adapted as part of phase 1, the variability of the response is unknown, and therefore justification is based on general terms of SD. With 64 subjects in both groups, the 95% CI width of the estimated effect will be 0.35 × SD. We expect to see a medium effect size (Cohen d=0.5). With this 95% CI width and expected effect size, we will have a sufficiently narrow CI of the true effect size to apply toward the planning of the future efficacy trial. If there was a ≈12% loss to follow-up such that 56 in each group have follow-up data, the 95% CI width would only increase to 0.375 × SD.

Data Analysis

Analyses will be conducted using SAS (SAS Institute Inc) [32]. We will screen univariate distributions for normality and influential outliers and confirm that the randomization process balanced demographic characteristics between groups. We will also document the number of participants who are lost in each group, the reasons for the loss, and unintended crossovers. This information will influence the design of a future trial, including the frequency and mode of communication with clinicians and participants. The effect of the D-CHAT on care partner preparedness will be estimated as the difference in mean change from baseline to study completion between groups. The 95% CI will be calculated using a t distribution. Cohen d effect size will be calculated as the effect of the D-CHAT divided by the pooled standard deviation. This will give us a sense of the magnitude of the effect in terms of SDs. If normality assumptions in the raw data are not met and a simple transformation of the data (logarithmic or square root) does not sufficiently normalize the distribution, then we will use a nonparametric equivalent methodology [33]. If greater than 10% of the participants are noncompliant with their group assignment, then a per-protocol sensitivity analysis will be conducted to assess how influential the noncompliance was on the results of the study. Noncompliance is based on whether the group assignment was followed.

Results

We anticipate this study to take approximately 60 months to complete, from study start-up procedures to dissemination. The 2 phases will take place between December 1, 2022, and November 30, 2027. We expect the following results:

- Phase 1—formative research: Results will provide a converged-upon, ready-for-feasibility testing, D-CHAT, to guide clinicians' identification and preparation of care partners in hospital care of people living with dementia. The D-CHAT will include caregiving domains unique to dementia caregiving and discipline-specific treatment to meet the needs of care partners.
- Phase 2—main trial: A total of 128 eligible care partners of hospitalized people living with dementia will be randomized into either the D-CHAT plus usual care or usual care-only groups. Descriptive and feasibility characteristics for delivering the D-CHAT will be collected. We expect that care partners who receive the D-CHAT will demonstrate larger improvements in caregiving preparedness than those in the usual care group.

Findings from both studies will be disseminated following best practices throughout the conduct of this research. The study is registered at ClinicalTrials.gov in accordance with current National Institutes of Health (NIH) policies and federal regulations (NCT05592366). Results will be posted to

XSL•FO
RenderX

ClinicalTrials.gov within 12 months of study completion. Across all stages of the research, we will publish peer-reviewed papers and present our findings at conferences attended by researchers and clinicians in diverse and relevant fields. We will also share the results of this study directly with relevant and interested parties by developing infographics. These will be distributed through dementia caregiving networks and established partnerships.

Discussion

Lack of caregiving preparedness is prominent and persistent among care partners of people living with dementia and is associated with increased risk for adverse clinical outcomes for people living with dementia [2,3] and increased levels of burden, depression, and morbidity for care partners. While clinical decision-support tools offer a valuable resource for addressing this gap in practice, no tool exists to guide the systematic identification and preparation of care partners for hospitalized people living with dementia [16].

We will involve a broad range of individuals in the participatory co-design process to create a converged-upon, ready-for-feasibility testing D-CHAT. Moreover, we will use the novel clinical decision-support tool to facilitate the timely identification and preparation of care partners during hospital-based care delivery processes. This work will help bridge the gap between recommendations or policy and practice by providing clinicians with guidance on how to identify and better prepare care partners for hospitalized people living with dementia.

The control group will be randomized to usual care delivered by medical and surgical acute care teams at 1 large academic medical system. While we realize that these teams could prepare care partners for people living with dementia without intervention, we consider the D-CHAT to be more of an individualized care approach that systematically and comprehensively identifies and prepares care partners to fulfill their caregiving responsibilities after the patient discharges from the hospital. The intervention may be seen as burdensome by some clinicians. Our protocol has plans in place to train clinicians on the D-CHAT to ease workflow demands prior to beginning the main trial phase. We are also aware of the potential for measurement bias in the study design (ie, care partners may underreport caregiving needs and preparedness). Therefore, this issue will be discussed during the formative research phase and brought up in the co-design process to develop the best approaches to minimize these potential concerns. We also recognize that hospitals may enforce visiting restrictions at any given point because of the COVID-19 pandemic. For this reason, we have collaborated with research directors and clinical nurse scientists at the academic medical system to identify ways to adapt our data collection and communication approach so that we minimize the potential risks to both hospitalized people living with dementia and their care partners.

Engaging diverse and interested parties to adapt the standardized CHAT for hospital-based dementia care will expand its potential reach. Further, findings from this pilot randomized controlled trial will enable future efficacy trials to advance the refinement and implementation of the decision-support tool that can enhance caregiving preparedness and improve health outcomes after hospital discharge [34]. We anticipate that the resultant D-CHAT will provide clinicians with guidance on how to identify and better prepare care partners for hospitalized people living with dementia. In turn, care partners will feel equipped to fulfill caregiving roles for their family members or friends living with dementia.

Acknowledgments

We especially acknowledge the considerable influence of Drs. Juleen Rodakowski, Richard Schulz, Lauren Terhorst, and Ms. Madelyn Carbery on the development of the Care Partner Hospital Assessment Tool. This work is supported by the National Institute on Aging (1K23AG080068-01). We want to thank the University of Wisconsin Hospitals and Clinics, the Center for Aging Research and Education, and the Alzheimer Disease Research Center for partnering with us in this work. We also want to thank Anne Mortensen for her ongoing support in project management.

Data Availability

The data sets generated during or analyzed during this study will be available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Veterans with psychiatric disorders want additional career development services to support their recovery and pursuit of meaningful employment. However, no career counseling programs have been designed for this specific population. We developed the Purposeful Pathways intervention to fill this need.

Objective: This study protocol aims to (1) evaluate the feasibility and acceptability of the Purposeful Pathways intervention for veterans living with psychiatric disorders and (2) explore preliminary clinical outcome data.

Methods: A total of 50 veterans who are participating in transitional work vocational rehabilitation services at a Veterans Affairs hospital will be randomized to either treatment as usual or the augmented treatment condition (treatment as usual plus Purposeful Pathways). Feasibility will be assessed via recruitment rates, clinician fidelity to treatment, retention rates, and acceptability of randomization procedures. Acceptability will be assessed via client satisfaction at treatment termination using quantitative and qualitative data collection. Preliminary clinical and vocational outcomes will be assessed at baseline, 6 weeks, 12 weeks (treatment termination), and a 3-month follow-up via quantitative measures assessing vocational functioning, vocational process, and mental and physical functioning.

Results: This pilot randomized controlled trial is beginning recruitment in June 2023 and is expected to continue through November 2025. Data collection is expected to be completed by February 2026, with full data analysis completed by March 2026.

Conclusions: Findings from this study will provide information on the feasibility and acceptability of the Purposeful Pathways intervention, as well as secondary outcomes related to vocational functioning, vocational process, and mental and physical functioning.

Introduction

Background

Meaningful employment is consistently associated with the health and well-being of individuals living with mental health conditions [1-3], yet veterans living with psychiatric or substance use disorders often experience high levels of unemployment or underemployment [4-7]. To address this problem, the Veterans Health Administration (VHA) offers robust vocational rehabilitation programming that has helped countless veterans with psychiatric disorders obtain competitive employment. The most widely used vocational rehabilitation service within VHA is transitional work (TW) [8]. While the TW intervention varies across Veterans Affairs (VA) health care settings, it usually provides veterans with rapid access to time-limited, paid work experiences provided by VA departments, other federal agencies, or community employers through partnerships with the VA. Positions are typically housed in the VA (eg, housekeeping, grounds, kitchens, and construction) but are sometimes located in the community. To be eligible for TW, a referral needs to be made by a health care provider, and the veteran must have a vocational and clinical problem.

Research examining participation outcomes in TW has demonstrated that consumers are more likely to engage in paid activity, work more total hours, work more weeks, and earn more in total wages compared to individuals receiving state-funded vocational rehabilitation services [9]. However, research also finds that TW may not be effective at helping veterans find and secure competitive employment, even though this is a goal of the TW program [8,9]. A recent study of national TW data (N=38,199) found that only 34.8% of veterans participating in TW at a community-based job site, and 30.3% of veterans participating in TW at a VA-based site, were competitively employed at discharge [8]. Additional interventions may be needed for veterans in TW to support their employment functioning.

Ancillary vocational services such as prevocational assessment and job clubs have been shown to increase the odds (1.12 and 1.32 odds ratios, respectively) of veterans securing competitive employment when paired with a main VHA Vocational Rehabilitation Services program such as TW [8]. Given this finding, researchers recommend evaluating the impact of ancillary vocational interventions on competitive employment outcomes of veterans when paired with TW [8]. This recommendation is aligned with the voices of veterans living with psychiatric disorders who report wanting ancillary vocational services such as vocational assessment and career planning to help support their pursuit of meaningful employment and their mental health and substance use recoveries [10,11].

The overarching goal of this study is to develop and evaluate a career counseling protocol to promote vocational outcomes for veterans living with psychiatric disorders. This study consists of three phases: (1) treatment development, (2) treatment refinement through an open trial, and (3) evaluating feasibility through a pilot randomized controlled trial (RCT). The first 2 phases of this study were completed between April 2021 and February 2023 and are discussed below.

Prior Work

During the first phase of this treatment development and evaluation project, our team conducted qualitative focus groups among veterans in TW (n=6), as well as among TW providers (n=7), to better understand the career development needs of veterans engaged in vocational rehabilitation services [12]. An advisory panel of practitioners, researchers, academic scholars, and administrators with expertise in vocational rehabilitation, career development, or treatment manualization (n=12) reviewed the findings from these focus groups and synthesized the results across the best available research and clinical practice. Collectively, four major treatment mechanisms emerged: (1) career exploration, (2) goal clarity, (3) job-searching skills, and (4) self-regulation skills.

A preliminary treatment manual was developed to address the 4 major treatment mechanisms identified. The preliminary manual was then reviewed by the 7 TW providers who previously participated in 1 of 2 focus groups. These providers offered suggestions for editing the manual. These suggestions were reviewed by the principal investigator (PI), a coinvestigator, and a research assistant and then used to revise the treatment manual. Modifications included developing additional handouts and worksheets for veterans to complete during treatment, offering more clinical case examples within the manual, and using more inclusive language.

During the second phase of our project, we conducted an open trial in which 10 veterans in TW received the newly developed career development intervention. The PI provided the treatment and maintained process notes on each session. After study completion, veterans provided qualitative feedback to a research assistant about their experiences in the intervention. In total, 7 veterans completed this exit interview, with 3 lost to follow-up. Generally, veterans provided positive feedback about the intervention. Minor adjustments were made to the manual based on their feedback, which focused on helpful counselor qualities and approaches rather than the intervention content. The PI completed a final version of the treatment manual in consultation with 2 expert consultants who previously participated on the treatment development advisory panel.

Description of the Purposeful Pathways Intervention

Purposeful Pathways is a manualized intervention to assist veterans in aspiring and pursuing meaningful employment.

XSL•FO
RenderX

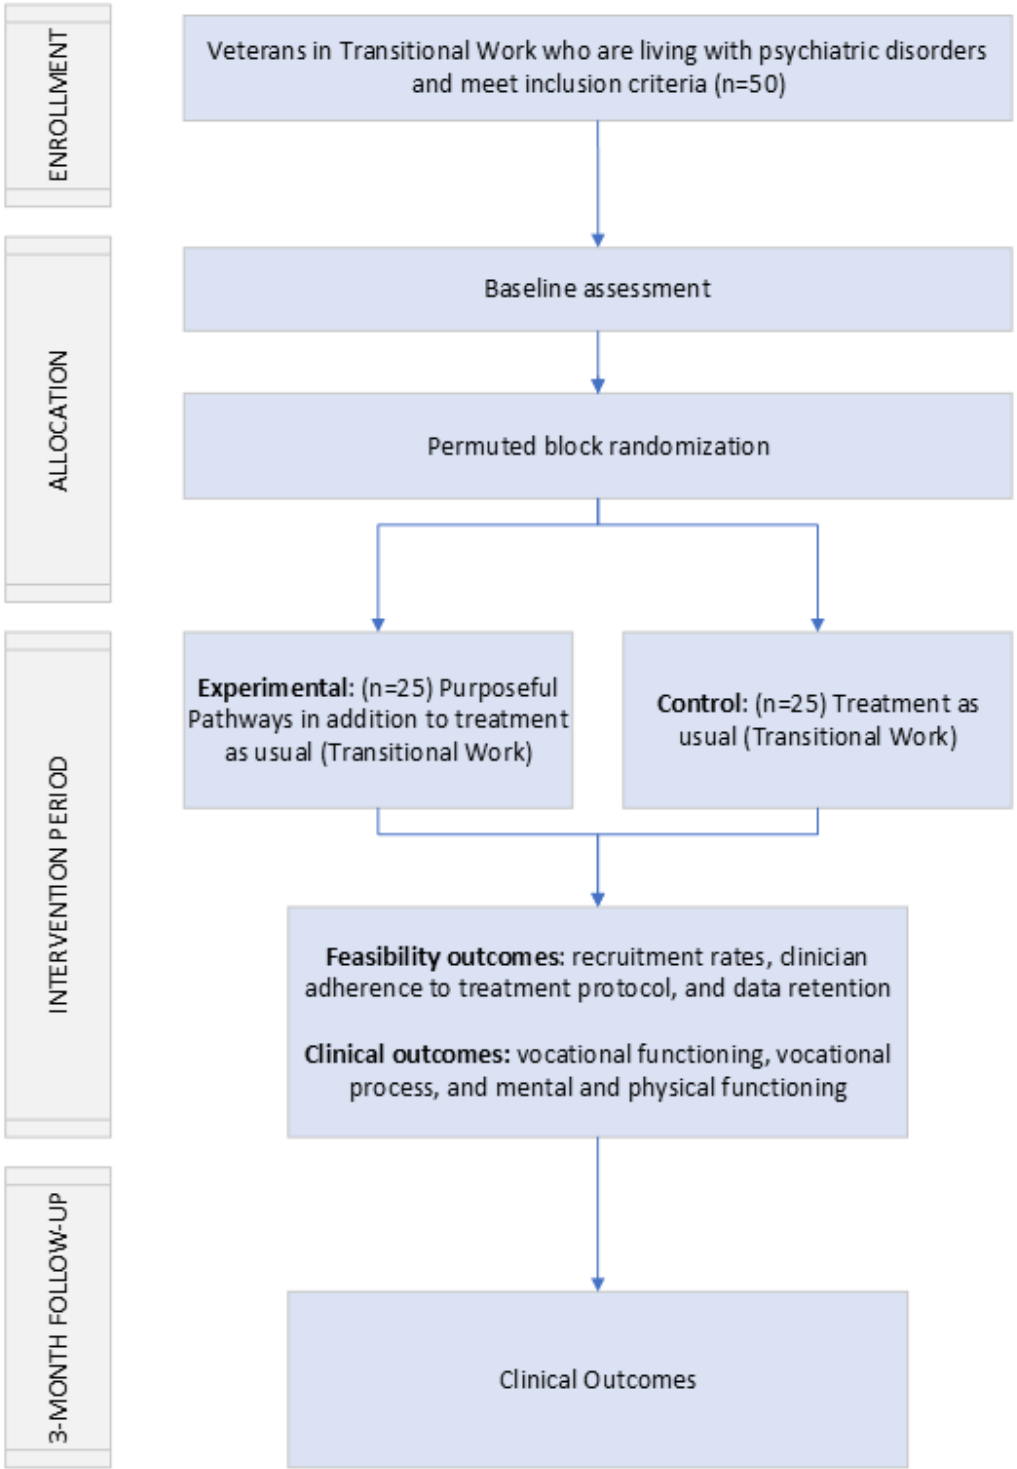
Purposeful Pathways is an individual counseling protocol delivered weekly for up to 12 sessions (50 minutes per session). The intervention is divided into three sections: (1) introductory sessions (up to 3 sessions), (2) middle sessions (up to 8 sessions), and (3) discharge planning sessions (at least 1 session). In the introductory sessions, the counselor engages the veteran in developing a therapeutic bond and collaboratively developing a treatment plan. During these sessions, the counselor focuses on introductions, reviewing the context of the treatment, establishing the treatment orientation, providing psychoeducation on career development, gathering a comprehensive vocational history, exploring the veteran's desired vocational outcomes, and collaborating on a shared understanding of the goals of their work together. In the middle sessions, the counselor and client work on 1 or all 4 of the following: career development tasks, career exploration, goal clarity, job-searching skills, and self-regulation skills. The choice of interventions is collaboratively decided upon between the counselor and veteran based on the veteran's needs and preferences. The counselor uses cognitive behavioral therapy and motivational interviewing strategies throughout the implementation of the various interventions, such as open-ended questions, affirmations, reflections, summaries, and motivating behavior change. Career exploration includes identifying the veteran's preferences, connecting the veteran's preferences to the world of work, identifying needed occupational accommodations, and working through indecision. Goal clarity includes developing a visual goals map (ie, developing a plan for achieving one's occupational goals). Job-searching skills include job-searching strategies, resume writing, and interviewing skill-building. Self-regulation skills include recognizing distractions, opportunities, and roadblocks to reaching employment goals, skills for sustaining career development over time, immediate coping skills for managing distress during recovery, and developing a vocational coping plan (ie, a plan for managing distress on a worksite). The final section of the manual, the Discharge Planning section, focuses on helping a veteran synthesize what they have learned in therapy and planning for their recovery once therapy ends. Discharge planning includes reviewing therapist and veteran perceived progress made toward goals, planning for booster sessions, and facilitating warm handoffs to additional treatment, as needed.

This Study

This protocol represents the third and final phase of this treatment development and evaluation study. This third phase aims to (1) evaluate the feasibility and acceptability of the Purposeful Pathways intervention among veterans living with psychiatric disorders and (2) explore preliminary clinical outcome data. To accomplish this aim, we will conduct a pilot RCT comparing Purposeful Pathways to a treatment as usual (TAU) control condition with a 3-month follow-up. This study has received approval from a local VA Institutional Review Board, and the protocol has been registered with clinical trials and will begin recruitment in June 2023.

Methods

Recruitment



In total, 50 veterans participating in a VHA TW vocational rehabilitation program will be recruited for this study. Inclusion criteria will include (1) eligible for and planning to enroll in TW, or within 16 weeks of having enrolled in TW; (2) the presence of a current psychiatric disorder, such as posttraumatic stress disorder, mood disorders (eg, bipolar disorders and major depression), anxiety-related disorders (eg, generalized anxiety disorder, panic disorder, agoraphobia, and obsessive compulsive disorder), psychotic disorders (eg, schizophrenia and schizoaffective disorder), substance use disorders (eg, alcohol, opioid, cannabis, cocaine, sedative, hypnotic or anxiolytic, and other stimulants), which is indicated by an International Classification of Diseases-10 diagnosis encounter in the participants' VA medical record within the last 6 months, inputted by a licensed mental health provider (psychiatrist, psychologist, licensed clinical social worker, and psychiatric nurse practitioner); (3) self-identification as either unemployed, underemployed (self-report of falling into 1 of 5 categories: overeducated, job-education mismatch, skill underuse, being involuntarily engaged in part-time, temporary, or intermittent employment [ie, hours underemployed], or earning wages in a job that are 20% less compared to a previous job, or for recent college graduates, earning wages that are 20% less compared to graduating peers of similar education or training [ie, pay underemployment] [13]), or self-report that they are employed but functioning poorly at work as a result of mental illness or substance use; (4) self-identification as not being on leave from a job for which there are arrangements to return to their job following the completion of TW; (5) having plans to work for 3 years beyond the end of this study; and (6) competency to provide written informed consent.

Exclusion criteria will include (1) acute suicide or homicide risk requiring treatment focused on safety to self or others based on self-report of current and active thoughts of harm to self or others with intent and plan that requires crisis stabilization in an acute psychiatric unit; (2) being not otherwise eligible for TW services; (3) current enrollment in compensated work therapy supported employment services; (4) Symptom Checklist-6 [14] score greater than 26; (5) Veterans RAND-12 physical component score [15] less than 12, and Veterans RAND-12 mental composite score [15] less than 8; (6) improbability that participant will complete the study for the following reasons: expected deployment, expected incarceration, expected long-term hospitalization, or expected relocation from the vicinity of the participating VA during the study period; and (7) unwillingness to engage in a weekly career development intervention.

Veterans who are eligible and complete the informed consent procedures will be randomized to 1 of 2 study arms: the treatment condition (n=25) or the control condition (n=25). An overview of the design of this pilot RCT is presented in Figure 1.

XSL•FO
RenderX

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram of the work trial.

Randomization Procedures

To ensure equal distribution across the intervention and control conditions, a permuted block randomization method will be used. Randomization will use computer-generated numbered lists, one for each condition (treatment and control). The lists will be generated through a block design where the block sizes are randomly selected among block sizes of either 4 or 6. There will be 5 rounds of each block size to randomize the 50 veterans into either the treatment or control condition. With this approach, every study arm assignment on the randomization list will consist of an even number of treatment or control assignments in random order. This approach has been discussed by previous researchers as guaranteeing balance in the 2 conditions while also ensuring that researchers are unable to predict the treatment sequence as they will not know if the block size is 4 or 6 [16]. This procedure will result in 25 participants per condition, which is in line with the recommendations of Rounsaville and colleagues [17], who suggest that each treatment condition in a stage 1b clinical trial should have at least 15 subjects. Subjects randomized to the treatment group will receive the Purposeful

XSL•FO
RenderX

Pathways intervention in addition to TAU. Subjects randomized to the control group will only receive TAU.

Participation in TAU

Both the experimental and the control condition will participate in TAU through TW. Upon admission into TW, veterans are quickly placed into a paid work setting, either at the VA hospital or in the community. There are minimal formal assessment or other vocational services prior to a veteran being placed into a worksite. TW program staff, which can range from peer support staff to master's-trained vocational counselors, provide some on-site and off-site job coaching to help veterans maintain their TW placement, in addition to some guidance on competitive job searching. TW program staff tend to have caseloads of 25-40 veterans [9].

Experimental Intervention

Veterans randomized to the experimental condition will augment their experience in TW with the Purposeful Pathways intervention. This intervention will be delivered to the veteran by a master's-level mental health clinician. This intervention will be delivered on an individual basis for up to 12 sessions (depending on the unique needs and experiences of the veteran-client). The intervention has been designed to be delivered face-to-face or through web-based telehealth platforms, depending on the preferences of the veteran-client.

Therapist Recruitment and Training

The PI will recruit and train at least 4 master's- or doctoral-level mental health clinicians in the delivery of Purposeful Pathways (2 clinicians per 15 months). Clinicians will have specialized training in clinical social work, counseling, or clinical psychology. Before implementing Purposeful Pathways, therapists will participate in a 6-hour training workshop held over 2 or 3 days. The training workshop will be facilitated by the PI of the study.

Therapist Adherence

There will be multiple fidelity checks to ensure treatment adherence among study clinicians. After completing the initial 6-hour training workshop, study clinicians will be required to attend weekly group consultations with the PI (1 hour per week) for the first 3 months of providing treatment to address technical issues in the provision of the manual. Additionally, all Purposeful Pathways sessions will be video recorded, and these sessions will be reviewed and rated (on a variable time schedule) for treatment adherence by 2 staff researchers using a fidelity checklist system, which includes both process and content variables necessary for treatment. Once a session is rated, researchers will provide in-person, individual feedback to clinicians.

Assessment Measures and Timeline

A variety of clinical outcomes will be assessed at baseline, 6 weeks, 12 weeks (treatment termination), and at a 3-month follow-up. Subjects will be compensated US $40 for completing the baseline assessment, US $40 for the completing assessment at week 6, US $80 for completing the assessment and exit interview at treatment termination or week 12, and US $40 for completing the assessment at a 3-month follow-up for a possible total compensation of US $200. Table 1 provides an overview of the administration schedule for the planned measures. Descriptions of each measure are provided after Table 1.

A demographic questionnaire will be used at the screening to gather basic demographic information. Information gathered will include age, gender, race, level of education, service-connected percentage, service-connected condition, receipt of disability pensions, housing stability, and history of substance abuse.

A vocational functioning questionnaire will gather common employment outcome information. The following employment outcomes will be assessed: (1) the mean number of jobs acquired, mean duration of each job acquired, mean pay rate, and total pay per job; (2) the total weeks worked and total hours worked during the follow-up period (if relevant); and (3) the total earned income.

Table 1. Timeline of measures.

XSL•FO
RenderX

Confidence and importance rulers are common tools used in motivational interviewing and cognitive behavioral therapy protocols to assess levels of confidence and importance related to a specific goal. For the purposes of this study, the specific goal would be to "find meaningful employment." On a scale of 1-10, participants will be asked to rate their level of confidence from 0 ("not at all confident") to 10 ("extremely confident") and the level of importance to them from 0 ("not at all important") to 10 ("extremely important") to find meaningful employment. Evidence of reliability and validity has been documented by others [18].

The Job Search Intensity Scale [19] will be used to assess the level of time one spends on various job-search activities. This 9-item measure asks respondents about the following job-search activities: preparing or revising resumes, reading classified or help wanted advertisements, looking for jobs on the internet, talking with friends or relatives about job leads, speaking with previous employers or business acquaintances about job leads, contacting employment agencies, making inquiries to prospective employers, sending out application letters, and preparing and going on job interviews. Responses to each activity are measured on a 5-point Likert-type scale to assess the amount of time spent on each activity. Possible scores for each item range from 1 ("no time at all") to 5 ("very much time"). A previous study found this measure to be valid and reliable [19].

The Career Adapt-Abilities Scale [20] will be used to measure one's level of career adaptability, a commonly used measure of career readiness. This is a 24-item measure that is grouped into 4 different subscales that capture total adaptability along with 4 dimensions—concern, control, curiosity, and confidence. Respondents are asked to rate how strongly they have developed each of these strengths using a 5-point Likert-type scale. Responses range from 5 ("strongest") to 1 ("not strong"). This is a widely used measure in the fields of vocational psychology and career development, with evidence of good validity and reliability [20].

The Vocational Identity Scale (VIS) [21] will measure the extent to which an individual possesses a clear and stable understanding of his or her goals, interests, and talents as related to vocational decisions. The VIS consists of 18 true or false items that ask respondents to identify whether the statement is mostly "true" or mostly "false." A respondent's total number of "true" responses makes up their final score (range 0-18), with higher scores indicating greater career indecision and lower scores indicating more crystallized vocational decidedness. The VIS is extensively used in vocational psychology literature and has undergone extensive psychometric analysis that has demonstrated validity and reliability as a measure of career indecision [22] and has been used in other studies among individuals with psychiatric disorders [23].

The Decent Work Scale [24] will be used to assess the quality of one's job with respect to (1) physically and interpersonally safe working conditions, (2) access to health care, (3) adequate compensation, (4) hours that allow for free time and rest, and (5) organizational values that complement family and social values. The scale is comprised of 5 subscales (based on the factors of decent work just described) and a total scale score. This self-report measure consists of 15 items on a 7-point Likert scale, ranging from "strongly disagree" to "strongly agree" with higher scores indicating greater levels of decent work. The Decent Work Scale has evidence of reliability and validity among employed adults [24].

The Work Needs Satisfaction Survey [25] will be used to measure one's satisfaction with their employment in terms of meeting their survival or power, social connection, and self-determination needs. This is a 20-item measure that prompts respondents to rate an item on a 7-point scale ranging from "strongly disagree" to "strongly agree." Evidence of validity and reliability was demonstrated by the scale developers [25].

The Quality of Life Enjoyment and Satisfaction Questionnaire–Short Form [26] will be used to measure general psychiatric functioning. The Quality of Life Enjoyment and Satisfaction Questionnaire–Short Form is a 16-item self-report measure of perceived functioning and is one of the most widely used outcome measures in psychiatric research. Reliability and validity of this measure have been extensively documented.

The Sheehan Disability Scale [27] will measure the level of functional impairment due to mental health and medical impairments. This self-report measure asks raters to how much their work or school, social life, and home life or family responsibilities are impaired by mental and medical symptoms. This is a 5-item measure using a 10-point visual analog scale. The Sheehan Disability Scale has received extensive psychometric testing for validity and reliability [27].

The Client Satisfaction Questionnaire–8 (CSQ-8) [28] will be used to measure satisfaction, perceived quality, and effectiveness of the treatment. This self-report questionnaire consists of 8 items, scored 1-4, with higher scores indicating higher satisfaction with treatment. The CSQ-8 has been used in mental health and other health centers and has acceptable internal consistency (α=.83 to .93) [28].

In addition to the above measures, subjects will complete a semistructured 30-minute exit interview at treatment termination or 12 weeks. This semistructured interview will be conducted by a researcher not involved in the delivery of treatment. These interviews will be recorded and transcribed for later analysis. The following content areas will be assessed through this interview: (1) general thoughts or experiences with treatment, (2) perceived benefits of participating in treatment, (3) specific changes and outcomes obtained because of participating in treatment, (4) perceived limitations of the treatment, and (5) recommendations for enhancement and improvement of services. We will also ask open-ended questions about the usability of measures and assessments.

Data Analysis

Primary analyses will involve the examination of the feasibility and acceptability. Feasibility will be verified by adequate (1) recruitment rates (ie, 2-3 veterans per month), (2) >90% fidelity of clinician adherence to the treatment protocol, and (3) data retention (ie, ≥70% of participants who attend at least 6 sessions of Purposeful Pathways. An acceptable level of attrition will be 30% in each condition). We will also examine the

XSL•FO
RenderX

willingness of veterans to be randomized with a goal of 80% of those approached who agree to randomization, the number of referrals from clinicians, ease of recruitment based on the average number of contacts needed to get consent, and the number of eligible participants from the pool of potential participants. We will compare veteran acceptability between groups by conducting an independent samples *t* test on the CSQ-8 [28]. We will compare attrition rates (<30% vs >30%) between the 2 groups using a chi-square and logistic regression analysis.

Qualitative data gathered during the exit interviews will be analyzed using the Hamilton Rapid Turn-around Analytic Approach [29]. This technique is suited to short-term projects using targeted interview guides. It improves on past rapid procedures through its systematic, rigorous approach, yielding results that are slightly less nuanced but more efficient. The PI will develop an analytic template organized by the topic areas from the semistructured interview guiding qualitative interviews. The PI and at least 2 other researchers will apply the template to summarize 2 interviews to test the usability and relevance of the template to the transcripts. The research team will then meet to establish consistency in how the template is used to summarize the transcripts. From here, all focus groups will be individually summarized (each focus group will be analyzed by at least 2 researchers to ensure reliability). The PI will then transfer all the summary points into a master matrix (respondent × topic area). Next, the PI will condense the summaries in the master matrix by identifying and organizing recurring themes. The other members of the research team will review the condensed matrix to the original master matrix to confirm all central themes have been identified and ensure consensus.

Finally, we will examine differences in our clinical and vocational measures to identify empirical targets for further refinement of the treatment and inform the design of future, fully powered efficacy trials. Based on the intent-to-treat principle, all participants randomized to treatment will be included in analyses. We will run descriptive statistics as well as internal reliability (Cronbach α) for all measures. We will additionally examine the Pearson *r* to look at relationships between variables, Cohen *d* for any continuous measures, and Cramer *V* for any categorical measures to look at effect size. We will also look at individual trajectories of response to gain better insight into which participants do particularly well (or poorly) in the 2 interventions. Effect sizes and 95% CIs will be used as only 1 element to estimate the power and sample size needed for future efficacy trials.

Ethical Considerations

All phases of this study were approved by the institutional review board of the VA Bedford Health Care System Research and Development Committee in Bedford, Massachusetts, United States, with initial approval granted in February 2021. This pilot trial was registered at ClinicalTrials.gov (NCT04698967).

Results

This study was funded in October 2020, with a project start date of April 2021. Participant recruitment for this phase 3 pilot RCT began in June 2023. We anticipate study recruitment to be completed by November 2025 and primary data analysis completed by March 2026.

Discussion

Anticipated Findings

This pilot randomized control trial will provide feasibility and acceptability data for the Purposeful Pathways intervention, a manualized intervention to assist veterans in aspiring and pursuing meaningful employment. This pilot RCT will also provide data regarding the feasibility of the protocol procedures, which can help inform future efficacy trials. Finally, the findings will produce preliminary data regarding significant effects on specific outcome measures, which will inform further refinement of the treatment protocol and the development of future efficacy trials.

Conclusions

Meaningful employment is associated with the health and well-being of individuals living with psychiatric disorders [1-3]; however, the benefits gained from meaningful employment extend to few veterans, who as a group face high levels of un- and underemployment [4-7]. While previous research has shown that an integration of services like vocational assessment along with a primary VHA vocational rehabilitation program improves the likelihood of veterans obtaining competitive employment [8], there remains a gap in our knowledge of evidence-based approaches to such services. This pilot study addresses this critical need for evidence-based career counseling and development services for veterans living with psychiatric disorders. The trial will serve as the first step in testing whether enhancing VA vocational rehabilitation services with a concurrent, targeted career counseling and development protocol is feasible and acceptable for veterans with psychiatric disorders, as well as initial estimates of potential benefits.

Acknowledgments

Abstract

Background: Binge eating (BE), characterized by eating a large amount of food accompanied by a sense of loss of control over eating, is a public health crisis. Negative affect is a well-established antecedent for BE. The affect regulation model of BE posits that elevated negative affect increases momentary risk for BE, as engaging in BE alleviates negative affect and reinforces the behavior. The eating disorder field's capacity to identify moments of elevated negative affect, and thus BE risk, has exclusively relied on ecological momentary assessment (EMA). EMA involves the completion of surveys in real time on one's smartphone to report behavioral, cognitive, and emotional symptoms throughout the day. Although EMA provides ecologically valid information, EMA surveys are often delivered only 5-6 times per day, involve self-report of affect intensity only, and are unable to assess affect-related physiological arousal. Wearable, psychophysiological sensors that measure markers of affect arousal including heart rate, heart rate variability, and electrodermal activity may augment EMA surveys to improve accurate real-time prediction of BE. These sensors can objectively and continuously measure biomarkers of nervous system arousal that coincide with affect, thus allowing them to measure affective trajectories on a continuous timescale, detect changes in negative affect before the individual is consciously aware of them, and reduce user burden to improve data completeness. However, it is unknown whether sensor features can distinguish between positive and negative affect states, given that physiological arousal may occur during both negative and positive affect states.

Objective: The aims of this study are (1) to test the hypothesis that sensor features will distinguish positive and negative affect states in individuals with BE with >60% accuracy and (2) test the hypothesis that a machine learning algorithm using sensor data and EMA-reported negative affect to predict the occurrence of BE will predict BE with greater accuracy than an algorithm using EMA-reported negative affect alone.

Methods: This study will recruit 30 individuals with BE who will wear Fitbit Sense 2 wristbands to passively measure heart rate and electrodermal activity and report affect and BE on EMA surveys for 4 weeks. Machine learning algorithms will be developed using sensor data to distinguish instances of high positive and high negative affect (aim 1) and to predict engagement in BE (aim 2).

Results: This project will be funded from November 2022 to October 2024. Recruitment efforts will be conducted from January 2023 through March 2024. Data collection is anticipated to be completed in May 2024.

RenderX

Conclusions: This study is anticipated to provide new insight into the relationship between negative affect and BE by integrating wearable sensor data to measure affective arousal. The findings from this study may set the stage for future development of more effective digital ecological momentary interventions for BE.

Introduction

Binge eating (BE), characterized by perceived overeating accompanied by a subjective sense of loss of control over eating [1], is a public health crisis associated with significant psychological and physical morbidity [2-6]. The frontline treatment for BE, cognitive behavioral therapy, fails to produce remission in 40%-70% of individuals [7,8]. There is a clear need to better understand specific risk factors for BE that could be targeted to improve outcomes.

The affect regulation model of BE posits that affect dysregulation (ie, difficulty tolerating or regulating negative emotional states) is a significant, momentary risk factor for BE, as BE is negatively reinforced by the alleviation of negative affect that it facilitates [9-11]. Although the affect regulation model of BE has been substantiated in extant literature [12-14], there remain several unanswered questions about the role of affect in BE.

Existing literature examining affect as a momentary predictor of BE has exclusively used ecological momentary assessment (EMA) [12,13,15-20]. EMA methodologies for BE typically involve completing multiple daily surveys on a smartphone to report binge episodes and contextual risk factors for BE. Although EMA allows for the examination of within-day relationships between affect and BE, these surveys are completed only every few hours, which precludes the examination of minute-to-minute changes in affect [21]. The field has already identified some inconsistent findings on the role of affect in predicting BE that have been attributed to the inability to measure proximal changes to affect before and after BE with EMA [14-16,18-20,22,23]. For example, an individual may experience rapid-onset negative affect related to an event (eg, intense anxiety or sadness upon hearing bad news) and engage in BE to quell the negative affect within the span of minutes, in contrast to the hours-long timescale on which the relationship between EMA-measured affect and BE is typically examined. Thus, it is critical to examine continuously measured affect to uncover the timescale on which negative affect increases BE risk.

Existing research using EMA to study BE has also focused on only 1 of the 2 key aspects of affect, affective valence (ie, the extent to which an affective state is pleasant or unpleasant). Measuring markers of affective arousal (ie, the degree of associated physiological activity) alongside affect valence may improve prediction of BE, as affect arousal may increase eating-related disinhibition [24] and the aversiveness of negative affect states [25].

A novel data collection method that could address the limitations of EMA is ambulatory passive sensing. Sensors are likely to augment EMA for the real time measurement of affect as they permit objective, continuous, and passive measurement of biomarkers of affective arousal. The use of sensors to measure physiological correlates of affect will allow for the observation of affect trajectories immediately before, during, and after EMA-reported binge episodes. Sensor data may also be able to detect negative affect before the individual is consciously aware of it, potentially facilitating earlier detection of risk for BE. Passive sensors also require substantially lower user engagement than EMA, which may produce higher compliance with data collection and reduce the requisite frequency of EMA.

Established biomarkers of affect that can be measured by ambulatory sensors include heart rate, heart rate variability, and electrodermal activity [26,27]. These features are measures of sympathetic nervous system arousal (eg, elevated heart rate, increased electrodermal activity) and parasympathetic nervous system inactivation (eg, decreased heart rate variability), which are hallmarks of affective arousal. A substantial number of studies have identified reliable changes in heart rate, heart rate variability, and electrodermal activity associated with negative affect [28-35], but only 2 studies have used ambulatory sensors to assess heart rate variability prior to BE [36,37]. These studies found that heart rate was elevated, and heart rate variability decreased prior to loss of control eating episodes relative to nonloss of control eating episodes, offering preliminary evidence that these variables may be biomarkers of affect that confer BE risk [36,37]. However, these studies were conducted among adolescents and retrospectively compared heart rate indices prior to loss of control and nonloss of control eating episodes, rather than examining the accuracy of using heart rate data patterns to predict engagement in BE. Using passive sensors to collect momentary, naturalistic affective data is likely to improve our understanding of the role of affect in maintaining BE and our capacity to accurately predict future BE.

One challenge to the use of passive sensors to measure affect is that physiological arousal may also be elevated during some high-arousal positive affect states in addition to negative affect states. Some previous research using sensors to measure affective arousal has identified distinct physiological features associated with negative affect such as longer duration of physiological arousal [38], greater changes in electrodermal activity and heart rate, and greater variability in interbeat

XSL•FO
RenderX

intervals associated with negative affect compared to positive affect [27,35,39,40]. Furthermore, models have been developed that can distinguish negative and positive affect based on physiological parameters in healthy individuals [41,42]. Given the incredibly large and dimensional data sets yielded by sensors, these previously developed models have used machine learning, an analytic approach well-suited to predict an output (ie, negative or positive affect) based on several input variables (eg, heart rate variability and electrodermal activity). However, the capacity for these models of sensor data to distinguish negative and positive affect has not yet been established among individuals with BE. Existing research using psychophysiological sensors among individuals with BE has demonstrated elevated autonomic reactivity to psychological stress in these individuals [43-45]. However, obesity, which affects 28%-42% of individuals with BE [3], has been associated with reduced sympathetic activity [46,47]. Given these contradictory findings, it is important to establish whether sensors can distinguish negative and positive affect in this specific population. If passive sensors can distinguish between positive and negative affect states, these sensors will provide information about both the occurrence of negative affect and the intensity of physiological arousal associated with that affective state. Even if passive sensors cannot distinguish positive and negative affect, information about the intensity of affective arousal may still improve the capacity to detect risk for BE above EMA alone.

Importantly, the use of sensor technologies to improve the field's capacity to predict risk for BE offers transformative potential to power momentary interventions that target negative affect. Improved prediction of BE could facilitate the development of more effective just-in-time adaptive interventions that promote the use of therapeutic skills (eg, emotion regulation skills) when an individual is at identified risk for BE. Accordingly, this study will use psychophysiological sensors and EMA to measure negative affect to improve the prediction of BE. The study will evaluate whether the features extracted from passive sensor data can distinguish positive and negative affect in individuals with BE (aim 1). Consistent with previous research using sensors to distinguish positive and negative affect in healthy populations, we hypothesize that sensor features will distinguish between EMA-reported negative and positive affect with ≥60% accuracy [33]. Second, the study aims to develop and compare machine learning algorithms using sensor- and EMA-measured negative affect to predict BE episodes. We hypothesize that the combined sensor- and EMA-based machine learning algorithm will be more accurate for predicting BE than the algorithm using only EMA data. Based on past findings using sensors to predict emotional eating and dietary lapses, we hypothesize that the combined sensor and EMA algorithm will classify the occurrence of BE episodes with ≥70% accuracy [48,49].

Methods

Study Design

This study will use an observational design to examine real-time associations between affect (measured by psychophysiological sensors and EMA) and BE.

Participants

Participants will be 30 individuals with recurrent BE (defined as at least 12 BE episodes in the past 3 months); we will enroll participants with objective binge episodes, subjective binge episodes, or a combination of both, as both behaviors are hypothesized to be maintained via the affect regulation model. Participants will be eligible for this study if they are 18-65 years old, have a BMI of ≥18.5 kg/m^2, own a smartphone, and are willing to wear a smartwatch and complete EMA surveys for the 4-week study protocol. Exclusion criteria include inability to speak, read, and write English fluently, current eating disorder–focused treatment, and current, severe psychopathology that would inhibit engagement in study protocols (eg, active suicidality, psychosis, and substance use disorder). As antecedents for BE episodes are similar in bulimia nervosa, binge eating disorder, and other specified feeding and eating disorder diagnoses, individuals with any of these diagnoses will be eligible for the study provided they meet all other inclusion or exclusion criteria. We will aim to enroll 15 female (50%) and 15 male participants (50%). Furthermore, given that individuals with minoritized racial and ethnic identities have been underrepresented in eating disorders research, we aim to enroll at least 15 participants (50%) belonging to minoritized racial or ethnic groups.

Study Recruitment and Procedures

Participants will be recruited from across the United States using social media and radio advertisements and ResearchMatch. Participants will complete an initial phone screen, followed by a baseline assessment to confirm eligibility. Participants will complete the Eating Disorder Examination, a diagnostic interview, at the baseline assessment to confirm eligibility and assess BE frequency [50]. Once eligibility is confirmed, participants will be enrolled in the study and begin the data collection protocol. Participants will be oriented to the use of the smartwatch and completion of EMA surveys at the baseline assessment. Participants will then complete EMA surveys and wear the Fitbit Sense 2 smartwatch daily for 28 days. Participation will be fully remote, with assessments conducted using Drexel Health Insurance Portability and Accountability Act–compliant Zoom platform and Fitbit Sense 2 sensor watches mailed to and returned by participants via prepaid shipping labels. Informed consent will be obtained from all participants.

Ethics Approval

Study procedures have been approved and will be overseen by Drexel University's institutional review board (approval received September 2022; protocol number 2207009376). All procedures will be conducted in accordance with the Helsinki Declaration.

Measures

Psychophysiological Sensors to Measure Affect

Fitbit Sense 2 watches are wrist-worn devices that include several psychophysiological sensors, including photoplethysmography sensor, accelerometer, galvanic skin response sensor, and infrared thermopile. The heart rate features extracted from data collected by the photoplethysmography

XSL•FO
RenderX

sensor will include time domain features, including average heart rate and root mean square of successive differences between normal heart beats (a measure of average variability in heart rate), and frequency domain features, including high-frequency heart rate variability (a measure of parasympathetic activity), and low-frequency heart rate variability (a measure of sympathetic arousal). These components were selected as they have been shown to change during conditions of elevated affective arousal among individuals with BE in laboratory and ambulatory studies [36,43,45,51,52]. Electrodermal activity features to be extracted from galvanic skin response data are tonic skin conductance level (average skin conductance level) and skin conductance responses (number of spikes in skin conductance), as these indices increase during periods of elevated negative affect among individuals with EDs characterized by BE [52-54]. The Fitbit Sense 2 watches contain sensors similar to devices that have demonstrated high validity for the measurement of heart rate indices and acceptable validity for the measurement of electrodermal activity during stressors [54-56].

EMA-Measured Eating Behaviors and Affect

Participants will complete signal-contingent and event-contingent EMA surveys during waking hours to report affect and the occurrence of BE and non-BE episodes (see Multimedia Appendix 1 for EMA questions). Signal-contingent surveys will be sent 6 semirandom times per day via Ethica EMA software (Ethica Data) [57]. Participants will be instructed to complete event-contingent surveys whenever they engage in BE (defined as overeating accompanied by a sense of loss of control). Consistent with BE EMA literature [12,22,58], all surveys will include ratings of positive and negative affect using the Short-Form Positive and Negative Affect Schedule modified to also include guilt, joy, excitement, and satisfaction [59]. Guilt will be included, given its established relevance to risk for BE [18] and joy, excitement, and satisfaction will be included as these items have high face validity with positive emotions individuals endorse, do not overlap with already included positive and negative affect schedule items, and have been used in previous EMA research on BE [60]. These items will be rated on a 5-point scale (1=very slightly or not at all to 5=extremely) and instances where a participant rates an item greater than 1 SD above their mean level (computed from all EMA ratings across the full study period) will be considered an instance of high negative affect or positive affect.

Statistical Analyses

Aim 1

To evaluate aim 1, instances of high positive and high negative affect will be identified from EMA data; instances of concurrent high negative and high positive affect (if observed) will be excluded from analysis for aim 1, as binary classification machine learning models require mutually exclusive, binary outcomes [61]. Sensor features from the 30-minute period surrounding (15 minutes before and 15 minutes after) EMA surveys with high positive or negative affect ratings will be included in the machine learning models. This time frame was selected, given prior research indicating that affective states typically last ≥30 minutes [62,63]. The 30-minute period will be split into six 5-minute moving windows, for which heart rate, heart rate variability, and electrodermal activity indices will be computed.

Supervised binary classification machine learning models will be developed using heart rate, heart rate variability, and electrodermal activity indices to distinguish instances of high negative affect from high positive affect. Lasso regression will be used to select features that distinguish instances of high positive and high negative affect. Machine learning models (eg, support vector machines, classification and regression trees, and neural networks) using the selected parameters will be developed using the first 3 weeks of data collected (training data) and will be evaluated for accuracy using the last week of data (test data) collected from all participants. The last week of data will be excluded from algorithm development to ensure that the algorithms can be evaluated on previously unseen data to select the most accurate algorithms and avoid overfitting. Both group-level and individual-level algorithms will be generated to reduce model variance and bias, thereby addressing concerns about both over- and underfitting [61]. This approach will balance the need for accurate prediction with developing a group-level algorithm that substantiates the general capacity to predict BE using negative affect. Given the greater importance of identifying all instances of negative affect-related risk for BE to power a future intervention than correctly classifying instances without negative affect, minimum model sensitivity thresholds of 70% will be prescribed. The best performing models will be selected by maximizing sensitivity while maintaining adequate (eg, >50%) specificity and the average accuracy will be computed for the best performing models.

Aim 1 Power

Previous studies conducted by our team using EMA to measure negative affect among individuals with BE indicate that these individuals endorse high negative affect at 22%-32% of surveys and high positive affect at 12%-34% of surveys. Previous EMA research on BE suggests overall rates of missing data of 9.7%-32.6% [12,22,58]. Conservatively estimating that approximately 20% of surveys will include high negative affect, 20% of surveys will include high positive affect, and 30% missing data, we expect at least 529 instances each of high negative and positive affect in the training data (~0.2×6 surveys per day×21 days×30 participants×0.7 compliance). Simulation studies have indicated that supervised machine learning models using highly dimensional data require ≥150 observations in each class to be powered at 0.80 to detect a small to medium effect, which 529 exceeds [64].

Aim 2

Two sets of supervised binary classification machine learning models will be developed to predict BE, 1 set using only EMA-reported negative affect data and the other integrating both EMA- and sensor-measured negative affect. Due to the dearth of research examining the timescale on which negative affect increases risk for BE, sensor patterns across several timescales (ie, 5-, 15-, 30-, and 60 minutes prior to the binge episode) will be included in the models, and the timescales that maximize model sensitivity will be retained. These time periods will be divided into 5-minute moving windows, for which heart

XSL•FO
RenderX

rate, heart rate variability, and electrodermal activity indices will be computed. Sensor features computed for each 5-minute window within the selected timescale will be included as predictors in each machine learning algorithm examined. As in aim 1, both group- and individual-level algorithms will be generated, and the algorithms will be developed using the first 3 weeks of data (training data) and evaluated on the last week of data (test data). Sensitivity will be set a priori >70% and the best fitting model for EMA-reported negative affect alone and for the combined data will be selected by maximizing sensitivity while maintaining adequate specificity.

Aim 2 Power

Previous studies conducted by our team and others have identified an average of 2-6 BE episodes per week per participant, with most episodes occurring on separate days [12,22,65,66]. Conservative estimates of 3 binge episodes per week will yield approximately 189 BE episodes (~3 episodes per week×3 weeks×30 participants×0.7 compliance) and 1134 non-BE episodes (~18 episodes per week×3 weeks×30 participants×0.7 compliance) in the training data. As in aim 1, since the number of observations in each class exceeds 150, the supervised machine learning models will be sufficiently powered [64]. 95% bootstrap CIs will be constructed for each set of models (combined and EMA-only) to evaluate their accuracy; if the intervals do not overlap, this indicates that 1 model is significantly more accurate. For the bootstrap CI comparison, a power analysis conducted in G*Power (version 3.1; Heinrich-Heine-Universität) (power=0.80; α=.05) indicated that ≥77 total test observations are required to detect a medium effect. Aim 2 will therefore be fully powered, given 63 binge episodes (~3 episodes per week×1 week×30 participants×0.7 compliance) and 378 anticipated non-BE episodes (~18 episodes per week×1 week×30 participants×0.7 compliance) in the test data [67].

Results

This study received funding from the National Institute of Mental Health (award number F31MH131262) for the period of November 2022 through October 2024. Recruitment began in January 2023 and is expected to continue through March 2024; as of April 2023, a total of 7 participants have been enrolled. We anticipate that data collection will be completed by May 2024, and all analyses will be conducted by July 2024.

Discussion

Principal Findings

We anticipate that findings from this study will clarify whether features extracted from passive sensor data can distinguish between positive and negative affect among individuals with BE and provide an estimate of the accuracy with which these features can distinguish these emotional states. Furthermore, the study findings will identify which features are useful for distinguishing positive and negative affect states, which we anticipate will include both heart rate and electrodermal activity features. The findings from the study will also clarify the extent to which sensor-measured negative affect improves upon EMA-measured negative affect for the accurate prediction of BE episodes and provide an estimate for the accuracy of machine learning algorithms using these data sources to predict BE.

If our hypotheses are supported, our findings will replicate previous algorithms using sensor data to distinguish positive and negative affect states in a population of individuals with BE [33]. Furthermore, this study will build upon previous research using psychophysiological sensors to measure autonomic indices of emotional arousal [28-35] and to assess autonomic activity prior to BE [36,37] among individuals with BE by using these sensors to predict ecological BE in real time.

Study Implications and Future Directions

This study will use an innovative data collection method to detect real-time risk for BE, potentially providing a new avenue to study the role of affect in BE. This study may set the stage for a future sensor-integrated momentary intervention system, a technological innovation that could enhance the efficacy of mobile health tools. The findings from this study will be disseminated via presentation at scientific conferences and publication in a peer-reviewed journal.

Strengths and Limitations

This study is strengthened by the use of psychophysiological sensors and EMA to measure affect and eating behavior in an ecologically valid way. The inclusion of a transdiagnostic sample and a high proportion of men and individuals of minoritized racial and ethnic identities will increase the generalizability of our findings to groups that are underrepresented in research on BE. This study is limited by the possibility of reactivity to wearing the sensors or completing EMA surveys and the potential impact of limited participant insight and social desirability on reporting affect and BE on EMA.

Acknowledgments

Research reported in this publication was supported by the National Institute of Mental Health of the National Institutes of Health under award number F31MH131262. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

The data sets generated during this study will be available from the corresponding author on reasonable request.

Abstract

Background: The southern India state of Kerala has among the highest proportion of older adults in its population in the country. An increase in chronic age-related diseases such as dementia is expected in the older Kerala population. Identifying older individuals early in the course of cognitive decline offers the best hope of introducing preventive measures early and planning management. However, the epidemiology and pathogenesis of predementia syndromes at the early stages of cognitive decline in older adults are not well established in India.

Objective: The Kerala Einstein Study (KES) is a community-based cohort study that was established in 2008 and is based in the Kozhikode district in Kerala state. KES aims to establish risk factors and brain substrates of motoric cognitive risk syndrome (MCR), a predementia syndrome characterized by the presence of slow gait and subjective cognitive concerns in individuals without dementia or disability. This protocol describes the study design and procedures for this KES project.

Methods: KES is proposing to enroll a sample of 1000 adults ≥60 years old from urban and rural areas in the Kozhikode district of Kerala state: 200 recruited in the previous phase of KES and 800 new participants to be recruited in this project. MCR is the cognitive phenotype of primary interest. The associations between previously established risk factors for dementia as well as novel risk factors (apathy and traumatic brain injury) and MCR will be examined in KES. Risk factor profiles for MCR will be compared between urban and rural residents as well as with individuals who meet the criteria for mild cognitive impairment (MCI). Cognitive and physical function, medical history and medications, sociodemographic characteristics, lifestyle patterns, and activities of daily living will be evaluated. Participants will also undergo magnetic resonance imaging and electrocardiogram investigations. Longitudinal follow-up is planned in a subset of participants as a prelude to future longitudinal studies.

Results: KES (2R01AG039330-07) was funded by the US National Institutes of Health in September 2019 and received approval from the Indian Medical Council of Research to start the study in June 2021. We had recruited 433 new participants from urban

XSL•FO
RenderX

and rural sites in Kozhikode as of May 2023: 41.1% (178/433) women, 67.7% (293/433) rural residents, and 13.4% (58/433) MCR cases. Enrollment is actively ongoing at all the KES recruitment sites.

Conclusions: KES will provide new insights into risk factors and brain substrates associated with MCR in India and will help guide future development of regionally specific preventive interventions for dementia.

Introduction

Background

India's older adult population (≥60 years old) currently is comprised of 146 million people and is expected to increase to 179 million people by 2030 [1]. Southern India (including the state of Kerala) has the highest number of older adults—one-quarter of India's older adults [2]. Kerala has had the highest life expectancy rates since the 1970s when compared with all other Indian states (Kerala: 75.2 years; India: 69.7 years) [3]. Kerala has the highest prevalence of older adults (16.5%) among all Indian states, and this number is projected to increase to 20.9% by 2031 [4]. High literacy rates, access to health care, and a relatively strong public health system in Kerala have been hypothesized to play important roles in this demographic profile.

The increase in the older adult population in Kerala is expected to be accompanied by an attendant increase in chronic age-related diseases, including dementia [5]. Only a few studies have examined the prevalence of dementia in Kerala, with prevalence rates ranging from 3.2% to 8.7% [6-9]. A dementia prevalence of 4.9% was reported in adults aged 55 years and older in Thiruvananthapuram, the capital city of Kerala [6]. Independent studies carried out in urban and rural areas of Ernakulam district in Kerala reported dementia prevalence rates of 3.36% (≥65 years old) and 3.39% (≥60 years old), respectively [7,8]. The Harmonized Diagnostic Assessment of Dementia for the Longitudinal Aging Study in India, the first cross-national study of dementia in India, reported higher dementia prevalence rates of 7.8% and 8.7% in urban and rural areas in Kerala, respectively [9]. A 10-year follow-up study in Kerala reported incidence rates per 1000 person-years for Alzheimer disease of 11.67 (95% CI 10.9-12.4) for those aged ≥55 years and 15.54 (95% CI 14.6-16.5) for those aged ≥65 years [10].

Recognizing the need for a comprehensive study of cognitive decline in this population, the Kerala Einstein Study (KES) was established in 2008 to understand the epidemiology of and risk factors for cognitive decline, Alzheimer disease, and related dementias [11-13]. The primary phase of recruitment of this study spanned from 2008 to 2016. During this initial phase, we successfully developed a clinical research center in Baby Memorial Hospital (BMH) [14] in Kozhikode City in Kerala, validated culture-fair cognitive tests, identified new dementia risk factors (eg, depression, polypharmacy, cardiovascular disease, and small vessel disease [SVD]) [12,15-17], and established magnetic resonance imaging (MRI) protocols and processing pipelines [18,19]. KES (2R01AG039330-07) was renewed by the National Institutes of Health in September 2019 and received approval from the Indian Council of Medical Research (ICMR) to start the study in June 2021.

In this KES project, we target risk factors and brain substrates of predementia syndromes, especially the motoric cognitive risk syndrome (MCR). MCR is a predementia syndrome characterized by cognitive complaints and slow gait, proposed by Verghese and colleagues in 2013 [20], and validated in multiple countries [13,21-23]. MCR predicts both Alzheimer disease and vascular dementia even after accounting for overlap with mild cognitive impairment (MCI) [13,20,21]. MCR is common; the prevalence was 9.7% in our 17-country study (including KES) [13]. Unlike MCI, complex cognitive tests or assays are not needed to diagnose MCR [13,20,21], increasing its clinical utility in resource-poor low- and middle-income countries (LMIC) like India. We have identified several potentially modifiable risk factors (depression, sedentary lifestyle, and obesity) for MCR in high-income countries [21], but their association with MCR in LMIC is unknown. In this KES project, we will study 2 novel risk factors for predementia syndromes in KES: apathy and mild traumatic brain injury (TBI). Recent investigations highlighted apathy as a separate entity from depression and uniquely associated with cognitive decline [13]. Although TBI is a leading cause of disability in LMIC, its role as a contributor to late-life cognitive decline in LMIC is underrecognized. We hypothesize that apathy and TBI will be associated with MCR and that these associations will be moderated by early-life (years of schooling) and late-life participation in cognitive activities. We also aim to explore commonalities and differences in risk factors for predementia syndromes such as MCR in urban (Kozhikode City) and rural (Kakkodi village) communities in Kozhikode district, Kerala (Figure 1).

Figure 2 shows the conceptual framework of the KES. This study will identify relationships between different risk and protective factors for MCR in this southern Indian population. This study will have a major impact on building sustainable research capacity in this region. The extensive data collected as part of this study will act as a rich resource for discovery as well as validation of risk factors of other age-associated phenotypes and syndromes.

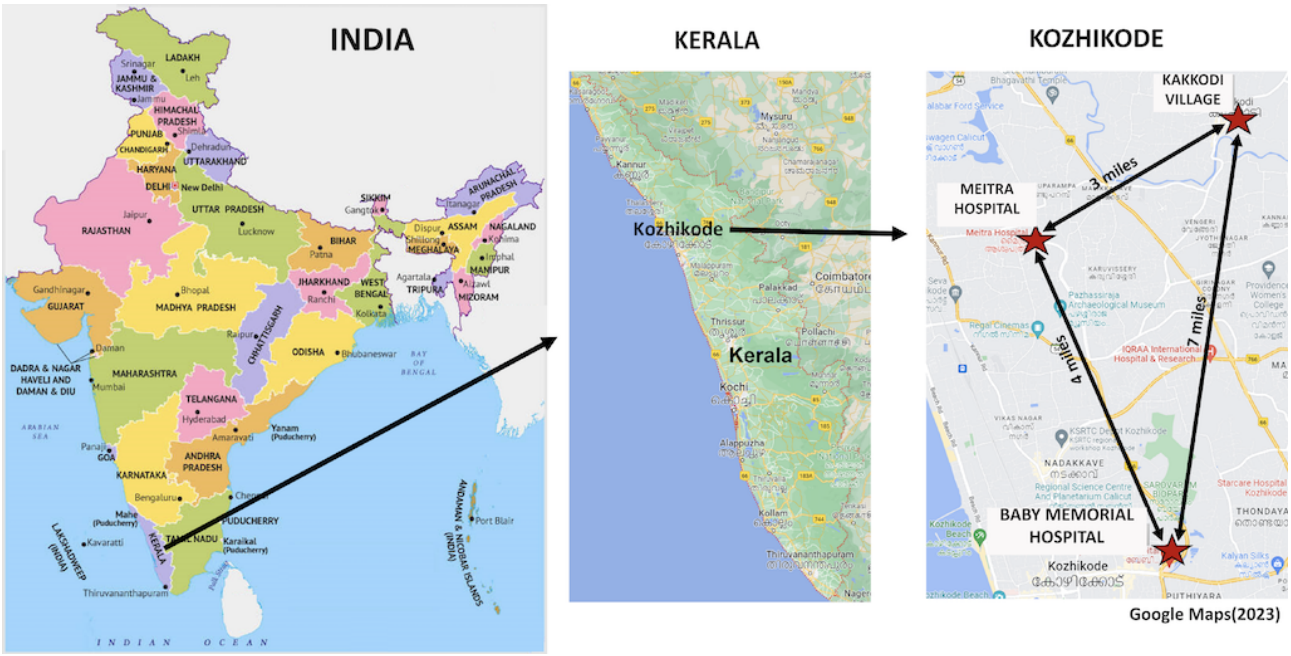

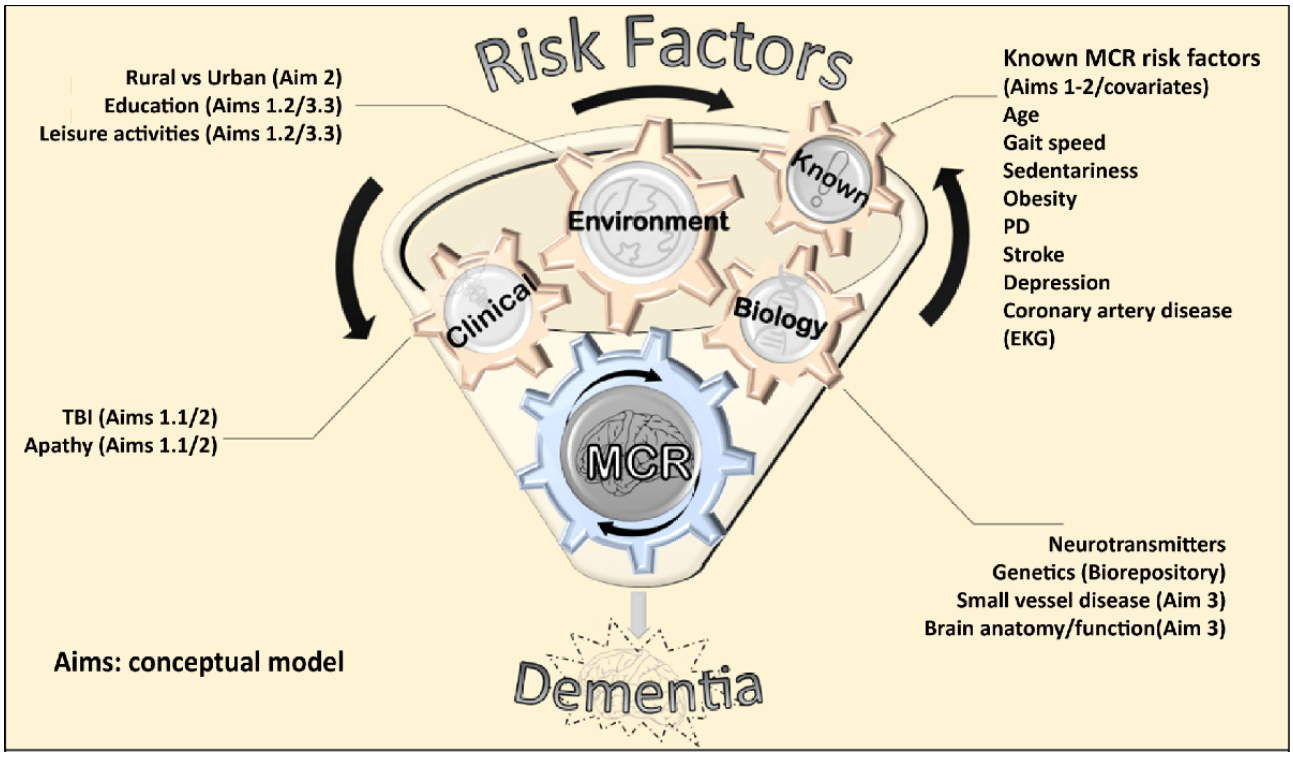

Figure 2. Conceptual framework of the Kerala Einstein Study. EKG: electrocardiogram; MCR: motoric cognitive risk syndrome; PD: Parkinson disease; TBI: traumatic brain injury.

Study Aims

The main aims of this observational study are threefold. First, the study aims to examine clinical risk factors for predementia syndromes (MCR and MCI) in 1000 older adults from Kerala: 200 already recruited in phase 1 of KES and 800 new recruits from urban and rural sites (Aim 1). The following will be conducted to support this aim:

- Examine the association of potentially modifiable risk factors previously identified in high-income countries as well as novel risk factors (apathy and TBI) with MCR and MCI in 1000 Kerala seniors (Aim 1.1)
- Examine if the relationship between apathy or TBI and MCR or MCI is moderated by early-life (years of schooling) and late-life participation in cognitive activities (Aim 1.2)

Second, we will explore commonalities and differences in risk factors for predementia syndromes in rural and urban Kerala older adults (Aim 2). Third, we will establish brain substrates and pathologies of MCR in Kerala older adults (Aim 3). The following activities will support this aim:

XSL•FO
RenderX

- Examine structural brain abnormalities (gray matter atrophy, reduced structural connectivity) and SVD pathologies in adults with MCR compared with healthy aging controls (Aim 3.1)
- Examine the relationship between structural brain abnormalities and MCR and the role of SVD in mediating this association (Aim 3.2)
- Examine the impact of early-life and late-life participation in cognitive activities on the association between structural brain abnormalities and MCR (Aim 3.3)

Methods

Study Design and Population

We propose a cross-sectional survey of 1000 older adults in urban and rural locations in Kozhikode district. We also propose follow-up assessments at 12-month intervals with participants at our rural site. This will be the first epidemiological survey of predementia syndromes from this region and will provide preliminary data to develop new biological hypotheses. The KES project is based in Kozhikode, a northern district in Kerala state with a metropolitan population of more than 2 million people, making it the 19th largest urban agglomeration in India. The initial phase (2008-2016) of the KES was based in BMH—one of the leading providers of medical care in Kozhikode City [14]. Participants (n=200) were identified from patients and caregivers attending the neurology clinic at BMH.

An additional 800 new participants will be recruited in this phase of KES. Brain MRI will be performed with 400 participants (180 completed in the initial phase of KES and 220 new studies in this project), and up to 154 repeat MRIs will be obtained at 12-month intervals. Large-scale neuroimaging investigations are limited in India. The KES will create a unique MRI database to examine brain substrates of cognitive decline in this population.

A new component included in this KES study is the addition of rural and exurban recruitment sites in Kozhikode district. The rural site will be in Kakkodi village (population: 42,866 people) [24]. Kakkodi village differs from Kozhikode City in several indicators such as socioeconomic status (lower), occupational types (agricultural and household work are the major occupations), health care access (no hospitals nor specialty clinics), educational institutions (only primary school and middle school), and transportation (limited bus service and no trains). These rural-urban differences disproportionately affect rural-dwelling older adults who may be less mobile. There are no hospitals in Kakkodi, but BMH maintains a community health center where 500 to 600 Kakkodi adult residents receive routine medical care annually. Patients with more acute or serious complaints are referred to BMH and other hospitals in Kozhikode City. We will utilize this BMH community health center to recruit rural-dwelling older adults. The second new site will be Meitra Hospital [25], located in an exurban (beyond the suburbs) location outside Kozhikode city. As in BMH, potential participants will include patients attending neurology and other specialty clinics as well as older caregivers or family members who meet KES eligibility criteria. Meitra Hospital is a multidisciplinary institution with outpatient and inpatient facilities. Although BMH and Meitra Hospital are in urban and exurban locations, respectively, the patient population in both hospitals includes a mix of urban and rural patients who are referred from all over Kozhikode district as well as neighboring districts. We will track urban or rural residency for our analyses (regardless of study site) based on participants' home addresses.

Inclusion and Exclusion Criteria

Inclusion criteria are (1) age of 60 years or older and (2) being able to provide informed consent. Exclusion criteria are (1) refusal to complete the study tasks (ie, we had <5% refusal rate in the initial KES phase), (2) previous physician-diagnosed dementia, and (3) presence of acute or terminal illnesses or (4) presence of severe auditory or visual loss that would make it difficult for the participant to complete cognitive tasks. In addition, for neuroimaging studies, standard exclusion criteria apply, such as presence of pacemakers; aneurysm clips; artificial heart valves; ear implants; and metal fragments or foreign objects in the eyes, skin, or body.

Data Collection and Measures

Study protocols were collaboratively developed by the KES team in India and the United States over the past decade. Study procedures, testers, and supervision will be uniform and harmonized across all 3 field centers in Kozhikode district. Several culturally appropriate strategies approved by the local institutional review board (IRB) are in place to optimize recruitment and retention. For instance, all testing will be administered in Malayalam (local language) or English, as preferred by participants [11,26-28]. Results of electrocardiogram (ECG) and neuroimaging studies will be provided to the participants to share with their medical providers.

Once participants provide informed consent, they and their caregiver, if appropriate, will complete a standardized interview with the research assistant (RA) to obtain demographic characteristics, comprehensive medical history including TBI history, current medications, functional status, and mood states. Participants also complete robust measures of cognitive and physical functioning and undergo ECGs. Those who consent for the neuroimaging substudy will also complete MRIs of the brain. KES assessments are described in detail in the following sections.

Cognitive Tests and Self-reported Measures

Neuropsychological measures will be completed to evaluate cognitive function and to diagnose cognitive impairment or dementia in this cohort. Table 1 provides a catalog of the neuropsychological tasks conducted in KES. All KES tests have established Malayalam and English versions.

[a]WMS-R: Wechsler Memory Scale-Revised.

[b]ADL: activities of daily living.

The Addenbrooke Cognitive Examination (ACE) [28] and picture-based memory impairment screen [11] will be used to provide estimates of global cognition and memory function, respectively. For those participants who agree to complete more comprehensive testing, neuropsychological measures will include those chosen from the ICMR-Neurocognitive Toolbox (NCTB), a validated battery created in India and translated into various Indian languages including Malayalam [42]. The following ICMR-NCTB measures will be selected: Verbal Learning Test (verbal learning and memory), Modified Taylor Complex Figure Test (visuospatial and visual memory), Trail Making Test Black and White (A and B; visuospatial attention, cognitive speed, and set-shifting), Category Fluency Test (verbal fluency), and Phonemic Fluency Test (verbal fluency). The Wechsler Memory Scale-Revised Digit Span Task, which was previously used and validated in Kerala, will be used to assess auditory attention and working memory [43].

Participants will complete validated self-report questionnaires assessing depressive symptoms (Geriatric Depression Scale-30 [GDS-30] [42]), anxiety (Generalized Anxiety Disorder [GAD-7] [36]), apathy (Apathy Evaluation Scale [AES] by Marin et al [44]), social networks (Social Network Index [45] and Medical Outcomes Study Social Support Survey [46]), happiness (Subjective Happiness Scale [39]), and current leisure activities (Leisure Activity Scale [47]).

Level of independent functioning will be measured using the Instrumental Activities of Daily Living Scale for elderly people, which was developed in Kerala as a scale of functional abilities [37]. Subjective cognitive complaints will be operationalized using the 20-item Cognitive Change Index [48] and Subjective Cognitive and Motoric Complaint Questionnaire**.** The latter instrument was developed by our team to ascertain participant concerns regarding their cognition and motoric function.

All cognitive tasks and questionnaires will be administered by KES RAs, trained and supervised by the KES clinical neuropsychologists (EFW and MS). RAs in Kerala are trained in the administration and scoring of neuropsychological measures via televideo by a licensed clinical neuropsychologist (MS) based in the United States. Training includes review and explanation of each of the neuropsychological measures, modeling of test administration, and practice administration and scoring. RAs will be cleared by the neuropsychologist (MS) to evaluate participants following acceptable televideo practice

XSL•FO
RenderX

administration. Quality control measures include regular meetings with the neuropsychologist (MS) and RAs to refresh and review procedures as well as periodic review of scored protocols by the neuropsychologist. In addition, all study protocols are double scored by a single dedicated RA (who did not administer the tests) to ensure consistency in scoring across RAs and to identify and correct any observed errors in administration and/or scoring procedures.

Physical Tests

Gait

Timed walks at a normal pace over a fixed distance (10 feet) will be completed by participants. Use of any walking aid will be noted. We have reported that older adults with MCI had slower walking times compared with cognitive normal controls in KES [49].

Unipedal Stance

The unipedal stance test is a widely used clinical test of balance. Participants will be timed as they stand on 1 leg (participant will choose which leg) for a maximum of 30 seconds [50]. "Failure" is defined as shifting the stance foot or placing the lifted foot on the floor [50]. The test is stopped and considered normal at 30 seconds.

Grip Strength

A Jamar handgrip dynamometer will be used to objectively measure grip strength as the maximum voluntary contraction in the dominant hand. Grip strength is used to define frailty and is a validated marker of physical function [51].

Repeated Chair Rise

To test leg strength and endurance, participants will perform the repeated chair rise test using a standard padded chair [52]. Participants are instructed to stand and sit down on the chair 5 times as quickly as they can with their arms folded across their chest. Time taken to complete the 5 trials will be recorded.

Neuroimaging: MRI Protocol and Assessment

Image Acquisition

Overview

All images are acquired on a 3T Siemens MAGNATOM-Skyra at Meitra Hospital. T1-weighted whole head structural images are acquired using axial 3D-MP-RAGE parameters over a 256 mm field of view (FOV) and 1.0 mm isotropic resolution (echo time [TE]=2.26 ms, repetition time [TR]=2300 ms, α=80). Diffusion-weighted images are acquired at b=1000 s/mm^2 for 64 gradient directions. In addition, 6 b=0 s/mm^2 volumes are collected, one-half with opposing phase encoding directions to correct for distortions. 3D fluid-attenuated inversion recovery (FLAIR) images are acquired over a 256 mm FOV with 0.89 mm resolution (TE=387 ms, TR=4,500 ms, inversion time=1800 ms). Finally, 3D-susceptibility-weighted images (SWIs) are acquired over 216x256 FOV with a 0.86 mm resolution (TE=20 ms, TR=27 ms). The Meitra Hospital neuroradiologist reviews each MRI scan. Any significant neuroradiological abnormality is communicated to the KES neurologists by the neuroradiologist for consideration of further action. The MRI reports are shared with the participant. Each MRI examination takes approximately 1 hour including safety screening, set up, and scanning.

Gray Matter Volume and Cortical Thickness: Preprocessing

Parcellation of the T1-weighted data into anatomical brain regions is important for examining gray matter volume and cortical thickness patterns associated with MCR and is a necessary step in processing data for examining structural connectivity associated with MCR. Each participant's structural T1-weighted image will be reconstructed using FreeSurfer v 7.2 [53]. The accuracy of FreeSurfer's subcortical segmentation and cortical parcellation has been reported to be comparable to manual labeling [54]. Gray matter segmentation and longitudinal alignment will be performed with the FreeSurfer longitudinal pipeline [53], which is robust to initialization points and avoids biasing toward any one time point by generating a median template for each participant based on the T1-weighted images at both time points using cubic spline interpolation in FreeSurfer [55]. Several processing steps, such as skull stripping, Talairach transforms, and atlas registration as well as spherical surface maps and parcellations will then be initialized with common information from the participant-specific template, significantly increasing reliability and statistical power. The gray matter volumes of 68 different regions extracted from the FreeSurfer processing pipeline are entered in subsequent statistical analyses.

Structural Connectivity: Preprocessing

Preprocessing of diffusion-weighted images consists of field distortion correction using topup distributed as part of the Functional Magnetic Resonance Imaging of the Brain Software Library (FSL; [56]) and eddy current and movement correction using the eddy tool in FSL. To evaluate any white matter changes as a function of MCR status, we will use Tracts Constrained by Underlying Anatomy (TRACULA) distributed as part of the FreeSurfer v 7.2 library. TRACULA uses probabilistic tractography to extract 42 major white matter tracts. The software performs informed automatic tractography by incorporating anatomical information from a training data set, provided by the software, with the anatomical segmentation of the T1 image of the current data set, thus increasing the accuracy of the white matter tract placement for each participant by incorporating each participant's anatomical data into the tractography algorithm. Parcellation results from the FreeSurfer longitudinal stream will be applied to TRACULA to increase sensitivity to longitudinal changes in white matter tracts. The software outputs white matter integrity measures for each voxel inside the 42 tracts with a mean of about 500 voxels per tract. Thus, for each participant, voxel-wise white matter integrity measures for 42 tracts at baseline and follow-up will be used to test the association with MCR.

Lacunes with presumed vascular origin are defined (consistent with recent consensus criteria) as round or ovoid, subcortical, fluid-filled cavity, 3-15 mm diameter, with a surrounding rim [57]. Infarcts located in white matter must be hypointense on T1-weighted and FLAIR images to distinguish from white matter hyperintensities (WMH).

WMH are automatically quantified from 3D FLAIR images using the lesion segmentation toolbox [58], which will be implemented with SPM12/MatLab [59]. The lesion segmentation

XSL•FO
RenderX

tool pipeline provides us with overall WMH lesion count and volume, as well as a voxel-based WMH probability map that can be entered into subsequent analyses.

Microbleeds are identified on SWI, a 3D T2* sequence attuned to detecting hemorrhage [60-63]. SWI was shown to detect 67% more microbleeds than conventional T2 [64,65]. Longitudinal tracking of microbleeds on SWI correlates with cognitive decline [64,65]. We will use the Microbleed Anatomic Rating Scale (MARS) to quantify microbleeds by number and location on SWI [66]. The MARS quantifies microbleeds in the following 9 regions: frontal, parietal, temporal, occipital, infratentorial (brain stem and cerebellum), basal ganglia, thalamus, capsule, and corpus callosum. Regional and overall number and presence of microbleeds will be examined. MARS was used in our MCR study based in KES.

ECG

A standard 12-lead ECG (Tricog Health) will be performed by a certified cardiac physiologist at BMH and Meitra Hospital [12,41]. Standard 12-lead ECG will be analyzed following the Minnesota code classification by a study clinician, blinded to neurological status including normal, MCR, or dementia diagnoses. Based on our previous KES projects, the following abnormalities will be reported: rhythm abnormalities, left ventricular hypertrophy, significant ST and T wave changes, Q waves, heart block, and bundle branch block [12]. Major ECG abnormalities are defined as the presence of any one of the following: Q-QS wave abnormalities, left ventricular hypertrophy, Wolff-Parkinson-White syndrome, complete bundle branch block or intraventricular block, atrial fibrillation or atrial flutter, or major ST-T changes.

Phenotypes of Interest

MCR

MCR is our primary outcome of interest and is algorithmically diagnosed using the criteria by Verghese et al [13,20,21] in KES participants who meet all 4 of the following criteria: (1) subjective cognitive complaint, (2) slow gait, (3) no functional decline, and (4) no dementia [13,20]. Assessment of the key MCR criteria is summarized in the following paragraphs.

Subjective cognitive complaints are assessed based on participant positive (abnormal) responses to standardized questions in the Subjective Cognitive and Motoric Complaint Questionnaire [67].

Consistent with prior MCR studies, including KES [13,21-23,68,69], slow gait is defined as a gait speed 1 SD below age and sex-specific means. Although gait is multifactorial with neurological and non-neurological causes (eg, arthritis) [70], multiple studies have shown that, irrespective of causes, slow gait predicts dementia, which supports the robustness of this sign [71,72].

MCI

We have implemented the following established criteria for MCI [73] in the KES [15,16,18]: (1) score 1.5 SD below age and education-adjusted means on any cognitive test (Table 1), (2) cognitive complaints, (3) no functional decline [37], and (4) no dementia.

Dementia

Diagnosis of dementia is made by consensus of study clinicians (neurologist and neuropsychologists) and research staff following review of all available clinical evaluations, neuropsychological test results, functional assessments, and medical history. The Diagnostic and Statistical Manual of Mental Disorders IV (DSM-IV) criteria for diagnosis of dementia will be used [74]. Dementia at baseline is an exclusion criterion for the KES.

TBI

Mild TBI is being examined as a novel predictor of MCR in the Kerala population. We will use the American Congress of Rehabilitation Medicine definition of mild TBI that is widely used in clinical and research practice [75]. Mild TBI results in ≤30 minutes of unconsciousness (cf >30 minutes in moderate/severe TBI), and the posttraumatic amnesia period is <24 hours. We will use a local adaptation of the Brain Injury Screening Questionnaire (BISQ) [76], a structured questionnaire that characterizes incidence and severity of lifetime exposure to head trauma and TBI [77-79]. The BISQ provides a profile of symptoms in the following 4 domains: attention and memory; depression, anxiety, and mood; aggression and impulsivity; and physical [78,79]. The BISQ may be completed via interview or self-administration. The BISQ has good-to-excellent test-retest reliability [76,78,79].

Apathy and Depressive Symptoms

Apathy has been reported to predict risk of developing predementia syndromes including MCR in the United States [80,81]. We will measure depression and apathy utilizing the GDS-30 [25] and the AES, respectively [44]. Confirmatory factor analysis has shown apathy-withdrawal to be a distinct domain of the GDS [82]. The GDS-3A is the apathy subscale of the GDS, consisting of the following 3 items (score range 0-3) [83]: (1) “Have you dropped many of your activities and interests?” (2) “Do you prefer to stay at home, rather than going out and doing new things?” and (3) “Do you feel full of energy?” A score of 2 or more indicates presence of apathy. Reported sensitivity and specificity of the GDS-3A varied from 29% to 69% and from 89% to 93%, respectively, in 3 large European cohorts of older adults [83,84]. GDS-3A has been used to measure apathy in our Bronx-based cohorts [85]**.** The AES [44], an 18-item questionnaire, assesses apathy symptom severity and 3 domains of apathy (behavioral, emotional, and cognitive). AES scores range from 18 to 72, with higher scores indicating greater severity [44]. The AES has been reported to have higher sensitivity than the GDS-3A, as well as excellent test-retest and inter-rater reliability [44,86]. The AES is recommended for evaluation of people with dementia [87,88] but has not been widely used in aging cohorts [44]. We will develop a local language version of the AES and pilot it in our new sites as an alternate apathy assessment. As the GDS-30 is more widely used, we will also use confirmatory factor analysis of the GDS-30 to partition out apathy from depression in order to

XSL•FO
RenderX

develop a more robust measurement model, which we will compare with the AES.

Statistical Analysis

Outcomes

The primary outcome of interest is MCR (and MCI) status. Predictors are continuous and categorical measures including apathy, mild TBI, cognitive reserve (education and leisure activities), and neuroimaging variables. We will examine modifiable predictors for MCR (identified in the United States) such as obesity and sedentariness [21] as well as novel risk factors that we associated with the presence of cognitive impairment or MCI in KES such as ECG abnormalities, apathy, and TBI [12,41]. Baseline distribution of variables will be examined using appropriate graphical procedures and summary statistics before analyses. Transformation of continuous biomarkers will be considered if severe skewness in distributions is detected. We will also address sex in our analyses, both adjusting for it as a covariate and conducting stratified analyses by sex. Cross-sectional associations between both established and novel predictors and MCR/MCI will be evaluated using logistic regression models. All models will adjust for age, gender, education, and other confounders including but not limited to medical illnesses, anthropometric measures, residency status, recruitment source, and global cognition (ACE score). We will compare risk factors for MCR/MCI between urban and rural older adults using logistic regression models in the overall sample as well as separately.

Gray matter volumes and cortical thickness of 84 brain regions will be extracted from the FreeSurfer processing pipeline and entered in linear mixed effects models (LMEMs) adjusted by standard covariates (age, sex, education, total intracranial volume, global health score, and MCI) to detect differences by MCR status. To evaluate white matter integrity or structural connectivity associated with MCR, voxel-wise white matter integrity—fractional anisotropy—measures for 42 tracts at each time point will be entered into LMEMs adjusted by standard covariates (age, sex, education, total intracranial volume, and global health score) to detect differences by MCR status. Finally, the influence of SVD in general as well as specific SVD pathologies (lacunes, WMH, and microbleeds) will also be examined in subsequent LMEMs adjusted by standard covariates (age, sex, education, total intracranial volume, and global health score) to detect differences by MCR and non-MCR status.

Power

With a proposed sample size of 1000 and estimated MCR prevalence of 15% [13], we can detect an odds ratio of 1.33, corresponding to a 1 SD increase in worsening apathy and TBI, with 80% power at a significance level of .05. Prevalences of modifiable risk factors for MCR in KES ranges from 10% to 70%, which allows a detection of odds ratios of 1.69 to 2.24 on the associations of these risk factors with MCR and MCI with 80% power [15,16,18].

Power (Neuroimaging)

With 400 participants with neuroimaging measures and a prevalence of 15% for MCR or MCI, we can detect a difference of 0.45 SD in structural brain abnormalities between participants with and without MCR or MCI with 80% power. For comparison, we derived a structural brain network of MCR in 267 participants [19].

Timeline

Over the 5 years of this project, we will seek to recruit approximately 400 urban-dwelling and 400 rural-dwelling participants. Of the 800 new participants, 220 from all sites will undergo neuroimaging, which, along with the 180 studies from the first KES phase, will provide a database of 400 neuroimaging studies. Participants from all 3 sites will be recruited for imaging studies. Given the restricted geographic location of our rural site (Kakkodi village) and very low rates of out-migration by older residents, we propose to follow up rural participants every 12 months. In our urban sites, we will attempt to conduct 12-month follow-up assessments with all participants undergoing neuroimaging. Given the larger catchment area, follow-up will be more challenging, but we will also consider home assessments to improve retention.

Ethics and Procedures

This study will be conducted in accordance with the Helsinki Declaration. The informed consent and recruitment processes follow local socially and culturally appropriate practices. The assessments and procedures have been approved by the IRB at BMH (BMH/IEC/02/2022), which also served as the local IRB for the first phase of KES. In addition, study design and consent procedures have also been approved by the ICMR (2020-10058), which is a requirement for epidemiological and experimental studies conducted in India. The study protocols have also been reviewed and approved by the Albert Einstein College of Medicine IRB (2006-368).

Results

We had recruited 433 participants as of May 17, 2023. The basic characteristics of the recruited participants at each of the research sites in Kozhikode are shown in Table 2. As the recruitment is ongoing, formal statistical group comparisons were not conducted. Most of the recruited participants are men (255/433, 58.9%), as noted in previous KES publications [12,13,15,16,18,49]. Most participants (293/433, 67.6%) recruited thus far, including those from BMH and Meitra Hospital, have rural residency. Of the 433 participants recruited thus far, 58 (13.4%) met the criteria for MCR, and 89 (20.6%) met the criteria for MCI.

Table 2. Demographic characteristics of participants recruited in the Kerala Einstein Study as of May 17, 2023.

Characteristics	Total (N=433)	BMH[a] (n=194)	Mietra Hospital (n=102)	Kakkodi (n=137)
Age (years), mean (SD)	68.89 (5.48)	68.46 (5.24)	70.89 (5.22)	68.02 (5.66)
Sex (female), n (%)	178 (41.1)	81 (41.8)	30 (29.4)	67 (48.9)
Residence, n (%)				
Rural	293 (67.6)	107 (54.9)	61 (59.8)	125 (91.2)
Urban	137 (31.7)	87 (44.6)	39 (38.2)	12 (8.8)
Education (years), mean (SD)	9.20 (3.65)	9.35 (3.76)	9.91 (3.93)	8.47 (3.13)
Addenbrooke Cognitive Examination (ACE) score, (range 0-100), mean (SD)	78.37 (13.07)	77.56 (14.73)	77.58 (11.42)	80.10 (11.51)
Picture-based Memory Impairment Screen (range 0-8), mean (SD)	6.95 (1.90)	6.94 (1.98)	6.12 (2.36)	7.59 (0.94)
Geriatric Depression Scale (range 0-30), mean (SD)	7.76 (6.06)	7.55 (6.71)	9.03 (4.83)	7.13 (5.81)
Generalized Anxiety Disorder (range 0-21), mean (SD)	3.56 (4.54)	2.30 (4.03)	6.49 (3.96)	3.15 (4.67)
Social Network Index, number of high-contact roles (range 0-12), mean (SD)	5.27 (1.26)	5.37 (1.09)	5.04 (1.28)	5.32 (1.43)
Social Network Index (number of people in the social network), mean (SD)	18.92 (8.38)	18.59 (7.91)	17.22 (7.15)	20.57 (9.49)
Social support score, mean (SD)	3.92 (0.65)	3.85 (0.61)	3.66 (0.49)	4.17 (0.70)
MCI[b], n (%)	89 (20.6)	37 (19.1)	40 (39.2)	12 (8.8)
MCR[c], n (%)	58 (13.4)	38 (19.6)	9 (8.8)	11 (8)

[a]BMH: Baby Memorial Hospital.

[b]MCI: mild cognitive impairment.

[c]MCR: motoric cognitive risk syndrome.

Discussion

KES aims to understand the risk factors associated with MCR in the Kerala population. The initial phase of KES has already played a key role in defining and establishing risk factors and pathologies for MCR and MCI in India [13,18]. In this new project, our focus will shift to studying the role of apathy and TBI (risk factors) as well as cognitive reserve (protective factor) on the pathogenesis of cognitive decline and predementia syndromes in Kerala. Research on predementia syndromes such as MCR in LMIC such as India is scarce [89,90]. Emerging evidence emphasizes the interactions among ethnicity, genetics, environment, culture, and neurobiology in influencing manifestations of dementia [90]. We will make use of the interdisciplinary expertise of the KES team, local research infrastructure established since 2008, access to unique populations, and strong foundation of research to address our research questions focusing on predementia, especially MCR. This study also lays down a strong foundation of neuroepidemiological research in this region. The Kerala population is homogenous in terms of race, language, and culture. Hence, any observed findings should also apply to the broader Kerala older adult population.

Apathy is one of the prevalent and challenging behavioral symptoms associated with dementia [91]. Our recent study of a cohort based in the United States has shown apathy to be associated with incident MCR but not MCI [81]. Mild TBI is a novel risk factor that we address in this project. Although severe TBI-related injuries and deaths are common in India, mild TBI has not been established as a risk factor for late-life cognitive decline in Indian older adults. Neuroimaging studies to understand the association of TBI and other neuroimaging correlates (SVD, WMH, lacunes, microbleeds, gray matter volume, cortical thickness, and structural connectivity) with predementia syndromes including MCR have been scarce in this part of the world. Hence, this new KES project will provide new insights into the nature of cognitive decline in the growing older Indian population.

KES's main strength is the extensive clinical data being collected from a unique population, which provides opportunities to carry out research focusing on cognitive decline as well as geroscience. This will also be the first as well as the largest organized study of predementia syndromes and cognitive decline in Kerala state. The research infrastructure established in past and current KES projects will be key to initiating future spin-off studies to understand other clinical and biological aspects of cognitive decline and aging. KES data can also be utilized to understand multiple other age-associated phenotypes and syndromes such as frailty and depression in the older adult population in this region.

The cross-sectional design of KES does not permit causal inferences. However, this will be overcome with the longitudinal study design, which will be initiated in this phase and expanded in the future. We have not proposed biological specimen

XSL•FO
RenderX

collection. We will explore local collaborations with the goal of establishing a biorepository facility in Kozhikode, which will aid in conducting genetic and bioassays.

This KES project builds on the foundation of our past successful collaboration. Recruitment for the new KES project has started and is going well. We expect to achieve our recruitment goals and aims within the proposed project period. This KES project will be a major step toward understanding risk factors and neuroimaging correlates associated with MCR in Kerala and will help improve identification of older individuals at risk of dementia as well as guide future development of preventive strategies for dementia in India and elsewhere.

Acknowledgments

This project is funded by the National Institute on Aging (2R01AG039330-07) and Fogarty International Center. The authors would also like to acknowledge the study participants and thank the KES research personnel for their dedication and enthusiasm.

Data Availability

The data set generated in this study is available from the corresponding author on reasonable request and with completion of the data user agreement.

Conflicts of Interest

None declared.

Abstract

Background: Sleep bruxism (SB) is an oral behavior characterized by high levels of repetitive jaw muscle activity during sleep, leading to teeth grinding and clenching, and may develop into a disorder. Despite its prevalence and negative outcomes on oral health and quality of life, there is currently no cure for SB. The etiology of SB remains poorly understood, but recent research suggests a potential role of negative emotions and maladaptive emotion regulation (ER).

Objective: This study's primary aim investigates whether ER is impaired in individuals with SB, while controlling for affective and sleep disturbances. The secondary aim tests for the presence of cross-sectional and longitudinal mediation pathways in the bidirectional relationships among SB, ER, affect, and sleep.

Methods: The study used a nonrandomized repeated-measures observational design and was conducted remotely. Participants aged 18-49 years underwent a 14-day ambulatory assessment. Data collection was carried out using electronic platforms. We assessed trait and state SB and ER alongside affect and sleep variables. We measured SB using self-reported trait questionnaires, ecological momentary assessment (EMA) for real-time reports of SB behavior, and portable electromyography for multinight assessment of rhythmic masticatory muscle activity. We assessed ER through self-reported trait questionnaires, EMA for real-time reports of ER strategies, and heart rate variability derived from an electrocardiography wireless physiological sensor as an objective physiological measure. Participants' trait affect and real-time emotional experiences were obtained using self-reported trait questionnaires and EMA. Sleep patterns and quality were evaluated using self-reported trait questionnaires and sleep diaries, as well as actigraphy as a physiological measure. For the primary objective, analyses will test for maladaptive ER in terms of strategy use frequency and effectiveness as a function of SB using targeted contrasts in the general linear model. Control analyses will be conducted to examine the persistence of the SB-ER relationship after adjusting for affective and sleep measures, as well as demographic variables. For the secondary objective, cross-sectional and longitudinal mediation analyses will test various competing models of directional effects among self-reported and physiological measures of SB, ER, affect, and sleep.

Results: This research received funding in April 2017. Data collection took place from August 2020 to March 2022. In all, 237 participants were eligible and completed the study. Data analysis has not yet started.

Conclusions: We hope that the effort to thoroughly measure SB and ER using gold standard methods and cutting-edge technology will advance the knowledge of SB. The findings of this study may contribute to a better understanding of the relationship among SB, ER, affect, and sleep disturbances. By identifying the role of ER in SB, the results may pave the way for the development of targeted interventions for SB management to alleviate the pain and distress of those affected.

KEYWORDS

sleep bruxism; emotion regulation; ecological momentary assessment; rhythmic masticatory muscle activity; heart rate variability; wrist actigraphy

Introduction

Background

Sleep bruxism (SB) is an oral behavior [1] characterized by high levels of repetitive jaw muscle activity during sleep, known as rhythmic masticatory muscle activity (RMMA), and expressed as teeth grinding and clenching [2]. When its occurrence is frequent and associated with oral damage, pain, or sleep or neurological comorbidities, it can be classified as a sleep-related movement disorder. With a general population prevalence of 5.5% to 16% [3,4], SB varies on a spectrum of frequency, severity, and awareness, with many experiencing subclinical levels of teeth grinding [5]. Despite its detrimental outcomes, including jaw pain and fractured teeth as well as impaired sleep, function, and quality of life, there is currently no cure for SB [6].

SB can be measured in terms of self-reported or physiological measures at either trait or state timescales. Self-reported individual-difference questionnaires ask about perceived symptoms over weeks or months to assess trait-level SB [7]. Momentary questionnaires probe current pain or teeth grinding during the preceding sleep period to assess state-level SB [8]. Although relatively inexpensive, self-reporting sleep behavior limits the validity of this method of assessing SB because individuals are not aware of the behavior unless told by an observer. Physiological measures have the advantage of unobtrusively assessing SB while the individual is asleep. In-laboratory polysomnography is considered the gold standard of objective sleep measurement [9], but it is not feasible for multiple nights. Alternatively, portable physiological devices are optimal for a multinight assessment within a participant's home because they are relatively inexpensive to purchase, easy to distribute, and ideal for self-application [10,11].

SB and Emotion Regulation

The etiology of SB is not yet well understood. It is widely thought to have multiple predisposing factors [6], including maladaptive personality traits, neurotransmitter imbalance, and psychosocial impairments. Recent research implicates negative emotions as a likely factor. Tensing of the jaw muscles can be part of an emotional motor response [12], and acute wake-time negative emotions can increase RMMA [13]. SB has also been associated with impaired affect regulation, either diminished use of adaptive regulation strategies or increased use of maladaptive regulation strategies [14-17]. However, this relationship remains unclear [18].

Emotion regulation (ER) is defined as "attempts to influence which emotions we have, when we have them, and how those emotions are experienced and expressed" [19]. Individuals can regulate their emotions by implementing ER strategies [19] such as cognitive change (generating alternative interpretations of an event to change its affective impact [eg, cognitive reappraisal]), attentional deployment (directing one's attention to other aspects of the situation [eg, distraction]), and response modulation (controlling experiential, behavioral, or physiological emotional reactions [eg, expressive suppression]). Cognitive change and attentional deployment are considered generally adaptive strategies, whereas expressive suppression is more so a generally maladaptive or harmful strategy [20]. One core aspect of ER is how frequently individuals use a specific ER strategy (ie, ER frequency or use). Another core aspect of ER is how individuals perceive their ability to successfully use an ER strategy to achieve the goal of the ER attempt (ie, ER self-efficacy or effectiveness) [21].

Similar to SB, ER can be measured in terms of self-reported or physiological measures at either trait or state timescales. Self-reported trait questionnaires and momentary assessments of ER strategy use tap into the domain of deliberate, reflective, and consciously accessible information, whereas physiological measures provide access to relatively unconscious and automatic processes [22] and circumvent the numerous limitations of self-report. Such limitations include response biases, limited insight, and one's motivational level. Research has shown a positive association between ER effectiveness and both resting and 24-hour heart rate variability (HRV) [23,24].

SB and Affective and Sleep Disturbances

Although affective and sleep disturbances play a prominent role in SB, there have been mixed patterns of findings in the current literature. In the domain of affective disturbances, depression, anxiety, negative affect, and perceived stress are key variables that have been related to self-reported, clinician-diagnosed, or physiologically based SB. Depression has been associated with self-reported [25] but not polysomnography-based measurements of SB [26]. Trait anxiety has been linked with self-reported [27] and physiological [28] measures of SB. Negative affect has been found to be greater in individuals with clinician-diagnosed SB than in those without in 1 study [29] but not in another study [25]. Perceived stress has been associated with self-reported or physiological measures of SB in some studies [16,30] but not in others [31,32].

In the sleep domain, sleep quality and sleep efficiency represent key variables that have been related to SB. Self-reported sleep quality, hereinafter referred to as sleep quality, integrates perceived experiences reflecting sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, the use of sleeping medication, and daytime dysfunction [33]. Some studies have found worse trait sleep quality with self-reported [34] or physiological measures (including polysomnography) [35] of SB, but this was not the case in another multimeasure study

XSL•FO
RenderX

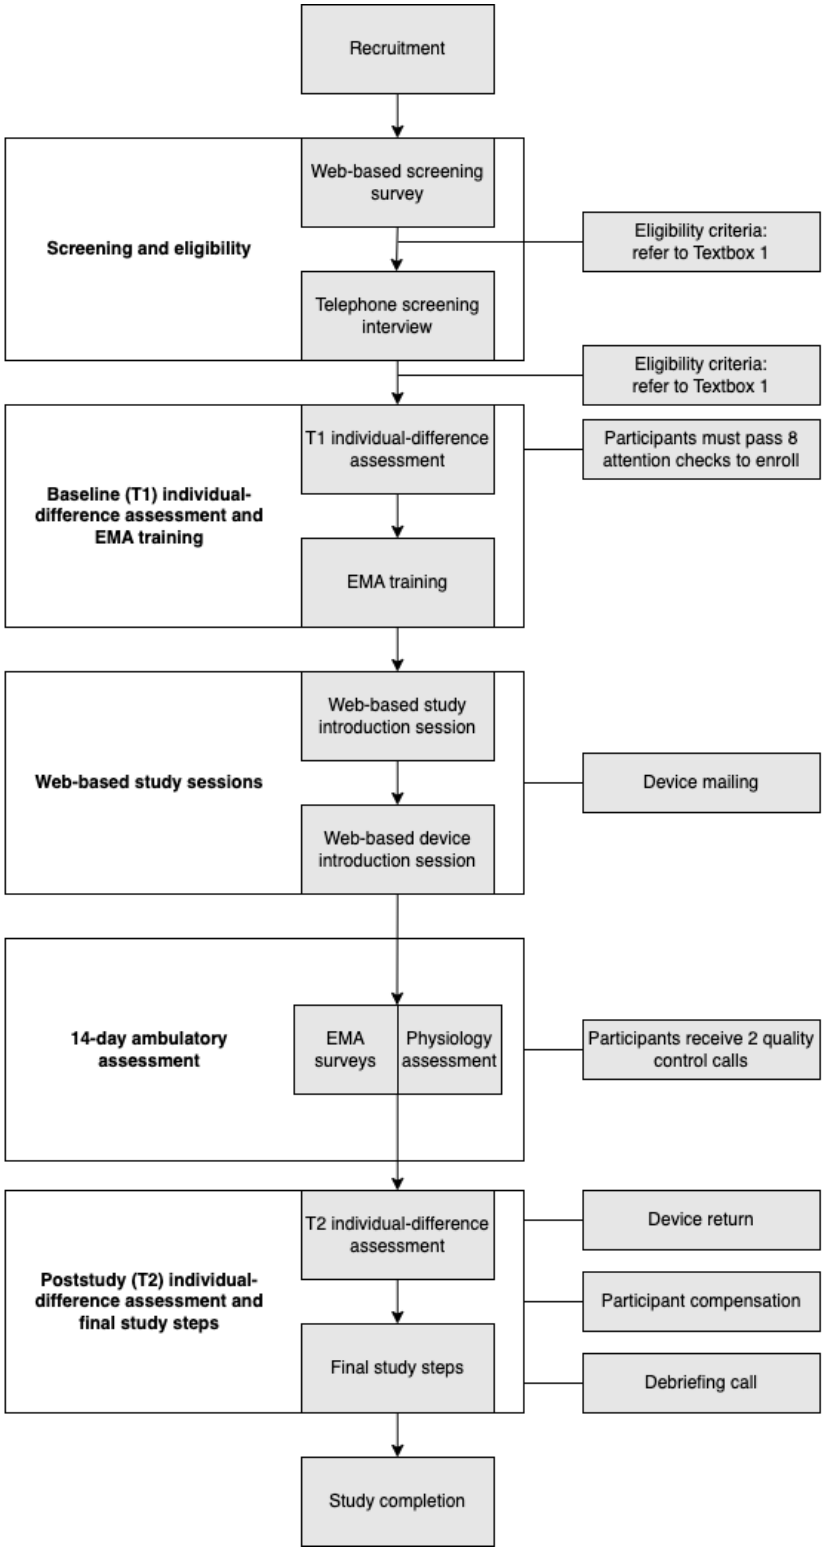
[32]. Worse state sleep efficiency (the ratio of time spent in bed asleep to the total amount of time spent in bed) has been found for both self-reported or clinically diagnosed [34] and home-based electromyography (EMG) [36] SB measures but not in a polysomnography sleep laboratory study [37].

The mixed patterns of results of SB in relation to affective and sleep disturbances suggest that an underlying cause may exist. We propose that ER may play this role. In fact, ER is a transdiagnostic factor in affective and sleep disorders [38]. This study proposes to phenotype ER in SB with both self-reported and physiological trait and state measures of SB and ER collected longitudinally in the context of a 14-day ambulatory assessment while controlling for affect and sleep.

Hypotheses and Objectives

We hypothesize that the effect of ER in those with SB remains when adjusting for associations with affect and sleep variables. Therefore, we expect that for those with greater (vs lower) self-reported or physiological trait or state SB, there will be a lower self-reported trait and state use of cognitive reappraisal and distraction (hypothesis 1a [H1a]), a greater self-reported trait and state use of expressive suppression (H1b), a lower self-reported trait and state effectiveness of cognitive reappraisal and distraction (H2a), a greater self-reported trait and state effectiveness of expressive suppression (H2b), and a lower physiological trait and state HRV (H2c).

The primary objective of this study is to test whether ER is associated with SB, while controlling for affect and sleep variables. As outlined in *Methods* section, we operationalized the core variables of SB, ER, affect, and sleep in terms of self-reported and physiological assessment modalities and trait and state temporal modalities. The secondary objective of the study is to test cross-sectional and longitudinal mediation pathways in the bidirectional relationships among SB, ER, affect, and sleep.



Methods

Study Design

This study applied a repeated-measures observational design. It did not use randomization, blinding, or assignment. As Figure 1 shows, participants went through a fully remote 5-step procedure, including screening and determination of eligibility, an assessment of individual differences, 2 web-based study sessions, the 14-day ambulatory assessment, and an abbreviated assessment of individual differences. As defined by the National Institutes of Health (NIH), this study is a basic behavioral science study at stage 0. It was preregistered at the National Institute of Dental and Craniofacial Research [39] of the NIH on July 8, 2020 (1R01DE026771-01, version 0.1).

XSL•FO
RenderX

Figure 1. Study design. As indicated in the white boxes, participants underwent 5 task components; criteria and additional procedures are noted to the right of these white boxes. EMA: ecological momentary assessment.

Ethics Approval

The protocol of this study was submitted to, and approved by, Institutional Review Board 7 of Stanford University, Stanford, California, United States (FWA00000935; protocol #50342).

Informed Consent and Risk Mitigation

Participants were informed of, and consented to, the study's potential risks, although the overall evaluation of risk was low owing to the use of noninvasive procedures and precautionary measures such as (1) measures taken to preserve participant confidentiality (eg, anonymous participant IDs, a password-protected database, separation of data and identifiable information, and access restrictions to data sets), (2) measures to mitigate risk of suicidal ideation (eg, the use of scripts assessing the severity of suicidality and following referral plans in the case of detected suicidal ideation), (3) measures to

XSL•FO
RenderX

mitigate the risk of uncovering an unknown health condition (eg, through the consent form stating that study team members are not responsible for communicating medical diagnoses to participants), (4) measures to mitigate experiencing minor skin irritation from electrodes (eg, the use of clinical-grade gels and adhesives, instructing participants to discontinue use in the case of a reaction, creating an explicit electrode removal and reapplication schedule, sending reminder emails and conducting check-in calls, and requesting participants to contact the study team at the first sign of potential skin irritation), and (5) measures mitigating the risk of negatively affecting participants' psychological well-being (eg, including a consent statement that explains risks and informs participants of their right to voluntarily withdraw from the study at any time).

Recruitment and Participants

A minimum sample size of 236 participants was determined by power analyses (G*Power; Heinrich Heine University Düsseldorf) [40]. The calculations were based on the detection of typical effect size estimates of prior studies investigating affect regulation in SB (Cohen d >0.21) [14-18], with at least 80% power for 2-tailed pairwise comparisons at Cronbach $\alpha \leq .05$.

Enrollment and data collection took place from August 2020 to March 2022. Participants were recruited through Facebook advertisement campaigns, research registries, web-based forums, web-based classroom visits, university email mailing lists, and flyers posted at medical clinics and on university campuses on the West Coast. We sought to enroll 275 participants approximately evenly distributed across SB severity and sex, as well as racial and ethnic diversity representative of that in the United States. Racial and ethnic details were collected via the web-based screening survey (Multimedia Appendix 1) that was used to determine study eligibility. We completed intermittent distribution checks to assess the need for targeted recruitment. Participants who completed all steps of the study were compensated with a US $80 gift card as well as a comprehensive sleep report.

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria are presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Living in the United States
- Aged between 18 and 49 years
- High school graduate
- At least 5 natural teeth per quadrant
- Normative bedtime (ie, bedtime no later than 1 AM and wake time no later than 10 AM)
- Refrain from consuming alcohol as well as nicotine and cannabis
- Refrain from consuming caffeine after 12 PM
- Maintain a stable bedtime routine (see 5th point in inclusion criteria)
- Pass at least 8 of 9 attention checks in the 90-minute baseline individual-difference assessment
- Have reliable access to the internet

Exclusion criteria

- Reporting as having health conditions other than sleep bruxism (SB), especially physical, mental, and sleep disorders known to affect SB or sleep
- A history of skin allergies
- Any traveling during the 14-day ambulatory assessment that affects circadian rhythm and thus bedtime routine
- Undergoing SB treatment
- Intake of any of the disqualifying medications (ie, antidepressants, anxiolytics, antipsychotics, antihypertensives, thyroid medications, antiasthmatics, anti–Parkinson disease medications, anticonvulsants, antihistamines, triptans, stimulants, and sleep medicines)
- Significant exposure to nicotine or cannabis products
- Caffeine use disorder
- Current pregnancy or pregnancy within the past year or the presence of infants aged <12 months
- Stomach sleeping or uncommon sleeping arrangement that would prevent the application of sensors

Screening and Eligibility

Web-Based Screening Survey

Potential participants were directed through a link from the recruitment medium to the 30-minute web-based screening survey.

Telephone Screening Interview

Potential participants who met the inclusion criteria assessed at the web-based screening survey completed a telephone interview to screen for psychiatric (Mini International Neuropsychiatric Interview) [41] and sleep disorders (Duke Structured Interview for Sleep Disorders) [42].

Materials

Study data were collected and managed using the electronic data capture tool REDCap (Research Electronic Data Capture; Vanderbilt University) hosted at Stanford University [43]. The ecological momentary assessment (EMA) training was presented, and the EMA surveys were collected, using the Qualtrics survey software and platform (versions 09-2020 to 04-2022; Qualtrics). The EMA surveys were delivered using a web application built by our research team (Multimedia Appendix 2). The study sessions were conducted via laptop computers running the secure Zoom software for videoconferencing (version 5.9.1, package 3506; Zoom Video Communications, Inc).

Baseline Individual-Difference Assessment and EMA Training

Baseline Individual-Difference Assessment

After the screening process and before enrolling in the study, participants completed the 90-minute baseline (T1) individual-difference assessment.

EMA Training

Upon completion of the T1 individual-difference assessment, participants were directed to the 30-minute EMA training via a web-based link.

Web-Based Study Sessions and Device Mailing

Web-Based Study Introduction Session

In the 30-minute study introduction session, participants were guided through signing the consent form to enroll in the study. Research assistants identified a timetable with the participant with SMS text messaging for the ambulatory assessment, considering the participant's wake, sleep, and general life schedule.

Device Mailing

After the study introduction session, the research team mailed the study equipment to the participants. The package included (1) an RMMA device with 18 pregelled adhesive pads (Butler GrindCare; Sunstar Suisse SA) and 14 alcohol swabs; (2) an electrocardiography (ECG) device (Vivalink VS-US4 - ECG Multi-Vital-Monitor; Vivalink, Inc) with 8 ECG device adhesives (Vivalink Hydrogel Adhesive [VSA-1, A13]; Vivalink, Inc), 10 skin-barrier film wipes (SNS80775; Safe n Simple), and 10 alcohol prep pads (CUR45585RBZ; Curad); and (3) an actigraphy wristwatch (Respironics Actiwatch Spectrum Plus; Philips), configured for the participant's data collection using the Actiware software (Philips), an instructional brochure, and a return envelope that participants were to use to return the devices to the study team. Each physiology device was fully charged and sanitized before we mailed it out. The study team kept a mailing protocol and recorded the serial numbers of all equipment sent out to participants on a device tracking form.

Web-Based Device Introduction Session

The 45-minute device introduction session took place after the participant had received the physiology devices. A research assistant instructed participants on device application, charging, and troubleshooting. The ambulatory assessment began at the end of this session and ended 14 days (336 hours) later.

14-Day Ambulatory Assessment and Quality Assurance

EMA Surveys

During the 14-day ambulatory assessment, 5 daily EMA surveys were sent to participants: 1 morning diary, 1 evening diary, and 3 daytime surveys (Multimedia Appendix 3 [44,45]). The EMA surveys were delivered using a web application built by our research team. The web application allows research assistants to enroll new participants and create a schedule for when EMA SMS text message reminders with the survey link are delivered to them. This system was hosted on a server (Amazon Web Services, Inc) that provides an on-demand cloud computing platform and application programming interfaces. EMAs were delivered through an automated SMS text messaging system (Twilio). The web application sent an application programming interface request to Twilio at the scheduled times, and Twilio sent predefined EMA SMS text messages to participants. Participants were instructed to complete the morning survey 15 minutes after getting out of bed, the evening survey 30 to 40 minutes before going to bed, and the 3 daytime surveys as soon as possible after they received the SMS text messages. The 3 daytime surveys were spaced at least 3 hours apart. All 5 surveys were set to arrive within a 30-minute window (jittered ±15 minutes from the scheduled time) to prevent the timing of the assessment from being a confounding variable. Participants were given a maximum of 3 hours to complete the surveys and received a follow-up SMS text message after approximately 30 minutes if no response was received. If there were no responses to the EMA surveys for >24 hours, the research team contacted the participant to ensure that there were no technical issues keeping them from completing the EMA surveys.

Physiology Assessment

Concurrently with the EMA surveys, participants wore 3 physiological devices for 14 consecutive days and nights (Multimedia Appendix 4). Participants were instructed to apply a facial EMG device each evening at bedtime and remove and charge it each morning after waking; continuously wear an ECG device, except for an approximately 4-hour charging period every 3 days; and continuously wear an actigraphy device. The EMG device was referred to as *Sleep Buddy* in communications with participants to avoid affecting RMMA behavior through expectations.

XSL•FO
RenderX

Quality Assurance

Research assistants followed a quality assurance protocol to monitor participant safety and data completeness during the ambulatory assessment, which involved participants receiving 2 quality control calls during the 14-day ambulatory assessment (Figure 1).

Poststudy Individual-Difference Assessment and Final Study Steps

Poststudy Individual-Difference Assessment

The day after their ambulatory assessment ended, participants completed an abbreviated poststudy (T2) individual-difference assessment with questionnaires about affect and sleep.

Device Return

At the end of the study, participants were instructed to mail back the physiology devices to the study team with the provided return envelope (Multimedia Appendix 5). Upon receipt, a research assistant exported and saved the data from the devices and remote servers.

Participant Compensation

Once data completeness status had been established, a research assistant issued participant compensation (Multimedia Appendix 5).

Debriefing Call

Research assistants administered a debriefing call to participants at the end of the study.

Monitoring of Data Collection

Stopping Guidelines

We stopped data collection upon reaching one of the stopping guidelines: (1) 275 participants had been enrolled in the study or (2) the enrollment window of April 1, 2022, had passed.

Premature Termination or Suspension of Study

Participants were able to stop participating at any point. The participation of a participant in the study could be terminated by the principal investigator, the institutional review board, or the funder in case of unexpected, significant, or unacceptable risk to participants [46]; insufficient adherence to protocol requirements; or insufficiently complete and evaluable data.

Measures

We present the core outcome measures among sleep- and affect-related constructs in Tables 1 and 2. At a minimum, participants had to complete the T1 individual-difference assessment, respond to 2 of the 5 EMA surveys each day on 7 of the 14 days, and wear the actigraphy device for 7 of the 14 days.

Demographics

We collected information on self-reported sex, age, ethnicity, race, and marital and socioeconomic status in the T1 individual-difference assessment.

SB Measures

Individual-Difference Assessment

We measured self-reported trait SB as follows (Multimedia Appendix 6 [33,47-53]).

The Sleep Bruxism Questionnaire, which was created by our research team based on prior questionnaires [54-56], assesses the perceived experience of SB.

The Patient-Reported Outcomes Measurement Information System (PROMIS) Pain Intensity-Short Form 3a v1.0 [47] measures subjective pain in the past 7 days and at present. It has a Cronbach α value of .906 and demonstrates high construct validity [57,58]. This questionnaire was adapted to ask about (1) orofacial pain and (2) other pain throughout the body.

The Oral Health Impact Profile-14 [48] is a short-form version that measures self-reported dysfunction and distress stemming from one's oral condition. It has a Cronbach α value of .880 and has strong construct validity [48].

Morning and Evening Diary Surveys

We measured self-reported state SB through morning diary surveys composed of single-item questions about past-night teeth grinding and current jaw pain in combination with evening diary surveys composed of 4 questions about teeth behaviors throughout the day that were adapted from the Oral Behaviors Checklist [44] (Multimedia Appendix 3).

Ambulatory Assessment

We measured physiological trait and state SB in terms of RMMA using Butler GrindCare (Sunstar Suisse SA), a portable single-channel EMG device (Multimedia Appendix 4). Past research supports the device's reliability and validity for assessing SB, consistent with gold standard measurement of SB through polysomnography [10,11,59].

ER Measures

Individual-Difference Assessment

We measured self-reported trait ER use and effectiveness as follows (Multimedia Appendix 6).

Two versions of the Emotion Regulation Questionnaire were used. The original version [49] assesses habitual use or frequency of ER strategies in terms of cognitive reappraisal (Cronbach α >.880) and expressive suppression (Cronbach α >.750) with strong overall validity [60]. The additional version assesses habitual use of distraction.

A derived measure [49] assesses the perceived self-efficacy of ER strategy use via reappraisal and suppression subscales (Cronbach α >.870) [61]. The other version assesses self-efficacy of distraction use.

Morning Diary and Daytime Surveys

We measured self-reported state ER use and effectiveness through the morning diary survey, which contained questions pertaining to presleep ER. Using the daytime survey, we measured the response to a negative event that had occurred since the last survey (within the past 3 hours) in terms of cognitive reappraisal, distraction, and expressive suppression (Multimedia Appendix 3).

Ambulatory Assessment

We measured physiological trait and state ER effectiveness using continuous ECG from a medical-grade wearable and reusable ECG sensor: VS-US4-ECG (Vivalink Inc) (Multimedia Appendix 4). This device has been demonstrated to be reliable and valid [62].

Affect Measures

Individual-Difference Assessment

We measured self-reported trait affect as follows (Multimedia Appendix 6 and 7).

The PROMIS Short Form v1.0-Depression 8a [50] assesses depression in terms of emotional distress caused by depressed mood in the last 7 days. The measure's Cronbach α values range from .920 to .980 [58], and it demonstrates strong validity [57].

The PROMIS Short Form v1.0-Anxiety 8a [50] assesses anxiety in terms of fear, anxious misery, hyperarousal, and somatic symptoms related to arousal in the last 7 days (Cronbach α=.950) [50], and the tool has strong validity [57].

The Positive and Negative Affect Schedule [51] assesses positive and negative affect over the past 2 weeks via 2 scales. The measure's Cronbach α values range from .860 to .900 and .840 to .870 for positive and negative affect scales, respectively; it has good validity [51].

The Perceived Stress Scale [52] assesses perceived stress in terms of appraisal of stress in daily life in the past month, where Cronbach α >.700 was reported with adequate validity [63].

Morning and Evening Diary and Daytime Surveys

We measured self-reported state affect through single-item questions about current positive and negative affect. We also administered single-item questions about past-day positive and negative affect and perceived stress (evening diary) (Multimedia Appendix 3).

XSL•FO
RenderX

Sleep Measures

Individual-Difference Assessment

We measured self-reported trait sleep quality and efficiency with the Pittsburgh Sleep Quality Index [33], which is composed of seven subscales: (1) subjective sleep quality, (2) sleep latency, (3) sleep duration, (4) habitual sleep efficiency, (5) sleep disturbances, (6) use of sleep medication, and (7) daytime drowsiness (Multimedia Appendix 6 and 7). The measure has a Cronbach α value of .830 and possesses strong validity [33].

Morning and Evening Diary Surveys

We measured self-reported state sleep quality and efficiency with *The Expanded Consensus Sleep Diary for Evening* morning and evening portions, respectively [45] (Multimedia Appendix 3). Research supports the Consensus Sleep Diary as a psychometrically sound daily assessment tool [64].

Ambulatory Assessment

We measured physiological trait and state sleep efficiency by recording activity, measured as movement, using the Actiwatch Spectrum Plus (Multimedia Appendix 4). Actigraphy has been found to be a reliable and valid indicator of sleep behavior compared with polysomnography in healthy adults [65].

Data Reduction and Preprocessing

For all data types, data will be cleaned by examining and applying necessary corrections for outliers, variable normality, and missing data in accordance with standard recommendations [66]. Self-report data will be scored, physiology data will be processed by response channel, and data aggregates will be calculated.

Data Analysis

Statistical analyses will be performed using R software (R Foundation for Statistical Computing) [67].

Preliminary Analyses

The incidence of missing data and technical or compliance deviations will be reported. Descriptive statistics will be presented using frequency tables for categorical variables and means and SDs or SEs of the mean for continuous variables. Pertinent group differences will be tested with chi-square tests, Mann-Whitney *U* tests, 2-tailed *t* tests, or analyses of variance.

Preliminary analyses will address the (1) evaluation of reliability and validity of core outcome measures; (2) evaluation of temporal convergence of core outcome measures based on T1 and T2 individual-difference assessments; (3) evaluation of construct convergence of core outcome measures based on self-reported and physiological state and trait measures; and (4) characterization of the sample regarding demographics and core outcome measures based on self-reported and physiological trait and state measures, including means, subgroups, internal reliability, and temporal variability.

Analyses for Testing Core Hypotheses

Preregistered analyses will address the primary objective of testing for ER impairment in those with SB and the secondary objective of testing for mediation pathways in the bidirectional relationships among SB, ER, affect, and sleep.

To address our primary objective, we will test our hypotheses by using SB measures such as self-reported and physiological trait and state SB (Table 1) as predictors and ER measures such as self-reported and physiological trait and state ER (Table 2) as outcomes in targeted contrasts based on the general linear model.

Control analyses will test whether the relationship between SB and ER remains when adjusting for the influences of affective and sleep measures, that is, self-reported and physiological trait and state affect (Table 2) and self-reported trait and state sleep (Table 1). To identify potential control variables, we will test for group differences and associations of SB and ER each with affective and sleep measures. Using the responses from web-based screening surveys, we will additionally test for associations with demographic variables, including sex, age, ethnicity, race, and marital and socioeconomic status. We will include in the primary-objective analyses those variables for which group differences or associations were identified using appropriate statistical methods [68].

To address our secondary objective, we will use cross-sectional and longitudinal mediation analyses on self-reported and physiological trait and state measures of SB, ER, affect, and sleep for contrasting various competing models of directional effects.

Results

This research received funding in April 2017. Data collection took place from August 2020 to March 2022. A total of 9378 participants were recruited, of whom 237 (2.53%) were eligible and completed the study. Data analysis has not yet started. We expect the first results to be published by the end of 2023.

Discussion

Expected Findings

This study seeks to examine the roles of ER, affect, and sleep in individuals with SB and those without through a remote longitudinal observational study. Although existing data on the association between SB and ER are conflicting and limited [14], our aim is to better phenotype ER in SB by (1) testing whether ER is impaired in SB while adjusting for the potential control variables of affect and sleep and (2) testing mediation pathways in the bidirectional relationships among SB, ER, affect, and sleep. We anticipate that the findings from this study will provide insights into the intricate interplay among these factors and their potential implications for understanding and managing SB.

Strengths and Limitations

This study has several strengths: the longitudinal at-home design enables more representative data collection and ecological validity of the night-to-night variable expression of SB than 1 or 2 nights in a sleep laboratory. This study also involves a large sample size of >200 participants, EMA that eliminates memory

XSL•FO
RenderX

bias, and ambulatory assessment of physiological data as objective indicators of SB, ER, and sleep.

This study also has limitations: first, it conducted data collection during the COVID-19 pandemic. The experience of the pandemic likely affected participants' SB [69], emotion generation and regulation [70], HRV [71], and sleep [72]. Second, this study used a descriptive observational protocol and no experimental manipulation, precluding causal inference. Third, although the remote nature of our study is novel, it presents unique challenges, increasing the risk of noncompliance and technical difficulties. Fourth and last, the EMA surveys may have caused participants to consider and process their emotions more frequently or in different ways than usual, potentially altering their typical SB, ER, affect, or sleep.

Conclusions

SB is a prevalent oral behavior that, if overexpressed, can be a disorder in susceptible individuals, with a significant negative impact on well-being for those affected [1,6]. The findings of this study may contribute to a better understanding of the relationship among SB, ER, affect, and sleep disturbances. If, as hypothesized, we find maladaptive ER in participants with SB, then this study will represent a meaningful step toward developing treatments for SB through ER intervention. Future studies will need to demonstrate a causal role of impaired ER in SB through extended longitudinal and experimental laboratory studies. We hope that the effort to thoroughly measure SB and ER using gold standard methods and cutting-edge technology will advance the knowledge of SB as well as initiate more effective interventions through ER to alleviate the pain and distress of those affected.

Acknowledgments

This study was preregistered at an independent institutional registry: the National Institute of Dental and Craniofacial Research (NIDCR) [39] of the National Institutes of Health (NIH). The authors thank the peer reviewers from the NIH involved in peer reviewing the study protocol (Multimedia Appendix 8). This work was supported by the NIDCR in part by grant R01DE026771 awarded to the principal investigator, JJG. The coordinating group includes AKA, ASB, JJG, Leah Harris, SDK, Hanqiu Li, SSL-G, Olivia Magaña, and Hannah Overbye. The steering committee consists of JJG, Clete A Kushida, GJL, and RM. The data management team consists of ASB and SDK. Study oversight is provided by NIDCR program officials (Dr Melissa Riddle, Medical Monitor Oversight Report-Quality Management Reporting Committee) and NIDCR Clinical Research Operations and Management Support. The authors thank research assistants Ella Becker, Alexander Bruckhaus, Yishu Chen, Victoria Costa, Isabel Gao, Addison Gills, Anusha Goyal, Rachel Hokanson, Rachel Huynh, Norhan Khafagy, Sewit Kidane, George Lausten, Gordon Luu, Olivia Magaña, Charlotte Ostrow, Priti Patel, Zoey Pham, Lorena Portillo, Yasamin Sadeghi, Sohrab Sami, Ann-Kathrin Schwientek, Purnima Seshadri, Elian Mateo Valencia, Michael Wicklein, Jocelyn Wilmore, and Sawyer Wisniewski for help with the data collection; Olivia Magaña and Yasamin Sadeghi for help with summarizing the literature; and Danny Nguyen for editorial support.

Abstract

Background: Technology and digital media (TDM) use is integral to modern adolescence; adolescents have been labeled as "digital natives," since they have had exposure to digital technology for their entire lives. Previous evidence has illustrated TDM's connections with adolescent risk behaviors such as increased alcohol use and social media exposure, as well as relationships with adolescent well-being such as improved socioemotional health and social media connections with peers. Although several recent review articles have described both the benefits and risks of technology use, most individual studies adopt a singular risk-centered approach. In addition, reviews suggest that little evidence exists on the potential mediating and moderating factors between TDM use and well-being and health outcomes, which limits our understanding of what influences the outcomes of interest. Therefore, there is an urgent need to fill these gaps.

Objective: This protocol addresses the need to understand how TDM exposure and use affect multiple developmental domains and health outcomes. We address the fragmented nature of previous research, the common focus on single behaviors or conditions, and the typical narrow lens on risks. Our approach further aligns with reviews that called for studies identifying and investigating the factors that moderate the relationships between social media and health behaviors and outcomes.

Methods: We will address our objective by longitudinally examining over a 2-year period a common set of adolescent participants (N=400, aged 13-15 years) across 3 studies that adopt a multimethodological approach. Study 1 will use TDM to understand the mechanisms behind adolescent health and risk behaviors. Study 2 will use functional magnetic resonance imaging to understand how positive and negative TDM experiences relate to mental and behavioral health in a subsample of 150 adolescents. Study 3 will use a mixed methods design to evaluate self- and other-generated TDM content as the predictors of socioemotional well-being in sexual and gender minority and non–sexual and gender minority adolescents.

Results: Recruitment is ongoing, and the initial results from the first wave of recruitment are expected in 2024.

Conclusions: This integrated approach to longitudinal data collection from a shared adolescent participant pool will lead to novel analyses and findings, allowing for the examination of the health and well-being risks and benefits associated with TDM use and factors that moderate these relationships. The findings from this study will advance conceptual models and inform new interventions to improve adolescent health.

Introduction

Background

Technology and digital media (TDM) use is integral to modern adolescence; adolescents have been labeled as "digital natives," since they have had exposure to digital technology for their entire lives [1-3]. The 2022 Pew Internet and American Life Project [4] estimated that 95% of US adolescents have their own personal smartphone. These rates have increased from 2014 to 2015, when 73% of adolescents reported personal smartphone access [5]. Moreover, teenagers have begun obtaining their first phone at a younger age, with most adolescents owning a phone by the age of 13 years [6,7]. The nearly ubiquitous and thus dominant form of TDM use among adolescents is social media use. Web 2.0 led to what has been called social media, which is also called immersive or interactive media.

Social media represents a set of Web 2.0 tools that are centered on interaction and sharing of content with others, although users may also consume content passively. In the world of social media, adolescents have become both creators of self-generated content and consumers of other-generated content. Messages and content can flow in all directions, from peers to other users, among other users, and across platforms through a seemingly endless array of potential paths. Social media is used for a variety of activities, including sharing information, interacting with peers, and developing an identity [8]. Most adolescents report the ownership of at least 1 social media account or profile, and most maintain them on several platforms [9]. Thus, today's adolescents have an increased capacity to interact with each other and the larger world using media, enhanced opportunities to explore and experiment via media, and an increased likelihood of being influenced by media experiences. The recent social isolation and disrupted school schedules experienced by adolescents during the COVID-19 pandemic have highlighted the diverse uses and values of TDM for adolescents [10].

Given that adolescents' development includes identity development, peer relationships, and independence, the tools offered by social media seem almost perfectly aligned with this period [11]. Research supports the idea that youths use TDM to achieve critical developmental tasks [12], such as seeking a coherent sense of self via self-presentation and experimenting with identity. This social media–based identity development may be even more important for adolescents who identify as part of minority groups, such as the lesbian, gay, bisexual, trans, queer, or intersex community [13,14], and for adolescents with chronic illnesses [15]. Further, social media can offer the opportunity to engage in aspirational development, providing a place to reflect on, complement, and reinforce offline relationships [16], practices, and behaviors [17]. Social media combines peer and media effects and thereby represents a powerful motivator of behavior, whether through self-generated or other-generated (ie, consumed) content. Social media brings together the power of interpersonal persuasion with the reach of mass media and led to a new concept of "mass interpersonal persuasion," which is "the most significant advance in persuasion since radio was invented in the 1890s" [18].

Many studies on adolescent TDM use have focused solely on risks and negative outcomes. Previous studies have illustrated that TDM use is associated with negative outcomes such as impaired sleep [19-21], decreased physical activity [20,22,23], problematic internet use [24-26], and risk for depression [27]. Although several recent review articles have described both the benefits and risks of technology use [8,28], most individual studies adopt a singular risk-centered approach [29,30]. The benefits of social media include increased social capital [31], safe identity exploration [32], social support, and an opportunity for self-disclosure [33]. Specifically, in the area of adolescent health, previous studies have shown that TDM offers opportunities to provide novel interventions for pediatric patients [34], advance reproductive and sexual health [35,36], and provide new approaches to mental health support [37]. Those who experience isolation, stress, and unmet needs in their offline worlds may find corrective experiences or buffering effects by going on the web [38,39]. For example, a qualitative interview study found that young people naturally and organically developed close-knit communities of close friends, often in the form of private Instagram (Meta Platforms, Inc) accounts, in which privacy was a priority and emotional disclosure was safe and commonplace [40].

This Protocol

Overview

In this protocol, we will address the fragmented nature of previous research, the common focus on single behaviors or conditions, and the typical narrow lens on risks. Although scholars have called for comprehensive approaches considering the benefits and risks of technology use [8,28], most existing studies focus on risks [29,30]. Our approach is aligned with a previous review that called for studies identifying and investigating the factors that moderate the relationships between social media and health behaviors and outcomes [8]. This approach is further highlighted in the 2023 US Surgeon General's Advisory on Social Media and Youth Mental Health, which calls for research examining the benefits and risks associated with specific social media designs, features, and content [41]. Studies in this protocol will incorporate a particular emphasis on 2 key attributes of adolescent development: identity development and social development.

Identity Development

Social media offers the opportunity for identity exploration and development via the creation of personal profiles and the sharing of self-generated content. A previous study found that adolescents who communicated more on the web had greater self-concept clarity, the ability to understand oneself clearly and stably [42]. For adolescents using social media to explore their identity, social media may provide a conducive environment for receiving positive or negative social feedback on their identity. Another aspect of web-based identity development is impression management [43]: adolescents use social media for impression management by using their self-representation to control or influence other people's perceptions of who they are and how they act. In all 3 studies in this protocol, evaluations will incorporate adolescents' self-generated content on social media.

XSL•FO
RenderX

Social Connection

Social connectedness and inclusion are essential for well-being during adolescent development. Social media offers adolescents the capacity to build peer connections by sharing content, endorsing each other's content, and communicating publicly and privately. By viewing their peers' content, adolescents may engage in social comparison [44] and potentially emulate behaviors or internalize the ideas seen in social media posts. Other-generated content may thus be persuasive through both peer and media effects. In all 3 studies in this protocol, we will incorporate evaluations of other-generated content consumed by adolescents via TDM.

Methods

Project Overview

Our overall objective for the 3 studies in this protocol is to understand the aspects of behavior and socioemotional well-being, alongside neurocognitive correlates, and how self-generated (ie, created) and other-generated (ie, consumed) social media content influence and associate with them. This comprehensive approach to investigation across multiple dimensions of health and technology use focuses on an integrated research strategy and interdisciplinary expertise. This protocol describes a program of research across 3 studies that leverage a shared participant pool and data to examine the health risks and benefits associated with social media use over a 2-year period during adolescence. Our long-term goal is to use the findings from this synergistic protocol to enhance health messaging campaigns, improve big data surveillance approaches, develop innovative interventions, and advance conceptual models. This program protocol includes the following 3 studies.

Study 1

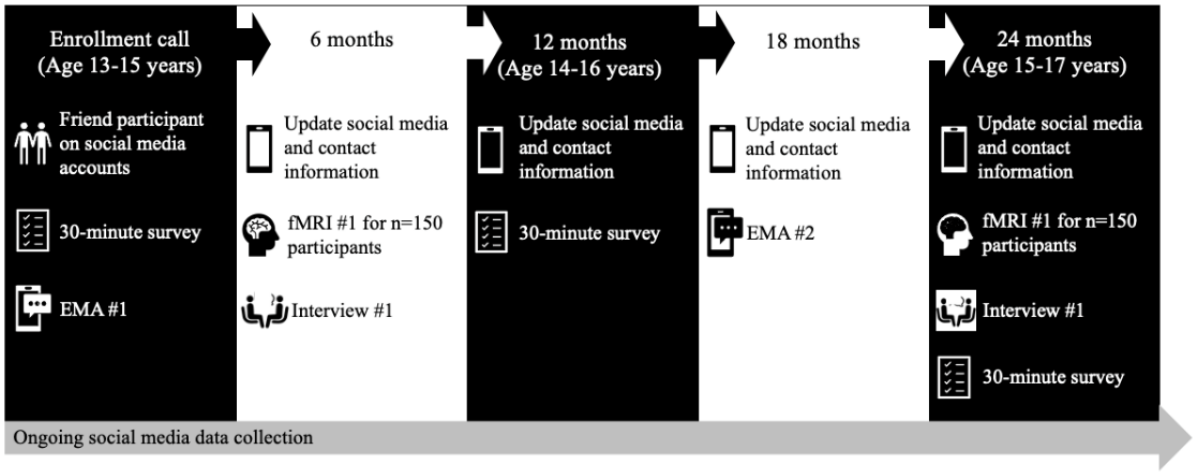
Study 1 will focus on TDM use to understand the mechanisms behind adolescent health and risk behaviors. Health behaviors will include behaviors that advance adolescent physical and mental health, including physical activity and sleep. Risk behaviors will focus on substance use, including the use of 10 categories of substances most often used by adolescents (eg, alcohol, tobacco, and marijuana). Substance use is connected with the major causes of morbidity and mortality in adolescents: accidents (particularly motor vehicle accidents), homicide, and suicide. Study 1 will include a 2-year data collection process, wherein social media data created by adolescents will be triangulated with self-reported health attitudes, social norms, intentions, and behaviors (aim 1). Study 1 will also include an assessment of other-generated TDM content reported by adolescents via an ecological momentary assessment (EMA) approach to capture real-time exposure to health and risk behavior content on TDM (aim 2). This study will also examine the persuasive elements of self-generated and other-generated content via functional magnetic resonance imaging (fMRI; aim 3). This project will include technology importance and parent involvement as moderators.

Study 2

Study 2 will use fMRI to understand how neural correlates associated with positive and negative TDM experiences relate to mental and behavioral health. Drawing on social media use data on health and risk behaviors and well-being, from studies 1 and 3, study 2 will assess reactivity (ie, neural activity) in reward-processing regions during social inclusion and reactivity in social pain regions during social exclusion at 2 time points, during middle school (time 1; 13 and 14 years of age) and after the transition to high school (time 2; 15 and 16 years of age). For study 2, aim 1 will include fMRI data collection at time 1 to examine whether the main effects of reactivity to social inclusion and exclusion predict health and risk behaviors and well-being at times 1 and 2. Aim 2 will include fMRI data collection at time 1 to examine whether neural reactivity to social inclusion and exclusion moderates the relationship between social media use (ie, likes, comments, number of friends or followers) and health and risk behaviors and well-being at times 1 and 2. Aim 3 will include fMRI data collected at times 1 and 2 to examine whether changes in reactivity to social inclusion and exclusion are associated with changes in one's social media environment (ie, positive valence peer interactions vs negative valence peer interactions) during the transition from middle school to high school, health and risk behaviors, and well-being, including technology importance and parent involvement as moderators, at time 2.

Study 3

Study 3 will use mixed methods to evaluate self- and other-generated TDM content as predictors of socioemotional well-being in sexual and gender minority (SGM) and non-SGM adolescents. Socioemotional well-being will include concepts of self-esteem, loneliness, stress, emotional difficulties, and subjective well-being, all of which are contributors to the overall mental health and subsequent morbidity and mortality in adolescents. Study 3 will involve data collection over 2 years to test a cross-lagged panel model of the relationships among self-generated social media content (aim 1), other-generated social media content (aim 2), and socioemotional well-being. Socioemotional well-being will be assessed through validated self-report instruments at baseline, 1 year, and 2 years. Self-generated social media content will be assessed using ethnographic observation and coding of participants' social media accounts for common patterns to create latent variables of self-generated content types. Other-generated content will be assessed through the direct observation of social media profiles that are followed by participants, which will be coded for common patterns and triangulated with participant interview data to create latent variables of other-generated content types. Study 3 will also examine self-generated and other-generated social media content of SGM participants, which will be qualitatively compared with the social media content of non-SGM participants (aim 3). SGM adolescents are at an increased risk for threats to socioemotional well-being and are also high-frequency users of TDM, warranting additional exploration of their social media experiences.



Study Design

This multimethodological protocol will recruit 400 adolescents aged 13 to 15 years to take part in a 2-year study on a rolling basis. Eligible participants will have at least 1 active social media account (ie, Instagram, Facebook [Meta Platforms, Inc],

XSL•FO
RenderX

Twitter [Twitter, Inc], or TikTok [ByteDance]). A subsample of 150 participants who meet the fMRI criteria will be recruited to participate in a 2–time point fMRI study in addition to the primary study. After gaining written informed assent from participants and consent from a parent or guardian, researchers will friend the social media accounts of participants to track their social media data over the 2-year enrollment period. Researchers will conduct a check-in at 6, 12, 18, and 24 months to update the research team on the current social media platform use. In addition, participants will complete a series of web-based self-report measures regarding health behaviors, well-being, and demographic information at the beginning of the study (0 mo), 12 months, and 24 months. Participants will also complete an EMA about health behaviors and social media content exposure at 0 and 18 months. Finally, participants will complete interviews at 6 and 24 months about their well-being and social media use. Participants enrolled in the fMRI portion of the study will also be asked to complete neuroimaging appointments at 6 and 24 months to collect neural responses associated with social connection (ie, self- vs other-generated social media posts, peer feedback, social influence, and social inclusion and exclusion) and self-reported individual difference measures and health behaviors. The study activities and participant experience timeline are summarized in Figure 1.

Figure 1. Study activities and participant experience timeline. On the basis of the shared participant pool, synergy in measures, and integration of data collection approaches, participants will have the same study experience even when starting at different time points. EMA: ecological momentary assessment; fMRI: functional magnetic resonance imaging.

Participants

Inclusion and Exclusion Criteria

Our inclusion criteria will include 400 adolescents living in Wisconsin who are aged 13 to 15 years at enrollment. Adolescents must own and maintain at least 1 social media profile on any of the social media platforms covered in our study (Facebook, Instagram, Twitter, and TikTok) at the time of enrollment. A social media profile will be defined as an individual (not a group or an organization) profile that the adolescent logs into and interacts with at least weekly. Participants must be able to speak, post content, and read in English.

A total of 150 participants (aged 13 and 14 years) from the 400 participants in the shared participant pool will be invited to take part in fMRI data collection. All fMRI participants will be right handed, not have claustrophobia, not currently be taking any psychoactive medications, have no history of psychiatric or neurological disorders, have normal (or corrected to normal) vision, not have metal in their body that is contraindicated for fMRI, and not currently be pregnant. Finally, participants should be in eighth grade at the time of the first scanning appointment to examine whether the social transition into high school alters neural function during development.

Recruitment and Enrollment

Participants will be recruited using a variety of methods (eg, on the web, mailers, recruitment ambassadors, speaking events, and pediatric clinics) from the state of Wisconsin, with efforts focused on the regions of and surrounding Madison, Green Bay, Beloit, and Milwaukee. To achieve our recruitment goal of including participants who represent communities of interest, we will use a quota sampling approach [45-47] and prescreen potential participants before enrollment. Screening will involve a brief demographic survey assessing age, race, ethnicity, gender identity, socioeconomic status (SES), and the identified sexuality. After screening, we will assess whether participants meet the criteria for recruitment based on the availability within each study quota. If a participant meets the recruitment criteria, we will proceed with consent and assent and recruitment.

The current protocol aims to recruit a sample reflective of the demographics of the United States in terms of sex, race, ethnicity, and SES. These demographics include, as of 2020, sex (50% female), ethnicity (18.7% Hispanic and Latino), and race (61.6% White, 12.4% Black, 6% Asian, 1.3% American Indian and Native Hawaiian or Pacific Islander, and 10.2% more than 1 race) [48]. Regarding SES, we will ask at screening whether an adolescent has free or reduced-price lunch at school. This proxy measure for SES will be useful for adolescents who are screened in the absence of a parent and may not know their household income. From 2019 to 2020, 52.1% of the students were eligible for free or reduced-price lunch [49]. Regarding

XSL•FO
RenderX

SGM status, given study 3's focus on SGM social media activities (aim 3), we will oversample individuals who identify as SGM. To reach theoretical saturation for qualitative analyses, we aim to recruit a minimum of 30 gender minority youths and 50 sexual minority youths. These estimates are based on our team's prior experiences with qualitative sampling.

Sample Size Calculations

Separate sample size calculations were performed for each of the 3 studies in this protocol based on the primary analyses that will be implemented. The primary hypothesis for study 1 is that adolescents' health and risk behavior displays will have a high positive predictive value (PPV) in identifying behaviors. In our previous work, self-generated alcohol displays were consistently and significantly positively associated with self-reported alcohol behaviors [50,51]. In our previous study, self-reported marijuana users had 1.7 higher odds of displaying marijuana use on social media compared with nonusers. For this study, a target sample size of 400 participants is proposed. A PPV of ≤60% for self-generated risk behavior displays will be considered unacceptably low. Hence, the null hypothesis that the PPV is at most 60% will be tested against the alternative hypothesis that the PPV is greater than 60%. Alcohol use has consistently been the most common risk behavior displayed on social media as well as reported by adolescents in our studies and national surveys. On the basis of the results of our previous study, it is estimated that at least 15% of participants will display alcohol use on social media over the period assessed. With the proposed sample size of 400 participants and an alcohol display rate of approximately 15%, the null hypothesis that the PPV is at most 60% will be rejected with 93% power at the 1-sided .05 significance level, assuming that the true PPV for alcohol display is 80% and an attrition rate of up to 15%. Furthermore, the proposed sample size will provide 55% to 78% power for detecting PPVs for less prevalent risk behavior displays (eg, marijuana use), assuming risk behavior display prevalence rates ranging from 5% to 10%, which is the lower end of prevalence we have seen in studies of older adolescents [52].

The primary goal of study 2 (fMRI) is to examine how the neural correlates of social TDM behavior relate to health and well-being outcomes in a within-participant design. A power analysis was conducted using G*Power based on a prior study that examined whether neural activity in the negative affect network during negative social feedback was related to behavior change (effect size=0.30; P=.05; power=0.95). The results indicated that a sample of approximately 110 participants would be large enough to detect a relationship between neural activity and behaviors outside the scanner within participants. In addition, a power analysis aimed at detecting neural differences between 2 time points was conducted based on a study examining reward activity differences within participants between 2-time points (mean of the paired difference 0.09, SD of the paired difference 0.26; P=.05; power=0.95). The results indicated that a sample size of 92 would be large enough to detect neural differences within participants. Therefore, a sample of 150 participants should be appropriate for the current design and will compensate for attrition and missing data.

Study 3 will incorporate ethnography and content analysis with data collected monthly. Research staff will immerse themselves in the self-generated content of the participant and take field notes on the participant's self-generated content using a template comprising the descriptions of the participant's posts as well as responses to their posts (eg, comments and the participant's responses to those comments). In addition, notes will be taken on the participant's overall profile, which may include the content they have been tagged in by others and personal information they use to self-describe. Profile and posts will also be coded for the type and themes of media content presented. Participant content will be assigned to the same research staff each month so that field notes can reflect the context of observable trends and changes within participants over time.

Social Media Data Collection

Platform Selection

We have selected social media platforms based on an affordance approach. Affordances are described as properties of artifacts that can be recognized by users and contribute to their functions or items that present an action possibility [53-55]. The goal of this framework is to increase the likelihood that an assessment or future intervention will hinge on replicable technological qualities as opposed to a platform's current popularity. This protocol design will focus on platforms with high identity affordances. Identity affordances include key attributes such as the use of individuals' names and personal photos and support sharing personal content, such as health behaviors [56]. Thus, higher identity affordances are an ideal approach to identify personal disclosures and behaviors. Of the platforms used by adolescents, Instagram, Twitter, and Facebook have been identified in previous studies as high–identity affordance platforms [57,58] and will be the focus of this protocol. TikTok, a newer platform, is widely used by adolescents and has identity affordances that are used to different degrees by adolescents based on whether they post content as an alter ego (eg, cosplay) or themselves. Thus, we will also include this platform for the evaluation of identity-focused content in this protocol.

Study Approaches to Social Media Data Collection

Social media data collection will occur over the 2-year enrollment period. This will be data collection through passive observation that requires no ongoing input from participants. With each 6-month check-in, participants will update the study team on their current social media platform use. Given that adolescents typically maintain several platforms and can change them over time, this will allow us to follow these patterns and observe data over the 2-year period. Social media observational data will be integrated into the 3 studies.

In study 1, we will perform a criterion-based content analysis using monthly profile assessments for health behaviors and risks. The main outcomes will be the frequency, prevalence, and content of health and risk behavior displays on social media, and the secondary outcome will be PPV for these displays associated with self-report.

Study 2 will examine social connectedness on social media by examining the number of friends or followers, conversion rates (number of comments/post), applause rate (number of

XSL•FO
RenderX

likes/post), and amplification rate (number of shares/post) [59]. In addition, a content analysis will be conducted on peer comments to determine how supportive (ie, positive valence) versus unsupportive (ie, negative valence) peer connections are on social media and the types of support provided, emotional support (eg, expressions of empathy and love), instrumental support (eg, aid and service), informational support (eg, advice and suggestions), and appraisal (eg, information for self-evaluation). The content and network interaction data can be combined to examine the sentiment and support provision, which can even allow for distinctions between message expression and reception [60,61].

Study 3 will incorporate ethnographic field notes collected monthly during the 2-year data collection period. During the monthly observation periods, the research staff will immerse themselves in the self-generated content of the participant for the previous week. The staff will take field notes on the participant's self-generated content using a template developed for web-based ethnography in our laboratory. The field note template comprises descriptions of the participant's posts as well as responses to their posts (eg, comments and the participant's responses to those comments). In addition, notes will be taken on the participant's overall profile, which may include the content they have been tagged in by others and personal information they use to self-describe. Participant content will be assigned to the same research staff each month so that field notes can reflect observable trends and changes within participants over time. In the field notes template, research staff will reflect on their own interpretations of the participant's self-generated content as well as any outstanding questions they have about the participant.

Self-Report Data Collection

The web-based self-report survey measures will be collected at 0, 12, and 24 months. This survey includes measures of demographics, health and risk behaviors, well-being, TDM exposure and use, and parental involvement. These measures will be used across all 3 studies included in this protocol. Full details are reported in Table 1.

XSL•FO
RenderX

Table 1. Self-report data collection.

Category	Measure
Well-being measures	• RSES[a] [62,63] • UCLA[b] Loneliness Scale [64] • Perceived Stress Scale [65] • Warwick Edinburgh Wellbeing Scale [66]
Mental health measures	• PHQ-9[c] [67,68] • GAD-7[d] [69]
Risk behavior measures[e]	• Substance use attitudes [70] • Substance use social norms [71] • Substance use behavioral intentions [72] • Substance use current and lifetime [73] • Substance use quantity and frequency [74,75]
Health behavior measures	• Physical activity [76]
Parent involvement measures	• Household media rules [77] • Parent-adolescent relationship [78]
Learning disability measures	• Diagnosed learning disabilities • IEP[f]
TDM[g] use and experience measures	• Emotional responses to social media experiences • Preferences for web-based social interactions • ADTI[h] [13,79] • Rosen Media and Technology Usage and Attitudes Scale (subscales: Usage and Attitudes) [80]
Demographic measures	• Age • Race • Ethnicity • School (grade, public vs private, and web-based vs in person) • Birth sex • Gender identity • Sexual orientation

[a]RSES: Rosenberg Self-Esteem Scale.

[b]UCLA: University of California, Los Angeles.

[c]PHQ-9: Patient Heath Questionnaire-9.

[d]GAD-7: General Anxiety Disorder-7.

[e]Web-based self-report measures were collected at 0, 12, and 24 months. Risk behaviors will examine the use of cigarettes, chewing tobacco, vaping tobacco, cannabis, vaping cannabis, alcohol, cocaine, hallucinogen, opiate, amphetamine, club drugs (methylenedioxy-methamphetamine, ecstasy, and molly), inhalants (nitrous oxide and whippets), and prescription drugs (for nonmedical reasons).

[f]IEP: Individualized Education Program.

[g]TDM: technology and digital media.

[h]ADTI: Adolescents' Technology Importance and Interactions Scale.

EMA Data Collection

EMA data will be collected at 0 and 18 months to measure exposure to content about health and risk behaviors. EMA, also called the experience sampling method, is characterized by a collection of data in real-world environments. These assessments focus on an individual's current or very recent behaviors and are particularly effective for behaviors that occur intermittently [81,82]. EMA avoids the reliance on retrospective reports, which may be subject to biases that challenge their reliability and validity [83]. To measure daily time spent using TDM and content exposure using EMA, surveys will be designed to be brief (<3 min) and allow responses via an SMS text message. Each brief SMS text message survey will begin with the following question: "When you got this text, were you using a digital device?" If participants respond "Y" for yes, these questions will follow: (1) "How long were you on the device in minutes?" (2) "Were you looking at a post or video? (Y or N)" (3) "Please list every topic that was in the post or video (this message is sent with an image that illustrates 9 topics of interest)." To describe their current content exposure, participants can enter all applicable options from the following predetermined content list: E=exercise, A=alcohol, F=food and cuisine, C=cannabis, L=lifestyle and self-improvement,

XSL•FO
RenderX

T=tobacco and nicotine, D=drugs, S=shows and entertainment, and O=other. If participants respond "N" to the first prompt, these questions follow: (1) "Have you seen a post or video since we messaged last? (Y or N)" and (2) "Please list every topic from the last post or video you remember" (this message is paired with the topic list image). After completing the survey, participants will receive this message: "Thanks for completing this prompt! Your answers are a contribution to science!"

Interview Data Collection

We will use a qualitative phenomenological approach to interviews, enabling us to capture individual lived experiences [84]. Our open-ended, semistructured interview method encourages the exploration of concepts important to the participant and provides the researcher with the ability to ask follow-up questions based on the participant's experience and let their narrative guide the interview process. This creates an opportunity for concepts that might not be detected through other, more structured methods to be introduced [85]. Research staff will conduct in-person or video interviews with participants 6 months after study enrollment and at study conclusion. During these interviews, the research staff will question participants about the social media accounts that they follow, reasons for following the accounts, and how the content from the accounts' feeds makes them feel. Participants will be encouraged to take out their device and use specific examples from their feed in real time to elicit the nature of each account from their perspective. Our laboratory has piloted similar interviews with adolescents in which study staff reviewed participants' own social media content in real time, and we have found that adolescents are open with interviewers and eager to teach them about the social media content they see. The data from these interviews (key quotes, observations, and insights) will be analyzed using a constant comparative approach. These findings will be collected and grouped by themes, culminating in a summary that captures key insights, frameworks, and principles to be triangulated with the study team codebook and applied to each participant's larger list of accounts they are following.

Neuroimaging Data Collection

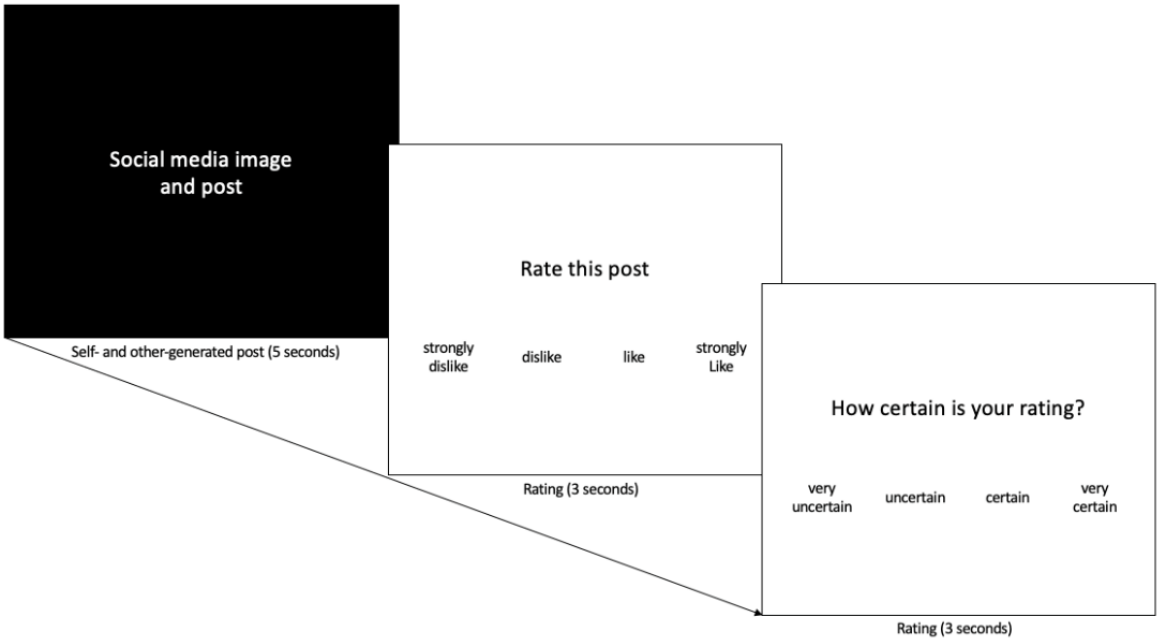
fMRI Data Acquisition

Brain imaging data will be collected using the 3T magnetic resonance imaging scanner (GE Healthcare MR750) and include longitudinal relaxation time (T1) and transverse relaxation time relaxometry using steady-state sequences (multicomponent Driven Equilibrium Single Pulse Observation of T1 and transverse relaxation time) [86,87]. Structural imaging of anatomical detail for morphometric analyses will be performed using a custom magnetization-prepared rapid acquisition gradient echo sequence, which removes the intensity variations from inhomogeneities in the coil sensitivities. Functional blood-oxygen-level-dependent images may be recorded using a reverse spiral sequence (repetition time=1000 ms, time to echo=32 ms, flip angle=60°, 56 sagittal slices, field-of-view=208 mm, slice thickness=2.5 mm, and voxel size=2.5×2.5×2.5 mm). Each sequence will take 1 to 10 minutes, and the total scan time will be 60 minutes.

Collecting Self-Generated TDM Content

Aim 3 of study 1 is to examine whether self-generated versus other-generated TDM content is processed differently and whether neural activity is associated with self-reported health behaviors. To collect self-generated posts, participants will be asked to complete a self-report survey during EMA data collection, which will ask participants to create self-posts that they have or would upload to social media. Participants will upload a picture and create a text post for 25 posts (20 posts will be used in the associated fMRI task). In addition, participants will be asked whether they have already posted the content on social media.

Scanning Session



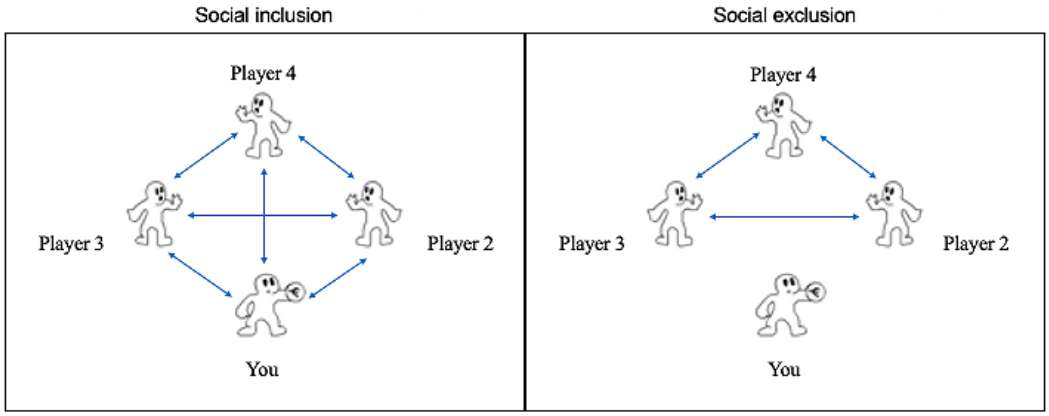
Participants taking part in the fMRI portion of the protocol will complete neuroimaging appointments at 6 and 24 months. Both neuroimaging appointments will consist of 4 neuroimaging tasks aimed at examining the neural processes associated with social connections. Before the scan, participants will be asked to complete a fMRI safety screening form and a series of self-report measures, including measures of well-being and health and risk behaviors. Next, participants will be trained on the fMRI tasks they will be asked to complete during the scanning session. Details regarding the 2 primary functional tasks (ie, self and other messages and Cyberball) are provided in the subsequent paragraphs. Details regarding the 2 secondary functional tasks (ie, peer feedback and social influence) and secondary self-report measures are provided in Multimedia Appendix 1 [70-75,88-107].

The Self and Other Message Task

Participants will first complete the self and other message task as part of study 1 aim 3. Participants will be exposed to 65 social media posts targeting health or risk behaviors. Messages (5 s/message) will be either self-generated using participants' own data provided in the survey detailed earlier (20 messages) or peer generated (45 messages; categories: vaping tobacco [5], alcohol [5], cannabis [5], exercise [5], nutrition [ie, high-caloric foods; 5], self-image [ie, idealized bodies wearing provocative clothing; 5], civic engagement [5], and generic or neutral [ie, everyday events, such as studying and hanging out with friends; 10]). The other-generated messages will be created by the study team and will be the same stimuli set for each participant. Following each message, participants will answer the question "how would you rate this post on social media" by pressing their pointer finger for 1 star (strongly dislike), middle finger for 2 stars (dislike), ring finger for 3 stars (like), or pinky for 4 stars (strongly like; 3 s). Next, they will rate their preference certainty (on a 4-point scale from 1="very uncertain" to 4="very certain;" 3 s). Ratings will be followed by a jittered fixation period (mean 3 s; range 1-5 s), which will serve as an implicit baseline (Figure 2).

XSL•FO
RenderX

Figure 2. Self and other message task. The self and other message task will measure neural activity during exposure to self-generated and other-generated social media posts.



The Cyberball Task

In addition, participants will complete a social inclusion and exclusion task (Cyberball). Cyberball is a game that allows the simulation of both inclusion and exclusion in an fMRI environment [108,109]. In this task, during the first fMRI session, participants will be told that they are engaging in a web-based ball-tossing game with 3 confederate participants playing the game on the web at a remote location. In reality, a preset computer program will control the other 3 players. Before the scan, participants will be shown screenshots of the web-based ball-tossing game and given instructions on how to throw the ball. In addition, they will be told that the only rule for the game is that you can throw the ball to any player; however, you cannot just hold the ball and do nothing. During the first part of the game, the other players will throw to one another and to the participant equally (social inclusion). In the second round, the other players will stop throwing the ball to the participant and only throw to one another (social exclusion).

The 2 rounds of Cyberball will each last 178 seconds. The social inclusion round will always be played first, in which all participants will receive the ball equally often. This will be followed in the social exclusion version of the game. The round of social inclusion will always be the first to preserve the psychological experience across participants. These rounds will be preceded by a period in which participants visually track a star as it moves on the screen (105 s). Each round will be separated by a 16-second dot-fixation rest period. This task will always be the final task during the fMRI session. Following the scanning session, participants will complete the Needs Threat Scale to measure self-reported distress following social exclusion in Cyberball [110] and will take part in an interview regarding the study to alleviate any stress experienced from Cyberball. Participants will not be debriefed on the true nature of the Cyberball task after the first scanning session to avoid contaminating the results during the second scanning session (Figure 3).

Figure 3. Cyberball task. The Cyberball task is a web-based ball-tossing game that measures neural activity during exposure to social inclusion and social exclusion.

Data Analysis

Study 1

Aim 1

Aim 1 is to determine the frequency and content of self-generated displays of health and risk behaviors on social media profiles. Aim 1a is to test the predictive value of self-generated health and risk behavior content on adolescents' social media profiles to represent attitudes, social norms, intentions, and behaviors. Hypothesis 1a is that adolescents' self-generated health and risk behavior content will have a high PPV in identifying behaviors. Aim 1b is to test the moderators of the relationship between self-generated health and risk behavior content and self-reported health and risk behaviors, including parenting involvement and the perceived importance of technology. Hypothesis 1b is that parenting and the importance of technology will serve as moderators such that the associations between self-generated health and risk behavior content on TDM and self-reported health and risk behaviors will be stronger for those with lower parenting involvement and greater technology importance.

In these analyses, the outcome measures will be self-reported behaviors, and predictor variables will be self-generated displays. Measures will be dichotomized based on established threshold values. We will use a generalized linear mixed-effects model with participant-specific random effects and an autoregressive correlation structure to account for repeated measures over time to identify and examine the factors of self-generated displays that predict the corresponding self-reported outcomes. Both univariate and multivariate analyses will be conducted. Study participants' baseline characteristics, including demographic variables and health and risk behavior variables, will be included as covariates in the multivariate analyses. The least absolute shrinkage and selection operator method for the variable selection of generalized linear mixed-effects models will be used to identify parsimonious models with independent predictors. To test the moderators of the relationship between social media displays and self-reported cognitions (eg, attitudes, social norms, and intentions) and behaviors, we will test interaction effects between social media displays and the moderators of parent involvement and technology importance and include significant moderators in these models. In exploratory analyses, we will examine possible differences in PPV by platform across health and risk behaviors.

Aim 2

Aim 2 is to determine adolescents' real-time TDM exposure to self-generated and other-generated health and risk behavior content using EMA and to test the association between TDM exposure to health and risk behavior content and self-reported health attitudes, social norms, intentions, and behaviors. Hypothesis 2 is that adolescents' exposure to other-generated health and risk behavior content will have positive associations with attitudes, social norms, and intentions, moderated by technology importance.

The association between TDM content exposure and self-reported intentions and behaviors will be evaluated using a generalized linear mixed-effects model with subject-specific random effects. The moderation effects will be evaluated by conducting a series of univariate and multivariate analyses with the corresponding predictor and median variables, and the Sobel test will be used to formally test for moderation effects [111]. As an additional exploratory analysis, we will determine an accurate measure of adolescents' daily TDM use. We will not ask participants to attempt to recall a full day or "typical time spent" on TDM because of strong evidence that these measures are inaccurate owing to response and recall bias. Instead, EMA data will be used to calculate daily TDM time as a measure of the quantity of use, which will be reported as descriptive data or incorporated into models across projects as appropriate. First, raw data for the duration of TDM use will be summarized using mean, SD, median, and range from the self-reported data. Second, we will calculate the proportion of time that participants mention that they were using TDM across each participant's responses of "Y" to indicate that they were actively using TDM. We will use a similar approach to investigate the frequency of content types they are exposed to via TDM. These proportions will be estimated using a generalized linear mixed-effects model with a logit link function and subject-specific random effects. To account for the correlations between time points, an autoregressive correlation structure of order one will be used. Third, we then will use a multilevel modeling approach that captures both within-participant and between-participant variations of the EMA data [112]. This includes subject-specific random effects and an autoregressive correlation structure to account for the correlations within each participant among the repeated measures over time in addition to the covariate of the percentage of time the participant mentions that they were on the web. If the distribution of the time spent is skewed, the data will be log-transformed before conducting the analysis to satisfy the normality assumption.

Aim 3

Aim 3 is to use fMRI to examine whether self-generated TDM content versus other-generated TDM content are processed differently and whether neural activity is associated with self-reported health behaviors. Hypothesis 3a is that the ventral medial prefrontal cortex (VMPFC) will show greater activation for self-generated messages compared with other-generated messages. Hypothesis 3b is that sharing more self-generated content on TDM will be associated with increased VMPFC activity compared with sharing more other-generated content. Hypothesis 3c is that VMPFC activity at time 1 will be associated with increased health and risk behaviors reported at time 2.

Data will be modeled at the participant-subject level using the general linear model, as implemented in Statistical Parametric Mapping version 12 (SPM12; Wellcome Department of Cognitive Neurology, Institute of Neurology). Details regarding fMRI data analysis can be found in study 2. The persuasion task will consist of 2 phases: message exposure (5 s), where participants will be exposed to self- versus other-generated messages, and then they will rate the effectiveness of each message (3 s) and provide confidence ratings (3 s), which will be used as baseline ratings for the social influence task. We will model the 5-second period during which participants will be exposed to the persuasive messages as a boxcar. Specifically,

XSL•FO
RenderX

we will cross the message source using 2 regressors, self and other, with whether the participant rated the messages as effective. In other words, we will have 2 regressors for each persuasive message condition noted earlier, depending on whether the participant rated the message as effective for that trial, resulting in 4 focal regressors crossing message condition and message effectiveness. Region of interest (ROI) analyses will be performed using independent sample 2-tailed *t* tests and linear regression. The primary ROIs will be regions associated with positive valuations [113], including the VMPFC. The ROIs will be constructed using the association test map in Neurosynth using the search term "valuation." Individual difference scores will be calculated for the positive valuation network based on a percent signal change score. This score will be created by dividing the average time-series signal (activation) across all voxels within the ROIs during the condition of interest by the baseline condition. The persuasion task will consist of examining differences in neural activity between the following conditions (self-generated>other-generated; self-generated+persuasive>other-generated+persuasive; self-generated+persuasive>self-generated+unpersuasive; other-generated+persuasive>other-generated+unpersuasive). Parallel whole-brain analyses will be performed to determine whether neural regions outside of our a priori ROIs are associated with self-generated versus other-generated content and health behaviors.

Study 2

Quality Checking

Quality checking of the brain data will be done before and after the preprocessing step to ensure that the results are not driven by abnormalities related to data acquisition or preprocessing (eg, scanner artifacts). All the brain images will be visually inspected for signal dropout or other abnormal data. In addition, motion parameters from SPM12 will be examined, and no runs displaying greater than 3 mm (translation) or 2 degrees (rotation) of head movement during a task run will be used.

Preprocessing

Functional data will be preprocessed and analyzed using SPM12. To allow for the stabilization of the blood oxygen level–dependent signal, the first 4 volumes (8 s) of each run will be discarded before analysis. Functional images will be despiked using the 3dDespike program as implemented in the Analysis of Functional NeuroImages toolbox. Next, data will be corrected for differences in the time of slice acquisition using sinc interpolation; the first slice will serve as the reference slice. Data will then be spatially realigned with the first functional image. We then will coregister the functional and structural images using a 2-stage procedure. First, in-plane T1 images will be registered to the mean functional image. Next, high-resolution T1 images will be registered to the in-plane image. After coregistration, high-resolution structural images will be skull stripped using the Computational Anatomy Toolbox 12 for SPM12 and then normalized to the skull-stripped Montreal Neurological Institute template provided by the Oxford Centre for Functional Magnetic Resonance Imaging of the Brain Software Library ("MNI152_T1_1mm_ brain.nii"). Finally, functional images will be smoothed using a Gaussian kernel (8-mm full width at half maximum). Following the preprocessing steps, motion parameters from SPM12 will be examined, and no participants who display greater than 3 mm (translation) or 2 degrees (rotation) of head movement during a task run will be included.

Construction of ROI

In both primary fMRI tasks (ie, self and other messages and Cyberball), the primary ROIs will be neural regions associated with social pain [108] and reward processing [114]. ROIs will be constructed using the association test maps in Neurosynth using the search terms "negative affect" and "reward." Individual difference scores will be calculated for the social pain and reward networks based on a percent signal change score. This score will be created by dividing the average time-series signal (activation) across all voxels within each ROI during the condition of interest by the baseline condition.

Primary Task (Cyberball)

Statistical Modeling

Data will be modeled at the single-subject level using the general linear model, as implemented in SPM12. The Cyberball (version 5) task consists of 3 phases: social inclusion (178 s), social exclusion (178 s), and visual tracking (105 s), and all 3 phases will be modeled as blocks and convolved with the synthetic hemodynamic response as provided by SPM12. For all tasks, the 6 rigid-body translation and rotation parameters derived from spatial realignment will also be included as nuisance regressors. Data will be high-pass filtered with a cutoff of 128 seconds. Volumes will be weighted according to the inverse of their noise variance using the robust weighted least squares toolbox [115]. The Cyberball task will involve examining neural activity in the contrast (social exclusion>social inclusion).

ROI Analyses

To examine neural reactivity to social inclusion and exclusion and its relationship with social media use, well-being, and health behaviors, we will conduct a series of linear regressions and moderation analyses. The specific hypotheses and analyses for each aim are outlined in the following paragraphs.

Aim 1

To test whether participants who show greater reactivity in social pain regions during social exclusion will be associated with poorer well-being and risk behaviors at time 1 (hypothesis 1a) and at time 2 (hypothesis 1b), we will test whether social pain activity during social exclusion compared with social inclusion is associated with subjective measures of well-being and risk behaviors at times 1 and 2. Next, to test whether participants who show greater reactivity in reward regions during social inclusion will be associated with better well-being and health behaviors at time 1 (hypothesis 1c) and at time 2 (hypothesis 1d), we will test whether reward activity during social inclusion compared with exclusion is associated with subjective measures of well-being and health behaviors at times 1 and 2.

Aim 2

To test whether the relationship between social media use and well-being and health behaviors will depend on the reactivity

XSL•FO
RenderX

of participants' brains to social pain during social exclusion at time 1, we will examine whether social pain activity during social exclusion compared with social inclusion moderates the relationship between social media use (ie, social connectedness measures) and subjective measures of well-being and health and risk behaviors at time 1 (hypothesis 2a) and time 2 (hypothesis 2b). In addition, we will examine whether reward activity during social inclusion compared with social exclusion moderates the relationship between social media use (ie, social connectedness measures) and subjective measures of well-being and health and risk behaviors at time 1 (hypothesis 2c) and time 2 (hypothesis 2d).

Aim 3

To test whether changes (time 2–time 1) in reactivity to social inclusion and exclusion will be associated with increased risk behaviors and worse well-being for those who have unsupportive social media experiences over time (hypothesis 3a) and associated with better health behaviors and well-being for those who have a more supportive social media experience over time (hypothesis 3b), we will examine whether changes in social pain activity during social exclusion compared with social inclusion and reward activity during social inclusion compared with social exclusion from time 1 to time 2 moderate the relationship between the social media environment (ie, support measures) and subjective measures of well-being and health and risk behaviors at time 2.

Study 3

Overview

We will run descriptive statistics and transform skewed outcome variables as necessary to ensure normality. We will address missing data by applying advanced statistical techniques, such as *multiple imputations*, using the multiple imputation procedure in the Statistical Analysis Services and Imputation and Variance Estimation Software Statistical Analysis Services macro. Bivariate analyses will be performed to examine potential covariates and covariates significantly associated with the predictor, and our outcomes will be included in the model.

We will begin by conducting an exploratory factor analysis using principal axis factoring with Promax rotation to examine how social media activities identified through the web-based ethnography load onto latent factors. We will then run a confirmatory factor analysis to establish whether the emerging latent factors are nested into our hypothesized higher-level factor structure, specifically self-generated content and other-generated content. Finally, we will conduct factorial invariance tests using the approach suggested by Kühne [116] to establish whether the same factor structure emerges at all measurement time points and between SGM and non-SGM adolescents.

Aim 1

Aim 1 is to test bidirectional relationships between self-generated TDM content and socioemotional well-being. Hypothesis 1a is that TDM engagement with peers (higher vs lower) will be predictive of socioemotional well-being (higher and lower, respectively) at times 1 and 2. Hypothesis 1b is that socioemotional well-being (higher vs lower) will be predictive of TDM engagement with peers (higher and lower, respectively) at times 1 and 2.

Aim 2

Aim 2 is to test the bidirectional relationships between other-generated TDM content and socioemotional well-being. Hypothesis 1a is that the consumption of TDM content connected with offline life (higher vs lower) will be predictive of socioemotional well-being (higher and lower, respectively) at times 1 and 2. Hypothesis 1b is that socioemotional well-being at baseline (higher vs lower) will be predictive of the consumption of TDM content connected with offline life (higher and lower, respectively) at times 1 and 2.

To test the direct and indirect associations of self-generated content and other-generated content with socioemotional well-being (aims 1 and 2), we will conduct a cross-lagged panel analysis (ie, a type of structural equation model), with unweighted data and a full information maximum likelihood estimator, using Mplus 8.4 [117]. As illustrated in Figure 1, self-generated content, other-generated content, and socioemotional well-being at *time 0 (baseline)* will be allowed to simultaneously predict these same variables at *time 1* and then again predict these same variables at *time 2*. In cross-lagged models, each person serves as their own control, and results can be interpreted as pertaining to within-person changes; therefore, it is not necessary to include control variables [118]. This analysis will allow us first to investigate the cross-sectional relationships between the variables of interest at *time 0*, *time 1*, and *time 2* (ie, to what extent self-generated and other-generated content are related to well-being), thus adding to prior cross-sectional research. More importantly, it will allow us to examine lagged relationships or relationships between our variables of interest over time (ie, to what extent self-generated and other-generated content at one time point predicts well-being at the next time point, controlling for well-being at the initial time point). These lagged relationships make it possible to longitudinally test whether well-being is (1) an outcome of self-generated or other-generated content (eg, if self-generated and other-generated content at *time 0* predicts well-being at *time 1* and *time 2*), (2) a predictor of self-generated or other-generated content (eg, if well-being at *time 0* predicts self-generated and other-generated content at *time 1* and *time 2*), (3) both (eg, if well-being at *time 0* predicts self-generated and other-generated content at *time 1 and* self-generated and other-generated content at *time 1* predict well-being at *time 2*), or (4) neither (ie, no relationships are statistically significant).

In other words, the lagged analyses will enable us to ascertain the direction of causality between well-being and self-generated and other-generated content on social media. An additional benefit of this statistical approach is the ability to tease out between-person effects (ie, group-level differences) from within-person effects (ie, individual-level differences). Of primary interest to us are within-person effects, which refer to how changes in an individual's activities affect their well-being over time (and vice versa). Thus, we will be able to investigate whether an adolescent's social media activities affect their well-being over time and whether an adolescent's well-being

XSL•FO
RenderX

affects the type of social media activities they engage in over time.

In cross-lagged designs, all variables are correlated with each other, resulting in just-identified models. Thus, model fit indices are not informative and do not need to be reported [118]. In addition, further tests of scalar invariance (ie, mean differences across groups in the latent construct) are not appropriate, given that the latent factors at the 3 time points are not independent of each other [119].

From the cross-lagged panel models, all mediated effects of interest will be estimated and tested using bootstrapping. Both the magnitude and statistical significance will be reported, with the significance level set at 2-sided α=.05.

Aim 3

Aim 3 is to compare the self- and other-generated TDM experiences of SGM adolescents with those of non-SGM adolescents. This exploratory aim will involve the use of qualitative comparison groups for future hypothesis generation.

Ethics Approval

This protocol is approved by the University of Wisconsin-Madison institutional review board (2022-1280).

Data Management

For eligible individuals who decide to participate in the study, all identifying information will be removed from the brain image files, survey, EMA, and interview data, and they will be labeled with a study code before they are transferred for storage or used in data analyses. Only trained research staff will analyze the data. Any forms that contain identifying information will be locked in file drawers or stored in password-protected files and accessible only to this study's research staff. There may be publications as a result of this study, but no identifying information will be included. Survey data will be collected through the use of REDCap (Research Electronic Data Capture; Vanderbilt University), and fMRI brain images will be collected on the Waisman Center server during the scanning session. Data will be permanently stored on a secure server run by the Department of Pediatrics. Only the study staff, who all have human participants certification, will have access to the data on these servers.

Reviewer Feedback

Reviewer feedback on the grant and author responses have been provided in Multimedia Appendix 2 [120-122].

Results

Data collection began in March of 2023 and is ongoing. Our long-term goal is to use the findings from this synergistic protocol program to enhance health messaging campaigns, improve big data surveillance approaches, develop innovative interventions, and advance conceptual models. This protocol will (1) include interdisciplinary studies of TDM use across adolescence using multilevel assessments of neurodevelopment to examine interrelated developmental changes in brain structure and function and complex behavior, (2) examine real-time measures of TDM exposure and use and how this use regulates adolescents' behavior, and (3) conduct research using converging methodologies to assess the relationship between TDM exposure and sensitive periods in brain development.

Discussion

Overview

This protocol will establish a fully integrated interdisciplinary program of research studies that are essential for developing a fundamental understanding of the complex interplay between adolescent health and development and TDM. Previous evidence has illustrated TDM's connections with adolescent risk behaviors such as increased alcohol behavior and social media exposure, as well as relationships with adolescent well-being such as improved socioemotional health and peer social media connections. The goal of the studies described in this protocol is to address the urgent need to understand how TDM exposure and use affect multiple developmental domains and health outcomes. Study 1 will use TDM to understand the mechanisms behind adolescent health and risk behaviors. Study 2 uses fMRI to understand how positive and negative TDM experiences relate to mental and behavioral health. Study 3 will use a mixed methods design to evaluate self- and other-generated TDM content as predictors of socioemotional well-being in SGM and non-SGM adolescents. Each study uses a 2-year longitudinal design and draws from a shared participant pool. Across studies, observed and measured data will be collected, including observed social media content and fMRI data, self-reported participant experiences and perceptions from surveys and interviews, and EMA for capturing real-time TDM exposure. This protocol prioritizes the dissemination of findings, both to scientific audiences and to the communities across Wisconsin to reach those who participated in this research. Thus, the protocol will enhance the ideas and outcomes obtained through the interactions of the 3 studies. This protocol will provide the scientific approach necessary to advance data-informed theories and conceptual models addressing how TDM exposure and use impact the developmental trajectories and health outcomes of adolescents. Because of the broad potential for advancing research and possible clinical translation of the results, these connected studies portend an opportunity to improve prevention and intervention approaches for adolescent health and TDM.

This project's data hold exciting potential in four areas:

1. Messaging campaigns: an understanding of key messages regarding health and risk behaviors or socioemotional well-being may inform prevention messaging campaigns. Using data from this protocol, targeted messages (such as tailored advertisements) could be made to automatically pop up
on social media when a specific type of risk-related post is present, providing a link to health education or a web-based intervention.
2. Surveillance: by identifying keywords or phrases associated with health and risk behaviors or well-being, big data approaches could be used to identify or track social media posts focusing on health and risk behaviors or well-being across a larger population or different social media platforms.

XSL•FO
RenderX

3. Intervention approaches: health behavior intention posts may represent an individual's consideration of behavior change or openness to intervention. Studies support that adults who are considering behavior change have more motivation and willingness to engage in alcohol interventions [123]. Identifying the markers of adolescents' intention to improve health may allow for novel intervention approaches tailored to this particular stage of development and intentionality.
4. Conceptual models: the findings from this study have the potential to enhance or update conceptual models focused on adolescent technology use, such as the Media Practice Model [124], which supports the idea that adolescents choose to interact with media based on who they are or who they aspire to be. The data from this protocol may also contribute to the development of new models.

Potential Limitations

A central benchmark of success for our protocol will be our capacity to recruit and retain a shared participant pool of 400 participants for the 3 studies. There are several reasons that support the planning and success of this study. First, authors MAM and ES bring experiences that span projects 1 to 3 in recruiting and retaining adolescent populations. Second, we will pursue recruitment and retention via recruitment ambassadors, who will provide us with a warm and familiar connection with adolescents and families during recruitment. We will leverage both intrinsic motivation, such as promoting emotional connection with the study by providing participants with appealing branded materials, and extrinsic motivation via escalating incentives to retain adolescents. Our investigator team collaboratively designed participant recruitment to occur on a rolling basis over the first 2 years of the protocol period. If recruitment is an issue, we will use alternative approaches, such as targeted social media advertisements and Qualtrics (Qualtrics International Inc) panel–based recruitment, to achieve recruitment goals. If we have retention issues, we will engage our recruitment ambassadors to obtain insights into continued engagement with the participant population. Given that our rolling recruitment efforts will extend over 2 years, we will also have the flexibility to recruit additional participants if early dropouts occur.

A second critical aspect of our study will be to build trust in participants to support their willingness to provide ongoing data in this longitudinal study. Our investigator team will use several evidence-based approaches to optimize adolescents' trust and comfort in this longitudinal study, including conducting frequent touch points via check-ins every 6 months and providing incentives with every touch point. We will work with trained staff who have centered their research career work on the adolescent population and have training in working with this study population.

Critical Considerations for Social Media Data Collection

Although adolescents may use other social media platforms, we focus on the selected 4 social media platforms based on several factors. First, authors MAM and ES selected these platforms based on the conceptual approach of affordances, and given this study's focus on the process of identity development, these 4 platforms represent venues that have strong identity affordances [125,126]. Further, these 4 platforms are popular and used across diverse adolescent demographic groups. Given the length of our planned protocol, there could be a rise of a new popular social media platform or a decline of a planned study platform. If a new platform aligns with promoting identity affordances, we would consider adding it to our study protocol. Content analysis (study 1) and digital ethnography (study 3) procedures require staff training and attention to the coding quality, both tasks that MAM and ES are familiar with owing to past projects. Although big data techniques allow text-based scraping from large data sets, they are limited in that they cannot assess hashtags or all types of photos. Further, big data approaches cannot always ascertain whether content is self-generated or other generated, which are central concepts in this proposal. For this study, we will rely on establishing a *friend* link between our research team profiles and our participants' profiles. We have several points of evidence to suggest that this approach will work. First, social media users' desire to accumulate more friends provides an incentive for them to *friend* our research team, as this number is associated with increased social capital [31]. Second, we have used this approach before in several studies to inform friending approaches [127] and collect data [120,128,129]. If a participant wanted to *defriend* us at some point in the study, we would consider this a voluntary withdrawal. On the basis of our previous longitudinal studies, we anticipate that this loss would be <5% of participants.

Acknowledgments

This protocol is funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development (P01HD109850-01) and the University of Wisconsin-Madison Vice Chancellor for Research and Graduate Education Matching Grant. In addition, functional magnetic resonance imaging data collection is supported in part by a core grant to the Waisman Center from the Eunice Kennedy Shriver National Institute of Child Health and Human Development (P50HD105353). The authors would also like to thank their coinvestigators Emily Falk, Dana Litt, Julie Lumeng, Megan Ranney, Dhavan Shah, Eva Telzer, and Catalina Toma for their help with developing this protocol. In addition, the authors would like to thank the study team members for their work on this protocol and help with data collection, particularly the staff leads for each project: Matt Minich, Bradley Kerr, and Victoria Adkins; their recruitment ambassadors and community partners for help with recruitment; their external advisory board for feedback on the protocol; and Caitlin M Carlson, Christine Richards, and Christine Pientok for help with the protocol and grant submission.

Abstract

Background: Just-in-time adaptive interventions (JITAIs) are designed to provide support when individuals are receptive and can respond beneficially to the prompt. The notion of a just-in-time (JIT) state is critical for JITAIs. To date, JIT states have been formulated either in a largely data-driven way or based on theory alone. There is a need for an approach that enables rigorous theory testing and optimization of the JIT state concept.

Objective: The purpose of this system ID experiment was to investigate JIT states empirically and enable the empirical optimization of a JITAI intended to increase physical activity (steps/d).

Methods: We recruited physically inactive English-speaking adults aged ≥25 years who owned smartphones. Participants wore a Fitbit Versa 3 and used the study app for 270 days. The *JustWalk JITAI* project uses system ID methods to study JIT states. Specifically, provision of support systematically varied across different theoretically plausible operationalizations of JIT states to enable a more rigorous and systematic study of the concept. We experimentally varied 2 intervention components: notifications delivered up to 4 times per day designed to increase a person's steps within the next 3 hours and suggested daily step goals. Notifications to walk were experimentally provided across varied operationalizations of JIT states accounting for need (ie, whether daily step goals were previously met or not), opportunity (ie, whether the next 3 h were a time window during which a person had previously walked), and receptivity (ie, a person previously walked after receiving notifications). Suggested daily step goals varied systematically within a range related to a person's baseline level of steps per day (eg, 4000) until they met clinically meaningful targets (eg, averaging 8000 steps/d as the lower threshold across a cycle). A series of system ID estimation approaches will be used to analyze the data and obtain control-oriented dynamical models to study JIT states. The estimated models from all approaches will be contrasted, with the ultimate goal of guiding rigorous, replicable, empirical formulation and study of JIT states to inform a future JITAI.

XSL•FO
RenderX

Results: As is common in system ID, we conducted a series of simulation studies to formulate the experiment. The results of our simulation studies illustrated the plausibility of this approach for generating informative and unique data for studying JIT states. The study began enrolling participants in June 2022, with a final enrollment of 48 participants. Data collection concluded in April 2023. Upon completion of the analyses, the results of this study are expected to be submitted for publication in the fourth quarter of 2023.

Conclusions: This study will be the first empirical investigation of JIT states that uses system ID methods to inform the optimization of a scalable JITAI for physical activity.

Introduction

Background

There is great interest in the promise of just-in-time adaptive interventions (JITAIs) to support behavioral medicine. A JITAI is a behavioral intervention that is designed to (1) provide interventions and support during *just-in-time (JIT) states*, defined as times when a person would have a *need for support*, an *opportunity to act* in accordance with the support, and *be receptive* to support [1]; and (2) adapt over time to a person's changing needs with the use of adaptation algorithms that strive toward enabling a person to meet clinically meaningful behavioral targets (eg, national recommendations for a given behavior) while accounting for the person's current capabilities and constraints. Although there is a lot of interest in this type of intervention, more work is needed to advance the understanding of the foundational concepts implied by JITAIs, particularly the JIT state. The JIT state concept is inherently context dependent, dynamic, and likely to manifest differently for different people over time. Given this complexity, much of the work on JITAIs has focused on either creating interventions that are theory driven in terms of specifying JIT states according to a priori decision rules or through more data-driven approaches such as reinforcement learning. An important gap is the lack of a conceptual understanding of JIT states, which could be achieved by conducting rigorous theory-testing protocols designed to test dynamic hypotheses about JIT states.

The purpose of this paper is to describe a research protocol for a National Institutes of Health–funded Smart and Connected Health study (R01LM013107) explicitly designed to produce rigorous empirical evidence to study JIT states in the context of a physical activity (PA) JITAI. The structure of the paper is as follows. First, background information is provided about JITAIs that is necessary to understand the motivation for our system ID protocol. Next, a description of the system ID experimental protocol is provided, including the specific goals of the project, experimental design procedures, measurement approach, and analysis plan. Finally, a discussion and the implications of this work are offered in terms of future research on JITAIs.

Improving Understanding of JIT States Within a Digital Health PA Intervention

There is convincing evidence indicating that PA is valuable for reducing the risk of colon, breast, endometrial, lung, and pancreatic cancers [2,3] and cardiovascular disease [4] and improving glycemic control [5]. With an aging population, step interventions could help prevent chronic diseases, reduce health care costs, and improve functional life years and quality of life [2-18]. The clinical guidelines for steps suggest 8000 steps per day for adults [19,20], but only one-third of this group meets the guidelines [21-31]. Across PA interventions for adults (eg, human-delivered and digital), results show increases of 496 steps per day achieved above baseline levels of 5000 steps per day, and even high-impact interventions peak at 1363 steps per day above baseline; both result in activity that is still below the guidelines. Even among interventions that produce an effect, maintenance is rarely measured, and when it is, it is not achieved by many participants [32-35]. Our long-term goal is to create a model-predictive controller-driven JITAI to increase walking that, we hypothesize, will be more effective than current PA interventions at supporting individuals in achieving and maintaining national guideline recommendations of at least 8000 steps per day averaged across a week [19,20].

Although there are many possible algorithmic approaches to achieve this, such as reinforcement learning [36] or recommender systems [37], this research effort is focused on the use of a model-predictive controller approach [38]. A model-predictive controller is an adaptation algorithm that uses time-series data from an N-of-1 unit [39,40] to support decisions over time in dynamic, often complex situations, such as dynamically providing support to a person to increase their PA. As the name implies, a central feature is a computational dynamical model, which is a series of mathematical equations that encode previous domain knowledge and include parameters that are estimated from data derived from each N-of-1 unit (ie, a person in this context), thus enabling the controller to account for individual differences in predictions. These computational models, similar to weather or climate forecasting models, enable rigorous simulations of a person's likely responses to different types of support provided both now and in the future. For example, the model could be used to simulate a person's

XSL•FO
RenderX

response to the provision of a notification meant to nudge them to walk within the next 3 hours. The model would generate predictions on the likelihood that a person will walk after receiving the notification at each moment. In addition, the model can be used to simulate the potential synergistic or antagonistic effects that might occur because of different decisions that could be made. For example, using the model, predictions could be made on the potential diminishing effects of providing notifications over time owing to habituation or growing annoyance, particularly if notifications are sent when a person does not need them.

As this description implies, model-predictive controller-driven JITAIs are complex and, thus, are difficult to create using theory alone, which, historically, was the dominant way in which adaptive behavioral interventions were developed [41,42]. Instead, JITAIs require robust experimentation that enables empirical optimization of their elements, particularly the generation of the computational dynamical models that the controller uses to run simulations and, by extension, make dynamic decisions. As described in previous work [43], the empirical estimation and validation of dynamical models occur through system ID.

The system ID study described in this paper had 2 complementary but distinct aims. First, it aimed to gather empirical evidence on the concept of JIT states. By varying whether a notification is provided when the person is thought to be in a state of need, when they have an opportunity to walk, when they are thought to be receptive, or combinations of these 3 states, the experiment collected initial evidence for which aspects of the JIT state are most important for supporting the effectiveness of JIT interventions and whether this changes over time.

Second, the experiment was designed to collect the data needed to optimize a digital health intervention, *JustWalk JITAI*. The goal was to estimate and validate dynamical models that can be used to construct a model-predictive controller that can make decisions on the provision of support in given moments to achieve and sustain clinically meaningful PA targets. Prior work was used as a foundation to achieve these aims, particularly a dynamic model of social cognitive theory (SCT) that encapsulates domain knowledge about behavioral processes that influence PA [44-46]. The SCT models were refined using the newly collected data both to help us better understand JIT states and to develop models that can be incorporated into a multitimescale model-predictive controller.

Methods

Overview

Aims

The aim of this study was to conduct a system ID experiment to empirically assess the conceptual elements of a JIT state and estimate and validate dynamical computational models relevant to JIT states. This work was conducted to inform the development of a future model-predictive controller-driven JITAI. We had three broad hypotheses: (1) walking bout planning prompts that are provided when the system determines that individuals meet all 3 conditions of a JIT state—have a need, have an opportunity to walk, and are receptive to intervention notifications—will be more effective than when such prompts are provided when only some or none of those conditions are met; (2) idiographic computational models (ie, models developed by and for individual participants) can be produced that are effective at predicting contexts in which suggestions to go for a walk will be effective and how such suggestions and adaptive step goals combine to support a person in achieving both daily step goals and sustained engagement in steps per day; and (3) nomothetic analyses (ie, insights gleaned from data aggregated across participants) will reveal meaningful clusters for different types of contextual patterns and trajectories of change across participants. These clusters will enable the selection of initial dynamical model parameters and, by extension, the development of a generic semiphysical model that can be used as a starting point for new participants in a future model-predictive controller-driven JITAI. In aggregate, these results will also be used to empirically test the added value of previous domain knowledge, as encapsulated in previous computational models, for improving model prediction and response, with a basic autoregressive model with external input as a reference model that only accounts for previous domain knowledge in the form of variable selection but not the structure of their relationships.

Study Design Overview

Building on prior work, including the mobile health app *HeartSteps* (which was relabeled *JustWalk JITAI* for this study to continue on the control systems side of JITAI development) [47,48], we conducted a system ID experiment designed to study the theoretical concept of JIT states as a tool for fostering behavior change. The system ID experiment focused on two key intervention components: (1) notifications delivered up to 4 times per day designed to increase a person's steps within the next 3 hours via either increased awareness of the urge to walk or via bout planning and (2) adaptive daily step goals. Both types of notifications prompting short walks within the next 3 hours were experimentally provided or not across variations of *need* (ie, whether daily step goals were previously met), *opportunity* (ie, the next 3 h are a time window when a person has an opportunity to walk based on their previous step data), and *receptivity* (ie, the person received <6 messages in the last 72 h and walked after notifications were sent). In addition, the suggested daily step goals also varied systematically across time rooted in a person's baseline levels of steps per day (eg, 4000 steps) and gradually increasing until they met clinically meaningful targets (at least 8000 steps/d on average). Participants wore a Fitbit Versa 3 and used the study app for 270 days.

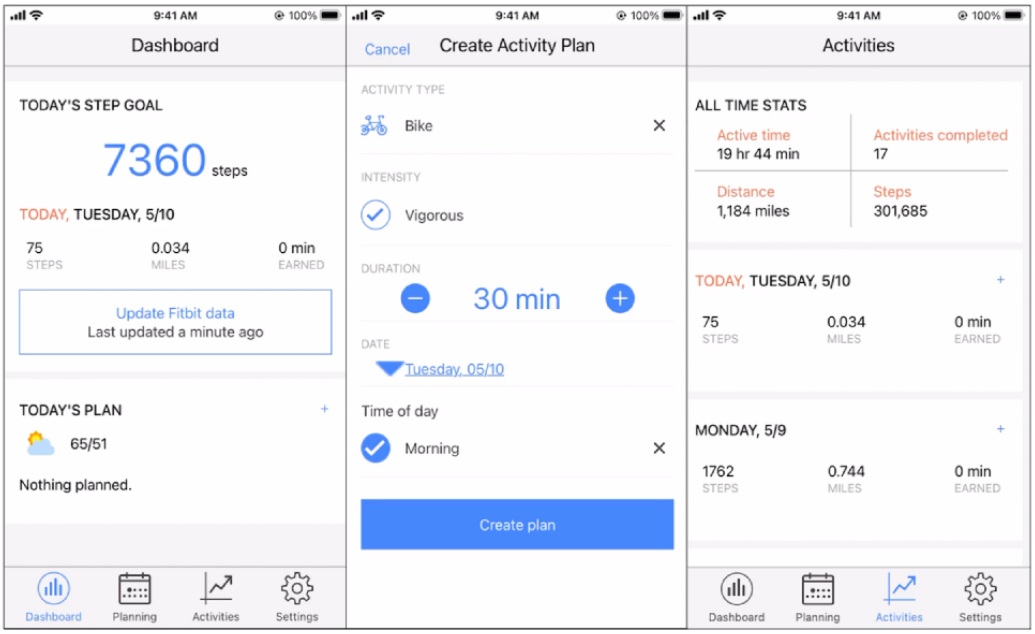
Technology

Wearable Sensor

The Fitbit Versa 3 is a wrist-worn, watch-style activity tracker that records participants' steps and minutes of moderate or vigorous PA (*active minutes* in the language used by Fitbit) that the tracker detects based on accelerometer and heart rate data. The Fitbit tracker records the step and activity data, automatically synchronizes with the Fitbit server, and pushes

XSL•FO
RenderX

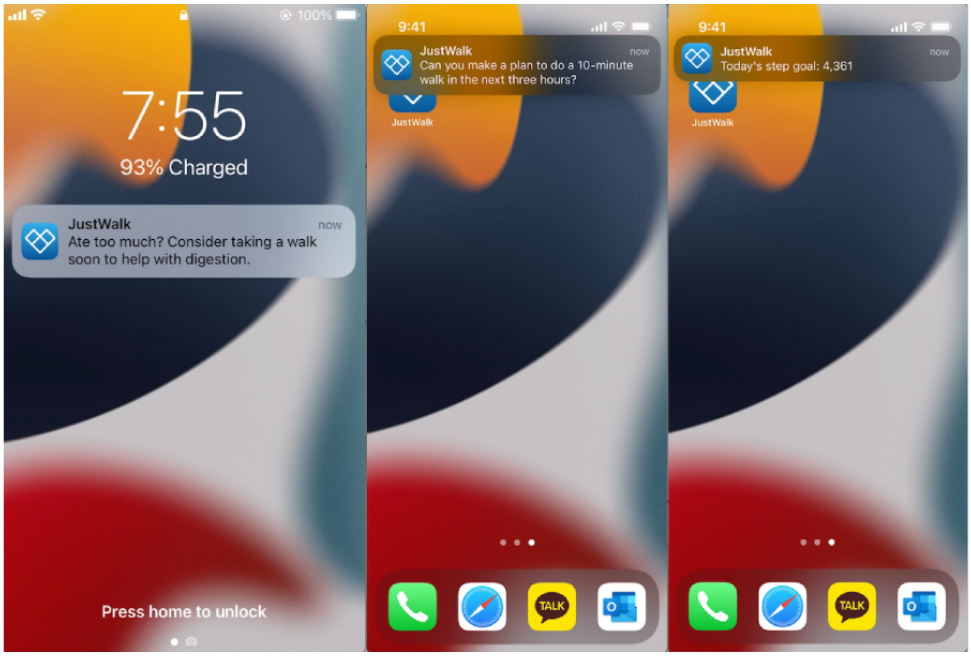
to the *JustWalk JITAI* servers using Fitbit's subscription application programming interface (API). It was recommended to participants to set the Fitbit to use one of the market-available watch faces with the following features: (1) always visible information about the current step count, daily step goal, and progress toward meeting the goal and (2) positive reinforcement (in the form of a fireworks display and vibrations) when the daily step goal is met. The list of watch faces that met these requirements was provided by the staff.



Mobile App

The *JustWalk JITAI* app contained (1) *pull* components that participants could access at any time by opening the *JustWalk JITAI* app (Figure 1), (2) *push* components that were sent to the participants as app notifications based on system-based rules (these were our key experimental manipulations and are described in the *Interventions and System ID Experimental Design* section and Figure 2), and (3) ecological momentary assessment (EMA) questions (described in the *Measures* section).

The *JustWalk JITAI* app consisted of 3 *pull components*, which were drawn from the *HeartSteps* app [48]. These were accessible through tabs along the bottom of the app screen (Figure 1; left):



1. *Dashboard*: the dashboard was the home screen of the app and was displayed whenever a participant entered the app or finished interacting with a *JustWalk JITAI* notification. The dashboard implemented 3 behavior change techniques [49,50]: self-monitoring, feedback on goal progress, and reminders of activity plans. At the center of the dashboard, a participant's progress toward their daily step goal was shown as feedback. If participants created an activity plan for the day, the dashboard also displayed this plan for the participants.
2. *Planning*: through the planning tab (Figure 1; center), participants could identify when they would plan to exercise that week. The planning tool was designed to operationalize the behavior change technique implementation intentions [51,52] by enabling participants to identify when they would be active and for how long and identify a specific activity to engage in.
3. *Activity log* (Figure 1; right): participants could see an activity summary for the last 2 weeks, including steps walked and distance covered each day, as well as the types of activities that the Fitbit tracker detected automatically or the user logged manually (eg, running, hiking, walking, and yoga). In addition, the activity log displayed Fitbit-derived active minutes for each day. Finally, the tab displayed the participants' all-time statistics—hours of active time, total distance walked, total counts of activities (detected or manually logged), and total number of steps recorded since the user started using the JustWalk JITAI system. These all-time statistics were intended to provide longer-time-frame feedback on what the participant accomplished over the duration of the study.

Participant Procedures

Recruitment

Participants were recruited nationally using a noncontact approach. Participants were recruited mainly through university mailing lists and word of mouth. The targeted number of participants was 50, with a final fully enrolled sample of 48 as 2 participants never showed up to preintervention meetings.

Eligibility

Inclusion criteria were participants who (1) were aged ≥25 years; (2) were inactive, defined as engaging in <60 minutes per week of self-reported moderate-intensity PA; (3) owned either an iPhone with iOS 11 or above or an Android phone with Android 5.1 or above; (4) stated a commitment to follow study protocols, including regularly carrying a mobile phone, using the *JustWalk JITAI* app, answering phone-based questionnaires, and wearing the Fitbit Versa 3 activity tracker at least 8 hours a day; and (5) were fluent in English.

The exclusion criteria were participants who (1) were incapable of providing informed consent or (2) had a psychiatric disorder that limited their ability to follow the study protocol, including psychosis and dementia.

Screening, Informed Consent, and Onboarding Meeting

All participant interactions occurred remotely. Recruitment materials directed participants to the study website, which included a contact entry form. Upon completion, participants were automatically sent a link to an eligibility screener, which asked about age and PA levels (as reported using the Global Physical Activity Questionnaire [53] and the revised Physical Activity Readiness Questionnaire [54]). The staff reviewed the survey responses to confirm eligibility.

Eligible participants were offered time slots for an informed consent meeting. Ineligible participants were informed of their ineligibility.

During the informed consent meeting, the following activities took place: (1) the study was described in detail via a guided read-through of the consent form, (2) participants were provided with a list of reasons to and reasons not to take part in the study, (3) participants were invited to develop a list of their own pros and cons for taking part in the study, and (4) participants were given time to ask any questions they had. If participants verbally agreed, the study staff asked them to sign the consent form via DocuSign (DocuSign, Inc).

Consented participants were asked for a mailing address to send a Fitbit. Participants were also sent instructions on how to set up the Fitbit and the app via email. Once confirmation of delivery of the Fitbit was received by the staff, a follow-up email was sent to participants inviting them to pick a time slot for the preintervention meeting.

During the onboarding internet-based meeting, participants were instructed on the following topics: (1) instructions on how to install and use the Fitbit and study app, (2) information on the 10-day baseline, (3) information on what to expect after the 10-day baseline period, (4) direction to complete a baseline survey, and (5) instructional videos with corresponding notes about how to use and maintain the Fitbit (eg, strategies to keep it charged and reminders to clean it to reduce skin irritation). All meetings between the participants and the staff took place via Zoom (Zoom Video Communications), and the interviews took place within 2 weeks after the time slots were sent.

Incentives

Participants received the following incentives: (1) Fitbit Versa 3 (received at study enrollment; US $229 in value), (2) US $25 gift cards provided to them up to 3 times (US $75 in total) if they completed at least 80% of the daily EMA items within each 3-month period, and (3) US $25 gift cards if they attended an optional postintervention interview.

XSL•FO
RenderX

Study Timeline

During the 10-day baseline, participants were asked to engage in their normal level of steps or PA and always wear the Fitbit except while charging. No interventions were provided, and no EMA questions were asked during the baseline period. When participants opened the app, 10 circles were shown designating the number of days they had met the minimal wear time requirements (ie, 8 h/d). If the participant did not wear the Fitbit for at least 8 hours a day, the circles did not fill up. Once all 10 circles were filled, the app automatically transitioned to the intervention phase, displaying a dashboard.

In the intervention phase, all app features were delivered, including the 2 push intervention components (ie, walking prompts and adaptive suggested step goals) and the daily EMA questions. The participants also gained access to other parts of the *JustWalk JITAI* app such as activity logs and planning support. Participants were asked to interact with the app whenever it sent them notifications and were told that they could open the app at any time if they wanted to access pull components and found them useful. Total interaction time with the app from push interventions and EMA notifications does not exceed 10 minutes each day, but participants may choose to spend more time on the app accessing other features. The interactions participants were prompted to do occurred in response to four types of notifications: (1) daily step goal notifications, (2) walking suggestion notifications, (3) prompts to complete the daily EMA battery, and (4) experience sampling prompts (ie, if Fitbit detected an activity) to complete EMA items throughout the day and in relation to the notifications to either increase the urge to walk or plan (for details about EMA, see the *Measures* section).

Interventions and System ID Experimental Design

System ID Overview

This study used a system ID approach to manipulate 2 intervention components experimentally: *walking suggestions* and *daily step goals*. To achieve the desired dynamics on the timescale of interest, we used 2 input signals, one for each of the 2 components. Although our study design enables traditional statistical analyses to examine the impact of intervention components on behavioral outcomes, that is not the primary focus of a system ID experiment. The primary goal of a system ID experiment is to estimate and validate dynamical computational models that are validated based on their ability to predict the future responses of each individual's behavior across time. These aims are achieved by having different intervention components—suggestions to walk in the next 3 hours and adaptive goal setting—delivered at different timescales and orthogonally, that is, statistically independent of each other. Our approach is analogous to a within-person factorial experiment (and, indeed, can be treated as such with all relevant nomothetic statistics used on the developed data set, which the team plans to perform as secondary analyses). The critical difference is that, in system ID studies, the designed input signals achieve statistical independence through orthogonality as verified in the frequency domain. Orthogonality enables separate study and estimation of the dynamics and impact of each intervention component. One can think of frequencies as different repeating rhythms across time, such as the notion of a minute-by-minute, daily, or weekly frequency. The study was designed to ensure that the intervention signals were disambiguated across time (via delivery at different frequencies). This enables a rigorous independent study of dynamical responses to both intervention components within the same experiment and, indeed, within each person, both proximally (eg, immediate responses following intervention delivery) and distally (eg, continued or delayed effects up to several days after any notification).

Specifically, both signals are designed to follow the guidelines presented in the study by Rivera et al [55], in which equation 1 is highlighted to define the effective frequency range of the input signal based on a priori knowledge of the dominant system time constant.

Equation 1 is the equation used to define the effective frequency range of the input signals of the *JustWalk JITAI* study based on a priori knowledge:

 and  represent the higher and lower bounds for the estimated dominant time constant of the system, meaning the range in which signals relevant to walking would occur naturalistically. α_s and β_s dictate the input signal's content of high and low frequency, respectively. The orthogonality of our intervention components was confirmed via the use of cross-correlation analysis (the appropriate approach for testing orthogonality via frequency domains) to the designed input signals.

Sample Size Considerations

The number of participants has little impact on the power estimate for system ID studies as system ID approaches mostly use dynamic models that consider individual-level changes over time [43]. Instead, different methods, such as study length and validation analysis, can be used to establish the equivalent notion of *power* [56]. A multisine signal's *cycle*, or predetermined time interval, serves as the foundation for the power calculation [57]. By dividing the cycles into estimation and validation data sets, this type of design maximizes the signal-to-noise ratio and aids in the evaluation of model fits.

Previous research has demonstrated that 3 independently excited harmonics per cycle can achieve a sufficient excitation to deliver dynamically meaningful data in relation to daily frequencies. This can be performed with 3 sinusoids per cycle, resulting in a cycle that lasts at least 12 days [58]. Estimating and comprehending the multitimescale dynamics of behavior change are the goals of this effort. A total of 9 excited harmonics were revealed through simulations to be necessary to provide persistence of excitation across relevant frequencies [59]. The result is that each cycle lasts 26 days. From this, the final study length was set at 10 cycles (260 d).

Intervention Design

Overview

An overview of the *JustWalk JITAI* intervention elements is provided in Textbox 1.

Textbox 1. Summary of the JustWalk JITAI intervention elements

Wearable sensor

- Fitbit Versa 3

Mobile app

- *HeartSteps* [47] (renamed *JustWalk JITAI*)

Walking notifications

- Walking notifications were pushed up to 4 times a day starting at the participant-set time (eg, 7 AM or 8 AM), with 3-h gaps between each possible notification (eg, 7 AM, 10 AM, 1 PM, and 4 PM as possible decision points for sending notifications).
- Notification texts were randomly chosen from a library of 50 messages that included 24 messages meant to inspire participants to plan a time when they would walk in the next 3 h and 26 messages meant to invite participants to become aware of internal urges that could inspire them to walk (Figure 2 and Multimedia Appendix 1).
- The experimentation setting used 4 just-in-time (JIT) definitions: (1) full JIT (need [N], opportunity [O], and receptivity [R]), (2) N+R, (3) N+O, and (4) random, with each element defined as follows:
  - *N*: on track to meet the daily step goal accounting for time of day when assessed (eg, 50% of steps accrued halfway in a person's day, using their self-selected start time as a reference and assuming 12-h windows)
  - *O*: next 3-h time window was predicted to have an 80% likelihood that someone could take steps using a previously published algorithm [60]
  - *R*: participant received <6 notifications and responded (ie, walked) to at least 50% of notifications sent to them within the previous 72 h

Adaptive step goals

- Each morning, participants were provided with a suggested daily step goal.
  - The notification also included a single-item ecological momentary assessment whether it was helpful or not.
- Daily step goals were calculated using the following procedures:
  - For the first cycle, median steps/d were used as a personalized reference to guide adaptive step goal suggestions. For cycle 1, a participant's personalized reference (ie, median steps/d) was calculated from their 10-d baseline period excluding nonwear days.
  - For all subsequent cycles, their personalized reference (ie, median steps/d) was calculated from the previous 26-d cycle (eg, cycle 2's median steps/d were calculated using all step/d data from cycle 1 excluding nonwear days).
  - Participants were provided with a step goal that ranged between their personalized reference (median steps/d) up to their personalized reference+4000 steps.
  - A multisine signal design that ranged from 0 (personalized reference) to 1 (personalized reference+4000 steps) was used. For example, if a person's median steps/d during the baseline period were 5000 steps/d, they would receive step goal suggestions between 5000 and 9000 steps/d.
  - Maximum step goals were set at 12,000 steps/d, and minimum step goals were 2000 steps/d.

Walking Notifications

Overview

The first component of the *JustWalk JITAI* was notifications meant to inspire short (eg, ≥10 min) walking bouts within 3 hours after receiving the notification. This component had two variations that targeted different behavioral processes: (1) an invitation for a person to create a microimplementation intention on when, where, and how to fit in a ≥10-minute walk in the next 3 hours—we label these suggestions as *bout planning*—and (2) an invitation for a person to become aware of interoceptive experiences and signals (eg, stiff muscles and lethargy) that may inspire them to go for a walk—we refer to these messages as *cultivating an urge*. Both types of walking notifications were drawn from a library of 50 messages (n=24, 48% on bout planning and n=26, 52% on cultivating an urge). Walking notifications were provided in the form of push notifications from the *JustWalk JITAI* app. The notification could be sent 4 times a day (ie, decision points) starting at the user-defined *start of day* time, which was gathered during the onboarding processes. Starting from the participant's self-described *start of the day*, the walking notification decision points occurred every 3 hours. For example, if a participant's day started at 8 AM, their decision points would be 8 AM, 11 AM, 2 PM, and 5 PM. For each participant, on each day of the study at each of the 4 decision times, the *JustWalk JITAI* system decided whether to send a walking notification based on the system ID procedure described in the following section.

XSL•FO
RenderX

Operationalization of JIT States

JIT states were experimentally varied via the use of different rules to define a *JIT* state. By nudging participants when they were in *JIT* states, the hypothesis is that the effect of the walking notifications should increase while maintaining a low level of burden on participants, thus minimizing notification fatigue.

A JIT state has been previously conceptualized [1] as a state in which a person is receptive to support (eg, if a notification is sent, a person would appreciate receiving said notification) and has the opportunity to engage in the desired behavior (or vulnerability to a negative behavior). Building on this theoretical formulation, a third theoretical parameter was added: the need for intervention support. For example, if someone is already meeting their daily step goals, they likely do not need additional intervention prompts to walk. For the purposes of this study, JIT states were operationalized as follows:

1. *Need (N)*: a person is defined as in a state of need if they did not meet the previous day's step goal (for the first decision point) or if they are not making steady progress toward that day's goal (for all other decision points). Sufficient progress was defined as the goal prorated to the current time of day:

2. *Opportunity (O)*: a person is deemed to be in a state of opportunity when they can feasibly walk. To operationalize this, a predictive algorithm described in the study by Park et al [60] used a threshold of 80% probability that, within the next 3 hours, a person may walk. We used the high threshold of 80% so that even a slight nudge to walk could effectively achieve short-term behavior change (note: whether notification is needed at such a high moment of opportunity is a question that we will be able to study retrospectively).
3. *Receptivity (R)*: a person is deemed to be receptive when they have received ≤6 messages in the last 72 hours *and* have responded (ie, walked in the following 3 h) after ≥50% of the walking notifications sent in that period.

The operationalizations of these 3 facets of a JIT state allow us both to define a full JIT state—that is, when need, opportunity, and receptivity are *all* present—and to empirically test how different operationalizations of JIT states (eg, states when only some of these components are present) influence walking notification effectiveness. Specifically, daily decision rules were tested that embodied four different levels of being in a JIT state:

1. *Full JIT state*: need, opportunity, and receptivity are present.
2. Partial JIT state (2 forms): *N+O* (only need and opportunity are present) and *N+R* (only need and receptivity are present).
3. *Not in a JIT state (random)*: notifications are randomized each time at 50% probability.

How and when each of these rules for defining JIT states was varied experimentally is described in the following section.

Previous Observations and Theoretical Considerations That Guided Our Study Design to Test JIT States

This specific study design was created based on data from the original *HeartSteps* trial [47] followed by engaging with previous domain knowledge, including behavioral theory and our previously developed SCT dynamical model [61], to guide the final study design such that this study could provide robust data for supporting computational model testing.

Concerning previous observations, in the *HeartSteps* trial related to the notifications designed to inspire bouts of walking, 3 empirical observations guided our understanding of JIT states. First, as reported previously [47], notifications had a diminishing proximal impact on the total number of steps taken within the 30-minute window after the notification. These results indicated a theorized diminishing value-to-burden ratio of the prompts, namely, a dynamic concept that balances, for each instance, a person's perceived value that they receive from an intervention compared with the perception of the level of burden of the intervention. This dynamic hypothesis, which conformed to the data, was that the value-to-burden ratio would diminish over time, with initial notifications being perceived as more valuable than burdensome; however, by the end of the study, this would shift toward a low or negative value in relation to the burden.

Second, it was observed that, if <2 notifications were sent on a given day, even later in the 6-week trial, then the bout notifications resulted in significantly improved steps taken within the 30-minute window after the notification. We interpreted this dynamic observation as representing a hypothesized *autorecovery* that could take place on a person's value-to-burden ratio. One could think of this as analogous to a neuron. Once a neuron fires, if new signals come in, the neuron will not fire again until it has sufficient time to recover, but this recovery process is automatic. It was hypothesized that a similar dynamic takes place regarding notifications. Namely, if notifications are sent at a rate that is faster than a person's autorecovery rate, habituation will set in and the notifications will be ignored (again, similar to a neuron not firing). If, in contrast, *sufficient time* has passed for autorecovery to take place (eg, such as a neuron re-establishing itself as ready for the next signal), then a notification sent would be more likely to be attended and reacted to by a participant. Previous data guided us to a population-based starting point of, on average, 2 notifications in a day, providing sufficient time for autorecovery. With that said, it was postulated that this autorecovery may vary among individuals. This study design enables us to study these individual differences in temporal responses.

Finally, it was observed that there was a trend in the daily timescale or frequency. Specifically, it was observed that there was an overall trend of increased steps per day over the 6-week intervention period. This third observation was translated into a hypothesized *internalization* process of the knowledge, skills, and practices that the intervention was meant to cultivate. This third dynamic hypothesis is the most critical target for designing an effective JIT intervention. Specifically, the goal is to create a JITAI that would enable a person to develop internalized knowledge, skills, and practices that could be maintained after

XSL•FO
RenderX

the cessation of the intervention while accounting for the likely diminishing value-to-burden ratio and the need for *recovery* between notifications. This complex, interactive dynamic hypothesis, which postulates 3 different underlying dynamics that interact together, is what is primarily being studied in this experiment. Most critically, it was hypothesized that *internalization*, observed in the form of increases in steps per day in a time series, would take place more often when notifications or interventions were provided using JIT states compared with times when notifications were offered without taking account of JIT states.

System ID Experiment Design via Simulation Studies

With these empirical observations as a foundation, previous behavioral literature was reviewed to (1) look for previous domain knowledge that could be used to guide the understanding of these dynamics and (2) support us in better operationalizing the dynamic expectations we hypothesize to be observed, particularly if interventions could be provided consistently taking account of JIT states. A computational model was developed guided by these empirical observations and building on principles drawn from operant learning and cognitive science, which is described elsewhere [62]. A set of simulations was run to model anticipated responses to receiving PA notifications during positive and negative JIT states. A key focus of the simulation work was to determine whether the models could produce the dynamics observed in *HeartSteps*, described previously, and to guide the anticipated length of time needed to observe a possible overall step per day increase across days when notifications are repeatedly delivered during positive JIT states. In this context, a positive outcome was operationalized as a person taking at least 1000 steps (as a proxy for 10 min) within the 3-hour window after receiving a walking notification. Overall, it was hypothesized that a greater number of positive outcomes when using the full JIT state operationalization (N+O+R) would be observed, with increased overall steps per day occurring across days during those times (accumulative internalization). In contrast, it was hypothesized that a relatively steady steps per day response would occur during times when notifications were sent at random (which was a replication of the original *HeartSteps* study and intentionally did not consider JIT states; thus, it was hypothesized that the random signals would replicate the observations from the original study). A set of additional simulations was run based on the SCT model [61], with the results of the simulation reported elsewhere [59] to further refine our study design.

On the basis of the simulation results from both models, a system ID study was devised that experimentally varied the use of different definitions of JIT states but did so in a way that would enable the study of possible accumulation or degradation of the dynamic effects across days. Specifically, 4 days was set as the minimal length of days needed to observe the effects of successive full JIT rules. It was anticipated that stabilization to degradation of effects would start to occur within 1 day of sending non-JIT notifications based on our simulation studies. With that said, given the highly novel study design and limited robust empirical data to guide this subtle study of dynamics, longer periods were used, particularly for the full JIT state (N+O+R). In other words, the experiment compared decision rules that range from not trying to intervene in a JIT state to trying to intervene in a full JIT state over a sustained period that, based on simulation studies, would be sufficiently long to detect accumulative effects if they occurred.

This resulted in a categorical 4-level design. To construct this categorical 4-level input signal, a pseudorandom binary sequence (PRBS) was used (for full justification and details, see the study by El Mistiri et al [59]). This base signal compares JIT with some form of partial JIT or random (ie, non-JIT) states. To incorporate the exploratory examination of differences between JIT operationalizations, a random multilevel sequence was superimposed over one of the PRBS binary levels to compare the 2 incomplete JIT decision rules (N+O and N+R) with the randomly sent walking notifications [59]. The input signal design parameters for the PRBS were chosen as =3 days, =3.5 days, α_s=2,β_s=2, which was done to cover the frequency range of interest based on the guidelines provided in equation 1. This resulted in a 60-day cycle with n_r=4 shift registers and switching time T_{sw}=4 days (Figure 3). This 60-day cycle enabled the team to (1) study the hypothesized dynamic, positive accumulative effect on steps within 3 hours of notification times, and steps per day when walking notifications were sent during theoretically defined JIT states; (2) compare these dynamics with the hypothesized dynamic degradation across days when walking notifications were delivered during partial or negative JIT states (ie, at random); and (3) as an exploratory aim, study if the dynamics vary across different JIT state operationalizations. In total, 4 cycles of a 60-day PRBS signal were generated to support both estimation and validation of the dynamical models that operationalized the hypothesized dynamics, which results in a 240-day period followed by a final period of full JIT state level to match the full study period (260 d), which was constrained by adaptive step goal cycles (26 d × 10 cycles).

Figure 4 provides a visualization of the spectral power density as it relates to the walking notifications. This visualization provides insights into the degree to which the theorized dynamics will be appropriately excited, enabling the detection of effects if they occur across various frequencies and, thus, the study of the proposed dynamic hypotheses. The results suggest sufficient persistent excitation by the number of harmonics included in the effective frequency range between 0.14 and 0.67 rad per day. This frequency range, determined by the time constant guidelines in equation 1, ensures that the appropriate slow dynamics (ie, low frequencies) and fast dynamics (ie, high frequencies) of the system are captured.

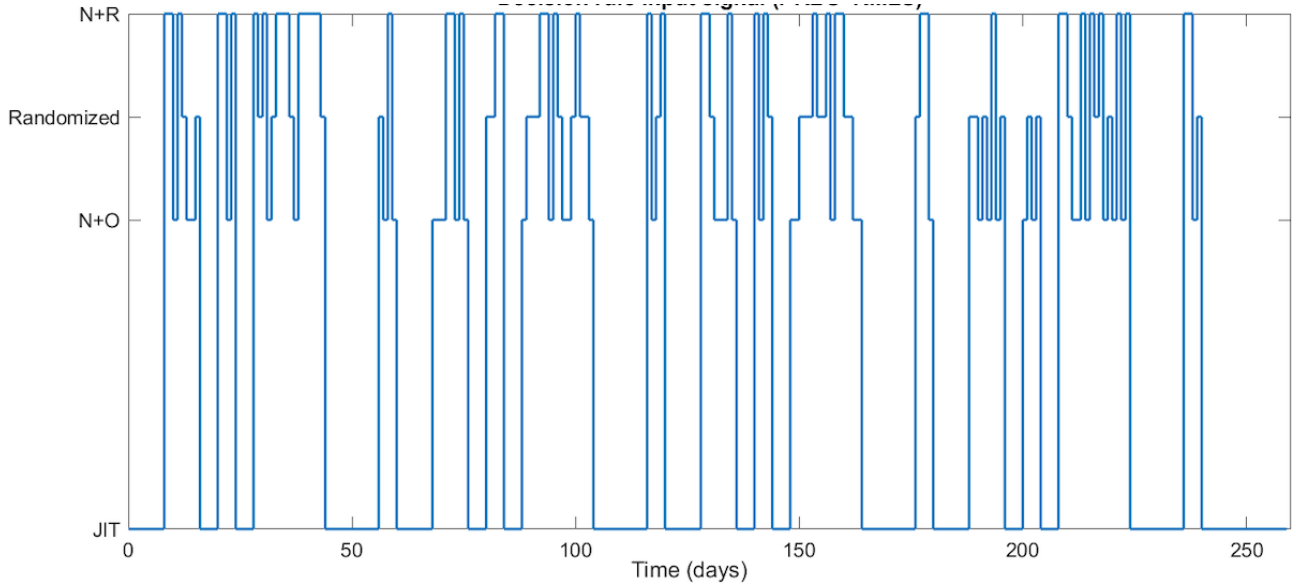
RenderX

Figure 3. The designed decision rules signal for the walking notification component of the intervention in the time domain in the JustWalk JITAI study. Each level represents one of the decision rules. The 4 signal levels were obtained by superimposing a 3-level random multilevel sequence (RMLS) signal on the base pseudorandom binary sequence (PRBS) signal. JIT: just-in-time; N+O: need and opportunity; N+R: need and receptivity.



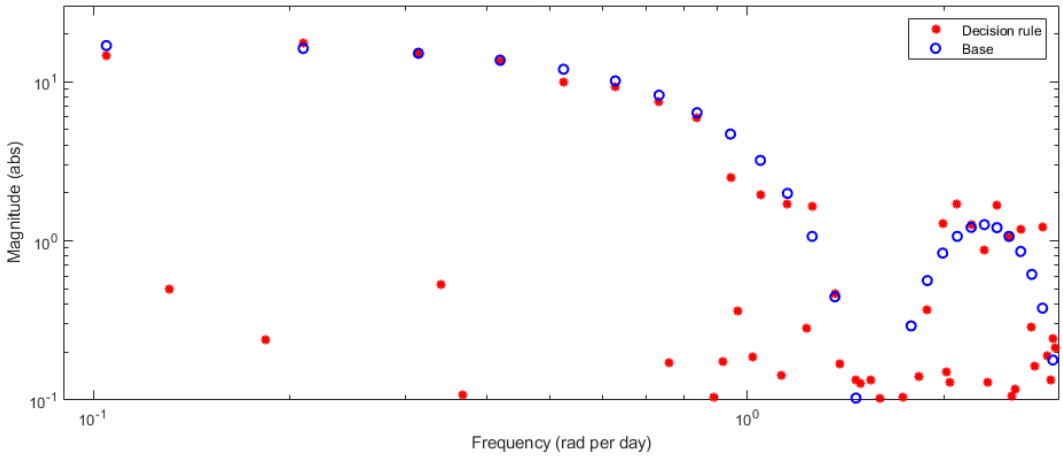


Figure 4. Spectral power density of the designed decision rule input signal of the JustWalk JITAI study. It is shown to determine whether sufficient excitation across key frequencies is established within the trial.

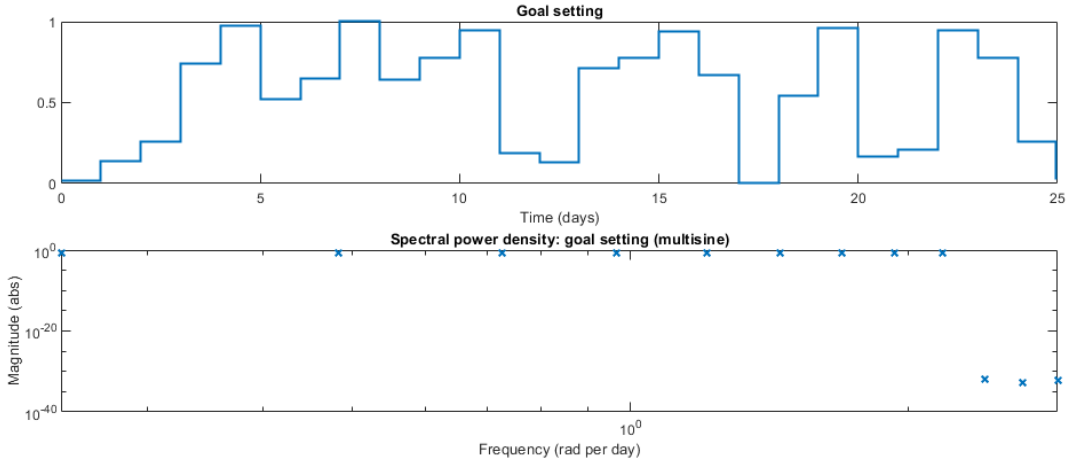
Adaptive Step Goals Intervention Component

Overview

The adaptive daily step goal component follows a similar structure to that of a previous system ID experiment whereby participants were given a specific suggested step goal to target each day [63]. Similar to this previous design, a key consideration is to design a *cycle*, which is a deterministic, repeatable pattern that defines the provision of intervention options to an individual. Intervention options can be provisioned to mimic randomness via pseudorandom signal designs that achieve the valuable properties of randomness for causal inference while still being deterministic and, thus, repeatable. This provides valuable properties for a system ID experiment as it enables a more robust comparison between cycles (for more details, see prior work [38]). In this study, the same basic logic of prior work was followed, specifically, using a pseudorandom signal design that varied step goals between an *achievable* target up to a plausibly *ambitious* target (how goals are assigned each day is described in greater depth in prior work [59]).

The definition of an *achievable* step goal was personalized to each participant, which was labeled as a personalized reference, defined as a person's median steps per day calculated from the previous 26-day cycle period [59]; note that, for the first cycle only, the personal reference was the 10-day-baseline period. Each morning, participants received a notification informing them of their targeted step goal for the day. The updated goal was also available to them on the *JustWalkJITAI* dashboard and was automatically synced by the *JustWalkJITAI* server to the participant's Fitbit account so that the feedback on the Fitbit app and the participant's Fitbit tracker always showed the correct goal progress each day. To further facilitate goal pursuit, participants were instructed to install a watch face providing the step goal number and a goal progress bar to enable always visible goal progress feedback. Fitbit's native visual and haptic feedback was used when the participant completed the daily step goals (ie, fireworks animation and vibrations).



XSL•FO
RenderX

Experimental Manipulation: Input Signal Design

To define a cycle for this component, a multisine signal was used. The input signal design parameters (=1 day, =2 days, α_s=2,β_s=2), as described in equation 1, were chosen based on the results from previous work and the simulation studies we conducted in preparation for staging this system ID experiment [59]. The design parameters result in a cycle length of 26 days, as shown in Figure 5. For each participant, a personalized realization of the multisine signal generates the daily goals throughout the 260-day intervention across 10 cycles by determining, for each day, the factor by which the 4000 steps per day range is multiplied and then added to the participant's personalized reference (ie, median steps/d), as described in Textbox 1.

The effective frequency range of the signal is related to the design parameters through equation 1, which yields the persistence of excitation between ω_*=0.25 rad per day and ω^*=2 rad per day approximately for the designed multisine signal, as it is highlighted in the power spectrum of the signal shown in Figure 5. This showcases that the designed input signal for goal setting creates variability in the relevant dynamical ranges of interest.

Figure 5. One cycle of the designed multisine input signal for the goal setting component of the JustWalk JITAI intervention in both the time (top) and frequency (bottom) domains. The multiplier factor varies between 0 and 1 over time. The spectral power density plot highlights the number of excited harmonics at the frequencies of interest.

Measures

Baseline Survey

The baseline survey includes (1) demographic information, including age, height, weight, ethnicity, gender, race, marital status, household size, employment status, and level of education; (2) personal characteristics related to the study (ie, how the participants spend their time and information about their routine and their neighborhood); (3) self-perception (ie, personality [64] and perceived stress [65]); and (4) life habits [66] and PA [67] (ie, how they feel about PA, how they engage in exercise, how much they intend to exercise, and how they notice the effects of exercise).

Continuous Measurement of Activity and Heart Rate

Steps per minute and minute-level heart rate were measured using the Fitbit Versa 3, a wrist-worn, consumer-level activity tracker that uses triaxial accelerometry to measure movement. Further details are provided in the next subsection. Moderate or vigorous PA was measured in four ways: (1) automatically triggered objective measurement (the Fitbit Versa 3 automatically detects vigorous movement [68] if the activity is sufficiently vigorous and long), (2) manually initiated objective measurement (the Fitbit Versa 3 or the Fitbit app on the smartphone has an *activity* tab to log activity manually), (3) manual logging in the Fitbit app, and (4) manual logging on the study app using the *activity* tab (which was also populated with any reporting on the Fitbit app). The Fitbit assesses steps, PA intensity levels, energy expenditure, start or end time point and type of activity, distance traveled, and number of floors. Prior work shows that Fitbits likely underestimate heart rates and, by extension, total activity, but they do so reliably, thus establishing a meaningful within-person comparison [69], which is the focus of this study.

EMA Items

Psychological constructs and process variables were asked daily for inclusion in our targeted, dynamic models via EMA conducted at 7 PM local time. The EMA items included concepts of (1) self-efficacy for walking, (2) self-efficacy for problem-solving, (3) positive context for walking, (4) negative context for walking, (5) supportive routine, (6) drive to walk, (7) relationships supportive of walking, (8) interoceptive awareness of cues that could inspire walking (eg, stiffness and fatigue), (9) negative reinforcement of walking, (10) behavioral repertoire, and (11) typical supportiveness for walking. Detailed items are included in Multimedia Appendix 2. Items 1 to 6 were asked daily, items 7 to 10 were asked every 4 days to minimize the burden of responding, and item 11 was asked every day for the first week of each month (ie, 7 times/mo).

In total, 2 other types of EMA question items were sent. Triggered by completed PA, the participants were asked if they felt healthy, fatigued, energized, and discomfort. We also asked if the participants thought that they could meet the daily goal.

XSL•FO
RenderX

Weather

Daily weather data (current weather and weather forecasts) were gathered from the public weather database API [70]. No actual location GPS data were gathered; instead, a self-reported home zip code was used to gather weather data.

Postintervention Interviews

After the 260-day intervention, participants were asked to fill out a brief postintervention survey and were also given the option to participate in a postintervention interview. During the postintervention interviews, participants were asked about their overall reactions, including both positive and negative aspects of using the app and any suggestions to improve the intervention. The interviews were audio recorded and transcribed.

The participants were also given a choice to either stop the use of the *JustWalk JITAI* intervention or continue to use it, in which case the data past the study end date would not be used in the analyses.

Treatment Fidelity Monitoring Procedures

Mobile App Use Logs

Mobile app use was recorded with time stamps for every page viewed in the *JustWalk JITAI* app, including opening notifications, opening the app, viewing pages within the app, and opening surveys. The one piece of information that could not be logged owing to operating system limitations was whether notifications (eg, walking notifications) were seen without being opened, such as when they automatically expanded on the iOS lock screen.

Monitoring the JustWalk JITAI Systems

The *JustWalk JITAI* server was automatically monitored every 10 minutes throughout the study period using a separate program to check for 5 performance and stability targets: the web server, the database server, the security firewall, the software framework for the server, and the Fitbit API. If the server stopped working or took too long to respond (>3000 ms), the program sent SMS text messages and emails to the study staff. The monitoring program was separately overseen by another program to ensure that monitoring was conducted properly. If any data operations failed (eg, if the Fitbit server was not responding), the study staff were immediately notified via email. If there was an error in the Fitbit data synchronization, when the data connection resumed, all the missing data were refetched to fill up any missing period.

Data Collection Monitoring

Data collection was monitored by the study staff on a weekly basis with automated visualizations to ensure that there were no technical errors that may compromise the study.

Study Adherence

Study adherence was monitored automatically using the *JustWalk JITAI* server. During the preintervention meetings, participants were asked to wear the Fitbit for a minimum of 8 hours a day, but it was suggested that they wear the Fitbit all day, even at night. Fitbit devices typically synchronize with the Fitbit server via the Fitbit phone app every 15 minutes. This synchronization stops if the Fitbit device runs out of battery or is not worn for several days. The *JustWalk JITAI* server regularly checks whether a participant's device has stopped syncing with the Fitbit server, and if so, it sends an adherence SMS text message to the participant.

As an operationalized protocol, at 15 minutes before the first decision point for walking notifications (eg, 6:45 AM local time for most participants), if a participant had no Fitbit app synchronization records for 60 minutes (eg, since 5:45 AM local time for most participants), the server sent an automated adherence SMS text message including an approximate length of the period for which the updates were missed (eg, a few hours, a day, or a while) to invite participants to recharge and synchronize their Fitbit on the Fitbit app.

This approach helped avoid making the mistake of responding too immediately to the problem of data drops caused by accidental battery discharges. As it can be assumed that people do not carry their Fitbit charger around during the day, sending an immediate *charge it now* message when data updates stop during the day is unlikely to be an effective remedy. In addition, given that it only takes approximately 30 minutes to charge a Fitbit from fully depleted to lasting more than a day, it was assumed that sending these reminders before the start of the day would give participants a chance to charge their Fitbit.

Modeling and Data Analysis

A series of system ID estimation approaches will be used to analyze the data and obtain control-oriented dynamical models to study JIT states. General data analysis will start with examining the cross-correlation of the data to verify the hypothesized structure of the system as operationalized via the computational models described previously. Nonparametric estimation methods such as correlational analysis and spectral analysis [71] will be used to obtain preliminary information about the responses of each individual (ie, time constants, gains, and orders). The knowledge gained from the nonparametric estimation methods will be used to obtain ideographic models through prediction error modeling approaches such as autoregressive with external input and output error [71] estimation and more elaborate gray box methods using the SCT model structure. In addition, the model-on-demand [72,73] estimation will be used to estimate more flexible models that address nonlinearities in the system. The estimated models from all approaches will be contrasted with one another, and the advantages or disadvantages of each will be assessed to inform future efforts.

Ethical Considerations

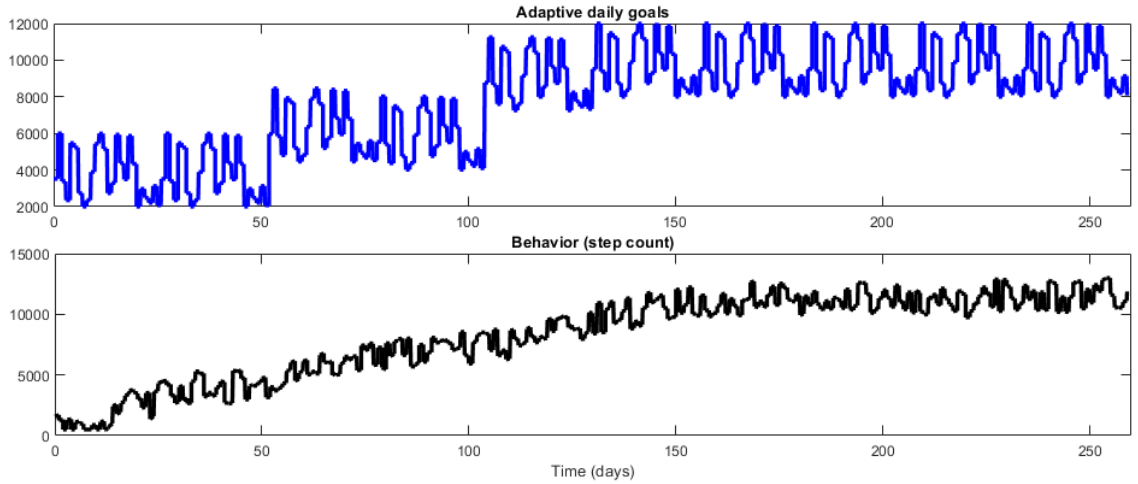
The study was approved by the University of California, San Diego, institutional review board (protocol 800132) and was preregistered on ClinicalTrials.gov (NCT05273437).

Results

Simulations

The input signal design for the 2 intervention components in this study involved an iterative procedure that relied on a priori knowledge and simulation results for different types of

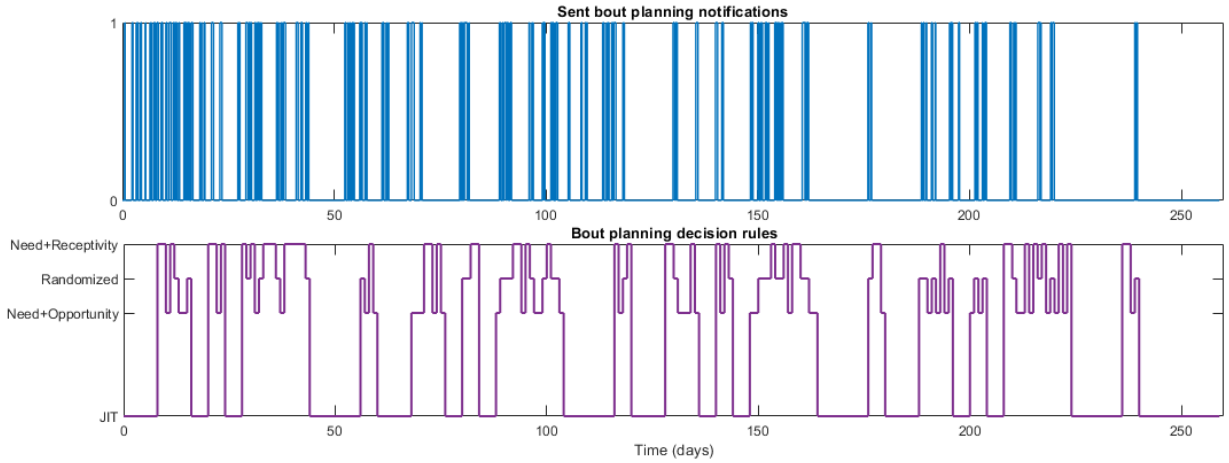
XSL•FO
RenderX



anticipated participants to guide the efforts. The simulations were based on a dynamic SCT model derived from a fluid analogy, which provided the means to guide specific conditions for the JIT states considered in the decision rules to ensure that both the number of notifications sent per day and the overall number of notifications sent throughout the intervention were not burdensome for the participants. Furthermore, the simulation framework with diverse scenarios provided insights into the *ambitious yet achievable* range of adaptive goals provided in each goal setting cycle. A detailed account of the model used in the simulations, technical details of the designed input signals, and simulation results that guided the design are provided in the study by El Mistiri et al [59]. In this section, the results for a hypothetical adherent participant are presented to illustrate the dynamic nature by which the daily goals adapt to the participant's performance, as well as the effectiveness of the JIT decision rules in limiting the provision of support only to times that are hypothesized to be beneficial.

Figure 6 [59] shows the implementation of the designed daily goal signal in a simulation setting. In this case, the goals in each cycle are adjusted to the performance of the participant in the previous cycle, as described in Textbox 1. Note that, in this case, a hypothetical adherent participant is capable of achieving the daily goals given to them in each cycle; consequently, the median of the participant's performance increases, which leads to an increase in the goals provided in subsequent cycles. As a result, the daily goals gradually increase over the span of the intervention, from a low of 2000 steps per day in the first 2 cycles of the intervention (the first 52 d) to a high of 12,000 steps per day in the last 5 cycles. This simulation result illustrates that the input signal design for this component is working as intended by adapting the daily goals to each participant in a personalized manner while nudging the participant toward higher levels of PA through a combination of *ambitious* and *achievable* goals.

Figure 7 [59] shows the walking notification component of the intervention in the simulated scenario for the hypothetical adherent participant. As shown in the figure, the decision rules work as intended in terms of dictating the nature of the notifications sent to the participant. At the beginning of the intervention, when the participant does not achieve the daily goals (hence, the need condition of the decision rules is met), the number of notifications sent to the participant is high across all levels of the decision rules. Later in the intervention, as the participant adopts healthier behaviors and meets the daily goals, the number of walking notifications sent on a daily basis is significantly lower. Furthermore, note that, on days when the receptivity condition is considered, the number of notifications sent follows the notification budget mentioned in Textbox 1.



Finally, as the need condition is not met by the participant toward the end of the intervention, walking notifications are only sent on days with fully randomized notifications. This design allows for comparing the impact on the participant of fully randomized notifications with that of notifications that are guided by JIT state conditions that should make them more beneficial. From these simulation results, the rate at which notifications are sent (ie, notifications or decision point) on full JIT state days is the lowest at 0.084, followed by days of need and opportunity (N+O) conditions at 0.148 and need and receptivity (N+R) conditions at 0.176. The highest rate of notifications is observed on days with fully randomized walking notifications at 0.488.

Figure 6. Simulation results illustrating the implementation of adaptive daily goals (top) in reaction to the performance of a hypothetical adherent participant in terms of daily step count (bottom) in the JustWalk JITAI study (adapted from the study by El Mistiri et al [59]).

RenderX

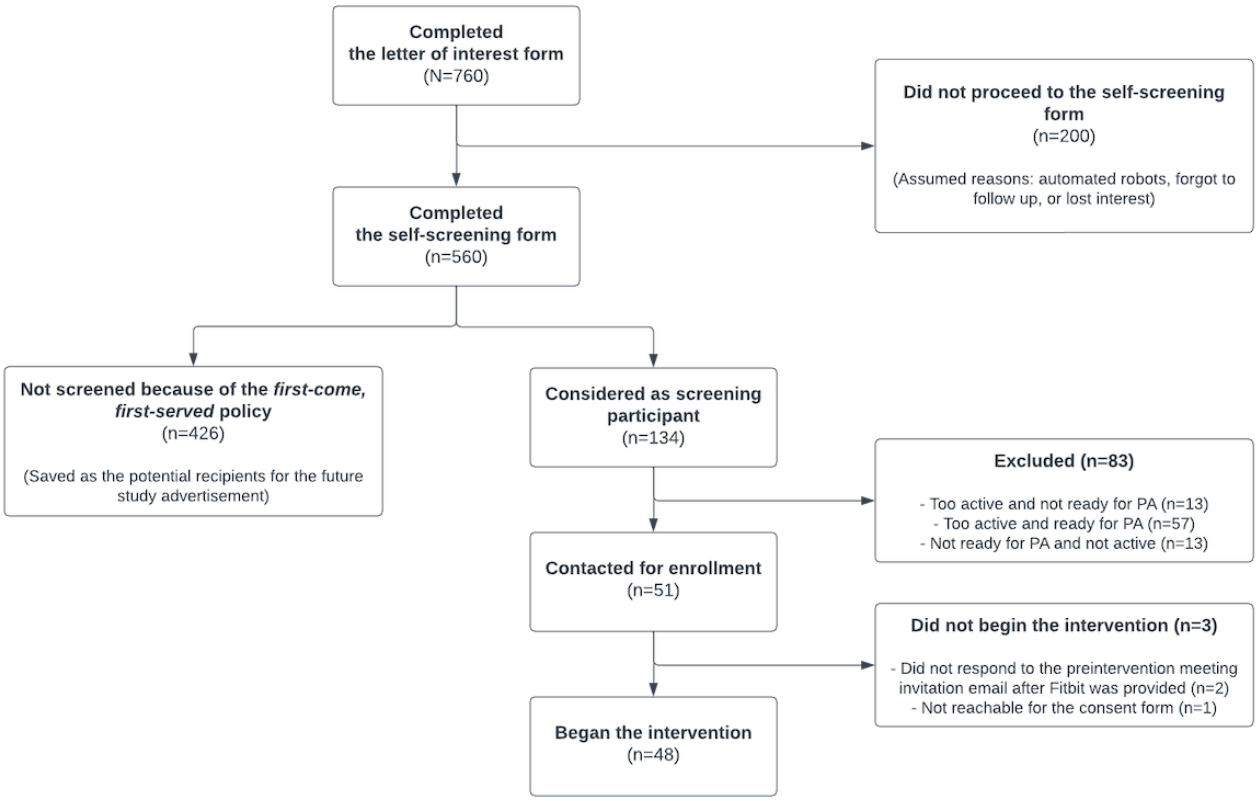

Figure 7. Simulation results for a hypothetical adherent participant illustrating the expected walking notifications (top) sent based on the designed decision rules signal (bottom) of the JustWalk JITAI study. For the sent notifications signal at the top, a 0 value implies that no notifications were sent at that decision point, whereas a value of 1 implies that a notification was sent (adapted from the study by El Mistiri et al [59]). JIT: just-in-time.

Recruitment

Enrollment began in March 2022 and ended in July 2022. In total, 761 potential participants submitted a letter of interest, and 48 (6.3%) were enrolled in the study. Figure 8 shows the CONSORT (Consolidated Standards of Reporting Trials) diagram [74]. The intervention was completed in April 2023. The data were gathered without major incidents. The source code for the server and the app is publicly available on the project's GitHub repository [75].

Figure 8. CONSORT (Consolidated Standards of Reporting Trials) recruitment diagram for the JustWalk JITAI study. PA: physical activity.

Discussion

This is a study protocol to investigate 3 JIT states (ie, need, opportunity, and receptivity) empirically and enable the empirical optimization of a JITAI intended to increase PA (steps/d) in adult populations with an inactive lifestyle.

There is well-documented evidence suggesting that digital health interventions to date have not lived up to their intended potential [76-78]. From issues of poor adherence; results that only produce limited effects; and questionable scalability, particularly among those with less access to digital devices, the potential of digital health interventions has not yet translated to a real-world impact [76,77,79]. A pathway for improving this is to focus on

XSL•FO
RenderX

producing evidence directly targeting and seeking to improve the fundamental shortcomings of digital health interventions [77,78].

In this study, our primary focus was to rigorously examine the notion of JIT states. To date, JIT states used to formulate intervention decision rules have either been assumed to be correctly defined—typically based on guidance from behavioral theory—but not empirically tested or they have been derived using data-driven approaches such as reinforcement learning whereby previous domain knowledge and understanding is underemphasized and, instead, there is hope that useful insights about intervention timing will emerge from data collected in intervention studies [80]. Although we believe that both of these paths have merit, this study protocol offers a middle ground whereby previous domain knowledge is encapsulated into computational models, which, through simulation studies, can then be used to guide the careful generation of evidence that can test dynamic hypotheses about the nature of JIT states.

This is important as a JIT state, conceptually, is an inherently nonlinear causal phenomenon [81]. There is no one causal factor that makes a given moment a JIT state, but instead, it is a mixture of different factors such as time of day, a person's current motivational levels, their relationships, recent experiences with the types of support given, and the degree to which support is well matched to a person's current needs. Such factors combine at a given moment to influence the decision to engage—or not—in the target behavior. This study protocol recognizes the inherent nonlinear causal nature of the phenomenon under study and provides a rigorous approach to gathering the data needed to make progress in the context of such complexity. By varying whether a notification is provided when the person is thought to be in a state of need, when they are thought to have an opportunity to walk based on their personal historical step data, and when they are thought to be receptive, or combinations of these 3, the experiment will collect initial evidence for which aspects of the JIT state are most important for supporting the effectiveness of JITAIs and whether this changes over time. Using this information, particularly when linked with slow dynamic processes of change (ie, daily goal setting), the experiment produces data needed to empirically optimize a digital health intervention, *JustWalk JITAI*. Specifically, this work will result in individualized, empirically validated dynamical models that can be used to predict each individual's response to the intervention options offered to them. These individualized or idiographic dynamical models can be applied to optimal personalized behavioral interventions through sophisticated control algorithms such as model-predictive control [43,82]. These model-predictive control–driven JITAIs could have the potential to work more effectively than previous digital health interventions.

The key limitations of this study stem from the high novelty of the overall experiment and its approach. To the best of the authors' knowledge, no system ID experiment of this sophistication for studying human behavior has ever been conducted. On the basis of this, there was very little robust previous evidence and examples that we could draw upon to guide study design decisions. Although we did compensate for this by drawing on some relevant data (largely from our own work, as already described) and via a number of simulation studies, overall, there are potential risks and limitations to our approach. For example, given the novelty of this experiment, it is unknown how well the assumptions we used to guide the experiment will hold up. With this, it is unclear exactly how informative those data will be for studying JIT states. Second, given the novelty of this experiment, it was unclear what an appropriate sample size should be. This point is critical for determining the degree to which any patterns or insights gleaned about JIT states from this sample will be transportable to other populations or settings.

With that said, the primary focus of any system ID experiment is the study and articulation of computational models that are predictive and foster robust control decisions for each *system*. In this context, a *system* is a person. This is critical to note because, as flagged previously, the notion of *statistical power* as is used in the classic frequentist inferential statistics used most commonly by health scientists does not have any direct translation or use within system ID experiments. Indeed, the key focus of system ID experiments is to work within each system to gain a deep understanding of its dynamics. This focus makes sense particularly for a concept such as JIT states, which, definitionally, will likely manifest idiosyncratically. The critical question is not whether some general pattern of JIT states can be inferred but, instead, whether the same algorithmic development processes can be conducted ideographically and in a replicable and scalable fashion to enable the insights that the algorithm can produce to guide intervention decision-making. This is the primary focus of our work. Thus, the limitation is less one of *statistical power* and more akin to what arises with regard to the right training data sets for machine learning algorithms. It is unclear at this time what variations across people, places, and time could occur in real-world contexts that would render our approach nonfunctional. With a sample of only 48 participants, a key limitation is that we very likely did not have diversity across variations in people and places where this type of algorithm could be used to test the robustness of our approach. With that said, given the great novelty of our overall approach, we contend that this is an appropriate trade-off. Most critically, it is likely that, even in the sample of 48 participants, we will discover some individuals from whom we can create computational models that are informative and others from whom we cannot. That will be the type of initial data we could use to then develop more rigorous hypotheses about the transportability of our methods, which can then guide future experimentation.

Overall, this work could feasibly be a key step in filling the gap between the hope of digital tools and current realities in terms of limited long-term impact and engagement based on the evidence. Although this is all still quite hypothetical, this trial is a critical step in testing the potential benefits of this overall approach for intervention optimization.

Acknowledgments

This study was funded by the National Library of Medicine (R01LM013107).

Michael Higgins and Shadia J Assi supported the operation of the clinical trial.

Data Availability

The study materials and analysis code will be available through a public repository. The data set generated in this study will be available from the corresponding author upon reasonable request and with completion of the data user agreement.

Authors' Contributions

MEM, RK, LG, GC, DER, PK, and EH performed theoretical foundation work and simulations. JP, MK, MEM, RK, DER, PK, and EH developed the intervention. JP and PK developed the technical systems, including the server and mobile app. Patrick Neggie, Rahul D'Costa, and Nick Reid supported the development and operation of the technical systems. JP, MK, RK, and SB conducted recruitment and interviews and worked on the trial logistics (eg, sending out Fitbits). JP and MK monitored the participants, communicated with them if necessary, and executed the adherence protocol. MEM, RK, and DER developed system ID programs. DER, PK, and EH provided guidance at each stage of the study. All authors contributed to the writing of the manuscript.

Conflicts of Interest

JP is an employee of the Ministry of Health and Welfare, Korean National Government. LG is an employee of Lufthansa Industry Solutions.

Abstract

Background: Daily stressors are associated with cognitive decline and increased risk of heart disease, depression, and other debilitating chronic illnesses in midlife adults. Daily stressors tend to occur at home or at work and are more frequent in urban versus rural settings. Conversely, spending time in natural environments such as parks or forests, or even viewing nature-themed images in a lab setting, is associated with lower levels of perceived stress and is hypothesized to be a strong stress "buffer," reducing perceived stress even after leaving the natural setting. However, many studies of daily stress have not captured environmental contexts and relied on end-of-day recall instead of in-the-moment data capture. With new technology, these limitations can be addressed to enhance knowledge of the daily stress experience.

Objective: We propose to use our novel custom-built Stress Reports in Variable Environments (STRIVE) ecological momentary assessment mobile phone app to measure the experience of daily stress of midlife adults in free-living conditions. Using our app to capture data in real time will allow us to determine (1) where and when daily stress occurs for midlife adults, (2) whether midlife adults' daily stressors are linked to certain elements of the built and natural environment, and (3) how ecological momentary assessment measurement of daily stress is similar to and different from a modified version of the popular Daily Inventory of Stressful Events measurement tool that captures end-of-day stress reports (used in the Midlife in the United States [MIDUS] survey).

Methods: We will enroll a total of 150 midlife adults living in greater Indianapolis, Indiana, in this study on a rolling basis for 3-week periods. As those in underrepresented minority groups and low-income areas have previously been found to experience greater levels of stress, we will use stratified sampling to ensure that half of our study sample is composed of underrepresented minorities (eg, Black, American Indian, Hispanic, or Native Pacific Islanders) and approximately one-third of our sample falls within low-, middle-, and high-income brackets.

Results: This project is funded by the National Institute on Aging from December 2022 to November 2024. Participant enrollment began in August 2023 and is expected to finish in July 2024. Data will be spatiotemporally analyzed to determine where and when stress occurs for midlife adults. Pictures of stressful environments will be qualitatively analyzed to determine the common

XSL•FO
RenderX

elements of stressful environments. Data collected by the STRIVE app will be compared with retrospective Daily Inventory of Stressful Events data.

Conclusions: Completing this study will expand our understanding of midlife adults' experience of stress in free-living conditions and pave the way for data-driven individual and community-based intervention designs to promote health and well-being in midlife adults.

Introduction

Daily stressors are associated with cognitive decline and increased risk of heart disease, depression, and other debilitating chronic illnesses for midlife adults [1-5]. Daily stressors tend to occur at home or at work and are more frequent in urban versus rural settings [6-8]. Conversely, spending time in natural environments such as parks or forests, or even viewing nature-themed images in a lab setting, is associated with lower levels of perceived stress and is hypothesized to be a strong stress "buffer," reducing perceived stress even after leaving the natural setting [9-12]. The role that natural environments can play in reducing stress arousal is particularly important when considering that neighborhoods with high poverty rates and higher proportions of racial or ethnic minorities have less access to green space and higher exposure to stressful elements such as abandoned buildings and crime [13-15]. However, many studies of daily stress have not captured environmental contexts and relied on end-of-day recall instead of in-the-moment data capture. With new technology, these limitations can be addressed to enhance knowledge of the daily stress experience [16].

In the United States, midlife adults are staying in the workforce longer and are engaging in higher levels of physical activity than previous generations, potentially extending their interactions with elements of the built and natural environments that influence their experience of daily stress [17,18]. Recent evidence has revealed that age-related linear increases in perceptions of well-being observed during past periods of economic prosperity have not continued during more recent, less economically prosperous times [19]. The seismic and unpredictable economic and social changes brought about by the COVID-19 pandemic have greatly altered the experience of daily stressors in the built and natural environment, a trend that is likely to continue well into the future [20].

In the midlife adult population, stress (or the lack thereof) plays an important role in the aging process. The relationship between various types of stress and alterations in cognitive functioning has been well documented, and there is growing evidence showing a relationship between daily stress in midlife and cognitive decline [2,3,21]. Perceived stress in midlife adults has also been closely linked with physical disability later in life [22,23]. A growing body of research has also found that perceived stress, particularly in the workplace, is closely related to heart disease [24]. Furthermore, while individual health and wellness in midlife is no doubt important, longitudinal studies have shown that the health and wellness of midlife adults is also pivotal to others in their workplace, society in general, and in the lives of those in younger and older generations who often are socioeconomically dependent on midlife family members [25].

Midlife adults of different socioeconomic statuses and races are subject to structural inequality in their living environments. Those living in urban environments with higher levels of poverty and violence experience higher levels of environmental stress than those living in suburban or rural environments [15]. In particular, it is well documented that underrepresented minorities are exposed to environmental stressors more than nonunderrepresented minorities [26,27]. One explanation for racial differences in exposure to stressors is residential segregation, resulting in a predisposition for low-income minorities' exposure to environmental stressors such as traumatic events, urban decay, and poverty [28]. Minority and low-income midlife adults' exposure to environmental stressors has been linked to unhealthy behaviors like cigarette smoking [29], as well as myriad negative health outcomes [30].

In response to this research gap, we propose to use our novel custom-built Stress Reports in Variable Environments (STRIVE) ecological momentary assessment (EMA) mobile phone app to measure the experience of daily stress of midlife adults in free-living conditions. Using our app to capture data in real time will allow us to determine (1) where and when daily stress occurs for midlife adults, (2) whether midlife adults' daily stressors are linked to certain elements of the built and natural environment, and (3) how EMA measurement of daily stress is similar to and different from a modified version of the popular Daily Inventory of Stressful Events (DISE) measurement tool that captures end-of-day stress reports (used in the Midlife in the United States [MIDUS] survey) [31].

Completing this study will expand our understanding of mid-life adults' experience of stress in free-living conditions and pave the way for data-driven individual and community-based intervention designs to promote health and well-being in midlife adults. Potential interventions that could stem from our data include technology-based "just-in-time" interventions that account for spatiotemporal location, mindfulness-based interventions that incorporate environmental stress triggers, and community-based interventions designed to eliminate

XSL•FO
RenderX

environmental stressors that are commonly experienced by midlife adults (eg, congested areas).

Methods

Overview

In this stage 0 (of the NIH Stage Model for behavioral intervention development) study, we propose an interdisciplinary mixed method approach to examine the occurrence of daily stressors in the moment they occur for midlife adults in the built and natural environment using mobile and wearable technology. A total of 150 midlife adults will be enrolled in this study on a rolling basis for 3-week periods. Participants will meet with a researcher in person at the start and end of their 3-week study period. They will be provided with a smartphone preloaded with the STRIVE app and a Polar Unite smartwatch. They will be instructed to carry the phone and wear the watch for the 3-week duration of the study. Each enrolled participant will use one or more daily stress measurement tools in any given week, randomized to account for participant priming. In 1 week of participation, participants will complete the DISE by the Research Electronic Data Capture (REDCap; Vanderbilt University) survey every evening. In another week of participation, participants will use the STRIVE app to report daily stressors in real time and complete the DISE every evening. In another week of participation, participants will only report stressors in real time through the STRIVE app. Automated SMS text messages will be sent to participants each day to remind them of what they need to do to remain active in the study and provide survey links when needed.

Participants will be recruited from the greater Indianapolis area in Indiana. As those in underrepresented minority groups and low-income areas have previously been found to experience greater levels of stress, we will use stratified sampling to obtain a sample that is racially and socioeconomically diverse (Table 1). Income levels are defined as the bottom, middle, and top third of household incomes based on 2020 US Census percentiles (low income: <US $39,535; middle income: US $39,535-$85,076; high income: >US $85,076) [32]. Participants will be recruited with the assistance of the Indiana Clinical and Translational Sciences Institute recruitment concierge services and their community partnerships. Recruitment materials will be posted on community-based social media pages, on paper flyers in public community spaces, and through all communication channels operated by community health partners.

Table 1. Study sample stratified by race and household income (N=150).

Race	Low income, n (%)	Middle income, n (%)	High income, n (%)
Black, American Indian, Hispanic, Native Pacific Islanders	25 (16.6)	25 (16.6)	25 (16.6)
White or Asian	25 (16.6)	25 (16.6)	25 (16.6)

Measurement of Stress With the STRIVE App

Study participants will be asked to carry the researcher's provided Android mobile phone with them at all times. The STRIVE app passively records the participant's GPS coordinates every 60 seconds throughout the data collection period (Table 2). Research participants are informed that their location is being tracked by the app. When participants experience a daily stressor, they are asked to open the app and provide a rating of their stress level, a description of the stressor, their preferred coping strategy, and optionally take a photograph of the environment where they experienced stress (Figure 1). Data input is kept to a minimum to reduce participant burden and burnout [33].

Figure 1. The Stress Reports in Variable Environments (STRIVE) app.

We have created a protocol to promote the safety of research participants during their reporting of daily stressors with the STRIVE app. If they cognitively appraise themselves as stressed and are in a situation in which it is unsafe to use their phones (eg, driving a car), they are asked to proceed to the nearest safe location before recording their experience. Participants will be asked to indicate when and where the stressor occurred if they are not reporting from the location in which the stress occurred in their later description of it. Many people go through a day without experiencing a stressor [43]; for days when this is the case, participants will be asked to indicate on their app that they had not experienced stress but were still actively participating in the study.

Measurement of Stress With the Modified DISE Tool

The DISE is recommended by the National Institute on Aging funded Stress Measurement Network for daily stress measurement. A modified version of the DISE will be administered through the REDCap survey each evening for 2 weeks of the study period. The modified version of the DISE includes questions about the number of times participants felt stressed over the course of the day, their overall stress level, and questions about specific stressor categories (eg, had an argument and had work stress) and how stressful each of those experiences was for the participant. The DISE was modified to allow for direct comparisons between STRIVE and DISE.

Geospatial Analysis

We will fit spatiotemporal regression models to determine the impact of specific elements of the built and natural environment on daily stressors. Given the nature of our spatially dependent data, traditional regression-based approaches (eg, Poisson or negative binomial regression) violate the independence assumption required for generalized linear models. Ignoring the dependence of spatial data can underestimate standard errors, resulting in overly narrow confidence interval estimates and, consequently, incorrect statistical inference [44]. Thus, we will use spatiotemporal models that can simultaneously account for dependence (autocorrelation) in geospatial locations and temporal measurements. We will do this using Integrated Nested Laplace Approximation (INLA) models. Specifically, we will fit zero-inflated negative binomial INLA models, as these models can account for the many instances where stress experiences are not recorded (zero inflation) while still adjusting for the spatial and temporal autocorrelation of each measurement [45,46]. Importantly, the INLA modeling approach is robust as it can incorporate individual-level characteristics and group-level (ie, neighborhood) characteristics while adjusting for the spatial and temporal autocorrelation [47]. INLA uses a Bayesian paradigm, can fit offsets for any necessary weightings (eg, population size or number of measurements), is able to handle both point process (ie, singular latitude and longitude locations) and irregular lattice data (ie, polygons of parks and census tracts), and can analyze the individual impact of temporal, spatial, and spatiotemporal effects [46]. Through this analysis, we can identify the magnitude, direction, and impact of participant attributes (including data collected through the pretest survey and real-time collection of heart rate and activity level data from the Polar Unite watch), neighborhood features, and location characteristics on daily stressors.

Qualitative Analysis of Reported Stressors

We will conduct an analysis of data reported through the STRIVE app in a 2-step process including open and axial coding [48]. Open coding will be conducted twice: first to code stressors into stressor types and second to code mentions of elements of

XSL•FO
RenderX

the built and natural environment that played a role in the stressful experience. This open coding process will be conducted on qualitative responses to the question, "Please discuss what is causing you stress." In this open coding process, researchers will be versed in previous research categorizing daily stressors to identify themes in the data that may overlap with commonly experienced daily stressors identified in previous research [49]. Any new themes that emerge will be given new names and detailed descriptions. In the second axial coding step, researchers will analyze stressor and environmental characteristic themes to look for those that may be related to identify linkages, creating meta-categories for daily stressors that may be similar in nature. Then, the open and axial coding processes will be conducted on participant photographs that accompany stressor reports. Characteristics of the environment in which stress occurs will be coded for each participant photograph, allowing for triangulation among themes generated by text-based responses and participant photographs**.** This data triangulation will allow us to understand how daily stressors are related to specific elements of the built and natural environment.

Comparison of STRIVE and DISE Stressor Data

We will compare the number of stressors reported, the type of stressors reported, and the subjective severity of stressors reported by the same individual using the DISE and STRIVE app across 3 time periods. The 3 time periods are designed to differentiate between stand-alone use of each instrument and concurrent use of both instruments, as there is potential for these instruments to be complementary in terms of the scope and depth of data captured. Thematic coding of stressors reported through the DISE and STRIVE app will be conducted to allow for comparison between the two. All stressors will be coded into 7 categories specified by the DISE to retain consistency. Stressful events are categorized into 1 of 7 broad classifications organized by interpersonal tensions, work or education, home, finances, health or accident, network, and miscellaneous. As the unit of analysis of the DISE is the "day," we will conduct a repeated measures ANOVA to compare the number of stressors reported per day, the average subjective severity of stressors per day, and the type of stressors reported per day across the 3 modes of daily stress reporting, including an interaction of group (STRIVE or DISE) and mode (using only one or both together) to test if there is any effect on the reported stressors by use. A factor will also be included for the order receiving the conditions to account for carryover effects. Models will also be adjusted by demographic variables.

Ethics Approval

This study has been approved by the Indiana University Institutional Review Board (study number 1910712088). Informed consent has been and will be obtained from all research participants. A special document outlining when and where it is appropriate and safe to take photographs of stressful environments will be provided to all research participants, with a focus on protecting the privacy of others. Further, a document highlighting that study participants are not to report stressors in dangerous situations (eg, while driving a car) will be provided. Although we will make efforts to deidentify study data as much as possible, certain elements of data collected (eg, pictures and GPS coordinates) could be used to identify participants. Participants are informed of this risk and may choose not to report stressors or take pictures in situations where they are concerned about their confidentiality. Each study participant will be paid US $150 for their participation in the study.

Results

This study will take approximately 24 months to complete and will take place between December 2022 and November 2024. Enrollment began in August 2023 and is expected to be completed by July 2024. We expect the following study findings:

1. A better understanding of where and when stressors occur for midlife adults in free-living conditions. We hypothesize that the quantity of stressors reported, type of stressors reported, and subjective severity of stressors reported by midlife adults will differ by location (eg, at home vs at a park) and time (eg, morning vs evening) throughout the built and natural environment.
2. An understanding of specific elements of the built and natural environment that contribute to midlife adults' daily stress. We hypothesize that distinct environmental characteristics (eg, abandoned buildings) will emerge as contributors to stress through the qualitative analysis of stressor descriptions and pictures of stressful environments.
3. An understanding of how the STRIVE-based EMA of daily stress is supplementary or complementary to the DISE. We hypothesize that, when reporting through the STRIVE app compared with when reporting through the DISE, midlife adults will report a greater number of daily stressors, a lower average stressor severity, and different types of stressors.

Throughout the study, we will present our research findings at relevant academic or professional conferences and publish peer-reviewed papers. We will also share our study findings with partner governmental organizations and nongovernmental organizations in the state of Indiana. These organizations will likely find our data useful for future community planning.

Discussion

Daily stress contributes to myriad negative health outcomes. Midlife adults are staying in the workforce longer than previous generations and are likely subject to greater environmental stressors than in the past. Technological advances, including smartphones and wearable technology, allow us to measure stress in situ, painting a clearer picture of how stress is experienced in real time. Our custom-built STRIVE EMA app allows us to reduce recall bias and geospatially locate stressors while simultaneously collecting health data (eg, heart rate, sleep, and physical activity), allowing for a clear picture of the role the built and natural environment play in the daily stress of midlife adults.

Completing this study will expand our understanding of midlife adults' experience of stress in free-living conditions and pave the way for data-driven individual and community-based

XSL•FO
RenderX

intervention designs to promote health and well-being in midlife adults: (1) technology-based "just-in-time" therapeutic interventions that account for spatiotemporal location, (2) mindfulness-based interventions that incorporate environmental stress triggers and stimuli, and (3) community-based interventions designed to eliminate environmental stressors that are commonly experienced by many midlife adults (eg, abandoned buildings, areas that often become crowded or congested, or other yet undiscovered stressful elements of the environment).

Abstract

Background: Perinatal depression affects >400,000 mother-child dyads in the United States every year and is associated with numerous adverse maternal and child developmental outcomes. Previous research implicates the dysregulation of oxytocin and the hypothalamic-pituitary-adrenal (HPA) axis functioning in mothers and children as potential mechanisms mediating or moderating the transmission of risk associated with maternal depression.

Objective: The Mood, Mother and Child study will examine the psychobiological sources of risk and resilience within mother-child dyads affected by maternal depression. This manuscript describes (1) the study rationale and aims, (2) the research design and procedures and how they were altered in response to the COVID-19 pandemic, and (3) the data analysis plan to test the study hypotheses.

Methods: This is a prospective longitudinal study with an embedded randomized controlled trial that examines (1) correlations among postpartum depression and anxiety symptoms, maternal and child oxytocin and HPA axis functioning, and child developmental outcomes and (2) the causal relationship between exogenous oxytocin and HPA reactivity. This study is funded by the National Institute of Child Health and Human Development with institutional review board approval.

Results: Recruitment and data collection have commenced, and the expected results will be available in 2024. Analyses are presented for testing the proposed hypotheses.

Conclusions: The unique combination of a prospective longitudinal research design with an embedded randomized controlled trial will allow the Mood, Mother and Child study to apply a developmental lens to the study of maternal depression and anxiety symptoms from birth to middle childhood and the psychobiological mechanisms promoting risk and resiliency for both mother and child outcomes. This will be the first study that simultaneously evaluates (1) the role of oxytocin using multiple methodologies, (2) the causal relationships between exogenous oxytocin and HPA axis functioning among mothers with differing levels of depression and anxiety symptoms, and (3) the multiple mediating and moderating roles of parenting behaviors and maternal and child psychobiological characteristics. The goals of these aims are to provide insights into the psychobiological effects of oxytocin in women and inform future clinical trials to treat perinatal mood disorders.

Introduction

Background and Study Design Considerations

Overview

Perinatal depression (PND) is a common, morbid condition affecting >400,000 mother-child dyads in the United States each year [1]. In addition to the direct effect of PND on mothers' health and well-being, it presents challenges for early child development, including reduced maternal sensitive caregiving [2]; impaired parent-child attachment relationships; and compromised child emotion regulation abilities [3,4], socioemotional development [5,6], and executive functioning (EF) [7,8]. These effects may occur even when mothers receive medication or psychotherapy for depressed mood [9], and they may extend well into adolescence and early adulthood [10,11]. Research has implicated the dysregulation of the oxytocin system [12] and the hypothalamic-pituitary-adrenal (HPA) axis [13] in the context of maternal depression as potential contributors to individual and parent-child relational dysfunction that increases the risk of nonoptimal child outcomes. The Mood, Mother and Child (MMC) study (funded by the National Institutes of Health; grant R01HD093901; grant review provided in Multimedia Appendix 1) addresses specific aims regarding the complex roles oxytocin functioning plays within the mother-child dyad, including the role of maternal oxytocin and HPA axis functioning as predictors of postpartum depression and anxiety symptoms (PDAS) and parenting behaviors and the role of child oxytocin functioning as both an outcome, mediator, and moderator of exposure to maternal depression and maladaptive parenting behaviors. This paper provides a brief synopsis of these goals and a detailed description of the MMC study protocol.

Both the severity and chronicity of maternal depression are associated with child developmental outcomes [14,15], and this association is (in part) mediated by dysregulated dyadic interactions between mother and child [16]. Symptomatic mothers are more likely to display withdrawn or intrusive behaviors when interacting with their infants in the first postpartum year [17,18], and these associations persist through early childhood, with the lowest levels of sensitive caregiving observed among mothers with chronic depression [19,20]. Building on previous research demonstrating the developmental risk associated with exposure to maternal depression, the MMC study will examine PDAS and associated parenting behaviors across early childhood as predictors of a variety of biopsychosocial outcomes in middle childhood, including EF, general cognitive development, and socioemotional adjustment. However, far less is known about the biopsychosocial processes underlying the manifestation of depressive symptoms in mothers and the transmission of risk in offspring. To address this gap, the MMC study will examine the roles of maternal and child oxytocin functioning, heart rate variability (HRV), and HPA axis functioning as potential sources of psychobiological risk and resilience.

Maternal Oxytocin Functioning, Depression, and Parenting

A subset of systems contributing to the biopsychosocial process underlying experiences of PND may include oxytocin and its effects on HPA functioning. Research suggests that PND is associated with dysregulation of the HPA axis [21] and that this association may (in part) be driven by dysregulated oxytocin functioning [22]. Previous studies on this topic—including research by the authors of this paper—have been mixed, including research demonstrating (1) no association between oxytocin during breastfeeding and PND [23], (2) an inverse association between oxytocin during breastfeeding and maternal symptoms of depression and anxiety at 2 months post partum [12], and (3) that oxytocin levels differentially predicted HPA axis reactivity in women with or without mood symptoms [13]. There are also candidate gene studies reporting correlations between oxytocin-related genetic variants and maternal depression [24] as well as oxytocin-related variants that predict developmental risk factors associated with maternal depression, such as stress reactivity [25,26], empathetic functioning [27], and parenting behaviors [28-30]. In addition, there is mixed evidence that exogenous administration of oxytocin can alter parenting behaviors [31-33] (for a systematic review, see the study by Szymanska et al [34]), although we are unaware of studies examining oxytocin administration and depressive symptoms. Furthermore, research on oxytocin and the psychobiology of PND has largely been conducted on mothers of infants and toddlers, with little empiricism on these topics in subsequent years of development. The MMC study will examine oxytocin functioning, oxytocin-related genetic variants, and HPA axis functioning as predictors of PDAS and parenting behaviors. This will be done using both a passive longitudinal design and a placebo-blinded trial examining the effects of exogenous administration of oxytocin on HPA axis functioning for mothers with and without depression diagnoses.

Child Oxytocin Functioning as a Potential Moderator and Mediator of PND

There is mixed evidence from candidate gene studies of oxytocin-related genetic variants functioning as moderators of the associations between adverse developmental exposures and subsequent child outcomes. For example, oxytocin receptor (OXTR) rs53576 G allele carriers who had experienced childhood maltreatment reported more depressive symptomatology compared with AA homozygotes, suggesting that the G allele confers increased vulnerability to stressors [35]; however, contradictory findings have reported that A allele carriage increased intergenerational transmission of maternal depression to child depressive symptomatology [36]. Meanwhile, a study of OXTR rs2254298 suggested that carriers of the A allele have increased developmental risk of anxiety and depression in the context of exposure to early-life adversity

XSL•FO
RenderX

[37,38]. Finally, several studies indicate that these associations may vary by child sex [39,40] in the form of both sex-specific diathesis-stress and differential susceptibility models of gene × environment interaction. The MMC study will examine oxytocin-related candidate genes (as well as child sex) as potential moderators of child exposure to PDAS and maternal parenting behaviors with respect to a variety of outcomes in middle childhood, including EF and socioemotional adjustment.

In addition to the genetic-based moderation of exposure to PDAS and parenting behavior, there is evidence suggesting that epigenetic alterations in children's oxytocin-related gene systems may mediate the associations between these exposures and child outcomes. Exposure to maternal depression is associated with differences in glucocorticoid receptor (NR3C1) methylation, which are thought to mediate associations between early-life adversity and subsequent psychopathology [41-45]. Furthermore, a recent genome-wide methylation study of children aged 1 year of mothers with or without major depressive disorder found differences across the epigenome [46]. It is also possible that the association between PDAS, maternal sensitivity, and child changes in epigenetic form may vary by child sex with respect to oxytocin functioning. Although speculative, research suggests that circulating oxytocin levels are comparable across boys and girls during the first 5 years of life [47,48]; however, oxytocin responsiveness to stress is significantly greater for girls who have a history of parental maltreatment as compared with girls without maltreatment or boys in either condition [49]. This alteration in functioning in girls may be a product of epigenetic changes in response to an extreme and maladaptive environment that accelerates reproductive development and individual fitness in the context of a dangerous environment; as such, if female individuals are genetically more sensitive to such environments, it is possible that markers of epigenetic change will be stronger for girls than for boys even at the age of 5 years. The MMC study will examine oxytocin-related changes in the epigenome from early infancy to middle childhood as potential mediators of associations between exposure to PDAS and parenting behavior and developmental outcomes, as well as the potential moderation of this pathway by child sex.

MMC Study Aims and Hypotheses

The MMC study will address 3 specific aims. The first aim is to examine the role of oxytocin in the prediction of PDAS and other biopsychosocial maternal outcomes (eg, stress reactivity and parenting behaviors)—and specifically to examine the causal relationships between exogenous oxytocin and HPA reactivity. The following three hypotheses will be addressed as part of aim 1: (1) more severe PDAS will be associated with oxytocin and HPA axis dysregulation in correlational analyses, and causal relationships between oxytocin activity and HPA axis reactivity will be evidenced through a placebo-blinded trial of intranasal oxytocin effects on serum cortisol levels in response to a social challenge (hypothesis 1a); (2) genetic variation in maternal oxytocin-associated pathways will predict PDAS severity (hypothesis 1b); and (3) genetic variation will moderate associations among depression and anxiety symptoms, maternal oxytocin and HPA axis physiology, and parenting behaviors (hypothesis 1c).

The second aim is to examine the associations between PDAS and child biopsychosocial outcomes (eg, child epigenetics, EF, and cognitive and socioemotional development). The following four hypotheses will be addressed as part of aim 2: (1) more severe PDAS will predict more adverse child biopsychosocial outcomes during early elementary school years (hypothesis 2a); (2) high stress reactivity and maladaptive parenting behaviors will mediate associations between more severe PDAS experienced during the first year post partum and adverse child biopsychosocial outcomes in years 5 to 7 (hypothesis 2b); (3) the direct and indirect effects of PDAS on externalizing behaviors at ages 5 to 7 years will be stronger for boys, the direct and indirect effects of PDAS on internalizing behaviors at ages 5 to 7 years will be stronger for girls, and the direct and indirect effects of PDAS on early elementary cognitive outcomes will be comparable across boys and girls (hypothesis 2c); and (4) the effects of PDAS on early childhood outcomes will persist even after accounting for concurrent maternal depression and anxiety symptoms (hypothesis 2d).

The third aim is to examine the associations from the previous aim as moderated by child oxytocin-related genotype and mediated by child oxytocin-related epigenetic changes over time. The following five hypotheses will be addressed as part of aim 3: (1) child genetic variation in oxytocin-associated pathways will moderate the associations between PDAS and child biopsychosocial outcomes (hypothesis 3a); (2) child genetic variation in oxytocin-associated pathways will moderate the associations between maternal parenting behaviors and child biopsychosocial outcomes (hypothesis 3b); (3) child sex will moderate relationships among child oxytocin genetic variation, PDAS, parenting behaviors, and child biopsychosocial outcomes (hypothesis 3c); (4) child epigenetic changes underlying oxytocin functioning between the ages of 2 months and 5 years will mediate the associations between PDAS exposure and parenting behaviors and child biopsychosocial outcomes (hypothesis 3d); and (5) the associations between PDAS or parenting behaviors and child epigenetic changes will be stronger for girls than for boys (hypothesis 3e [exploratory hypothesis]).

Methods

Overview

The MMC study recruits mother-child dyads who previously participated in the Mood, Mother and Infant (MMI) study [50]. Although MMC study data collection focuses on mothers and children during the middle childhood period (age of approximately 6 y), using this existing sample will provide for longitudinal analyses spanning from the prenatal period to the current age of the child. Participation involves completing 2 laboratory-based data collection visits along with web-based surveys completed outside the visit (typically at home before the final visit). The first visit involves data collection using a double-blinded randomized experimental design and involves only the biological mother. During this visit, nonpregnant mothers are randomized to either the nasal oxytocin or placebo condition (based on a randomization table created using a random number generator from the University of North Carolina

XSL•FO
RenderX

at Chapel Hill investigational drug service). The second laboratory visit involves data collection with mothers and children for the purpose of hypothesis testing within the passive longitudinal design.

Data collection began on February 7, 2019, and was scheduled to continue until the spring of 2022. However, data collection was interrupted by the COVID-19 pandemic. On March 14, 2020, data collection was halted entirely and did not resume until August 25, 2020, at which point an adapted protocol was implemented for the safety of participant families and research staff. On April 21, 2021, the original protocol was largely reinstated and will be implemented until the completion of the project (participants continued to wear masks beyond this date, and the order of the child data collection protocol remained the same as during the pandemic). Descriptions of the data collection protocols for the pre– and post–COVID-19 periods and the protocol during the COVID-19 period are provided in the following sections.

Participants

Participants for the MMC study are recruited from the MMI sample (N=222). Table 1 provides a summary of descriptive information for this sample. Mothers in the MMI study were initially recruited in the third trimester of pregnancy and had a singleton pregnancy, and all reported intention to breastfeed (this was relevant because of the centrality of breastfeeding to the oxytocin assessments and hypotheses in the MMI study). The sample was enriched with women at a high risk of depression or anxiety such that 87 (39.2%) had a Structured Clinical Interview for the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)–verified current diagnosis of depression or anxiety or were in active treatment with psychotherapy or antidepressants, 64 (28.8%) had a past diagnosis of depression or anxiety, and 71 (32%) were low risk with no history of depression or anxiety. After completing the final in-person data collection visit at 12 months of child age, mothers were invited to participate in web-based follow-up questionnaires every 6 months until the child was aged 4 years. Of these mothers, 92% (138/150) chose to participate in ongoing data collection, leading to a projected enrollment of 150 dyads for the MMC study. Owing to additional attrition and suspension of data collection because of the COVID-19 pandemic, the MMC enrollment target has been reduced to 110 dyads.

Procedures

Visit 1: The Randomized Controlled Trial Administration

Pre– and Post–COVID-19 Protocol

Following the mother's arrival and informed consent procedures, each participant provides a urine sample used immediately for pregnancy testing, and only nonpregnant participants proceed with the oxytocin randomized controlled trial (RCT) visit. Research staff apply MindWare cardiovascular sensors (MindWare Technologies LTD) to monitor HRV and the cardiac pre-ejection period (PEP), a SunTech Tango monitor (SunTech Medical, Inc) assesses blood pressure and heart rate, and an antecubital intravenous catheter is placed for interval blood sampling. Next, the mother is left to adapt to the testing chamber for a 10-minute habituation period [51,52]. Following the habituation period [53-56], participants are randomized by risk level in a 1:1 allocation to either 24 international units of nasal oxytocin or a placebo nasal spray in an identical bottle. Both participants and study team members are blinded to allocation. The study drug and placebo are obtained from Apotheke Roter Ochsen. A total of 40 minutes after the nasal spray administration, mothers participate in the Trier Social Stress Test (TSST). The TSST includes a speech performance task and a math performance task, which reliably induce large and consistent HPA and cardiovascular responses [52,57]. Following the guidelines for examining HPA stress reactivity, intravenous blood samples are collected at baseline; at 20 and 40 minutes

XSL•FO
RenderX

of the post–nasal spray rest period; during the speech and math tasks; and at 10, 20, and 30 minutes of the post-TSST recovery period [52,58]. Across these 8 samples, a total blood volume of 113 mL is collected. Each maternal blood sample is collected into prechilled vacutainer tubes, immediately cold centrifuged, aliquoted into prechilled cryotubes, and stored at −80 °C. Owing to conflicting evidence regarding the optimal timing of stress testing [59,60], visits are scheduled for 1 PM to increase the likelihood of detecting a stress response unopposed by the circadian influence [22]. Previous findings suggest that the possible menstrual cycle phase does not affect TSST results [61,62]; therefore, although the date of the last menstrual period and hormones are not used for scheduling data collection visits, these data are recorded for analytic control purposes. Staff also conduct the nonpatient version of the Structured Clinical Interview for the DSM-IV (SCID-NP), to assess the mother's current psychiatric symptoms [52] at this visit.

Protocol Amendments Owing to COVID-19

During the months affected by the COVID-19 pandemic, the MMC study visit 1 protocol was amended as follows. First, participants completed informed consent protocols over the phone using DocuSign (DocuSign, Inc). The research staff reviewed a COVID-19 information sheet and symptom screening before arriving at the study visit. Participants were also screened for symptoms upon arrival. Second, the SCID-NP was conducted via phone call instead of in person. Finally, research staff and participants further enhanced safety protocols by requiring masking for all, limiting contact by leaving the testing chamber when possible, keeping the door open for increased air circulation, and remaining a minimum of 6 feet away as much as possible. The TSST committee members were seated >6 feet away from the participant and from each other. These protocol amendments will be implemented for the remainder of the study.

Visit 2: Mother and Child Data Collection for Hypothesis Testing

Pre–COVID-19 Protocol

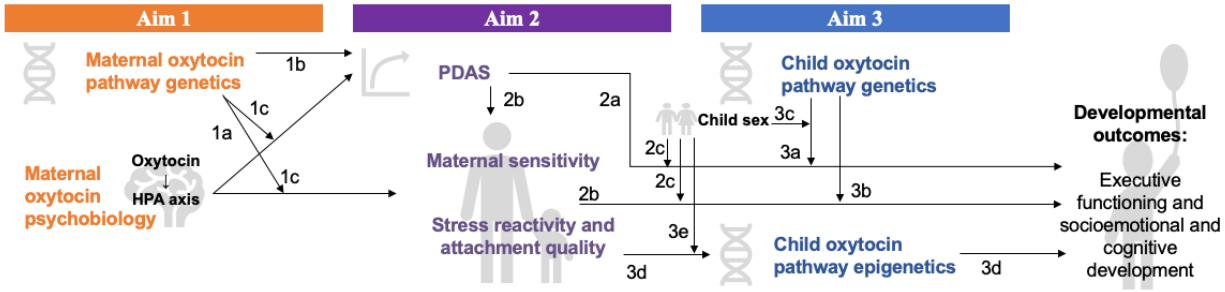
Following the mother's arrival and informed consent procedures, MindWare cardiovascular sensors were placed on the mother and child, 6 cheek cell swabs were collected from the child, and the child's height and weight were recorded. After a 5-minute habituation period to the testing chamber, the mothers were taken into a neighboring room, and the children remained in the assessment room with the research staff. The children were then assessed for EF ability using the EF Touch assessment (a computerized EF battery validated for use in children aged 4 to 7 y). This lasted for approximately 30 to 45 minutes (including practice, administration, and breaks between tasks). Finally, child IQ was assessed using the 6 subscales of the Wechsler Preschool and Primary Scale of Intelligence that comprise the full-scale IQ (FSIQ) measure [56]. While the children completed the EF and IQ assessments, the mothers were asked to complete a series of computer-based EF assessments from Inquisit, including the Wisconsin Card Sorting Test, Visual Simon Task, Symbol Search, Simple Visual Reaction Time Task, Self-Ordered Pointing Task, Digit Symbol Substitution Task, Counting Span Task, Stroop Task, and Tower of London Task, which took approximately 45 minutes. Mothers then completed the Child Behavior Checklist (CBCL) and a recorded speech for which they were instructed to talk for 5 minutes about their child.

Once the mothers and children were done with their separate tasks, a maternal antecubital intravenous was placed for interval blood sampling. The dyad was then reunited for an additional 5-minute baseline rest period. After this period, the mother and child participated in a set of 3 parent-child interaction tasks designed to assess parent and child behaviors within a dynamic interaction context [63]. Three 5- to 10-minute tasks were used in this interaction. The first was a tower-building task in which the dyad was instructed to recreate a large wooden block tower using smaller, differently shaped wooden blocks. The dyad was instructed that the task was for the child to complete but the mother could provide any assistance she chose. The second task involved a simple card game with a standard deck of playing cards divided evenly between the mother and child. Each was instructed to simultaneously turn over a card and place it face up in the space between them. This continued until one of the cards was a jack, at which point the first person to slap the jack card won all the cards that had accrued to that point. The goal of the game was to win as many cards as possible. For the third interaction task, the dyad was provided with an Etch A Sketch toy (Ohio Art Company) and a line picture of a sailboat. Mothers were instructed to use one of the Etch A Sketch knobs, and the children were instructed to use the other; their goal was to recreate the picture of the sailboat on the Etch A Sketch by working cooperatively with each using a separate turning knob on the toy. These parent-child interaction tasks were recorded for later behavioral coding. Maternal blood was collected before and immediately after the parent-child interaction tasks; a total blood volume of 59 mL was collected. Each maternal blood sample was collected into prechilled vacutainer tubes, immediately cold centrifuged, aliquoted into prechilled cryotubes, and stored at −80 °C. Once participants were deinstrumented, research staff collected hair samples from the mother and child for cortisol analysis.

Post–COVID-19 Protocol

During the months affected by the COVID-19 pandemic, the MMC study visit 2 protocol was amended as follows. First, we suspended maternal blood sampling, mother and child MindWare data and hair sample collection, and child cheek cell collection to reduce contact between staff and participants. Second, upon arrival (after completion of wellness screening), mothers and children were directed into a cleaned, unoccupied room without research staff where they could remove their masks to complete the parent-child interaction tasks (cameras were operated remotely for recording). These safety accommodations were important as it was necessary to observe these interactions without masks to code mother and child facial affect. Once the parent-child interaction tasks were complete, mothers and children resumed mask wearing. Suspended protocols were gradually reintroduced as COVID-19 restrictions were reduced. On April 21, 2021, cheek cell collection resumed. On August 23, 2021, MindWare data collection for the children and the baseline rest period were reintroduced. On June 26, 2022, hair samples were reintroduced and moved to the beginning of the protocol. Maternal blood collection and

XSL•FO
RenderX



MindWare data collection were not implemented for the remainder of the study. Owing to this, the second baseline rest period was never reintroduced, either. The research staff reviewed a COVID-19 information sheet and symptom screening before arriving at the study visit. Participants were also screened for symptoms upon arrival. Research staff and participants increased safety protocols, including required masking for all, limiting contact by leaving the chamber when possible, keeping the door open for increased air circulation, and remaining a minimum of 6 feet away as much as possible. These protocols will be implemented for the remainder of the study.

Measures

Overview

MMC study measures are presented in the following sequence. First, measures pertinent to the RCT examining oxytocin and HPA axis functioning are presented. Next, measures pertinent to testing the hypotheses in aims 1, 2, and 3 are presented in order of appearance in the passive longitudinal design (Figure 1). This begins with maternal oxytocin functioning and oxytocin genetics as primary predictors (maternal oxytocin psychobiology and oxytocin genetics) followed by maternal biopsychosocial outcomes (PDAS and maternal parenting behaviors) and then child biopsychosocial outcomes (child oxytocin epigenetics, stress reactivity, and cognitive and socioemotional outcomes). Summaries of potential moderators and control variables are also provided.

Figure 1. Conceptual model for the Mood, Mother and Child Study. HPA: hypothalamic-pituitary-adrenal; PDAS: postpartum depression and anxiety symptoms.

RCT Measures

Independent Variable: Intranasal Oxytocin Administration

Mothers in the experimental condition are administered 24 international units of nasal oxytocin, and mothers in the placebo condition are administered an equivalent volume of an inert nasal spray. After a rest period, mothers are trained and observed to self-administer 6 separate nasal spray inhalations at approximately 30- to 60-second intervals, alternating between the right and left nostril.

Dependent Variable: HPA Axis Functioning

Maternal blood samples from the first laboratory visit (including baseline; during the TSST speech and math tasks; and at 10, 20, and 30 min of the recovery period following the TSST) will be assayed for adrenocorticotropic hormone in ethylenediaminetetraacetic acid–treated plasma and serum cortisol using commercially available radioimmunoassay reagents from MP Biomedicals.

Primary Predictors: Maternal Oxytocin Functioning

Maternal Oxytocin Secretion

Oxytocin in ethylenediaminetetraacetic acid–treated plasma, with aprotinin added to prevent peptide degradation, will be determined through enzyme immunoassay with extraction (Enzo Life Sciences), as previously described [64]. Interpretation of the oxytocin literature is complicated by controversies in the assay technique [65] as many studies report results for unextracted samples. These results are difficult to interpret given that Szeto et al [66] found no correlation between the extracted and unextracted oxytocin values. A key strength of our study is that we will use the extracted oxytocin for all measures.

Maternal Oxytocin Genetics

DNA extracted from maternal blood collected during the MMI study will be used for genotyping. Genome-wide single nucleotide polymorphism (SNP) arrays will be used to identify genetic variations in individual genes (in addition to clusters of genes) whose products interact in pathways that have been implicated in maternal depression, stress reactivity, and parenting behaviors (such as oxytocin). To estimate genetic ancestry in our diverse population, we will apply both structure and Eigensoft SmartPCA to linkage equilibrium-pruned array data.

Maternal Biopsychosocial Outcomes

Maternal Depression and Anxiety

Depression and anxiety symptoms are measured at multiple times (Table 2), including the SCID-NP [53] in the third trimester of pregnancy (for the MMI study) and again at the first data collection visit at 5 years of child age in the MMC study. The Structured Clinical Interview for the DSM-IV is a semistructured interview for assessment of major DSM-IV axis-I diagnoses and is considered the gold standard instrument for rigorous assessment of lifetime and current psychiatric illness (the nonpatient version was specifically developed for use in research studies). In addition, monthly assessments were conducted during the first year of life using the Edinburgh Postnatal Depression Scale [67]; assessments at 2, 6, and 12 months were conducted using the Beck Depression Inventory–II [68] and the Spielberger State-Trait Anxiety Inventory [69];

XSL•FO
RenderX

and all 3 measures were collected every 6 months thereafter from the ages of 1 to 4 years and then again at the current MMC study visit.

Table 2. Maternal depression and anxiety measurement over time.

	Prenatal—third trimester	Year 1 (month)												Year 2 (month)		Year 3 (month)		Year 4 (month)		Years 5-7—month 60 onward

SSA[d]	✓		✓				✓						✓	✓	✓	✓	✓	✓	✓	✓

[a]SCID: Structured Clinical Interview for the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition.

[b]EPDS: Edinburgh Postnatal Depression Scale.

[c]BDI: Beck Depression Inventory.

[d]SSA: Spielberg State-Trait Anxiety Inventory.

HRV Measure

Mobile Impedance Cardiographs (MindWare Technologies LTD) are used to measure cardiac rate, interbeat interval, and PEP in mothers and children. MindWare HRV software will be used to derive respiration and calculate high-frequency HRV and respiratory sinus arrhythmia from the interbeat interval series as indexes of parasympathetic activity. Respiratory rate will be used in all HRV analyses. MindWare Impedance Cardiography Analysis software will calculate cardiac time intervals, stroke volume, and cardiac output. PEP will index sympathetic activation.

Chronic HPA Activation

Hair cortisol will be assayed from 20 to 25 strands of hair [70] collected from mothers and children using a commercially available immunoassay with chemiluminescence detection (IBL-Hamburg) that has been validated using liquid chromatography mass spectrometry.

Parenting Behaviors

Video recordings of parent-child interactions collected at visit 2 will be coded by a team of trained and certified researchers led by WRM-K. Ratings of maternal sensitivity, detachment, intrusiveness, positive regard, negative regard, stimulation of cognitive development, and animation will be made using a 5-point Likert scale (ranging from 1 as *not at all characteristic* to 5 as *highly characteristic*). On the basis of previous empirical findings and theoretical models of parenting dimensions, we anticipate that these scales will load onto 2 broad dimensions of maternal parenting behavior—*overall sensitivity* (comprising sensitivity, detachment [reversed], stimulation, positive regard, and animation) and *negative-controlling behaviors* (negative regard and intrusiveness). The ultimate creation of parenting dimensions will be guided by factor analyses comparable with those in previous studies by WRM-K [71].

Child Biopsychosocial Outcomes

Child Epigenetics

DNA extracted from child cheek swabs at the ages of 2 months and 5 years will be used to assess genome-wide DNA methylation using the Illumina MethylationEPIC BeadChip. This platform interrogates 850,000 methylation sites across the genome at single-base resolution; target gene regulatory regions include enhancers, CpG islands, promoters, and open chromatin sites. Methylation probes are dropped from the analysis for bad genome mapping, missingness (>0.01), and low detection (<0.05). Raw microarray signal intensity (SI) data are first corrected using the Illumina probe type, followed by individual methyl and nonmethyl channel quantile normalization using the *limma* package in Bioconductor. The methylation status of each CpG site is then calculated as the β value based on the following definition: β value = (SI of the methylation detection probe) / (SI of methylation detection probe + SI of non–methylation detection probe + 100). Cell type composition will be estimated as a covariate for association analyses using the *minfi* package in Bioconductor. Interindividual DNA methylation trajectories will be identified from the age of 2 months to 5 years. Although all relevant methylation sites will be examined, particular emphasis will be placed on oxytocin pathways and their effects.

Child EF

Children's EF is assessed at visit 2 via performance on the EF Touch instrument, which is a computerized battery of EF tasks using a capacitive touch screen monitor to record child responses [72]. Working memory is assessed using the Working Memory Span Task [73] and the Pick the Picture Game [74,75]; inhibitory control is assessed using the Silly Sounds Stroop [76], Spatial Conflict Task [77], and animal Go or No-Go Task [78]; and attention shifting is assessed using the Something's the Same Game [79]. Each of these 5 tasks takes 3 to 7 minutes to complete. For complete descriptions of these tasks and extensive psychometric and reliability information, see the study by Willoughby et al [80].

XSL•FO
RenderX

Child IQ

Child IQ was assessed at visit 2 using 6 subscales of the Wechsler Preschool and Primary Scale of Intelligence that comprise the FSIQ composite. These include the Block Design (assessing spatial reasoning), Information (assessing cultural knowledge), Matrix Reasoning (assessing visual processing), Bug Search (assessing speed of processing), Picture Memory (assessing working memory), and Similarities (assessing logical thinking) subscales. The FSIQ composite is considered the most reliable and representative measure of broad cognitive functioning in middle childhood [81].

Child Maladaptive Behaviors

Mothers completed the CBCL for school-age children [82]. The CBCL is a highly used instrument that assesses emotional and behavioral problems in children and produces broad-band (internalizing problems, externalizing problems, and total problems) and narrow-band (eg, attention problems, sleep problems, anxiety or depression, and aggressive behavior) scales with standardized T scores.

Potential Moderating Variables

Child Sex

Maternal report of child sex at birth will be used as a moderating variable in hypotheses 2c, 3c, and 3e.

Child Oxytocin Genetics

DNA extracted from child cheek swabs will be used for genome-wide SNP arrays to identify (1) aggregate genetic risk (eg, genetic risk scores for psychiatric outcomes) and (2) genetic variation of individual genes (in addition to clusters of genes) associated with oxytocin functioning; these data will be used as moderating variables in hypotheses 3a and 3b.

Potential Control Variables

In addition to demographic controls (eg, maternal or child race and ethnicity and maternal education, age, and family income), additional control variables will be collected and used as appropriate for specific hypothesis testing. For example, analyses of child EF and IQ outcomes will include control variables for maternal EF [55]. Child temperament (assessed using the Children's Behavior Questionnaire [83]) will be used to control for genetic confounds between mothers and children as well as passive gene-environment correlations within the family system. Current psychiatric treatment for maternal depression and anxiety (both pharmacological and nonpharmacological) will be included as appropriate.

Data Analysis Plan

Characterizing PDAS

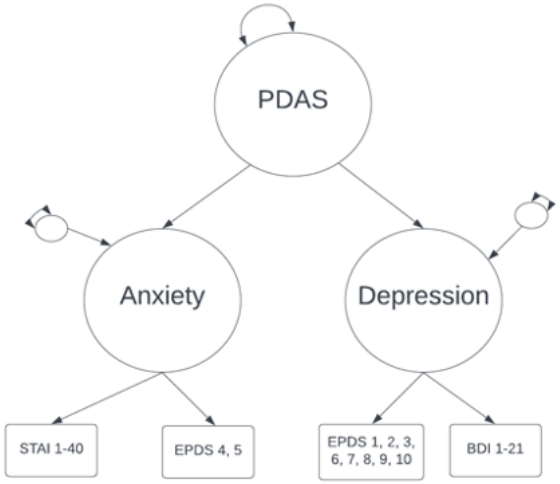
We plan to integrate PDAS measures obtained from repeated assessments of the Edinburgh Postnatal Depression Scale, Beck Depression Inventory–II, and State-Trait Anxiety Inventory by constructing a hierarchical confirmatory factor analysis (HCFA) model with a general PDAS factor giving rise to anxiety and depression subdomains (Figure 2). We will incorporate orthogonal method factors (not shown in the figure) to account for the scale of origin. The HCFA model will be estimated using 1 randomly drawn observation from each mother's first year of postpartum data. Once we have obtained a good-fitting HCFA model, we will use the parameter estimates from the calibration model to generate time-varying maternal PDAS factor score estimates—1 per month during the first year post partum [84].

Once time-varying PDAS scores have been obtained, we will determine the optimal method for characterizing maternal PDAS. We will consider three approaches: (1) latent mean, (2) growth parameters, and (3) growth mixture classes. We describe each of these approaches in the following paragraphs.

First, we will generate spaghetti plots to examine the shape and heterogeneity of PDAS scores over time. We will use linear mixed models to construct univariate growth models for PDAS to determine empirically whether scores follow a linear, quadratic, or cubic average trajectory and whether there is significant individual heterogeneity in change over time. The following set of equations presents an example of a quadratic growth trajectory for PDAS, where i=1...N indexes individuals and t=0...12 indexes time in months, starting immediately post partum. Time is centered at 6 months post partum in the equation. The b parameters are the fixed effects that characterize the PDAS trajectory for the average participant. The u parameters are individually varying random effects that define each participant's unique PDAS trajectory. We assume that the u terms follow a multivariate normal distribution centered at 0 and that the residual error is normally distributed at each time point. The residual error is assumed to be uncorrelated with the random effects.

$$PDAS_{ti} = b_0 + b_1 \times (t - 6) + b_2 \times (t - 6)^2 + u_{0i} + u_{1i} \times (t - 6) + u_{2i} \times (t - 6)^2 + r_{ti} \quad (1)$$

If we do not find a significant fixed effect of time (ie, if b_1 and b_2 are not significantly different from 0), we will output empirical Bayes estimates of the random intercept and use these scores to represent each participant's average PDAS score . We refer to this first approach as the latent mean approach.



If individual trajectories follow the same general form (eg, all linear but with continuously varying slope values), we will output empirical Bayes estimates of mother-specific intercepts ($int_i = b_0 + u_{0i}$, representing the average PDAS at 6 mo post partum) *and* slopes ($slope_i = b_1 + u_{1i}$, representing the direction and rate of change over time). In this "growth parameter" approach, we will represent PDAS trajectories using a combination of 2 or more growth parameters.

Finally, if we find visual and empirical evidence of substantial heterogeneity in the *shape* of PDAS change over time, we will use growth mixture models to estimate a small number of prototypical PDAS trajectory shapes and then use posterior probability scores to assign participants probabilistically to a trajectory class. This third approach will allow for a small number of different trajectories (eg, 1 stable trajectory, 1 increasing linearly, and 1 decreasing to a plateau). Each participant will receive a posterior probability of membership

XSL•FO
RenderX

to each trajectory class. Once PDAS trajectories have been operationalized as (1) latent means, (2) growth parameters, or (3) growth mixture classes, we will use the resulting measures to address the study hypotheses.

Figure 2. Hierarchical confirmatory factor analysis model of postpartum depression and anxiety symptoms (PDAS) factor. Numbers reflect child age (in months) at time of assessment. BDI: Beck Depression Inventory; EPDS: Edinburgh Postnatal Depression Scale; STAI: Spielberg State-Trait Anxiety Inventory.

Aim 1 Hypothesis Testing

First, we will use a general linear model to test the hypothesis that participants who are randomized to receive nasal oxytocin experience lower HPA reactivity during the TSST to evaluate this proposed causal pathway (hypothesis 1a). Next, we will also evaluate whether observed oxytocin functioning or genetic variation in oxytocin-associated pathways correlates with PDAS and will then use structural equation modeling (SEM) to assess whether mothers' HPA functioning mediates the association between oxytocin variation and PDAS (hypotheses 1a and 1b). The SEM framework will enable us to model uncertainty in the growth parameters or latent class membership while simultaneously estimating the 2 mediation pathways (oxytocin to maternal HPA functioning [*a* path] and maternal HPA functioning to PDAS [*b* path]). We will use bootstrapped SEs to conduct significance tests for the indirect effects.

Finally, multigroup SEM will be used to examine the potential of moderated mediation, with maternal genetic variation in oxytocin-related pathways moderating the associations between maternal oxytocin and HPA functioning and PDAS (hypothesis 1b). We will also test whether maternal genetic variation moderates the associations between PDAS and maternal HPA functioning, oxytocin functioning, and parenting behaviors (hypothesis 1c). Significant moderation effects will be probed following procedures outlined by Preacher et al [85] to obtain estimated effect conditions on genetic variation within the range of our data.

Aim 2 Hypothesis Testing

Our next step of analysis will be to evaluate the extent to which PDAS predicts more adverse child biopsychosocial outcomes during early elementary years (hypothesis 2a), whether high stress reactivity or maladaptive parenting behaviors mediate this association (hypothesis 2b), whether the direct effects of PDAS on child outcomes remain significant after accounting for concurrent maternal depression and anxiety severity (hypothesis 2b), and whether sex moderates the associations between PDAS and child outcomes such that the effects of PDAS on child externalizing are stronger for male individuals and the effects of PDAS on child internalizing are stronger for female individuals. We will continue within an SEM framework for aim 2 analyses as this approach allows for the simultaneous modeling of mediation, moderation, and a variety of response distributions.

In addition to demographic control variables, we will include child temperament (assessed in infancy and concurrently at the age of 5 y) to control for genetic confounds between mothers and children as well as passive gene-environment correlations within the family system.

Aim 3 Hypothesis Testing

For aim 3, we will conduct SEM analyses in two ways: (1) including estimated risk scores and (2) stratified by child OXT and OXTR genotypes to determine if child genotype moderates the associations between PDAS and developmental outcomes (hypothesis 3a) and between maternal sensitivity and developmental outcomes (hypothesis 3b). Next, we will test whether the pathways tested in aims 1 and 2 vary by child sex by introducing 2-way interactions between PDAS and child sex and parental sensitivity and child sex and probing significant effects. We will test whether the methylation status of oxytocin-related genetic regions mediates associations among PDAS exposure, sensitivity, attachment quality, and developmental outcomes (hypothesis 3d). Finally, we will conduct exploratory analyses using multigroup models to examine whether the effects of PDAS and maternal sensitivity on epigenetic changes in child oxytocin functioning are stronger for girls than for boys (hypothesis 3e). We will use bootstrapped SEs to conduct significance tests for the indirect effects. Moderation effects will be probed following the procedures outlined by Preacher et al [85].

Missing Data

The proposed study design incorporates extensive repeated assessments. Growth models and SEMs are estimated using full

XSL•FO
RenderX

information maximum likelihood, which permits the assumption that missing data are missing at random conditional on observed measures. We will rely on this assumption when data are missing exclusively on endogenous variables. We will use multiple imputation for all analyses involving missing covariates to avoid listwise deletion of cases with missing exogenous variables.

Power Analysis

As described previously, attrition and suspension of data collection because of COVID-19 resulted in a lower enrollment in the MMC study than we had hoped; however, we anticipate enrolling 110 dyads from the original sample. With this sample size and a type-I error rate of Cronbach α=.05, we will have 80% power to detect a correlation of $r \geq 0.26$, a mean difference of Cohen $d \geq 0.5$, and an odds ratio of ≥2.02. Thus, broadly, we expect to have the power to detect moderate, clinically meaningful effects; however, we will have limited power to detect smaller effect sizes that tend to occur in mediation and moderation analyses.

Ethics Approval

This project received ethics approval from the University of North Carolina at Chapel Hill institutional review board (21-0421).

Results

The trial was registered with ClinicalTrials.gov on July 20, 2018 (NCT03593473). The study began in September 2018 and continues through August 2024. Recruitment and data collection have commenced; as of June 1, 2023, a total of 102 participants have been enrolled. Study results should be available in 2024.

Discussion

Previous research has documented associations between PND and offspring developmental outcomes in middle childhood [30,86] and evidenced the role of oxytocin in PND [87]. However, no study has evaluated the role of oxytocin using multiple methodologies (eg, circulating oxytocin, exogenous oxytocin administration, SNP, and epigenetic analyses) in mothers and children using a longitudinal design spanning infancy to middle childhood. Our unique combination of methodologies will allow for potential attributions of causality with respect to oxytocin administration while allowing us to unpack the psychobiological processes underlying these effects with the ongoing longitudinal design. These results will provide unique insights into the psychobiological effects of oxytocin in women and may inform future clinical trials to treat perinatal mood disorders [88]. Furthermore, we will be the first to report on interindividual measures of oxytocin-related DNA methylation in children as a function of maternal depression and parenting experiences [89]. Previous studies have approached these topics in a piecemeal fashion within time and across single levels of analysis, whereas our integrated, multilevel, multi-method longitudinal approach will elucidate the role of oxytocin in dyadic development and identify psychosocial, genetic, and epigenetic markers that can be leveraged to cultivate resilience across 2 generations.

Acknowledgments

The Mood, Mother and Infant and Mood, Mother and Child studies are funded by the National Institute of Child Health and Human Development (R01HD073220 and R01HD093901). They have institutional review board approval from the University of North Carolina at Chapel Hill (institutional review board study 12-2061) and are registered with ClinicalTrials.gov (NCT03593473). The authors are grateful especially to the participants and their families for their time and effort in being part of this study.

Data Availability

The data sets generated from this study are not publicly available because of ongoing data collection protocols but will be available at the conclusion of this study from the corresponding author upon reasonable request following guidelines stipulated by the National Institutes of Health.

Authors' Contributions

AMS (principal investigator), WRM-K (principal investigator), KG, NGO, SEM-B, and JDG are investigators on the Mood, Mother and Child study; each made significant contributions to the grant proposal funded by the National Institute of Child Health and Human Development to support this study. BP and CGS are key research associates; each made significant contributions to the final design and execution of this study. WRM-K wrote the first draft of the paper with significant assistance from each coauthor. All the authors approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: American Indian and Alaska Native peoples experience poor end-of-life care, including more hospitalizations and lower use of hospice and do-not-resuscitate orders. Although advance care planning (ACP) can improve end-of-life care, ACP rates are disproportionately low in American Indians and Alaska Natives.

Objective: We culturally tailored and delivered an existing evidence-based ACP program for an American Indian tribal community. Here, we present the protocol for assessing the intervention's feasibility and efficacy.

Methods: We measured feasibility via participant recruitment, participants' evaluation (acceptability, appropriateness, comprehension, and satisfaction), and intervention fidelity. Recruitment was measured with participant screening, eligibility, enrollment, and retention. Participant's evaluation of the intervention was measured with surveys. Fidelity was measured with direct observation and the Make Your Wishes About You (MY WAY) Fidelity Checklist Tool. To assess the intervention's efficacy, we used a quasi-experimental waitlist control design with 2 cohorts who were surveyed each on three separate occasions. The intervention's efficacy was assessed by the following: ACP barriers and facilitators as well as ACP self-efficacy, readiness, and completion.

Results: A total of 166 participants were screened for eligibility; 11 were deemed ineligible, and 155 participants were enrolled in the study. Of those enrolled, 113 completed the intervention and will be included in subsequent analyses. We finalized data collection in January 2023, and analyses are underway. Study enrollment was successful, and we expect that participants will report high levels of acceptability, appropriateness, comprehension, and satisfaction with the intervention. We expect that the intervention was implemented with fidelity and will demonstrate decreases in ACP barriers and increases in ACP facilitators, self-efficacy, readiness, and completion.

Conclusions: Enrolling over twice as many participants as we had hoped suggests that members of this tribal community are willing to engage in end-of-life ACP. We were able to implement a waitlist study design to show that a culturally tailored ACP program for a tribal community is feasible.

KEYWORDS

American Indian or Alaskan Native; advance care planning; end-of-life care

Introduction

Background

American Indian and Alaska Native peoples experience poor end-of-life care, including a higher likelihood of being hospitalized at the end of life; receiving futile treatment at the end of life; and lower rates of hospice [1], palliative care, do-not-resuscitate orders [2-4], and advance care plans [3,5]. Advance care planning (ACP) is a process that allows people to make health care decisions if they are unable to speak for themselves because of serious or terminal illness. ACP is associated with goal-concordant care, decreased anxiety about end-of-life decision-making, and reduced stress among primary caregivers [6].

ACP rates are disproportionately low among American Indians and Alaska Natives. Research with 270 American Indian and Alaska Natives in the Northwest Plains found that none had heard of palliative care and 93% had never heard of a living will [4]. When compared to non-Hispanic White people, American Indians and Alaska Natives were half as likely to have a living will or a health care power of attorney [3]. A medical chart review of a New Mexico Indian Health Service facility found that information about advance directives, as required by the Patient Self-Determination Act, was in only 20% of charts [7]. Despite being twice as likely to die from type 2 diabetes and 4 times as likely to die from chronic liver disease than non-Hispanic White people [8], little work has been done to increase opportunities for American Indians and Alaska Natives to express their end-of-life care wishes. To date, there are no randomized controlled trials (RCTs) that have demonstrated the efficacy of ACP for American Indians and Alaska Natives [5], and there are limited other ACP research studies with American Indians and Alaska Natives [2,3,9-11].

The lack of ACP among American Indians and Alaska Natives is not a reflection of unwillingness to engage in conversations about death [4,9,12]. Rather, American Indians and Alaska Natives are presented with formidable barriers to ACP including lack of access to such opportunities and experiences of health care professionals' stereotypes that American Indians and Alaska Natives do not want to engage in end-of-life conversations [13]. Further, typical ACP models may be unsuitable for many American Indians and Alaska Natives because they are conventionally delivered by health care professionals in clinical settings that American Indians and Alaska Natives have historically valid reasons for not trusting [11,13-16]. ACP approaches for American Indians and Alaska Natives should be developed with guidance and input from the intended community [11,17] and incorporate culturally relevant values [18] as well as beliefs and practices concerning the end of life and death, which vary within and across Indigenous populations [19].

A previous RCT study demonstrated that the program, Make Your Wishes About You (MY WAY), increases ACP self-efficacy, readiness, and completion rates for patients with chronic kidney disease [20,21]. However, as the Consolidated Framework for Implementation Research asserts, interventions that are not tailored to a population of interest are usually a poor fit [22]. To deliver interventions that are sensitive to a group's worldview, language, cultural meanings, and values, a systematic approach to tailoring is suggested [23,24]. Tailoring includes modifying the intervention delivery, that is, the delivery person, channel, or location, and modifying content, such as certain information in the intervention materials [25].

Objectives

The objective of our study was to use a community-based participatory research (CBPR) approach to culturally tailor the existing MY WAY [21] for a tribal community. Specifically, our study had three aims: (1) culturally tailor MY WAY for a specific tribe, (2) assess the feasibility of the culturally tailored MY WAY, and (3) examine the efficacy of the culturally tailored MY WAY. At the successful completion of this project, we expect to develop a feasible, culturally tailored MY WAY that, through a quasi-experimental waitlist control design, shows promise as an efficacious program. Here, we describe the protocol for assessing the feasibility and efficacy of the culturally tailored MY WAY.

Methods

Ethical Considerations

The project received approval from our institutional review board (blinded to protect confidentiality; #2022-01-24-01-02), a tribal institutional review board, and a tribal council (resolution #412-2021).

Conceptual Framework

Our approach relied on the Consolidated Framework for Implementation Research, which provides a practical structure for complex, interacting, multilevel, and momentary constructs by consolidating key elements from implementation theories [22]. The framework's main premise is that for implementation to be effective, the following domains must be considered: intervention characteristics, setting, individuals involved, and implementation process. Methodologically, our approach also adhered to the CBPR principles, including recognizing the community as a unit, building on strengths and resources within the community, facilitating collaborative partnerships in all phases of the research, integrating knowledge and action for the mutual benefit of all partners, promoting a co-learning and empowering process that attends to social inequalities, involving a cyclical and iterative process, and disseminating knowledge gained to all parties [2,26].

Setting

Our study was conducted with a federally recognized tribe whose lands span five rural counties with approximately 16,000 enrolled members (personal communication with the personnel at the tribal enrollment office, May 23, 2023; the name of person and tribe deidentified for confidentiality).

Intervention Characteristics

Overview

The original MY WAY project developed and used *Planning Today for Tomorrow's Healthcare*, an ACP patient guide, and *A Curriculum Guide for ACP* to assist health care providers in having ACP discussions with patients in a nephrology clinic. Both guides are grounded in the stages of change theory and use motivational interviewing techniques [21]. The previous RCT demonstrated that the MY WAY curriculum was effective in increasing self-efficacy, readiness, and completion of ACPs when used with a trained coach, especially in ACP "conversation ready" health care settings [27]. For the cultural tailoring effort, we were guided by the Consolidated Framework for Implementation Research and were informed by community engagement. Our approach included a cyclical process of listening, learning, and analyzing at each phase. The framework is shown in Figure 1 and described below.

Figure 1. Cultural tailoring framework.

In phase 1 of the cultural tailoring process, we identified community needs and receptivity through collaboration with local leaders and health care providers, and by holding two listening sessions. This phase also included tailoring the delivery of the program to create a 2-step intervention: (1) community information sessions and (2) one-on-one sharing sessions with project staff (support stars) who were trained to deliver the intervention. At the end of this phase, we applied for and received National Institutes of Health funding in response to PAR 19-0587 entitled "Strategies to Provide Culturally Tailored Palliative and End-of-Life Care for Seriously Ill American Indian and Alaska Native Individuals."

Phase 2 included the greatest number of activities. First, we created a community advisory board (CAB) and a professional advisory board (PAB). In CAB and PAB meetings, we shared data from the listening sessions and discussed ways to incorporate the feedback. We also hosted four additional listening sessions to obtain feedback on the original MY WAY materials. We used a grounded theory approach to analyze the listening session data to guide subsequent tailoring. We held an additional meeting with the CAB and PAB to share findings and elicit feedback that was used to further tailor MY WAY.

After the first revisions of MY WAY materials, we met individually with 7 of the listening session participants to solicit their reactions to the materials' usability and acceptability. We then met the CAB and PAB for a third time to share the interview findings and incorporate additional revisions to further tailor MY WAY. In phase 2, we also used the process, as described by Lynn [28], to quantitatively evaluate the content validity of the culturally tailored materials. A self-administered web-based survey was sent to all CAB and PAB members that included items about the personal and curriculum guides concerning the appropriateness of the images and language, and if the content was culturally relevant, culturally sensitive, respectful, and clear. If a respondent indicated an issue, they were then prompted for suggestions as to how to address it.

Phase 3 included implementing, delivering, and testing the culturally tailored MY WAY. First, participants attended a community information session on ACP, which was held at a venue within the tribal community. After attending a community information session, participants scheduled a one-on-one meeting or a sharing session. Topics covered in the community information session and sharing session included an overview of the project, health care agents, future health care wishes, writing an ACP, sharing the ACP, and Physician Orders for Life Sustaining Treatment (POLST) forms. The sharing sessions allowed participants to ask personal and private questions of the support star. These sessions were held in a location of the participant's choice (eg, their home or community club), and they were encouraged to bring family members. The support star also notarized ACPs, if desired, at any point in the process. The implementation phase lasted approximately 10 months. Finally, in phase 4, the investigators met again to conduct a final tailoring of the materials based on impromptu feedback that was received during implementation (phase 3). This included eliminating the term "healthcare agent" and adding information on how participants can share their notarized ACP with their health care provider. More information on the cultural tailoring can be found elsewhere (Goins, Haozous, Anderson, and Winchester, unpublished data, under review).

Research Design

Feasibility

Assessing feasibility was a primary objective for this study as there are no clinical trials on ACP interventions for American Indians and Alaska Natives and limited other work for ACP with this population. Although American Indians and Alaska Natives are willing to talk about and plan for end-of-life events, it was still necessary to assess whether there were other reasons

XSL•FO
RenderX

that American Indians and Alaska Natives have lower than usual ACP rates. Conceptually, feasibility was measured with participant recruitment, participant evaluation (acceptability, appropriateness, comprehension, and satisfaction), and the fidelity of the intervention.

Efficacy

In addition to determining feasibility, we also sought to measure the efficacy of the culturally tailored intervention to address the disproportionate rates of ACP for this population. We used a quasi-experimental waitlist control study design to test the hypothesis that the intervention participants would experience decreased ACP barriers and increased ACP facilitators, self-efficacy, readiness, and completion rates. Rather than deny a portion of our sample the intervention, as in a traditional RCT, we planned to implement both steps of the intervention twice such that our intervention group, cohort 1, would comprise those who participated in the first round of both the community information sessions and sharing sessions. Our comparison group, cohort 2, would comprise those who participated in the second round of both the community information sessions and sharing sessions. To test the efficacy, we used the combined 2-cohort sample of those who participated in both steps of the intervention and compared intervention baseline measures to those measured post program.

Study Population and Sample Size

Eligibility criteria for the study population included tribal members, spouses of tribal members, tribal first descendants, and other American Indians and Alaska Natives residing in the tribal community, aged ≥18 years, and residing within the tribe's service area. Participants with cognitive impairments were excluded. Participants were recruited via purposive sampling. Existing collaborative relationships established in the tailoring phase helped the recruitment process. Recruitment efforts included numerous in-person announcements at tribal venues at events, a video on the local television station, social media postings, and several billboards.

Based on the risk ratio of completing an ACP indicated in the previously implemented MY WAY intervention (1.79, 95% CI 1.18-2.72) and using 90% power as a threshold, we used G*Power (Axel Buchner) with 3 predictors and the primary outcome of ACP completion to estimate that we would need at least 60 participants to find effects. As effect sizes for ACP self-efficacy and readiness were smaller in the original intervention, our goal was to enroll a total of 70 participants with 35 in each cohort.

Procedure

Overview

Feasibility

Recruitment was measured by documenting the number of potential participants in attendance and completing each intervention event or measure. Participant's evaluation of the intervention was measured twice: once at the end of the community information session with a self-administered survey and once 1 week after the sharing session with a telephone interviewer-administered survey. We conducted fidelity checks on 40% of the community information sessions and 18% of the sharing sessions.

Efficacy

Procedures varied across cohorts. Cohort 1 completed intervention baseline surveys immediately before the intervention and completed postprogram surveys about 9 weeks after the intervention. Cohort 1 also completed follow-up surveys approximately 6 months after their intervention baseline surveys. Cohort 2 completed a control baseline survey approximately 4 months before the intervention, and a second intervention baseline survey right before the second set of community information sessions. Cohort 2 then completed a postprogram survey approximately 3 months later. Table 1 describes the data collection schedule by cohort.

A timeline describing the steps of the intervention and data collection is shown in Figure 2.

Figure 2. Cohorts' timeline.

Measurement

Feasibility Measurements

Recruitment

Recruitment was captured by documenting the number of potential participants who were screened, deemed eligible, enrolled, and engaged in the full intervention, and the retention rates (number who completed the entire intervention, number who completed postprogram surveys from both cohorts, number in cohort 1 who completed the follow-up survey, and the number who dropped out from the control baseline to the intervention baseline in cohort 2).

Participant Evaluation

Acceptability, appropriateness, comprehension, and satisfaction of the intervention experience were assessed with a self-administered survey immediately following the community

XSL•FO
RenderX

information sessions. Sharing session evaluations measuring the same concepts were administered by interviewers via telephone. Acceptability and appropriateness of the community information sessions and the sharing sessions were captured with the Acceptability of Intervention Measure and the Intervention Appropriateness Measure [29]. Comprehension and satisfaction were assessed with eight items, with response options ranging from strongly agree to strongly disagree, and a single item about how they rated the session, with response options ranging from excellent to poor.

Implementation Fidelity

Implementation fidelity was measured with the MY WAY Fidelity Checklist, which was developed and used in the MY WAY RCT. This checklist tool was a modified version of the Treatment Adherence Fidelity Tool [30], which allowed us to assess the adherence to the intervention delivery and content, intervention pacing, participant responsiveness, intervention delivery quality index, and support stars' competence level in judgment and delivery.

Efficacy Measurements

Barriers and Facilitators

We also used the ACP Facilitators and Barriers survey instrument [31] used in the original MY WAY RCT [27]. Barriers and facilitators were created based on findings from a former study [31] that found barriers to be related to perceptions of relevancy, personal barriers, relationship concerns, information needs, time constraints, and problems with the advance directives.

Self-Efficacy and Readiness

We used the 9-item ACP engagement survey instrument, including measures of self-efficacy and readiness as identified in behavior change theory [32,33]. Self-efficacy and readiness items have Likert responses of "not at all, a little, somewhat, fairly, extremely" and have good reliability and discriminant validity [32,33].

ACP Completion

ACP completion at baseline was operationalized with the number of participants who answered yes to the following question on the baseline survey (intervention and control): "Do you have an advance care plan?" The project coordinator confirmed a survey self-report of ACP completion by reviewing documentation as to whether the support star had notarized the advance care plan, which was confirmed with the official notary records.

Analyses

At the time of this publication, analyses for this study were not complete. Below, we report on our planned analysis.

Feasibility

Recruitment will be reported in raw counts. Participant evaluation and fidelity will be analyzed using descriptive statistics (mean, SD, and frequency scores for each).

Efficacy

Participant demographic characteristics will be examined using descriptive statistics and stratified analyses (eg, by demographics, attendance, and ACP completion) to examine the association between demographics and intervention outcomes. Since there may likely be significant attrition from community information sessions to sharing sessions, we will also run Heckman selectivity analyses to determine if there were differences between those who completed both intervention steps and those who completed only baseline measures for community information sessions. If there are differences in attrition, we plan to include the inverse Mills ratio. The comparison of measures between each cohort's intervention baseline scores will ensure that there are no significant differences between the cohorts that would keep them from being combined. ACP barriers, facilitators, self-efficacy, readiness, and ACP completion will then be compared between those who do and do not engage in both intervention steps and between cohorts 1 and 2. The comparison analysis will consist of Student *t* tests or a similar nonparametric test for differences in means if necessary.

After these preliminary analyses, the cohorts will be combined to examine changes in ACP outcomes (barriers, facilitators, self-efficacy, readiness, and completion) from the intervention baseline to the postprogram survey results. In the full sample of participants who experienced both steps of the intervention, the intervention baseline results for cohort 1 will be combined with the intervention baseline results for cohort 2 (as both occurred immediately before the intervention began) and compared to the combined sample of the postprogram surveys. Repeated measures of ANOVA will be used to compare these outcomes before and after the intervention. We will also assess changes in cohort 1's ACP outcomes from the intervention baseline to the postprogram survey and compare them to changes in cohort 2's ACP outcomes from the control baseline to the intervention baseline. Cohort 2 received no intervention between the control baseline and the intervention baseline, making this comparison analysis a control for natural variations over time. To ensure that changes can be attributed to the intervention and not the result of the passage of time or contamination from participants hearing about ACP in the community, we will measure two changes: (1) the change in cohort 1's intervention baseline to postprogram scores and (2) cohort 2's change from the control baseline to the intervention baseline.

Results

This project was funded in March 2021 and the cultural tailoring process began immediately. The cultural tailoring of the delivery and content of MY WAY has been completed and the intervention has been delivered to both cohorts. Data collection for the intervention began in February 2022 and ended in January 2023. A total of 166 participants were screened for eligibility, and we enrolled 155 participants in the study, including 114 participants in cohort 1 and 41 in cohort 2. A total of 113 participants (cohort 1: n=81; cohort 2: n=32) completed both steps of the intervention and data collection. Data analyses of the intervention's feasibility and efficacy have

XSL•FO
RenderX

begun and are expected to be completed in the fall of 2023. During the project, we have kept our study participants informed through a periodic project newsletter. The culturally tailored MY WAY curriculum and personal guides are available for free on the project website.

Discussion

Principal Findings

There is a dearth of research on ACP interventions with American Indians and Alaska Natives and no culturally tailored ACP interventions for American Indians and Alaska Natives, despite having a high occurrence of chronic diseases such as diabetes [8], high rates of preventable hospitalizations [34], high premature mortality rates [35], and low hospice use rates compared to White people [2,36]. This study culturally tailored an existing evidence-based ACP program for an American Indian tribe. Though our data analyses have not been finalized, we were able to enroll over twice the number of participants (n=155) as hypothesized (n=70). Further, we successfully implemented a waitlist control design with this population.

Interpretations, Implications, and Comparisons

Our study's success at enrolling 155 participants and completing the waitlist design suggests that members of this tribal community were willing to engage in end-of-life discussions and ACP. Prior studies have indicated that providers often believe American Indians and Alaska Natives are reluctant to engage in end-of-life care or that discussions about the end of life are taboo [11-14]. We hypothesize that this study will show that tailored ACP interventions can increase facilitators; decrease barriers; and demonstrate increases in self-efficacy, readiness, and completion rates [4,12]. Tailoring interventions is believed to generate greater buy-in, acceptance, and ultimately the intended outcomes, and is considered preferable when working with populations in which the evidence-based program was not originally tested.

Limitations

This study has several limitations, most specifically in that it only represents 1 of 574 federally recognized tribes [37], each with its own set of values and preferences concerning the end of life. However, the process of culturally tailoring and engaging the community can be replicated so that other tribal nations and their members can benefit from ACP. Like other CBPR studies, our approach required flexibility with the community's needs, which created challenges in adhering to the strict timeline for the RCT. Instead, we adopted the waitlist approach. Additional cultural tailoring and testing of the MY WAY ACP intervention will be needed to test its effectiveness with other American Indian and Alaska Native tribes. However, this study will be the first to report on the effectiveness of a culturally tailored ACP intervention with an American Indian tribe. Our study results will provide valuable information for the health care community about American Indian readiness and confidence to engage in culturally tailored ACP. If more American Indians and Alaska Natives can express their health care wishes related to the end of life, it could lead to decreased suffering and hospitalization, increased hospice use, goal-concordant care, and increased patient and family satisfaction [6].

Potential Problem and Alternate Plans

Recruitment for cohort 2 proved challenging. Many participants were unwilling to wait approximately 6 months to receive the intervention. This challenge led to a large difference in the number of participants enrolled in cohort 1 compared to cohort 2. Our planned analyses should determine if there are any differences between the cohorts, however, which will account for this discrepancy.

Acknowledgments

This project was funded through the National Institutes of Health (1R21NR019910). We would like to express deep gratitude to Roseanna Belt, Thomas Belt, Onita Bush, and Carol Long for serving on the project's community advisory board and Bonnie Claxton, Lisa Lefler, Dale Lupu, Nicole Wikjord, and Blythe Winchester for serving on the project's professional advisory board.

Data Availability

The data sets generated or analyzed during this study are not publicly available due to tribal institutional review board restrictions. Readers interested in accessing the data can contact the corresponding author on how to initiate tribal institutional review board permission.

Conflicts of Interest

None declared.

Abstract

Background: Familial hypercholesterolemia (FH) is predominantly caused by mutations in the 4 FH candidate genes (FHCGs), namely, *low-density lipoprotein receptor (LDLR)*, *apolipoprotein B-100 (APOB-100)*, *proprotein convertase subtilisin/kexin type 9 (PCSK9)*, and the *LDL receptor adaptor protein 1 (LDLRAP1)*. It is characterized by elevated low-density lipoprotein cholesterol (LDL-c) levels leading to premature coronary artery disease. FH can be clinically diagnosed using established clinical criteria, namely, Simon Broome (SB) and Dutch Lipid Clinic Criteria (DLCC), and can be identified using the Familial Hypercholesterolemia Case Ascertainment Tool (FAMCAT), a primary care screening tool.

Objective: This study aims to (1) compare the detection rate of genetically confirmed FH and diagnostic accuracy between the FAMCAT, SB, and DLCC in the Malaysian primary care setting; (2) identify the genetic mutation profiles, including novel variants, in individuals with suspected FH in primary care; (3) explore the experience, concern, and expectation of individuals with suspected FH who have undergone genetic testing in primary care; and (4) evaluate the clinical utility of a web-based FH Identification Tool that includes the FAMCAT, SB, and DLCC in the Malaysian primary care setting.

XSL•FO
RenderX

Methods: This is a mixed methods evaluation study conducted in 11 Ministry of Health primary care clinics located at the central administrative region of Malaysia. In Work stream 1, the diagnostic accuracy study design is used to compare the detection rate and diagnostic accuracy of the FAMCAT, SB, and DLCC against molecular diagnosis as the gold standard. In Work stream 2, the targeted next-generation sequencing of the 4 FHCGs is used to identify the genetic mutation profiles among individuals with suspected FH. In Work stream 3a, a qualitative semistructured interview methodology is used to explore the experience, concern, and expectation of individuals with suspected FH who have undergone genetic testing. Lastly, in Work stream 3b, a qualitative real-time observation of primary care physicians using the "think-aloud" methodology is applied to evaluate the clinical utility of a web-based FH Identification Tool.

Results: The recruitment for Work stream 1, and blood sampling and genetic analysis for Work stream 2 were completed in February 2023. Data collection for Work stream 3 was completed in March 2023. Data analysis for Work streams 1, 2, 3a, and 3b is projected to be completed by June 2023, with the results of this study anticipated to be published by December 2023.

Conclusions: This study will provide evidence on which clinical diagnostic criterion is the best to detect FH in the Malaysian primary care setting. The full spectrum of genetic mutations in the FHCGs including novel pathogenic variants will be identified. Patients' perspectives while undergoing genetic testing and the primary care physicians experience in utilizing the web-based tool will be established. These findings will have tremendous impact on the management of patients with FH in primary care and subsequently reduce their risk of premature coronary artery disease.

Introduction

Familial hypercholesterolemia (FH) is an autosomal dominant genetic disorder characterized by elevated low-density lipoprotein cholesterol (LDL-c) that leads to premature atherosclerotic cardiovascular disease, particularly coronary artery disease (CAD) [1,2]. Genetic mutations in 3 FH candidate genes, namely, *low-density lipoprotein receptor* (*LDLR*), *apolipoprotein B-100* (*APOB-100*), and *proprotein convertase subtilisin/kexin type 9* (*PCSK9*), are responsible for the autosomal dominant form of FH [2], while other rare mutations in the *LDL receptor adaptor protein 1* (*LDLRAP1*) gene and *apolipoprotein E* (*APOE*) gene have been reported to be responsible for the recessive form of FH [3,4]. Mutations in the *ATP-binding cassette subfamily G members 5* and *8* (*ABCG5 and ABCG8*, respectively) genes have been associated with sitosterolemia, an autosomal recessive disorder characterized by increased plant sterol levels [5].

Phenotypically, FH presents in the form of either heterozygous FH (HeFH) or homozygous FH (HoFH) [1,2]. An estimated 70%-90% of cases are HeFH, while HoFH is less common [6,7]. Individuals with HeFH typically present with LDL-c levels of more than 4.9 mmol/L, whereas those with HoFH present with LDL-c levels of more than 13 mmol/L [6,7]. If left untreated, men with FH have a 50% risk of developing CAD by the age of 50, and women with FH have a 30% risk of developing CAD by the age of 60 [8]; however, most individuals with HoFH experience severe CAD before the age of 20 and generally do not survive beyond 30 years of age [6]. Early detection of FH and treatment with lipid-lowering therapies can effectively prevent premature CAD by extending CAD-free life up to 18 years, compared with untreated individuals [9].

Globally, the prevalence of HeFH ranges from 1 in 200 to 1 in 500 in various populations [10], while the prevalence of HoFH is estimated to range from 1 in 160,000 to 1 in 300,000 [6]. In Malaysia, a recent study [11] has estimated that the prevalence of clinically diagnosed FH was 1 in 100. Based on the current total population of 32 million people, a staggering 320,000 individuals are estimated to have FH [11]. A majority of these cases were previously undiagnosed and lipid-lowering medications were prescribed to 30.5%-54.5% of these individuals, but none of them achieved the therapeutic LDL-c target [11]. The under-detection and under-treatment of FH in the Malaysian population resulted in lost opportunities to prevent premature CAD [11]. This common autosomal dominant condition has undeniably contributed to the high prevalence of premature CAD which accounted for 10%-15% of acute coronary syndrome in Malaysia [12]. According to a national report, 23.8% of patients admitted with acute coronary syndrome were younger than 50 years old [13]. Among patients with confirmed premature CAD, 45.5% had clinically diagnosed FH [14]. Therefore, identifying and treating FH early, and subsequently reducing the incidence of premature CAD is a key national priority in Malaysia [15].

Improving FH identification in primary care has been recognized as a cost-effective strategy to reduce premature CAD [16]. In Malaysia, primary care physicians (PCPs) are ideally positioned at the forefront of primary care service where they manage common atherosclerotic cardiovascular disease risk factors such as hypercholesterolemia, hypertension, obesity, and diabetes [17]. However, substantial gaps in knowledge regarding FH have been identified, including knowledge on prevalence, inheritance, and risk of CAD as well as on awareness of FH clinical guidelines and diagnostic criteria [18]. These gaps in knowledge, awareness, and practice regarding FH among PCP could be a significant contributing factor to the poor detection

XSL•FO
RenderX

of FH in Malaysia [18]. Efforts are currently being undertaken to address these gaps through a partnership with the FH Ten Countries Study to improve awareness of FH among PCP in Malaysia [10,18].

Currently, individuals with FH tend to be discovered incidentally in primary care practice. It has been suggested that primary care should be the key target area to increase identification of new FH index cases and to initiate cascade screening [19-22]. Researchers in the United Kingdom have shown that early identification of FH is achievable in primary care [23-26]. However, the 2 established clinical criteria, namely, Simon Broome (SB) and Dutch Lipid Clinic Criteria (DLCC), are of limited use for case-finding in primary care [24]. These clinical diagnostic criteria were originally developed from secondary care FH registries. Furthermore, these criteria would require a comprehensive physical examination (tendon xanthoma and arcus cornealis), recording of family history, and genetic mutation testing, which are not routinely assessed or inadequately documented in primary care. As a consequence, researchers in the United Kingdom have developed a new tool, the Familial Hypercholesterolemia Case Ascertainment Tool (FAMCAT), based on a risk prediction algorithm developed and validated using primary care databases [26].

The FAMCAT has been shown to perform well as an initial case ascertainment tool to identify FH in the UK primary care setting when it was tested among 3.7 million British patients with cholesterol measurements in primary care electronic health records [25]. Compared with other established diagnostic criteria, the FAMCAT is 20% more accurate in identifying FH than SB criteria and 15% more accurate than DLCC [25,26]. Targeted case-finding for FH in the primary care setting has already been shown to be cost-effective by prioritizing those with the highest likelihood of having FH for further assessment and genetic testing in secondary care [27-29]. This measure would efficiently allocate resources toward those who would benefit the most [27,29].

The performance of the FAMCAT in the United Kingdom has been well recognized [23-26]. However, its performance in the Malaysian primary care setting remains unknown. To improve identification of patients with FH in the Malaysian primary care, we developed a web-based FH Identification Tool to collect key information to identify individuals with suspected FH using the FAMCAT, DLCC, and SB criteria. Using these criteria, patients were screened for features of FH. Those who were suspected to have FH clinically were offered genetic testing. Genetic testing is not routinely available in Malaysia. However, it can be offered if resources are available as it is the gold standard to diagnose FH [30]. We hypothesize that the rate of detection of genetic mutations using the FAMCAT will be higher compared with the SB criteria and DLCC score, thus showing better performance.

Overall, this study aims to enhance detection of individuals with high probability of FH in the Malaysian primary care setting who can then be genetically tested and subsequently referred for further clinical management and cascade screening of family members in multidisciplinary specialized lipid clinics, maximizing efficient use of limited resources. The specific objectives of this study are to (1) compare the detection rate of genetically confirmed FH and the diagnostic accuracy between the FAMCAT and the established clinical diagnostic criteria (SB and DLCC) in the Malaysian primary care setting; (2) identify the genetic mutation profiles, including novel variants, in individuals with suspected FH in the Malaysian primary care setting; (3) explore the experience, concern, and expectation of individuals with suspected FH who have undergone genetic testing in the Malaysian primary care setting; and (4) evaluate the clinical utility of a web-based FH Identification Tool that includes the FAMCAT, SB, and DLCC in the Malaysian primary care setting.

Methods

Study Overview

This is a mixed methods evaluation study that used both the quantitative and qualitative research methods to answer complex research questions, and to understand the process and to strengthen the impact evaluation [31]. Methodologically, this study was divided into Work streams 1, 2, and 3. In Work stream 1, the diagnostic test accuracy study design is used to compare the detection rate of genetically confirmed FH and discriminatory accuracy between the FAMCAT, SB, and DLCC in the Malaysian primary care setting. In Work stream 2, the targeted next-generation sequencing (NGS) is used to identify the genetic mutation profiles among individuals with suspected FH in the Malaysian primary care setting. In Work stream 3a, a qualitative semistructured interview methodology is used to explore the experience, concern, and expectation of individuals with suspected FH who have undergone genetic testing in the Malaysian primary care setting. Lastly, in Work stream 3b, a qualitative real-time observation of PCPs using the "think-aloud" methodology is applied to evaluate the clinical utility of a web-based FH Identification Tool containing the FAMCAT, SB, and DLCC in the Malaysian primary care setting.

Work Stream 1: Comparing the Detection Rate and Diagnostic Accuracy of Genetically Confirmed FH in the Malaysian Primary Care

Study Design and Setting

This is a diagnostic test accuracy study. The study was conducted at 11 Ministry of Health (MOH) primary care clinics located in the urban and suburban areas at the central administrative region of Malaysia (in the states of Selangor, Kuala Lumpur, and Putrajaya). These areas were chosen due to their commutable proximity to the Universiti Teknologi MARA (UiTM) Lipid Specialist Clinic where patients who are genetically confirmed to have FH are referred for further management and cascade screening of their family members.

Site Selection

To be eligible for selection, the clinics must be equipped with an electronic medical record (EMR) system, have minimum attendance of 500 patients per day, and be led by a family medicine specialist (FMS).

In total, there were 21 MOH primary care clinics (15 clinics in Selangor and 6 clinics in Kuala Lumpur and Putrajaya) that

XSL•FO
RenderX

fulfilled the aforesaid selection criteria. The FMS leading these 21 clinics were invited for a briefing to introduce the study. Out of the 21 clinics, 11 clinics were interested in participating and therefore were included in the study (6 are located in Selangor and the other 5 are located in Kuala Lumpur and Putrajaya).

The site selection for this study was completed in February 2020. Table 1 shows the demographic characteristics of the study sites. All the clinics are located in the urban and suburban areas. The population served ranged from approximately 78,000 to 500,000, with most from the low to middle household income groups. All the clinics have multidisciplinary team members consisting of doctors (FMS and medical officers), assistant medical officers, nurses, dietitians/nutritionists, and pharmacists.

Table 1. Demographic characteristics of the study sites.

Number	Clinic name	Area	Total number of populations served, n	Description of populations served	Total number of multidisciplinary team members, n
1	Precinct 18, Putrajaya	Suburban	91,900	• Middle to high income • Majority are civil servants	180
2	Section 7, Shah Alam	Urban	511,153	• Low to middle income • Majority are working in the private sector	103
3	Sungai Buloh	Suburban	466,163	• Low to middle income • Majority are unemployed and self-employed	183
4	Jinjang	Urban	132,272	• Low to middle income • Majority are self-employed and unemployed	205
5	Pandamaran	Urban	150,000	• Low to middle income • A mixture of private sector workers and civil servants	200
6	Kelana Jaya	Suburban	180,000	• Low to middle income • A mixture of private sector workers and civil servants	171
7	Taman Ehsan	Suburban	78,693	• Low to middle income • A mixture of private sector workers and civil servants	103
8	Selayang Baru	Urban	212,164	• Low to middle income • A mixture of private sector workers and civil servants	150
9	Tanglin	Urban	400,000	• Low to middle income • A mixture of private sector workers and civil servants	170
10	Kuala Lumpur	Urban	105,000	• Middle income • A mixture of private sector workers and civil servants	217
11	Batu Muda	Suburban	180,000	• Low to middle income • A mixture of private sector workers and civil servants	158

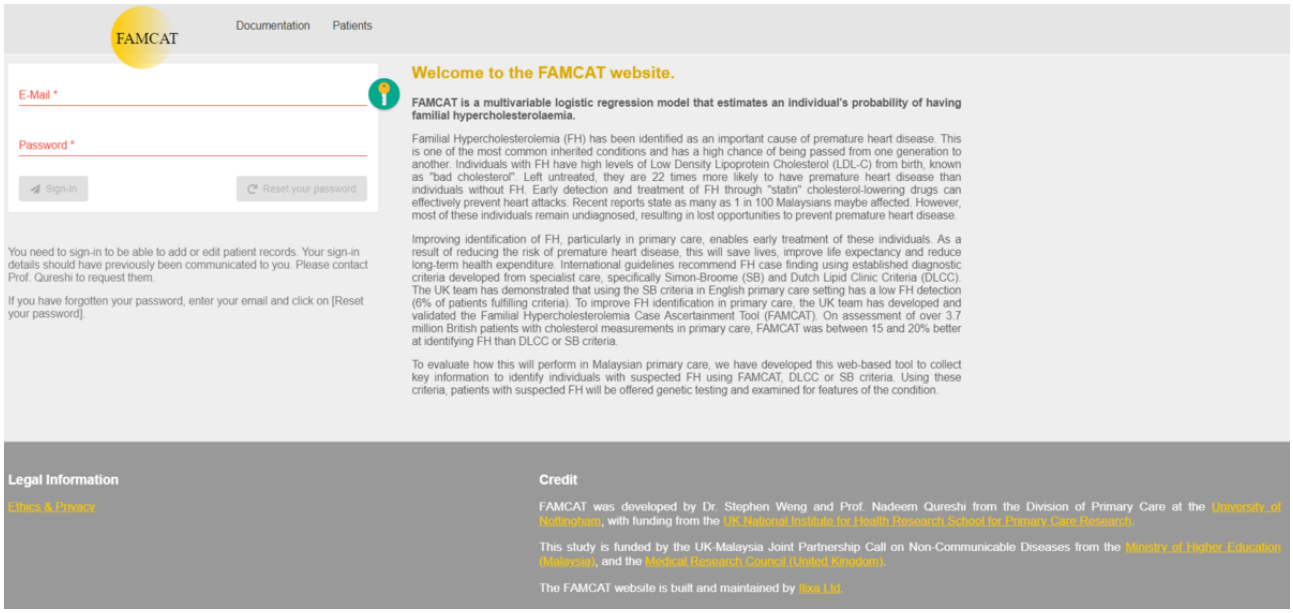
Study Population

Patients registered at the 11 MOH primary care clinics were recruited according to the inclusion and exclusion criteria. This study included patients aged 18 years or older and who had an LDL-c level of 4.0 mmol/L or more recorded in their EMR. Those who were previously diagnosed with FH by genetic testing, were pregnant, or did not have the mental capacity to provide informed consent were excluded.

Study Tool and Variables

This study used the FAMCAT web-based FH Identification Tool, developed by and based at the University of Nottingham, UK. This web-based tool contains 3 index tests, namely, the FAMCAT, SB, and DLCC. Figure 1 shows the interface of the FAMCAT web-based FH Identification Tool. Table 2 shows the variables needed to identify patients with suspected FH using the FAMCAT web-based FH Identification Tool.

XSL•FO
RenderX



The variables entered into the FAMCAT web-based FH Identification Tool identified patients with suspected FH who were indicated to have genetic testing based on either one of the following definitions:

- The FAMCAT algorithm relative risk score >1 (high probability of FH).
- Clinical diagnosis of “definite” or “possible” FH by SB criteria.
- DLCC score ≥6 (clinical diagnosis of “definite” or “probable” FH by DLCC).

The disease of interest is the HeFH and the reference standard for diagnosis is genetically confirmed HeFH determined by targeted NGS of pathogenic variants (PVs) in 4 FH candidate genes (ie, *LDLR*, *APOB-100*, *PCSK9*, and *LDLRAP1*).

Full details of the genetic testing methods are presented in Work stream 2. The laboratory staff analyzing the samples and the specialist interpreting the genetic test results were blinded to the index tests results.

Figure 1. Interface of the FAMCAT web-based FH Identification Tool.

XSL•FO
RenderX

Table 2. Clinical diagnostic variables for the FAMCAT[a], SB[b], and DLCC[c].

Index tests	SB criteria	DLCC	FAMCAT
Lipid levels	• Total cholesterol >7.5 mmol/L • LDL-c[d] >4.9 mmol/L	• LDL-c ≥4 mmol/L	• The highest LDL-c ever measured • The highest total cholesterol ever measured • Triglycerides during LDL-c measurement • Age during LDL-c measurement • Lipid-lowering treatment during LDL-c measurement
Physical examination	• Tendon xanthomas	• Tendon xanthomas • Corneal arcus <45 years of age	• Nil
Personal history	• Nil	• Personal history of premature CAD[e], cerebrovascular accident, or peripheral vascular disease (<55 years in men, <60 years in women)	• Personal history of premature myocardial infarction (<55 years in men, <60 years in women) • Diagnosis of diabetes • Diagnosis of chronic kidney disease
Family history	• Tendon xanthomas in a first- or second-degree relative • Family history of premature myocardial infarction <60 years in a first-degree relative or <50 years in a second-degree relative • Family history of elevated total cholesterol >7.5 mmol/L in a first- or second-degree relative • Family history of elevated total cholesterol >6.7mmol/L in a child or siblings ≤16 years old	• A first-degree relative with tendon xanthomas or corneal arcus • A first-degree relative with premature CAD, cerebrovascular accident, or peripheral vascular disease (<55 years in men, <60 years in women) • A first-degree relative with LDL-c >95th percentile • Children <18 years with LDL-c >95th percentile	• Family history of premature myocardial infarction (<55 years in men, <60 years in women) • Family history of familial hypercholesterolemia

[a]FAMCAT: Familial Hypercholesterolemia Case Ascertainment Tool.

[b]SB: Simon Broome.

[c]DLCC: Dutch Lipid Clinic Criteria.

[d]LDL-c: low-density lipoprotein cholesterol.

[e]CAD: coronary artery disease.

Patients Recruitment and Sampling Method

Patient recruitment was conducted by the research assistants (RAs) under the supervision of clinician investigators, who were the FMS. A list of patients with LDL-c levels of 4.0 mmol/L or more was extracted from the EMR. These patients were then stratified into 4 groups (≥7.0 mmol/L, 6.0-6.9 mmol/L, 5.0-5.9 mmol/L, and 4.0-4.9 mmol/L). Patients in these 4 groups were invited to participate via social media messaging service. This comprised a concise invitation message and a flyer containing information about the study. Invitations were sent to all patients in the highest LDL-c groups of 7.0 mmol/L or more and 6.0-6.9 mmol/L. Equal numbers of patients in the other 2 groups (5.0-5.9 mmol/L and 4.0-4.9 mmol/L) were invited to participate. If the patient did not respond to the invitation message sent via the social media messaging service, the RA followed up with a telephone call. Those who agreed to participate were given an appointment to be screened according to the inclusion and exclusion criteria at the primary care clinic.

At the primary care clinic, the patients received the study information sheet and informed consent form. This is available in either Malay or English language according to patients' preference. It contains important information pertaining to the study and included background; purpose; benefit and risk; information regarding participation, including possibility of genetic testing (if indicated), study procedure, confidentiality status, and contact information. The RA gave the information verbally when the patients required further information or clarification.

Those who verbally consented to participate were screened for eligibility according to the inclusion and exclusion criteria. Screening for the eligibility criteria was conducted by the RA through structured interviewing of the patients. Those who fulfilled the eligibility criteria and agreed to participate were recruited; and written informed consent was obtained by the RA.

Patients were recruited until the sample size was achieved. Sample size calculation for this study is described later in this manuscript.

Data and Sample Collection Procedures

Data collection at the primary care clinics was conducted by the RA under the supervision of the clinician investigators. Prior to data collection, a training workshop for the RA and the clinician investigators was conducted to ensure standardization of study procedures. The training included physical examinations to identify tendon xanthomata and corneal arcus, and taught the participants how to use the FAMCAT web-based

XSL•FO
RenderX

FH Identification Tool. At the primary care clinic, the RA also had an on-site hands-on training on how to interview patients, review the EMR, identify clinical signs of FH, and enter data into the FAMCAT web-based FH Identification Tool. During the first 2 months of the study, the clinician investigator directly observed the RA during the data collection and physical examination procedures. Further, they were trained on how to counsel patients for genetic testing.

Data were collected using the data collection form and standardized questionnaires, both of which have been translated into the Malay language. Participants were requested to fill in the sociodemographic data (age, ethnicity, education level, marital status, household income) and the Family History Questionnaire [32]. Clinical data (ie, significant medical history, medication history, and previous lipid profile results [total cholesterol, triglycerides, and LDL-c]) were retrieved from the EMR in the presence of the patients. Physical examination to identify tendon xanthomata and corneal arcus was performed by the RA, supervised by the clinician investigators. To identify patients who may need immediate medical attention, the WHO Rose Angina Questionnaire [33] and Edinburgh Claudication Questionnaire [34] were administered.

All of the variables that were collected on paper were double entered by the RA into a Microsoft Excel spreadsheet and the FAMCAT web-based FH Identification Tool to identify patients with suspected FH who were indicated for genetic testing. The criteria for genetic testing have previously been described in the "Study Tool and Variables" section.

Patients with suspected FH who were indicated to have genetic testing were given another set of patient information sheet and informed consent form in either Malay or English language. It contains important information pertaining to genetic testing. Participants were counseled regarding their risk of having FH, the pattern of inheritance, the genetic testing procedure, confirmation of diagnosis after the genetic testing, further management, and the need for cascade screening of family members once they are genetically diagnosed. Written informed consent was obtained from those who agreed to participate. Approximately 4 mL of venous blood sample was collected from each participant into an ethylenediaminetetraacetic acid (EDTA) tube. These samples were kept in a temperature-controlled container and were delivered to the Institute of Pathology, Laboratory and Forensic Medicine (I-PPerForM) Genetic Laboratory within 3 hours.

Sample Size Calculation

A previous study, in a UK population, found the detection rate for genetically confirmed FH using the FAMCAT to be 28% [35]. Therefore, a sample size of 310 will allow for a single proportion of 28% to be estimated with a 95% confidence level within a 5% margin (ie, from 23% to 33%).

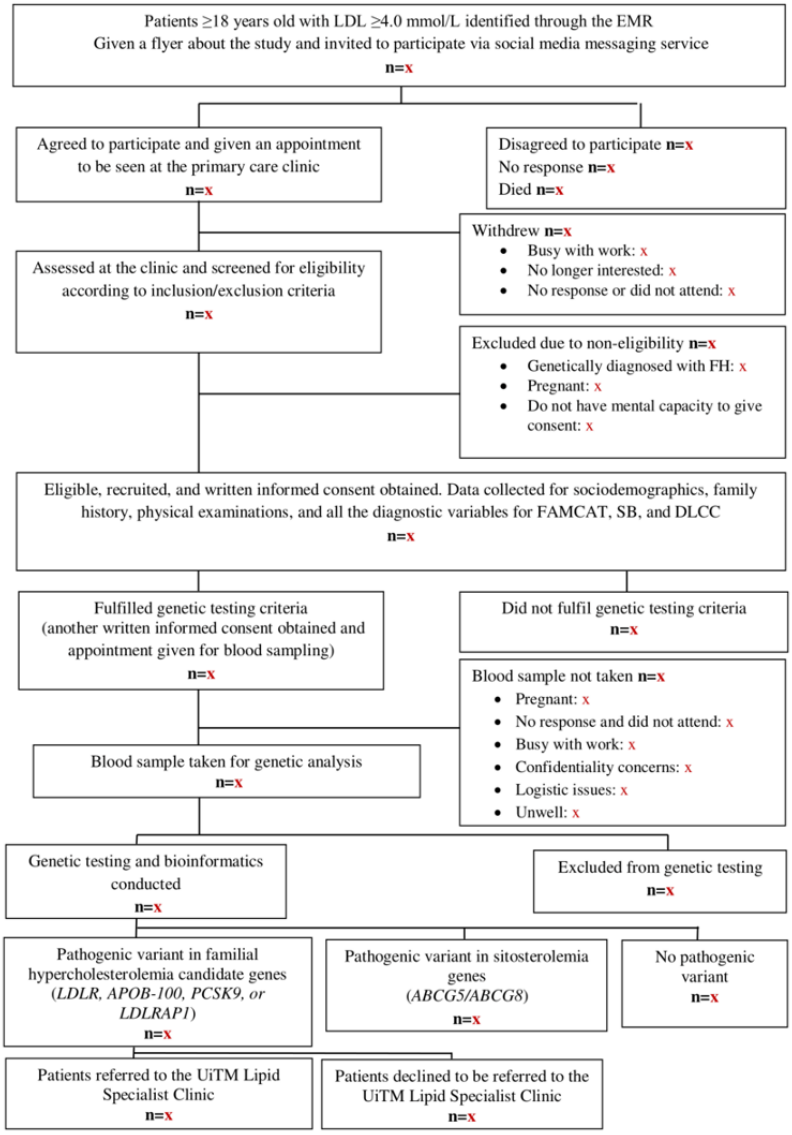
Study Outcomes and Process Measures

Primary Outcomes

- Comparison of detection rate of genetically confirmed FH between the FAMCAT, SB, and DLCC.

Secondary Outcomes

- Sensitivity and specificity;
- Area under the curve;
- Positive and negative predictive values;
- Diagnostic odd ratio.



Process Measures

- Number of patients who are screened through the EMR and invited to participate.
- Number and proportion of patients who disagree to participate or do not respond (out of those invited).
- Number and proportion of patients who agree to participate and are given appointment to be seen at the primary care clinic (out of those invited).
- Number and proportion of patients who withdraw after being given an appointment (out of those given an appointment).
- Number and proportion of patients who are assessed for eligibility according to the inclusion/exclusion criteria at the primary care clinic (out of those given an appointment).
- Number and proportion of patients who are excluded due to noneligibility (out of those who are assessed at the clinic).
- Number and proportion of patients who are eligible, recruited, and for whom written informed consent was obtained (out of those who are assessed at the clinic).
- Number and proportion of patients with complete diagnostic variables data entered into the web-based FH Identification Tool (out of those who are eligible and recruited).
- Number and proportion of patients who fulfilled the genetic testing criteria (out of those who are eligible and recruited).
- Number and proportion of patients who give consent and have blood sample taken for genetic analysis (out of those who fulfilled the genetic testing criteria).
- Number and proportion of patients who are identified to have PV in any of the 4 FH candidate genes (out of those who have blood sample taken for genetic analysis).
- Number and proportion of patients who agree to be referred to the lipid specialist for further care (out of those who have PV in any of the 4 FH candidate genes).

Figure 2 shows the flowchart of participants screening and recruitment at the primary care clinics.

XSL•FO
RenderX

Figure 2. Flowchart of the participants screening and recruitment.

Statistical Analysis Plan

The demographics and clinical characteristics of the participants included in the study will be reported using descriptive measures, where frequencies (with percentages) will be used for categorical outcomes and either means (with SDs) or medians (with IQRs) will be used for continuous outcomes. Measures of diagnostic accuracy (detection rate, sensitivity, specificity, positive and negative predictive values, area under the curve, and diagnostic odds ratio) for each of the 3 index tests will be reported with their corresponding 95% CIs, with genetic testing as the reference standard. The diagnostic accuracy of the FAMCAT compared with SB and DLCC will be conducted using paired analyses by constructing a joint classification table and estimating the relative diagnostic odds ratio and relative likelihood ratios, with corresponding 95% CIs. Stratified analyses will be conducted to assess the impact of ethnicity (genotyping profile) and sensitivity analyses will be conducted excluding people with hypothyroidism. Process outcome measures will be reported as frequencies (with percentages).

Work Stream 2: Identifying Genetic Mutation Profiles of Individuals With Suspected FH

Study Design and Setting

Targeted NGS of the 4 FH candidate genes (FHCGs), namely, *LDLR*, *APOB-100*, *PCSK9*, and *LDLRAP1*, and 2 hypercholesterolemia-associated genes (HCAGs), namely, *ABCG5* and *ABCG8*. The study is performed at the I-PPerForM Genetic Laboratory located in UiTM Sungai Buloh Campus, Selangor, Malaysia.

Sample Collection

The EDTA tubes containing venous blood samples were delivered in a temperature-controlled container from the primary care clinics to the I-PPerForM Genetic Laboratory within 3 hours. Once received, the whole blood was stored in a freezer at –20°C before further analysis.

DNA Extraction

The DNA extraction was conducted by an RA who was blinded to the index tests results (FAMCAT, SB, and DLCC) using standardized method [36]. The frozen blood samples were

XSL•FO
RenderX

thawed at room temperature before being subjected to DNA extraction using MasterPure DNA Purification Kit for Blood Version II (Lucigen Corporation). A total of 200 µL whole blood and red cell lysis solution (600 µL) were pipetted and mixed in a microcentrifuge tube. The mixture was incubated at room temperature for 5 minutes and then briefly vortexed. After centrifuging for 25 seconds, the supernatant was removed, leaving approximately 25 µL of pellet (white blood cells). The white blood cells were resuspended in 300 µL tissue and cell lysis solution by pipetting. RNase A (1 µL) was added and thoroughly mixed. The samples were then incubated for 30 minutes at 37°C. The samples were placed on ice for 3-5 minutes, followed by addition of the MasterPure Complete protein precipitation reagent (175 µL) into the lysed sample. The mixture was vigorously vortexed for 10 seconds. The debris was pelleted by centrifugation for 10 minutes at 10,000*g* or more in a microcentrifuge. The supernatant was transferred to a clean centrifuge tube and the pellet was discarded. Isopropanol (500 µL) was added to the recovered supernatant. The DNA was pelleted by centrifugation at 4°C for 10 minutes in a microcentrifuge. The isopropanol was carefully removed, without dislodging the DNA pellet. The DNA pellet was rinsed 2 times with 70% ethanol (EtOH; Fisher Scientific), without dislodging the pellet. All the residual EtOH was removed. Approximately 3-9 µg of DNA was acquired, which was then resuspended in 35 µL of Tris-EDTA (TE) buffer (Sigma). The DNA was then quantitated. The extracted DNA was stored in a –20°C freezer to preserve its integrity.

Quantification and Quality Control

QuickDrop Quantification

The concentration and purity of samples were determined using the SpectraMax QuickDrop Micro-Volume Spectrophotometer (Molecular Devices). TE buffer (1 µL) was then used as the blank and 1 µL sample was pipetted onto the sample port. The reading for the concentration (ng/µL) and purity were recorded. Samples with concentration of 20 ng/µL or more and purity of A260/A280=1.70-2.00 were subjected to electrophoresis that was performed to clarify the intactness of DNA.

Qubit Quantification

The Qubit dsDNA HS (High Sensitivity) Assay Kit (Thermo Fisher Scientific) was used to further assess DNA quality. Samples with concentration of 50 ng/µL or more based on the QuickDrop readings were diluted to 18-30 ng/µL in case the reading was underestimated before proceeding to Qubit quantification.

The Qubit working solution was prepared by diluting the Qubit dsDNA HS Reagent in the Qubit dsDNA HS Buffer with a ratio of 1:200. The Qubit dsDNA HS assay requires 2 standards for calibration. The standards were prepared by mixing 190 µL Qubit working solution and 10 µL of each Qubit standard. The solution was then mixed by vortexing for 2-3 seconds. For sample preparation, 2 µL of the sample was added to 198 µL of the Qubit working solution. The solution was then mixed by vortexing for 2-3 seconds. The tubes were allowed to incubate at room temperature for 2 minutes before being read by the fluorometer. The actual concentration of DNA was obtained by calculating the readings from Qubit and times with the number of dilutions.

Ethanol Purification

One part of sodium acetate solution (3.0 M; pH 5.2; Sigma) and 2 parts of cold absolute EtOH were added to 10 parts of the DNA sample volume. The mixture was vortexed for 10 seconds and kept in a –70°C freezer for 20 minutes. The mixture was then transferred into a column tube and centrifuged for 10 minutes, at 14,000*g* in 4°C. The supernatant was carefully discarded without moving the DNA pellet, which was later washed with 500 µL of 70% EtOH, followed by centrifugation for another 10 minutes, at 14,000*g* in 4°C. The supernatant was discarded and the washed pellets were air dried. The pellets were resuspended in 40 µL elution buffer (EB) buffer and requantified using QuickDrop, followed by agarose gel electrophoresis and Qubit fluorometer reading.

Next-Generation Sequencing

Custom Targeted Gene Sequencing

The NGS [37] was run using an AmpliSeq Custom DNA panel (Illumina), which was designed using the Illumina DesignStudio Sequencing Assay Designer. The targeted NGS employed the amplicon sequencing method, where PCR primers were used to amplify the sequences of interest. Samples used for amplicon sequencing were transformed into libraries and enriched via PCR amplification individually and barcoded by ligating the indexes into the amplicons. The libraries were then pooled and analyzed using a bench-top sequencer. The panel in this study was designed to identify the 4 FHCGs, namely, *LDLR*, *APOB-100*, *PCSK9*, and *LDLRAP1*, and the HCAGs, namely, *ABCG5* and *ABCG8*, with an overall gene coverage of 98.61% [38-40].

Quantification and Dilution of DNA

The samples were diluted to an intermediate concentration of about 20-50 ng/µL using low TE followed by requantification using the Qubit fluorometer. The samples were then further diluted into the desired final concentration of 3.5 ng/µL using low TE.

Amplification of DNA Targets

For each sample, 7 µL of 5× AmpliSeq HiFi Mix and 10.5 µL DNA samples (3.5 ng/µL) were combined in a fresh 1.5-mL microcentrifuge tube to bring the total volume of the master mix to 17.5 µL. About 5 µL of the master mix was transferred into a 96-well PCR plate. Because of the complexity of the panel design, each sample was separated into 3 different wells and separately added with different 5 µL of 2× AmpliSeq Custom DNA Panel Pool (the primer pool). In total, each well contained 5 µL sample master mix and 5 µL primer pool for a total of 10 µL per well. The plate was properly sealed and briefly centrifuged. The plate was placed in a preprogrammed thermal cycler and run with the following settings: preheat lid option, 105°C; reaction volume, 10 µL; 99°C, 2 minutes; 19 cycles of –99°C for 15 minutes and –60°C for 4 minutes; and 10°C for up to 24 hours.

XSL•FO
RenderX

Partial Digestion of Amplicons

After PCR, the 3 separated products amplified from the same sample were then combined into 1 well, making the total volume per sample as 30 µL. Then, 3 µL of the FuPa reagent was added to each combined sample. The plate was sealed, briefly vortexed at 1600 rpm for 1 minute, followed by centrifugation at 280*g* for 1 minute. The plate was placed in the thermal cycler and run with the following settings: preheat lid, 105°C; reaction volume, 33 µL; 50°C for 10 minutes; 55°C for 10 minutes; 62°C for 10 minutes; and 10°C for up to 1 hour.

Ligate Indexes

Switch solution (6 µL), AmpliSeq CD indexes (3 µL), and finally DNA ligase (3 µL) were added sequentially into each well containing the digested amplicons (33 µL) to a total volume of 45 µL for each sample. The plate was then sealed, vortexed, centrifuged, and placed into the thermal cycler and run with the following settings: preheat lid, 105°C; reaction volume, 45 µL; 22°C for 30 minutes; 68°C for 5 minutes; 72°C for 5 minutes; and 10°C for up to 24 hours.

Cleanup Library

A total of 45 µL of AMPure XP beads were added to each library. The plate was then sealed, vortexed, centrifuged, and incubated at room temperature for 5 minutes. The plate was then placed on a magnetic stand until the mixture became clear (approximately 2 minutes). While still on the magnetic stand, the plate was unsealed, and the supernatant was carefully pipetted out from each well. The beads were washed by adding 150 µL freshly prepared 70% EtOH to each well, followed by incubation at room temperature until the solution became clear (approximately 30 seconds). Without disturbing the pellets, the supernatant was again discarded from each well. The washing step was repeated once again. The plate was sealed, briefly centrifuged, and placed on the magnetic stand in the same position as before. The plate was unsealed and all residual EtOH was removed from each well.

Amplify Library

In a fresh 1.5 µL microcentrifuge tube, 1125 µL of 1× Lib Amp Mix was combined with 125 µL of 10× Library Amp Primers for a total of 1250 µL amplification master mix. The master mix was vortexed and centrifuged briefly. The plate was removed from the magnetic stand and 50 µL of the master mix was added to each well and the plate was sealed again, vortexed, centrifuged, and placed into the thermal cycler and run with the following settings: preheat lid, 105°C; reaction volume, 50 µL; 98°C for 2 minutes; 7 cycles of 98°C for 15 seconds and 64°C for 1 minute; and 10°C for up to 24 hours.

Second Cleanup

About 25 µL of AMPure XP beads were added to each well containing approximately 50 µL library and the plate was sealed again. The library was vortexed, centrifuged briefly, and incubated at room temperature for 5 minutes. The plate was placed on the magnetic stand for another 5 minutes until the liquid is clear and the plate was unsealed. The entire supernatant that contains the desired amplicon library (approximately 75 µL) was transferred to a new plate and 60 µL of AMPure XP beads were added to each well in the new plate. The plate was briefly vortexed, centrifuged, and incubated at room temperature. After 5 minutes, the plate was placed on the magnetic stand for another 5 minutes until the liquid cleared. The plate was unsealed. Without disturbing the beads, the supernatant was discarded from each well. The beads were washed by adding 150 µL freshly prepared 70% EtOH to each well, followed by incubation at room temperature until the solution became clear (approximately 30 seconds). Without disturbing the pellets, the supernatant was discarded from each well. The washing step was repeated once again. All residual EtOH was pipetted out, and the plate was air dried on the magnetic stand for 5 minutes. Low TE (30 µL) was added to each well and mixed well. The plate was sealed again, vortexed, and centrifuged briefly to disperse the beads. It was then placed on the magnetic stand until the liquid cleared and then unsealed. About 27 µL supernatant that contains the amplicon library was transferred to a new plate.

Libraries Checking

Each library was subjected to Qubit quantification to ensure the concentrations were approximately 1-10 ng/µL.

Bioanalyzer Reading

Each sample was diluted to 0.5-1.0 ng/µL before the bioanalyzer step. Size distribution of the library was checked using the Agilent High Sensitivity DNA Kit (Agilent Technologies). Nearly 15 mL of high-sensitivity DNA dye concentrate was added to a vial containing high-sensitivity DNA gel matrix. The mixture was vortexed and transferred to a spin filter, and subsequently centrifuged to obtain the elution. The gel-dye mix elution was allowed to equilibrate to room temperature for 30 minutes before use. A high-sensitivity DNA chip was put on the chip priming station. About 9 µL of the gel-dye mix was pipetted into the loading well on the chip. A priming plunger was used to push the gel-dye mix to the entire sample wells on the chip. About 5 µL marker was pipetted into each sample well and a ladder well. Nearly 1 µL high-sensitivity DNA ladder was also pipetted in the ladder well. Then, 1 µL sample was also pipetted into each sample well. The chip was vortexed for 1 minute at 2400 rpm, and then run in the Agilent 2100 Bioanalyzer instrument (Agilent Technologies) within 5 minutes after its preparation. Each library size was recorded in a Microsoft Excel sheet and the average library size measured was determined. The molarity of the library was calculated using the following formula [41]:

$$\text{Molarity (nM)} = [(\text{ng}/\mu\text{L}) \times 10^6]/[660\ (\text{g/mol}) \times \text{average library size (bp)}]$$

Dilution of the Library to the Starting Concentration

Samples (about 5 µL) were pipetted into separate microcentrifuge tubes. EB-0.1% Tween 20 mix was pipetted into each sample tube, where the volume varies so the final molarity of each sample was 4 nM. Next, 5 µL of each library was pooled into a single microcentrifuge tube. The library pool was subjected to Qubit to confirm the 4 nM concentration.

Sequencing

The Illumina iSeq 100 is a benchtop high-throughput sequencer, measuring 1 ft^3 in size. This sequencer is useful for sequencing

XSL•FO
RenderX

small genome, transcriptome, long amplicon, and targeted resequencing applications, generating up to 1.2 Gb data per run.

The cartridge was first thawed overnight in a water bath (20-25°C) in its foil bag. When the cartridge is ready, 4 nM library pool was diluted to 50 pM loading concentration using EB. About 10 nM of PhiX (control library) was diluted to 50 pM using EB. Then, 2 µL of PhiX (50 pM) was added to 98 µL library pool (50 pM), making the final pool volume as 100 µL.

The cover of the loading reservoir on the thawed cartridge was first teared using a pipette tip. Then, 20 µL final pooled library was pipetted into the bottom of the reservoir. Flow cell was inserted into the cartridge. Then, the cartridge-flow cell assembly was inserted into the iSeq 100 tray. Run was initiated using instrument control software. The total runtime was up to 17.5 hours.

Bioinformatics Analysis

The iSeq100 run monitoring was executed using BaseSpace Sequence Hub (Illumina) cloud-based software, where GRCh37 hg19 human reference assembly [42] was used to map genomic sequences. Variant calls and differential expression results for amplicon panels were produced using BaseSpace Sequence Hub and Local Run Manager (on-board).

The variant call format (VCF) files were extracted and downloaded from BaseSpace Sequence Hub. Variants with minor allele frequency of 0.05 or less, based on either the gnomAD or 1000 Genome database, were considered as rare gene mutations.

Variant Call Format Analysis

The VCF files were outsourced (BioEasy Sdn Bhd) for data cleaning and bioinformatics interpretation [43]. Gene filtering for *LDLR, APOB-100, PCSK9, LDLRAP1, ABCG5,* and *ABCG8* was conducted by coordination using the BED format file downloaded from the UCSC Genome Browser, and each VCF format file was subjected to gene filtering using BCFtools. The overlapping list of variants was merged into 1 single list of variants consisting of 1 sample per column using BCFtools. Consistent gene annotation was performed using the SnpEff and Genome Analysis Toolkit/GATK. The cumulative allele frequency and the global minor allele frequency (GMAF) values were annotated using BCFtools. REVEL scores for hg19 were prepared for annotation using BCFtools. The SIFT annotation was performed using the SIFT4G annotator program, while PolyPhen-2 annotation was prepared using BCFtools. Variants with no GMAF values and GMAF ≤5% were separated into different files.

Pathogenicity Interpretations

The cleaned and combined VCF files were further analyzed for variant pathogenicity using modified American College of Medical Genetics and Genomics guidelines [44,45]. The American College of Medical Genetics and Genomics guidelines classify variant pathogenicity based on the type of mutation and other clinical evidence such as medical history, population frequency, in silico prediction, functional study, and segregation data. Additional reliable sources of references were identified using ClinVar [46] and Leiden Open-source Variation Database [47] websites. The variants were ultimately classified into "pathogenic" (PV), "likely pathogenic," "benign variant," or "variant of unknown significance." The RA, Genetic Laboratory staff, and the lipid specialists who were involved in analyzing and interpreting the genetic results were blinded to the index tests results (FAMCAT, SB, and DLCC) and the relevant variables collected in Work stream 1.

Delivery of the Genetic Results

The genetic analysis results for individual patients will be delivered by the clinician investigators. Patients who are genetically confirmed to have FH will be counseled regarding the nature of the genetic mutations, mode of inheritance, the need for pharmacological management, and cascade screening of first- and second-degree relatives. The importance of adherence to lifestyle modification and pharmacotherapy will also be emphasized. Lipid-lowering treatment for each patient will be reviewed and uptitrated to achieve an LDL-c target of <1.8 mmol/L [48,49]. Patients will also be supported psychosocially on how to adapt with the condition. They will be referred to the UiTM lipid specialists for further management and cascade screening of family members.

Work Stream 3a: Exploring the Experience, Concern, and Expectation of Individuals With Suspected FH

Study Design, Setting, Population, and Method

This is a nested qualitative study performed in MOH primary care clinics. The study population included patients with suspected FH who have undergone genetic testing. Semistructured interviews and thematic analysis of data are performed.

Sampling Method

Patients with suspected FH who have received their genetic analysis results are purposefully sampled to reflect their social, ethnic, and educational diversity, and range of results including those who are genetically confirmed to have FH and those with negative results. Written informed consent is obtained from the participants.

Data Generation

Semistructured in-depth interviews are conducted face-to-face or virtually using the online platform Google Meet (Google LLC/Alphabet Inc.) by an RA, supervised by a Malaysian lead qualitative co-investigator (SAR) who is an expert in qualitative study methods. A topic guide developed for the interview (Multimedia Appendix 1) is used to help explore patients' experience and concern of being identified with suspected FH, of undergoing FH genetic testing, and understand their experience of receiving the results and undergoing follow-up assessment and referral processes [50]. The interviews are conducted for up to 45 minutes, and they are audio- and video-recorded. Recruitment and data generation will continue until saturation of themes. This is expected to be achieved by interviewing approximately 10-15 patients [51,52].

Data Analysis

Data from the interviews will be transcribed verbatim and translated into English. Data will be organized using NVivo

XSL•FO
RenderX

qualitative software (QSR International) [53], and analyzed thematically by JK, SAR, and LC. Coding and development of analysis will involve a minimum of 2 qualitative researchers (SAR and LC).

Work Stream 3b: Evaluating Clinical Utility of the Web-Based FH Identification Tool in Malaysian Primary Care

Study Design, Setting, Population, and Method

This is a nested qualitative study conducted in MOH primary care clinics. The study population included PCPs working at the MOH Primary Care Clinics. The "think-aloud" interview method [54] is applied.

Sampling Method

PCPs are purposefully sampled to reflect their varied lengths of clinical experience, and range of use of the FAMCAT web-based FH Identification Tool in practice. Written informed consent is obtained from the participants.

Data Generation

Interviews are conducted using the "think-aloud" method [54] in which participants are required to talk aloud while using the FAMCAT web-based FH Identification Tool. A user manual and task scenarios (Multimedia Appendix 2; also see [26,55,56]) have been created to assist clinicians in performing clinical tasks simulation using the web-based tool. The clinical scenarios are standardized for all participants, regardless of their level of clinical experience. The task scenarios are reviewed by the research team members, including experienced and practicing PCPs, to ensure that the content, format, and presentation are representative of real clinical use and addressed the major functional components of the application.

The "think-aloud" interview method generates direct data on participants' ongoing thought processes during task performance. The underlying assumption of "think aloud" is based on human cognition where it is postulated that only information capable of being verbalized in situ is being actively processed in the working memory and so is taken as an active representation of task performance [54]. The output of this process is called a verbal protocol, which is then transcribed and systematically analyzed to develop a model of the persons' task behavior.

Video-based observational data are collected to record the participants' interaction with the interface and functionality of the FAMCAT web-based FH Identification Tool. These data are time-locked for analysis to the verbal protocols. Following the end of the task simulations, participants complete a short questionnaire to capture a subjective measure of their user satisfaction with the interface and functionality of the FAMCAT web-based FH Identification Tool. Recruitment and data generation will continue until saturation of themes and this is expected to be achieved by interviewing approximately 10-15 participants [51,52].

Data Analysis

Each verbal protocol will be transcribed and coded using a predefined coding scheme following the categories of interest. Similarly, the audio-video–recorded simulation will provide a range of images on all of the tasks including time to completion, types of clinical knowledge, resources accessed, participants' statements, and the tasks associated therewith. Two qualitative researchers will independently map the statements made by participants and the video observations, identifying both "positive" and "negative" mental heuristics; the former demonstrating potential features that are acceptable to the needs of participants, and the latter to determine whether there are any possible refinements that might be made to the FH Identification Tool.

Ethics Approval

This study protocol was approved by the respective research ethics committees in Malaysia, namely, the UiTM Research Ethics Committee [(REC/03/2020) (FB/48)] and the Medical Research Ethics Committee of the Ministry of Health Malaysia [NMRR-20-272-52797 (IIR)].

Results

The recruitment for Work stream 1 and blood sampling and genetic analysis for Work stream 2 were completed in February 2023. The data collection for Work stream 3a and 3b was completed in March 2023. Data analysis for Work streams 1, 2, 3a, and 3b is projected to be completed by June 2023, with the results of this study anticipated to be published by December 2023.

Discussion

Expected Findings

To the best of our knowledge, this is the first study to assess the diagnostic accuracy of different clinical diagnostic criteria (SB, DLCC, and FAMCAT) in identifying FH in the Malaysian primary care setting, with molecular diagnosis targeting the 4 FHCGs (*LDLR*, *APOB-100*, *PCSK9*, and *LDLRAP1*) as the gold standard. The findings will also include molecular analysis of the 2 HCAGs (*ABCG5* and *ABCG8*). The full spectrum of genetic mutations in these 6 genes including novel PVs will be identified. This study also included nested qualitative research exploring the experience, concern, and expectation of patients with suspected FH who have undergone genetic testing and also real-time observation of PCPs using the "think-aloud" method to evaluate the clinical utility of the FAMCAT web-based FH Identification Tool in the Malaysian primary care setting. In a nutshell, it is a comprehensive mixed methods study that uses both quantitative and qualitative research methods to answer complex research questions, understand the process, and strengthen the impact evaluation [31].

A previous diagnostic accuracy study that included 755 individuals with an LDL-c level of 4.0 mmol/L or more from secondary care clinics and community health screenings in Malaysia showed that the SB criteria appeared to be the most useful in identifying FH compared with the Japanese FH Management Criteria and the US Make Early Diagnosis to Prevent Early Deaths criteria, when assessed against the DLCC as the gold standard [57]. However, unlike this study, genetic testing was not performed in the previous study.

XSL•FO
RenderX

Recent studies have shown that NGS is the method of choice [58,59] and is cost-effective in the genetic diagnosis of FH in primary care [60-62]. The targeted NGS method [37] that is being used in this study is robust and efficient in terms of speed, read length, and throughput, designed to identify the 4 FHCGs and the 2 HCAGs, giving an overall gene coverage of 98.61% [38-40].

The nested qualitative research exploring the patients' perspectives while undergoing genetic testing and the PCPs experience in utilizing the web-based tool will add tremendous value in developing a clinical care pathway that is patient-centered [63]. A recent qualitative study [64] showed that the main benefit of genetic diagnosis from the patients' perspective lies in its ability to provide accurate information to their younger family members to undergo screening, and subsequently receive timely management to reduce their risk of having premature CAD. In the United Kingdom, patients and practitioners reported a positive experience when genetic testing was introduced with electronic case-finding for FH in primary care [63].

Implications on Clinical Practice

The findings from this study will be shared through scientific publications, conference presentations, and through a resource impact report with the key stakeholders. The resource impact report will include a patient-centered clinical care pathway that will be implemented by the stakeholders in primary care. FH management training modules for primary care providers will also be developed and delivered through online webinars or face-to-face workshops, to enhance their knowledge and skills in managing FH. Dissemination of knowledge regarding FH and its genetic causes will also be made available to the general public through public health campaigns using various mass media channels and social media platforms. All of these imperative measures will accelerate early FH identification in the Malaysian primary care setting and subsequently reduce the risk of premature CAD.

Limitations

This study has several limitations. First, the selection of sites was limited to the clinics located in the urban and suburban conurbations that can access genetic testing facility at the I-PPerForM Genetic Laboratory. Future research should include a wider selection of clinics including those in the rural parts of Malaysia. Second, only those clinics with EMR were invited to participate as the screening for patients with elevated LDL-c levels was conducted through the EMR. This could potentially cause selection and recruitment bias. To minimize this bias, purposive sampling was conducted by targeting those with the highest LDL-c levels, with study invitations sent to all patients in the highest LDL-c groups of 7.0 mmol/L or more and 6.0-6.9 mmol/L, while an equal number of patients were invited from the lower LDL-c groups of 5.0-5.9 mmol/L and 4.0-4.9 mmol/L.

Third, this study will provide insights into the nature of mutations in the 6 targeted genes, but it does not include functional studies to validate the pathogenicity of the potential PV, which is warranted in future studies. The polygenic hypercholesterolemia genes were also not included as they are not within the scope of this study. Therefore, future studies are warranted to evaluate the impact of polygenic hypercholesterolemia genes on patients with clinically suspected FH without any PV. Additionally, the targeted NGS method used in this study was not able to detect large gene rearrangements, which may account for a small proportion of PV in patients with FH [65,66].

Fourth, the molecular analysis was performed only in index cases. Cascade screening of family members will be conducted and they will be clinically diagnosed with SB or DLCC. Unfortunately, we are not able to offer genetic testing to the family members due to financial constraints and this is also beyond the scope of this study.

Conclusions

This comprehensive mixed methods study will provide objective evidence on which clinical diagnostic criterion is the best to detect FH in the Malaysian primary care setting against molecular diagnosis as the gold standard. The full spectrum of genetic mutations in the 6 targeted genes including novel PVs will be identified. Patients' perspectives while undergoing genetic testing and the PCPs experience in utilizing the web-based tool will be established in this study. These findings will have a tremendous impact in advancing the scientific knowledge and skills on the clinical and genetic diagnosis of patients with FH in primary care and subsequently reduce their risk of premature CAD.

Acknowledgments

This study is funded by the Newton-Ungku Omar Fund (NUOF): The UK-Malaysia Joint-Partnership Call on Non-Communicable Diseases—Reducing Premature Coronary Artery Disease by Early Identification of Familial Hypercholesterolemia, Grant references 100-TNCPI/GOV 16/6/2 (002/2020)-02 and MR/T017384/1. ASR and NQ are co-corresponding authors, with ASR representing the Principal Investigator for Malaysia and NQ representing the Principal Investigator for the UK. We thank the Director General of Health, Malaysia for his permission to publish this article. The authors also like to express gratitude to Dr Stephen Weng for providing the expertise for the statistical analysis plan during the initial stage of this study and Dr Nazrila Hairizan Nasir for her assistance in providing access to the MOH primary care clinics. Our gratitude also goes to all the site investigators: Dr Rozita Zakaria, Dr Hazira Hanum Mohd Yusof, Dr Nurzaitil Aswani Zainuddin, Dr Mohd Khairi Mohd Noor, Dr Fauziah Ahmad, Dr Nor Azlina Siddik, Dr Siti Khamsiah Abd Shukor, Dr Noor Harzana Harrun, Dr Baizury Bashah, Dr Azira Baharuddin, Dr Nagammai Thiagarajan, Dr Rosnah Mat Isa, Dr Nik Mazlina Mohammad, Dr Nor Faizah Ghazali, Dr Valarmathi Masilamani, and Dr Lee Yeow Siong. Our special thanks also go to all the research assistants who have worked on this project,

the nurses at the MOH primary care clinics, and all the staff at the I-PPerForM Genetic Laboratory for their assistance rendered in data collection and performing the genetic analysis.

Data Availability

Raw data are kept at the Institute of Pathology, Laboratory and Forensic Medicine (I-PPerForM), Universiti Teknologi MARA, Selangor, Malaysia and encrypted data are kept at the University of Nottingham, United Kingdom in secured databases. Unidentified data will be shared by the corresponding authors upon request after all the results of this study have been published; and the data are subjected to the data protection regulations of Malaysia and the United Kingdom.

Authors' Contributions

This study was conceptualized and designed by ASR, NQ, HAH, JK, and HN. The funding for the study was acquired by ASR and NQ. ASR is the Principal Investigator for Malaysia and NQ is the Principal Investigator for the United Kingdom. ASR, NQ, HAH, and HN contributed to the project administration. The data were curated by AK and JDK, with supervision provided by ASR, SAR, MSMY, NB, SFBS, and AFAA. NSS conducted the genetic analysis supervised by HN, AAK, YAC, NAMK, and SHSAK. LC and SAR lead the qualitative study. RKA will conduct the formal analysis of the quantitative data. ASR, NQ, HAH, LC, LS, RKA, YAC, AAK, and JLB drafted the manuscript. All authors contributed to the critical revision and editing of the manuscript and have read the final version of this manuscript.

Abstract

Background: The COVID-19 pandemic has significantly affected Los Angeles County and disproportionately impacted Black and Latino populations who experienced disparities in rates of infection, hospitalizations, morbidity, and mortality. The University of Southern California (USC), USC Keck School of Medicine, Southern California Clinical and Translational Science Institute, USC Mann School of Pharmacy and Pharmaceutical Sciences, Annenberg School for Journalism and Communication, and Children's Hospital Los Angeles will launch a collaborative public health campaign called VaccinateLA.

Objective: VaccinateLA will implement a community-based, community-partnered public health campaign that (1) delivers culturally tailored information about COVID-19 and available vaccines; and (2) addresses misinformation and disinformation, which serves as a barrier to vaccine uptake. The campaign will be targeted to communities in Los Angeles with the highest rates of COVID-19 infection and the lowest vaccination rates. Using these criteria, the campaign will be targeted to neighborhoods located in 34 zip codes in the Eastside and South Los Angeles. The primary aim of VaccinateLA will be to design and deliver an evidence-based multimedia public health campaign tailored for Black and Latino populations. A secondary aim will be to train and deploy community vaccine navigators to deliver COVID-19 education, help individuals overcome barriers to getting vaccinated (eg, transportation and challenges registering), and assist with delivering vaccinations in our targeted communities.

Methods: We will use a community-based, participatory research approach to shape VaccinateLA's public health campaign to address community members' attitudes and concerns in developing campaign content. We will conduct focus groups, establish a community advisory board, and engage local leaders and stakeholders to develop and implement a broad array of educational, multimedia, and field-based activities.

Results: As of February 2023, target communities have been identified. The activities will be initiated and evaluated over the course of this year-long initiative, and dissemination will occur following the completion of the project.

Conclusions: Engaging the community is vital to developing culturally tailored public health messages that will resonate with intended audiences. VaccinateLA will serve as a model for how an academic institution can quickly mobilize to address a pressing

XSL•FO
RenderX

public health crisis, particularly in underrepresented and underresourced communities. Our work has important implications for future public health campaigns. By leveraging community partnerships and deploying community health workers or *promotores* into the community, we hope to demonstrate that urban universities can successfully partner with local communities to develop and deliver a range of culturally tailored educational, multimedia, and field-based activities, which in turn may change the course of an urgent public health crisis, such as the COVID-19 pandemic.

KEYWORDS

community engagement; COVID-19; vaccine; vaccination; public health; population health; health equity; social media; vaccine hesitancy

Introduction

The COVID-19 pandemic significantly affected Los Angeles County [1] and disproportionately impacted Black and Latino populations in Los Angeles who experienced disparities in rates of infection, hospitalizations, morbidity, and mortality. [2,3].

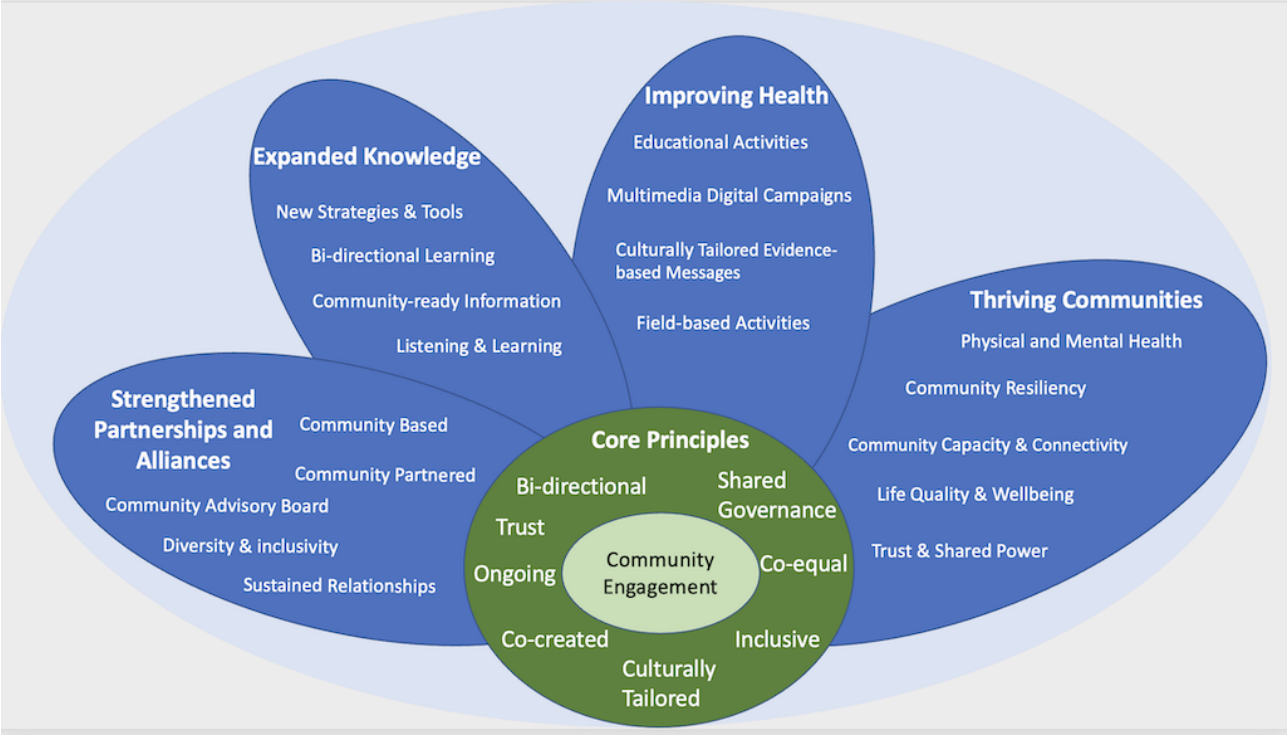
In response, the University of Southern California (USC), USC Keck School of Medicine, Southern California Clinical and Translational Science Institute, USC Mann School of Pharmacy and Pharmaceutical Sciences, and Annenberg School for Journalism and Communication, and Children's Hospital Los Angeles will launch a collaborative year-long public health campaign called VaccinateLA. Given the size and diversity of Los Angeles County (ie, more populous than 42 other US states), we will focus this campaign on communities with the highest rates of infection and the lowest rates of vaccination. Using these criteria, the campaign will be delivered in neighborhoods located in 34 zip codes located in the Eastside and South Los Angeles. The overarching aim of VaccinateLA will be to design and deliver an evidence-based multimedia public health campaign tailored for Black and Latino populations. A secondary aim will be to train and deploy community vaccine navigators (CVNs) to deliver COVID-19 education, help individuals overcome barriers (eg, transportation and challenges registering) to becoming vaccinated, and assist with delivering vaccinations in our targeted communities. In this paper, we describe VaccinateLA, including our planned approach to partnering with the community to develop and implement a broad array of evidence-based educational, multimedia, and field-based activities.

Methods

Approach

The overarching goal of VaccinateLA is to implement a community-based, community-partnered public health campaign intended to deliver culturally tailored information about COVID-19 and available vaccines, as well as to address misinformation and disinformation, which can serve as barriers to vaccine uptake. The difference between misinformation and disinformation is intent [4]. Misinformation is erroneous information reported as fact, whereas disinformation is a form of misinformation that is intended to deceive or mislead [4]. The aims of VaccinateLA will be accomplished through a range of public health campaign strategies.

Conceptual Model



Through VaccinateLA, we seek to strengthen existing partnerships and forge new relationships in our targeted communities, as well as to engage the public health community and other key stakeholders throughout the greater Los Angeles County area (eg, with the Los Angeles County Departments of Public Health, Health Services, and Mental Health).

We plan to use a community-based, participatory research approach to shape VaccinateLA's public health campaign. Our work will be guided by a conceptual model that was adapted from a framework developed by the National Academy of Medicine's Leadership Consortium: Collaboration for a Value & Science-Driven Health System [5]. Our conceptual model, titled *VaccinateLA Public Health Campaign: Building Health Equity Through Community Engagement*, takes a holistic approach to engaging multiple communities and key stakeholders to promote equity (Figure 1).

Our core principles of community engagement include work that is bidirectional, inclusive, culturally tailored, and co-equal and has shared governance to build trusting relationships. When developing a public health campaign, the work should be cocreated and ongoing. Our goals are to *strengthen community partnerships and alliances* and *expand our knowledge* through bidirectional learning (eg, listening to community members and learning from them about their experiences and needs will guide our work), with the goal of being able to develop effective, resonant, and community-ready messages, strategies, and tools. We will be able to succeed through the sustained relationships that are developed through this process, which includes a diverse and inclusive community advisory board (CAB). VaccinateLA intends to develop culturally tailored evidence-based messages and a multimedia digital educational campaign and launch education and field-based activities to *improve the health of our targeted communities*. Trust and shared power will help guide this community-based, community-partnered initiative, resulting in our ability to promote *thriving communities*. By engaging multiple communities and key stakeholders, we can increase community connectivity and the capacity to develop and sustain beneficial public health programs that address physical and mental health, ideally improve quality of life and overall well-being, and ultimately support and enable community resiliency

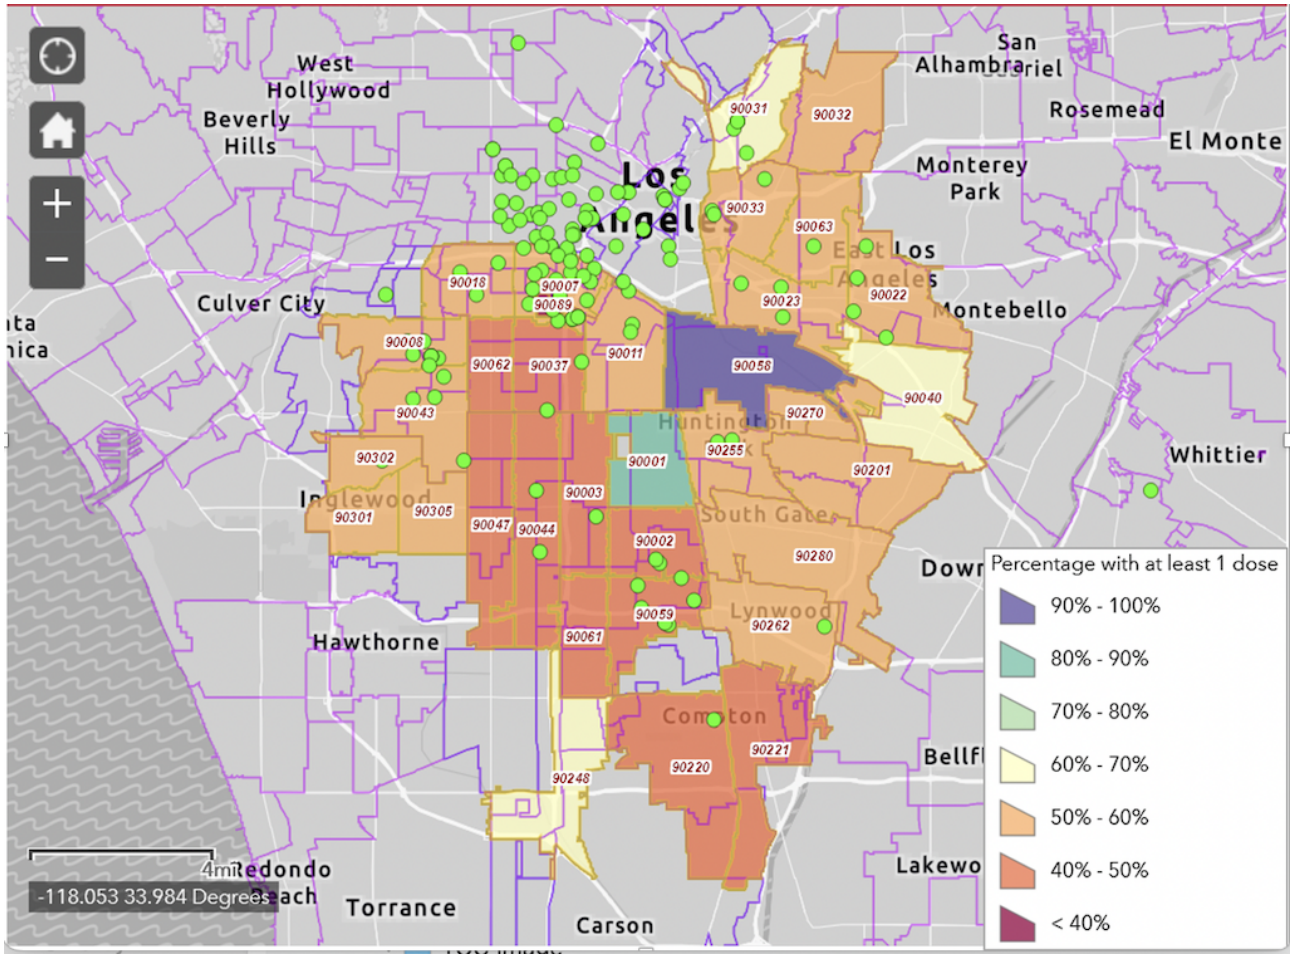
Figure 1. Conceptual model, titled VaccinateLA Public Health Campaign: Building Health Equity Through Community Engagement.



Description of Our Targeted Communities and Populations

Community Overview

Los Angeles County is a large and diverse county that is more populous than 42 states in the United States. In Los Angeles County, 185 languages are spoken and 42% of residents are Spanish speakers [6]. Given the sheer size of Los Angeles County, we plan to target the campaign to communities with the highest rates of infection and the lowest vaccination rates. Using these criteria, we identified 34 zip codes located in the Eastside and South Los Angeles. A map of neighborhoods in these zip code areas (based on vaccination rates from May 2021) is shown in Figure 2. The goal will be to work closely with existing partners and forge new partnerships in these same communities. The campaign will target to five distinct segments of the population: (1) Latino and Black residents of South Los Angeles; (2) Latino and Black residents in the Eastside of Los Angeles; (3) members of the lesbian, gay, bisexual, transgender, and queer (LGBTQ+) community; (4) parents of school-age children, both vaccinated and unvaccinated; and (5) community health workers in Spanish-speaking communities, called *promotores de salud*.

XSL•FO
RenderX

Figure 2. VaccinateLA map of targeted zip codes and vaccination rates. The green dots represent our 160 community partners.

South Los Angeles Community

This area has historically been predominantly Black; however, approximately 28% of current South Los Angeles residents are Black. Low-wage, temporary jobs are common in this area, as is poverty and unemployment [7].

East Los Angeles Community

East Los Angeles is historically a predominantly Latino area, and approximately 96% of current residents in this area identify as Hispanic or Latino. Spanish is the first language for most residents aged 5 years and older [8]. The median household income is just over US $46,000, and approximately 20% of the population live at the poverty line [8].

Parents

The pandemic's effect on parents included hardships such as facilitating online learning, new safety measures at school, and an overwhelming amount of information about vaccine and booster eligibility. Balancing multiple priorities at work and at home, caring for sick family members, and experiencing loss and unemployment also take a toll.

LGBTQ+ Community

The LGBTQ+ community is also facing challenges and barriers to getting vaccinated. In California, 5.3% of the population identify as gender and/or sexual minority individuals [9]. Reliable statistics for county-level data could not be identified. These individuals regularly experience challenges in accessing medical care, are often stigmatized and discriminated against, and experience high rates of violence [10].

Community Health Workers

Our final group of interest is *promotores de salud* [11]. We will partner with an organization, called Vision y Compromiso, which provides comprehensive and ongoing leadership development, capacity building, advocacy training, and support to over 4000 *promotores* throughout the State of California and in a region within Mexico [12]. We will conduct a focus group with *promotores* to understand the challenges that local communities experience during the pandemic.

VaccinateLA Public Health Campaign Strategies

As a starting point, we will first establish a CAB and then initiate a *listening tour* using a semistructured interview guide to listen to and learn from the community. Then, in partnership with the community, we will develop and deliver a combination of *educational* (town halls and workshops), *multimedia* (radio, local newspapers, social media campaigns, and project website), and *field-based activities* (pop-up vaccination clinics, deployment of a cadre of embedded community workers, and restorative circles). The following provides a description of each of these activities, the sequencing of which can be found in Table 1.

[a]✓: denotes the timepoints at which these activities will be completed.

Establishing a CAB

The CAB will consist of 10-15 members, including trusted and respected community leaders, social service providers, and residents from our targeted communities. The CAB will include both men and women and a diverse racial/ethnic representation; the CAB will be chaired by a member of the board. The CAB will meet virtually on a monthly basis or more, based on what is needed. CAB members will receive an electronic gift card in the amount of US $25 to compensate them for their time and effort. The aim of the CAB is to provide valuable insight and important feedback to inform our outreach activities, multimedia educational materials, and dissemination strategies. CAB members will also help introduce us to new community partners and provide guidance on how to liaise with the community. Representatives from the Los Angeles County Department of Public Health and the Los Angeles Unified School District will also be invited to serve on the CAB.

Focus Groups to Listen to and Learn From the Community

We will begin by conducting a series of focus groups with various segments of the community to understand sources of concern, vaccine hesitancy, and barriers to becoming vaccinated. We will then conduct additional focus groups to inform our educational campaign. These focus groups will be conducted with various segments of the population, including community leaders and key stakeholders, young adults, older adults, members of the LGBTQ+ community, parents of vaccinated and unvaccinated children, community health workers in the Latino community (ie, *promotores de salud*), and community residents from 2 large public housing developments.

We plan to conduct a total of 40 to 45 focus groups, each with 7 to 8 participants. These focus groups will be conducted in both English and Spanish depending on the primary language of the participants. The groups will be conducted virtually using a semistructured interview guide with questions that focus on barriers, misinformation, and experiences at vaccination sites. These sessions will last 60-120 minutes. Following each session, discussions and comments will be transcribed, deidentified, and coded by researchers trained in qualitative research. Findings will then be summarized to inform real-time, culturally tailored educational campaign messages. Focus group participants will receive US $50 to compensate them for their time and effort.

Educational Activities

Town Halls

A series of virtual townhall events for community members will be delivered. The format will be to have 1 or 2 guest speakers offer short presentations (approximately 10 minutes), followed by up to 60 minutes for questions and answers. Our guest speakers will include trusted community leaders, local physicians, pediatricians, and other health care providers. Guest speakers will provide up-to-date information about the pandemic, infection rates in local communities, and the safety and efficacy of available vaccine/boosters. Information about available resources will also be presented (eg, how and where to access vaccinations/boosters). Town hall events will also be offered to specific segments of the population, including parents of children eligible for the vaccine and booster, Spanish-speaking parents, members of the LGBTQ+ community, and congregations within the faith community. We will advertise and promote these events through email listserves, targeted outreach to community partners, flyers, and social media. The flyer will include information about how to RSVP online, as well as how to submit questions in advance of the event. After each townhall event, we will develop frequently-asked-question sheets based on the questions asked by the community.

XSL•FO
RenderX

Workshops

Educational workshops will be offered virtually to smaller groups, allowing for more focused discussions as well as more time allotted to address attendees' questions/concerns. These workshops will be delivered by *promotores* on our staff. Workshops will be offered multiple times per week and regularly updated to reflect the most recent data and information regarding vaccine and COVID-19 regulations and requirements. Due to the skills and background of our *promotores*, workshops can be developed quickly to meet the evolving educational needs of the community. Attendees will be asked to provide feedback after each workshop to help inform future workshop topics.

Multimedia Digital Educational Campaign

Overview

We will work with local artists, content creators, and film makers to develop and produce a variety of still images and messages for social media, public service announcements (PSAs), brief #ShareYourWhy testimonial videos, short films, and a fotonovela. In addition to partnering with the local community, we will also be partnering with Wondros, a creative design and production agency, to help us craft engaging messages to address common fears, misinformation, and questions about the safety and efficacy of the vaccines. Once developed, we will solicit input from community leaders and CAB members before the products are disseminated. With each product, individuals will be directed to the VaccinateLA website for more information [13]. Most importantly, the website will also include links to additional information and resources, such as a list of local vaccination sites, a link to make a vaccination appointment, and a way to request assistance from a vaccine navigator. The following provides more information about the planned multimedia campaign.

Print and Digital Fotonovela

We will work with the USC Mann School of Pharmacy and Pharmaceutical Sciences to develop a bilingual fotonovela entitled *Infectious Rumors*. We will partner with La Opinión, a popular local newspaper, to print and distribute 40,000 copies to their subscribers as an insert in their paper; an additional 10,000 copies will be distributed to community partners, pediatric offices, and schools and at vaccine pop-up clinics. Fotonovelas are print versions of telenovelas, which use storytelling as an educational tool and are popular among Latino populations [14].

Culturally Tailored Short Films

We will partner with the USC's Annenberg School for Journalism and Communication and USC School of Cinematic Arts to produce two 8-minute films. These will be coproduced and directed by local Black and Latino filmmakers, who will assist with storyboarding, planning, filming, and editing. One film, called *Happy Birthday Granny*, will feature a birthday celebration of a Black family. A second film, called *Of Reasons and Rumors*, will feature 2 young Latinas discussing rumors and misinformation associated with the vaccine (in both English and Spanish). Both films will use the art of storytelling as an approach to deliver evidence-based information about COVID-19, routes of transmission, and the safety and efficacy of the vaccine, as well as to address common misinformation and disinformation about COVID-19 and the vaccines. The videos will be posted on the VaccinateLA's website, on project-dedicated YouTube and Vimeo accounts, on social media accounts created for VaccinateLA, and with organizations such as the American Association of Public Health and the National Alliance for Hispanic Health with its 15 million Latino members nationwide.

#ShareYourWhy Testimonials

Local leaders, community members, physicians, nurses, and pediatricians will be asked to share their experiences and reasons for why they chose to be vaccinated; these testimonials will be recorded and edited into short 1-minute videos, called #ShareYourWhy. The #ShareYourWhy videos will be produced by a local video production and editing company, called Everyone Can Eat.

PSAs

We will partner with USC's Hollywood, Health & Society to produce multiple PSAs. USC's Hollywood, Health & Society will also partner with LifeNoggin, to develop an animated video to be titled, *What if everyone got the COVID vaccine?* LifeNoggin is a YouTube channel that uses animation to deliver scientific content to its more than 3.26 million subscribers.

Social Media Campaign

The VaccinateLA team, with assistance from Wondros and Everyone Can Eat, will launch a full-scale social media campaign on Facebook, Instagram, Twitter, and YouTube. We will create original content in both English and Spanish using still images, reels, and short videos with captions and video end cards directing individuals to our website to learn more or schedule an appointment. Data analytics will be reviewed to ensure we successfully reach our targeted audiences

Field-Based Activities

Pop-up Vaccination Clinics

We will partner with the USC Mann School of Pharmacy and Pharmaceutical Sciences, to offer pop-up vaccination clinics in locations chosen by the community (eg, church parking lots, health fairs, local YMCAs, places of employment, and other local venues). At pop-up clinics, we also will host food banks, back-to-school backpack distributions, and tables with information and access to resources such as housing assistance and employment. We will coordinate with social services, such as Women, Infants, and Children and rent relief resources, to distribute essential products such as diapers, personal protective equipment, and personal hygiene and household products such as detergent and shampoo. In addition, we will provide preventive health screenings such as blood pressure screenings and wellness counseling. Members of our team and CVNs will staff these events. Toolkits with advice on how to replicate such pop-up vaccine clinics will be developed and available on the VaccinateLA website.

CVNs in Targeted Communities

We will train and deploy community-embedded health workers and *promotores* to be CVNs in our targeted communities. This

XSL•FO
RenderX

virtual training will involve 6 to 8 hours of teaching and instructor-led educational content over multiple days, culminating in a 4.5-hour experiential field training. CVNs will learn about COVID-19 transmission, risk mitigation, how to identify and refer people to credible sources, vaccine efficacy, and how to schedule vaccine appointments on someone's behalf. At the end of their training, each CVN will receive a toolkit to reinforce the training. In South Los Angeles, we will partner with the Southern California National Council of Negro Women, Inc. to deploy CVNs. We will be partnering with Vision y Compromiso to train and deploy CVNs in our targeted Latino communities.

Restorative Circles

We intend to conduct in-person restorative circles facilitated by community partners with Black men aged 18 to 35 years and individuals who identify as LGBTQ+. A restorative circle is an intentional gathering of people who have a shared, often traumatic or painful, experiences. These circles serve as a safe space for sharing struggles and expressing grief and trauma, ideally providing a path to healing and connection with others who may have had similar experiences. They are designed to address the longstanding historical trauma and pain around topics such as medical and institutional racism and police brutality against people of color and gender and sexual minority groups, which have worsened and been made more visible during the pandemic. Meals will be provided, and each participant will be offered a parting gift designed by the facilitator, such as journals, pens, and additional information about self-care, mental health, and domestic services in the Los Angeles area.

Ethics Approval

Data collection protocols for the proposed qualitative focus group interviews have received approval from Children's Hospital Los Angeles' Institutional Review Board (CHLA-21-00152). All participants will be identified through community outreach; screened for eligibility; and if eligible, invited to participate. All participants will provide written informed consent using DocuSign during a virtual consenting visit with project staff. Participants will be consented in both English and Spanish and will be provided a hardcopy of their signed consent form.

Results

As of February 2023,target communities have been identified. The activities will be initiated and evaluated over the course of this year-long initiative, and dissemination will occur following the completion of the project. The activities will be sequenced according to the project timeline in Table 1.

Discussion

Universities are in a unique position to leverage their immense resources and partner with local communities to respond to emerging community and public health crises [15]. This is especially true in underresourced urban communities [15]. To build trust, it is critical to develop meaningful partnerships with local leaders and other key stakeholders. It is through these partnerships and authentic community engagement that public health messages can be developed and delivered in a culturally tailored and culturally responsive way [16].

Our work and the VaccinateLA campaign will build upon a growing literature that describes best practices to forging academic-community partnerships. This literature demonstrates that local communities welcome the opportunity to partner with academic, health, and public health institutions if the goal is to improve community health [16,17]. Moreover, our work will be grounded in a framework recently developed by the National Academy of Medicine [5].

VaccinateLA will be a true academic-community–partnered initiative designed to respond to a public health crisis. A crucial first step will be to listen to and learn from the community. Findings from a variety of data-gathering activities (ie, focus groups, feedback during workshops, and the CAB) will in turn be analyzed and used to help determine *who the right messengers are*, *what are the right messages*, and *how these messages should be delivered* to reach individuals living and working in our targeted, high-impact communities. We will evaluate this effort to determine if VaccinateLA's educational and multimedia campaigns were successful at reaching our intended audience, encouraging individuals to become vaccinated, and if CVNs and field-based activities helped to reduce practical barriers to becoming vaccinated. Ultimately, we hope to demonstrate that VaccinateLA did successfully increase rates of vaccinations in our targeted communities.

It is our hope that the proposed VaccinateLA initiative might also have important implications for other public health campaigns. Indeed, we believe that VaccinateLA will serve as a model for how academic institutions can quickly mobilize and respond to a pressing public health crisis, particularly in underrepresented and underresourced communities. Additionally, we hope to demonstrate that such an academic-community partnership can successfully engage with and be responsive to the local needs in underresourced communities. Furthermore, it is our hope that VaccinateLA will serve as a model for how to develop and deliver culturally tailored evidence-based messages that might also be generalizable and potentially used to address other acute public health crises and chronic health conditions (eg, cancer screening, diabetes prevention and care, and asthma prevention).

Abstract

Background: Improving childhood health is complex due to the multifactorial nature and interaction of determinants. Complex problems call for complex intervention thinking, and simple one-size-fits-all solutions do not work to improve childhood health. Early awareness is important, as behavior in childhood often is manifested across adolescence and into adulthood. To facilitate shared understanding of the complex structures and relationships that determine children's health behavior, participatory system approaches in, for example, local communities have shown promising potential. However, such approaches are not used systematically within public health in Denmark, and before being rolled out, they should be tested for their feasibility within this context.

Objective: This paper describes the study design for Children's Cooperation Denmark (Child-COOP) feasibility study that is aiming to examine the feasibility and acceptability of the participatory system approach and the study procedures for a future scale-up controlled trial.

Methods: The feasibility study is designed as a process evaluation of the intervention with the use of both qualitative and quantitative methods. A local childhood health profile will provide data for childhood health issues, for example, daily physical activity behavior, sleep patterns, anthropometry, mental health, screen use, parental support, and leisure-time activities. Data at system level are collected to assess development in the community, for example, readiness to change, analysis of social networks with stakeholders, rippled effects mapping, and changes in system map. The setting is a small rural town in Denmark, Havndal, with children as the primary target group. Group model building, a participatory system dynamics method, will be used to engage the community, create consensus on the drivers of childhood health, identify local opportunities, and develop context-specific actions.

Results: The Child-COOP feasibility study will test the participatory system dynamics approach for intervention and evaluation design and survey objective measures of childhood health behavior and well-being among the ~100 children (6-13 years) attending the local primary school. Community-level data will also be collected. We will assess the contextual factors, implementation of interventions, and mechanisms of impact as part of a process evaluation. Data will be collected at baseline, at 2 years, and 4 years of follow-up. Ethical approval for this study was sought and granted from the Danish Scientific Ethical Committee (1-10-72-283-21).

XSL•FO
RenderX

Conclusions: s: The potential of this participatory system dynamics approach includes opportunities for community engagement and local capacity building to improve children's health and health behavior, and this feasibility study holds the potential to prepare an upscaling of the intervention for effectiveness testing.

Introduction

Children's health and well-being are of great concern worldwide [1], with decreasing levels of physical activity, more sedentary time, emerging rates of childhood obesity, and more children living with mental health problems [1-5]. Childhood health is closely related to the socioeconomic status of the family, for example, children raised in families with low socioeconomic status more often have mental health problems, obesity, and a sedentary behavior [2,3,6]. Several studies suggest that it is possible to improve childhood health despite inequalities in health [2,3,7-10], and early interventions have shown to be important in childhood health promotion [11]. Childhood health is a result of a complex interplay between many factors at individual, family, and society levels. Hence, declining childhood health must be viewed as a complex problem and calls for multilevel interventions and broader societal awareness [12]. Within childhood obesity, interventions building on community-based participatory research, and system dynamics have shown promising results in addressing complex health problems of children [13] by involving whole of communities in complex problem-solving at multiple levels of actions. Researchers have highlighted such participatory and system dynamic approaches as a potential way forward [14,15], addressing complex health problems in communities [13,16].

However, before applying a full-scale participatory system dynamics intervention in Denmark, feasibility testing is needed to underpin decisions about whether or not and how to progress [16]. The 2021 Medical Research Council (MRC) framework for complex interventions stresses the importance of considering the phases of intervention development in an iterative manner, from development, testing, and evaluating to implementation of interventions. Moreover, it identifies important core elements such as context, engage stakeholders, and development of a program theory [16].

Building on Australian experience with the participatory system dynamics approach [13] and the MRC framework as guidance [14], this paper describes the Children's Cooperation Denmark (Child-COOP) feasibility study design that is aiming to examine the feasibility and acceptability of the participatory system dynamics approach [17] and the study procedures intended for a future larger scale-up controlled trial.

Methods

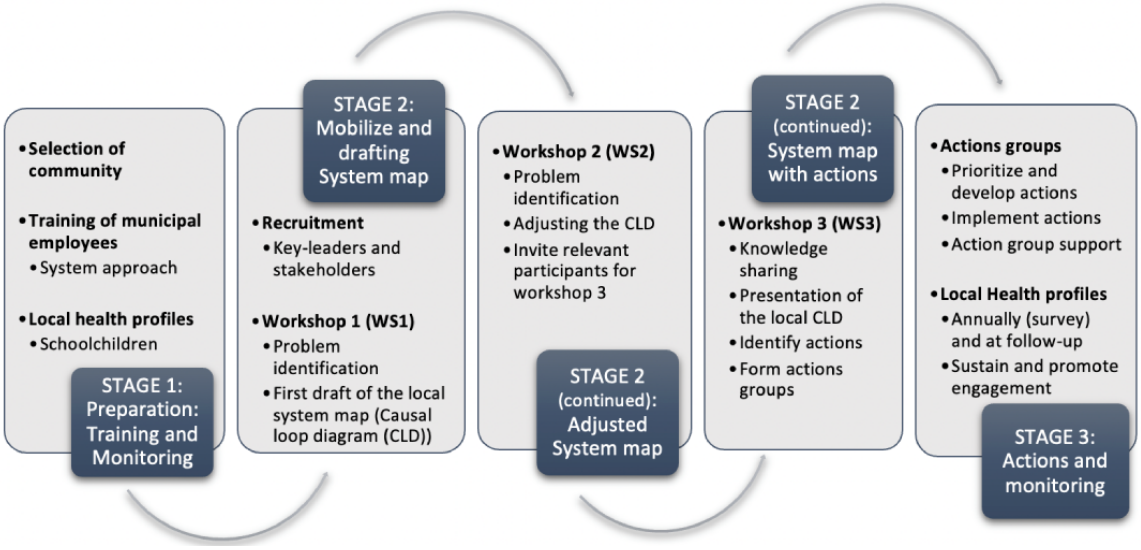
Design

The Child-COOP feasibility study will apply a participatory system dynamics approach, and the MRC framework [16] informs the design of the feasibility study and guidelines for applying feasibility studies [18]. As suggested by the MRC, feasibility studies should be designed to assess the intervention and evaluation design.

The Community

The Child-COOP feasibility study will be tested and evaluated in a small community in a rural town area (Havndal) with approximately 900 citizens, located in the northeastern part of a large Danish Municipality, Randers. Including the surrounding area, the local community consists of approximately 2000 citizens. The community holds an integrated school and kindergarten "The Child Village" with approximately 100 children in grades 0 to 6 and approximately 40 children in the kindergarten. A few shops such as a local fitness provider, leisure-time sport provider, and a relatively small business environment exist within the area.

Populations



The target population is primary school–aged children (grades 0 to 6, 6-13 years of age; n=110), and all children attending the local primary school will be invited to participate in the health monitoring (described later in "Childhood Health: Outcome and Data Collection" section). Another target population is the key stakeholders of the local community, the local stakeholders, and municipality leaders and staff working within the community. These could include local politicians, grocery owner, chairperson of sports clubs, school board leader and members, local parents (with children at the school), leader of the municipality health department, and other municipality leaders, among others. The town of Havndal is one of the areas in Randers Municipality with the lowest social class and highest unemployment rate.

Intervention

The Child-COOP feasibility study will apply a participatory system dynamics approach and consists of several elements illustrated in Figure 1 and described in the following sections.

XSL•FO
RenderX

Figure 1. Illustration of the participatory system dynamics approach including the group model building processes. CLD: Causal loop diagram.

Monitoring

A local childhood health profile will be generated at baseline, for example, daily physical activity behavior, sleep patterns, anthropometry, mental health, screen use, parental support, and leisure-time activities (Table 1).

XSL•FO
RenderX

Table 1. Outcome measurements at child level in the Children's Cooperation Denmark feasibility study.

Concept	Outcomes of interest	Instrument or measure	Method	Data collection
Anthropometry	• Height • BMI • Fat mass • Prevalence of overweight	• Tanita Leicester transportable height measure • InBody 230 multifrequency body composition (bioelectrical impedance analysis)	Individual measurement	Examination at baseline and after 2 and 4 years
Physical activity and sedentary behavior	• Minutes per day spent on moderate and vigorous physical activity and sedentary activity • Minutes per day spent on • Step counts	• Accelerometer (Axivity AX3)	Individual measurement	7 days at baseline and after 2 and 4 years
Physical literacy	• Motivation and confidence • Physical competence • Daily behavior • Knowledge and understanding	• A Danish version of the Canadian Assessment of Physical literacy	Individual measurement of physical competence (including motor skill test, aerobic capacity run, and torso strength test) and daily behavior (self-report weekly participation in moderate- to vigorous-intensity physical activity and objectively measured average step count for 1 week). Survey of motivation or confidence and knowledge or understanding.	Baseline and after 2 and 4 years
Mental health	• General well-being • Social relations—peers • Loneliness • Bullying • Stress	• Børnungeliv.dk	Survey	Baseline and after 2 and 4 years
Sleep	• Hours of sleep • Time of sleep week days or weekends • Quality of sleep • Use of electronic devices	• Børnugeliv.dk and accelerometer (Axivity AX3)	Survey and individual measurement	Baseline and after 2 and 4 years
Leisure time	• Participation in sport and other activities • Use of computer, tablet, and other electronic devices	• Børnungeliv.dk	Survey	Baseline and after 2 and 4 years
Body and movement	• Active transport to school • Time spent on physical activity in school • Frequencies of high-intensity activity • Physical fitness level • Facilities for sports and play in the neighborhood • Body satisfaction	• Børnungeliv.dk	Survey	Baseline and after 2 and 4 years
Food and meals	• Breakfast, lunch, and dinner • Cooking at home • Intake of fruit and vegetable, sugar-sweetened beverage, candy, and cake	• Børnungeliv.dk	Survey	Baseline and after 2 and 4 years

XSL•FO
RenderX

Concept	Outcomes of interest	Instrument or measure	Method	Data collection
Family relations	• Siblings • Country of origin (child and parents) • Relation to parents • Place of residence	• Børnungeliv.dk	Survey	Baseline and after 2 and 4 years

Recruitment of Key Leaders and Local Stakeholders

A coordinator from Randers Municipality together with the research team identify and recruit key leaders (eg, local politicians, department heads, and municipality leaders) and local stakeholders (eg, school board members, school principal, school nurse, and sport club representatives). Key leaders and local stakeholders will be selected based on the authority and capacity to initiate actions that are likely to influence the children's health behavior across sectors and organizations. During this stage, key leaders must commit to allocating resources to ensure subsequent implementation. The aim is to recruit 12-15 key leaders and local stakeholders from the community.

Group Model Building Process and System Mapping

A total of 3 group model building (GMB) workshops (WS1, WS2, and WS3) will be held during the 3 stages of the process (see Figure 1). The GMB method is an evidence-based method for solving complex challenges [13]. During WS1, the local childhood health profile will be presented, and based on this information, key stakeholders will discuss what health-related topic they find most important to their community (eg, obesity, physical activity, and mental health). In WS1 and WS2, the key leaders and stakeholders will map the system by creating a causal loop diagram (CLD) to understand how the perceived local system affects the prioritized childhood health topic in their community. For developing the CLD, the web-based software tool Systems Thinking in Community Knowledge Exchange (STICKE; version 3.0.14; Deakin University) was used [13]. STICKE stands for Systems Thinking in Community Knowledge Exchange and is developed to facilitate community knowledge exchange to foster shared understanding of complex problems.

In WS3, all community members willing to engage in changing the local system will be invited to identify priority areas for action based on the developed CLD from WS1 and WS2.

Actions and Support

The output of WS3 is the formation of local working groups that will focus on implementing the chosen actions using cocreation ideals [13]. The working groups will be supported and supervised by a backbone office formed by the Child-COOP municipality coordinator and the research team. A follow-up workshop will be held with the key stakeholders 6 months after the completion of WS3 to review the consolidated priority actions. To increase and maintain motivation and actions in the local community, subsequent follow-up meetings will be held with the working groups when needed after WS3.

Assessment of the Evaluation Design

The feasibility study of the evaluation design for Child-COOP will involve multiple levels and perspectives with a focus on key aspects such as recruitment, data collection tools and processes, analysis, and unintended outcomes [16]. In Child-COOP, the evaluation design will include both quantitative and qualitative methods. The evaluation design includes (1) evaluation of childhood health and (2) evaluation of community readiness to change, social network, actions implemented, and system changes.

Child-COOP will be considered feasible if it meets the following criteria: (1) The GMB sessions were conducted as planned. (2) Working groups are formed and active in implementing interventions arising from GMB. (3) Outcome measures were collected and considered complete (>75% considered acceptable at baseline). (4) Response rate considered acceptable (>75% considered acceptable at baseline).

Childhood Health: Outcome and Data Collection

Overview

All measurement instruments are listed in Table 1 and briefly explained. The measures will be conducted over 2 test days at the local school to assess the health of the children and test the data collection procedure. On day 1, children in grades 4, 5, and 6 are invited to participate, and on day 2, those in grades 0, 1, 2, and 3 are invited to participate. All children available on the day of data collection, whose parents have given written consent, will be included. A team of trained data collectors will collect the data on the test days with assistance from the class teachers. The longitudinal design makes it possible to study the changes over time within the local community, with limited effectiveness testing due to the limited power, as this is a feasibility study.

Anthropometry

All included children will have height, weight, and fat mass measured, wearing light clothes and barefoot, by the school nurse (Table 1).

Physical Activity and Sedentary Behavior

Physical activity and sedentary behavior will be measured continuously over a 7-day and -night period using Axivity AX3 accelerometers (Table 1). The accelerometer will be attached to the skin on the medial front of the right thigh using skin tape. The procedure is described in detail elsewhere [19]. The accelerometer is water-resistant, and the skin tape is intended to be water-resistant; thus, the accelerometer can be worn when swimming and bathing. The OMGui software (version 1.0.0.43; GitHub Inc), which is available on the internet, will be used for instrument initialization and data download [20].

XSL•FO
RenderX

Physical Literacy

The Danish version (DAPL) of the Canadian Assessment of Physical Literacy [21] will be used to measure physical literacy for children in grades 1 to 6 [22]. Grade 0 children will not be included in the assessment tool and have neither been used nor validated, as we consider these children too young for the assessment [22].

Self-reported Health and Well-being

The children will fill a questionnaire at school with assistance from their teacher and trained data collectors, more questions for children in grades 4 to 6 and less for children in grades 0 to 3. The parents will also fill a questionnaire about their child's health and well-being with more questions for children in grades 0-3 and less for children in grades 4-6.

We will use a Danish-validated questionnaire instrument (Danish: BørnUngeLiv, English: ChildYouthLife) developed by researchers and practitioners from the municipalities to use in the municipalities of Denmark to assess the health and well-being of children [23]. Topics that will be covered in the questionnaires are mental health, sleep, leisure-time activities, body and movement, food and meals, and family relations (see Table 1).

System Level: Outcomes and Data Collection

Data at system level will be collected continuously from baseline and with 2- and 4-year follow-up. All outcomes and measurement instruments are listed in Table 2 and briefly explained.

Table 2. Community outcome measurements in the Children's Cooperation feasibility study.

Item	Outcomes of interest	Instrument or measure	Method	Data collection
Readiness to change	Baseline and change in: • Community knowledge about child obesity • Existing community efforts • Community knowledge of the efforts • Leadership • Community attitudes • Resources related to child obesity	• The community readiness model	• One-to-one interviews	• 12 interviews of 45-75 minutes • Collection before WS1[a] • 1-year follow-up
Social network	Strength and importance of relationships • Density • Centrality • "Opinion leader" And change over time	• Social network dynamics	• Survey • Semistructured interviews	• Survey delivered to stakeholders • Collection before WS1 • 1-year follow-up • 2-year follow-up
Actions implemented	• Number of actions implemented • Place of influence within the CLD[b] • Stakeholders	• REM[c] • Add action variables within system dynamics software (STICKE[d])	• Ongoing communication with working groups after WS3[e] • Semistructured interviews with working group leaders	• Using REM as a method to track actions developed • 1-year follow-up • 2-year follow-up • 4-year follow-up
Change in system maps	• CLD	• CLD using STICKE	• Monitoring CLD • Focus groups • Adjustment of CLD	• CLD at WS3 • Collection of focus groups at • 2-year follow-up • 4-year follow-up • Based on focus groups

[e]WS3: workshop 3.

Readiness to Change

To assess whether changes occur in the community's readiness and capacity for making system changes, we use the community readiness model [24] forward-and-back translated to Danish [25]. Community capacity and readiness here refer to a "community's ability to identify, mobilize and address public health problems" [26]. Responses will be used to measure the changes in community capacity by scoring the descriptive responses on anchored scales [24,25]. Data will be collected

XSL•FO
RenderX

from key leaders in the community including school principal and staff, local government leaders, parent representatives, among others. It is hypothesized that Child-COOP will change the readiness to change in the local community.

Social Network Analysis

Social network analysis will be used to assess the development of relationships between people and organizations [27]. Social network analysis can calculate network statistics including density and centrality and "opinion leader" positions [13]. Furthermore, social network dynamics will be applied with longitudinal network models in mind to determine how the networks change over time and the role of the network in the diffusion information, knowledge, and practice [28]. Data will be collected using the COMPACT Stakeholder-driven Community Diffusion Survey [29] adapted to a Danish context. It is hypothesized that Child-COOP will change and connect more people within the community's social networks.

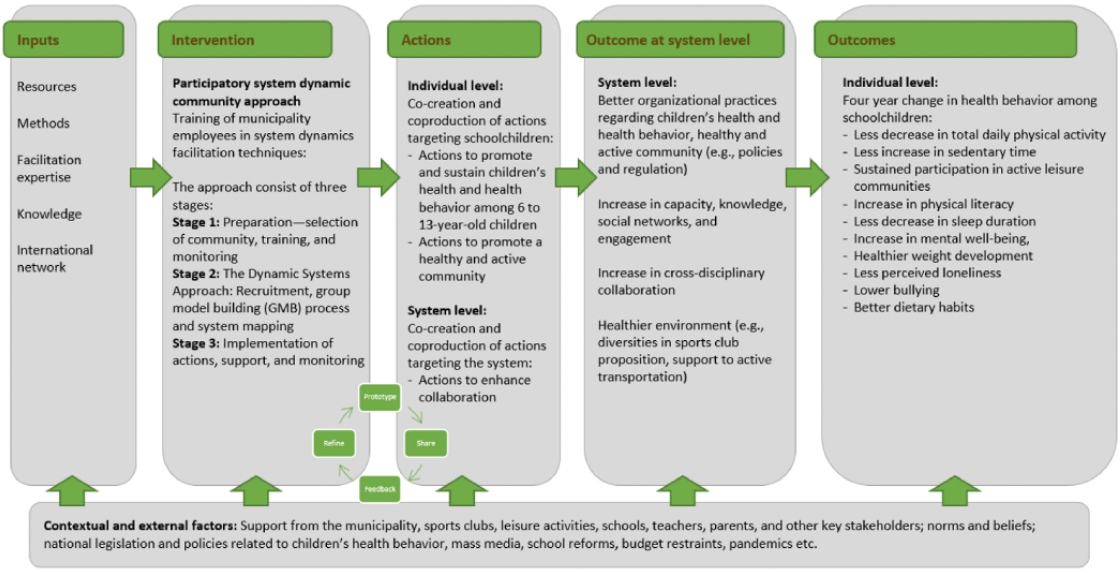
Actions Implemented

Proxy indicators of system change will be actions initiated by the community, and these will be monitored from baseline and followed up annually using the STICKE software [30]. The number of community actions will be tracked as proxies of community-level engagement [13]. Semistructured interviews with working group leaders will also be used to understand and provide deeper information on the actions implemented (eg, goal, content, and setting) [31]. To track the actions developed and implemented in the local community, we will use "ripple effect mapping" (REM) [32]. REM is a method used to better understand the complex, dynamic nature, and wider impacts of system dynamics intervention [33]. Unlike traditional evaluation designs, REM is aimed at understanding contribution; how may an intervention, action, or policy contribute toward changing a larger system? [32-34] During the workshops, participants (stakeholders, citizens, municipality employees, etc) visualize the impacts of the actions and how these impacts may go beyond those, which Child-COOP was designed to achieve [32].

Change in System Map

Tracking of change in the CLD and the communities' responses to the participatory system dynamics approach will be monitored through a revised system map at 2 and 4 years post the initial CLD [13]. The STICKE software [30] will be used to track changes in the system and the interaction among key actors, actions, and the system.

Assessment of the Intervention: Process Evaluation



The process evaluation aims to understand the functioning of an intervention by examining mechanisms of impact, implementation, acceptability, and context.

Through analyses, crosscutting qualitative and quantitative results on the implementation (adherence, dose, quality of delivery, participant responsiveness, and reach), mechanism of impact, acceptability, and context will be synthesized to gain knowledge on how the participatory system dynamics approach was delivered and implemented and inform a final program theory.

Mechanism of Impact

What are the change mechanisms for Child-COOP and how do they align with program theory? These questions will be addressed through 12 semistructured interviews with key stakeholders and the municipal coordinator, addressing the research questions: *What are the mechanisms of change associated with the participatory system dynamics approach? What hinders or enables implementation of the participatory system dynamics approach?* Our program theory is a tentative developed program theory for the overall study (see Figure 2), while the developed CLD will be considered a form of logic model [16].

Figure 2. Child-COOP tentative program theory for feasibility study in Havndal, Denmark. Child-COOP: Children's Cooperation Denmark.

XSL•FO
RenderX

Implementation

What is delivered in Child-COOP? Here, we aim to understand how the "implementation" is done locally in the community assessing (1) fidelity (is the participatory system dynamics approach delivered as intended?); (2) dose (who is reached by the participatory system dynamics approach and to what strength?); (3) adaptions (have any significant changes to the participatory system dynamics approach been made?); (4) reach (how many are part or affected by the participatory system dynamics approach?); and (5) process (understanding the implementation process?). These elements are sought to understand through structured observations by registration and participation (number of participating stakeholders or established working groups or initiated actions) and a questionnaire for stakeholders.

Acceptability and Context

How is "acceptability" of the Child-COOP approach among the participants? Through 12 semistructured interviews with key stakeholders and participants, we will collect data aiming to understand the following: *How do participants involved in workshops and implementation of actions react to and engage in the Child-COOP approach?* Furthermore, we aim to conduct follow-up phone interviews with dropout key stakeholders to provide a realistic perspective.

Ethics Approval

This study will be carried out in accordance with the Declaration of Helsinki. Ethical approval for the study has been granted by The Regional Scientific Ethics Committee of the Central Denmark Region, Danish National Committee on Health Research Ethics (1-10-72-283-21). Any protocol amendments will be reported and submitted to the Ethics Committee. Anonymity and confidentiality of participants will be ensured by assigning a study ID number to all participants. Informed consent will be obtained from parents in order to include the children in the health assessments. No results of the anthropometric measurements will be visible to, or available for, the children to reduce risk of the bullying and stigmatizing.

Consent for Publication

Informed consent will be collected from parents on behalf of the children taking part in the study. Informed consent will be collected from all participants in the workshops.

Results

The Child-COOP feasibility study has officially started with baseline measures in September 2021, recruitment of participants and delivery of the GMB phase started in 2021-2022. The 2-year follow-up will be the next step and will reveal the first results of the study—this is expected in 2023. Furthermore, process evaluation is underway and will be concluded at the 2-year follow-up in 2023. The project will conclude with the 4-year follow-up, which will provide the final results—these are expected in 2025. In September 2022, a large grant was given for the Child-COOP Denmark project, focusing on children's physical activity behavior. This project will include 5 municipalities and 10 communities, building on the experiences of the Child-COOP feasibility study. It will begin immediately after the conclusion of the process evaluation of the Child-COOP feasibility study in late 2023 or early 2024.

Discussion

Expected Findings

The Child-COOP feasibility study will provide new knowledge on the potential to implement a participatory system dynamics approach targeting childhood health in a Danish context. Childhood health is a complex health problem and evidence points to system science as one of the best means of identifying and addressing such complex and dynamic problems [13]. The approach will be tested out in a small disadvantaged community in Denmark, and therefore, it may be applicable in similar settings upon a positive feasibility assessment.

Strengths of the Study Design

Interventions building on a participatory system dynamics approach as Child-COOP have already been suggested as a feasible way to address complex problems, as they combine the current evidence base on prevention, best practice, and local wisdom to achieve new knowledge and create solutions [16,34]. The participatory system dynamics approach in Child-COOP based on the co-creation and close collaboration between the municipality, community, and facilitating research team will most certain be a strength of the Child-COOP feasibility study. In addition, this study builds upon existing evidence and shows a positive effect of a participatory system dynamics approach in improving the childhood health and obesity rates [13]. Furthermore, to investigate the complex relationship of childhood health drivers in the community, the active involvement of the local community in mapping, developing action plans, and maintaining the efforts may provide sustainability and empower the local community [13]. The extensive evaluation design using multiple methods for data collection at the individual level as well as the system level also serve as a strength of this study.

Potential Challenges

Potential challenges of the study include the long-term engagement of the local community, which may decline over time; however, this feasibility study will provide insight into the magnitude of the support from the research team, local leaders, or coordinators to develop, facilitate, and support the working groups to continue to implement and adjust actions in their local community. Moreover, a potential challenge is that the community will not take the chance to change and influence the local system affecting the health and well-being of the children.

In addition, external factors may challenge the implementation of the intervention, for instance, the COVID-19 pandemic or local and municipality economic challenges. However, the participatory system dynamics approach is flexible and can be adapted to be conducted largely on the internet while still representing the local context. Finally, we acknowledge that a whole of system approach for evaluation may never be fully achievable, as changes in a complex system will always give rise to more uncertainties than a single evaluation can

XSL•FO
RenderX

satisfactorily capture [34,35]. However, with our feasibility assessment, we focus on the most important areas of uncertainty and to justify decisions of which assessment of impact can be expected to be meaningful at a system level.

Conclusions

In conclusion, the Child-COOP feasibility study is crucial in evaluating the potential for a full scale-up study in a Danish context. If feasible, this participatory system dynamics approach in Child-COOP provides opportunities for the application of local capacity building by applying a practical approach to complex health problems in a local community [34]. This study will be able to inform both the content of the participatory system dynamics approach and the future larger-scale evaluation design. Furthermore, the community outcomes included may help to better understand the changes in the community and the mechanisms leading to changes in childhood health within communities [13]. If proven feasible, the Child-COOP study will be scaled and tested for the effectiveness in relation to improving childhood health in a Danish context.

Acknowledgments

We like to thank Stine Klitgaard and Ulla Skov Aldahl from Randers Municipality on their tireless engagement in the project in the municipality and the local community. We also thank Annette Nejmann-Laursen, principal at “Børnebyen,” for her great help in assisting the project. Last but not least all children and citizens in Havndal, Denmark.

Authors' Contributions

KR, JNØ, and HK adapted and designed the intervention, prepared the first drafts of the paper, revised the manuscript, and approved the final submission. SA and HTM contributed to the design of the intervention, revised the manuscript, and approved the final submission. SA contributed to the education of the research group. CB and ASEA revised the manuscript and approved the final submission.

Conflicts of Interest

HK and JNØ are employed at Steno Diabetes Center Aarhus, a public hospital and research institution situated in Central Denmark Region, which is partly funded by an unrestricted grant from the Novo Nordisk Foundation. HTM is employed at Steno Diabetes Center Copenhagen, a public hospital and research institution situated at the Capital Region of Denmark, which is partly funded by an unrestricted grant from the Novo Nordisk Foundation.

Abstract

Background: Soil underpins most terrestrial systems; hence, its degradation should concern everyone. In 2021, Soilsafe Aotearoa surveyed the adult population of New Zealand about how they value soil, particularly values related to how they care about and are concerned about soil. Pursuant to this study, Soilsafe Kids (the outreach branch of Soilsafe Aotearoa) developed a combined research and outreach program to collect a supplemental data set of children's soil values, so both adults' and children's voices can be considered when understanding the implications of different practices and how to care for presently "uncared for" or neglected soils in the future.

Objective: The program not only asks primary school students about their soil values but also aims to teach them about soil from many disciplinary perspectives to enhance their understanding and awareness of soil, and, more broadly, for knowledge production.

Methods: Here we describe the research protocol used in this Soilsafe Kids program. This program uses surveys (in the form of worksheets), focus groups (introduced as group discussions), and art projects to learn what children think about soil in Tāmaki Makaurau Auckland. We have received ethics approval from the University of Auckland's Human Participants Ethics Committee (reference number 23556) on March 25, 2022, for 3 years.

Results: We have begun recruiting participants and delivering the Soilsafe Kids program in schools across Tāmaki Makaurau Auckland. Our data collection is ongoing with final student engagement in the first quarter of 2023. We expect to analyze data at the start of 2023 and to disseminate results later this year.

Conclusions: Once this study is complete, we will disseminate the final results to the research community, stakeholders, and the local community through conference presentations, journal articles, hui (meetings), on our website, and in art exhibits. We note that although Tāmaki Makaurau Auckland is home to the majority of people living in Aotearoa New Zealand, the Auckland region only represents a small portion of Aotearoa New Zealand's land, and findings are not generalizable to Aotearoa New Zealand as a whole.

Introduction

While encounters with soil tend to be everyday and be mundane, many of us do not think deeply, or much at all, about its connections or its diverse values (eg, as calculative, emotive, or utilitarian). Soil underlies spaces we interact with and is a medium in which animate entities grow. Additionally, soil is a site of biodiversity and recreation and has its own intrinsic value. Particularly important for the context of this study are Māori Indigenous values of soil and the broader environment, with vital connection to the *whenua* (land) and *atua* (creators) [1], and the context of largely conventional "valuation" of soil taking place by way of settler-colonial knowledge frameworks, with soil being both *tī puna* (ancestor) and stolen land simultaneously. Globally, soil quality is decreasing for reasons such as its use as a platform for development, its overuse in food and resource productivity, and as a deliberate or accidental sink of waste, holding contaminants such as metals and pesticides. Nonetheless, soil is a foundation to human settlements, we relate to it in diverse ways, and food is generated out of soil. In fact, some of us produce that food at home. Domestic and community gardening has long been a solution for populations in Tāmaki Makaurau (Auckland), and Aotearoa New Zealand (hereinafter "NZ"), to gain access to affordable, adequate, and culturally appropriate food supply [2]. Of concern, then, is the significant scholarship that discuss soil degradation as the number 1 threat to food security and environmental sustainability; for example, Krzywoszynska [3] and Osman [4,5].

In particular, there is concern for soil degradation in the form of soil metal contamination. Lead is one metal of notoriety in urban soils because of its toxicity, persistence, and ubiquity in cities [6,7]. In urban locations, there is a legacy of leaded petrol use in vehicles, industrial pollution, waste incineration, and leaded paint usage [8-11]. While the use of paints containing lead was outlawed in New Zealand between 1965 and the early 1980s (different paints were banned at different times), older homes may still therefore contain lead-based paint [12], and house paint that is poorly maintained will flake into surrounding soil. Contaminated garden soils are a global problem [13], as demonstrated in Canada [14], Denmark [15], France [16], Hungary [11], Italy [16,17], and the United States [18,19]. Other heavy metals—such as mercury, arsenic, chromium, and cadmium—have also been found in soils, including soil that is used for growing food, thus creating an exposure pathway for metal absorption by humans [20]. Soil contamination can also be a multigenerational problem, where the contamination does not "go away" but rather is retained in situ within soils until disturbed or mobilized (eg, through water, by wind, manually by humans, or where it is taken up by plants). There are numerous links to the importance of children learning about soil quality, including potential sources of contamination and an appreciation of less documented benefits that soil brings that relate to its intrinsic (nonutilitarian) and well-being values [21].

Soilsafe Kids is a research and outreach project that sits under the umbrella of Soilsafe Aotearoa [22]. Soilsafe Aotearoa launched in 2021 in NZ as a program to examine diverse soil values, including those that are scientific, cultural, ecological, economic, political, and artistic. After a year of learning about why the public values soil and their concerns about soil, Soilsafe Aotearoa launched a citizen science project to test domestic garden soils for metal contaminants, free of charge, in response to the concerns raised [22], including a study on gardening values (eg, EL Sharp, F Porter, N Strawbridge et al, unpublished data, January 2023) and matters of soil care and concern. All respondents in this study of soil care and concern were adults.

This leads us to question "Who are the *public*?" Nearly a quarter of NZ's population is younger than 15 years [23,24]. Although children spend more time outdoors than adults [25], we know very little about what children think, feel, or know about soil. In order to understand what the *broader* public values about soil, it is paramount that we understand what children value, not just adults; further, the diversity in the known and unknown perspectives of adults and children, rather than just an adult-child binary, is of interest here.

Soilsafe Kids launched in 2022, with keystone activities including a research study gathering "soil values" parallel to that undertaken by Soilsafe Aotearoa with adults, instead of children, and the opportunity for the families of the participating children to take part in Soilsafe Aotearoa's heavy metals soil testing, along with an in-class educational component to teach children about factors that might lead to the risk of soil contamination or human exposure to contamination. Ultimately, this information would guide *whānau* (families) in their decision-making about whether their gardens are safe places to grow food, and, if not, what to do about it to reduce contaminant exposure, including government guidance regarding practices such as eliminating sources of contamination depending on the metal, growing food in commercially available soils that are brought to the site (not growing in ground soil), moving the location of the food garden, or reducing food or hand-to-mouth exposure to contaminants.

The delivery of a combined educational and research program offers diverse benefits to children, their communities, and researchers. First, it establishes a reciprocal relationship with participants, where we provide knowledge and demonstrations of practice as well as obtaining data from participants [26], demonstrating the value of the knowledge imparted to us. Second, it prioritizes and highlights the value of knowledge dissemination in ethical research practice by emphasizing children's right to be heard and seriously considering their views in relation to policy and planning [27]. Third, educational and research activities offered jointly mean that knowledge can be coproduced in the community and knowledge previously produced can be returned to communities who can use it. The aforementioned benefits of combining teaching and research into 1 program, as the Soilsafe Kids program does, are important given children's increasing roles and participation in contemporary issues, as evidenced by the COVID-19 pandemic [28] and the climate crisis [29].

This Soilsafe Kids program is intended to run over 2-3 days depending on the context of the individual school's needs. Our research question is, "what do children (aged 6-10 years) think about soil, and how do they value it?"

The program is composed of 8 workshops designed and run by social, physical, and health scientists with support from scientists

XSL•FO
RenderX

from the New Zealand Crown Research Institutes GNS Science and AgResearch, charities Oke and Garden to Table Trust, 2 community artists, a Māori tikanga advisor, and a Royal Society of New Zealand Te Apārangi Teaching Fellow. The benefits of this type of transdisciplinary research—that encourages children to raise awareness in their communities through environmental activism—include unique educational opportunities [28] and embracing education as a driver for sustainable development [30].

To address our research question, the program is planned to include surveys at the beginning and end of the program, supplemented with focus groups and drawings throughout the workshops. Here, we describe our study design and outline how we will analyze our data and disseminate our findings, allowing us to consider the potential impact of this work.

Methods

Soilsafe Kids aims to understand what children know about soil and how they value it. This takes a child-centered approach [31,32] throughout our workshop series with 8 primary school classes in Tāmaki Makaurau Auckland. Class sizes are planned for approximately 30 students, resulting in a convenience sample of ~240 participants. Data collection and student engagement began in 2022 and is intended to last approximately 9 months, with dissemination of results intended for early 2023.

Ethical Considerations

The University of Auckland's Human Participants Ethics Committee approved this study (reference number 23556) on March 25, 2022, for 3 years. Principals, teachers, and families will provide informed consent via written consent forms; all children (ie, "the participants") will provide assent by signing forms as their reading level precludes truly informed consent. As required by ethics approval processes, Soilsafe Kids has developed participant information sheets (PIS), consent forms (CF), assent forms, and recruitment posters with specific wording and sections of information [33]. When writing the student versions, we were cognizant that we would be working with students who may have rudimentary reading skills, so these documents have larger text, less text, and a limited vocabulary to ensure that the information is child-friendly. During our first interactions with principals, we have received a few comments about the amount of reading that will be required of families. While the PIS and CF are a page each (front and back), they are dense documents. Even though these forms are a standard part of the ethics approval process, this has led to discussions about how to make the recruitment stage more approachable in the future. In each of these forms, we acknowledge that we will maintain the confidentiality of all participants in research outputs but that we cannot guarantee anonymity as participation will occur in a public manner (ie, in a classroom setting).

Our program was designed before young students were eligible to be vaccinated against COVID-19. To help ensure that we minimize the risk of introducing COVID-19 into classes, our in-school team is fully vaccinated and boosted against the virus. Although NZ's vaccine mandate for teachers and staff has since dropped, we are maintaining a vaccination requirement for our in-school team to enter schools. We also respect that schools may not want visitors during periods of high COVID-19 transmission. Thus, we have the ability to transition our program fully outdoors or remotely—this would allow for students to learn about soil in an environment that prioritizes their health.

Although we strongly prefer that students participate in Soilsafe Kids' research component, we understand that some families and students may not want to. Because Soilsafe Kids has both research and educational outreach objectives, we will ensure that students can partake in the educational component without participating in the research component. We have designed each workshop to accommodate this preference. For example, multiple focus groups will be held simultaneously with some groups being recorded as data while others being carried out as unrecorded discussions. Through simultaneous focus groups with the same topics and structure, looking around the classroom will not indicate who is and is not participating in the research. Such choices will help make our lessons more accessible to all students, regardless of their and their families' feelings about participating in research.

All participants (including students, families, teachers, and principals) will have several opportunities to learn about our results. We will send a summary of school-specific results of the children's values of care and concern for soil back to the principal within a few weeks of the final workshop. At the end of the year, we will host a webinar to describe our combined findings about children's collective soil values. This format will enable our results to be disseminated, irrespective of people's locations or the COVID-19 restrictions at the time, thus allowing us to highlight students' communication outputs. Additionally, all participants will have the opportunity to request the study results in written form. By offering multiple ways of summarizing the study results, we hope to be able to reach a wider audience that is able to engage in a way that is appropriate to them. Results of the citizen science metal testing of home garden soil, as per the Soilsafe Aotearoa's own protocol, are only shared back to the citizen science participant and not the wider public. While this protocol is counter to many citizen science movements that are working toward "open" science, data, and access, the choice to manage data in this way was made because of the risks of this openness [34]—in this study, the politics and potential harmful effects of particular locations being labeled as "contaminated places." Despite the plans to communicate this, there is awareness that some may choose not to participate, given the unequal impacts of this type of environmental monitoring, as well as the known reduced participation of more marginalized communities in community science due to limitations of time and resources and possible surveillance and engagement fatigue concerns among Indigenous communities [34].

All participating schools were given gift cards worth NZ $500 (US $316.89 [exchange rate as on February 14, 2023, is indicated here]) of gift cards, while each student in the participating class (regardless of research participation status) received a NZ $30 (US $18.83) gift card to Booksellers Aotearoa New Zealand. By providing every student with a gift card, we ensure that we do not disclose the participation (or nonparticipation) status of a student.

Participant Recruitment

Participant recruitment is planned in 3 stages at each school. Initially, using a combination of our networks and cold approaches to schools, principals are approached with a recruitment flier, a PIS, and a study protocol document [33]. This targeted recruitment approach will ensure that our sample is composed of a range of geographical locations and settings, communities of low and high socioeconomic status, and an ethnic distribution that reflects Tāmaki Makaurau Auckland. At this point, we are happy to address any questions either electronically or in person as in keeping with the NZ Ministry of Health's COVID-19 public health measures. Once the principal or school's board of trustees has decided that their school will participate and signed a CF, we will share a recruitment flier, PIS, and the study protocol with the principal and request that their front office share these documents with appropriate teachers. These second-stage documents will provide teachers general information about Soilsafe Kids and address how students can be part of the teaching and research components of the program, just the teaching components, or abstain altogether. With a signed teacher CF, the third stage of recruitment will commence and focus on families and students. Teachers will be provided with recruitment fliers, PIS, and consent and assent forms to distribute to parents and potential student participants.

As the potential student participants will be early readers, we have developed documentation equivalent to the adult documentation to build students' confidence and responsibility. To ensure that learner-appropriate vocabulary has been used, a registered and student teacher both assessed all documents [35,36]. Students are participants if their principal, teacher, and caregiver all return signed CFs and have signed an assent form.

Accessibility

Traditionally, schools in close proximity to research centers have more opportunities to work with researchers [37,38]. While this is convenient, it also means that students attending schools farther away have fewer interactions with researchers and are less likely to imagine themselves as researchers [39]. With this in mind, we will begin recruitment by reaching out to principals of suburban and rural schools first. We hope that this will provide different students an opportunity to participate in research and humanize researchers.

Data Collection

This program is composed of 8 workshops that will be led by a team of researchers and expert practitioners. Each workshop is designed and will be led by a social, natural, or health scientist, an artist, or local charity. This diversity of backgrounds ensures that students gain a transdisciplinary understanding of soil. When possible (see the *Discussion* section for more information), the person who designed the workshop will also deliver it with support from other researchers.

The topics addressed on the first day of workshops include the following: an introduction, te ao Māori (the Māori worldview) on soil, composting, and how to sample soil for heavy metal analysis, as well as information on reducing exposure or introduction of contaminants into backyard soil. The topics addressed on the second day of workshops include the following: soil as an artistic medium, soil characteristics from a Western soil science perspective, and the relationship between food and soil. The second day ends with a science communication workshop in which students then create an output sharing the importance of soil and how to keep it healthy. Depending on the communication method, the Soilsafe Kids team will return for a third day to help the students share their soil messaging with their communities.

During the workshops, data are collected in the form of surveys presented as worksheets, art projects, focus groups that are labeled as "small group discussions," a hands-up survey, and an interview with the teacher. As the students participating in Soilsafe Kids are still in early primary school (aged between 6 and 10 years), they may not be proficient readers or writers, so many of our activities revolve around art tasks. The Soilsafe Kids team will also write a critical researcher reflection, using the framework developed by Fook and Gardener [40] at the end of each day.

Results

One of the goals of this program is to center students in knowledge production, so they realize their agency in the world. Thus, the final format of the data will be decided by the students. We anticipate using NVivo [41] to conduct automated and manual thematic analysis [42] to analyze the qualitative data [43], which will supplement our previous data set of adults' soil values.

Public Involvement

Local practitioners and stakeholders are central to the formation and operation of Soilsafe Kids. We have partnered with local practitioners, and stakeholders from Soilsafe Kids' inception and will continue to involve them in the conduct of workshops, depend on them as advisors in the data analysis phase, and provide inputs regarding the dissemination of the results and knowledge transfer stages of the project.

When we were initially designing this program, our artists, local charities, and Royal Society Te Apārangi Teaching Fellow helped decide and shape our workshop series. The Teaching Fellow's guidance and 2 of the authors' teacher education training help ensure that Soilsafe Kids is aligned with the local curriculum. These partnerships have continued to evolve and grow as we have developed the Soilsafe Kids program.

To help foster relationships with the schools, we intend on offering meetings with all principals, boards of trustees, and teachers who might want to run the Soilsafe Kids program. Our aspiration is that the people we meet with will become ambassadors for the program during family and student recruitment. We will request that teachers make the first approach to families to minimize the transfer of personal information and ensure that a known contact makes first contact with families.

This program was designed for students who are familiar with school formats, who may not yet see themselves as having the authority to teach others in their community. Our workshops

XSL•FO
RenderX

will aim to shift this view, especially in the final science communication workshop. This is important because these students not only are providing their current views on soil but also will inherit values of caring for the environment and soil. Actions taken now will affect the state of the soil that they have to work with in the future, so children need to view the soil as something they can influence now, not just later on.

Dissemination

Our anticipated dissemination can be categorized as targeting the research community, stakeholders (eg, Auckland Council, the Ministry of Education, schools, students and their families, environmental education groups, Auckland Regional Public Health, Auckland District Health Board, and environmental artists), and the local community. Our results will be disseminated to the research community at academic conferences and through peer-reviewed academic journal publications. We maintain relationships with stakeholders and offer periodic updates in meetings and by sharing our research results. To transfer our new knowledge to communities, we will conduct a webinar for participants and partners and post updates on our blog. Our lessons also aim to empower students to share their learnings with their communities about soil, which is why our last workshop focuses on science communication. Additionally, Soilsafe Aotearoa held several soil-themed art exhibitions in 2021. We would like to use students' artistic outputs to host such galleries for the public in the future. Finally, we will invite students to participate in Soilsafe Aotearoa's soil testing for heavy metals. The results from this testing will be disseminated back directly to students' families who contributed soil samples with a special child–friendly insert explaining their results in child-friendly terms. The results will only be shared back to the citizen science participant who takes part in this project and not the wider public, as explained in the *Ethical Considerations* section above.

Data Storage

Paper consent forms will be stored in a locked cabinet in the locked office assigned to one of the Soilsafe Kids coleads (Sophia Tsang, Victoria Egli, or Emma Sharp). All data for this project will be stored digitally to ensure that the entire research team has access and that data are regularly saved and backed up. Given that we have many Indigenous participants, the guidelines set out by Te Mana Raraunga | the Māori Data Sovereignty Network [44] have shaped our data storage processes. This includes only using document transfer and backup systems that have domestic servers. To ensure that none of our data are transferred offshore, we will use the University of Auckland's Webdropoff Service and local (ie, internal to the University of Auckland) storage. More information about our data storage can be found in our data management plan [45].

Discussion

Expected Findings

The Soilsafe Kids program is unusual due to its transdisciplinary nature while also combining educational outreach and research aims. This protocol describes our considerations as we designed the program to teach early to middle primary school students in NZ about soil. This will enable us to use mixed methods to gather student soil values that can supplement ongoing Soilsafe Aotearoa work that investigates adult soil values.

This program was designed to be accessible to schools in rural areas and to students with low reading levels during the COVID-19 pandemic (2020 to present). While accessibility and the pandemic guided the development of this program, we also were focused on ensuring that we provide students with an age-appropriate experience that supports their developing leadership potential, which all students could participate in the educational program without the research component without having their nonparticipation status disclosed to classmates, and that we followed best practices as laid out by Te Mana Raraunga | the Māori Data Sovereignty Network [44]. In line with the transdisciplinary Soilsafe Kids team, we will collect both quantitative and qualitative data to be analyzed, and we aim to share our results widely among academic circles, policy makers, and the public. To do so, we will disseminate our work in a variety of manners.

Limitations

Everyone's opinions and values are influenced by our contexts irrespective of whether they are spatial, temporal, cultural, or many others. We recognize that the results of Soilsafe Kids are not generalizable for 2 primary reasons related to the students we are working with. Although Tāmaki Makaurau Auckland is the largest population center in NZ, it is very urban compared to the rest of the country. While we aim to include more rural schools than in most programs, our results will not be representative of the country as a whole due to the schools' proximity to Tāmaki Makaurau Auckland. Additionally, students who are currently in early to middle primary school will be shaped by current events and contemporary culture; a student who is currently 8 years old likely views the world and soil differently than a 15-year-old. Thus, additional work must be designed and undertaken to increase the robustness of our data set to students of different backgrounds including settings and ages.

Conclusions

The Soilsafe Kids Three-Day program is a comprehensive way to ask children to consider the soil under their feet thinking through multiple worldviews. Through this program, we will gather students' soil values while also encouraging them to participate in Soilsafe Aotearoa's heavy metals soil testing. This not only will provide students a better understanding of the health of their soil at home but also ensures that they know if their home gardens are safe places to be growing food. By testing each students' soil individually and communicating their results back with considerations and suggestions for improvement where necessary, students and families can make informed decisions about their gardens and if the plants they would like to grow could pose a health concern due to heavy metal uptake.

Acknowledgments

The authors deeply appreciate the time Georgia McLellan has given to advise Soilsafe Kids. We would like to thank Ekarasa Doblanovic, Nicole Johnston, Victoria Bernard, Ani Brunet, Candace Weir, Angela Flemming, and Nicole Schon for their help designing workshops for the Soilsafe Kids Three-Day program. We would also like to acknowledge Paul Dickson, Alisi Kivalu, and Tonya Wyatt for their support in helping design the Soilsafe Kids Three-Day program and web-based resources. We are also grateful to Adam Martin and Rose Turnbull at GNS Science | Te Pū Ao for ensuring that all of our participants receive soil metal and metalloid testing results. Finally, we thank our anonymous reviewer for their thoughtful suggestions to improve this paper. This work was supported by New Zealand's Ministry of Business, Innovation, and Employment's Unlocking Curious Minds contestable fund (grant MBIE 3725049) and Te Pūnaha Matatini (grant 3725823).

Data Availability

An extended protocol document can be found in Tsang et al's study [33].

Authors' Contributions

ST, VE, and ES conceptualized the Soilsafe Kids program and drafted the original manuscript. ST and BCM developed the study's methodology and resources. ST, VE, ES, BCM, and LEM are carrying out the detailed investigation. MK serves as a scientific mentor for Soilsafe Kids. All authors reviewed and edited this article.

Abstract

Background: Medication safety is increasingly challenging patient safety in growing aging populations. Developing positive patient safety cultures is acknowledged as a primary goal to improve patient safety, but evidence on the interventions to do so is inconclusive. Nursing home residents are often cognitively and physically impaired and are therefore highly reliant on frontline health care providers. Thus, interventions to improve medication safety of nursing home residents through patient safety culture among providers are needed. Using cocreative partnerships, integrating knowledge of residents and their relatives, and ensuring managerial support could be beneficial.

Objective: The primary aim of the Safe Medication of Nursing Home Residents Through Development and Evaluation of an Intervention (SAME) study is to improve medication safety for nursing home residents through developing an intervention by gaining experiential knowledge of patient safety culture in cocreative partnerships, integrating knowledge of residents and their relatives, and ensuring managerial support.

Methods: The fully integrated mixed method study will be conducted using an integrated knowledge translation approach. Patient safety culture within nursing homes will first be explored through qualitative focus groups (stage 1) including nursing home residents, their relatives, and frontline health care providers. This will inform the development of an intervention in a multidisciplinary panel (stage 2) including cocreators representing the medication management process across the health care system. Evaluation of the intervention will be done in a randomized controlled trial set at nursing homes (stage 3). The primary outcome will be changes in the mean scale score of an adapted version of the Danish "Safety Attitudes Questionnaire" (SAQ-DK) for use in nursing homes. Patient safety–related outcomes will be collected through Danish health registers to assess safety issues and effects, including medication, contacts to health care, diagnoses, and mortality. Finally, a mixed methods analysis on patient safety culture in nursing homes will be done (stage 4), integrating qualitative data (stage 1) and quantitative data (stage 3) to comprehensively understand patient safety culture as a key to medication safety.

Results: The SAME study is ongoing. Focus groups were carried out from April 2021 to September 2021 and the workshop in September 2021. Baseline SAQ-DK data were collected in January 2022 with expected follow-up in January 2023. Final data analysis is expected in spring 2024.

XSL•FO
RenderX

Conclusions: The SAME study will help not only to generate evidence on interventions to improve medication safety of nursing home residents through patient safety culture but also to give insight into possible impacts of using cocreativity to guide the development. Thus, findings will address multiple gaps in evidence to guide future patient safety improvement efforts within primary care settings of political and scientific scope.

Introduction

Background

Medication Safety in Nursing Homes

Despite years of focus, medication safety is still troubling patient safety globally, with increasing demands on health care systems challenged by aging populations [1]. Physical and social environments constitute system factors that are thought to be the main factors influencing health of older adults [2]. Medication errors and unsafe medication practices are the leading causes of avoidable harm in health care, playing a key role in jeopardizing patient safety. Nursing home residents constitute a marginalized, medically complex, and underresearched group who are in high risk of experiencing preventable medication-related harm [3]. Worldwide, older adults in need of specialized health care delivery through primary care, including nursing home care, is expected to increase [2,4]. In terms of improving medication safety in primary health care settings, focus on the most dangerous aspects of systems and the people who are most at risk have been suggested [5]. Highest rates of preventable medication harm have been found in older adult patient care settings [6]. Moreover, nursing homes provide health care for the older adults who are most at risk of experiencing risk factors of medication errors [3,7-9]. In 2021, an 11% increase in adverse events, with a total of 326.416 adverse events, was reported by the Danish Patient Safety Authority in Denmark, and approximately 60% of the events were related to medication errors. A substantial proportion of this increase is reported from municipality health care settings, including nursing homes. This is supported by international findings regarding medication errors in European nursing homes and community care context [7,8,10]. Thus, focus on the interventions to improve medication safety of older adults living in nursing homes is needed. Moreover, multiple work system factors, including persons (resident and staff), organization, tools and technology, tasks, and environment, have been found to affect medication safety in nursing homes. One of the organizational factors, namely, interprofessional collaboration was reported as a relevant factor [11]. These findings reflect recent suggestions for taking a systems approach with focus on organizational issues in terms of minimizing mistakes related to the medication management process [12]. Managing medication of nursing home residents is a highly complex task, often implicating a relatively invisible, multidisciplinary, and cross-sectoral team of health care professionals, providers, as well as the residents and their relatives [13]. However, existing literature remain sparse, heterogenous, and inconclusive when it comes to interventions to improve medication safety in nursing homes [14].

Complexity of Context in Primary Care—Toward a Safety II Theoretical Perspective

Absence of accidents and incidents is often referred to as *safety*, which is, ensuring that things do not go wrong. The theoretical underpinning can be defined as Safety I theory, which has been the primary driver of safety improvement efforts globally [15]. Nevertheless, as primary health care constitutes a complex system structure, safety cannot be hypothesized to be achieved through measuring errors to avoid them from reoccurring. The human ability to adapt to varying conditions, thereby increasing resilience within health care systems, cannot be overruled. In theoretical terms this can be defined as Safety II theory, where understanding why things go right most of the time becomes the primary investigatory question to answer [15]. Safety II theory has recently been suggested as a guidance to avoid harm in health care [16], thus enabling prevention of errors through determining underlying mechanisms and resources already in play before errors happen and improving patient safety through no-blame cultures in nursing homes [17]. However, there are no specific evidence-based guidelines on how to realize such safety culture [18,19]. Knowledge on the effects of quality improvement initiatives and interventions to improve medication safety in primary care is based on sparse, highly heterogenous evidence [20,21]. In Denmark, nursing homes are under the responsibility of municipalities who constitute an important part of primary health care. The nursing home setting is highly complex, being both a private home and a center of health care delivery for the residents.

Interventions to Improve Medication Safety in Nursing Homes

Development and evaluation of interventions fit to the complex context of nursing homes in large-sample, longitudinal studies have been suggested beneficial to obtain positive, long-lasting effects on medication safety [22]. Within hospital settings, multifaceted approaches and inclusion of stakeholders has been found to be associated with a decrease in medication errors and a positive change in patients' satisfaction [23]. This supports earlier studies arguing that future interventions targeting medication safety could benefit from being based on

XSL•FO
RenderX

multidisciplinary teams focusing on quality as a shared commitment; being multifaceted; and involving all stakeholders, including residents and their relatives [24,25]. Nevertheless, findings are contradictory. A recent study investigating a multifaceted intervention to improve medication safety of nursing home residents did not find positive effects on the health status of nursing home residents [22], contrary to a study aimed to improve medication safety in a hospital setting through a multifaceted interventional strategy [23]. Overall, studies on interventions to improve medication safety in residential health care for older adults are heterogenous in terms of methodologies with inconclusive results [14]. This corresponds to findings of a review on the interventions to optimize medication use within nursing homes [26].

Thus, medication errors and unsafe medication practices continue to concern health care systems worldwide, including nursing home settings. However, earlier research clearly reflects a gap in the knowledge about interventions to improve medication safety in nursing home settings. Patient safety culture is acknowledged as a key to patient safety, both in terms of improvement and effect evaluation [16,27-29] and has been associated with medication errors, also showing improvement potential [19,30]. In 2021, a guiding report on avoiding harm in health care added the importance of focus on primary health care settings, involvement of stakeholders, and cocreation to conquer the challenge of patient safety, including medication safety [16]. Moreover, safety cultures were recommended to be integrated within research designs and as for efforts within health care organizations [16]. This is in alignment with the most recent health work paper by the Organization for Economic Cooperation and Development stating patient safety culture as a recognized factor of importance at all levels of health care. Moroever, instruments to measure patient safety cultures are already in use in 20 of 24 member countries [20].

Patient Safety Culture

Patient safety culture is a complex phenomenon that is thought as a subclass of organizational cultures referring to the safety culture related to patients [21]. It is defined as "the values shared among organization members about what is important, their beliefs about how things operate in the organization, and the interaction of these with work unit and organizational structures and systems, which together produce behavioral norms in the organization that promote safety" [31]. Instruments that aim to capture reflections of patient safety cultures have been developed and validated [20,32], with one of the most widely translated and adapted being the "Safety Attitudes Questionnaire" (SAQ), originally developed in the United States in 2006 [33]. The SAQ can be used with dualistic perspectives both to compare different health care employees perceptions and to monitor changes over time [32]. In addition, it allows for comparison between large numbers of sites across settings [33]. Although evidence is sparse and contradictory [34], there is evidence indicating that SAQ is a proper proxy measure of patient safety [35]. SAQ scores have been reported to be directly associated with patient outcomes [32]. The SAQ has been adapted and validated for use in both secondary care and primary care settings [36-40], including Western European nursing homes [38,41] and Danish hospital settings [36].

Prior Work

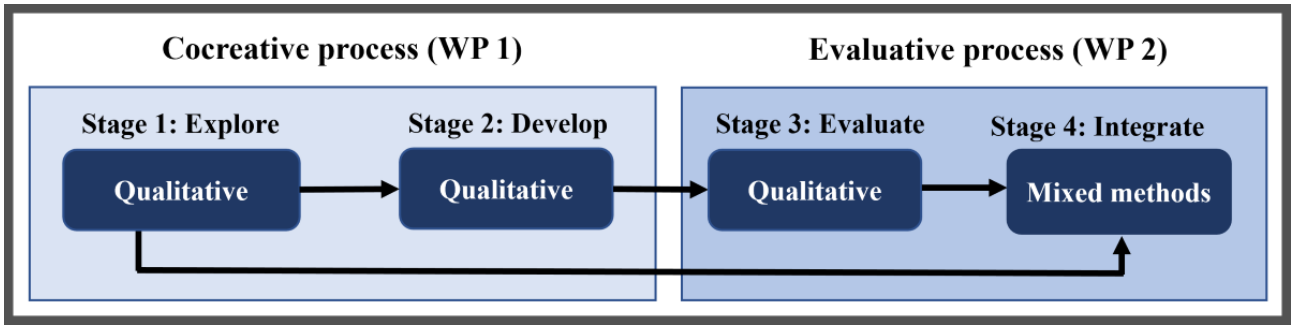
International studies have found lower measures of patient safety culture in nursing homes compared with hospital settings [42,43]. Importantly, no single instrument can capture the complexity of safety culture [44], which is regarded a multilayered construct. Outermost layers are considered to be visible and measurable (layers 1 and 2), whereas the deepest layer holding the essence of a culture is measurable only through qualitative means (layer 3) [45]. Layer 3 has not been reflected by earlier research [46], resulting in evidence on patient safety culture in nursing homes being mainly based on quantitative studies. This gap in knowledge could weaken medication safety improvement initiatives [45] and implies a need for in-depth exploration of patient safety culture, including qualitative methods [44-46]. An integrative mixed methods approach to analysis could further strengthen results to gain comprehensive understanding of patient safety culture as a target of intervention to improve medication safety [47].

Study Objective and Research Questions

Therefore, the primary objective of the Safe Medication in Nursing Home Residents (SAME) study is to develop and evaluate an intervention to improve medication safety of nursing home residents through patient safety culture. First, we aim to develop an intervention to improve medication safety of nursing home residents in a cocreative process, including (1) exploration of patient safety culture as perceived at the frontline of nursing homes (stage 1) and (2) development of a knowledge-based intervention in a multidisciplinary panel informed by findings from focus groups interviews exploring patient safety culture (stage 2). Second, we aim to evaluate the intervention in a randomized controlled trial (RCT) set at nursing homes (stage 3), including a register-based study on patient safety–related outcomes in nursing home residents. Finally, we aim to perform an integrative mixed methods analysis on patient safety culture in nursing homes to comprehensively understand patient safety culture as a complex phenomenon and target of medication safety improvement (stage 4). This could potentially drive a new theory on patient safety culture to guide future efforts to improve medication safety of older adults living in nursing homes. Using an integrated knowledge translation (IKT) approach, we aim to enhance knowledge translation from research into practice through generation of partnership-based, meaningful, acceptable, and feasible results to address medication safety in nursing homes, incorporating the voices of nursing home residents and their relatives. As no current golden standard exists for IKT approach in research, and as the existing guiding tool is based on general assumptions toward cocreativity and knowledge creation, we chose to pragmatically use the 8 guiding principles of IKT [48] that was recently developed to guide research on spinal cord injury, but follow general assumptions and definitions concerning cocreation and knowledge generation, to frame the overall research process of the SAME study. In addition, the IKT project proposal worksheet [49] based on the Canadian Institutes of Health Research's merit review criteria [50] will be used in the secondary objectives, which are to (1) explore and identify patient safety culture perceived by knowledge users at the frontline of nursing homes, including health care providers and

XSL•FO
RenderX

receivers, and find out whether it is possible to explicitly describe implicit, core elements of patient safety culture through in-depth qualitative explorative analysis; (2) cocreate an intervention within existing resource frame to increase medication safety in nursing homes by including stakeholders and knowledge users, and it is based on patient safety culture as perceived at the frontline and guided by Safety II theory; (3) explore the impact of cocreativity in the development of an acceptable and feasible complex intervention to improve medication safety through patient safety culture in nursing homes; (4) develop new, comprehensive understanding of patient safety culture as a complex target to improve medication safety within high-risk complex primary care settings through mixed methods integrative analysis including both in-depth qualitative data on patient safety culture and quantitative data on patient safety climate in nursing homes; and (5) describe the impact of the intervention on quantitative health-related outcomes for safety assessment.



Methods

Study Design

Overview

The SAME study applies an overall theory-informed, fully integrated mixed methods study design that includes an exploratory sequential and IKT-guided research process, integrating 2 work packages including a cocreative intervention developing process (stages 1 and 2) and an evaluative process, including RCT (stage 3) and mixed methods integrative analysis of the intervention (stage 3 and 4). Integration will occur at design, method, and reporting levels to reach comprehensive understanding of patient safety culture as a target to improve medication safety. The SAME study aims to reach partnership-developed results through an IKT approach, thereby increasing the chances of achieving translation of research into practice with a focus on the empowerment of stakeholders, end users, and decision makers to generate useful, meaningful, acceptable, and feasible results. Thus, shifting roles of knowledge users to cocreators will be of primary focus throughout the study (Figure 1). To follow current political recommendations to shift perspective in terms of patient safety, Safety II theory [15] will inform data collection.

Figure 1. Safe Medication of Nursing Home Residents Through Development and Evaluation of an Intervention overall study design: a fully integrated, mixed methods study following sequential stages covering a cocreative process and a randomized controlled trial to develop and evaluate an intervention to improve medication safety of nursing home residents (black arrows indicate points of data integration). WP: work package.

Setting

Nursing homes registered within the Municipality of Aalborg, The North Denmark Region, Denmark, constitute the main setting of the SAME study. A nursing home is defined as "a facility with a domestic-styled environment that provides 24-hour functional support and care for persons who require assistance with activities of daily living and who often have complex health needs and increased vulnerability" [51].

Recruitment

A purposive sampling strategy will be followed through all the stages of SAME, conducted in partnership between the research team and municipal advisory board. The municipal advisory board will actively take part in recruitment through establishing contact with eligible cocreators (stages 1, 2, and 3) and participants (stage 3), including those employed at nursing homes, by sending out information material electronically (email). The research team will be responsible for the recruitment of cocreators not directly employed within municipal settings, including an external consultant in cocreativity and communication, risk managers at hospitals, and volunteers representing nursing home residents and their relatives.

Overall Eligibility Criteria

Participants will be eligible for inclusion in the SAME study according to the following criteria: (1) sufficient knowledge of spoken Danish language, (2) being directly or indirectly implicated in the medication management process of nursing home residents, (3) being employed for >2 months at a nursing home registered within the Municipality of Aalborg, and (4) being actively engaged in older adult health care at political or societal level within the Municipality of Aalborg. To represent nursing home residents, we aim to include volunteers from "the senior-council Aalborg" and "The council of elderly" (Table 1); both the groups are characterized by independent, voluntary participation.

XSL•FO

Table 1. Cocreators of the Safe Medication of Nursing Home Residents Through Development and Evaluation of an Intervention study: subgroups, definitions, and roles.

Subgroup	Definition	Role
Knowledge users		
Municipal management advisory board	Municipal management of the Department of Care for the Elderly and Disabled and Unit of Quality and Innovation	• Knowledge on practice • Decision makers • Feasibility
Nursing home managers	Nursing home managers and assistants	• Knowledge on practice • Empowerment • Feasibility
Nursing home care staff	Nursing home care staff (social and health assistants and helpers and home care and nursing home nurses)	• Knowledge on practice • Empowerment • Acceptability • Feasibility • Scope
Hospital risk managers	Employed as risk manager at Aalborg University Hospital or employed within the Municipality of Aalborg	• Knowledge on practice • Feasibility • Scope
General practice dedicated to nursing homes	NH-GP[a]	• Knowledge on practice • Empowerment • Acceptability • Feasibility • Scope
Representatives of residents and relatives	Actual relatives of nursing home residents of included nursing homes within the Municipality of Aalborg and representants of "The Senior-council, Aalborg" and "DaneAge Association"	• Knowledge on practice • Empowerment • Acceptability • Feasibility • Scope
Stakeholders		
Researchers	A multidisciplinary research group will ensure expertise in fields, including qualitative, quantitative, and mixed methods designs in addition to focus on general practice, nursing, and clinical pharmacology	• Scientific knowledge • Knowledge translation: merging theory and practice
External consultant in cocreativity and communication	An external expert will play an active part in the research team in the qualitative study stages, from facilitation to data analysis	• Knowledge translation: actual practice of cocreativity within municipalities • Empowerment of cocreators
VELUX FONDEN	Noncommercial foundation with grant areas including scientific, environmental, social, and cultural purposes in Denmark and internationally	• Funding

[a]NH-GP: Nursing home general practitioners

Patient and Public Involvement

We aim to achieve active engagement and empowerment of patients, health care professionals, decision makers and other stakeholders through developing partnerships, with emphasis on equal power but acknowledgment of different roles and responsibility (Table 1). To do so, an overall iterative IKT approach will be applied. IKT is viewed as "an approach or set of processes that can lead to the generation of knowledge for optimizing health care delivery systems and improving health system performance and associated outcomes" [52]. A total of 8 IKT guiding principles are available to support meaningful research, mitigating risk of tokenism. Although relatively recent, the IKT approach has been found useful in other research areas [48] and is in broad terms similar to other collaborative research approaches, including aiming at true partnerships rather than simple engagement; focusing on essential components and processes rather than labels; enabling collaborative research orientations rather than research methods, core values, and principles; and extensive time and financial investment [53]. Thus, in the SAME study, we aim to shift participants and researchers to the role of cocreators following an IKT approach. For practical implication, cocreators include the term "knowledge user" referring to "…an individual who is likely

XSL•FO
RenderX

to be able to use the knowledge generated through research to make informed decisions about health policies, programs and/or practices" and "stakeholders" as "individuals, groups or organisations with shared interest in the research; may be in the geographic locality of the research setting or it may be affected by the environmental effects of the research but may not necessarily use the generated knowledge" [54]. To describe and evaluate the level of participation, we will use the International Association for Public Participation Spectrum of Public Participation [55].

Thus, we aim to develop an intervention that will improve medication safety of the older adults with frailty living in nursing homes, and it will be based on coknowledge, generating results perceived as meaningful, useful, acceptable, and feasible by those affected by the research to inform clinical practice. This could help support the ongoing development of sustainable, accessible, and equitable health care systems [56], making room for positive change.

SAME Study Cocreators

Table 1 shows an overall presentation of participants in the SAME study. We aim to achieve equally powered partnerships between participants and researchers, shifting participants and researchers into the role of cocreators [53] divided into subgroups following the SAME study IKT approach [57].

Work Package 1: A Developing Cocreative Process

To reach the overall aim of the SAME study, an intervention to improve medication safety of nursing home residents is aimed in a 2-staged cocreative process (Figure 1). Safety II theory will be used to obtain recommended shift in perspectives in facing health care issues [15,16]. The overall IKT approach of the SAME study will guide the development of cocreators. (Table 1).

Stage 1: Qualitative Exploration of Patient Safety Culture in Nursing Homes

The primary objective of stage 1 is to explore patient safety culture in nursing homes, with the perspectives of frontline health care providers being the primary focus. Experienced knowledge will inform the development of the intervention (stage 2) collected through semistructured focus group interviews [58,59]. In addition, field notes will be used as a data source. The medication management process of nursing home residents will be integrated in the development of the semistructured interview guide to ensure the development through medication safety lens of the SAME study.

Semistructured Focus Group Interviews

Focus group interviews can be used to gain in-depth understanding of a topic and to identify group norms and cultural values and minimize risk of discrimination regarding reading and writing abilities. Thus, using focus groups to explore patient safety culture could be beneficial with the aim of reaching in-depth knowledge, which is not achieved through quantitative methods [58-60]. All focus group interviews will be facilitated by the external consultant in cocreativity and communication (Table 1). In addition, a researcher (Table 1) will attend to observe and write field notes (Table 1). The first focus group interview will be set to ensure space for the needed adjustments before proceeding with data collection. The municipal risk manager (Table 1) will be invited as an observant of this interview and for a short reflection session at the end of each of the following interviews of approximately 15 minutes.

Semistructured Interview Guide

A semistructured interview guide will be developed in collaboration with the research group and an external partner in cocreativity and communication (Table 1). The latter will focus on presentability and general structure of the interview guide, whereas the researchers will account for theoretical information–based and evidence-based outline. To reach in-depth results, 9 intangible domains of organizational culture defined in a recent umbrella review on patient safety culture [44] will inform the interview guide development that will be structured based on Schein's model of safety culture [45]. Duration of each focus group will be ≤3 hours. This decision was made to face medication safety as a risk area with an expected need for slowly developing a "safe space" for knowledge users not expected to be formerly involved in similar projects, increasing the chance of reaching in-depth results.

Study Sample and Size

To help ensure that subgroup norms do not affect data generation negatively and allowing for intimacy, we aim to include a minimum of 3 and ≤5 participants in each focus group. Focus groups will therefore be formed by defined professional subgroups. We aim to include 4 to 6 focus groups, including social and health care assistants, social and health care helpers, general practitioners dedicated to nursing homes, home care nurse and nursing home nurses, and representatives of nursing home residents and their relatives (Table 1). Focus on organizational subgroups could minimize potential negative effects of possible existing hierarchical structures.

Outcomes

The primary outcome of stage 1 will be qualitative themes.

Data Analysis

Qualitative data will be both field notes and audio recordings that will be transcribed and stored according to current law. Themes will be generated following a triangulated in-person process including researchers with expertise in both qualitative and quantitative methods as well as a representant of end users in the sense of the external consultant in cocreativity and communication, representing cocreators of the SAME study (Table 1). Data analysis will be done following the principles of analyzing in the present [61]. Further validation of the generated themes will be sought through individual triangulation by including researchers representing relevant clinical functions and expertise, including a pharmacist, a nurse, a general practitioner, a qualitative expert, and a quantitative expert.

Stage 2: Development of a Knowledge-Based Intervention

In stage 2, the design of the new intervention will be formed. This will be done in a 2-phased process embedded a co-designing process. First, we aim to develop idea generation in a multidisciplinary panel representing a systems view in terms

XSL•FO
RenderX

of the medication management process of nursing home residents, and the panel includes nursing home residents and their relatives as well as decision makers. Second, triangulation of ideas will be done with focus on research knowledge. To meet the possibility of using an inadequate number of cocreators to reflect the entire system, the cocreative process will include the investigation of acceptance and usefulness of the intervention through semistructured qualitative focus group interviews with knowledge users and stakeholders in stage 3. The municipal advisory board will play an essential role in stage 2, acting not only as partners in idea generation but also as decision makers in relation to the final intervention design.

Data Sources—Collection and Analysis

Data will be qualitative and collected as electronic recordings. Also, a collaborative field note worksheet will be written by facilitators after the workshop. Data analysis will be informed pragmatically by the Delphi method and through a process of data triangulation including stakeholders.

Phase 1: Multidisciplinary Panel Workshop

In this phase, we aim to generate ideas based on shared knowledge as an innovative base and to include systems perspective. Experiential knowledge on patient safety culture perceived by nursing home care staff, nursing home residents, and their relatives (Table 1; stage 1, Figure 1) will inform this phase. This will ensure the presence of voices of all knowledge users and minimize potential negative effects of power hierarchical structures. We will ensure acceptable, useful, and meaningful consensus through the presentation of the experiential knowledge from stage 1 as paradoxes by integrating multiple views and possible heterogeneity in the cocreated process. The workshop will be facilitated by the external consultant in cocreativity and communication and 3 representants of the research group (Table 1). The workshop will run over a full working day.

Study Sample and Size

A purposive sampling strategy to recruit a multidisciplinary, cross-sectoral panel consisting of knowledge users (Table 1) will be used. This will visualize the relatively invisible team who function in everyday practice and who are implicated in the medication management process of nursing home residents across professions, departments, and health care sectors, including the following:

1. Social assistants and health assistants (n=2)
2. Social helpers and health helpers (n=2)
3. Municipal management (n=2)
4. Nursing home management (n=2)
5. Nursing home general practitioners (n=2)
6. Home care nurses and nursing home nurses (n=2)
7. Risk managers employed at hospital and by the municipality (n=2)
8. Relatives of nursing home residents (n=2)
9. Representants of nursing home residents (“DaneAge association” and “Senior-council, Denmark”; n=2)

Outcome, Data Sources, and Collection

The primary outcome of phase 1 will be generation of ideas to improve medication safety, focusing on shared knowledge. A part of a cocreative process, data collection methods have not been predefined but will be developed as part of the research process. The external consultant in cocreativity and communication (Table 1) will play a key role. Both electronic records and field notes will be used as data sources. Results will inform phase 2.

Phase 2: The Co-designing Process—Data Sources, Collection, and Analysis

Data will be qualitative and collected as electronic recordings. In addition, a collaborative field note worksheet will be written by facilitators during and after the workshop. Data analysis will be done in a process of data triangulation including relevant stakeholders.

First, a preliminary intervention will be co-designed based on ideas generated at the workshop. Qualitative data will be analyzed guided by “analyzing in the present” [61] based on a triangulated process between participating facilitators after the workshop, following the cocreative approach including the external consultant in cocreativity and communication (Table 1).

Second, a co-designing phase including researchers and decision makers (Table 1) will be done to undertake an organizational and contextualized perspective. This will increase feasibility and acceptability potential of the final intervention design to be evaluated in the RCT (stage 3). Purposely sampled cocreators will be consulted in person through the presentation of the preliminary intervention, thereby leaving room for revision and correction. We aim to include cocreators having expertise in general practice, nursing, and pharmacology, in addition to those from qualitative and quantitative research fields in this phase.

Third, the municipal advisory board will be consulted, as their knowledge concerning organizational factors implicating the intervention will be essential to ensure a local contextualized, final intervention design.

Finally, the intervention will be designed by the research team in terms of explicating the decisions made by all the cocreators. The final intervention will be presented to the municipal advisory board, minimizing the risk of misinterpreted information and increasing the potential for adaptability through management support.

Work Package 2: Evaluation of Intervention and Understanding of Patient Safety Culture

Stage 3: Quantitative Evaluation of the New Intervention in an RCT

In stage 3, we will evaluate the new intervention in a randomized controlled study set at nursing homes. Data on primary outcome will be collected at baseline before rollout of the intervention and at 6-month to 9-month follow-up according to intervention rollout at individual participating nursing homes. Data on secondary outcomes will be collected during the intervention period.

XSL•FO
RenderX

Study Sample and Size

A total of 36 public nursing homes were registered within the Municipality of Aalborg in 2021. We expect to recruit a minimum of 22 nursing homes to participate in this phase. Inclusion criteria are the following: to be eligible for inclusion within this study, nursing homes must be supported by a general practitioner registered by the Municipality of Aalborg. Exclusion criteria are the following: if a conflict appears, for example, in relation to other initiatives targeting medication, the Municipality will ensure exclusion of specific nursing homes. Nursing home care staff will be included according to the overall eligibility criteria and definitions defined in Table 1.

As no other studies have investigated the effect of a complex intervention in a mixed methods study design in primary care on SAQ, the sample size cannot be based exclusively on previous study outcomes. We aim to recruit as many respondents as possible from the included nursing homes.

Based on previous studies focusing on related health care setting and culture, we expect mean scale scores of SAQ of 32 to 75 [62,63], and we expect to find an increase of at least 4.0. We expect a lower SD than that reported in previous studies, as these studies have investigated more variable groups of professions. The overall SD (all domains) in home care services have been reported as 9.8 [62]. Thus, with a power of 0.8, significance level (α) of .05, and an expected SD of 9.8, it has been estimated that 192 respondents (96 respondents in the intervention group and 96 respondents in the control group) will be sufficient.

Outcomes

The initial problem statement that emerged from the Municipality of Aalborg was that adverse events were increasingly reported, yielding a legally bound challenge that is not yet overcome. Thus, the Municipality sought help for lowering the number of medication errors and unsafe medication practices through collaboration. Although reporting adverse events is an intended goal in safety terms in Denmark, the number of adverse events is not a proper estimate of medication safety.

As a proxy for the overall medication safety, including medication errors, the SAQ has been suggested. A Danish reliable and valid version is available (Danish Safety Attitudes Questionnaire, SAQ-DK). An increase in SAQ-DK would indicate a decrease in medication errors, whereas a decrease would indicate a worsening. We are aware of using the SAQ-DK as the primary outcome with precaution, as the intended increase in reporting adverse events within primary care is still an ongoing issue. However, to the best of our knowledge, no other more suitable measure is available, and therefore, we chose the SAQ as the most reliable and relevant proxy for medication safety in the SAME study.

The primary outcome will be focused on the nursing home frontline, including nursing home care staff's and nursing home managers' (Table 1) self-reported perceptions of patient safety culture measured as mean scale SAQ-DK score [36]. The SAQ-DK will be adapted for use in Danish primary health care settings, including nursing homes following the cocreative approach of the SAME study.

Secondary outcomes will include the following: qualitative—perceptions of patient safety culture of relevant cocreators collected through semistructured focus group interviews or individual interviews, depending on the results of the research process; quantitative—register data; that is, sociodemographic data and data on health-related outcomes will be collected at baseline and at follow-up. Data will be collected from relevant Danish registries.

Statistical Analysis

An evaluation of the new intervention will be done through comparison of primary outcomes and secondary outcomes between the intervention group and control group of the trial at baseline and 12-month follow-up. Results will be presented as SAQ-DK mean scale scores and SD, using Poisson regression statistical modeling.

Qualitative data will be transcribed and stored according to the current law. A structured codebook will be generated to guide thematical analysis [64]. Analysis will be performed by a junior researcher triangulating findings with a senior researcher with expertise in the qualitative research field, using NVivo (QSR International) [65].

Quantitative data will be registered and stored in REDCap [66] subsequently being transferred for analyses in Stata (StataCorp).

Safety Assessments and Effects

Patient safety–related outcomes will be analyzed through quantitative data collected through national registers; these data include (1) medication (number and type); (2) contacts to a health care system (hospital, nursing home general practitioner, and out-of-hour general practitioner); (3) diagnoses (somatic and psychiatric 10th revision of the International Statistical Classification of Diseases diagnoses); and (4) mortality. Descriptive statistics will be used to compare groups.

Stage 4: Mixed Methods Integrative Analysis of Patient Safety Culture: Mixed Methods Analysis

Through a mixed methods integrative analysis, the SAME study aims to gain comprehensive understanding of patient safety culture as a multilayered construct and target of medication safety intervention (stage 4) via different data sets, including (1) a quantitative questionnaire on nursing home care staff and nursing home management's (Table 1) self-reported perceptions of patient safety climate (SAQ-DK), (2) qualitative data on patient safety culture, and (3) qualitative data from individual interviews with knowledge users. The different sets of data will be collected and analyzed separately for final integration through use of "joint display of data" [67] in a mixed methods analysis. Results could lead to the development of a new theory on patient safety cultures in Danish nursing homes, informing future research and clinical practice in the area.

Ethics Approval

The North Denmark Region Committee on Health Research Ethics has reviewed and deemed the SAME study exempt according to the study design and the emphasis on the sole use

XSL•FO
RenderX

of survey, interview, and national register methodology (2020-000992). The study was registered at and approved by the institutional data protection department, Department of Research Data and Statistics, Aalborg University Hospital (2021-015) and in ClinicalTrials.gov (NCT04990986). Participation will be voluntary, and informed consent will be obtained and can be withdrawn at any point in time. The SAME study will be conducted according to the Declaration of Helsinki (64th WMA General Assembly, Fortaleza, Brazil, October 2013).

Results

The SAME study is ongoing. Idea groups and experience groups (stage 1) were carried out from April 2021 to September 2021 and the workshop in September 2021. Baseline SAQ-DK data were collected in January 2022, with expected follow-up in January 2023. We expect to finish data analysis in spring 2024.

Discussion

Principal Findings

Mixed Methods

To impact decision-making, research could benefit from including multiple ways of understanding complex concepts leading to new understanding [68]. Thus, study designs combining mixed methods with participatory approaches could improve research outcome with increasing complexity of the area under investigation, allowing for a deeper understanding of complex phenomena [69-72]. Although sparse, mixed methods studies have been reported, underpinning the benefits in the development and evaluation of interventions [73-75]. Community-based organizations are important stakeholders in health systems, often called upon to use research evidence to inform health care delivery [76]. Consulting key stakeholders and service users, therefore, seems crucial to allow for evidence that is "probably more realistic, acceptable and likely to produce more change" [68]. Combining mixed methods with participatory research approach can help the translation of research into practice and may facilitate meaningful, evidence-based change [69]. Moreover, integration can occur at the level of knowledge. Thus, it is expected that integrative mixed methods analysis including in-depth qualitative exploration will provide a more comprehensive understanding of the complex phenomenon of patient safety culture within high-risk primary care settings, minimizing risk of generating misleading results to guide future clinical practice.

IKT Approach

IKT can be used to identify a problem and be able to implement the research recommendations through collaborative research processes. This will form partnerships between researchers and service users [57] aiming to produce meaningful, useful, acceptable, and effectful results [52,57,77]. Importantly, perspectives of representants of an entire organization should be accounted for in terms of investigating safety cultures [44]. Patient participation in the medication process has been stated essential in preventing adverse events, including medication errors [78]. This supports the acknowledgment of patient involvement to avoid harm in health care [16]. Moreover, a scoping review on the IKT approach reported by few studies that included patients who are knowledge users as partners, whereas decision makers were highly represented. Thus, it is anticipated that the IKT approach of the SAME study will increase the chance of identifying and acting upon needs and priorities of knowledge users, including decision makers, nursing home care staff, nursing home residents, and their loved ones, who are rarely integrated as active partners within research on patient safety culture.

Overall Discussion Resume

The SAME study will provide insight and knowledge to bridge the gap between research and clinical practice on medication safety strategies targeting older adults with frailty, with emphasis on cocreation. Moreover, understanding patient safety culture through an integrative method could lead to new opportunities of using and analyzing results based on instruments already in play. Including the SAQ as a primary outcome will help generate comparable results. This could increase learning potential across national borders, health care sectors, and local health care organizations and departments as a key to meet the global challenge of patient safety [20]. There is a possibility that results generated could guide the development of a novel framework to facilitate cocreation to improve medication safety in nursing homes.

Limitations

Systems and nursing home organizational–related factors such as political changes, time schedules, and resources could be limitations in all stages of the SAME study. Moreover, engagement in a knowledge user-researcher partnership is complex, nonlinear, and changeable, presenting a limitation of this study in terms of generalizability, transparency, and feasibility.

Conclusions

With growing aging populations, there is an increasing scope to analyze medication safety as one of the challenges facing patient safety. The SAME study will help generate evidence on patient safety culture that could help inform and guide future improvement efforts within primary care settings within both political and scientifical scopes.

Acknowledgments

All the authors of the SAME study would like to acknowledge the Municipality of Aalborg, Department for Senior & Care, for their contribution to study design and for their willingness to take active participation in the project. The work is funded by VELUX FONDEN (case 0034143).

Abstract

Background: Adherence to antiretroviral (ARV) therapy is critical for achieving HIV RNA suppression in people living with HIV and for preventing HIV infection in uninfected individuals using preexposure prophylaxis. However, a high level of adherence can be challenging to achieve for people living with HIV on lifelong ARVs and for HIV-negative individuals using daily preexposure prophylaxis who are not at daily risk for HIV infection. Current biological measures of adherence are invasive and use bioanalytical methods that do not allow for real-time feedback during a clinic visit. This study was designed to test the feasibility and acceptability of using MedViewer, a novel, minimally invasive, hair-based assay that measures longitudinal ARV drug adherence in real time and provides an output for provider-patient discussion.

Objective: The primary objectives were to investigate the feasibility of delivering the MedViewer results as planned, the acceptability of participation in a discussion of the MedViewer results, and the appropriateness of using MedViewer for adherence counseling. The secondary objectives were to investigate additional dimensions of feasibility, acceptability, and appropriateness of using the MedViewer test during a routine clinic visit for people with HIV.

Methods: The proposed study was a single-arm cross-sectional study among patients receiving HIV care and providers of HIV care in a southeastern infectious disease clinic. The study originally planned to implement the MedViewer test with 50 eligible patients who were living with HIV across 2 viral load strata (undetectable or detectable plasma HIV RNA over the previous 2 years), administer brief visit-specific questionnaires to all patient and provider participants, and conduct qualitative in-depth interviews and quantitative end-line questionnaires with a subsample of patient participants (n=30) and all provider participants.

Results: The Establishing Novel Antiretroviral Imaging for Hair to Elucidate Nonadherence study was funded by the National Institute of Allergy and Infectious Diseases and approved by the local institutional review board on November 4, 2019. Provider participant enrollment began on January 17, 2020, and patient participant enrollment began on January 22, 2020. Participant enrollment was halted on March 16, 2020, because of the COVID-19 pandemic (16 providers and 10 patients on study). Study activities resumed on February 2, 2021, with COVID-19 modifications approved by the local institutional review board. Participant enrollment closed on October 8, 2021, and data collection closed on November 15, 2021. In total, 36 unique patient participants, representing 37 samples, and 20 provider participants were enrolled. Data analysis and manuscript writing will take place throughout 2023.

Conclusions: We anticipate that the data collected through this study will provide important insights regarding the feasibility, acceptability, and appropriateness of incorporating new real-time longitudinal, minimally invasive adherence tests into routine clinical care and identify potential barriers to medication adherence among patients.

HIV; AIDS; adherence; hair; infrared matrix–assisted laser desorption electrospray ionization; IR-MALDESI; antiretroviral therapy

Introduction

Background

HIV RNA suppression in blood plasma is a key factor in controlling the HIV epidemic. Adherence to antiretroviral (ARV) therapy (ART) is an effective way to achieve viral suppression, maintain good health for people living with HIV, and prevent the transmission of HIV to uninfected individuals [1]. However, it can be challenging to maintain adherence to lifelong drug therapy. Poor adherence to ARVs can result in the development of viral resistance and worsened patient morbidity and mortality [2]. Having an accurate measure of ARV adherence for patients and providers can facilitate early interventions to improve adherence. Blood plasma or intracellular ARV concentration monitoring has been considered the "gold standard" for biological measures of adherence. However, this approach has its own set of limitations, including being invasive, requiring advanced processing (eg, intracellular measures) or specific storage conditions, being a short-term measure of drug-taking behavior (depending on the half-life of the analyte), and requiring long turnaround times [3]. Therefore, valid noninvasive longitudinal measures of adherence such as hair analysis are critical for optimizing ARV effectiveness.

In this study, we proposed a novel solution to bridge the gap in adherence monitoring to improve clinical outcomes based on hair. Hair is unique in that it has the potential to provide information about drug intake over a longer period compared with other biological fluids, including plasma [4], blood cells [5], and urine [6]. Recent studies have used sensitive analysis of hair strands through liquid chromatography–mass spectrometry to evaluate ARV concentrations. These studies have demonstrated that ARV drug concentrations scale proportionally with dose frequency [7] and can predict virologic success [8]. Liquid chromatography–mass spectrometry methods typically evaluate hair segments of ≥1 cm; this length corresponds to at least a month of hair growth. Our approach uses infrared (IR) matrix–assisted laser desorption electrospray ionization (MALDESI) technology for mass spectrometry imaging (MSI) to visualize and quantify ARV concentrations longitudinally over the previous month of hair growth. An IR-MALDESI MSI method has been validated for the quantification of emtricitabine (FTC) and dolutegravir (DTG) in hair strands. As part of this validation, we have determined the lower limits of quantification for each of these 2 ARVs (FTC: 0.27 ng/mg; DTG: 0.04 ng/mg) using a series of prepared hair standards and ensured that our sensitivity is within the range of incurred samples we have evaluated as part of study aim 1. The benchmarking of this IR-MALDESI MSI longitudinal ARV profiling has been conducted through a 3-phase (single dose, daily dose, and dose proportionality) directly observed therapy study with FTC+tenofovir and DTG (ClinicalTrials.gov NCT03218592). Our preliminary results suggest that this method has potential value in measuring longitudinal drug exposure [9] and distinguishing between different adherence patterns [10].

Objectives

For ease of communicating regarding the IR-MALDESI MSI approach with patients and providers, we named this approach "MedViewer" and will refer to it as such throughout this protocol paper. In preliminary studies, we demonstrated that MedViewer can rapidly and accurately provide noninvasive and longitudinal evidence of drug ingestion and thereby has the potential to provide clinicians, researchers, patients, and study participants with feedback on adherence performance [3]. However, little is known about how such a tool would be accepted as an adherence-enhancing intervention by patients or providers or how best to implement it feasibly in the context of a clinic setting. The primary objectives of this study were to investigate the feasibility of delivering the MedViewer analysis as planned, the acceptability of discussing the MedViewer results, and the appropriateness of MedViewer use for adherence counseling. Secondary objectives of this study were to investigate additional dimensions of feasibility, acceptability, and appropriateness of using MedViewer to provide feedback to people living with HIV regarding longitudinal patterns of medication adherence. The goal of this work was to develop a simple, rapid, noninvasive, longitudinal monitoring tool of ARV adherence that will provide useful feedback for clinicians and patients to improve ARV adherence. As this was a feasibility study, of note, no change in clinical care was initiated based on information assessed with the intervention.

Methods

Intervention

The study intervention included four components: (1) a standardized training session for medical providers; (2) an informational video for patients; (3) the hair sample, MedViewer test, and accompanying MedViewer report (patient and provider versions); and (4) communication aids for providers.

All research activities were conducted in as private a setting as possible.

All medical providers that consented to participate in this study attended a standardized training session. Training sessions were offered in person and in a web-based format. The training sessions lasted between 30 and 60 minutes and were held at the start of the study as well as at various points throughout the study (for providers who were new or had not enrolled at the

XSL•FO
RenderX

study start). The training introduced the providers to the MedViewer patient video (described in the following paragraph), the MedViewer test and report, and provider communication aids. The training also prepared providers to incorporate the delivery of the investigational MedViewer test results into discussions with patients during routine HIV care appointments by providing an opportunity to practice interpreting and discussing MedViewer results with patients using an example MedViewer report. The training session was required for all enrolled providers participating in the study before they could be scheduled to see enrolled patients for visits to review their MedViewer report. Supplemental training sessions with the same training materials were offered as needed. Although providers used the investigational MedViewer reports during their conversations with patients about ARV adherence, provider participants still only used currently accepted measures of ARV adherence (eg, plasma HIV RNA, HIV genotyping, and plasma therapeutic drug monitoring of ARVs) for making clinical decisions.

An 8-minute informational video was used to introduce patients to the MedViewer test, the hair collection process, and how test results can be useful for conversations between patients and providers about adherence. More specifically, the video explained (1) how ARVs are processed in the body and end up in the hair, (2) what the hair sample collection process would be like, (3) how the hair sample would be processed and how data and reports would be generated, (4) how the hair sample would be disposed of, (5) how the provider might review the results with the patient, and (6) how the test results could inform conversations about the patient's adherence. The video also addressed potential patient concerns about the test (as identified in a formative study conducted as part of intervention development) [11]. Potential concerns included but were not limited to whether it was painful to provide a hair sample and how patient privacy would be protected. This video was part of the informed consent process for patient participants to facilitate their understanding of the MedViewer aspect of the study. Eligible and interested patients watched the video during the informed consent process either in a private room in the research center or clinic or via an institutional review board (IRB)–approved videoconferencing call. Patients had the opportunity to watch the video multiple times as needed.

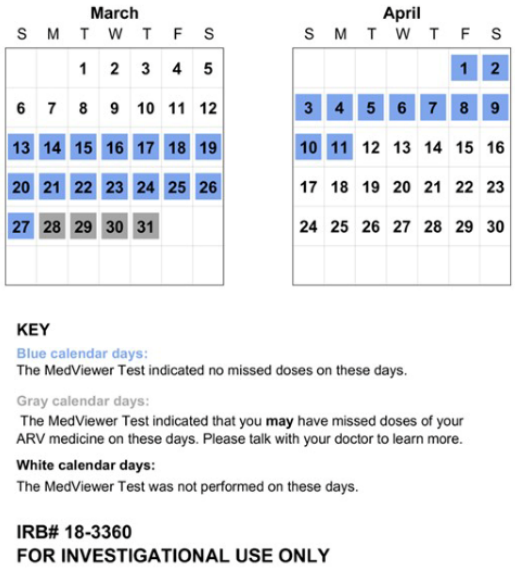
After providing informed consent, patient participants provided a hair sample for MedViewer testing. Hair sample collection took place in the research center or clinic initially. After the pandemic, hair sample collection could also take place in a private remote location where the patient participant felt comfortable, such as their home, to minimize study participants' exposure to the clinic environment. To collect the sample, a trained clinical research staff member used tweezers to pluck 5 strands of hair from the back of the patient's head. The research team member then placed the hair on a foil package and affixed the distal end of the hair with a label. The folded foil was placed into a resealable biohazard bag in a closed container and then transported promptly to the laboratory for testing in accordance with local environmental, health, and safety policies. The date and time of sample collection and transportation were documented on a paper case report form. At the laboratory, the laboratory scientist placed the sample in the IR-MALDESI instrument to run the test [3].

As suggested by our formative research findings [11,12], after the hair sample was run in the IR-MALDESI instrument, the laboratory scientist generated 2 distinct visual reports of the results intended for patients (Figure 1) and providers (Figure 2). The patient version presented a calendar indicating whether the IR-MALDESI output from each day achieved a sufficient threshold consistent with daily dosing, whereas the provider version displayed more detailed quantification of the IR-MALDESI output with a bar chart. The laboratory scientist then sent both reports via secure email to the research team, who printed the reports and delivered a hard copy or electronic version to the appropriate provider participant in the infectious disease (ID) clinic. The laboratory scientist that ran the test recorded the time the analysis process was started and the time the report was available for the research team on the same paper case report form. These times were used to assess the duration of this component of the intervention.

Before seeing the patient, the provider reviewed the provider and patient reports. During the patient's regularly scheduled appointment at the ID clinic, the provider and patient viewed the patient version of the report together and used them to have a conversation about the patient's ARV medication adherence. If the provider thought that the patient would be interested in the more detailed provider report, the provider could elect to also review that report with the patient. If the MedViewer report was not available during the patient's regularly scheduled ID clinic appointment, the provider and patient participants had the option to discuss them during a separately scheduled MedViewer appointment within 4 weeks of hair sample collection. The provider participants did not follow a standardized script to discuss the results with the patient; rather, the provider conducted the appointment based on their clinical judgment and discretion, drawing on information from the provider training session and communication aids, medical expertise, and their clinical judgment regarding the individual needs and circumstances of the patient participant (Figure S1 in Multimedia Appendix 1). If the provider chose to follow suggested communication strategies listed in the MedViewer intervention reference sheet, they could discuss MedViewer reports with patients by explaining the summary statistics printed with the results or pointing out any patterns of insufficient drug concentrations and adherence successes, asking patients about event-level or chronic and psychosocial causes of missed doses, asking patients about successful adherence strategies, working with patients to identify personalized strategies that could help them overcome causes of missed doses in the future or to replicate successes, offering encouragement for good adherence, and working with patients to set goals for improving future adherence.

XSL•FO
RenderX

Figure 1. Example patient MedViewer report. ARV: antiretroviral; IRB: institutional review board.



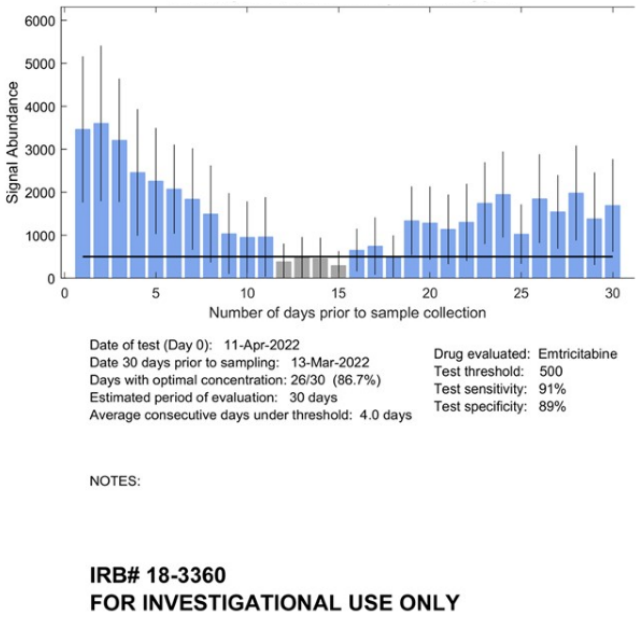


Figure 2. Example provider MedViewer report. IRB: institutional review board.

Owing to their investigational nature, the MedViewer reports were not entered into the patients' electronic health records, did not become a formal part of the clinical patient record, and were not used for clinical decision-making. After the provider and patient reviewed the MedViewer reports, both versions of the report were destroyed in accordance with standard medical document destruction procedures. A copy of each was stored in the research record. The research team documented receipt of the MedViewer report by the provider on the study forms.

Recruitment

Recruitment and Retention Strategies for Patient Participants

We planned to enroll 50 patient participants from a large hospital-based outpatient ID clinic in the southeastern United States. Data collection occurred in the clinic, in a clinical research center, or at remote locations to minimize exposure to the clinic environment in response to the COVID-19 pandemic. The ID clinic has a full-time research screener to assess patient eligibility for open research projects. Of all the patients in the ID clinic who are living with HIV, approximately 95% have consented to having their patient information available in a secure clinic database from which it can be viewed by a research screener to identify potential eligibility for open research studies and to being notified of studies for which they are potentially eligible (as per IRB form 99-MED-408). Patients in the database have indicated all the methods of contact to which they have and have not agreed for contact by researchers for potential participation. We used an IRB-approved screening process that has been used in the ID clinic for >10 years whereby the clinic screener or a trained research team member prescreened patients scheduled for an appointment in the upcoming week in the clinic database. After using the clinic database to identify potential patients, the screener or trained research team member assessed the patients' electronic health record for eligibility criteria under

XSL•FO
RenderX

an IRB-approved limited waiver of the Health Insurance Portability and Accountability Act (HIPAA). At regular intervals, the clinic screener shared with the research team the list of scheduled patients who met eligibility at prescreening.

Using the list of potentially eligible study participants, the research team contacted patients by phone before their next scheduled HIV appointment using an IRB-approved phone screening questionnaire to notify them about the study and assess their interest. Phone calls were conducted in a private room to prevent inadvertent disclosure of participant information. Participants could also contact study staff in response to IRB-approved study recruitment flyers. For participants who expressed interest on the phone, the researchers continued with the phone contact to verify their eligibility using a brief standardized IRB-approved script and screening form (with questions pertaining to patient age, amount of time as a patient at the University of North Carolina at Chapel Hill [UNC] ID clinic, HIV appointments in the last year, current and past prescribed ARV medications, and length of caput hair), and if confirmed to be eligible for a screening visit and the patient agreed, they provided basic demographic data needed to schedule their appointment in the clinical research management system. This was done under an IRB-approved limited HIPAA waiver. Full HIPAA and informed consent occurred during the first patient participant visit. All contact attempts were documented in a recruitment log.

To ensure a sufficient number of patients with a history of detectable viral loads (VLs; who represented a minority in the clinic), we enrolled participants into 2 VL groups with a target of 25 participants in each group. Group A included those with plasma HIV RNA below the limit of quantification (<40 copies per million) over the previous 2 years with documentation of at least one test in the previous 6 months. Group B included those who had had at least one plasma HIV RNA result above the limit of quantification within the previous 2 years. We anticipated enrolling an average of 7 patients per month over the course of 7.5 months (33 weeks) to reach our target of 50 total participants. We screened and enrolled patients of all gender identities, racial identities, ethnicities, and ages (>18 years) such that the demographic distribution of screened participants reflected that of patients at the UNC ID clinic who are living with HIV.

Recruitment and Retention Procedures for the In-depth Interview Subsample of up to 30 Patient Participants

We also planned to enroll a subsample of up to 30 patient participants (up to 15 per VL group) enrolled in the larger study, to participate in a follow-up study visit including an in-depth interview (IDI) and brief end-line questionnaire. We invited every enrolled patient to participate.

Recruitment and Retention Procedures for Provider Participants

We aimed to recruit and enroll all (up to 30) medical providers who provided care to patients in the ID clinic (eg, attending physicians, fellows, nurse practitioners, physician assistants, nurses, and pharmacists) during the study period.

Most of our initial provider participant contacts were completed through email, wherein an IRB-approved email invitation to attend the provider training and participate in the study was sent. If the provider was willing to participate, they scheduled their training with the research team and completed the informed consent process before the training. Full informed consent and screening occurred before the provider training.

Ethics Approval

This study received ethical approval from the University of North Carolina at Chapel Hill instituional review board (reference ID 336881).

Informed Consent, Compensation, and Confidentiality

The investigators obtained informed consent from each patient and provider participant before starting any study procedures according to the standards set forth in the International Conference on Harmonization Good Clinical Practice guidelines and per local standard operating procedures. The process included reviewing consent forms with potential participants in a confidential setting and explaining all risks and benefits associated with participation in the study. The IRB-approved consent form was read with the participant in a private space, after which questions were solicited from the participant. The participant was allowed time alone to rereview the form and questions were again solicited. To ensure understanding, study staff asked questions of the participants regarding study procedures. The consent forms used language sufficiently simple for lay persons to comprehend. Participants were not coerced into taking part. Children aged <18 years, adults with impaired decision-making skills, and non-English speakers were not enrolled in this study. Each participant was provided with a photocopy of all the documents they signed. The informed consent process covered all elements required by research regulations. In addition, the process specifically addressed the following topics of importance to this study: (1) the unknown safety and unproven efficacy of the study interventions, (2) the importance of patients in both study groups to the success of the study, (3) the importance of adherence to the study visit and procedure schedule, (4) the potential medical risks of study participation (and what to do if such risks were experienced), (5) the potential social harms associated with study participation (and what to do if such harms were experienced), (6) the limited benefits of study participation, (7) the distinction between research and clinical care, and (8) the right to withdraw from the study at any time.

During the consent process, the patient participants watched the aforementioned short, IRB-approved video describing MedViewer. Participants who were not able to demonstrate adequate understanding of key concepts after exhaustive educational efforts were not enrolled in the study. The informed consent process included an assessment, through a series of questions, of each potential participant's understanding before enrollment and sequential assignment of concepts identified by the protocol team as essential to the informed consent decision.

Finally, the participants were offered the opportunity to sign the consent form or provide verbal consent for follow-up IDI study visits using an IRB-approved verbal consent process. All

XSL•FO
RenderX

participants also reviewed and signed a HIPAA form approved by the IRB.

Participants were compensated for all parts of the study that they completed. Payment was provided in the form of Visa gift cards, and the amount per activity was reviewed and approved by the local IRB to not be coercive. Patient participants received US $5.00 for providing a hair sample, US $15.00 for providing a blood sample, US $20.00 for completing the baseline questionnaire, and US $10.00 for completing the postvisit questionnaire. When study operations were resumed after the COVID-19 pandemic, patient participants were provided with an additional US $20.00 to cover any telephone minutes or internet data they may have had to purchase to complete study activities. If a patient participant did not complete all parts of the study, their payment was adjusted. If the patient participant agreed to participate in the subsample, they were compensated for these activities as well. Patient participants received US $30.00 for taking part in the IDIs and US $10.00 for the questionnaire administered at the end of the interview. As these interviews were conducted in a web-based format after the COVID-19 pandemic, an additional US $20.00 was added to the gift cards to cover any telephone minutes or internet data they may have had to purchase to complete study activities. Provider participants received US $20.00 for attending the provider training session and completing all baseline questionnaires, US $30.00 for completing the postvisit questionnaires for all MedViewer patient visits they conducted during the study, US $20.00 for completing the IDI, and US $10.00 for completing the end-line questionnaire.

Confidentiality was maintained throughout the study by storing all specimens for current and future use with a unique identifying number, which was linked to the participant's name, social security number, address, telephone number, and hospital medical record number. The principal investigators and study staff were the only people with access to the identifying information. Any information provided to other people working on this study was given with the study ID number, not other identifying information. The records were secured in a locked file cabinet in a locked room in a badge access–only office suite of the principal investigator.

All electronic data for this study were stored on a dedicated university server with extensive protections and securities that exceed the standards of the UNC privacy of electronic information policy.

Participant confidentiality and privacy were strictly held in trust by the participating investigators, their staff, and the sponsors and their interventions. This confidentiality was extended to cover testing of biological samples in addition to the clinical information related to participants. Therefore, the study protocol, documentation, data, and all other information generated were held in strict confidence. No information concerning the study or the data was released to any unauthorized third party without previous written approval of the sponsor.

The study participants' contact information was securely stored at each clinical site for internal use during the study. At the end of the study, all records continued to be kept in a secure location for as long a period (6 years after completion of the research) as dictated by the reviewing IRB, institutional policies, or sponsor requirements. The period of 6 years is consistent with the requirements of Title 45 of the Code of Federal Regulations 46.115(b) and Title 21 of the Code of Federal Regulations 56.115.

To further protect the privacy of study participants, a Certificate of Confidentiality was issued by the National Institutes of Health. This certificate protects identifiable research information from forced disclosure. It allows the investigator and others who have access to research records to refuse to disclose identifying information on research participation in any civil, criminal, administrative, legislative, or other proceeding whether at the federal, state, or local level. By protecting researchers and institutions from being compelled to disclose information that would identify research participants, Certificates of Confidentiality help achieve the research objectives and promote participation in studies by helping assure confidentiality and privacy to participants.

Study Objectives and End Points

The study objectives and end points are outlined in Table 1.

XSL•FO
RenderX

Table 1. Objectives and end points for the study.

Objectives	End points	Justification for end points
Primary		
• Investigate the feasibility of delivering the MedViewer intervention as planned, the acceptability to patients of participation in the MedViewer intervention, and the appropriateness of MedViewer use for adherence counseling	• Feasibility: proportion of participants receiving the MedViewer report during their provider visit as planned (ie, the results are delivered to the designated research staff member within 2 hours of initiation of hair processing and the results are discussed with the provider or pharmacist within 4 weeks of hair collection) • Acceptability: proportion of contacted patients who are eligible for a screening visit (not including inclusion criterion 9) who agree to participate in the MedViewer intervention pilot study • Appropriateness: perceived usefulness of the MedViewer intervention for adherence counseling	• Evaluation of these implementation domains will indicate the potential for future application of MedViewer in routine care and help identify needed modifications to the MedViewer intervention to improve delivery. The framework by Proctor et al [13] for outcomes in implementation research indicates the importance of assessing feasibility, acceptability, and appropriateness.
Secondary		

• Investigate additional dimensions of feasibility, acceptability, and appropriateness of using hair IR[a]-MALDESI[b] MSI[c] (MedViewer) to provide patients living with HIV with feedback regarding longitudinal patterns of medication adherence	• Feasibility:
	  • Reasons for patients' nonreceipt of the MedViewer report during a visit with the provider or pharmacist within 4 weeks of hair collection (if applicable)
	  • Reasons for nondiscussion of the MedViewer report with the provider or pharmacist (if applicable)
	  • Length of time (in minutes) from initiation of hair processing to MedViewer report delivery to the designated research staff member
	• Acceptability:
	  • Provider-reported likelihood of recommending MedViewer to future patients
	  • Patient-reported likelihood of agreeing to future MedViewer use
	  • Patient comprehension of the MedViewer report
	• Appropriateness:
	  • Perceived usefulness of MedViewer to promote ART[d] adherence
	  • Perceived impact of MedViewer use on patient-provider communication and relationship
		• Evaluation of these implementation domains will indicate the potential for future application of MedViewer in routine care and help identify needed modifications to the MedViewer procedure to improve delivery. The framework by Proctor et al [13] for outcomes in implementation research indicates the importance of assessing feasibility, acceptability, and appropriateness.

Exploratory		

XSL•FO
RenderX

Objectives	End points	Justification for end points

• Assess exploratory aspects of MedViewer feasibility and acceptability and patient and provider views of and experiences with the MedViewer test
• Explore the impact of adherence counseling using MedViewer on ART adherence and hypothesized mechanisms of change (adherence information, motivation, and behavioral skills)
	• Feasibility:
	  • Patient-reported maximum out-of-pocket cost willing to pay for MedViewer
	  • Cost of MedViewer delivery per person
	  • Compatibility of MedViewer with current clinic practices
	• Acceptability:
	  • Patient-reported reasons for declining participation in the MedViewer intervention pilot study
	  • Reasons why participants would or would not agree to (patient-reported) or recommend (provider-reported) future MedViewer use
	  • Acceptability of specific components of the MedViewer procedure:
	  • Sufficiency of provider training and materials
	  • Sufficiency of patient education (video)
	  • Provider satisfaction with results delivery (discussion format and content)
	  • Patient satisfaction with results delivery (person, discussion format, and content)
	• Adherence-related:
	  • ART adherence measured via self-reported assessment of 3-, 7-, and 30-day adherence
	  • Adherence information (qualitative assessment of information and understanding gained of patient adherence resulting from use of MedViewer)
	  • Adherence motivation (quantitative and qualitative assessment of adherence motivation resulting from use of MedViewer)
	  • Adherence behavioral skills (quantitative and qualitative assessment of adherence behavioral skills and self-efficacy resulting from use of MedViewer)
		• Preliminary assessment of MedViewer's impact on the intended behavioral outcome (ART adherence) and hypothesized mechanisms of influence (based on the Information–Motivation–Behavioral Skills model) will be used to inform the design of a future randomized trial to evaluate the effect of MedViewer on these end points [14].

• Further explore the accuracy of the MedViewer test as an adherence measure	• ARV[e] concentrations in blood collected for first patient study visit and follow-up patient study visit when applicable • Patient viral load assessed with a clinical care visit linked to a patient-provider MedViewer visit and abstracted from the medical record by study staff • log10 ARV drug response in hair via IR-MALDESI collected for first patient study visit and follow-up patient study visit when applicable	• These end points will allow for comparison of reported concentrations of medication in hair with recent ART adherence, as measured via Mitra and current viral load. These comparisons will provide further evidence to assess MedViewer accuracy (in addition to that gathered in aims 1 and 2) among a larger group of patients.

[a]IR: infrared.

[b]MALDESI: matrix-assisted laser desorption electrospray ionization.

[c]MSI: mass spectrometry imaging.

[d]ART: antiretroviral therapy.

[e]ARV: antiretroviral.

Assessments

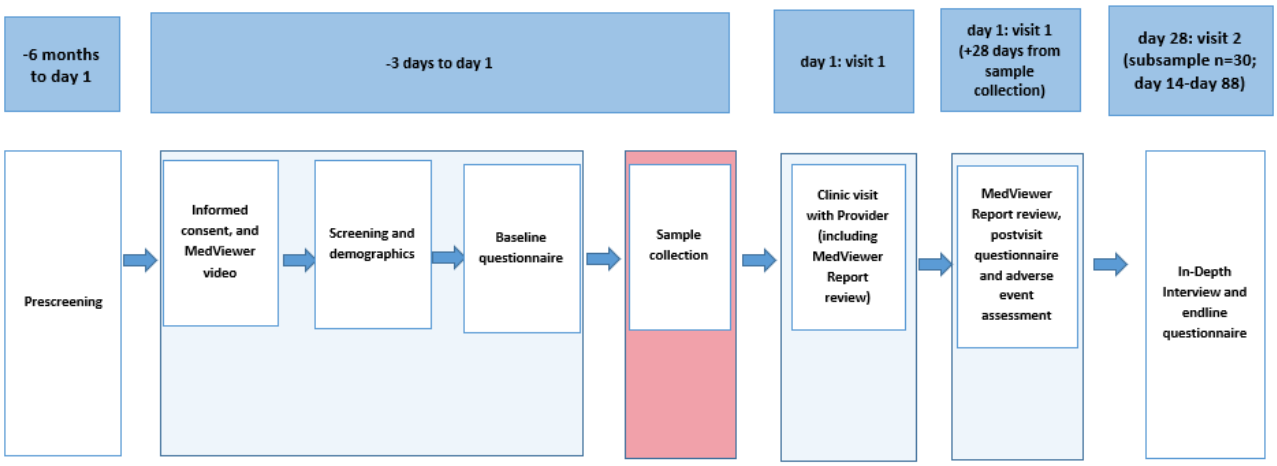
Data Collection Procedures

Patient and provider participants were administered IRB-approved questionnaires at different points during their study participation to assess outcome measures (Figures 3 and 4). These questionnaires were designed by trained qualitative researchers. Patient participants were administered a baseline computer-assisted self-interviewing (CASI) questionnaire after providing informed consent but before receiving and discussing the MedViewer reports with their provider. This questionnaire contained items asking about self-rated health, patient sociodemographic information (time to travel from home to the ID clinic, age, sex assigned at birth and gender identity, sexual orientation, race and ethnicity, current marital status, education level, income in the previous year, current employment status, health insurance status and type, and method of paying for ARVs), comprehension and sufficiency of video content,

XSL•FO
RenderX

self-reported ARV adherence over the previous 30 days, and adherence motivation and self-efficacy. After receiving and discussing the MedViewer report with their provider, patient participants were administered a postvisit CASI questionnaire. This 13-item questionnaire comprised questions regarding experience receiving and discussing the MedViewer report, with whom they had discussed the report, their comprehension of the report, and acceptability of the process.

Figure 3. Patient participant study schema. Sequence of the Establishing Novel Antiretroviral Imaging for Hair to Elucidate Nonadherence study activities for patient participants. Note: MedViewer Report review can be conducted up to 28 days from hair sample collection if not completed at day 1 clinic visit with providers.



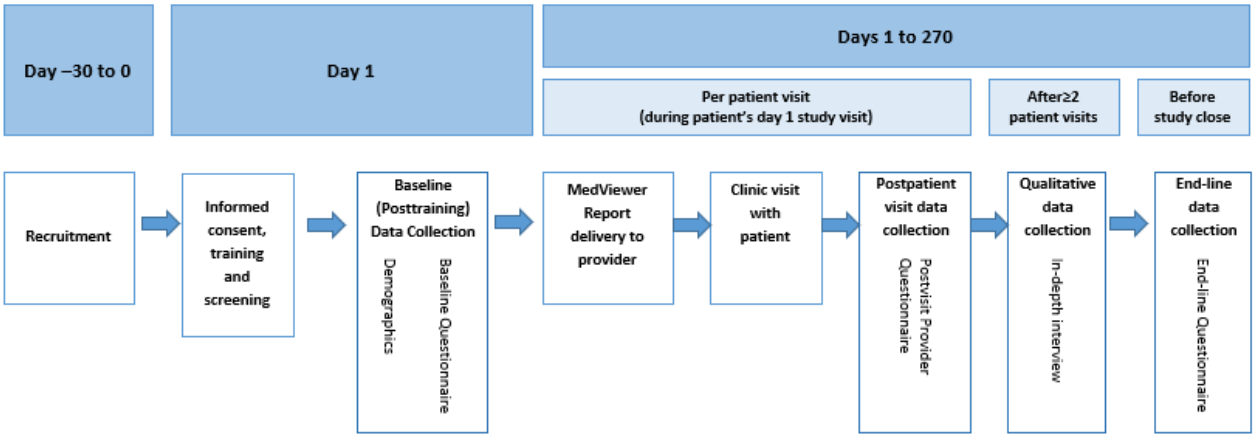


Figure 4. Provider participant study schema. Sequence of the Establishing Novel Antiretroviral Imaging for Hair to Elucidate Nonadherence study activities for provider participants.

The subsample (up to 15 from each VL group) of patient participants who returned for an IDI completed semistructured IDIs either in person or remotely via an IRB-approved videoconference. Interview topics included perceived usefulness of the MedViewer report for adherence counseling; reasons why the patient participant would or would not use MedViewer in the future if available; satisfaction with the patient education video; comprehension of the MedViewer report; satisfaction with adherence counseling discussion using the MedViewer report; attitude toward wait time and hair sample collection process; anticipated effect of regular MedViewer report use on patient-provider relationships and communication; and perceived effect of the MedViewer report on comprehension of own adherence behavior, adherence motivation, and adherence behavioral skills. All IDIs were approximately 1 hour in length. Trained research staff experienced in qualitative research conducted the IDIs using a semistructured interview guide that included open-ended questions corresponding to each qualitative outcome. Interviewers had the flexibility to probe patient responses and pursue discussion diverging from the initial interview questions if relevant to the outcomes of interest. Each interview was digitally recorded and transcribed verbatim for analysis. After completing the IDI, patient participants also completed a brief CASI questionnaire pertaining to their perceived adherence over the previous 3, 7, and 30 days as well as their adherence motivation and maximum out-of-pocket cost that they would be willing to pay for future MedViewer reports.

After completing the provider training session, provider participants were asked to complete a short baseline questionnaire. The questions pertained to their satisfaction with the training quality, content, perceived knowledge gained of the MedViewer test and study procedures, and self-efficacy to deliver the MedViewer report to patients. Each time a provider saw a patient participant for a MedViewer report discussion, they were asked to complete a postvisit questionnaire. These questionnaires assessed if the MedViewer reports were discussed, how long the discussion took, their perception of the

XSL•FO
RenderX

patient's comprehension of the MedViewer report, and their perceived usefulness of the MedViewer report as an adherence tool. All provider participants enrolled in the study were asked to complete an IDI with research staff either after having reviewed the report with at least 2 patients or before study close, depending on which occurred first. The topics of the provider IDIs included the usefulness of the MedViewer report in encouraging patients to sustain or improve adherence, reasons why they would or would not recommend future MedViewer use, their satisfaction with the MedViewer report and adherence counseling using the report, perceived ease of delivering and discussing MedViewer results during a typical appointment, perceived level of disruption to clinic flow by MedViewer procedures, and the anticipated effect of regular MedViewer use on patient-provider communication and relationships. All provider IDIs were audio recorded with participant consent, and the audio file was transcribed for analysis. At the end of a provider's participation in the study, they were asked to complete an end-line questionnaire. The items on this questionnaire pertained to the likelihood of recommending MedViewer to other patients, satisfaction with adherence counseling discussions using the MedViewer report, perceptions of the most appropriate clinician for future MedViewer counseling, perceived usefulness of the MedViewer report in encouraging patients to sustain or improve adherence, and the influence of the MedViewer report on patient-provider communication and relationships.

Outcome Variables and Measures

Primary Outcomes

Feasibility

- Proportion of Patient Participants Receiving the MedViewer Report During Their Clinic Visit as Planned

This primary feasibility outcome is the proportion of participants who both (1) had their MedViewer report delivered to the designated research staff member within 2 hours of initiation of hair processing and (2) discussed the results with a provider (ie, their medical provider or the HIV care pharmacist) within 4 weeks of hair collection. To assess this primary feasibility outcome, the numerator was calculated using 2 separate data sources. First, to assess whether the designated research staff member received the patient's MedViewer report within 2 hours of initiation of hair processing, a study tracking log was maintained by the study team on which the following times were recorded: hair collection, hair transport, hair processing, and delivery of the report to the designated research staff member. The patient participants were asked to indicate on the self-report postvisit questionnaires whether the MedViewer report was discussed following clinic visits with their medical provider or the HIV care pharmacist; the study team also noted which clinician reviewed the report with the patient participant. As a backup data source, providers were also asked in their postvisit questionnaire if they discussed the report with the patient. The numerator of the primary feasibility outcome was a single dichotomous (yes or no) measure. Patients were counted in the numerator of the primary outcome if (1) the study team member indicated on the tracking log that, yes, study staff received the patient's results within 2 hours of initiation of hair processing in the laboratory—this was determined by subtracting time 1 (when hair processing was initiated) from time 2 (when the results were delivered to the designated research staff member—and (2) the patient self-reported on the postvisit questionnaire that, yes, they discussed the results with the provider. The proportion of enrolled participants who achieved the primary feasibility outcome will be estimated. An estimated proportion and corresponding 95% Wilson-Score CI was used to analyze this outcome and all similar dichotomous (ie, binary) outcomes.

Acceptability

The acceptability primary outcome was assessed based on the proportion of contacted patients who were eligible and agreed to participate in the MedViewer intervention feasibility study. Data for this outcome were obtained from the recruitment log. This was a single dichotomous (yes or no) measure for each individual participant. To create this measure, the denominator included all potential patient participants who were contacted and found to be eligible for the study as documented on their prescreening questionnaire. The numerator was those who agreed to participate in the study as documented by their informed consent form. The acceptability primary outcome is descriptive. The proportion of potential patient participants eligible for a screening visit who achieved the acceptability primary outcome (accepted enrollment) was estimated. An estimated proportion and corresponding 95% Wilson-Score CI was used to analyze this outcome.

Appropriateness

The appropriateness primary outcome (perceived usefulness of MedViewer for adherence counseling) was assessed using data obtained from the IDIs.

Secondary Outcomes

Feasibility

- Reasons for Patient's Nonreceipt of the MedViewer Report During a Visit With Provider or Pharmacist Within 4 Weeks of Hair Collection

This secondary feasibility outcome was only assessed for the subsample of patient participants for whom nonreceipt of the MedViewer report was reported (either by a provider in the provider postvisit questionnaire or by a research team member in a study activity tracking log). Reasons for nonreceipt were assessed using a 1-item multiple-choice question with a "check all that apply" approach in the provider postvisit questionnaires and an open-ended response on study tracking forms completed by the research team.

- Length of Time (in Minutes) From Initiation of Hair Processing to MedViewer Report Delivery to Designated Research Staff Member

This secondary feasibility outcome was defined as the amount of time elapsed (in minutes) from the time of initiation of hair processing in the laboratory to the time the results were delivered to the designated research staff member. This variable was determined by subtracting time 1 (when hair processing was initiated) from time 2 (when the results were delivered to the designated research staff member). This variable was

XSL•FO
RenderX

measured using the study visit hair sample tracking log. The log was maintained by the study team, who reported the time at which each study activity occurred.

Acceptability

- Provider-Reported Likelihood of Recommending MedViewer to Future Patients

This secondary acceptability outcome was assessed using a single Likert-type item among providers in a self-reported end-line questionnaire administered by study team members. Providers were asked to rate their likelihood of recommending MedViewer, if available for regular use, to other patients in the future. This item was rated on a 4-point scale (*definitely would not recommend* to *definitely would recommend*). We calculated the proportion of providers reporting each response category (count/denominator and percentage).

- Patient-Reported Likelihood of Agreeing to Future MedViewer Use

This secondary acceptability outcome was assessed among patients in the self-reported postvisit questionnaire administered by the study team members after the participant had received and discussed their MedViewer report with their provider (or completed their visit without a discussion). This was measured using a Likert-type item. Participants were asked to rate their future likelihood of agreeing to MedViewer use if recommended by a provider. This item was rated on a 4-point scale (*definitely would not use* to *definitely would use*). We calculated the proportion of patients reporting each response category (count/denominator and percentage).

- Patient Comprehension of MedViewer Report as Perceived by Patients and Providers

This secondary acceptability outcome was assessed in postvisit questionnaires and IDIs. In the postvisit questionnaire following the MedViewer report discussion, patients were asked to rate their comprehension of the information presented in the report. Providers completed a parallel item in their postvisit questionnaire to assess their view of how well patients understood the information in the MedViewer report. The patient item was rated on a 4-point scale (*very difficult to understand* to *very easy to understand*). The provider item was rated on a 5-point scale (*understood poorly* to *understood excellently*). We calculated the proportion of patients reporting each response category (count/denominator and percentage). We calculated similar proportions for provider responses regarding their perception of each patient's comprehension as a proportion of patients. Patient comprehension of the report was also assessed qualitatively—during the patient IDIs, we conducted a cognitive interview to assess patient comprehension of adherence information presented in the MedViewer report. We used the data from the IDIs to summarize the extent to which patients understood the content of the reports and describe the primary content and formatting features of the report that were poorly understood by participants, if applicable.

Appropriateness

- Perceived Usefulness of MedViewer to Promote ART Adherence

This secondary appropriateness outcome was measured in the patient postvisit questionnaire administered by the study team members following the MedViewer discussion, in the provider postvisit questionnaire following each visit with an enrolled patient, in the patient and provider end-line questionnaires, and in the patient and provider IDIs. Participants were asked to rate their agreement with statements regarding MedViewer's usefulness in promoting adherence over the following 30 days, adherence motivation, skills, and strategies to avoid missed doses. These items were rated on a 5-point scale (*not at all useful* to *extremely useful*). For each item, we calculated the proportion of patients and providers reporting each response category (count/denominator and percentage).

- Perceived Impact of MedViewer Use on Patient-Provider Communication and Relationship

This secondary appropriateness outcome was assessed using the postvisit questionnaires for patients and the end-line questionnaires for providers as well as through questions during the IDIs. In the postvisit questionnaires administered to patients following the MedViewer visit, patients were asked to rate the comparative satisfaction with the patient-provider interaction during the MedViewer visit as compared with a typical visit. In the end-line questionnaires administered to providers, they were asked to rate the effect of using MedViewer on their relationships with their patients. The patient questionnaire item was rated on a 5-point scale (*much less satisfied than usual* to *much more satisfied than usual*), and the provider questionnaire item was rated on a 5-point scale (*very negatively affected relationships* to *very positively affected relationships*). For each questionnaire item, we calculated the proportion of patients and providers reporting each response category (count/denominator and percentage). During the patient and provider IDIs, participants were asked to discuss the anticipated effect of regular MedViewer use on patient-provider communication and relationships.

Statistical Analysis of Quantitative Data

General Approach

As this was a feasibility study, our analytic approach focused on calculating precise estimates of the outcomes. Descriptive statistics of categorical variables (eg, race, sex, gender identity, and VL cohort) were presented as counts and percentages, and descriptive statistics of continuous variables (eg, age) were presented as means with SDs or median, IQR, and ranges. We plotted and visually inspected the distribution of continuous variables. Generally, we did not anticipate variable transformations other than those prespecified in the Study Objectives and End Points and Outcome Variables and Measures sections (eg, $\log_{10}$ VL).

Statistical Analyses

With respect to estimation, a maximum likelihood estimate will be presented together with a 95% CI for the proportion or arithmetic mean of a continuous variable. Estimated proportions will be presented with a corresponding 95% Wilson-Score CI, and estimated means will be presented with a corresponding t-distribution 95% CI. If an estimated proportion is unexpectedly

XSL•FO
RenderX

near the 0 or 1 boundary (eg, <0.1 or >0.9), an exact Clopper-Pearson 95% CI will be used as a sensitivity analysis.

Main protocol analyses will be conducted within the 2 enrolled VL strata separately as the strata sample sizes were selected for stratum-specific estimation and precision. We anticipate that patients in group B will be oversampled for study participation compared with the general clinic population. At the time of final analysis, data from the clinic cohort database will be used to define weights for each VL stratum such that a combined, weighted analysis can be used to generalize back to the clinic population. Details of a combined analysis will be prespecified in a separate analysis plan with consideration of additional patient characteristics such as gender, race and ethnicity, and age. Some exploratory analyses may be conducted using the 2 VL groups.

Qualitative Data Analysis

Data analysis consisted of 4 key steps. The first was reading for content. We began with data reading until the content became intimately familiar. As data were reviewed, emergent themes were noted. The second step was coding. A list of structural codes related to the interview questions was developed. Code definitions were documented in a codebook. Qualitative research assistants were trained to apply the codes using software for qualitative analysis. The codebook was piloted with 5 interview transcripts—each transcript was double coded to reconcile code application, and codes and rules for their application were modified as needed. To ensure intercoder reliability, 100% of the data were double coded. Independent coders reviewed areas of discrepancy until complete agreement was achieved on coded text. The third step was data reduction. We summarized participant responses pertaining to each interview topic and described variation in responses between individuals or among subgroups. We worked with the data related to each code to identify principal subthemes that reflected finer distinctions in the data. The fourth step was data display. Matrices and tables that categorize and display data were used to help facilitate comparisons (eg, across VL strata).

Primary Sample Size Consideration

We estimated the probability that participants would have their hair sample–based MedViewer report delivered as planned (for primary feasibility) within each VL strata with a corresponding 95% Wilson-Score binomial CI. The same approach was used for acceptability, appropriateness, and additional binary end points. A sample size of 50 would enable sufficient precision for a feasibility study to estimate main and secondary outcomes as well as sufficient power for exploratory data analyses.

Results

The Establishing Novel Antiretroviral Imaging for Hair to Elucidate Nonadherence study was approved by the local IRB on November 4, 2019. Provider participant enrollment began on January 17, 2020, and patient participant enrollment began on January 22, 2020. Participant enrollment was halted on March 16, 2020, because of the COVID-19 pandemic. When participant enrollment was halted, there were 16 provider participants and 10 patient participants on study. Study activities resumed on February 2, 2021, with COVID-19 modifications approved by the local IRB. Participant enrollment closed on October 8, 2021, and data collection was closed on November 15, 2021. In total, 36 unique patient participants, representing 37 samples, and 20 provider participants were enrolled. Data analysis and manuscript writing will take place into 2023.

Discussion

Expected Findings

Over the past 10 years, hair analysis has gained importance in forensic sciences, drug testing [15,16], toxicology investigations [17], and drug adherence [18]. Hair is unique in that it has the potential to provide information about drug intake over a longer period compared with other biological fluids, including plasma [4], blood cells [5], and urine [6]. Advances in bioanalytical technology have transitioned hair analysis from gas chromatography–mass spectrometry methods to more efficient and sensitive liquid chromatography triple-quadrupole mass spectrometry (LC-MS/MS) methods. However, several limitations exist. Some ARVs require collecting a thatch of up to 100 strands of hair [19]. As no one multiplex LC-MS/MS method exists to measure all ARVs in a single sample, multiple thatches are required for complete ARV evaluation. This can be a considerable deterrent for individuals with short hair, those who require hair collected between braids, or those who object to the collection of large amounts of hair for cultural reasons [20]. Although sensitive and specific, LC-MS/MS data require at least 7 steps to process hair for analysis, including segmentation, washing and decontamination, cutting or grinding, extracting, and purifying before analysis can occur [21].

Conversely, our IR-MALDESI MSI method uses single hair strands for analysis. Our method can also determine the identity and distribution of multiple drugs and their metabolites in biological matrices with 1 test without complicated labeling approaches [22-24]. IR-MALDESI MSI requires minimal sample processing, allowing sample analysis to be completed within 2 hours of collection.

Poor medication adherence is widespread among those living with HIV and on lifelong ART [25]. Research, including our statewide survey of North Carolina HIV health care providers, has found that physicians face challenges when counseling their patients about ART adherence [26-34] and that health care professionals would benefit from additional support to effectively address adherence [34-36]. Our research, and that of others, has demonstrated that counseling with accurate adherence feedback can enhance medication adherence [25,37-42].

Therefore, this paper described the rationale and method of a new adherence-enhancing intervention that is based on a novel measure using IR-MALDESI MSI of a hair sample to generate a longitudinal ARV adherence report as objective feedback during a routine clinic visit. This technique is noninvasive and can show daily medication response for the previous month depending on the length of the hair tested. In this study, we aimed to transform these medication responses into easily digestible visual aids for both patients and providers.

XSL•FO
RenderX

Our model is unique in that it assesses both the IR-MALDESI assay and the social behavioral impact of the intervention on the patient's motivation to adhere to their medication. Furthermore, the study measures the perceived impact on providers' abilities to counsel their patients and their ability to implement MedViewer in the clinic.

We anticipate that the data collected in this study will provide important insights regarding the feasibility and acceptability of incorporating this new tool into routine clinical care and accentuate potential barriers to medication adherence among patients.

Limitations

This study allowed participants to self-report data about hair treatments (which could make them ineligible), medication adherence, and social behaviors. Self-report measures in research may present social desirability biases as well as recall bias. On patient and provider questionnaires, respondents may have underreported socially undesirable attitudes or answered questions in a favorable manner. To mitigate social desirability bias, questionnaires were self-administered on computers or tablets whenever possible, and the confidentiality of responses was made clear to participants. On the basis of statistical power calculations, 50 patient participants were anticipated to enroll in this pilot study. This limited sample size may limit our ability to detect differences for exploratory comparisons per strata. Another limitation of this study was the recruitment challenges surrounding patients in group B (detectable VL). Barriers included cancellations, no-shows, lost contact, and a very small number of patients with detectable plasma HIV RNA in the clinic. Hair sampling also has limitations, including needing to exclude patients with bald or shaved heads. A total of 6.7% (10/150) of potentially eligible patients were ineligible because of either having insufficient hair on their head or having recently treated their hair with chemical products. Of the eligible patient participants contacted about taking part in the study, 16% (24/150) declined participation for various reasons, including time constraints, distance lived from clinic, and no longer wanting to participate in research as a whole. Of the eligible providers contacted about study participation, 16% (5/32) declined to take part and 28% (9/32) never responded to contact attempts.

The COVID-19 pandemic presented unique challenges that required a protocol amendment after the first 27% (10/37) of patient participants were enrolled in the study. The remaining 73% (27/37) of patient participants were enrolled using the methods in the protocol amendment. The amendment was designed to limit in-person contact and ensure the safety of patients, research staff, and providers. Revisions to our methodology included redefining a real-time visit as "delivery of the report to the designated research staff member within 2 hours of initiation of hair processing" rather than "...within 2 hours of hair sample collection." Furthermore, hair collection during study visit 2 (IDIs) was removed from the protocol. Thus, patient adherence over time was not assessed via hair during the pandemic. To increase safety and flexibility, patient visits were conducted in a web-based format, and telehealth visits were available to patients and providers. Web-based data collection may have affected the results. The nature of the pandemic may have also created interpersonal challenges that discouraged patients from being contacted, seeking care, or expressing interest in participating in research.

Conclusions

To advance the understanding of adherence issues and help inform future research, this project provides insights on the feasibility, acceptability, and appropriateness of integrating MedViewer as an adherence monitoring tool into real-time clinical visits. A strength of this study is that it includes both patient and provider participants to measure the impact on patient behavior and whether it assists providers in their discussions with patients.

This project will contribute to the knowledge gap in the HIV adherence literature and have an effect on ending the HIV and AIDS epidemic. It will advance research by shaping important goals of public health, improving patients' medication adherence, and facilitating a semistructured method for providers to counsel their patients regarding adherence. Data from this study will determine whether having a broader, more comprehensive picture of how well a patient has adhered to their medication approximately 30 days before a routine clinic visit provides patients and their providers with a motivational tool with detailed information to engage in or sustain medication adherence.

Abstract

Background: The COVID-19 pandemic and the associated social restrictions may have disrupted the provision of essential services, including family planning (FP) and contraceptive services. This protocol is adapted from a generic study protocol titled "Health systems analysis and evaluations of the barriers to availability and readiness of sexual and reproductive health services in COVID-19 affected areas," conducted by the World Health Organization (WHO) Department of Reproductive Health and Research.

Objective: This study aims to assess the availability and use of FP and contraceptive services in primary health facilities during and after the COVID-19 pandemic; assess the risk perceptions of COVID-19 stigma, barriers to access, and quality of services from clients' and providers' perspectives in the COVID-19–affected areas; and assess the postpandemic recovery of the facilities in the provision of FP and contraceptive services.

Methods: In-depth interviews will be conducted with clients—women in the reproductive age group and their male partners who visit the selected health facilities for FP and contraceptive services—and health providers (the most knowledgeable person on FP and contraceptive service provision) at the selected health facilities. Focus group discussions will be conducted with clients at the selected health facilities and in the community. The in-depth interviews and focus group discussions will help to understand clients' and health service providers' perspectives of FP and contraceptive service availability and readiness in COVID-19–affected areas. A cross-sectional health facility assessment will be conducted in all the selected health facilities to determine the health facility infrastructure's ability and readiness to provide FP and contraceptive services and to capture the trends in FP and contraceptive services available during the COVID-19 pandemic. Scientific approval for this study is obtained from the WHO Research Project Review Panel, and the WHO Ethics Review Committee has given ethical approval in the 3 countries.

XSL•FO
RenderX

Results: Using a standardized research protocol will ensure that the results from this study can be compared across regions and countries. The study was funded in March 2021. It received ethics approval from the WHO Ethics Review Committee in February 2022. We completed data collection in September 2022. We plan to complete the data analysis by March 2023. We plan to publish the study results by Summer 2023.

Conclusions: The findings from this study will provide a better understanding of the impact of the COVID-19 pandemic on FP and contraceptive services at the facility level, which will help policy makers and health managers develop and strengthen FP policies and services in health facilities to be more responsive to community needs.

KEYWORDS

contraception; family planning; stock-out; COVID-19; facility assessment

Introduction

Background

COVID-19 was first reported in December 2019 and has since spread rapidly around the globe, being declared a pandemic by the World Health Organization (WHO) on 11 March 2020 [1]. The pandemic led to an unprecedented increase in demand on health systems to care for people infected with COVID-19.

Lessons from the Ebola and Zika virus outbreaks have highlighted the severe disruptions in sexual and reproductive health (SRH) services that expose women and girls in particular to preventable health risks [2]. The United Nations Population Division has suggested that the COVID-19 pandemic can result in 60 million fewer users of contraceptive methods worldwide, with projected declines expected to be most significant for injectables (–20%), condoms (–10%) and the pill (–10%) [3]. It is expected that during the pandemic, access to family planning (FP) services will disproportionately affect the rural populations, as supply lines and services are more thinly distributed and contraceptive methods that require medical consultations will have particularly noticeable falls, whereas methods that can be used independently will be less affected [3,4]. According to the United Nations Population Fund, overwhelmed with COVID-19 cases, clinical staff may not have the time or personal protective equipment needed to provide FP counselling and commodities [5]. Women refrain from visiting health facilities due to movement restrictions or fears about COVID-19 exposure. Meanwhile, supply chain disruptions are limiting the availability of contraceptives in many places [6]. It is anticipated that significant levels of lockdown-related disruption over 6 months could leave 47 million women in low- and middle-income countries unable to use modern contraceptives, leading to a projected 7 million additional unintended pregnancies [7]. Furthermore, studies have modelled the potential impacts, showing that even a 10% reduction in essential SRH services could lead to an estimated 15 million unintended pregnancies, 3.3 million unsafe abortions, and 29,000 additional maternal deaths during the next 12 months [7-9].

There is some scientific evidence on the impact of COVID-19 on FP and contraceptive services. A recently published scoping review [10] included 55 studies on the impact of COVID-19 on contraceptive services in low- and middle-income countries. Nearly all studies reported a decline in contraceptive service provision of varying magnitudes, but severe disruptions were relatively uncommon or of limited duration. Most included studies showed declines in at least some indicators of access to contraceptive services during the COVID-19 pandemic. Another scoping review on the global impact of the COVID-19 pandemic on SRH services included 24 studies that showed a decrease in access or use of contraceptive services, especially long-acting reversible contraception, evenly distributed across various contexts and populations [11]. A systematic review reported substantial decreases in contraceptive access and use in all 5 included studies on the impact of the COVID-19 pandemic and the associated lockdowns [12].

This research protocol details a mixed methods study to evaluate the impact of the COVID-19 pandemic on the primary health system's capacity to provide FP and contraceptive services and the perceptions of clients and health care providers about the access and use of FP and contraceptive services in 3 countries: India, Nigeria, and Tanzania. This protocol has been adapted from a generic study titled "Health systems analysis and evaluations of the barriers to availability and readiness of sexual and reproductive health services in COVID-19 affected areas" conducted by the WHO Department of Reproductive Health and Research [13].

Study Aims and Objectives

The study aims to assess the availability of FP and contraceptive services in primary health facilities during the COVID-19 pandemic. The specific study objectives are the following:

- To explore the availability of FP and health facilities' readiness to provide FP and contraceptive services in regions most affected by the COVID-19 pandemic.
- To assess the risk perceptions of COVID-19 stigma as well as barriers to access, use, and quality of services from clients' and providers' perspectives in the COVID-19–affected areas.
- To assess the postpandemic recovery of the facilities in the provision of FP and contraceptive services.

Methods

Study Design

This is a mixed methods study that uses both quantitative and qualitative methods. In-depth interviews (IDIs) and focus group discussions (FGDs) will be used to understand clients' and

XSL•FO
RenderX

health service providers' perspectives of FP and contraceptive service availability and readiness in COVID-19–affected areas. A cross-sectional health facility assessment will be conducted to determine the health facility infrastructure's ability and readiness to provide FP and contraceptive services and to capture the trends in FP and contraceptive services availability during the COVID-19 pandemic. Table 1 summarizes the study design, analysis plan, and the expected outcomes.

Table 1. Overview of study methodology.

Study type and method	Respondent	Study setting	Study tools	Analysis plan	Variable measured
Qualitative study					
In-depth interview	• Women of reproductive age • Men of reproductive age	Health facility	• Semistructured interview guide for women • Semistructured Interview guide for men	Computer- assisted thematic analysis using NVivo or ATLAS.ti	• Knowledge of COVID-19 • Gaps in service provision • Risk perception, beliefs, and concerns • Enablers and barriers in availing services
In-depth interview	• Health care providers	Health facility	• Semistructured interview guide for health care providers	Computer- assisted thematic analysis using NVivo or ATLAS.ti	• Knowledge of COVID-19 • Gaps in service provision • Risk perception, beliefs, and concerns • Recovery in service availability
Focus group discussion	• Women in reproductive age • Men in reproductive age	Health facility	• Focus group discussion topic guide for women • Focus group discussion topic guide for men	Computer- assisted thematic analysis using NVivo or ATLAS.ti	• Knowledge of COVID-19 • Gaps in service provision • Risk perception, beliefs, and concerns • Enablers and barriers in availing services
Focus group discussion	• Women in reproductive age	Community	• Focus group discussion topic guide for women	Computer- assisted thematic analysis using NVivo or ATLAS.ti	• Knowledge of COVID-19 • Gaps in service provision • Risk perception, beliefs, and concerns • Enablers and barriers in availing services
Quantitative study					
Health facility assessment	• Senior Health care provider or administrator	Health facility	• Health facility assessment questionnaire	Database will be developed. SPSS will be used for descriptive analysis.	• Knowledge of COVID-19 • Gaps in service provision • Risk perception, beliefs, and concerns • Recovery in service availability
General client information	• All men and women who participate in Focus group discussions and in-depth interviews	Health facility	• General client questionnaire	Database will be developed. SPSS will be used for descriptive analysis.	• Sociodemographic information

Study Setting

This study will be conducted in India, Nigeria, and Tanzania by the Indian Council of Medical Research—National Institute of Research in Reproductive and Child Health, the University of Ilorin Teaching hospital, and the Ifakara Health Institute, respectively. These 3 countries are selected as they are a part of the WHO FP Accelerator project [14], and we leveraged the support from the project funds to support the research. Other criteria included the willingness of the Ministry of Health to participate in the study as well as the capability and capacity of research institutions in the 3 countries.

In each country, the research team will select study sites based on geographical location (ease of access and areas with a high incidence of COVID-19 cases), organization of FP and contraceptive services, and epidemic status, where the COVID-19 pandemic is likely to have significantly affected service delivery.

Study Population

The study population will be women and their male partners who visit the selected primary health facilities for FP and contraceptive services during the study period. It also includes health providers who provide FP and contraceptive services at

XSL•FO
RenderX

the selected health facilities. In countries where it is not customary for men to accompany their partners when they seek FP and contraceptive services, other options will be used to recruit male partners.

Health Facility Selection

The minimum criteria should be the selection of primary health care facilities providing FP services and the availability of human resources qualified to provide FP and contraceptive services. Rural and urban representation of the primary health facilities in each region will be ensured.

Qualitative Study

Selection of Women and Male Clients

Women and their male partners seeking FP and contraceptive services at the selected facilities will be approached to participate in the IDIs and FGDs. The women and men will be purposively selected, if they fulfil the following criteria: (1) being of reproductive age (18-49 years), (2) having sought or received FP and contraceptive services from the selected primary health facilities, and (3) being comfortable discussing their experience seeking FP and contraceptive services in a group (for FGDs).

A health provider from the selected health facility, who is not a part of the study, will help identify potential participants based on the inclusion criteria and ascertain their willingness to participate in the study. Participants will be purposively selected to obtain a sample of women and men from all socioeconomic backgrounds in the area. The health provider will identify potential participants from among the women visiting the facility for FP and contraceptive services and will ask the women their age and willingness to participate in an FGD using screening questions to check for eligibility. The provider will approach the clients after they have been attended to or while waiting to be attended. The screening will occur in a private room selected by the provider and agreed upon by the study team. Clients who agree to participate will be introduced to the study research team. All participants will be given comprehensive information about the study, and all their questions and concerns will be addressed. Written informed consent will be obtained from all participants.

To provide a holistic picture of the knowledge and perceptions about FP and contraceptive services during the COVID-19 pandemic in the community, FGDs will be conducted with women in the community who have not obtained FP and contraceptive services from the selected public health facility but may have sought FP services from other private or public facilities. The community health workers will help identify participants for this FGD. Interested women will be asked to contact the study team.

The study will recruit a purposive sample of 10 to 15 women (or until saturation) and 6 to 12 male partners (or until saturation) per health facility for the IDIs. At each health facility, one FGD will be conducted with women clients, one with male partners, and one with women in the community.

Selection of Health Care Providers

Health care providers will be purposively selected to participate in the IDIs. Health care providers need to fulfil the following inclusion criteria: (1) those who deliver FP and contraceptive services, (2) are knowledgeable about the readiness and availability of FP and contraceptive services, and (3) are stationed in the FP clinic and have been working at the clinic for at least six months before the pandemic started. The health care provider will be selected after obtaining information from the facility in charge. Participation will be voluntary, and only the health care providers who accept to participate after talking with the study gatekeepers will be referred to the study team for interviews. Approximately 1 to 2 health care providers per health facility will be selected to participate in the IDIs. Depending on the norms and standards for providing FP services in different country contexts, they will include medical doctors, nurses, midwives, nurse assistants, allied health professionals, and other cadres.

Quantitative Study

A general questionnaire for clients will be used to collect sociodemographic data from all participants of the qualitative study. The most knowledgeable person on FP and contraceptive service provision in each selected health facility (senior health care provider or administrator) will be selected to assist in completing the health facility assessment.

Data Collection

Qualitative Study

Qualified researchers with experience in conducting IDIs and FGDs will be selected and trained to ensure the validity of data collection, build trust with participants, and protect participants' privacy and confidentiality. Male facilitators will facilitate the IDIs and FGDs with men, and female facilitators will facilitate FGDs and IDIs with women. The interviews will be conducted in a place that is convenient and safe for the participants to discuss the subject matter freely. The interviews will commence after the introduction and informed consent processes are completed. To ensure all information is captured, interviews will be audio-recorded. The researcher will also take notes on the participant's nonverbal communication during the interview. We expect each IDI to last approximately 40-60 minutes and each FGD to last 60-90 minutes.

To guarantee the anonymity of the participants, any personal or family identifiers will be removed. After each IDI or FGD, the moderators will send the recording to the team supervisor, who will store them securely for transcription. To protect the data from unintended use, the audio files will be encrypted and sent to an electronic database, which will also be shared with the WHO. Therefore, only the research team will be authorized to listen to the recordings. These audio recordings will be retained until the researcher has transcribed and checked them for accuracy, after which they will be destroyed.

Quantitative Study

The health facility assessment survey will be implemented using a cross-sectional survey design. All facilities identified in the selection phase will be assessed. The assessment will include

XSL•FO
RenderX

a review of health facility records of FP and contraception to assess the availability, type, and range of commodities offered prior to, during, and after the pandemic. Records for 6 months prior to the start of the pandemic will be reviewed to determine the recovery in service availability and readiness in health facilities. The assessment will also highlight gaps or service delivery issues during the COVID-19 pandemic. The quantitative data will be collected on paper in India and electronically in Nigeria and Tanzania.

Pilot studies will be conducted in all 3 study sites to ensure the validity of the questionnaires in the local context.

Data Collection Tools

The qualitative study includes 5 data collection tools: (1) IDI topic guide for women, (2) IDI topic guide for men, (3) IDI topic guide for health care providers, (4) FGD topic guide for women, and (5) FGD topic guide for men. These tools will help understand the psychosocial effects of COVID-19 on fertility desires, knowledge of COVID-19, risk perceptions and concerns about the COVID-19 effects on SRH, care-seeking behaviors, experiences and barriers in accessing FP and contraceptive services, the influence of men on access to FP services, and the role the male partners play when their partners require contraception.

The quantitative study includes 2 data collection tools: (1) a general questionnaire to collect sociodemographic information from all participants of the qualitative study and (2) a health facility assessment questionnaire. The health facility assessment questionnaire follows and adopts the WHO's Service Availability and Readiness Assessment tool [15] and the health facility checklist developed by the WHO Health Emergency department [16] for assessment of infrastructure and services. This will help to understand how health systems delivered FP and contraceptive services during the emergency response to the COVID-19 pandemic. The following indicators will be used to assess the availability and readiness of health facilities in the provision of FP and contraceptive services: (1) policies and plans, (2) services maintenance and referrals, (3) infrastructure, (4) commodities, and (5) human resources.

The data collection tools will be translated into local languages: Yoruba and Hausa in Nigeria, Kiswahili in Tanzania, and Hindi and Marathi in India.

Data Analysis

The audio-recorded data will be transcribed verbatim and deidentified using ID numbers. Interviews conducted in local languages will be translated to English and back-translated to ensure there is no distortion of information. The data will be analyzed using general content analysis approach according to the suggested steps by Elo and Kyngäs [17]. This will involve reading through the verbatim transcripts and notes to understand what was being expressed by the participants, noting down emerging themes and patterns in the data, and condensing the data into codes. The codes will be used to generate categories and condensation of related categories into themes that convey the meaning of the data. The coding method and progress will be systematically discussed between the researchers and the project coordinator. The analysis will be done using NVivo software (version 12; QSR International). Two researchers will analyze the same data set and be guided by general questions, specific questions, and comparisons. The analysis will begin while data collection is ongoing to assess progress and determine any data collection problems and patterns.

Quantitative data from the facility assessment survey will be entered into an electronic database using SPSS (IBM Corp). Descriptive analysis will be used to illustrate the basic characteristics of the different facilities, including the monthly number of clients, types of procedures provided, number of medical staff, and stocks of drugs. In Tanzania, the Open Data Kit platform will be used to collect data digitally on tablets, and the KoboCollect App will be used in Nigeria on the research staff's phones for data collection.

Ethics Approval

Scientific approval for this study in 3 countries has been obtained from the WHO Research Project Review Panel. The WHO Ethics Review Committee has given ethical approval for this study in 3 countries (protocol IDs CERC.0103K, CERC.0103J, and CERC.0103I). Each study site is required to obtain ethical approvals based on the specific requirements in each country.

Results

We expect to gain more insight into the impact of the COVID-19 pandemic on FP and contraceptive services at the primary health care level and the trends in contraceptive uptake during and after the pandemic. The study was funded in March 2021 and approved by the WHO Ethics Review Committee in February 2022. Data collection was completed between April and September 2022. The project is ongoing. Expected results will be published in summer 2023.

Discussion

Expected Outcomes

This paper outlines the design of a multicountry study determining the impact of the COVID-19 pandemic on FP and contraceptive services at the primary health care level in India, Nigeria, and Tanzania. This study will explore the availability of FP and health facility readiness to provide FP and contraceptive services; it will assess the risk perceptions of COVID-19 stigma and barriers to access and use services as well as their quality from clients' and providers' perspectives; it will also assess the postpandemic recovery of the facilities in the provision of FP and contraceptive services.

A cross-sectional study was conducted across 10 states of Nigeria to determine the impact of the COVID-19 pandemic on the provision of SRH services at primary health facilities [18]. Findings showed that 97.7% of the 307 primary health centers offered FP services before the pandemic and lockdown, which decreased to 95.8% during the lockdown and reduced to 92.5% after the lockdown. A rapid qualitative study among young men and couples in 2 districts from 2 states of India (Bihar and Uttar Pradesh) showed a marked increase in the demand and use of condoms compared to pre–COVID-19 times,

XSL•FO
RenderX

while women avoided the use of oral contraceptive pills due to the misperception of its ill effects on their health [19]. A mixed methods study in 3 purposively selected districts from 3 regions of Tanzania (Unguja, Pemba, and Dar es Salaam) revealed low uptake of FP services because of changes in clinic schedules, fear of COVID-19 infection, and unavailability of contraceptives [20]. Additionally, the quantitative analysis of FP use between January and March in 2019, 2020, and 2021 showed a decrease in FP use in 2020 for continuing clients, whereas an increased trend was noted for new clients in 2020 and 2021. A web-based survey among 51 clinicians and stakeholders in 29 countries showed that 86% perceived access to contraceptive services was less or much less because of the pandemic [21]. On the other hand, a population-based survey in 4 sub-Saharan African countries (Burkina Faso, Democratic Republic of the Congo, Nigeria, and Kenya) showed that among the 7245 women surveyed, there were no deleterious effects of the pandemic on contraceptive access and use [22].

In the scoping review by Polis et al [10], the study design of most of the included studies (69%) were cross-sectional or longitudinal surveys, and many were conducted on the web or by phone due to the pandemic [10]. However, our study uses a mix of quantitative and qualitative methods to assess the health facilities' availability and readiness to provide these services and clients' and providers' perceptions of the availability and readiness of these services in COVID-19–affected areas. Data in our study will be collected in person.

Polis et al [10] report the reasons for the change in the contraceptive demand as lack of awareness that contraceptives were provided during the pandemic, preferences for methods accessible with no or fewer visits to health facilities, use of condoms to attempt prevention of COVID-19 transmission, and the stigma that respondents perceived or experienced at health facilities. The reasons for disruptions in the provision of contraceptives were reported as reduced availability or stock-outs, not being able to offer provider-administered methods, health providers advising FP clients not to seek services at health facilities, fewer clients permitted in clinics due to social distancing measures, and service disruptions across multiple humanitarian contexts due to mandatory restrictions, lockdowns, and curfews. Key barriers to accessing contraceptive services during the pandemic included fear of infection in general and in health facilities, lack of transport or travel-related restrictions, costs, increased waiting times, limited home visits by health workers who would normally provide contraceptive services, lack of supplies, and for adolescents in humanitarian settings, the compounding effect of other pandemic challenges, such as being out of school and isolated from peers [10].

Limitations

We anticipate certain limitations for this study. The study focuses on primary health care facilities and only in a few sites per country. The information gained might not be generalizable to the situation in other public facilities and private facilities as well as all over the country. However, information on FP access at this level is necessary because it indicates the situation the most vulnerable in the society are facing and would call for prompt intervention. The use of a standardized research protocol can ensure that the results from these studies can be compared across regions and countries and will potentially improve the quality of observational studies by identifying and minimizing biases. Since most of the countries are out of the pandemic, there can be recall bias because participants would be reproducing the experiences from the past 2 years. However, as the pandemic and lockdowns are rare events, many might remember their personal experiences.

Conclusions

The findings from this study will provide a better understanding of the impact of the COVID-19 pandemic on FP and contraceptive services at the subnational and facility level, which will help policy makers and health managers develop and strengthen policies and services to be more responsive to community needs. These policies and services will ensure the availability of a contraceptive method mix that is accessible, affordable, and women-centered during emergency situations like the COVID-19 pandemic.

Acknowledgments

We want to thank Dr Moazzam Ali for the generic study titled "Health systems analysis and evaluation of the barriers to availability, utilization and readiness of sexual and reproductive health services in COVID-19 affected areas" that was adapted for this study.

We would like to acknowledge the support of the World Health Organization (WHO) Family Planning (FP) Accelerator Project 2019-2022, which provided technical assistance to the countries.

This research is funded by the Canadian grant to the WHO Department of Sexual and Reproductive Health and Research; this includes the United Nations Development Programme (UNDP), The United Nations Population Fund (UNFPA), United Nations International Children's Emergency Fund (UNICEF), WHO, World Bank Special Programme of Research, and Development and Research Training in Human Reproduction (Human Reproduction Programme [HRP]). This protocol has been peer reviewed by HRP. The funding agency has no role in the design of this protocol and will not have any role in the implementation, analysis, and reporting of the study results.

Authors' Contributions

RK, KPA, JK, BJ, EE, and TMA were involved in the conception and study design. TMA, BJ, EE, AO, DT, RKP, MR, and DS are responsible for assuring the quality of data acquisition and will be responsible for data analysis and interpretation.

Abstract

Background: Research and policy demonstrate the value and need for the systematic inclusion of care partners in hospital care delivery of people living with Alzheimer disease and related dementias (ADRD). Support provided to care partners through information and training regarding caregiving responsibilities is important to facilitating their active inclusion and ultimately improving hospital outcomes of people living with ADRD. To promote care partners' active inclusion, a toolkit that guides health systems in the identification, assessment, and training of care partners is needed. User-centered approaches can address this gap in practice by creating toolkits that are practical and responsive to the needs of care partners and their hospitalized family members and friends living with ADRD.

Objective: This paper describes the study protocol for the development and refinement of the ADRD Systematic Hospital Inclusion Family Toolkit (A-SHIFT). A-SHIFT will provide health care systems with guidance on how to effectively identify, assess, and train care partners of hospitalized persons living with ADRD.

Methods: The A-SHIFT study protocol will use a 3-aimed, convergent mixed method approach to iteratively develop and refine the toolkit. In Aim 1, we will use a systems-engineering approach to characterize patterns of care partner inclusion in hospital care for people living with ADRD. In Aim 2, we will partner with stakeholders to identify and prioritize health care system facilitators and barriers to the inclusion for care partners of hospitalized people living with ADRD. In Aim 3, we will work with stakeholders to co-design an adaptable toolkit to be used by health systems to facilitate the identification, assessment, and training of care partners of hospitalized people living with ADRD. Our convergent mixed method approach will facilitate triangulation across all 3 aims to increase the credibility and transferability of results. We anticipate this study to take 24 months between September 1, 2022, and August 31, 2024.

Results: The A-SHIFT study protocol will yield (1) optimal points in the hospital workflow for care partner inclusion, (2) a prioritized list of potentially modifiable barriers and facilitators to including care partners in the hospitalization of people living

XSL•FO
RenderX

with ADRD, and (3) a converged-upon, ready for feasibility testing of the toolkit to guide the inclusion of care partners of people living with ADRD in hospital care.

Conclusions: We anticipate that the resultant A-SHIFT will provide health systems with a readiness checklist, implementation plan, and resources for identifying, assessing, and training care partners on how to fulfill their caregiving roles for people living with ADRD after hospital discharge. A-SHIFT has the potential to not only improve care partner preparedness but also help reduce health and service use outcomes for people living with ADRD after hospital discharge.

caregiving; co-design; dementia; health care; systems; mixed methods

Introduction

Persons living with Alzheimer disease and related dementias (ADRD) experience not only poorer health outcomes, but more hospital admissions and readmissions, longer hospital stays, and higher health care costs than older people who have not been diagnosed with ADRD [1-6]. Research and policy call for the systematic inclusion of care partners of people living with ADRD in hospitalizations to improve these health service use outcomes**.** Care partner inclusion has been associated with reduced readmissions and increased net savings [7,8]. Furthermore, when included in care, care partners report feeling more satisfied and less burdened [9]. Moreover, the policy has been mandated to better assist care partners in the hospital setting, including the Caregiver Advise, Record, and Enable Act. Across 44 states, hospitals are required to (1) provide patients with the opportunity to identify a care partner; (2) inform the patient and care partner when the discharge is to occur; and (3) provide the patient and care partner training regarding the discharge care plan [10]. Despite the supporting research and policy, care partners often report feeling unprepared to fulfill caregiving roles during and after a hospitalization of a family member or friend living with ADRD [11,12]. This is problematic as the 2022 National Strategy to Support Family Caregivers outlines federal, state, and local actions to help strengthen care partner services, including “recognizing them as essential partners in care teams of the person to whom they are providing support” (Outcome 2.1) [13].

Although research and policy work endorse the need for inclusive care practices, to our knowledge, no toolkit exists to guide health care systems when working with care partners of people living with ADRD [14]. To address this gap, in accordance with the National Institutes of Health Stage Model for Behavioral Intervention Development [15], we propose to conduct the critical Stage 0 and IA activities to develop the ADRD Systematic Hospital Inclusion Family Toolkit (A-SHIFT). We will use a user-centered approach to address each stage and to (1) uncover key hospital workflow intervention points, (2) identify and prioritize barriers and facilitators to care partner inclusion at multiple system levels (Stage 0), and (3) guide the transformation of these factors through stakeholder co-design into a comprehensive toolkit to help facilitate the inclusion of care partners of hospitalized people with ADRD, which is adaptable for use by different health systems (Stage IA). The following specific aims will be accomplished:

- Aim 1: describe the current practices around care partner identification, assessment, and training for hospitalized people living with ADRD.
- Aim 2: identify and prioritize health care system facilitators and barriers to the inclusion of care partners of hospitalized people living with ADRD.
- Aim 3: collaborate with stakeholders to co-design an adaptable toolkit to facilitate the inclusion of care partners of hospitalized people living with ADRD.

Toolkits, such as A-SHIFT can provide health care systems practical guidance regarding how to systematically include, assess, and train care partners of hospitalized people with ADRD. Further, A-SHIFT will be scalable to health care systems across the United States, providing the foundation for fulfilling the needs of care partners and alleviating their feelings of being unprepared to provide care following discharge.

Methods

Design and Conceptual Framework

Our interdisciplinary team will use a convergent mixed method approach [16] using systems engineering methods to conduct the necessary Stage 0 and IA activities of the National Institutes of Health Stage Model [15] to develop A-SHIFT across 3 aims (Figure 1). Our aims are guided by the System Engineering Initiative for Patient Safety (SEIPS) 2.0 model (Figure 2) [17]. SEIPS 2.0 has been used to design and implement health care processes in myriad health care settings [18-23]. SEIPS 2.0 expands upon Donabedian’s structure-process-outcome model [24] by providing a detailed and expanded structure (ie, work system) of interacting components (people [or teams]; tasks; tools and technology; organizational factors [eg, policies and teamwork]; physical environment [lighting, noise]; and external environment) that influence health care processes (eg, identify, assess, and train care partners of hospitalized people living with ADRD) and outcomes [4]. The model depicts a system that adapts to process changes and outcomes. SEIPS 2.0 will be used to guide data collection and analysis to ensure the identification of factors influencing care partner inclusion across all system components.

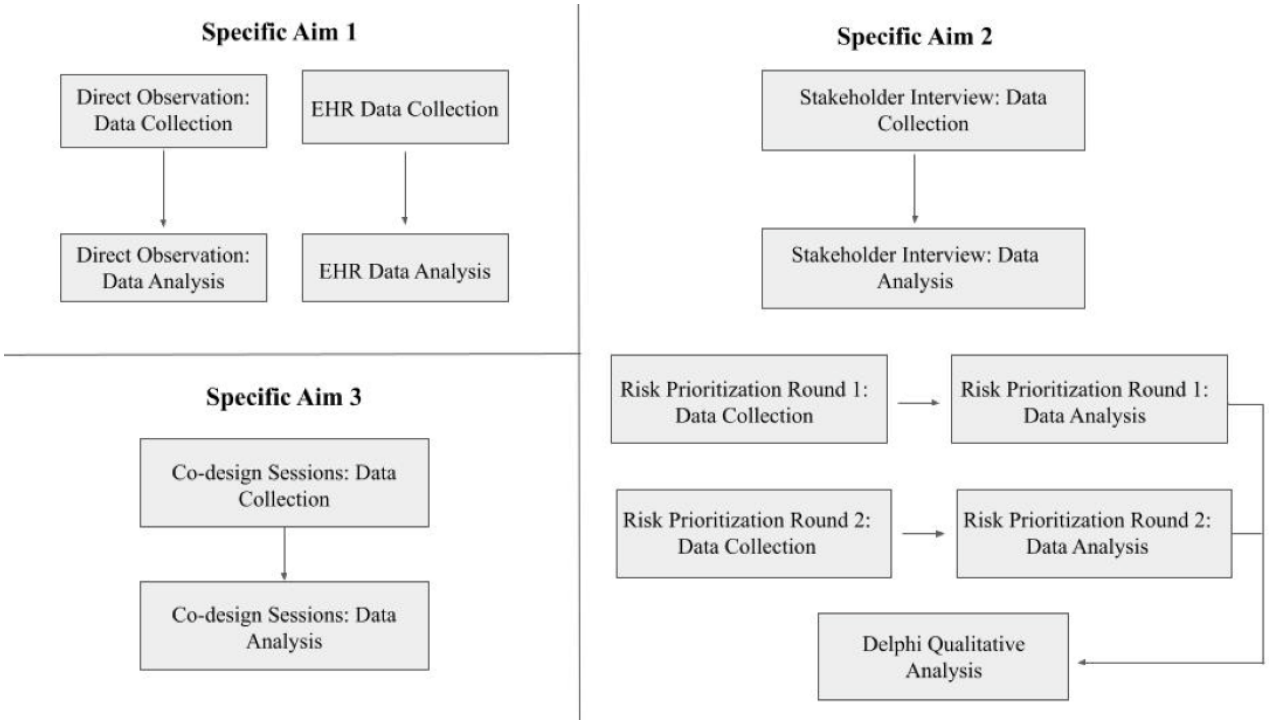

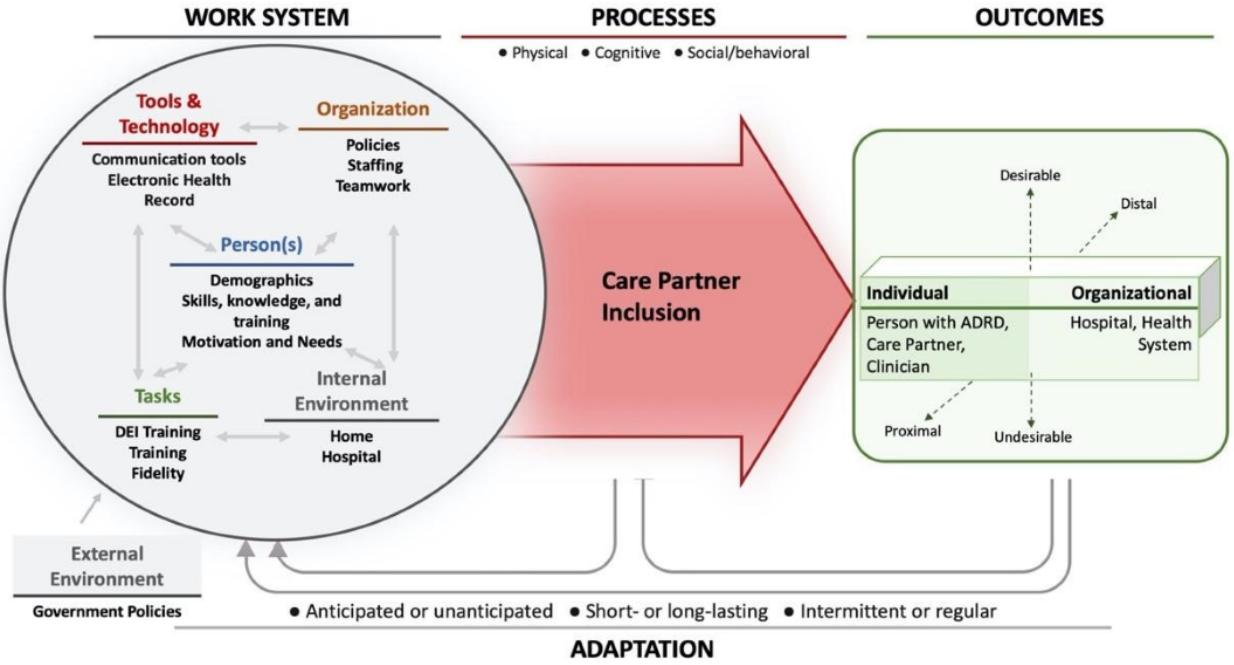

Figure 2. System Engineering Initiative for Patient Safety 2.0. ADRD: Alzheimer disease and related dementias; DEI: Diversity, Equity, and Inclusion.

Aim 1: Using Direct Observation and Electronic Health Record Data to Characterize Patterns of Care Partner Inclusion in Hospital Care for People Living With ADRD

Setting

We will collect observation and electronic health record (EHR) data from a large academic health care system in the Midwest. This system serves more than 600,000 patients each year with approximately 1750 physicians and 2100 staff at 7 hospitals and more than 80 outpatient sites. A major focus of this health care system is to put patients and their families, health plan members, employees, and community at the center of everything they do and create a model that ensures patient and family-centered care.

Direct Observation Sample

We will purposively select 4 diverse inpatient units from this health care system for direct observations, such as a trauma or medical surgical unit, an orthopedic unit, a family practice unit, and a neuroscience or stroke unit. These units allow for more

XSL•FO
RenderX

heterogeneity of admitted patient conditions, providing us greatest exposure to various care partner needs.

EHR Sample

We will purposively select EHRs for patients across all hospitals in the health care system who meet our selection criteria: (1) aged >18 years with an ADRD diagnosis, (2) admitted to an inpatient unit, and (3) care partner identification, assessment, or training documented during patients' hospital stay. To enhance rigor and reproducibility, there will be no exclusion based on sex, race, ethnicity, or HIV status. Records will be excluded for same-day surgery patients and patient discharge disposition that is not home (eg, skilled nursing facility).

Direct Observation Data Collection

We will capture care partner interactions on each selected unit using a structured SEIPS 2.0-based observation guide in Vosaic Software (Table 1) [25]. Observations will be conducted across 3 days in each unit. Each observation session will consist of a 3-hour block of time that represents morning, afternoon, and evening shifts to maximize understanding of different care points and care partners' availability. In total, we will collect 27 hours of direct observations of direct care experiences (3 hours×3 days×3 units). Research team members will be trained to use the observation guide on department-owned laptops stored in a locked room. Training will consist of at least 2 meetings with the PI and research team members to discuss example observations for each code and review consent processes. Before starting data collection, the unit director will give a brief overview of the project to the clinicians on the unit and introduce the research team members. The team members will complete the observation guide for each interaction a clinician has with an admitted patient and any present care partners. Within a given interaction, team members will use Vosaic Software [25] to record each time they witness a code in the observation guide. To increase trustworthiness in our observations, each team member will create memos describing their observations of patient care and care partner inclusion, in addition to using the observation guide.

Table 1. Observation and electronic health record (EHR) data collection examples.

SEIPS[a] component	Observation protocol	EHR fields
Work system organization internal environment	• Are care partner policies, education, or trainings posted? • What is the staff/patient ratio? • Are there designated areas for care partners?	• Hospital location (suburban, urban, and rural), size of unit
Work system personnel	• Do providers invite care partners into patient interaction? • How many providers did the care partner interact with?	• International Classification of Diseases (ICD)-10 code, length of stay, discharge disposition, patient age, Patient sex, marital status, reason for admission
Process care delivery	• At what point in the stay is the observation occurring: admission; during stay; discharge • How do providers involve care partners: assessment; hands-on demonstration; verbal instruction; written instruction • Were care partners notified of upcoming patient discharge?	• Medical service (ie, provider type), patient or care partner education topic (eg, prescriptions, pain management, food and fluids, and preventing infections), patient or care partner taught (eg, patient, child, and spouse), patient or care partner education method (eg, oral instruction, demonstration, printed materials, and teach back)
Outcome patient	• Do patients and care partners seem satisfied with their care experiences?	N/A[b]
Work system technologies	• Do care partners have access to EHRs or other tools? • Did providers document care partner interactions?	N/A

[a]SEIPS: System Engineering Initiative for Patient Safety.

[b]N/A: not applicable.

Direct Observation Data Analysis

Data will be summarized as frequencies and proportions, as appropriate. Frequencies will represent the number of times our study team observed a given phenomenon, such as the use of a care partner assessment by a provider. Proportions will provide a nuanced picture of the relative frequencies of certain codes, such as how often care partner education was initiated by the provider versus the care partner themselves. We will then create a SEIPS 2.0-based process map of the current hospital workflow to include care partners using both observation and memo data. We have developed methods for using SEIPS 2.0 to create process maps that simultaneously depict workflow and the system barriers associated with each stage of the workflow [26].

EHR Data Collection

We will select EHR fields that align with SEIPS 2.0 domains (Table 1). Data will be obtained from January 2019 to August 2022 to capture care practices before and during the COVID-19 pandemic. This time frame will allow us to better understand

XSL•FO
RenderX

the impact of any visitor restrictions on care partner inclusion practices.

EHR Data Analysis

To calculate the sample size, we conducted an a priori power analysis using G*Power 3.1 [27]. For a chi-square goodness-of-fit test with a small effect size of 0.3, an α level of .05, a power level of 0.80, and 10 degrees of freedom (the maximum for any of our variables), a sample size of 181 was determined. We anticipate identifying several thousand patients in the hospital system who meet our inclusion criteria. We will not be able to gather EHR data from the same patients we observe due to the time it can take to record, process, and submit documentation for billing purposes. We will use SAS 9.4 [28] for data management and statistical analysis of the EHR data. We will conduct descriptive analyses of means, SDs, medians, and frequencies for all project variables.

Merging the Observation and EHR Data

We will use our direct observation data to identify ways in which to stratify the EHR care partner inclusion characteristics. For example, our direct observations may indicate that clinicians tend to include care partners in hospital care in distinct ways. We may also learn from our direct observations that patients with certain admitting conditions (ie, ICD-10 code) are more likely to have their care partners included in care. Depending on how we stratify care partner inclusion characteristics, we will use bivariate analyses: *t* test or ANOVA (continuous variables) and chi-square tests (categorical variables). We will also use classification and regression tree analysis to look for patterns in care partner inclusion across competing prediction variables. Classification and regression tree produces clear classification criteria and a visual "tree" showing the hierarchical relationships between variables within subgroups of the sample, which facilitates interpretation and direct translation to practice.

Aim 2: Using Stakeholder Interviews and Risk Prioritization Methods to Identify and Prioritize Health Care System Facilitators and Barriers to the Inclusion of Care Partners of Hospitalized People Living With ADRD

Setting

Based on established relationships with UW Health, the University of Pittsburgh National Center on Family Support, and the Johns Hopkins University School of Medicine, we will recruit stakeholders from 3 geographical locations, Wisconsin, Pennsylvania, and Maryland. These locations will provide increased exposure to various health care system facilitators and barriers to the inclusion of care partners of hospitalized people living with ADRD.

Sample

Stakeholders will be purposefully selected from the following groups: (1) health care administrators and payers, (2) frontline clinicians (eg, hospital-based physicians, nurses, pharmacists, and therapists), and (3) hospitalized patients with ADRD and their care partners. These groups were selected because they will help our research team better understand dementia care in the hospital setting based on direct experiences. In each geographical location, we will recruit 5 health care administrators and payers, 5 frontline clinicians, and 5 patient and care partner dyads that meet eligibility criteria (Table 2).

Table 2. Sampling plan.

Stakeholder	Reason for inclusion	Eligibility criteria	Target, n
Health care administrators and payers	Knowledge and expertise related to the day-to-day operations of hospital, patient eligibility, enrollment, claims, and payment of health services	• Have at least 5 years professional experience in position • Speak and understand English	15
Frontline clinicians	Knowledge and expertise related to the delivery of health services	• Have at least 5 years professional experience in their position • Speak and understand English	15

Patients with ADRD[a] and their care partners	Knowledge and experience related to receiving hospital care	• Patient:
		  • Admitted to, or recently (within the last year) discharged from a hospital
		  • Diagnosed with some form of dementia
		  • Identified a care partner
		• Care partner:
		  • provide unpaid care to a relative or partner with ADRD
		  • be at least 18 years of age or older
		  • speak and understand English
			15 dyads

[a]ADRD: Alzheimer disease and related dementias

Stakeholder Interviews Data Collection

We will conduct semistructured interviews either face-to-face or over the telephone with stakeholders. The semistructured interview guide will be developed based on SEIPS 2.0 (Table 3) and will be tailored to each stakeholders' experiences and responsibilities. Interviews will last up to 60 minutes and will be audio recorded, transcribed verbatim using department desktops in a locked lab space, and analyzed in NVivo 12 [29].

XSL•FO
RenderX

Table 3. Example System Engineering Initiative for Patient Safety (SEIPS) 2.0–guided interview questions.

SEIPS 2.0 domain	Stakeholder	Interview questions
Work system (Organization and Environment)	Health care administrators	In what ways, if any, does your organization demonstrate patient and family-centered care?
Process (Care Delivery)	Frontline clinicians	In what ways, if any, do you communicate discharge plans with care partners?
Outcome (Patient)	Patient and care partner dyad	In what ways do you feel you were prepared to carry out health care tasks once home?
Work system (Technologies)	Frontline clinicians	In what ways, if any, are care partner inclusion practices documented within the EHR[a]?
Outcomes (Organizational)	Wisconsin-based payers	In what ways, if any, are care partner inclusion practices evaluated?

[a]EHR: electronic health record.

Stakeholder Interviews Data Analysis

We will perform directed content analysis [30] guided by SEIPS 2.0. The research team will review a subset (ie, 2-3) of interview transcripts and use SEIPS 2.0 to develop high-level codes of facilitators and barriers to the systematic inclusion of care partners in hospital care. For example, under the high-level code of "tools and technology," there will be a subcode for barriers and for facilitators. We will use these codes as guides to review subsequent transcripts and revise codes as needed until the codebook is formalized. Two team members will apply the codebook to independently code 20% of the data. We will then use the coding comparison query function in NVivo 12 to measure intercoder reliability. A threshold will be set at 80% agreement based on suggested values of intercoder reliability [16]. The team members will discuss disagreements and continue to code 2-3 interviews independently until this threshold is reached. Once the threshold is met, team members will finish the remaining coding. After the qualitative coding of interviews is completed, frequencies of code usage and percentages of all coded texts will be computed to quantify the degree to which certain aspects of SEIPS 2.0 were represented.

Risk Prioritization Data Collection

We will use a modified Delphi approach [31] where the same stakeholders who participated in interviews will conduct risk prioritization ratings in 2 rounds. We will conduct the first round of the Delphi over a 1-month period. Each group of stakeholders will be sent a web-based questionnaire using the Qualtrics survey platform. They will be asked to rate each barrier and facilitator identified from the stakeholder interviews on the following three categories, each on a 5-point scale: (1) frequency of occurrence (very high frequency to very low frequency), (2) level of importance in influencing the inclusion of care partners in hospitalizations (very high importance to very low importance), and (3) likelihood that the factor is modifiable (very high to very low). We will also provide an optional free-text field for each entry so that stakeholders can provide comments about each barrier and facilitator or their rating decision. Stakeholders will also be able to enter suggestions for additional content that they think is missing and important to add. The free-text data will allow for an in-depth understanding of the rationale underlying ratings and will also serve as a member-checking process to ensure validity of the data. Following the same procedures from round 1, we will conduct round 2 of the risk prioritization. In this round, stakeholders will be provided with a reminder of what their ratings were in round 1, and will also be provided with, and asked to consider, the combined responses from all other stakeholders in round 1.

Risk Prioritization Data Analysis

We will use descriptive statistics to summarize responses. We will then assign each potential item an overall prioritization score by multiplying the individual scores from each category. Factors that received over 75% consensus among stakeholders will be considered to have met consensus in round 1. Items will be considered to have met consensus when at least 75% (34/45) of stakeholders agree within 1 point on the Likert scale, for example, over 75% of participants rate an item as likely (4) or extremely likely (5). Factors that receive less than 75% consensus will be used in the second round of ratings. A systematic review of Delphi studies indicated that 75% was the median threshold for percent agreement-based consensus across studies [32]. Factors that do not reach over 75% consensus after round 2 will not be included in the prioritization index. However, factors not reaching consensus will be presented for consensus discussion by design teams in Aim 3.

The free-text data will be uploaded to NVivo 12 for qualitative analysis. We will use an interdisciplinary team-based thematic analysis [33] to identify themes related to stakeholders' rationale for ratings. Coding will be performed by research team members independently, and themes will be developed iteratively following the 6 phases outlined by Clarke and Braun [33]. In phase 1, we will familiarize ourselves with the data from both rounds of risk prioritization. In phase 2, we will thoroughly code the data using a systematic process guided by SEIPS 2.0. Team discussions will be used to reach a consensus on codes throughout this phase [34]. We will then move into phase 3, which involves a generation of initial, or candidate, themes and an exploration of relationships between themes. This phase will produce a thematic map to display these relationships. In phase 4, we will assess our candidate themes against the coded data to evaluate how well the themes fit the coded data. If a good fit is determined, the research team will assess candidate themes against the entire data set, editing the themes as needed. This process will continue until the research team members have come to a consensus and are satisfied with the definitive themes. Phase 5 will involve generating definitions for each theme. This process will conclude with phase 6, which consists of writing up the findings of this analysis [33].

XSL•FO
RenderX

Aim 3: Using a Co-design Process to Iteratively Develop an Adaptable Toolkit to be Used by Various Health Care Systems to Facilitate the Inclusion of Care Partners of Hospitalized People Living With ADRD

Setting and Sample

We will convene 2 co-design groups using the same recruitment settings and stakeholders from Aim 2. One group will consist of patient or care partner dyads and the other group of health care administrators, payers, and clinicians. Each design team will have approximately 5 to 7 stakeholders, which is within the standard range of stakeholders used in participatory design research [35]. The odd number of stakeholders allows for a tie-breaking perspective in the groups. The small number of stakeholders in groups (ie, rather than 10-14 in one group) reduces the potential for groupthink (ie, by having products from 1 group evaluated by the other) and ensures that all stakeholders have ample time to provide their perspectives [36].

Co-design Data Collection

Design teams will complete 5 co-design videoconference sessions occurring in parallel across 4 months, with 3 weeks between each session. The design process can be conceptualized as a funnel [6] in which we start with myriad divergent ideas and then begin to work toward convergence through the sessions. In session 1, we will present the teams with the prioritized list from our risk prioritization process completed in Aim 2. We will lead discussion, interpretation, and respectful debate among design team members to begin to generate health care system process changes to optimize the inclusion for care partners of hospitalized people living with ADRD. We will ensure progress toward solution convergence from session to session. The design teams will conduct sessions independently, but in between sessions will swap solutions and provide feedback, which we will summarize and present in subsequent sessions. Each session will last up to 90 minutes. Sessions will be audio recorded for subsequent analysis. Sessions will be held virtually to support retention using our established web-based process for participatory design, which has been a successful alternative to in-person design sessions.

Co-design Data Analysis

Analysis of design session outputs such as sketches, use of case scenarios, ratings, research team memos, and stakeholder notes will occur both within and between sessions. Within sessions, we will guide stakeholders in generating, grouping, and converging upon design solutions. Within the 3-week period between sessions, we will review the audio recording of the session and use the rapid identification of themes from audio-recordings method [37] to identify design specifications. We will combine the themes from the rapid identification of themes from audio recordings with synthesized outputs from the session (eg, sketches and ratings) to provide inputs to stakeholders at the following design session. Following the design session completion, we will continue to refine the A-SHIFT, applying input from the final design session, and performing member checking by reviewing changes with the stakeholder groups [38].

Ethics Approval

The study was approved by the Institutional Review Board (IRB) at the University of Wisconsin-Madison on March 23, 2023 (approval no. 2022-0024). All protocol modifications will be reviewed and approved by the IRB as needed. We will obtain a waiver of signed consent using a process that employs an IRB-approved information sheet.

Results

We anticipate this study to take 24 months to complete. All 3 aims will take place between September 1, 2022, and August 31, 2024. We expect the following results:

- Aim 1 expected results: observations and EHRs will provide 2 views of care partner interactions—whether care partners are included in hospital care and how inclusion is documented. Analyses are in progress and will result in the identification of optimal points in the hospital workflow for care partner inclusion that will be presented during stakeholder interviews in Aim 2.
- Aim 2 expected results: a prioritized list of potentially modifiable barriers and facilitators to including care partners in hospitalization of people living with ADRD will be presented to the Aim 3 co-design teams. This information will provide the basis for designing A-SHIFT.
- Aim 3 expected results: results will provide a converged-upon, ready for feasibility testing of A-SHIFT to guide inclusion of care partners in hospital care of people living with ADRD. We anticipate that the A-SHIFT will include strategies on when and how to identify care partners in hospital care, tools for assessing the needs of care partners and their caregiving preparedness, methods for how to train care partners to fulfill caregiving roles for people living with ADRD after hospital discharge, a health care system readiness checklist and implementation plan, and suggested measures of successful implementation.

Study results will be disseminated in peer-reviewed journals and presented at annual scientific meetings. We will also share the results of this study directly with stakeholders by developing infographics. These will be distributed through dementia caregiving networks and established partnerships.

Discussion

Despite research and policy calling for the systematic inclusion of care partners in hospitalizations to improve outcomes of persons living with dementia, no toolkit exists to guide health care systems on how to effectively identify, assess, and train care partners.

We will be using a user-centered, systems engineering approach to develop A-SHIFT that is well-suited to address real-life barriers to care partner inclusion in health systems. Our systems-engineering approach to development increases the likelihood of the successful implementation of A-SHIFT in health systems. In using SEIPS 2.0, we will acquire a comprehensive understanding of the work systems, processes, and outcomes related to care partner inclusion that will enable us to create a toolkit that addresses barriers in each of these

XSL•FO
RenderX

areas. SEIPS is an inherently user-centered model, which places the people at the center, and as such, promotes the design of systems that optimally support the people in the system. Additionally, we will use a mixed methodology in our data collection, which will provide us with a rich understanding of current practices of care partner inclusion that quantitative and qualitative methods could not provide on their own. Most importantly, our methodology involves stakeholders from multiple disciplines, sites, and geographical areas, which will increase the likelihood of A-SHIFT being implemented across a range of health systems. Our user-centered approach, including engaging stakeholders as co-designers, has been recognized as an important approach by the World Health Organization [39], the National Institute of Standards and Technology [40-42], and the International Standards Organization [43,44]. The user-centered approach is the epitome of person-centered methodologies [45] and is critical to the design of an A-SHIFT that meets the needs of all stakeholders.

We may find that stakeholders will not wish to participate in this study, or that we cannot retain them as expected. We have infrastructure, however, for successfully recruiting and retaining stakeholders, and strong partnerships to expand recruitment strategies. For example, our team has secured funding to provide stakeholders compensation and we have access to technology support. We have also designed our approach to reduce stakeholder burden. In particular, we will use phone and videoconferencing to conduct interviews and design meetings and we will mail stakeholders remuneration. Although we have adapted our risk prioritization methods to be delivered using a Delphi approach as a COVID-19 precaution, we recognize that this approach is slower than traditional in-person focus groups or meetings. Our research team has also fostered collaborative partnerships with representatives from 3 different health care systems to increase the generalizability of A-SHIFT. Although the direct observations and EHR data from Aim 1 will only represent 1 academic medical setting, these results will serve as a basis for discussion with stakeholders from all 3 systems in Aims 2 and 3.

A-SHIFT will provide diverse health care systems guidance on how to identify, assess, and train care partners of hospitalized people living with ADRD. Our inclusion of stakeholders from health systems in different geographical locations will promote the creation of a toolkit that is more generalizable across health systems. The development and refinement of A-SHIFT are critical for the next planned R-series grant proposals, which will address Stage 1B feasibility testing followed by hybrid efficacy or effectiveness testing of A-SHIFT's effectiveness at improving care partner preparedness and reducing avoidable hospital readmissions by people living with ADRD. Care partners that are well-prepared have the potential to increase their own well-being and also help optimize health and service use outcomes for people with living ADRD after hospital discharge. Furthermore, we hope our study protocol can be used as a model for researchers to develop additional toolkits to target key areas of concern across health care systems. Our comprehensive, systems-engineering approach promotes the creation of user-centered toolkits that meet all stakeholder needs to foster sustainable change in health care system processes to ultimately improve patient and care partner outcomes.

Abstract

Background: Prevalence estimates for mental health–related problems, including above-average stress, psychological distress, and symptoms of mental illnesses have increased significantly among Canadian postsecondary students. As demand for downstream mental treatment has surpassed many institutions' abilities to deliver timely care, there is a need for innovative upstream supports that foster mental health promotion and mental illness prevention among this population.

Objective: Supported by an extensive network of student volunteers, Canada's Student Mental Health Network is a virtual, one-stop shop for centralized mental health education and evidence-based resources tailored to postsecondary students. This article describes a protocol for the comprehensive evaluation of the Network.

Methods: Development of the Network was developed using a participatory action research framework. Network content is created and curated by students and reviewed by subject matter experts. The proposed program evaluation will include both a formative process evaluation and a summative impact assessment to determine the feasibility, acceptability, and utility of the Network in addition to assessing change in the 3 primary outcomes of interest: mental health literacy, perceived social support, and help-seeking behavior. Participants will be recruited directly from the Network website using a "rolling" recruitment approach to allow for continuous data collection and evaluation. A combination of qualitative (ie, interviews) and quantitative (ie, surveys) methods of data collection will be used.

Results: The process of evaluation of the Network will begin in September 2022, collecting data for 1 year. In September 2023, the impact evaluation will begin using the same follow-up schedule. Data collection will then remain ongoing to facilitate the continued evaluation of the Network. Reports detailing evaluation data will be released annually.

Conclusions: The Network is a novel and innovative method of delivering universal mental health promotion to Canadian postsecondary students by providing centralized and freely accessible mental health education and resources, created by students and validated by subject matter experts. The continued creation and curation of resources for the Network will be ongoing to meet the evolving needs of the target population.

Introduction

Background

Prevalence estimates for above-average stress, psychological distress, and symptoms of mental illnesses have increased significantly among Canadian postsecondary students over the past several years [1]. Excessive stress has been linked to a number of negative academic (ie, decreased performance and decreased motivation) and health (ie, anxiety and depression) outcomes among students [2,3]. Indeed, data collected from Canadian postsecondary institutions through the 2019 National College Health Assessment II survey revealed large proportions of students feeling hopeless (63.6%), overwhelmed (88.2%), and anxious (68.9%) within the past 12 months [4].

Existing research has highlighted the variety of stressors students experience within the postsecondary setting [5,6]. The COVID-19 pandemic produced additional, novel stressors, with national data suggesting postsecondary aged Canadians were the most likely to report increased symptoms of anxiety and depression throughout the pandemic [7]. Over the past decade, demand for downstream mental health services (ie, counseling and pharmacotherapy) has surpassed institutions' capacities to deliver timely care [8]. In the wake of the pandemic and its mental health-related fallout, there is reason to believe that this demand will only continue to increase [9]. Placing additional focus on upstream mental health supports (ie, those that aim to intervene before the development of psychological distress) may contribute toward alleviating the bottleneck currently observed at the downstream level. Upstream supports can help to bolster students' resilience and well-being by providing them with the skills and resources required to monitor and respond to the changes in their mental health, as well as providing education around appropriately aligning level of help seeking with level of need.

While some form of mental health promotion is offered by many institutions, a national review of mental health and well-being services on Canadian postsecondary campuses found that only 70% of respondents felt students were well-informed about available resources on campus, and about mental health issues in general [10]. Many respondents (84%) also indicated that they felt there was room for improvement in the mental health promotion supports currently offered on their campus [10]. One of these barriers is the cost associated with accessing some forms of mental health education. For example, many institutions now offer for-credit mental health courses, but students must be formally registered at a substantial cost. Training courses such as Mental Health First Aid, SafeTALK, and others sometimes also require a registration fee. The second barrier lies in the reality that some institutions have more available budget than others to put toward campus mental health supports. Larger schools tend to have more funding and can therefore offer more robust mental health support to students compared to smaller schools. At most institutions, the majority of the mental health budget is skewed toward downstream services, typically leaving upstream supports to operate on more limited resources. Finally, accessibility and logistics barriers are another consideration. Many mental health promotion supports provided by institutions take the form of on-campus workshops and events. This poses a barrier for some groups of students who may be left out (ie, web-based students, students studying abroad, and students who commute to campus), as well as students with multiple competing priorities to manage (ie, coursework, extracurricular activities, sports, and employed work). These observed gaps demonstrate a need for cost free, universally accessible mental health promotion.

Introducing Canada's Student Mental Health Network

Canada's Student Mental Health Network (hereafter, "the Network") is a virtual, one-stop shop for mental health education and evidence-based resources, tailored specifically to postsecondary students. Development of the Network's website began in 2020, using a participatory research design wherein members of the target population work alongside researchers as contributors, helping to provide a deeper understanding of their thoughts, needs, and experiences [11]. In line with this approach, all content on the Network is created and curated by students and reviewed for validity by subject matter experts (ie, researchers and health care practitioners) using a collaborative approach to the cocreation and translation of knowledge. Based on the extant literature consistently highlighting mental health education, social support, and help seeking as major predictors of positive mental health outcomes for students, the Network targets these 3 areas as primary objectives: (1) to improve mental health literacy; (2) to encourage the development of strong social support networks; and (3) to improve awareness of available resources and encourage appropriate help seeking. The content on the website is aligned with these objectives, centered around 3 pillars: learn, connect, and access.

Learn

Mental health literacy (MHL) refers to "understanding how to obtain and maintain positive mental health; understanding mental illnesses and their treatments; decreasing stigma related to mental illnesses; and enhancing help-seeking efficacy (knowing when and where to seek help and developing competencies designed to improve one's mental health care and self-management capabilities)" [12]. MHL has been identified as a foundational component in mental health promotion and mental illness prevention [12]. Improved mental health education not only enables an individual to recognize changes in their mental health and well-being, but also empowers them to respond appropriately [13,14]. Given that MHL is context specific, it is important for resources to be tailored appropriately to the target population (ie, students) and the postsecondary setting [14]. The *learn* section of the Network facilitates access to free and evidence-based mental health education. Education is provided in an interactive, accessible, and aesthetically appealing format. Some features in this section include: a series of web-based mental health education modules, created by Network volunteers and validated by subject matter experts; a curated library of informational and educational TedTalks; a library of free, web-based mental health courses; and a library of detailed toolkits, providing guidance on topics including financial literacy, relationship management, and an introduction to cognitive-behavioral therapy techniques.

RenderX

Connect

The development of strong social support networks is a key predictor of positive mental health outcomes and overall well-being across the course of life, but particularly during adolescence and early adulthood [15,16]. The majority of Canada's postsecondary students are "emerging adults," defined as ages between 18 and 25 years [16]. Students navigate a number of major transitions during this time, including the transition to a postsecondary setting, integration into a new social environment, and increased autonomy and responsibility. A lack of social support when faced with these adjustments can lead to social isolation, loneliness, and homesickness [17]. In fact, many students struggle to form new, meaningful friendships at university or college and can find it difficult to maintain pre-existing relationships, such as those with their parents or childhood friends [18,19]. Together, the breakdown of previous social ties and difficulty finding a new social support network at school can result in mental health deterioration [20]. Social support has also been found to be a protective factor against student burnout [21]. Burnout is common in students in academic settings and is linked to psychological distress and perceived stress [22,23].

The *connect* section of the Network encourages students to develop healthy social support networks by providing access to resources designed to encourage peer connection. Some features in this section include: a clubs portal, which provides single-click access to student club listings for every university and college across Canada; the Student Mental Health Network podcast, featuring interviews with subject matter experts and students on a variety of topics relevant to student mental health, including sharing lived experiences; and a library of web-based forums designed to foster peer connection.

Access

Commonly perceived barriers to help seeking for mental health-related problems among students include a preference for self-management [24], a lack of time [24,25], perceived stigma [26-28], and a lack of awareness around availability of resources [27]. Structural barriers also exist; students are sometimes surprised to learn of the mental health–related services and supports available to them through their institution and frequently report not knowing where to physically access them [29]. This is particularly evident on sprawling campuses, where health supports are split across several different buildings rather than in a centralized location [29]. Additionally, some students are predisposed to structural barriers as a result of socioeconomic status, race or ethnicity, or gender [30]. Increasing awareness of available services and supports both on and off campus, as well as educating students about aligning their level of mental health need with the level of mental health support sought, is essential to supporting the mental health and well-being of the postsecondary population [30].

Rather than provide services, the goal of the *access* pillar of the Network is to improve students' awareness of existing resources and services available to them, as well as to improve education regarding appropriate levels of help seeking. These resources include: (1) a mental health resource bank, which includes one-click access to Student Wellness Services websites for every university and college across Canada, as well as a library of community mental health resources (both in person and web-based) at the provincial and national levels; (2) a library of evidence-based and physician recommended mental health mobile apps; (3) an interactive mental health services map detailing locations of mental health support on Canadian campuses across the country; and (4) a bank of stress management resources tailored specifically to postsecondary students based on the stressors measured by the Postsecondary Student Stressors Index [31].

Methods

Project Overview

The overall goal of the Network is to reduce barriers and facilitate universal access to upstream mental health supports for postsecondary students across Canada. This study describes a protocol for a comprehensive evaluation of the Network, including a formative process evaluation and a summative impact assessment. The key objectives of this evaluation are to determine the feasibility, acceptability, and utility of the Network in addition to assessing change in the 3 primary outcomes of interest aligning with website content: mental health education, perceived social support, and help-seeking behavior.

Study Design

The proposed program evaluation will include a formative process evaluation and a summative impact assessment. The logic model we have developed for the purposes of evaluating the Network can be found in Multimedia Appendix 1. Process evaluations are intended to assess 2 key components of program function: (1) whether the program is reaching the intended targeted population (*acceptability*) and (2) whether its delivery and function is consistent with program design specifications (*feasibility*) [32]. Impact assessments are intended to assess the observed change in the outcomes of interest and estimate the degree to which that change may have occurred in the absence of the intervention (*utility*) [33]. Alignment of evaluation design with initiative life span is imperative. For example, conducting an impact assessment when a program is too "young" for observable change to have occurred in outcomes of interest may lead to the incorrect conclusion that the program or initiative is not effective. Given that the Network is a newly developed initiative, we will begin with a formative process evaluation that focuses on the user experience in terms of feasibility and acceptability. A summative impact assessment will be conducted after the Network has been in operation for a minimum of 1 year.

Increasingly, mixed methods approaches to studying complex public health problems have been recommended, as the use of qualitative and quantitative methodologies in tandem provides a more holistic and thorough understanding than either approach individually [32]. A concurrent mixed methods study design will be used to facilitate a comprehensive evaluation of the Network, where both quantitative and qualitative data will be used to facilitate both depth and breadth of understanding.

XSL•FO
RenderX

Measures

Process Evaluation

Data for the process evaluation phase of this project will be drawn from 2 sources: (1) Google Analytics and (2) cognitive interviews (Table 1). To collect information regarding the reach of the Network in terms of website engagement and user experience, we will analyze website metrics collected through Google Analytics. These metrics include total number of users, average number of users (weekly, monthly, and annually), average engagement time (time spent on each component of the website), user "stickiness" (average length of visits), page views, event counts (clicks and file downloads), and user region.

We will use individual cognitive interviews employing a "think aloud" technique [34] to further evaluate the user experience and highlight gaps in content. Participants will be asked to screen share over Zoom as they navigate through the Network website and talk us through their navigation, identifying content-related issues or preferences as well as any navigational challenges. The interviews will include questions related to sociodemographic characteristics, important website attributes, and perceived acceptability and feasibility (Table 1). Collecting this additional in-depth qualitative data on website attributes and navigation will augment the quantitative data collected through Google Analytics and allow us to identify gaps and areas for improvement to ensure the best possible user experience.

Table 1. Process evaluation measures.

Mode of data collection and component	Measures/item	Qualitative/quantitative
Cognitive interviews		
Sociodemographic characteristics	• Age • Gender • Ethnicity • Year of study • Level of study • Area of study • International student (Y/N)[a] • First generation student (Y/N) • Identify as a visible minority (Y/N) • Identify as a person with a disability (Y/N) • Self-reported SES[b] • Grade Point Average • Current self-rated mental health • Mental health diagnoses (lifetime) • Impact of COVID-19 on mental health • Previous access of mental health supports and type	Quantitative/qualitative
Website attributes	• Appearance • Content • Interactivity • Inclusivity and representation • Accessibility	Qualitative
Google Analytics		
Website engagement and user experience	• Total number of users • Average number of users (weekly, monthly, and annually) • Average engagement time • Page views • User stickiness (average length of visits) • Event counts (visits, clicks, scrolls, and file downloads) • User location (country, region, and city)	Quantitative

[a]Y/N: yes/no.

[b]SES: socioeconomic status.

Impact Assessment Evaluation

Data for the impact assessment evaluation of the Network will be drawn from 2 sources: (1) web-based surveys and (2) interviews (individual and group) (Table 2).

The impact assessment survey will include questions related to sociodemographic information (eg, age, gender, ethnicity, year of study, level of study, area of study, and estimated grade point average) and important website attributes (eg, appearance, content, interactivity, inclusivity or representation, and accessibility). However, the survey will also include several validated instruments designed to evaluate change in each of the outcomes of interest (eg, scales evaluating mental health literacy, perceived social support, and help-seeking behaviors). The majority of the survey will consist of closed-ended, quantitative questions, with a few open-ended, qualitative response options. More in-depth descriptions of each of the

XSL•FO
RenderX

selected measures and their associated psychometric properties can be found in Multimedia Appendix 2.

Web-based interviews will be held in both individual and focus group formats, depending on recruitment. A semistructured interview guide will be used to assess students' perspectives on changes in the outcomes of interest as well individual understandings of mechanisms that may have contributed to the change (eg, improved mental health literacy due to completion of Network modules). Interviews will be used to evaluate students' experiences engaging with the website, as well as their perceptions of potential mechanisms through which they observed change in their mental health education, connections with members of their social support network, and help-seeking attitudes and behaviors.

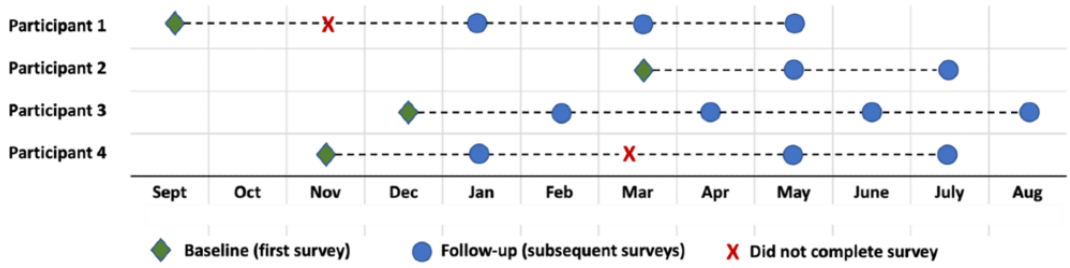
Table 2. Impact assessment evaluation measures.

Mode of data collection and component	Measure/item	Qualitative/quantitative
Web-based survey		
Sociodemographic characteristics	• Same as process evaluation	Quantitative/qualitative
Mental health	• Perceived stress scale, 4-item [35] • Kessler Psychological Distress Scale, 6-item [36] • Brief-postsecondary student stressors index [6]	Quantitative/qualitative
Mental health literacy	• Mental health literacy scale, adapted [37] • Social distance subscale of OMS-WA[a] [38]	Quantitative/qualitative
Social support and resilience	• Multidimensional scale of perceived social support [39] • Connor-Davidson Resilience Scale (10-item) [40]	Quantitative/qualitative
Help seeking	• Barriers to care evaluation, revised [41] • Self-stigma of seeking help scale [42] • General help seeking questionnaire [43]	Quantitative/qualitative
Interviews		
User experience and impact of website engagement	• User experience • Website navigation • Perceived impact	Qualitative

[a]OMS-WA: Opening Minds Scale–Workplace Attitudes.

Procedure

Participants and Recruitment Strategy



Canadian postsecondary students who have engaged with the Network are the target population for the proposed evaluation. Students attending any type of postsecondary institution (ie, college, university, etc) will be eligible to participate. Participants will be recruited through 3 possible avenues: (1) directly from the Network website through a posted call for participants; (2) through the Network's social media channels; or (3) through a snowball sampling method. Network contributors will communicate the opportunity to become involved in the evaluation study through word-of-mouth as the first point of contact. To avoid bias, contributors themselves will not be eligible to complete the impact assessment survey. Participants who complete the survey will have the opportunity to refer 5 other students to complete it in exchange for 1 entry into our raffle draw per completed survey submitted by a referral.

The process evaluation, recruitment, and data collection period will take place between May 2022 and May 2023, allowing for a formative assessment of the first year of operation. A "rolling" recruitment approach (Figure 1) will be used for the impact assessment, allowing participants to complete the survey at any time within the data collection period of September 2023 to September 2024. This approach will allow for continued data collection as new users engage with the Network over time. Rolling recruitment approaches have been shown to reduce recruitment delays and improve statistical power by minimizing the effects of loss to follow-up [44]. Students may participate in process evaluation, impact evaluation, or both.

The appropriate sample size for the process evaluation interviews will be determined by the length of time it takes to reach saturation. For the impact assessment survey, we will aim to obtain a total sample size of 10,000 respondents. Statistics Canada data for the latest academic year (2020-2021) indicates that a total of 2.2 million students are enrolled in a postsecondary program [44]. Our goal will be to obtain responses from students across Canada, with relative contributions by region (Western ~30%, Atlantic ~5%, and Central Canada ~65%) in order to obtain a sample that is generalizable to the broader Canadian postsecondary population. We determined the relative contributions by region using Statistics Canada's Postsecondary Student Education Dashboard [35].

XSL•FO
RenderX

Figure 1. Visual depiction of rolling recruitment strategy.

Data Collection and Processing

Google Analytics data will be continually collected from the website over the lifetime of the Network for program monitoring purposes. Cognitive interviews will be conducted, recorded, and transcribed through Zoom [36]. Participants will be compensated for their participation in a cognitive interview with a US $14.97 electronic gift card to Amazon.

Web-based surveys will be administered through Qualtrics survey software [37]. A letter of information (LOI) for the evaluation will appear as the first page of the survey, communicating the purpose of the evaluation, survey content, incentives to participate, process for withdrawing submitted responses, data deidentification and confidentiality, and consent for use of data in future analyses. After reviewing the LOI, participants will indicate their informed consent before being granted access to the survey questions. The only identifying information on the survey will be students' institutional email addresses used to link their responses across surveys. Emails will be permanently deleted and replaced with numeric participant numbers at the end of the data collection period (September 2024), effectively deidentifying data. The impact assessment survey will consist of approximately 30 close-ended questions and is expected to take around 30 minutes to complete. Following the submission of their first survey, participants will be invited to submit a brief follow-up every 2 months, enabling us to track their responses over time. Participants who "miss" a follow-up will continue to be invited to complete a survey every 2 months throughout the data collection period, unless they choose to opt out of receiving additional surveys. Data will be linked between survey iterations wherever possible.

Participants will be compensated for their submission of each survey with an entry into a prize draw for a chance to win 1 of several electronic gift cards. They will also be provided with an additional entry into the raffle for every individual they refer who completes the survey, per the snowball sampling strategy outlined above. Prize draws will be completed at the end of each academic term.

At the end of the survey, participants will be asked whether they would be interested in participating in an interview to further discuss their engagement with the Network. Participants who express interest will be contacted by email to indicate their preference for either a one-on-one interview or a focus group interview, depending on recruitment numbers. We will attempt to place students from the same region in focus groups together to encourage participants to draw on common experiences and promote idea sharing. Participants will be provided with a letter of information and asked to verbally consent to keeping discussions confidential as well as to interviews being recorded and transcribed. Individual interviews will be 1-hour in length, while the length of focus group interviews will depend on the number of participants included. All interviews will be facilitated over Zoom to accommodate collaboration with participants across Canada. Participants will be compensated for their participation in interviews with a US $20 electronic gift card to either Amazon or Starbucks.

Risk Mitigation

The risk associated with the proposed evaluation is low. However, to mitigate any feelings of elevated stress or emotional distress participants may feel after completing a survey, an interview, or both, we will refer participants to the access section of the Network which includes contact information for campus Student Wellness Services across the country as well as other evidence-based resources.

Analysis

Process Evaluation

Quantitative data and website metrics collected through Google Analytics will be analyzed through the use of descriptive statistics (eg, frequencies, measures of central tendency, and dispersion) using R statistical software [38]. Cognitive interview data will be analyzed through the use of the problem codes displayed in Table 3, which were adapted from those proposed for use in the evaluation of new survey tools [39,40]. Following each interview, corrective action will be taken to assess the identified problems, ensuring that each interview provides maximum value to the improvement of the Network. In the event that a new issue arises that is not captured by existing problem codes, a new code will be added to the list for use in subsequent interviews. After problem codes have been applied, interview transcripts will also be coded using a thematic analysis framework [41,42]. A total of 2 research assistants will independently review interview data and generate initial codes, subsequently meeting to share interpretations and develop a codebook. A third researcher will be available to break ties where disagreements arise. Research assistants will then return to the data to generate initial themes and categories.

XSL•FO
RenderX

Table 3. Cognitive interviewing problem codes.

Problem code	Description	Corrective action
1. Clarity	Participant was confused by website content	Revise content
2. Relevance	Respondent felt that website content was not relevant to postsecondary student mental health and well-being	Revise content/remove content
3. Redundancy	Respondent felt that website content was repetitive or redundant, or could be combined with another content piece	Revise content/remove content
4. Bias	Respondent felt the presentation of website content was biased or leading in some way	Revise content/remove content
5. Missing	Respondent felt there was content missing from the website	Add content
6. Navigation	Respondent felt website content was difficult to navigate or locate	Optimize navigation/revise content organization
7. Accessibility	Respondent felt website content was not accessible	Optimize accessibility
8. Representation	Respondent felt website content did not represent all equity-deserving group	Optimize representation/revise content

Impact Assessment

Both descriptive (eg, frequencies, measures of central tendency, and dispersion) and inferential statistics will be calculated for quantitative data collected through the impact assessment survey using R statistical software. We will explore (1) relationships between sociodemographic variables and outcomes of interest (ie, mental health literacy, perceived social support, and help seeking), (2) the degree of change in outcomes of interest over time, and (3) the relationship between degree of engagement with the Network and degree of change observed in outcomes of interest. Trend analyses examining changes in stress, mental health, and the primary outcomes of interest over time will be conducted once enough data has been collected to facilitate these analyses.

Transcripts derived from individual and focus group interviews will be coded in NVivo [43] using a thematic analysis framework [42] using the approach described above. Qualitative interview data will be triangulated with participants' quantitative survey data, with qualitative data used to provide more context and facilitate a more in-depth understanding of the user experience and the mechanisms of change in outcomes of interest.

Ethical Considerations

The Tri-Council Policy Statement TCPS2 regarding ethical conduct for research involving humans states that Research Ethics Board (REB) approval is exempted in cases of program evaluation activities normally administered in the ordinary course of operation (Article 2.5) [45]. Moving forward, should the research team choose to conduct additional secondary data analyses to answer emergent research questions, REB approval will be sought. Despite the program evaluation being exempt from REB approval, participants will still be provided with a LOI to obtain their informed consent to participate through survey completion.

Results

Phase 1 of this project entailed the development of the Network website, including the curation and creation of relevant resources for the web-based space. Moving forward, content developed for the Network will continue to be informed by the evolving needs of our target population. Phase 2 entails the formative process evaluation, the data collection period for which is from May 2022 to May 2023. Data analysis and the dissemination of a freely available web-based report will take place in summer 2023. For the final phase of the project, the summative impact assessment, data collection will take place between September 2023 and September 2024. Following this period, the results of the evaluation will be made publicly available through the Network, in addition to being published and presented at academic conferences.

Discussion

The anticipated main findings of the proposed evaluation are that the Student Mental Health Network will fill existing gaps in the mental health promotion supports currently provided at postsecondary institutions across Canada. In doing so, we hypothesize that engagement with the Network will result in improvements in mental health education, the ability to develop strong social support Networks, and awareness of available help-seeking resources. Further, improving students' access to effective upstream mental health promotion supports may contribute toward alleviating the long wait times and general overwhelm that downstream mental health services currently face by increasing students' awareness of the spectrum of available services from low- to high-intensity options and helping students access services that align with their level of mental health need.

The accessibility of the Network is vital to its utility and is an important strength of the project; it is available to all postsecondary students on the internet at no cost. The "for-students, by-students," participatory approach to development ensures that content is meaningful and tailored to the target audience while maintaining relevance and timeliness. Given the nation-wide accessibility of the Network and recruitment for the participatory research design, we hope to obtain a wide sample variation spanning postsecondary institutions across the country. This may allow for the identification of inequities in the outcomes of interest between

XSL•FO
RenderX

regions. Further, relationships between sociodemographic variables and these outcomes of interest will be investigated, and findings may be used to tailor the development of future website content to combat identified inequities. Lastly, although the Network takes an upstream health promotion-focused lens, it also serves to connect a generation of students with an interest in mental health and well-being. Through the provision of information and facilitation of social connection, the Network may empower collective action to advocate for institutional, political, and service-level change in current approaches to postsecondary mental health—"for-students, by-students." The Network is a first-of-its-kind initiative that aims to fill the urgent, evidence-supported gaps in student mental health through an innovative, collaborative design.

Importantly, the overarching goal of the Network is to provide opportunities for knowledge translation and exchange that will support postsecondary students' mental health and well-being. To that end, a technical report detailing evaluation results as well as a summary of Network resources will be made publicly available on an annual basis, with reports released in August. Network users will be invited to sign up for a mailing list, through which they will receive a copy of each report as it becomes available. We will also seek to share our annual reports through organizational connections such as the Best Practices Network [46] and the Center for Innovation in Campus Mental Health [47]. Transparency in the communication of the results of our evaluation of the Network will contribute toward a positive community impact by allowing institutions to examine the efficacy of the Network as a universal mental health promotion initiative. Results may also inform improvements to campus-specific mental health promotion and mental illness prevention resources and programming.

The novelty of the Network is both a strength and a limitation, as there is currently no set process for developing or evaluating this form of content. It is challenging to predict what uptake of the site will look like, but website usage statistics and social media interactions have demonstrated that the Network is receiving increasing attention from students since it was made public in May 2022. In terms of the analysis, it is not possible for residual confounding to be eliminated and observed changes in outcomes will not be attributable to the Network alone. There will also inevitably be some loss to follow-up, although a rolling recruitment strategy and raffle entry with each completion of the survey will be used to limit the effect on study power. Content on the Network is in English, and thus may be less accessible to French-dominant parts of Canada, international students, immigrants, and other groups who do not speak English as their first language. Further, not all students have equitable access to technology and social media or the time to navigate the Network and participate in voluntary surveys, which may result in some degree of selection bias.

Conclusion

Strategies to address postsecondary mental health have emerged at the national, provincial, and institutional levels [10]. Over the past decade, many postsecondary institutions have attempted to improve students' mental health by offering both upstream and downstream mental health supports, though typically the majority of resources are placed downstream [5,10]. Bolstering upstream supports like mental health promotion may help alleviate the current bottleneck observed at the downstream service level. Many students default to seeking help from high-intensity downstream services (ie, counseling and pharmacotherapy) when their level of mental health need does not necessarily align with this level of help seeking (ie, those who have not yet become symptomatic or reached a clinical threshold). There is a need to increase both the provision and awareness of lower-intensity upstream supports available on campuses to provide options for students experiencing a lower level of mental health need. This will in turn alleviate the pressure on downstream campus mental health services and ensure more timely downstream care for students who require it [29,30].

The Student Mental Health Network is a first-of-its kind web-based one-stop shop for mental health education and evidence-based resources, targeted specifically toward postsecondary students and uniquely developed using a participatory "for-students, by-students" approach. The Network will fill gaps in existing upstream mental health promotion supports provided by postsecondary institutions across the country, including eliminating fees and facilitating universally accessible mental health promotion for postsecondary students across Canada. The evaluation described here will allow us to assess the feasibility, acceptability, and utility of the Network, in addition to its effectiveness in improving the 3 primary outcomes of interest—mental health education, perceived social support, and help-seeking behavior—which are each proven predictors of positive mental health outcomes among students. This initiative has the potential to improve the mental health and well-being of postsecondary students across the country by providing access to the tools and resources required to build resiliency and respond to changes in one's mental health.

Acknowledgments

The authors would like to acknowledge and thank all the student contributors involved in the development and curation of content for the Student Mental Health Network.

Data Availability

Evaluation data will be made publicly available in a repository following the data collection period.

Protocol

Culturally Adapting a Digital Intervention to Reduce Suicidal Ideation for Syrian Asylum Seekers and Refugees in the United Kingdom: Protocol for a Qualitative Study

Abstract

Background: The conflict in Syria has produced the largest forced displacement crisis since the Second World War. As a result, Syrians have experienced various stressors across the migratory process, putting them at an increased risk of developing mental health issues, including, crucially, suicidal ideation (SI). Despite their high rates of SI across Europe, there remain various barriers to accessing treatment. One way to increase access is the use of culturally adapted digital interventions, which have already shown potential for other minority populations. To culturally adapt the intervention, further research is needed to better understand Syrian asylum seekers' and refugees' cultural conceptualizations, coping strategies, and help-seeking behavior for SI. To do so, this study will use a unique cultural adaptation framework to intervene at points of lived experience with the migratory process where Syrian culture and signs of psychopathology converge. Likewise, co-design events will be used to adapt points of experience with the intervention where Syrian culture and the intervention conflict. As the first cultural adaption of a digital SI intervention for Syrian asylum seekers and refugees, this study will hopefully encourage further development of culturally sensitive interventions for the largest refugee population in the United Kingdom and the world.

Objective: The objective of the study is to increase access to mental health treatment for Syrian asylum seekers and refugees in the United Kingdom by culturally adapting a digital intervention to reduce SI.

Methods: The study will use experience-based co-design, an action research method, to culturally adapt a digital intervention to reduce SI for Syrian asylum seekers and refugees in the United Kingdom. This will involve conducting 20-30 interviews to understand their lived experiences with the migratory process, cultural conceptualizations of mental health and SI, coping strategies, mental health help-seeking behavior, and perceptions of digital mental health interventions. In addition, 3 co-design events with 6 participants in each will be held to collaboratively adapt the intervention. Touchpoints and themes extracted from each phase will be prioritized by a community panel before adapting the intervention.

Results: The study began in November 2022 and will continue until the last co-design event in August 2023. The results of the study will then be published by December 2023.

XSL•FO
RenderX

Conclusions: Access to treatment for some of the most severe mental health issues is still limited for Syrian asylum seekers and refugees in the United Kingdom. Cultural adaptations of digital interventions developed for general populations have the potential to increase access to treatment for this population. Specifically, adapting the intervention for Syrian asylum seekers' and refugees' experiences with SI in relation to their lived experience with the migratory process may enable greater recruitment and adherence for users of various cultural and ethnic subgroups and levels of SI.

Introduction

Background

Since 2011, the civil war in Syria has resulted in the loss of over half a million lives and the largest forced displacement crisis since the Second World War [1]. By recent estimates, this includes 6.7 million displaced within Syria and 6.8 million refugees living abroad [2]. Of those displaced, over 1 million Syrians have reached Europe. As asylum seekers and refugees, they are likely to experience high rates of mental health issues, including major depressive disorder, posttraumatic stress disorder, and suicidality [3]. It is therefore important to improve the understanding and care of mental health for Syrian asylum seekers and refugees arriving in the United Kingdom.

Suicidal Ideation

One of the most concerning mental health issues for asylum seekers and refugees across Europe is suicidal ideation (SI), with research showing high rates in Sweden, 33.9% [4] and 48% [5]; Switzerland, 42.1% [6] and >30% [7]; and the United Kingdom, 40.9% [8]. Asylum seekers' and refugees' elevated rates of SI may be explained by their experiences of the migratory process [9]. While in their countries, they are often exposed to bombings, torture, and bereavement [1,3,10]. The journey to their first country of asylum often involves encountering human traffickers [11], unsafe modes of transport including inflatable boats and closed containers [12], and harsh living conditions in refugee camps [13]. Upon arriving in the first country of asylum, asylum seekers may face punitive immigration control policies [12] or a prolonged asylum application process [14]. After receiving refugee status, they may continue to experience stressors associated with a loss of social networks and environmental mastery [3,15,16], with acculturation, with discrimination, and with mental health services based on dominant models of illness in Western developed countries [17]. Thus, in order to develop acceptable and effective treatments, more research is needed to understand the specific determinants of SI for asylum seekers and refugees, and in particular Syrians, the largest refugee population globally and in the United Kingdom.

Despite asylum seekers' and refugees' elevated risks for SI, they still underuse mental health services [18-21]. Some of the barriers to accessing treatment include a lack of knowledge about mental health services, a lack of culturally competent treatment, fears about confidentiality, limited proficiency in English, and logistical issues such as transport difficulties and immigration status [21]. Again, further research is needed to understand the specific barriers and facilitators of mental health help-seeking among Syrian asylum seekers and refugees in the United Kingdom.

Cultural Adaptation

As a complex problem, reducing SI among asylum seekers and refugees in the United Kingdom will inevitably require complex structural interventions. However, reducing SI can start with the short-term individual adoption of simple clinical interventions [22]. Specifically, treatment for SI among Syrian asylum seekers and refugees in the United Kingdom may be improved with culturally adapted digital mental health interventions [23,24], which already seem promising for ethnic minorities [25], refugees in general [26,27], and Syrian refugees specifically [28].

Cultural adaptation involves "the systematic modification of an evidence-based treatment...or intervention...protocol to consider language, culture, and context in such a way that it is compatible with the client's cultural patterns, meanings, and values" [29]. Based on the universality of emotional expression, Bernal and colleagues' [29] framework of cultural adaptation asserts that while mental health beliefs and help-seeking behavior differ across cultures, the distinct signs and symptoms of psychopathology are universal. They therefore hold that cultural adaptations should attempt to maintain the integrity of the original intervention as much as possible. Conversely, Horrell [30] asserts that rather than adapting existing interventions, entirely new interventions should be developed for different cultural groups. Although her framework is more situated, it still does not acknowledge the dynamic nature of culture within cultural groups. These contrasting frameworks can perhaps be integrated by identifying the signs of psychopathology through shared experiences that give rise to core affect, including hedonic valence and physical arousal, and conceptual knowledge [31]. Thus, an embodied and experience-based approach to emotions will allow one to use changes in experience [32] to predict a person's core affect and core beliefs [33]. Importantly, where cognitive behavioral therapy (CBT) commonly involves challenging distorted core beliefs through cognitive reconstruction, in some circumstances, mental health issues may arise as a result of experiential challenges to a person's core beliefs, such as the inherent value of one's life and safety. In which case, challenges to the core belief could result in identity crisis [33] and suicidal behavior [34]. Thus, the cultural

XSL•FO
RenderX

adaptation process can be simplified by focusing on points of lived experience with the migratory process at which signs of psychopathology such as SI and Syrian culture coincide [35]. In addition, due to Syrian education policies, Syrian ethnic and linguistic groups are only able to read and write in Modern Standard Arabic [35]. Therefore, based on a lived experience paradigm, the intervention will be adapted for Modern Standard Arabic but will identify and adapt marked language use. A possible research approach to simplify the cultural adaptation process is experience-based co-design (EBCD) [36]. Specifically, this will entail identifying crucial moments, known as touchpoints, that make a difference in Syrian asylum seeker and refugee experiences with the migratory process such as their experiences of SI in response to torture or the asylum process. After culturally adapting the intervention using the themes and touchpoints identified during interviews, Syrian asylum seekers and refugees will participate in co-design events to collectively identify and adapt touchpoints of the intervention at which Syrian culture and the intervention's core mechanisms of change conflict.

Digital Intervention

This study will build on Eylem and colleagues' [24] cultural adaptation of the Leven onder Controle (literally "Living under Control") intervention, a guided 6-week CBT-based digital intervention to reduce SI developed by van Spijker and colleagues [37]. The intervention includes 6 modules: thinking about suicide, dealing with thoughts and feelings, thinking about the future, thinking about the self, thinking about others, and repetition and relapse. Randomized controlled trials of the intervention have found it to be effective in reducing SI compared to treatment as usual—an information website—for general Dutch (d=0.2) [38] and Belgian populations (d=0.34) [39], but not for Australian populations [40].

Based on Bernal and colleagues' [29] cultural adaptation framework, Eylem and colleagues [24] adapted the intervention for Turkish immigrants in the United Kingdom and the Netherlands by including cultural metaphors, treatment concepts, and goals, as well as the context and methods of the intervention. Although largely successful in culturally adapting the intervention, Eylem and colleagues [24] were unable to recruit enough participants for a full randomized controlled trial. They therefore suggested a need for further optimization of the recruitment process and intervention including culturally appropriate strategies for recruitment, identifying the determinants of SI, and a diversity of case studies both in terms of culture and SI severity.

Aims

This research aims to improve the understanding and treatment of SI among Syrian asylum seekers and refugees arriving in the United Kingdom. As the research has shown varying rates of SI among asylum seekers and refugees [4-8], lived experience data will help to identify the determinants of SI across the migratory process and specifically for Syrian asylum seekers and refugees in the United Kingdom. Moreover, EBCD will help simplify the cultural adaptation process and increase access to treatment for SI for a greater number of Syrian cultural, ethnic, and linguistic subgroups.

Objectives

The first phase of the study will involve one-to-one semistructured interviews to (1) identify touchpoints across the 3 stages of migration (pre-, peri-, and postmigration); (2) explore how Syrian refugees conceptualize, cope with, and seek help for mental health and SI; (3) identify cultural, linguistic, and structural barriers and enablers for seeking help for mental health and SI; and (4) understand Syrian refugee perceptions of digital mental health interventions. The second phase will include community panel discussions and co-design events to (5) prioritize touchpoints and themes extracted from interview data with a community panel to adapt the intervention; (6) conduct co-design events to identify touchpoints to culturally adapt the intervention; and (7) prioritize touchpoints and themes from the co-design events with the community panel to adapt the intervention.

Methods

Study Design

In this study, an accelerated version of EBCD will guide the cultural adaptation process of a digital intervention to reduce SI for Syrian asylum seekers and refugees in the United Kingdom. EBCD is an action research method for collaboratively improving health care services and interventions [36]. Although traditionally used to improve existing services, EBCD has more recently been used to incorporate users' lived experiences of mental health problems into digital interventions [41]. For example, Lewis and colleagues [41] used EBCD to develop a mental health mobile app for health care workers affected by COVID-19. They conducted photo interviews with up to 30 health care workers to understand their mental health needs and lived experiences. The photos were used to draw out touchpoints related to health care workers' experiences during the pandemic and the effects on their mental health. Touchpoints were then further explored during co-design workshops to develop content for the app. Similarly, this study will involve semistructured interviews to gather Syrian asylum seeker and refugee lived experiences with the migratory process. Given the traumatic nature of some asylum seeker and refugee experiences, the 3 phases of migration, pre-, peri-, and postmigration, will be used to structure interviews and draw touchpoints instead of using photos. The interviews will also explore their cultural conceptualizations, coping strategies, and help-seeking behavior for mental health and SI, as well as their perceptions of digital mental health interventions. The study will be accelerated by focusing data collection on specific stakeholders, Syrian asylum seekers and refugees in the United Kingdom, rather than mental health professionals whose role was more important during the initial development of the intervention. Instead, touchpoints and themes identified in the interviews will be prioritized by a community panel during group meetings before adapting the intervention in preparation for co-design events. The community panel will consist of researchers, mental health professionals, and cultural brokers associated with the Syrian community in the United Kingdom. Similar to Lewis and colleagues' [41] study, the cultural adaptation process will include co-design events where participants will be presented with the partially adapted

XSL•FO
RenderX

intervention and collectively identify and adapt touchpoints related to the intervention. The use of co-design events to empower participants to directly culturally adapt the intervention is another methodological innovation of the study, with previous attempts having only involved participants indirectly [24]. Again, the community panel will meet after touchpoints and themes are extracted from the co-design events to balance any need for cultural adaptation with maintaining the integrity of the intervention's core mechanisms of change.

Setting

As Syrian asylum seekers and refugees are dispersed across the United Kingdom, interviews and co-design events will be held on the web to lower barriers to participation.

Participants

In total, 40-50 male or female Syrian asylum seekers and refugees in the United Kingdom, aged 18 years and older will participate in one-to-one semistructured interviews and 3 focus groups (co-design events). Recruitment objectives include 20-30 participants for interviews and 18 participants for 3 focus groups with 6 participants in each group. The participants will include different genders (male and female), age groups (18-39 years and 40 years and older), ethnicities (Arab, Kurdish, and other), religious groups (Muslim, Christian, and other), and refugee status (asylum seeker or refugee). Previous research has shown that most of the information is revealed in the first 5-6 interviews [42]; however, due to the stigma associated with suicide, participants may underreport their experiences with SI. Therefore, 20-30 participants will be recruited to increase the likelihood of identifying participants with experiences of SI. Likewise, a minimum level of SI will not be set for inclusion but rather individuals with serious SI, defined as a score of 4 and above on the SI subscale of the Columbia-Suicide Severity Rating Scale, will be excluded from participation [43,44]. This decision was made to avoid risks of harm to the participants and has thus far not resulted in the exclusion of any participants. To reduce the time spent on recruitment, interview participants will be asked to participate in a co-design event focus group.

Sampling

The study will use purposive sampling to recruit participants from various demographic backgrounds including age, gender, religion, ethnicity, and refugee status. Participants will be recruited via correspondence with nongovernmental organizations and charities and adverts on social media. At the time of writing, 16 participants have already been recruited through Syrian cultural brokers with no participants from NGOs or charities. The main barrier to recruitment through NGOs and charities has most often been low capacity. As suggested by Eylem and colleagues [24], cultural brokers can increase recruitment capacity where certain organizations produce an institutional barrier for subgroups of migrants [45]. In fact, this may be true for all Syrians who, due to government-sanctioned repression, have understandably developed a mistrust for authority structures in general [46].

Data Collection

Lived Experience Interviews

The first phase of the study will involve one-to-one semistructured interviews with Syrian asylum seekers and refugees in the United Kingdom. The interviews will follow a topic guide including open-ended questions about participants' lived experience with the migratory process and the effects it has had on their mental health; their cultural and personal conceptualizations of mental health and SI; the ways in which they cope with mental health and SI; the barriers and facilitators for seeking help for mental health and SI; and their perceptions of digital mental health interventions (programs). Given the stigma attached to mental health [21], semistructured interviews that focus on Syrian refugees' mental health in relation to their experiences with the migratory process are more likely to encourage participation and also reduce researcher bias. Touchpoints will be extracted from the interviews to better understand the mechanisms by which SI arises for this population and provide culturally relevant and appropriate case examples in the intervention. Previous cultural adaptation work on this intervention conducted by Eylem and colleagues [24] found case examples over emphasized SI and traditional values. Therefore, focusing on Syrian asylum seekers' and refugees' experiences with the migratory process should provide a shared paradigm for a culturally diverse population with varying levels of SI. Since asylum seekers and refugees are dispersed across the United Kingdom, interviews will be conducted remotely using Microsoft Teams or over the phone. Prior to conducting the interviews, participants will provide oral consent, which will include consenting to being audio-recorded and indirectly quoted in any publications. Participants' consent will be recorded by the researcher on an oral consent form, and only digital copies will be kept by the researcher and participant. Digital case report forms will also be used to collect data about the participants age, gender, ethnicity, religion, refugee status, and general practitioner registration. Subsequently, the interviews will be conducted for 30-45 minutes, which will be voice recorded and then transcribed and translated into English.

Co-Design Events

The co-design events will involve collecting data through 3 focus groups with 6 participants in each. This will involve bringing participants of diverse backgrounds together to identify key touchpoints of the intervention for cultural adaptation. The adaptation will build on Eylem and colleagues's [24] Turkish cultural adaptation of van Spijker and colleagues' [37] 6-week guided CBT-based web-based intervention to reduce SI. Prior to the focus group, participants will be given access to 2 modules that have already been translated and partially adapted. Modules will be paired based on the order in which they are provided in the intervention. The 2 modules will be presented again at the beginning of each focus group. Subsequently, participants will be asked to identify the main touchpoints and ways to adapt the modules. The focus groups will be conducted on the web using Microsoft Teams to facilitate participation from various locations across the United Kingdom. Prior to conducting the focus groups, participants will provide oral consent in the same manner as the interviews. Digital case report forms will also be

XSL•FO
RenderX

used to collect demographic data including age, gender, ethnicity, religion, refugee status, and general practitioner registration. The focus group will then be conducted for no longer than an hour and a half, which will also be voice recorded, transcribed verbatim, and translated into English for analysis.

Data Analysis

Semistructured interviews will be transcribed verbatim, and thematic analysis will be used to identify themes, as well as touchpoints of participants' lived experience with the migratory process to culturally adapt the intervention. Thematic analysis was chosen for its epistemological flexibility [47]. Analysis will combine both realist and social constructionist paradigms. Braun and Clarke [47] describe thematic analysis as identifying semantic themes for specific areas of interest in the data or latent themes spread across the data. Moreover, they assert that semantic themes are revealed through description, whereas latent themes only arise after interpretation. However, the distinction between semantic and latent meaning disregards the primary roles of intentions and context in meaning interpretation and construction [48]. In other words, what is obvious in one context may be latent in another and vice versa, hence, the need for cultural adaptation. For example, mental health issues may be latent in discussions about mental health but obvious in discussions about lived experiences with the migratory process. Additionally, mental health issues may be latent during the premigration phase and more obvious in the postmigration phase. Thus, to combine both epistemologies, the analysis will be inductive but will be bound by the objectives of the study. The code system and themes will be developed in accordance with the 6 phases outlined by Braun and Clarke [47] and will be checked by another member of the research team. The stages include data familiarization, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and producing the report. Internal reliability will be ensured by an iterative review of themes as well as checking for consistency between members of the research team [49]. Where irreconcilable differences in interpretations arise, preference will be given to the interpretation in line with participants' shared lived experience and the objectives of the study. Such differences are likely to arise due to an analyst's background knowledge either as a researcher or from lived experience. Therefore, adherence to the objectives of the study and the participants' lived experiences in analysis is as essential to the cultural adaptation process as adherence to the intervention's mechanisms of change and participants' lived experience is to maintaining implementation fidelity. Internal validity will be ensured by iteratively checking for correspondence between the thematic map and the data set [49]. Given the study involves semistructured qualitative data, this will involve comparing the thematic map to the original codes before structuring them into themes. The use of a thematic map to guide the analysis is also important as NVivo, a qualitative analysis software produced by Lumivero, mostly supports the representation of linear and not complex relationships. The co-design events will also help to determine the credibility of the analysis through participant validation of lived experience case examples, coping strategies, and help-seeking behavior [49]. The co-design event data will be analyzed using the same methods, and themes will be prioritized by a community panel before the final adaptation of the intervention.

Ethics Approval

Ethics approval has been provided for the study by the Central University Research Ethics Committee at the University of Oxford (R81752/RE001).

Informed Consent

Eligible participants will receive a participant information sheet for either an interview or focus group. This will describe, in both Arabic and English, the goals and limitations of the study, the way interviews and focus groups will be performed, the way data will be collected and handled, and any risks involved in participating. Participants will be informed that they are free to withdraw from participation at any time, for any reason, without consequence, and are not obliged to provide the reason for their withdrawal. The contents of the participant information sheet will be explained verbally by the DPhil researcher, OB, or one of the members of the research team before conducting the interview or focus group, and participants will have the opportunity to ask questions. Oral informed consent will then be obtained from participants before screening for inclusion and exclusion criteria and participating in an interview or focus group. Informed consent will be recorded on an oral informed consent form on behalf of the participant, and digital copies will be given to the participant and kept on university servers for at least 3 years from the time of publication.

Safety Protocol

Although the study will not necessarily involve the recruitment of participants directly experiencing SI, if OB suspects that any participants are at risk of harming themselves or in need of help, he will encourage them to contact their local general practitioner and provide them with information for alternative sources of help. Likewise, participants will be informed in the participant information sheet that confidentiality could be broken where there is a risk of harm to themselves or others. In which case, OB will report any risk of harm to the principal investigator, KB, who will in turn review the circumstances and act according to his judgment. If there is a risk of immediate harm, the emergency services will be contacted via 999. If further steps are necessary, the matter will be referred to the Multi-Agency Safeguarding Hub within 1 working day of first receiving the information from the participant. The local area designated officer will then advise on the next appropriate steps to take.

Data Management

Access to personal data will be restricted to only authorized individuals. Personal names will be replaced with unique participant numbers on consent forms and audio recordings and transcriptions of interviews. Focus group audio recordings and transcriptions will be given a unique focus group number and individual electronic case report forms will be labeled with the participant's initials. All audio recordings will be deleted once they have been transcribed. The remaining data will be kept on university servers for 3 years from the time of first publication in accordance with Oxford University policy and then deleted by the principal investigator.

XSL•FO
RenderX

Dissemination

The findings of this study will be disseminated through publication and web-based Syrian asylum seeker and refugee communities. Likewise, the feasibility and acceptability of the culturally adapted intervention will be assessed in a later study as part of OB's dissertation research.

Results

The first phase of the study, lived experience interviews, was initiated in November 2022. Since commencing, 16 participants have been recruited and interviewed. The second phase of the study, co-design events, will commence in June 2023. The study, including the write-up period, is expected to end in December 2023.

Discussion

Expected Findings

This paper describes the study protocol for the cultural adaptation of a digital SI intervention for Syrian asylum seekers and refugees in the United Kingdom. The main aim of the study is to improve the understanding and treatment of SI among Syrian asylum seekers and refugees arriving in the United Kingdom. Accordingly, the study will consist of two phases: (1) semistructured interviews and (2) co-design events. First, interviews will be conducted to explore the lived experiences of Syrian asylum seekers and refugees in the United Kingdom with the migratory process; their mental health and SI conceptualizations, coping strategies, and help-seeking behavior, including cultural, linguistic, and structural barriers; and their perceptions of digital mental health interventions. This integrative approach to cultural adaptation identifies lived experience as the source of both psychopathology and their subsequent cultural interpretations and help-seeking. Specifically, this includes touchpoints, crucial moments that make a difference to Syrian asylum seeker' and refugee' experiences with the migratory process. Importantly, touchpoints can highlight the ways implicit boundaries of lived experience such as refugee status impact mental health. Second, co-design events will be held to enable Syrian asylum seekers and refugees to collaboratively and culturally adapt the intervention. While digital evidence-based interventions have generally been effective in reducing SI, most studies have revealed low adherence rates, with participants completing only half of the intervention [50-52]. Thus, rather than evaluating intervention outcomes, the study will help achieve greater access to treatment for this population by optimizing the recruitment process and the intervention.

Limitations

While the cultural adaptation of a digital mental health intervention for Syrian asylum seekers and refugees is aimed at reducing barriers to treatment for SI, it nonetheless will not affect their ongoing lived experiences with the migratory process. It is therefore hoped that digital mental health interventions will help Syrian asylum seekers and refugees in the United Kingdom cope with the asylum process, which will often involve reopening the wounds caused by their experiences of conflict in Syria. It is also important to acknowledge the difficult ethical dilemma of balancing the need to explore their lived experiences and the effects it might have on their mental health. This study is therefore indebted to the Syrian asylum seekers and refugees who have already shared their experiences with the expectation that this research will be used for the benefit of their community. While digital SI interventions may have limited capacity for systems change, their most substantial contribution is to help preserve the lives and mental health of those who must live in them. The study design is also limited to culturally adapting the digital intervention; however, its feasibility and acceptability to Syrian asylum seekers and refugees in the United Kingdom experiencing SI will be assessed in a future study.

Conclusions

The conflict in Syria has resulted in the largest forced displacement crisis since the Second World War [1]. As a result, Syrian asylum seekers and refugees have been exposed to several stressors throughout the migratory process, including dangerous journeys and a prolonged asylum process [9]. Their experiences have put them at an increased risk of developing mental health issues including crucially SI [3]. Despite their elevated rates of SI, Syrian asylum seekers and refugees often fail to seek treatment due to language barriers, the lack of culturally competent services, mental health stigma, and the fear of deportation [18-21]. Thus, access to treatment for SI among Syrian asylum seekers and refugees in the United Kingdom may be improved with culturally adapted digital mental health interventions [23]. In this study, this will involve using EBCD, an action research method for collaboratively improving health care services and interventions, to culturally adapt a digital SI intervention developed for the general population [36]. Syrian asylum seekers and refugees in the United Kingdom will be interviewed to explore their cultural conceptualizations, coping strategies, and help-seeking behavior for SI in relation to their lived experiences with the migratory process. They will then collaboratively and culturally adapt the intervention during 3 co-design events to reduce any negative consequences of the cultural adaptation and improve engagement. Cultural adaptation frameworks have traditionally consisted of various components [29], and therefore, EBCD was chosen for its focus on experience touchpoints. Touchpoints of lived experience will not only provide signs of psychopathology behind cultural interpretations and responses but points at which both interact. Co-design events will also enable participants to identify shared touchpoints in the intervention in a similar way to their lived experience with the migratory process. Studies that include opportunities for co-design not only facilitate engagement but could also increase mental health literacy among their target population. Finally, it is hoped that the cultural adaptation of a digital SI intervention for Syrian asylum seekers and refugees in the United Kingdom provides an example of procedural fairness in facilitating equal access to mental health care.

Acknowledgments

This study is solely funded by OB and is indebted to the Syrian asylum seekers and refugees who bravely and kindly shared their experiences with the migratory process and mental health, as well as those involved in the research.

Abstract

XSL•FO
RenderX

Background: Stress-related mental disorders are highly prevalent and pose a substantial burden on individuals and society. Improving strategies for the prevention and treatment of mental disorders requires a better understanding of their risk and resilience factors. This multicenter study aims to contribute to this endeavor by investigating psychological resilience in healthy but susceptible young adults over 9 months. Resilience is conceptualized in this study as the maintenance of mental health or quick recovery from mental health perturbations upon exposure to stressors, assessed longitudinally via frequent monitoring of stressors and mental health.

Objective: This study aims to investigate the factors predicting mental resilience and adaptive processes and mechanisms contributing to mental resilience and to provide a methodological and evidence-based framework for later intervention studies.

Methods: In a multicenter setting, across 5 research sites, a sample with a total target size of 250 young male and female adults was assessed longitudinally over 9 months. Participants were included if they reported at least 3 past stressful life events and an elevated level of (internalizing) mental health problems but were not presently affected by any mental disorder other than mild depression. At baseline, sociodemographic, psychological, neuropsychological, structural, and functional brain imaging; salivary cortisol and α-amylase levels; and cardiovascular data were acquired. In a 6-month longitudinal phase 1, stressor exposure, mental health problems, and perceived positive appraisal were monitored biweekly in a web-based environment, while ecological momentary assessments and ecological physiological assessments took place once per month for 1 week, using mobile phones and wristbands. In a subsequent 3-month longitudinal phase 2, web-based monitoring was reduced to once a month, and psychological resilience and risk factors were assessed again at the end of the 9-month period. In addition, samples for genetic, epigenetic, and microbiome analyses were collected at baseline and at months 3 and 6. As an approximation of resilience, an individual stressor reactivity score will be calculated. Using regularized regression methods, network modeling, ordinary differential equations, landmarking methods, and neural net–based methods for imputation and dimension reduction, we will identify the predictors and mechanisms of stressor reactivity and thus be able to identify resilience factors and mechanisms that facilitate adaptation to stressors.

Results: Participant inclusion began in October 2020, and data acquisition was completed in June 2022. A total of 249 participants were assessed at baseline, 209 finished longitudinal phase 1, and 153 finished longitudinal phase 2.

Conclusions: The Dynamic Modelling of Resilience–Observational Study provides a methodological framework and data set to identify predictors and mechanisms of mental resilience, which are intended to serve as an empirical foundation for future intervention studies.

Introduction

Background

Stress-related disorders, such as depressive disorders, anxiety disorders, posttraumatic stress disorder, and addiction, are highly prevalent globally and pose a significant burden on individuals, the economy, and society in general [1-4]. Years lost to disability owing to mental disorders have increased by 45.2% from 1990 to 2016 [3], and mental disorders are associated with a reduced life expectancy by a median of 10.1 years [5]. Mental and substance use disorders are particularly prevalent in people in their 20s, and anxiety disorders and major depression have a high long-term stability [6]. Many mental health studies have focused on the mechanisms and predictors of vulnerability (risk) and dysfunction. However, we and others have argued that a focus on resilience, aiming to investigate factors and mechanisms contributing to the maintenance and recovery of mental health despite adversity [7], is a complimentary, helpful approach to reveal novel intervention targets and to help avert (chronic) mental health problems before they develop. Here, we describe the protocol of a longitudinal study designed to gain a better understanding of resilience.

Resilience is the maintenance of, or quick recovery toward, mental health during and after times of adversity, such as trauma, difficult life circumstances, challenging life transitions, or physical illness [8,9]. It is becoming increasingly clear that resilience is the result of a dynamic process of successful adaptation to stressors [9-14]. Besides person-environment interactions and the activation of dispositional coping strategies, there is accumulating evidence that individuals *change* while they successfully cope with stressors. These adjustments can manifest at various levels, such as altered perspectives on life [15], the emergence of new strengths or competencies [16], partial immunization against the effects of future stressors [17-19], or epigenetic alterations and modified gene expression patterns [20,21]. Neurobiological studies in animal models indicate that adjustments at the brain level are causal for the preservation of normal behavior [22-25]. From a dynamic perspective, resilience results from change and not just inertia, insensitivity to stressors, or merely a passive response to adversity.

Consequentially, resilience should no longer be understood as a fixed personality trait or predisposition (the *resilient personality*) that will determine successful coping independent

XSL•FO
RenderX

of other factors. Rather, we should take a dynamic stance and investigate the complex, interactive, and time-varying processes (*resilience processes*) that lead to a positive long-term outcome relative to the number of stressors to which an organism is exposed. These processes will partly be determined by individual dispositions, including traits, habits and skills, beliefs, genotype, brain architecture, and physical constitution ("resilience factors"). Although some of those will be quite stable and define a person's typical coping patterns throughout a stressful life period, other resilience factors may themselves undergo change, for instance, by increasing their effectiveness or frequency of use. The latter would constitute allostatic resilience processes, in which the system learns to change its mode of operation to remain stable. Allostatic adjustment is more likely when an external perturbation (a stressor) taxes the system. In contrast, homeostatic resilience processes are defined as mental stability in the absence of individual change [13].

By definition, resilience as an outcome cannot be measured through any one-time (cross-sectional) assessment (eg, a questionnaire, brain scan, and genotype) performed before adversity occurs, as the trait-like conceptualization of resilience implies. Instead, resilience can only be determined by assessing both stressors and mental health longitudinally, thus capturing the dynamic nature and time course of the stressors, as well as the changes in mental health that these stressors may or may not induce [9,11]. This should be complemented by assessing potential resilience factors at study baseline and, ideally, also repeatedly during the course of observation [13]. Moreover, the factors and processes of resilience should ideally be studied at different levels of organization, from the molecular (including genetic), physiological, neural, and cognitive levels to behavioral, experiential, and social levels [26].

This Study

The observational study Dynamic Modelling of Resilience–Observational Study (DynaM-OBS) of the Consortium "DynaMORE (Dynamic Modelling of Resilience)," funded by the European Union Horizon 2020, is designed to unravel such multilevel mechanisms of outcome-based resilience. The targeted sample is young students who find themselves in the transition from family and school life to work or academics—a life period characterized by new unfamiliar environments and demands, which is associated in some individuals with the exacerbation of existing, or the onset of new, stress-related psychological problems. The rationale of focusing on young people is that many mental disorders have their first onset or even peak during this critical life transition phase [27], and stress-related mental problems appear to be a particular problem in the student population [28-33]. To enrich our sample with at-risk individuals, we added two further inclusion criteria: participants must (1) have a history of at least 3 adverse life events [34] and (2) score in the mid-to-high range in the General Health Questionnaire (GHQ), a self-report instrument for internalizing symptoms [35], in addition to being a student or undergoing an apprenticeship. The study started in October 2020, when the second wave of the COVID-19 pandemic began in Europe, which formed an additional general stressor to the sample population at the time of data assessment [36].

DynaM-OBS is a longitudinal study with a baseline assessment, a dense observation period of 6 months (longitudinal phase 1), and a subsequent less dense observation period of 3 months (longitudinal phase 2) for each participant. DynaM-OBS features four core components: (1) an extensive baseline characterization (baseline battery) measuring potential social, psychological, and biological resilience factors; (2) a biweekly web-based assessment of stressor exposure and mental health during phase 1; (3) repeated measurement of a subset of potential resilience factors at different time points during the study; and (4) every 4 weeks, 1-week–long ecological momentary assessments (EMAs) and ecological physiological assessments (EPAs) of mood and stress reaction patterns during real life conducted using smartphones and wristbands, respectively.

The DynaM-OBS biweekly stressor and mental health assessments (study core component 2) apply the frequent stressor and mental health monitoring (FRESHMO) paradigm introduced recently to operationalize and measure resilience in longitudinal studies [13]. In the data analysis, we will use normative modeling of stressor reactivity (SR) as an approximation of resilience. Specifically, we will regress participants' average mental health problem score from all assessment time points in phase 1 over their average stressor exposure score from the same time points, and thus, we will establish the sample's normative stressor exposure–mental health problem relationship during the study. At any single assessment time point or series of subsequent time points, the deviation of a participant's (average) mental health problem score from the norm relationship (its regression residual) expresses the participant's individual mental health reactivity to stressor exposure during that time window. A positive SR score reflects higher than predicted reactivity, whereas a negative SR score reflects lower than predicted reactivity. Importantly, SR scores inherently correct for different degrees of stressor exposure between individuals and can thus be compared between them.

On this basis, the inverse of the SR score calculated from the average stressor exposure and mental health problem scores over the entire longitudinal phase 1 time window of the study can be considered a dimensional measure of a participant's outcome-based resilience over these 6 months. We will also build within-participant time courses of SR scores by building the score in sliding windows of several averaged biweekly stressor exposure and mental health problem measurements. This permits us to index temporal fluctuations in reactivity and to detect potential substantial changes that would be a strong indicator of allostatic adjustment at the level of resilience factors, without which relevant increases or decreases in reactivity are difficult to imagine.

Thus, the time series–based approach to SR assessment goes beyond the mere prediction of a longer-term resilience outcome (here, the inverted 6-month SR score of phase 1) from a single measurement of more or less stable resilience factors (here, DynaM-OBS baseline battery, study core component 1). In combination with repeated measurement of resilience factors (DynaM-OBS core component 3)—some biweekly and some at study entry and study exit—the approach allows for relating changes in the outcome to potentially underlying allostatic

XSL•FO
RenderX

changes in resilience factors (toward the good or bad). Another more distal source of change in the outcome may lie in the stressor exposure itself, which may increase to a degree that the system reacts allostatically by ideally strengthening the existing or developing new coping mechanisms, which then, in turn, improve SR [13].

Core component 4 of DynaM-OBS (EMA and EPA) serves to examine whether stressor exposure, mental health, and SR measured using web-based questionnaires over periods of weeks or months (refer to component 2) are reflected in individuals' patterns of SR measured at a higher temporal frequency in real life. EMA combined with EPA will allow us to quantify, among others, the frequency of self-reported real-life stressors, the magnitude of mood or physiological changes in response to these stressors, the speed of recovery, and the alterations of recovery speed.

Relation to Other Studies

The FRESHMO paradigm [13] in its combination with repeated resilience factor measurement is or has been used in several other longitudinal studies by our consortium and partners, including the studies "MARP (Mainz Resilience Project)" (study protocol in preparation, functional magnetic resonance imaging [fMRI] battery and results published by Kampa et al [37,38]), "LORA (Longitudinal Resilience Assessment)" [39], and "DynaCORE-L (The DynaMORE Longitudinal Study on Psychological Resilience to the Mental Health Consequences of the Corona Crisis)" [40]. MARP and LORA are ongoing since 2016 and are monitoring stressors and mental health every 3 months and resilience factors approximately every 1.5 years over many years of participants' lives (refer to the publication by Kalisch et al [13]). DynaCORE-L was conducted over 6 weeks during the early phase of the COVID-19 pandemic in 2020 and involved weekly stressor, health, and resilience factor monitoring. Similar to DynaM-OBS, all studies also include baseline resilience factor assessment. DynaM-OBS thus covers a time range lying in between MARP and LORA on the one hand and DynaCORE-L on the other hand. A similar approach is also used in the ongoing Healthy Brain Study, which uses 3 waves of assessments to calculate dynamic resilience scores [41].

In DynaCORE-L, we observed that several baseline resilience factors prospectively predicted average SR over the full monitoring period, whereas week-to-week changes in resilience factors were not predictive of SR changes in the subsequent week [42]. This indicates that allostatic adaptation processes may occur over longer timescales. Another possibility is that the relatively mild stressor exposure in DynaCORE-L, which occurred after the first wave of the pandemic had subsided, permitted homeostatic coping. Owing to its longer time range and more severe at-risk constellation, DynaM-OBS should be more sensitive than DynaCORE-L in detecting allostatic processes. At the same time, DynaM-OBS allows us to test the generalizability of the baseline resilience factors discovered in DynaCORE-L to a different sample. Another source of hypotheses is the unpublished preliminary analyses of the MARP and LORA data sets. In synopsis with the anticipated results from these long-term studies, DynaCORE-L and DynaM-OBS will yield a good picture of the temporal dynamics of allostatic resilience processes.

DynaCORE-L had further detected that week-to-week changes in stressor exposure predate subsequent changes, specifically in the resilience factor of active behavioral coping, which were, however, not translated into improvements in SR. Again, this may have been the consequence of the limited duration or limited exposure severity in the study. With DynaM-OBS we, therefore, also aim to detect mediated relationships between stressors, resilience factors, and SR. The addition of EMA and EPA is intended to detect potential relationships at much higher (within-week and within-day) temporal resolution, which is possible neither in DynaCORE-L nor in MARP and LORA.

In addition to answering questions about resilience factors and processes, a purpose of DynaM-OBS is to establish a methodological framework for a subsequently planned intervention study (DynaMORE intervention study [DynaM-INT]) that aims to find new ways to prevent stress-related mental illness in at-risk individuals with the help of mobile training apps targeting specific resilience factors. In the context of such interventions, regular monitoring of SR and resilience factors can provide information on the desired outcome (lastingly reduced SR) and potential working mechanisms (lastingly strengthened resilience factors), whereas a baseline battery of both resilience and risk factors (RFs) may inform us about the individual characteristics that predict intervention success.

Statistical Methods Development

The conceptual framework and the types of data generated by DynaM-OBS require new analysis methods. Although the time-sensitive regression models used in DynaCORE-L were appropriate for analyzing time point–to–time point (week-to-week) effects, they were also limited. Notably, they only tested each of the multiple, partially correlated resilience factors in a separate model, and they did not consider interrelations between resilience factors; they did not test for time-lagged effects between either stressors and resilience factors or resilience factors and SR extending beyond 1 week; and they did not test for changes or change points in the time series of stressor exposure, resilience factors, or SR. Therefore, we also use DynaM-OBS (together with the other mentioned studies) as a test bed for new methodological developments. These include regularized regression methods [36,43], network models [12], landmarking methods [13], and individualized deep dynamic methods in combination with deep generative models, allowing, for example, additional quantification of resilience, multiple imputation, and dimension reduction [43]. We will also use the data for potential improvements in the calculation of SR scores, including partial least squares methods [44], serving notably to improve the mental health problem variance explanation by stressor exposure and the better integration of stressors of various sources into stressor exposure [13]. Thus, DynaM-OBS has a strong exploratory character from a methodological perspective.

XSL•FO
RenderX

Research Questions and Hypotheses

Nevertheless, we formulate a set of hypotheses that will be tested using established methods, as described in the *Methods* section. A major theoretical background of DynaM-OBS is Positive Appraisal Style Theory of Resilience (PASTOR) [9,45]. Positive appraisal style (PAS) is the tendency to appraise potential threats to one's goals and needs (stressors) in a way that avoids unnecessarily negative but also highly unrealistically positive (delusional) appraisals. Instead, appraisals typically produced by individuals exhibiting PAS range from realistic to slightly unrealistically positive appraisals. Therefore, positive appraisers generate appropriate, optimally regulated stress reactions that are sufficient to cope with a threat but do not use more resources than necessary and have more time for recovery and rebuilding of resources and more opportunity to make growth experiences than individuals who are inclined toward catastrophizing, pessimism, or helplessness.

Questionnaires

DynaM-OBS uses a PAS self-report questionnaire developed to assess the cognitive processes or mental operations that lead to positive appraisal contents (Perceived Positive Appraisal Style Scale—process focused [PASS-process]; refer to the *Methods* section) in its baseline battery, its biweekly web-based monitoring, and in the exit questionnaire battery applied in month 9 of the study. We hypothesize (a) that the baseline PASS-process negatively predicts the SR score covering the first 6 months of the study (phase 1, henceforth: SR_1), (b) that changes in PASS-process from time point to time point in the biweekly monitoring inversely cofluctuate with the corresponding SR score, (c) that such changes also negatively predict time-lagged changes in SR (where the duration of the PASS-process change necessary to entail SR changes and the duration of the time lag are to be explored), and (d) that changes in PASS-process from study baseline to study exit are negatively related to the SR score covering the entire study period (phases 1 and 2, SR_{1+2}).

An alternative PAS self-report instrument used in the DynaM-OBS baseline and exit batteries focuses on positive appraisal content instead of focusing on the processes that generate such appraisals (Perceived Positive Appraisal Style Scale–content focused [PASS-content]; refer to the *Methods* section). Hypotheses a and d, therefore, analogously apply to PASS-content.

In this manner, we will also test other baseline and exit questionnaires that specifically assess positive appraisal tendencies on single threat appraisal dimensions, namely, the dimensions of threat probability (optimism), threat coping potential (general self-efficacy and control), and threat magnitude and costs (inverted anxiety sensitivity score).

In the combined multivariate analysis using regularized regression of the PAS scales and the latter instruments, we will also address the question of which of these scores are best in explaining SR. In a complementary approach using factor analysis, we will ask whether there are interpretable latent variables across questionnaires that can be considered dimension-reduced representations of the PAS construct and whether these predict SR.

Finally, we will ask whether PAS (assessed with the "winning" instrument or instruments in the comparative multivariate analysis or, alternatively, with suitable cross-questionnaire factors) mediates the effects of perceived social support on SR and whether its effect on SR is in turn mediated by perceived good stress recovery (refer to the studies by Kalisch et al [9] and Veer et al [36] for rationale). For these mediation analyses, we will again use either baseline scores (for explanation of SR_1; hypothesis a) or baseline-to-exit change scores (for explanation of SR_{1+2}; hypothesis d).

The complete battery of RFs assessed in the baseline and exit questionnaires will be evaluated for its ability to explain SR scores in a more exploratory manner, using the abovementioned and potential newly developed methodological approaches.

Neuroimaging

In the development of PASTOR, we have emphasized the problems associated with self-report assessment in general (which knows various sources of bias) and self-report assessment of appraisal processes and contents in particular (not all of which may be accessible to consciousness and be verbally reportable) [9]. Therefore, we also use a complementary approach, namely, to indirectly index the effectiveness and efficiency of participants' positive appraisal processes through objective measures of their behavioral, physiological, or neural reactions to stressors in the laboratory or in real life. To this end, we generated a baseline neuroimaging battery where fMRI tasks are (partly) accompanied by behavioral and physiological recordings. The battery includes tasks from the corresponding MARP battery (reward sensitivity, differential fear conditioning, and situation-focused volitional reappraisal [37]), all of which provide reproducible imaging data [38] and were either found to be predictive of SR in initial analyses in MARP (unpublished) or were retained because of their special theoretical interest (refer to the study by Kampa et al [37] for task rationales in the context of PASTOR). A purely behavioral stress reactivity and recovery task in the MARP battery is replaced in the DynaM-OBS battery using a dedicated neuroimaging variant [46,47]. To link the battery with other neuroimaging cohort studies, a frequently used implicit emotional processing task is also used [48,49]. These tasks are complemented by structural and resting-state fMRI measurements.

For the neuroimaging data, we hypothesize (based on initial MARP findings and PASTOR) that SR_1 will be negatively predicted by activity related to (a) high gain anticipation (gain>zero anticipation contrast), (b) low loss anticipation (loss>zero anticipation contrast), (c) high threat safety discrimination during the processing of fear-conditioned stimuli (CS) (threat-predictive CS+ > non–threat-predictive CS- contrast), (d) low threat generalization (CS- contrast), (e) high volitional reappraisal (R>NR contrast). Finally (f), we hypothesize that SR_1 will inversely correlate with amygdala-ventromedial prefrontal functional connectivity during implicit emotion processing as measured using a faces versus shapes matching paradigm [50]. For details on contrasts, refer

XSL•FO
RenderX

to the studies by Kampa et al [37] and Wackerhagen et al [50]. Similar to the questionnaire measures, PASTOR-related neuroimaging measures will be additionally analyzed using multivariate regression and factor analysis to identify best or latent predictors, respectively, of SR. We will also attempt cross-modality analyses including both questionnaires and neuroimaging measures.

Similar to longitudinal resilience data, the neuroimaging data will be used for the development of analysis methods.

Other Data Modalities and Hypotheses

PASTOR claims that the effects of other social, psychological, and biological resilience factors on resilience are mediated by how they shape PAS [9]. In this framework, we used a range of additional questionnaires, neuropsychological tests, and biological samples (blood for genotyping, DNA methylation, plasma proteome analysis, and also cytokines at 1 site; stool for gut microbiome analysis; and saliva for cortisol analysis). Well-known risk factors and sociodemographic variables were also assessed. The latter will be included as covariates in several planned analyses, along with other potentially confounding factors such as the study site.

Methods

Study Centers and Study Period

The data were acquired in a multicenter setting at 5 research sites: Charité–Universitätsmedizin Berlin, Department of Psychiatry and Psychotherapy in Berlin, Germany; Universitätsmedizin Mainz, Neuroimaging Center (NIC) in Mainz, Germany; Donders Centre for Cognitive Neuroimaging (DCCN) in Nijmegen, The Netherlands; Sagol Brain Institute, Tel Aviv University (TAU) and Tel Aviv Soursaky Medical Center, Tel Aviv, Israel; and University of Warsaw, Faculty of Psychology in Warsaw, Poland. Each site's official language was used to communicate with the participants, as well as in the study materials (informed consent form, tasks, questionnaires). Participants enrolled in the study between October 2020 and September 2021, which was during the second wave of the COVID-19 pandemic, as indicated in the details provided in Multimedia Appendix 1. Phase 1 assessments were completed in March 2022, and phase 2 assessments were completed in June 2022.

Participants

A total of 250 mentally healthy male or female participants who were studying or in vocational training at the time of recruitment were planned to be included at the 5 research sites (n=50 each). The exact number of participants per site will be reported in the follow-up reports. The permitted age range was 18-25 years at all sites, except for TAU, where the age range was 18-27 years because most young adults in Israel complete 2 to 3 years of military service and spend 1 year abroad before entering vocational training or university. Participants were included if they had experienced ≥3 stressful life events [34], which they rated as burdening, and if they reported an elevated level of general psychopathology (internalizing symptoms), defined by a score of >20 in the GHQ-28 [35]. The complete list of the inclusion criteria is provided in Table 1.

XSL•FO
RenderX

Table 1. List of inclusion criteria and format in which they were assessed. Participants who were found eligible for criteria 1 to 10 in the anonymous web-based screening were invited to an on-site interview to check eligibility for criteria 9 to 13, to receive written and verbal information about the study, and to provide written informed consent.

Number	Criterion	Format
1	Age between 18 and 25 years (18 and 27 years at Tel Aviv University)	Web-based
2	≥3 life events rated as burdening	Web-based
3	GHQ-28[a] score of ≥20	Web-based
4	BMI between 18 and 27	Web-based
5	No hormonal treatment and no consumption of steroids or treatment with steroids	Web-based
6	Proficiency in the official language of the country of study enrollment (minimum level of C1 in the Common European Framework of Reference for Languages)	Web-based
7	Eligibility to participate in ecological physiological assessment using a wearable device (no skin disease in the wrist or chest area, no medical condition that increases the risk of infection through electrodes, and no medication with phototoxic side effects)	Web-based
8	Eligibility to participate in the fear conditioning task (no skin allergy or allergy to adhesive electrodes)	Web-based
9	No lifetime diagnosis of any severe mental or organic disorder that affects neurodevelopment owing to its pathological mechanism or treatment (eg, schizophrenia, bipolar disorder, anorexia or bulimia nervosa, attention-deficit hyperactivity disorder, autism spectrum disorder, meningitis, epilepsy, multiple sclerosis, stroke, brain cancer, brain concussion, or coma)	Web-based and interview
10	Eligibility for undergoing the functional magnetic resonance imaging protocol (normal or corrected-to-normal eyesight, no hearing impairment, no claustrophobia, no nonremovable ferromagnetic metal in or on the body, not pregnant, and no large tattoo on the head or neck area)	Web-based and interview
11	No diagnosis within 9 months before inclusion of any mental disorder other than a mild depressive episode (ICD-10[b] F32.1), tobacco abuse or dependence (ICD F12), or substance abuse, as assessed by trained psychologists using the Mini-International Neuropsychiatric Interview [51]	Interview
12	No consumption of any psychoactive drug or substance up to 4 weeks before the first psychological assessment and before the magnetic resonance imaging assessment	Interview
13	The participant has received all relevant information about the study, is able to obtain full insight and is fully contractually capable, is willing and able to comply with the protocol, and agrees to participate by giving written consent	Interview

[a]GHQ-28: General Health Questionnaire.

[b]ICD-10: International Classification of Diseases, Version 10.

Ethics Approval and Consent to Participate

The study was reviewed and approved by the local ethics committees of all participating sites: the ethics committee of Charité–Universitätsmedizin Berlin, Germany (ethics approval number [EAN] EA1/319/19); the ethics committee of Radboud University Medical Center, Nijmegen, The Netherlands (Commissie Mensgebonden Onderzoek Arnhem-Nijmegen; EAN 2019-5613); the ethics committee of TAU, Tel Aviv, Israel, and the Helsinki committee of Tel Aviv Souraski Medical Center (EAN 0055-19-TLV); the ethics committee of the State Medical Board of Rhineland-Palatinate, Mainz, Germany (EAN 2019-14731_1); and the Ethics Committee for Scientific Research at Faculty of Psychology, University of Warsaw (Komisja Etyki Badań Naukowych Wydziału Psychologii Uniwersytetu Warszawskiego; EAN 03/04/2020), Warsaw, Poland. All study participants provided written informed consent.

Materials

Self-Report Variables

Self-report variables included demographic characteristics, stressor exposure, mental health, potential psychological resilience, and, to a lesser extent, risk factors. RFs are grouped into primary and secondary RFs. Primary RFs are of main interest in this study based on previous findings and the theoretical background of our consortium [9,36,40], whereas secondary RFs are based on hypotheses drawn from the literature. Where available, validated versions of the questionnaires and their translations into the site-specific languages were used. Self-developed questionnaires are provided at the Center for Open Science, Open Science Framework (OSF) [52]. Refer to Tables 2-5 for an overview of all questionnaires and Table S1 in Multimedia Appendix 2 [37,53-55] for an overview of all collected sociodemographic information. Refer to Multimedia Appendix 3 for an overview of validation studies of all questionnaires and their translated versions used at the different study sites.

Name	Construct
Life Events Questionnaire	A total of 28 stressful life events (eg, death of a friend or family member, separation or divorce of the parents, and illness or injury). For each event, participants indicate whether and at what age it has occurred and how positive or burdensome it has been experienced [34].
List of COVID-19–related stressors	A list of 23 stressors specific to the COVID-19 pandemic (eg, being at increased risk for an infection, loss of social contact, and having COVID-19 symptoms), for which participants report whether the situation occurred and how burdensome it was perceived on a 5-point scale. The list was self-developed in March 2020 for the DynaCORE[a] studies on psychological resilience during the COVID-19 pandemic [36,40].
Mainz Inventory of Microstressors	A total of 58 minor stressors of daily life (eg, loss or displacement of an object, conflict, bad weather, and traffic). Participants report whether the events have occurred and how straining they were experienced on a 5-point scale [56].

Table 4. List of self-report questionnaires used to assess primary resilience and risk factors. Please note that only the original publications are cited here and not the validation studies of versions translated into the 4 study languages. Self-developed questionnaires are provided on the Open Science Framework website [52].

Name	Construct
Brief Resilience Scale	The subjective ability to cope with and recover from stress (10 items) [59].
Cognitive Emotion Regulation Questionnaire	Different strategies of emotion regulation such as self-blame, other blame, rumination, catastrophizing, positive re-focusing, planning, positive reappraisal, putting into perspective, and acceptance (18 items) [60].
Coping Orientation to Problems Experienced Inventory	Emotion regulation strategies such as self-distraction, active coping, denial, substance use, use of emotional support, use of instrumental support, behavioral disengagement, venting, positive reframing, planning, humor, acceptance, religion, and self-blame (28 items) [61].
General Positive Appraisal Style Scale–content based	General style of positive appraisal in stressful situations, focusing on appraisal contents (29 items; self-developed). Validation and condensation into a PASS-content[a] in progress.
General Self-Efficacy Scale	Perceived ability to cope with a variety of difficult demands in life (10 items) [62].
Internal External Locus of Control-4	Degree to which individuals perceive themselves the outcomes of their behavior to be determined by their own actions or by forces outside their control (4 items) [63].
Life Orientation Test–Revised	Dispositional optimism and pessimism (10 items) [64].
NEO[b]-Neuroticism	Neuroticism scale of the NEO Five Factor Inventory (12 items) [65].
Oslo 3 Item Social Support Scale	Degree to which participants perceive themselves as surrounded by people who are close, concerned, and supportive [66].
Perceived Positive Appraisal Style Scale—process based	Assessment of positive appraisal style focusing on cognitive processes that generate positive appraisal contents in stressful situations (as opposed to assessment of the resulting appraisal contents themselves, as in PASS-content above in this section). PASS-process[c] includes correlated items of the Brief COPE[d], the CERQ[e] short, as well as 2 own-formulated items on distancing (detachment), which are all readily interpretable as indexing processes leading to positive appraisals (distancing, positive reappraisal, acceptance, putting into perspective, and humor). A previous version is referred to as PASS[f] in the study by Veer et al [36].
Psychological Flexibility Questionnaire	Subjective psychological flexibility, assessed via 5 factors including positive perception of change, characterization of the self as flexible, self-characterization as open and innovative, a perception of reality as dynamic and changing, and a perception of reality as multifaceted (20 items) [67].

[a]PASS-content: Perceived Positive Appraisal Style Scale—content focused.

Table 5. List of self-report questionnaires used to assess secondary resilience and risk factors. Please note that only the original publications are cited here and not the validation studies of versions translated into the 4 study languages. Self-developed questionnaires are provided at the Center for Open Science [52].

Name	Construct
Anxiety Sensitivity Index	Beliefs of negative implications of anxiety experiences (18 items) [68].
Bem Sex Role Inventory	Subjective gender roles (30 items) [69,70].
Body Awareness Questionnaire	Subjective attentiveness to nonemotive body processes, such as the sensitivity to body cycles and rhythms, the ability to detect small changes in normal functioning, and the ability to anticipate bodily reactions (18 items) [71].
Connor-Davidson Resilience Scale	Subjective ability to cope with stress (10 items) [72].
Dimensional Anhedonia Rating Scale	Multiple facets of hedonic function such as desire, motivation, effort, and consummatory pleasure across hedonic domains (17 items) [73].
Emotion Regulation Questionnaire	Habitual use of the emotion regulation strategies “cognitive reappraisal” and “expressive suppression” (10 items) [74].
Green Space Questionnaire and geographic information	Self-developed questionnaire assessing the degree to which participants have access to and make use of green spaces (parks and forests) in their living environment. In combination, geographic analysis of a participant’s address data is used to determine the degree of green space in their living environment (12 items).
Maltreatment and Abuse Chronology of Exposure	Abuse and neglect during development (52 items) [75].
Perceived Social Status Scale	Subjective socioeconomic status by means of a drawing of a ladder with 10 rungs, described to represent where people stand in society. Participants are instructed to indicate the rung that best represents where they stand on the ladder. In addition, the same question is asked for the dimensions of academic and occupational status [76].
Ruminative Thought Style Questionnaire	Components of ruminative thinking including problem-focused thoughts, counterfactual thinking, repetitive thoughts, and anticipatory thoughts (15 items) [77].
Sensitivity to Punishment and Sensitivity to Reward Questionnaire	Tendency for aversive and appetitive behavior (48 items) [78].
State Trait Anxiety Inventory	Symptoms of anxiety as a state and as a general trait (40 items) [79].
Toronto Alexithymia Scale	Deficiency in understanding, processing, or describing emotions (20 items) [80].

Neuropsychological Measures

The neuropsychological test battery included paper-pencil paradigms such as the Trail Making Test [81,82] to assess visual attention and task switching speed, the Hamburg-Wechsler-Intelligenztest für Erwachsene (HAWIE) Matrices to assess nonverbal logical reasoning [83], and the HAWIE Digit Symbol Test to assess processing speed [83]. Furthermore, a computer-based paradigm, the Stab/Flex task [53,54], was administered to assess cognitive flexibility (refer to section 1 and Figure S1 in Multimedia Appendix 2).

Neuroimaging

Magnetic Resonance Imaging Data Acquisition

At all sites except for Warsaw, brain imaging data were acquired using identical models of 3 Tesla MAGNETOM Prisma systems (Siemens Healthineers) with 32-channel head coils (at TAU 64-channel head coil) using the following settings: multiband gradient-echo echo planar imaging (EPI) sequences (repetition time [TR]=800 ms, time to echo [TE]=37 ms, flip angle=52°, field of view [FOV]=208 mm, voxel size=2.0 × 2.0 × 2.0 mm, 72 slices, multiband acceleration factor=8, and phase-encoding direction=posterior to anterior [PA]) from the Center for Magnetic Resonance Research, University of Minnesota, as adopted from the Human Connectome Project, were used for blood oxygen–level dependent fMRI [84]. Before each task, a pair of blip-up and blip-down EPI sequences were acquired (TR=8000 ms, TE=66 ms, flip angle=90°, FOV=208 mm, and voxel size=2.0 × 2.0 × 2.0 mm), 1 with an anterior to posterior phase-encoding direction and 1 with a PA phase-encoding direction. Furthermore, a T1-magnetization-prepared rapid gradient echo (MPRAGE) sequence (TR=2500 ms, TE=2.22 ms, flip angle=8°, FOV=256 mm, and voxel size=0.8 × 0.8 × 0.8 mm), a fluid-attenuated inversion recovery (FLAIR) sequence (TR=9000 ms, TE=83 ms, flip angle=150°, FOV=220 mm, and voxel size=0.7 × 0.7 × 3.0 mm), and 2 diffusion-weighted imaging sequences (1. TR=3600 ms, TE=92 ms, flip angle=78°, FOV=210 mm, voxel size=2.0 × 2.0 × 2.0 mm, 50 directions b=1000, 50 directions b=2000, 5 b0 volumes, multiband acceleration factor=3, phase-encoding direction=anterior to posterior and 2. TR=3600 ms, TE=92 ms, flip angle=78°, FOV=210 mm, voxel size=2.0 × 2.0 × 2.0 mm, 6 directions b=2000, multiband acceleration factor=3, phase-encoding direction=PA), adopted from the UK Biobank scan protocol [85], were acquired.

In Warsaw, a 3 Tesla MAGNETO Trio system was used. There, multiband gradient-echo EPI sequences were acquired with the following settings: TR=1410 ms, TE=30.4 ms, flip angle=56°, FOV=210 mm, voxel size=2.5 × 2.5 × 2.5 mm, 60 slices, multiband acceleration factor=3, and phase-encoding direction=PA. Blip-up and blip-down EPI sequences before each task (identical settings as other sites, except for voxel

XSL•FO
RenderX

size=2.5 × 2.5 × 2.5 mm), T1-MPRAGE (TR=1100 ms, TE=3.32 ms, flip angle=7°, FOV=256 mm, voxel size=1.0 × 1.0 × 1.0 mm), a FLAIR sequence with identical settings as described in the previous paragraph, and 2 diffusion-weighted imaging sequences (identical settings as above, except TE=97 ms) were acquired as well.

Head movement was restricted by foam pads and a tape on the forehead. All task paradigms were presented using the software Presentation (Neurobehavioral Systems) [86] on a monitor placed behind the scanner bore via a mirror that was fixed on the head coil.

Reward Sensitivity

To capture neural responses during reward and loss anticipation, an adapted version of the monetary incentive delay task [87] was used, as described in detail by Kampa et al [37]. Participants were instructed that they can win or lose a small amount of money if they pressed a button fast enough as soon as the target stimulus appeared on the screen. Before the target appeared, participants were presented with a cue for 2 seconds, which indicated whether they could win or lose money in the current trial (+€3, 12, or zł12; +€0.5, 2, or zł2; ±0; −€0.5, 2, or zł2; and −€3, 12, or zł12). The conversion rates at the time of study enrollment were €1=US $1.17, 1=US $0.29, and zł1=US $0.26. The cue was followed by a jittered anticipation phase of 2 to 2.5 seconds, after which participants had to press a button as soon as a target stimulus (white star) appeared on the screen. Each trial ended with a 2-second numeric feedback on the participant's trial outcome and the overall gain. To ensure that the reward experience did not differ between participants depending on task performance, an adaptive algorithm was applied that changed the target duration for the participant within each condition based on their past performance. If the participant's hit rate was <66%, the target duration was increased by 25 ms; otherwise, it was reduced by 25 ms. Reaction times and hit rates were collected as behavioral outcomes. A graphical depiction of the task design is provided in Figure S2 in Multimedia Appendix 2.

Differential Fear Conditioning

We used the fear conditioning part of a safety learning and memory paradigm, as described by Kampa et al [37]. Three different geometrical shapes (squares, circles, and triangles) served as the CS. Electrotactile stimuli delivered to the back of the right hand were used as the unconditioned stimuli. Two background images of different conference rooms were inherited from the original paradigm in which they served as context variables. Each background image showed a screen on which the CS were depicted to make them part of the scene in a naturalistic way (Figure S3 in Multimedia Appendix 2). Before the main experiment, a short training session was given during which the different stimuli and the rating scale were shown, but no electric stimuli were delivered. During the experiment, 2 of the CS were paired with an unconditioned stimulus in 100% of the trials. These stimuli worked as CS+. The other stimulus (CS−) was never paired with an unconditioned stimulus. Each CS trial lasted for 6 seconds. During the first 4.5 seconds of the trial, participants rated their fear of receiving an electric stimulus between 1 and 100 using a visual analog scale at the bottom of the screen. The intertrial intervals lasted from 9 to 15 seconds. The background images and stimuli were counterbalanced across participants.

The stimulus intensity was calibrated beforehand using a calibration procedure developed to reach a stimulus level that was highly unpleasant but not painful. Participants received an initial stimulus at the lowest level (1) and were asked to rate its severity on a scale ranging from 1 (not unpleasant at all) to 5 (painful). The desired rating was 4. Stimulus intensity was adapted after each stimulus according to a predefined scheme (Figure S4 in Multimedia Appendix 2).

Stimulation was performed using 2 sticky electrodes (INVISATRACE Adult electrocardiography (ECG) Electrode) placed on the back of the hand. Except for the DCCN, all sites used a Digitimer DS7A stimulator. One electrical stimulation consisted of a train of 3 square-wave pulses of 2-ms duration each, with an interval of 50 ms apart from each other. The electric potential was 400 V, and the current varied with the calibration, starting at a minimum of 10 mA. At the DCCN, the electric stimuli were delivered using an Innostim Tens 2000 (formerly named MAXTENS2000, Bio-Protech Inc) [88]. The stimulus duration was 200 ms, and the intensity ranged between 0 V to 40 V and 0 mA to 80 mA.

At TAU, the electric stimulus was replaced by white noise with a duration of 50 ms. The volume was maximized to create a startle response. All the other conditions (background and reinforcement schemes) remained the same. A pilot study at TAU revealed similar activation patterns as the typical activation patterns found using an electric stimulus.

Situation-Focused Volitional Reappraisal

In this task, participants were instructed to positively reinterpret or just view photographs that are either negative, positive, or neutral and to rate their affective state on a nonverbal scale. The paradigm has been previously described by Kampa et al [37] and was adapted from the study by Kanske et al [89]. Stimuli were selected from the International Affective Picture System and EmoPics [90] based on normative ratings of valence and arousal [91]. In a fully balanced, 3-by-2 factorial design, the 3 types of picture valences were combined with either situation-focused reappraisal or viewing the pictures as a control condition (Figure S5 in Multimedia Appendix 2).

Implicit Emotion Processing

To assess neural responses during implicit emotion processing, we used an adaptation of the face matching task [48,49]. In each trial, participants were presented with a trio of pictures and were instructed to select the matching pair by pressing a button. In the emotion condition, the trios contained grayscale photographs of Ekman faces [92] with angry or fearful expressions, counterbalanced for sex and emotion valence. In the control condition, the trios contained geometric shapes (circles, horizontal ellipses, and vertical ellipses). Four blocks per condition were presented in alternation. Each block consisted of 1 instruction (2 seconds) and 6 trials (5 seconds each; refer to Figure S6 in Multimedia Appendix 2 for the task design).

XSL•FO
RenderX

Resting State

A resting-state scan was acquired before and after the stress task, during which participants were instructed to keep their eyes open and to focus on a fixation cross on the screen.

Social Stress

To examine brain activation and cortisol levels in response to stress, an adaptation of the ScanSTRESS paradigm was used [93-95]. In this task, the participants were instructed to perform mental rotation and arithmetic subtraction exercises. During the performance, task speed and difficulty were automatically adjusted so that the participants fail most of the tasks. Furthermore, participants were presented with a live video screen showing the face of the experimenter observing and giving negative nonverbal feedback on the performance. Thus, the task involves both social evaluative threat components (verbal and nonverbal feedback from the experimenter) and uncontrollable components (task difficulty, time constraints, and mock feedback of poor performance). The original version of the task is composed of 2 runs, both containing control (no feedback and no video) and stress (feedback and live video of experimenters) blocks, 1 run before and 1 after negative verbal feedback by the experimenter. Here, we used the adapted version by Sandner et al [47], in which all stress blocks are presented in one run and all control blocks in another run, both presented before and after negative verbal feedback by the experimenter. However, we shortened this version by discarding the control runs and using only stress runs. Specifically, a shorter practice run of stress blocks was presented first, followed by negative verbal feedback, after which a full run of stress blocks was presented during scanning. Brain responses to the stress paradigm are estimated by comparing task blocks with baseline (fixation cross). An overview of the task design is provided in Figure S7 in Multimedia Appendix 2.

Biosamples

Blood was collected for the purpose of DNA extraction from whole blood (to determine participants' genotype and DNA methylation patterns using next-generation sequencing) and—at 2 sites only—for blood plasma preparation (to perform proteome analyses using immunoassays). Additional blood collected at 1 site was used to determine interleukin (IL)-10, IL-6, tumor necrosis factor α (TNF-α), and C-reactive protein levels. Stool samples were collected for the purpose of gut microbiome analysis by 16S rRNA profiling. Saliva samples were collected to determine cortisol and α-amylase levels. Details of the analyses performed will be provided in individual publications.

Ambulatory Assessments

During monthly burst weeks (6 days) in phase 1, EMA and EPA were measured.

EMA Technique and Design

At the beginning of each burst week, participants received a smartphone (Motorola Moto E6 Play) with the app "RADAR-active RMT (Remote Assessment of Disease and Relapse Remote Monitoring Technology)" for EMA data collection [96]. Questionnaires were sent 10 times per day during the participants' usual wakening hours using push notifications ("beeps"). Notifications were scheduled to appear within 90-minute blocks semirandomly, that is, for all participants, the notifications appeared at the same time. Similarly, 2 notifications never occurred closer than 15 minutes to each other (refer to Table S2 in Multimedia Appendix 2 for the beep schedule). The participants received a reminder notification 5 minutes after the initial notification. The EMA questionnaire remained available for 10 minutes after the initial push notification. Every beep questionnaire (approximately 3 minutes) included in-the-moment self-assessments of mood, (virtual) social context, physical context, event appraisal, substance use, and anticipation of pleasure. In addition, participants were instructed to start a separate morning questionnaire (approximately 1 minute) about the previous night's sleep immediately after waking up. Immediately before going to bed, participants were instructed to start an evening questionnaire (approximately 2 minutes) about the evaluation of the day, the most negative and positive event of the day, stress anticipation for the upcoming day, and whether the questionnaire influenced their mood during that day. All EMA items are shown in Figures S8 and S9 in Multimedia Appendix 2.

EPA Technique

EPA was measured for 23 hours a day during each burst week using the Chill+ wristband developed by Interuniversity Microelectronics Centre [97]. The wristband measures the photoplethysmography-based heart rate, galvanic skin response, skin temperature, and movement through a 3-axis accelerometer and 3-axis gyroscope. Furthermore, participants were instructed to press a button on the wristband to actively report stressful events.

Procedure

Overview

Participants underwent a screening for inclusion criteria, 2 assessment days at baseline (Table 6), and longitudinal follow-up assessments (phase 1 and phase 2; Multimedia Appendix 4). Before each on-site appointment, a short screening interview about potential COVID-19 symptoms including measurements of or questions regarding body temperature was conducted to minimize the risk of transmission. The participants and experimenters wore filtering facepiece masks (level 2) or surgical masks, used disinfectants, and maintained a distance of at least 1.5 m.

[e]FLAIR: fluid-attenuated inversion recovery.
[f]DTI: diffusion tensor imaging.
[g]EMA: ecological momentary assessment.
[h]EPA: ecological physiology assessment.

Recruitment and Prescreening

Participants were recruited via web-based advertisements in mailing lists and on social media platforms. After receiving brief information about the study purpose, methods, and prerequisites, participants were invited to anonymously fill in a web-based screening survey via the platform SoSci Survey [98], in which the eligibility criteria (Table 1) of the study were checked using an automated algorithm. When starting the screening survey, participants were instructed to generate an anonymous code, which they later provided to the study staff in case of their inclusion, to link their screening data to their participant ID. The screening data of nonincluded participants remained anonymous. After completing the web-based screening questionnaire, eligible participants received an invitation to participate and a request to contact their study site. The complete study information material was then sent to the participants via email, and an on-site appointment was made.

On-site Screening

During the on-site appointment, the participants received verbal information about the study and provided written informed consent. Then, further inclusion criteria were assessed in a standardized interview with trained researchers (Mini-International Neuropsychiatric Interview [MINI] [51]). Afterward, a urine-based drug screening test (SureStep Multi-Drug One Step Screen Test Panel, Innovacon Inc) for amphetamine, barbiturates, benzodiazepines, buprenorphine, clonazepam, cocaine, fentanyl, heroin, ketamine, cannabis, methadone, methamphetamine, methylenedioxymethamphetamine, morphine, opiate oxycodone, phencyclidine, propoxyphene, tramadol, and tricyclic antidepressants was administered, after which participants who were included started with the baseline assessment (baseline day 1).

Baseline Day 1

Baseline assessments were distributed across 2 appointments on 2 days (Table 1).

Neuropsychological Assessments

During neuropsychological assessments, 1 participant per session was assessed by 1 study assistant. The participant was placed at a desk with a computer in a room with minimized potentially distracting stimulation (eg, noise, visual distractions, and other people). Telephones were muted or in airplane mode. The first task (Stab/Flex) was presented on the computer, and all other tasks were instructed verbally and executed in a paper-and-pencil format (refer to the *Materials* section).

Blood Sampling

One blood sampling was performed at baseline day 1 or baseline day 2, and another one was performed at month 6 (Multimedia Appendix 4). Nine milliliters of blood (10 at DCCN) was drawn from each participant into an ethylenediaminetetraacetic acid (EDTA) tube (red monovette; Sarstedt) and stored as whole blood at −20 °C or colder until assay of DNA and DNA methylation. At the study sites NIC and DCCN, an additional 9 mL (NIC) or 10 mL (DCCN) of blood was sampled into EDTA tubes for proteomic analyses. At these sites, all blood was drawn between 12:30 PM and 3:30 PM, and participants arrived at least 5 hours sober to limit the influence of metabolism or diurnal oscillations on proteomics measurements. Blood samples for the proteomics assay were centrifuged, and serum was divided into 8 to 16 aliquots (depending on volume), which were stored at −80 °C until assay. At TAU, 2 additional tubes (1 EDTA and 1 VACUETTE TUBE 3.5 mL coagulation

XSL•FO
RenderX

activator tube Serum Separator Clot Activator) of blood samples were taken between month 1 and month 6 to derive IL-10, IL-6, TNF-α, and C-reactive protein.

Stool Sampling

Stool samples were collected using an OMNIgene-gut feces kit (OM-200, DNAgenotek). Participants received a test kit, an instruction sheet about the collection procedure, the Bristol Stool Scale [99], and verbal instructions from the test leader. Participants were instructed to collect the stool sample as close as possible to the appointment, to take several small samples from different locations in the stool material, to fill out the Bristol Stool Scale, and to store the sample in a dark place without direct sunlight. Participants brought the sample to the study center at the next appointment, where it was stored at −20 °C until the assay of the gut microbiome, or, at DCCN, directly shipped to the laboratory processing the microbiome.

Postassessment Procedures

After the baseline day 1 assessments, a personalized schedule was created with the participant, indicating the upcoming magnetic resonance imaging (MRI) appointment and timings of the upcoming phase 1 and phase 2 assessments. Furthermore, participants received all necessary information about the web-based questionnaires and were introduced to the web-based survey platform SoSci Survey [98] by filling out a dummy questionnaire. Finally, to ensure the participant's well-being, they were asked if they have experienced emotional disturbances triggered by any questions asked during the preceding session in a standardized interview. If they reported emotional disturbance and a need for help, they were directed to a clinician associated with the study.

Baseline Day 2

Overview

At baseline day 2, neuroimaging and a briefing about ambulatory assessments were performed. Before testing, participants returned their stool sample (except for DCCN), and another urine-based drug screening test (refer to the description for baseline day 1) was conducted. Participants with a negative test result then received a brief training session on MRI paradigms. During the training, they were given an on-screen presentation of the tasks, and the experimenter explained the tasks and asked questions to ensure that the participants understood the instructions. To account for diurnal or metabolism-related variations in cortisol levels, all scanning took place between 12:30 PM and 5 PM. Participants were instructed to get up from bed at least 4 hours before the appointment; not to eat, smoke, or drink beverages containing caffeine or sugar at least 2 hours before starting the MRI; to refrain from physical exercise that day; and not to drink alcohol within 24 hours before the appointment. They were reminded of these instructions via email before the appointment.

Physiological and Subjective Measures During Neuroimaging

During all fMRI sequences, the participants' heart rates were assessed using a wireless pulse oximeter (Siemens Healthineers). Furthermore, to assess salivary cortisol levels in response to the MRI tasks, 9 saliva samples were collected before, in between, and after the scanning sequences using Salivette collection kits (Sarstedt). For each saliva sample, the participant's subjective level of distress was assessed on a scale from 0 (not stressed) to 10 (extremely stressed). Before scanning, the participants were introduced to the saliva sampling technique while donating their first saliva sample. The participant received a plastic tube containing a cotton swab and was instructed to put the cotton swab into their mouth without touching it with their fingers. They were instructed to moisten the cotton swab for 1 minute and to put it back into the plastic tube. This procedure was repeated for 8 times, of which the participant was inside the scanner 5 times (Table 6).

Neuroimaging

When placed in the MRI scanner, the participants were provided with earplugs. To respond to tasks during functional MRI scans, participants operated a 4-button Inline Fiber Optic Response Pad (Current Designs; home-designed system in Warsaw [100]) with their right hand. Further, an electrode for the fear conditioning task was attached to the back of the right hand. A wireless pulse oximeter was attached to the index finger of their left hand. Via a mirror placed on the head coil, they were presented with the visual stimulation of the tasks on a monitor placed behind the scanner bore. Before and after each task, the test leader provided verbal instructions via an intercom system and received feedback from the participant. Specific instructions were repeated verbally on the screen and by the test leader before each task. An overview of the procedure steps during neuroimaging and further details of the tasks are provided in Table 6 and Multimedia Appendix 2. After scanning, participants were asked to fill in an MRI exit interview questionnaire (paper-pencil), which asked about the experiences and potential difficulties with the fMRI tasks.

EMA and EPA Briefing

After scanning, the participants were thoroughly briefed on the EMA and EPA devices and procedures. Contraindications for using the wristband collecting EPA (skin disease around the wrist area, wounds or skin allergies, and medication with phototoxic side effects) were ruled out. The devices (mobile phone, wristband, and chargers) were handed to the participants, and their functions were explained. Furthermore, the purpose of EMA and EPA, the app, and questionnaires were explained, and it was discussed with the participant how to ensure that beeps are not missed in everyday life. Further details are provided in the *Materials* section and Multimedia Appendix 2.

Post-MRI Debriefing

After donating their last saliva sample, participants were debriefed about the stress task (refer to the *Materials* section) and were informed that the task was programmed to adapt to the participant's performance and induce stress, instead of measuring their cognitive performance. Furthermore, identical to baseline day 1, participants were interviewed about emotional disturbances triggered by any questions asked during the preceding session in a standardized fashion. If they reported emotional disturbance and a need for help, they were offered counseling by a clinician associated with the study.

XSL•FO
RenderX

Longitudinal Phase 1

In the first week after the baseline day, a baseline battery of questionnaires was administered on the web. Longitudinal phase 1 spanned from month 1 to month 6 and contained the web-based monitoring for the FRESHMO paradigm [13]. In biweekly web-based questionnaires, stressor exposure, mental health problems, and process-based PAS (PASS-process) were assessed on the web. For this, participants received a link to the SoSci Survey platform at the beginning of each web-based monitoring week and had 1 week to complete the questionnaire. Furthermore, 1-week EMA and EPA assessments took place in the second week of each of the 6 study months, for which participants received 10 beeps per day (Multimedia Appendix 4).

Before and after the EMA and EPA weeks, the participants came to the laboratory to pick up or return the devices used for EMA and EPA (smartphones and wristbands). During these appointments, the participants were again interviewed about potential emotional disturbances to ensure their well-being. At months 3 and 6, further stool samples were collected. At month 6, a second blood sample was collected (Multimedia Appendix 4).

Longitudinal Phase 2

In longitudinal phase 2, which spanned from month 7 to 9, assessments of stressor exposure, mental health problems, and PASS-process took place only once a month, and no EMA and EPA was conducted. The final questionnaire battery at month 9 contained additional assessments of the resilience factors (Multimedia Appendix 4).

Remuneration

Complete participation in all assessments was remunerated with €290 (1224 in Tel Aviv and zł1200 in Warsaw). Participants could win about €10, 40, or zł40 on average during the reward task in the neuroimaging battery. Furthermore, those who completed all assessments until month 6, week 3, were included in a lottery to win 1 out of 3 additional awards of €100, 400, or zł400. To maintain compliance throughout the longitudinal assessments, money was disbursed in tranches at different timepoints throughout the study (Table S3 in Multimedia Appendix 2). The conversion rates to at the time of study enrollment were €1=US $1.17, 1=US $0.29, and zł1=US $0.26.

Results

Participant inclusion started in October 2020, and data acquisition was completed in June 2022. A total of 249 participants completed baseline days 1 and 2, whereas 209 completed the EMA part of longitudinal phase 1, and 153 completed longitudinal phase 2. At the time of manuscript submission, preprocessing and quality checks of the data are ongoing. First results are expected to be published by the end of 2023.

Discussion

Aims of This Study

DynaM-OBS targets a gap in resilience research: providing a dense longitudinal database to assess resilience as a long-term outcome and the underlying resilience processes. This approach and framework offer new possibilities to test current hypotheses about putative resilience factors as well as to explore novel ones. Specifically, our main hypothesis is that a PAS is both contemporaneously and prospectively predictive of resilience, operationalized as SR. Moreover, we expect several secondary predictors of resilience, ranging from specific brain network configurations during acute stress to high reward sensitivity, threat safety discrimination, and volitional reappraisal processes, among others.

Strengths and Limitations

Despite its strengths, which are mainly reflected in the study's richness of longitudinal and multimodal data on resilience factors, processes, and outcomes, DynaM-OBS also has several limitations. Although we were trying to be exhaustive in our assessment of stressors (including potential life events, a large number of microstressors in a wide range of life domains, and pandemic-related stressors), we cannot exclude the possibility that some relevant types of adversity were missed. For example, we did not collect information on parental traumatic exposure, which may transmit to children, and did not ask specific questions on the exposure of participants to stressors that only became more apparent over the course of data collection (eg, Russia-Ukraine war). Moreover, because of the multicenter nature of our study, we could not entirely rely on previously validated questionnaires for each study site's language and therefore translated some questionnaires ourselves, without validating them. This may pose a threat to the construct equivalence and validity between the nonvalidated and validated versions of the questionnaires. Another consequence of the multicenter nature of DynaM-OBS is that different COVID-19 restrictions applied at the different sites. Among other things, this led to the interruption of participant inclusion at Charité–Universitätsmedizin Berlin from mid-December 2020 to the end of February 2021, although all other study sites continued participant inclusion. For the interested reader, we present an overview of the general COVID-19 situation at all sites over the course of data collection in Multimedia Appendix 1.

Conclusions

Despite these limitations, the dense investigation of the most important resilience factors and resilience processes and the multi-modal database generated in DynaM-OBS have the potential to serve as a foundation for future studies on interventions and trainings aiming to enhance resilience factors and adaptive processes in at-risk individuals.

Abstract

Background: Nutrition in pregnancy is pivotal to optimizing infant growth and maternal well-being. The factors affecting Indigenous people's food and nutrition intake are complex with a history of colonization impacting the disproportionate effect of social determinants to this day. Literature regarding the dietary intake or dietary priorities of Indigenous women in Australia is scarce, with supportive, culturally appropriate resources developed for and with this group rare. Research suggests mobile health (mHealth) tools are effective in supporting health knowledge of Indigenous people and positive health behavior changes when designed and developed with the expertise of Indigenous communities.

Objective: This study seeks to build the body of knowledge related to nutrition needs and priorities for Indigenous women in Australia during pregnancy. Further, this project team and its participants will co-design an mHealth digital tool to support these nutrition needs.

Methods: The Mums and Bubs Deadly Diets study recruits Indigenous women and health care professionals who support Indigenous women during pregnancy into 2 phases. Phase 1 (predesign) uses a mixed methods convergent design using a biographical questionnaire and social or focus groups to inform phase 2 (generative). Phase 2 will use a participatory action research process during co-design workshops to iteratively develop the digital tool; the exact actions within a workshop will evolve according to the participant group decisions.

Results: To date, this project has undertaken phase 1 focus groups at all Queensland sites, with New South Wales and Western Australia to begin in early to mid-2023. We have recruited 12 participants from Galangoor Duwalami, 18 participants from Carbal in Toowoomba, and 18 participants from Carbal in Warwick. We are expecting similar numbers of recruits in Western Australia and New South Wales. Participants have been both community members and health care professionals.

XSL•FO
RenderX

Conclusions: This study is an iterative and adaptive research program that endeavors to develop real-world, impactful resources to support the nutrition needs and priorities of pregnant Indigenous women in Australia. This comprehensive project requires a combination of methods and methodologies to ensure Indigenous voices are heard at each stage and in all aspects of research output. The development of an mHealth resource for this cohort will provide a necessary bridge where there is often a gap in access to nutrition resources for women in pregnancy in Indigenous communities.

Introduction

Pregnancy is an opportune time for promoting nutrition and health behaviors given the nutritional needs of rapid mental growth and development [1,2]. Inadequate intake of key nutrients during pregnancy can have lifelong effects on brain function and in childhood. It can lead to stunting and increased risk of chronic disease in adulthood, including obesity, cardiovascular, metabolic, and endocrine diseases [3]. Globally, it has been reported that women commonly find it challenging to meet the pregnancy nutrition targets [4]. In 2019, the National Health and Medical Research Council of Australia sought applications for a Targeted Call for Research that specifically addressed nutrition in Aboriginal and Torres Strait Islander Peoples with one of the identified areas identified for research being mothers and their children.

The factors affecting Aboriginal and Torres Strait Islander (hereinafter respectfully referred to as Indigenous) people's food and nutrition intake are complex. Colonization of Australia by European settlers since the late 18th century has created a legacy of trauma and dispossession for many members of Indigenous communities [5]. Traditional cultural practices that included ceremony, language, and the hunting, fishing, and gathering of diverse and rich animal and plant food sources were banned or greatly restricted by the colonizers, which has continued to impact the health of Indigenous communities nationally to this day [6]. Food insecurity, often linked to the introduction of Western diets, limited access to traditional food sources, and the prohibitive expense of and lack of access to nutritious foods in many homeland communities is an ongoing concern for Indigenous communities [5]. Social determinants, including housing, education, economic status, and access to services all impact on health. Indigenous Australians are disproportionately affected by food insecurity and socioeconomic determinants that can contribute to unhealthy food patterns (ie, the affordability of fast food) and development of diet-related chronic diseases [7]. For instance, Indigenous adults in Australia experience type 2 diabetes at a rate 3.3 times higher than non-Indigenous adults, this increases further in remote and very remote areas [8]. Lee and Ride [9] also reported that nutrition-related chronic conditions (diabetes, cardiovascular, and kidney diseases) account for at least 75% of the mortality gap between Indigenous and non-Indigenous adults.

In Australia, very few studies have explored what Indigenous Australian pregnant women are consuming or the quality of their dietary intake [9,10]. Further, there is a dearth of information regarding nutritional knowledge during pregnancy for Indigenous women; particularly lacking is literature describing Indigenous Australians' worldviews on their needs and priorities around pregnancy nutrition [11]. Lee and colleagues [10] published the first report on an Australian Indigenous cohort (n=56; the Gomeroi Gaaynggal cohort) exploring the nutritional adequacy of maternal dietary intake during pregnancy. When compared to the Australian Guide to Healthy Eating food groups serving recommendations, the analysis found that none of the women in this cohort met the recommended daily food group servings. In addition, of the 5 key nutrients for optimal reproductive health (folate, iron, calcium, zinc, and fiber), the nutrients with the highest percentage of pregnant women achieving the nutrition reference values were zinc (77.6%) and folate (68.9%), whereas iron was the lowest (1.7%) [10,11]. The authors recognized the low generalizability of the study, though called for urgent strategies to optimize the dietary patterns of pregnant women in this cohort. Iron, iodine, and folate are critical nutrients for growth and development, yet intakes are often reported as inadequate in general populations of pregnant women [11].

The use of digital tools such as mobile apps or websites to aid in knowledge sharing or tracking of health is defined as mobile health (mHealth). Often, Indigenous communities in Australia lack access to traditional health care, and mHealth has been successfully used to bridge this gap in some communities [12]. These instruments can be effective in supporting the health knowledge of Indigenous people and aid positive health behavior changes when designed and developed with the expertise of Indigenous communities [13]. A recent study of Aboriginal and Torres Strait Islander women aged 16 to 49 years found 89.2% owned a smartphone and 93.1% had access to the internet at home [14]. Furthermore, research suggests when development of mHealth tools is led by Indigenous peoples for inclusion of Indigenous participants, the outcomes are improved [12,15,16]. Though many existing mHealth options for Indigenous Australians focus on general health behaviors or mental health [13], to date, this form of health tool is currently underused for nutrition and pregnant women alike [15,17]. This project offers a unique opportunity for the co-design and development of an mHealth app or digital tool that enhances community members' understanding of health issues and actively engages women in

XSL•FO
RenderX

the planning and management of their own nutrition during pregnancy. As part of ensuring that this project is easily identified by Indigenous community members as a culturally safe project, the title "Mums and Bubs Deadly Diets" has been chosen. In Australian slang, the term *bub* is often used for baby, and *deadly* is well-known slang within Australian Indigenous communities to mean something is excellent, wonderful, and community-driven.

This project team seeks further understanding of the behaviors of Indigenous women who are pregnant across approximately 7 sites of Australia. A mixed methods biographical survey and social or focus groups in phase 1 deliver the predesign phases of intervention and behavior stage mapping, while co-design workshops in phase 2 will address the digital tool elements necessary for program production and implementation. Ultimately, the goal is to create a digital tool that supports the provision of nutritional information and access to resources Indigenous Australian women require during pregnancy and to operate within holistically embedded Indigenous research values and principles.

Methods

Aim

The aim is to further build the body of knowledge related to diet intake, food insecurity, and nutrition support needs, which may include behavior change strategies relevant for Indigenous women from diverse urban, rural, and remote communities in Australia. This team will co-design a specification document and with further funding, an mHealth app or digital tool to support the nutrition needs of Indigenous women during pregnancy.

Study Design

This study comes from an Indigenous standpoint and is underpinned by critical self-reflexive practices that are aligned with a number of Indigenous research methods, including Aboriginal participatory action research [18]. The project will be undertaken in 2 phases that will use both mixed methods and co-design methodologies. The method builds on Sanders and Stappers [19] co-design framework, with a particular focus on the "predesign phase" (phase 1) and the "generative phase" (phase 2). Phase 1 will use a mixed method convergent design following an adapted shortened biographical narrative interpretive method (BNIM). The methods for phase 1 are based on the BNIM, which reconstructs data to understand a topic through 2 tracks of a participant's perspective [20]. First, how they lived their life, and secondly, how they interpret the relevant events as told through their personal stories within the focus group.

Findings from the focus groups in phase 1 will inform phase 2. Phase 2 will use a participatory action research process during co-design workshops with participants. This phase adopted the Kaupapa Māori method for phase 2 workshops [21]. Kaupapa Māori clearly speaks to the goals of the co-design process. This method will be adapted as needed for the Indigenous Australian context but the concept of creating meaning together, enabling research by Indigenous peoples, for Indigenous peoples, and with Indigenous peoples is inherent within the Kaupapa Māori approach [21]. Due to the nature of this method (co-design) and the Aboriginal participatory action approach that is being undertaken, the exact actions within a workshop will evolve according to the participant groups' direction.

Governance and Ethics

Governance

Study governance includes the research team of both Indigenous and non-Indigenous academics from a broad cross-section of academic backgrounds (research team), the Indigenous Steering Committee (ISC), and partner organizations. The study has been closely developed with the Aboriginal community–controlled health sector, and the project is partnered with Galangoor Duwalami Primary Healthcare Service (Maryborough, Queensland), Carbal Medical Services (Toowoomba and Warwick, Queensland), Pius X Aboriginal Corporation (Moree, New South Wales), and Moorditj Koort in the Perth metropolitan area in Western Australia.

The investigatory team are committed to the concept of making meaning together and have developed the governance with the ISC, an integral part of the project. Each partner site has nominated members to the ISC who are recognized as having appropriate cultural, community, and nutritional knowledge to be representing their community. Additionally, Indigenous members of the research team are active members of the ISC and anticipate that this facilitates strong relationships across the project. The ISC will meet quarterly and have an active role in project management, data storage and retention, data analysis, publications, and dissemination.

Ethics Approval

The project has been approved by ethics committees aligned with the principles in the Australian Institute of Aboriginal and Torres Strait Islander Studies (AIATSIS) Code of Ethics for Aboriginal and Torres Strait Islander Research (2020) as follows: Mater Misericordiae (62512), University of Queensland (2021/HE002031), Aboriginal Health and Medical Research Ethics Committee of New South Wales (1966/22), and Western Australia Aboriginal Health Ethics Committee (HREC1102). Indigenous ways of knowing, practices, and cultural expressions are fully incorporated into the study methods as per the AIATSIS Code of Ethics for Aboriginal and Torres Strait Islander Research (2020) [22].

Settings

This project is being undertaken across 3 states (Queensland, New South Wales, and Western Australia) to ensure that the project is broadly representative of the views and needs of Indigenous women across Australia. It is not feasible to work with every Aboriginal or Torres Strait Islander nation of Australia, but these sites were chosen for their diversity in cultural community, community sizes, socioeconomic status (measured by Socio-Economic Indexes for Australia; SEIFA), and rurality (measured by the Modified Monash Model). The average community SEIFA score is 1000, where SEIFA measures the relative level of socioeconomic disadvantage or advantage based on a range of community characteristics taken

XSL•FO
RenderX

from the national census. As the index decreases from 1000, so too does the socioeconomic index; likewise, as it increases above 1000, the affluence of the community increases. It is worth noting that the SEIFA score shown for the communities in Table 1 is for an entire community or town and is only an indication for a region. To reflect the economic diversity of the participants, we will also be asking about their household income in our surveys. The Modified Monash Model scale from 1 to 7 defines the rurality of a community, whereby 1 is a major city and 7 is a very remote community [23]. Table 1 shows the characteristics of the sites for this study and highlights the diversity of population size, rurality, and socioeconomic status.

Table 1. Demographic characteristics of study locations.

Site	Primary cultural identification	Total population, n (significant urban area according to ABS[a]) [24]	Indigenous population [24], %	Modified Monash Model scale [23]	SEIFA[b] score [25]

[a]ABS: Australian Bureau of Statistics.

[b]SEIFA: Socio-Economic Indexes for Australia.

[c]SEIFA score available for Local Government Area.

Participant Recruitment

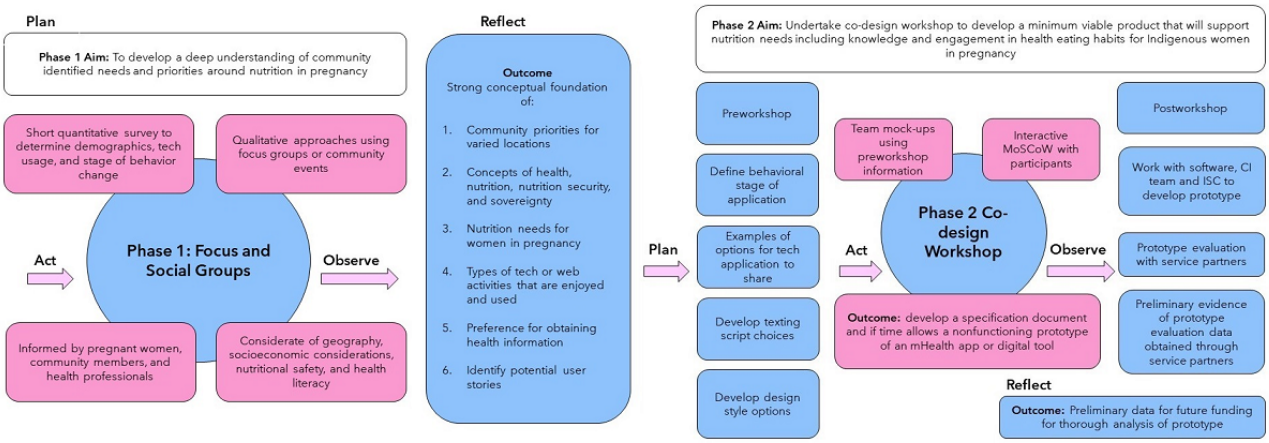
Participant recruitment strategy has been determined in collaboration with each site. Each organization has prominently displayed posters (on their noticeboards and electronic sites) and has flyers available for potential participants, with a QR code included on both documents leading to detailed participant information and contact information for the research team if potential participants have any questions. Some participating sites, Carbal (Warwick) and Galangoor Duwalami (Maryborough), have indicated the study is an ideal activity for existing community groups within their organizations, including women's groups, mother and baby groups, and Elder groups. In these instances, the research team has attended these organizations' community groups in advance to deliver a short presentation to group members about the study and answer questions asked by potential participants. Following the research team presentation to the site and to potential participants, the site arranged a time for data collection with the group of participants who consented. All participants are advised that only deidentified data will be used for this project and are given a full explanation of how data will be stored safely.

Consent forms are signed by all participants upon arrival at the data collection activity following a further opportunity for participants to clarify any concerns of consent. In recognition of the commitment by participants to the study, participants involved in phase 1 and phase 2 are offered a gift or voucher to the value of Aus $50 (US $33.45) for each phase as advised by the partner organizations.

Inclusion and Exclusion Criteria

This study is recruiting 2 different types of participants. We are specifically recruiting women who identify as having Aboriginal and Torres Strait Islander heritage. These women may either be currently pregnant or have raised children in their lifetime. The study also includes women who are older community members or Elders to ensure that experiences of all women in the community are represented. Additionally, health care professionals from Aboriginal community–controlled health organizations who support women's health are being

XSL•FO
RenderX



recruited. This participant group can include either male or female participants who may or may not identify as having Aboriginal and Torres Strait Islander heritage. Aside from health care professionals, this study will exclude male community members. The digital tool is designed to be used during pregnancy; therefore, men are not appropriate participants for the project.

Approach

Overview

Phase 1 and phase 2 will occur as face-to-face discussions unless during the current pandemic health advice suggests otherwise. The project takes the holistic approach precedented by Chamberlain et al [31] using intervention mapping and action research cycle as shown in Figure 1. This study uses Aboriginal participatory action approaches discussed by Dudgeon et al [18] and also draws upon the guidelines to co-design mHealth systems developed by Noorbergen et al [32].

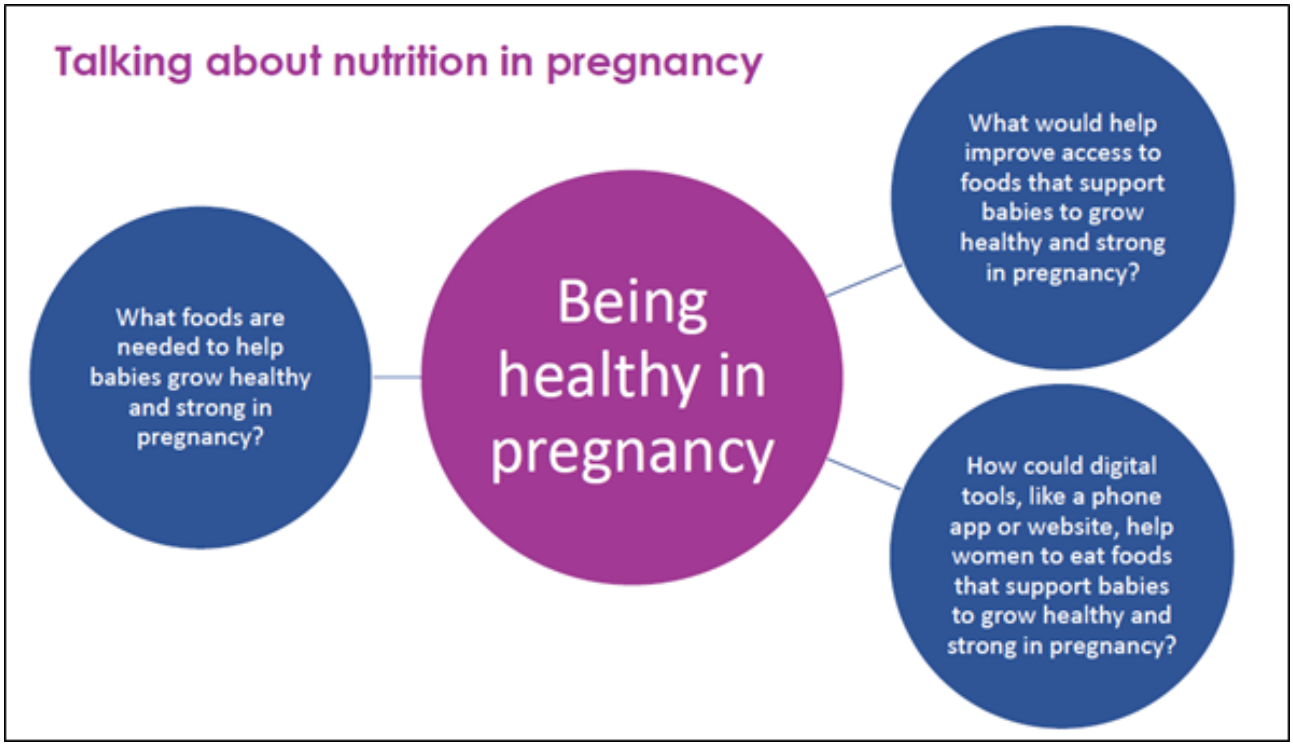
Figure 1. Co-design methods used and the integration of information from the phases 1 and 2 research cycle. CI: Chief Investigator; ISC: Indigenous Steering Committee; mHealth: mobile health; MoSCoW: must have, should have, could have, and would not have.

Phase 1: Understanding Community Worldview (Predesign Phase)

Overview

Focus and social groups will be held with at least 2 members of the research team. One member will be the primary group facilitator, and the other attendee will be there to assist with consent and survey paperwork. The other attendee will also take field notes during the discussions. The facilitator and other research team members will introduce themselves at the start of the focus group and spend some time talking informally to give participants time to relax prior to the start of the group.

Focus groups with community members and health professionals will use similar prompt questions (Textbox 1) with the facilitator rephrasing these as appropriate for each group. To further aid discussion, visual aids are used to generate conversation during the social and focus groups and are placed around the room and to be used by participants throughout the discussion (Figure 2).



All participants attending will complete a short-answer survey designed by the research team. This will be completed at either the start or end of the group discussion. The survey contains standard demographic questions, current nutrition issues and food access experiences, and questions regarding current use of mobile phone apps, access to the internet, computers, and the types of activities used on the phone. When designing this survey, the team were aware that many research participants can feel that some questions have no relevance to the study. They made a conscious effort to only include questions that were directly related to the study outcomes and would be used in the data analysis for this study, and for which they could justify the use of the data to a participant who may query its purpose. Group discussions are between 1 and 2 hours depending on the group.

Textbox 1. Discussions with both women from the community and health care professionals are centered around the same prompts, reworded to suit their context.

- What are the foods you or your community need to help babies grow healthy and strong in pregnancy?
- What would help you and your community to access foods that support babies to grow healthy and strong in pregnancy?
- How could digital resources, like a mobile phone app or a website, help you and your community to eat foods that support babies to grow healthy and strong in pregnancy?

XSL•FO
RenderX

Figure 2. Social and focus group visual aid.

Data Analysis

Survey data will primarily be assessed using descriptive statistics and later integrated with qualitative results in matrices. All focus groups are audio-recorded with participant permission and transcribed verbatim with thematic analysis undertaken. Transcripts and audio recordings are cross-checked for accuracy prior to analysis. Both deductive and inductive analyses will be undertaken. Analysis of the literature will provide a set coding framework (the deductive approach) that will be used across all sites and focus group transcripts by the research team. The inductive approach will develop site- or community-specific knowledge, while the deductive approach will provide a clear analysis framework that can be used for all sites that is specific to the objectives of the project. Inductive qualitative evaluation of the transcripts will use thematic techniques and insights to this cohort outlined by Sherriff et al [33] to guide the interpretation, thematic analyses, and reporting of this data. Using NVivo (version 12, 2018; QSR International Pty Ltd) qualitative data analysis software, identified themes will be compiled into a coding frame and, as new themes emerge, they will be compared against the initial coding frame and either added as new themes or used to expand and modify existing themes, until all data are accounted for.

The ISC will be enlisted to assist in the coding framework and contribute their understanding of any themes represented in the data using a chunk-by-chunk analysis format. Data analysis will be undertaken using constant comparison methods, and matrix displays will be used to explore similarities and differences across groups on key themes.

Prephase 2 (Generative Phase)

Data analysis of phase 1 will be completed from all sites prior to undertaking the phase 2 co-design workshops. Additionally, many resources to inform the co-design workshops will be compiled or developed by the research team based on the findings from phase 1.

Development of the workshop resources will occur in an active partnership with the ISC. Personas of potential users of the app will be determined and included in the developed presentation. The behavior stages of these potential personas will be identified to assess where the cohort's understanding may be regarding a topic, ranging from precontemplation, contemplation, planning and preparation, action, and maintenance [34,35]. The team will compile initial concepts and themes for the app or tool and design or feature ideas to test and refine in co-design workshops with participant groups.

Phase 2: Co-design Workshop (Generative Phase)

Overview

Co-design workshops will be held with participants from phase 1 who can attend. However, it is expected that there will be a reduction in participant numbers as phase 2 workshops will take several hours. The start of co-design workshops will include additional introduction of new research team members attending and a short presentation of findings from phase 1 (likely delivered by the phase 1 facilitators). It is likely that this workshop will have 3 to 4 research team members attending throughout the workshop.

An additional interactive presentation will be delivered that will include mock-ups, ideas, and other information developed by the research team and the ISC during the prephase preparation. This will include a suite of technology probes (eg, screenshots of existing or relevant mHealth technology). The research team will discuss personas they have developed with the participants to consider if the target audience of the mHealth app or digital tool is appropriate. A facilitator from the research team will

XSL•FO
RenderX

follow this with a 1-hour interactive discussion to build on feedback on these initial concepts with participants.

Regular breaks will be held throughout the workshop. Following a break, a further co-design activity will be undertaken with participants. This will be facilitated by one of the research team and it will include a strong focus on MoSCoW (must have, should have, could have, and would not have) activities [36]. This method is used in software development to assess how potential elements should be prioritized depending on participant opinion and is an ideal way of progressing from an idea through to the minimum viable product needed in mHealth product developments [36]. For a minimum viable product, such as the Mums and Bubs Deadly Diets project, the focus will be on the development of the "must haves" and "should haves." Participants will be able to identify other desirable elements for the tool, with the research team ensuring that participants are aware of the timeline and budgetary considerations that can impact on the inclusion of these elements. In this case, elements will be identified in workshop activities such as a sticky notes exercise. Ideally, this workshop would have all participants and facilitators in 1 room throughout; however, with pandemic restrictions, the research team will be guided by health advice.

Data Analysis

Data collected in this phase includes audio recordings, transcripts, observer field notes as well as the collection of participant-developed workshop materials such as sticky notes and flip charts. The analysis of phase 2 is dependent on the outcomes of the co-design workshops and nature of workshop-developed materials. Using the aspects of interpretive phenomenological consensus analysis [37], the goal of this assessment is to identify exactly what these participants want in the project outcome. This may be the type of mobile technology, how it can be used, and the elements it contains, including nutrition knowledge and aspects related to health behavior change.

Data Ownership and Management

Data management of this project has been undertaken to ensure that it reflects the 8 Indigenous Data Sovereignty principles identified by Trudgett et al [38]: ownership, control, accessibility, custodianship, accountability to Indigenous people, amplify the voice of the community, relevant and reciprocal, and sustainably self-determining. For the purposes of this study protocol, data refer to voice recordings, transcripts, survey responses, and files arising from the focus or interview recordings, including field notes and observations. The data arising directly from the participants of the study remain owned by the individuals; however, the analysis arising from the participants' contributions is owned by the research team.

To ensure ownership and control, participants will have the option for their data to be handled in one of three ways after the project is complete, specifically 5 years after the final action of the project: (1) the data can be disposed of appropriately, (2) the survey and focus group data can be donated back to the community organization, or (3) all data can be donated to the AIATSIS data repository. This decision will be individual for survey data but must be unanimous for focus groups and workshops. Where a unanimous decision cannot be made, disposal of data will be the default. Whether data are returned to the community organization or AIATSIS, it will be sustainably held with Indigenous custodianship and appropriately accessible to the community.

During the life of the project, deidentified aggregate reports of initial findings will be shared with each site after each phase. These reports will be provided as an act of reciprocity to assist service strategic planning and amplify the voice of the participants.

Dissemination of Results and Publications

This project seeks to follow the Consolidated Criteria for Strengthening the Reporting of Health Research Involving Indigenous Peoples (CONSIDER) statement [39]. This statement, developed through a meta-synthesis of international guidelines by a working group, identifies 8 key domains to guide the appropriate reporting of health research involving Indigenous peoples.

Results will be disseminated in several ways to meet the needs of the community and research team, including forums for the partner organizations and community members. Individual participants will be provided study outcomes and will also be encouraged to attend any public forums and research presentations. Publication of the outcomes from this work and this goal are embodied and enacted through the collaboration and Terms of References for the ISC and agreements made with partner organizations that include how the sharing and publication of material will occur.

Results

To date, this project has undertaken phase 1 focus groups at all Queensland sites with New South Wales and Western Australia to begin in early to mid-2023. We have recruited 12 participants from Galangoor Duwalami, 18 participants from Carbal in Toowoomba, and 18 participants from Carbal in Warwick. We are expecting similar numbers of recruits in Western Australia and New South Wales. Participants have been both community members and health care professionals. Despite not asking specific questions about stages of behavior change, both community members and health professionals have raised this in a number of ways. Women and mothers have identified the things that they are currently practicing in their diets as well as areas where they are seeking further information and strategies, while health professionals have identified specific nutrition information that is challenging to explain related to pregnancy needs and highlighted the types of clients that would benefit and how best this information could be used in their practice. This will form part of the findings to inform phase 2. Preliminary findings have been disseminated to each of the Queensland sites as planned. Analysis is underway in preparation for phase 2.

Discussion

Principal Findings

This study has been designed using a combination of methodologies and methods to ensure such a major program is iterative, holistic, and culturally appropriate. A critical component to Indigenous research practice and more specifically the iterative nature of this project was reflexivity. This process encouraged shared understandings between the research team members and other collaborators, encouraging the positioning of Indigenous perspectives central to the project, allowing the research to remain ethical, meaningful, and useful throughout the many learnings and changes throughout the project [40].

The project takes a similar approach as that by Chamberlain et al [31] using intervention mapping and action research cycles to frame a co-design project from predesign and generation to implementation. Phase 1 will include the first 3 steps of intervention mapping: logic modeling of the problem, logic modeling of the change, and program design. Phase 2 will then address program production and some implementation concerns, though full implementation of evaluation will be addressed with future funding [41]. The action research cycle is used to intertwine the 2 phases in an iterative manner as highlighted in Figure 1. The dual cycle steps of "plan, act, observe, and reflect" among the 2 phases are linked, so the findings from surveys and group discussions of phase 1 inform phase 2.

The phase 1 biographical survey informs the lived life track through BNIM methods so that we may use the qualitative information to focus on the told stories track. Field notes and observations will be assessed to identify moments in the group conversation dynamics, linking transcripts to reality, emotions, and relationships. This process was adopted to allow this phase the in-depth understanding required to set the foundations for this project.

As highlighted by Noorbergen et al [32], prior to phase 2, the findings from phase 1 will have developed an intimate understanding for the research team of nutrition priorities for women during pregnancy. This will aid in determining what stages of behavior change the digital tool should focus on or may be added at each stage to support the journey of pregnant mothers. The behavioral stages identify where a person or cohort's understanding may be regarding a topic [34,35]. This is an important component to designing the digital tool in a way that targets the correct level of comprehension and commitment of the target user. Although questions related to behavior change were not included in focus group guides, our preliminary analysis of phase 1 shows health professionals and community members have identified that they have distinct needs and varied stages of behavior change that they would like to address in the mHealth tool. This will encourage true engagement and retention with the information.

Prior to the workshops, the research team and the ISC will consider the types of user (persona) who will likely use this nutrition mHealth tool to ensure that each of these users is represented within its usage. For example, a technology tool focused on pregnancy nutrition for Indigenous women could be used by a woman during her pregnancy or used by a health professional to support health education during pregnancy. It will only be during the phase 1 that the team will be able to identify what needs are important for the community.

During phase 1, participants identify how they currently use their phones and consider how these could assist them with nutrition needs. These findings will assist in compilation of suitable technology approaches that can be shared, types of design options, as well as texting and script options that will be presented in phase 2 workshops. Feedback on probes will help to uncover types of technology and functions likely to be most effective in addressing the nutrition needs and priorities of Indigenous communities. The activities included are important to determine what aspects of the app must be standalone and what can be uploaded when an internet connection is available. It also helps with determining how diverse the activities within the app can or should be. For example, should it just contain written material, or are videos and pop quizzes more suitable to engage participants?

Kaupapa Māori concepts will be used throughout data analysis from phase 1 and during the co-design workshops in phase 2. This framework originally resonated with the research team due to these underpinning values that encapsulate the concepts of similar Indigenous Australian research concepts including Aboriginal participatory action research methods [18,42]. Embedding Kaupapa Māori principles positions the project within a research paradigm of epistemic self-determination. Indigenous Australian values, knowledge, and voices influence all aspects of the project.

Phase 2 has specifically been identified to require more research team members present, as differing areas of expertise will be required on the day. To ensure best outcomes from the workshops, all efforts will be made by the research team to relax participants, so that participants feel comfortable and confident to voice their opinions throughout. Breaks will no doubt be needed; however, they serve the dual purpose of people chatting informally and getting to know one another, which will aid in participation from all.

Strengths and Limitations

The study's priority is to inform and co-design a culturally appropriate digital tool to support nutrition needs of Indigenous women in pregnancy. The strength of this study is the co-design methods and approaches to "making meaning together" with Indigenous governance and partnered communities across the country. The consolidation of the co-design method, the development of an Indigenous governance structure, and the research team comprising Indigenous researchers and leaders ensure the study is culturally safe.

As a priority, this study endeavors to include sites across Australia in order to truly include the end users in the development of this tool and seeks to be respectful of Indigenous communities in Australia and their incredibly diverse values, traditions, and customs [12,16,43]. It is not possible to include every single Indigenous country of Australia (there are over 250 individual Aboriginal and Torres Strait Islander nations contained within Australia); therefore, these results may not be

XSL•FO
RenderX

generalizable to all Indigenous Australian women. However, the spread across rural, coastal, and metropolitan communities and cultural groups will provide diversity to develop the mHealth product.

The COVID-19 pandemic continues to be a distinct limitation for this project. Local lockdowns and restrictions meant delays to project timelines, and significant modifications have been made to community engagement plans. Initial engagement meetings were moved to web-based platforms, which limited the ability to develop rapport with partner organizations and delayed the start of the study. Further, many community members have reduced their attendance to organized programs such as mothers groups, creating early challenges to recruitment. However, as we move further away from the major pandemic waves, we hope that COVID-19-related challenges are reduced.

The predicted users of this tool would be pregnant Indigenous women and potentially their health care professionals. As such, we felt it reasonable to limit our cohort to these 2 groups. However, participants have mentioned they would like their male partner or their children's fathers to be engaged in the conversation as they may rely on them to do nutrition tasks within the home. The restriction of the study cohort to women may be a limitation of this study; however, they are the target intended users. Future research could consider including the entire family unit in these conversations.

Conclusions

The Mums and Bubs Deadly Diets study is an iterative and adaptive research program that endeavors to develop real-world, impactful resources to support the nutrition needs and priorities of pregnant Indigenous women in Australia. This project addresses a problem from beginning to end, which requires a combination of methods and methodologies to ensure Indigenous voices are heard at each stage and in all aspects of research output. A mixed methods biographical survey and social or focus groups in phase 1 will deliver the predesign phases of intervention mapping, while co-design workshops in phase 2 will address the digital tool elements necessary for program production and implementation. The development of an mHealth resource for this cohort will provide an essential bridge, where there is often a gap in access to nutrition resources for women in pregnancy in Indigenous communities.

Acknowledgments

The authors acknowledge Carbal Aboriginal Medical Service and the Jarowair, Giabal, and Githabul people; Galangoor Duwalami Primary Health Care Service and the Butchulla people; Pius X Aboriginal Medical Service and the Kamilaroi people; as well as Moorditj Koort, Aboriginal Women's Health Service; the Ngangk Yira Elders Council; and the Whadjuk Noongar peoples of Western Australia for allowing our access into their country and sharing their invaluable opinions and knowledge. The authors gratefully acknowledge the assistance of Mieka Thorogood in the preparation of this paper. This study has been supported by funding from the National Health and Medical Research Council (GNT1178993). KMR is supported by funding from Mater Foundation and Equity Trustees (ANZ Queensland Community Foundation, Queensland Community Foundation–ANZ Bank Fund, Queensland Community Foundation–Thomas George Swallow Trust, and the Herbert John Hinchey Charitable Trust). CEC is supported by a National Health and Medical Research Council of Australia Leadership Fellowship (APP2009340).

Data Availability

In line with ethics approval, the data collected as a part of this study will not be publicly available. However, the data may be made available upon request for specific purposes to the corresponding author and with the agreement of the Indigenous Steering Committee.

Abstract

Background: Web-based tools for people with dementia and their family caregivers have considerably increased over the years and offer promising solutions to several unmet needs such as supporting self-care in daily life, facilitating treatment delivery, or ensuring their ability to communicate. The use of web-based tools in the field of advance care planning (ACP) for people with dementia and their family caregivers has yet to be explored and requires careful consideration, given the sensitive topic and the specific needs of people with dementia and their families.

Objective: This paper reports the protocol for a study aiming to develop and simultaneously test the usability of an ACP website designed for, and with, people with dementia and their families.

Methods: The development of the website is based on a process map for the development of web-based decision support interventions and on the Medical Research Council framework for complex intervention development and evaluation. Additionally, we apply a user-centered approach in combination with patient and public involvement (PPI) throughout the development process. We describe our iterative development approach to the website. Participants and a PPI group give feedback on 4 prototypes of the ACP website. For each iteration, we aim to include 12 participants (3 people with dementia, 3 family caregivers, and 3 dyads) in usability testing. In the first 3 iterations, usability testing includes (1) a think-aloud exercise, (2) researcher observations, and (3) the System Usability Scale questionnaire. The last iteration of usability testing is composed of a semistructured interview assessing the layout, content, face validity, and readability of the website. Qualitative data from the think-aloud exercises and interviews are analyzed using thematic analysis. Mean scores are calculated for the System Usability Scale questionnaire.

Results: This study received approval from the Ethical Review Board of Brussels University Hospital of the Vrije Universiteit Brussel. Recruitment began in October 2021. The target date for paper submission of the results of the development and usability testing will be in 2023.

Conclusions: The methods in this protocol describe a feasible and inclusive approach to the development of an ACP website together with people with dementia, their family caregivers, and other stakeholders. We provide a clear overview of how to combine PPI input and user-centered development methods, leading to a transparent and reliable development process. This protocol might stimulate the active participation of people with dementia, their caregivers, and regional stakeholders in future studies on web-based technologies. The results of this study will be used to refine the design and create a relevant and user-friendly ACP website that is ready to be tested in a larger evaluation study.

Introduction

Background

Web-based tools for people with dementia have considerably increased over the years and offer promising solutions to several unmet needs [1,2]. Many web-based tools have targeted the different needs of people with dementia by, among others, supporting self-care in daily life, facilitating treatment delivery, or facilitating communication [3]. Further, many people with dementia are enthusiastic and positive about using technologies to facilitate their independence [4]. However, the use of web-based tools in the field of advance care planning (ACP) for people with dementia has yet to be explored. To the best of our knowledge, no web-based ACP tool has been developed for people with dementia.

ACP has been defined as an ongoing process that enables individuals to explore and identify their values, reflect upon the meanings and consequences of serious illness scenarios, and define goals and preferences for future care and medical treatment [5,6]. ACP encourages people to discuss these preferences with family and health care providers, appoint a proxy decision maker, and record these preferences and choices [5,6]. We adopt a public health approach to ACP. This approach originated from an ongoing shift in the ACP concept; going from a clinician-led and documentation-focused process that highlights the need of advance directives to a broader concept of ongoing communication among patients, family, and health care providers about several aspects of future care and treatment planning [7,8]. The public health approach to ACP highlights the need to normalize and reconfigure the way decisions are made by reframing ACP as a health-promoting activity through public education and engagement. Underlying this approach is the need to have conversations about end-of-life preferences, death, and dying not only within a medical context (between patients and health care providers) but also within the family context.

Considering the progressive decline in cognitive and functional abilities associated with dementia, ACP can be particularly relevant for people living with dementia, as they become more vulnerable and more dependent on others throughout the disease trajectory [9,10]. Yet, research has shown that ACP is not a widespread practice among people with dementia [11]. People living with dementia and their families are often not well informed about ACP, as they might not be aware of ACP at all or there might be many uncertainties concerning this complex topic, which can be due to a lack of familiarity with the process or with the specific content of ACP [12-14]. Talking about ACP has been found to be complicated as people with dementia and their families experience tensions and perceive this as emotionally difficult conversations [15]. Moreover, people with dementia have quite specific needs in terms of ACP compared to other illnesses. They have a need for a clear understanding of the dementia disease trajectory and what ACP can achieve or not [14]. Furthermore, the more the disease advances and cognition declines (in a nonlinear gradual way), the more family plays a crucial role in ACP in this population [16]. As their condition evolves, many people with dementia may require a surrogate decision maker or legal representative [17].

In other patient groups than dementia, many ACP tools have been developed that are not web-based, such as trainings for professionals or documentation booklets. These have generally aimed to facilitate engagement in ACP discussions by helping patients and family caregivers in reflecting about or making decisions for future care and treatment in coordination with health care professionals [18]. However, web-based tools can have many advantages over paper-and-pencil or face-to-face tools. Web-based ACP tools can be accessed on the internet at any preferred time and place, can be used at everyone's own pace, with or without the presence of a health care professional or family caregiver, and can reach a larger audience [19]. Additionally, one of the most important features of web-based tools is the use of interactive elements allowing for tailoring to the specific needs and preferences of individuals, which seems particularly relevant for dementia [20]. A recent systematic review identified 10 existing web-based ACP tools published in international peer-reviewed literature. However, they were mostly developed in and limited to the United States [21]. None were designed for people with dementia or tested with people with dementia, despite the specific needs of this population.

Objectives

In this paper, we describe the protocol of a study that aims to develop and test the usability of an ACP website especially designed for, and with, people with dementia and their families. Furthermore, the website should be user-friendly, interactive, and accessible at any preferred time, so that people with dementia and family caregivers can use the ACP website at their own pace and within the family context.

Methods

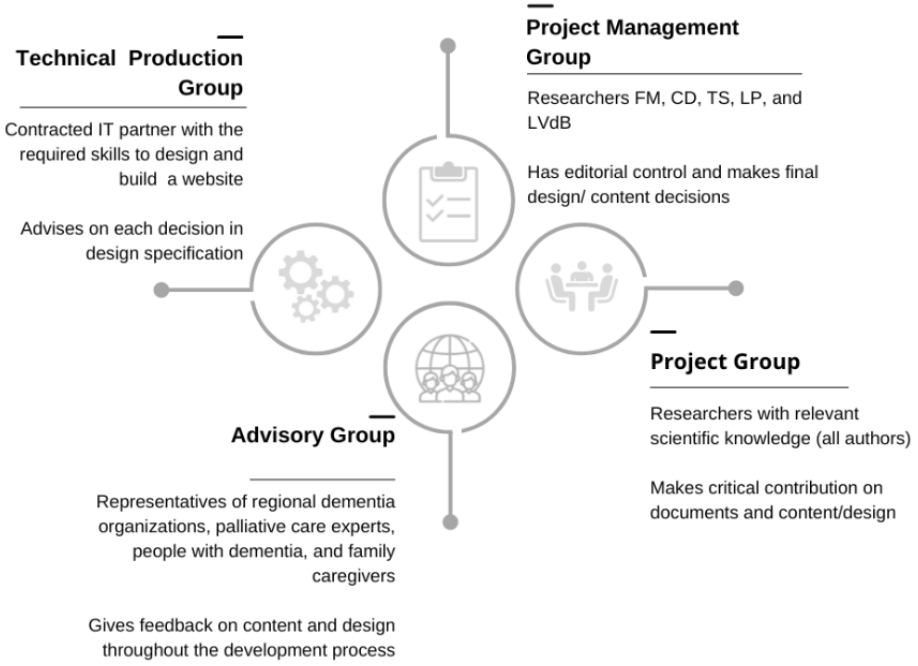
Development Overview

The methods selected for the development of the ACP website are based on a process map for the development of web-based decision support interventions for a specific audience as proposed by Elwyn and colleagues [22] and follow the Medical Research Council (MRC) framework for the development of complex interventions [23]. Given the complexity of the intervention, combining these approaches is warranted for the development of a website that is both evidence- and theory-informed.

This study focuses on the development stage of the MRC framework for the development of complex interventions [23]. Within the development stage of the MRC framework, we use

XSL•FO
RenderX

the process map for the development of web-based decision support interventions, which provides a clear development approach for digital interventions especially. It is composed of main steps such as (1) content specification, with an emphasis on considering patients' perspectives in addition to synthetizing the current scientific evidence, and (2) creative design, including storyboarding and field and usability testing [22]. Furthermore, as recommended in the MRC framework, we build in theory and integrate continuous stakeholder engagement. Thus, in the first content specification phase, we specify the information that should be included in the ACP website by identifying relevant existing evidence and conducting an assessment of needs among people with dementia, family caregivers, and dementia experts. In the second creative design phase, prototypes of the ACP website are developed and revised in several iterations.



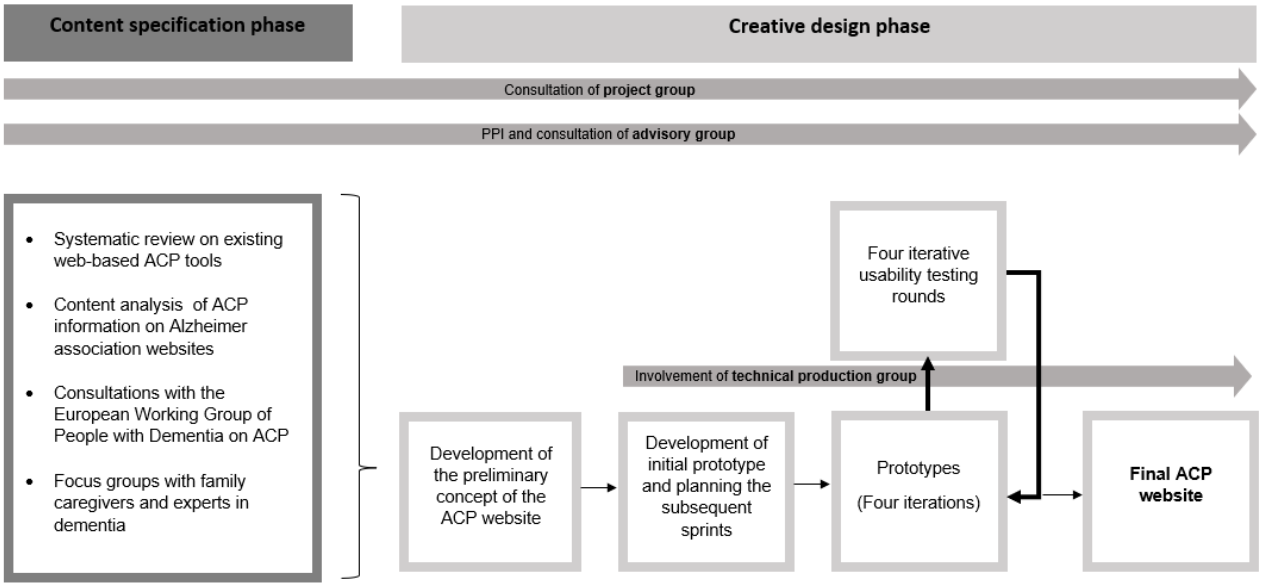
User-Centered Design and Patient and Public Involvement

In all phases of the development process, we incorporate user views as recommended in recent literature reviews on the development of technological interventions [4,24]. We adopt a user-centered approach throughout the development of the ACP website. User-centered design is a recognized method for complex intervention development [23] and is an evidence-based approach that emphasizes the importance of the needs of end users during the development [25]. Additionally, as advocated by Alzheimer Europe, we integrate meaningful patient and public involvement (PPI) consultation sessions at different stages of the development process to enhance the quality and relevance of the ACP website [26]. PPI sessions are conducted with an advisory group composed of people with dementia, family caregivers, representatives from local dementia associations, and palliative care experts (nurse and consultant for ACP). This group is consulted throughout the development process, in parallel to user testing with study participants, through online meetings and emails.

Stakeholder Groups Involved in the Development Process

The development of the ACP website is supported by 4 groups as suggested by Elwyn et al [22]: a project management group (composed of FM, CD, LVdB, LP, and TS), a project group (composed of all authors of this paper), an advisory group (a PPI group composed of representatives of regional dementia and palliative care organizations and experts in Flanders, people with dementia, and family caregivers), and a technical production group (contracted IT partner). Figure 1 gives an overview of each group's responsibilities.

Figure 1. Overview of the stakeholder groups involved in the development process.



Content Specification Phase of the ACP Website

In this phase, we specify the information that should be included in the ACP website by identifying relevant existing evidence and conducting an assessment of needs among people with dementia, family caregivers, and dementia experts. An overview of the activities conducted in this phase and their main output is presented in Figure 2. Results from the research activities in the content specification phase are reported separately [27-29]. In this content specification phase, we summarize the evidence from these activities. This includes ensuring the content and structure of the website are in line with previous research on a web-based ACP tool, the information already provided on the internet by dementia associations, and the needs expressed by people with dementia and their families for ACP and an ACP website, as well as with the opinion of experts in the field.

XSL•FO
RenderX

Figure 2. Overview of the development process and usability testing of the ACP website [28,29]. ACP: advance care planning.

Creative Design Phase of the ACP Website

Results from the content specification phase inform the design phase of the ACP website. The findings from the evidence base and the user needs assessment are used to build the first concept of the website. An overview of this study, its aims, and all involved groups is shown in Figure 2.

We adopt an agile development approach to build the ACP website. This approach is characterized by an iterative and dynamic development process while collaborating with several groups of stakeholders. It is based on the principles of continuous design improvement and testing based on rapid feedback and change and allows for high-quality adaptive software [30,31]. Such an approach is thus in line with a user-centered approach. Within the agile development approach, we use the Scrum method, as it particularly emphasizes the role of feedback loops. The core characteristic of the Scrum method is the sprint, which is a short development timeframe of approximately 4 weeks [32]. Each sprint requires careful preparation from recruitment of participants to meetings with the advisory group and the technical production group. Based on the complexity of website development and previous work using a Scrum in the development of health-related interventions [33], we estimate that the development of the ACP website will be conducted in 5 successive stages, including 4 sprints. An overview of the sprints is shown in Table 1.

In the presprint, the project management group summarizes and synthetizes the evidence found in the content specification phase. Then, the preliminary concept of the ACP website is discussed in a meeting with the advisory group. The project management group drafts a specification document based on the evidence synthesis and the discussions of the advisory group. Based on this specification document, the technical production group develops the first prototype of the ACP website.

Table 1. Overview of the sprints executed during the iterative development process.

Sprints	Objective	Content	User testing	
			Data collection	Participants, n
Presprint	Development of the first prototype	• Development of initial prototype • Planning of the subsequent sprints	• Feedback from advisory group and project group	N/A[a]
Sprint 1	Evaluate the usability of the first 3 features	• Usability testing of the home page, structure of the website	• Think-aloud method • Survey • Feedback from advisory group	12 participants (3 people with dementia, 3 family caregivers, and 3 dyads)
Sprint 2	Evaluate usability of the following 3 features	• Usability testing of the informational part of the website	• Think-aloud method • Survey • Feedback from advisory group and project group	12 participants (3 people with dementia, 3 family caregivers, and 3 dyads)
Sprint 3	Evaluate usability of the remaining features	• Usability testing of the communication part of the website and the web-based tools	• Think-aloud method • Survey • Feedback from advisory group and project group	12 participants (3 people with dementia, 3 family caregivers, and 3 dyads)
Sprint 4	Test the content, face validity, and readability of the tool, and its layout and ease-of-use	• Content, face validity, and readability of the whole website	• Semistructured interviews • Feedback from advisory group and project group	12 participants (3 people with dementia, 3 family caregivers, and 3 dyads)

[a]N/A: not applicable.

Usability Testing

We follow the definition of the International Organization for Standardization of usability (ISO 9241-11), that is, "how well users can learn and use a product to achieve their goals and how satisfied they are with that process" [34]. This includes the evaluation of the ease of learning, efficiency of use, memorability, error frequency, and satisfaction [35].

People with dementia, family caregivers, and dyads evaluate several versions of the prototype of the ACP website. Based on their input as well as feedback from the advisory group, the technical production group adapts and extends the tool in several iterations (sprints). After 3 usability sprints (sprints 1 to 3), the latest prototype of the ACP website is evaluated by people living with dementia, their main family caregivers, and dyads in terms of content, face validity, readability, and layout (sprint 4). The findings are used to develop the final prototype of the ACP website. An overview of the usability testing is provided in Table 1. The following sections explain the procedure in more detail.

Participants

We aim to include 48 participants in total. We organize the testing with people with dementia, family caregivers, and dyads. For each iteration (sprint), we aim to include 12 participants (3 people with dementia, 3 family caregivers, and 3 dyads) who are asked to test the prototype and fill in the System Usability Scale (SUS) questionnaire. For every sprint, we seek to enroll new participants. For people with dementia, the inclusion criteria were being aware and informed of their diagnosis, having an interest in and being willing to test an ACP website (including using a computer and the internet), speaking and understanding Dutch, being able to understand the information about this study, and being able to sign a written informed consent form. For family caregivers, the inclusion criteria were as follows: being the main or primary caregiver of a person formally diagnosed with dementia, having an interest in and being willing to test a web-based ACP tool, being 18 years of age or older, and speaking and understanding Dutch.

Recruitment

We ask participants to use a computer and the internet, which can be challenging, as one needs to have a certain level of computer literacy. The topic of ACP can also be sensitive and can evoke emotional reactions. Therefore, we use a process of active volunteering in our recruitment, that is, potential participants have to indicate themselves if they want to participate in this study. Thus, it is a self-assessment of willingness to participate and interest in the topic.

We recruit participants through different organizations such as the Flemish Alzheimer Liga, memory clinics, or Belgian sickness funds. Individuals who are interested in participating are asked to contact one of the researchers, who in turn sends an information letter and an informed consent form about the study through email. Potential participants are asked to reply to the email or send back the forms if they still want to participate in the study after reading the study information letter and informed consent.

Data Collection

Sprints 1 to 3

The usability tests are conducted in individual sessions with people with dementia, family caregivers, and dyads. Each session is conducted according to a pretested protocol, in the

XSL•FO
RenderX

following order: (1) a think-aloud exercise on a set of predefined tasks [36], (2) researcher observations, and (3) a usability questionnaire. The aim of combining these methods is to gather more diverse data. The same type of session is performed with the participants in the sprints 1 to 3. The sessions are conducted in a familiar setting, for instance, the location where they are recruited or in the homes of the participants.

First, we ask the participants to fill in a demographics questionnaire. We give them tasks and oral instructions on how to go through the features of the ACP website prototype. People with dementia, their family caregivers, and the dyads are asked to navigate through each prototype version using a "think-aloud" method. This involves asking participants to verbalize their thoughts, impressions, and feelings while engaging with the tool. A researcher is present to observe and note the participants' physical cues, successes in tasks, mistakes, difficulties, or comments [36]. Guidance or interference from the researcher is kept to a minimum to investigate whether the ACP website prototype is intuitive. However, if the participants fall silent for too long (eg, if the researcher notices that a participant has silently moved on to a new task or is experiencing difficulties without expressing them), the researcher reminds them to keep thinking aloud using prompts [36].

In addition, participants' perspectives on usability are further assessed through the SUS questionnaire [37]. The SUS is a widely used and a simple, reliable, and validated 10-item scale that measures subjective usability and that has already been used by people with dementia [36,37]. The SUS score measures users' perception of the usability of the prototype in terms of effectiveness, efficiency, and satisfaction. Each item is scored on a 5 - point Likert scale (strongly disagree = 1 and strongly agree = 5). Higher scores (range 0 - 100) represent better usability [37].

Sprint 4

We ask all participants to fill in a demographics questionnaire. Then, we ask people with dementia, family caregivers, and dyads to navigate the ACP website and answer questions in a semistructured interview about the content, face validity, and readability of the website, as well as about its layout.

Data Analysis

The data from the think-aloud sessions and interviews are audio-recorded and transcribed verbatim. The field notes from the observations serve to further support the data collected during the think-aloud exercise. From sprint 1 to 3, the think-aloud sessions are analyzed through thematic analysis of the notes taken by the researchers and, if the notes were not sufficient, we listen back to the audiotapes to complete the notes. After sprint 4, the data from the transcript are analyzed using thematic analysis [38]. The data are coded by 2 researchers to identify key themes. The researchers meet and discuss the preliminary codes before agreeing on a final list of codes. Disagreements are resolved through discussion.

The data from the SUS questionnaire complements the findings from the think-aloud sessions and interviews. Data are analyzed with SPSS (version 25; IBM Corp). The SUS score is calculated by summing the score contributions of each item. For items 1, 3, 5, 7, and 9, the score contribution is the scale position minus 1. For items 2, 4, 6, 8, and 10, the score contribution is 5 minus the scale position. To obtain the overall value of the SUS score, the sum of the scores must be multiplied by 2.5. Mean scores are calculated, and comparisons between types of participants are considered. A score of 68 or above will be deemed acceptable [39]. Descriptive statistics are used to describe participant demographic characteristics.

Ethics Approval

This study received approval from the Ethical Review Board of Brussels University Hospital of the Vrije Universiteit Brussel on June 26, 2021 (BUN 1432021000437). To determine the ability of people with dementia to give informed consent, we ask them to read the informed consent form out loud. We ask them per line if they understand their rights and whether they understand what is asked of them. One of the researchers (CD) ensures participants with dementia understand what they sign by discussing the statements formulated in the informed consent form with them. A family caregiver is also present to help the researcher assess the understanding of the person with dementia. If everything is clear, they are asked to sign the informed consent. We also ask the family caregivers to sign the informed consent form of the persons with dementia as witnesses, as recommended by the Alzheimer's Association National Board of Directors [40]. All data are coded anonymously, and pseudonyms are used when quoting participants.

Results

We began recruitment of participants in October 2021, and participant enrollment has been completed. A total of 48 participants took part in the usability testing across 4 prototypes of the ACP website, and we conducted a total of 6 advisory group meetings. Data analysis has not started.

Dissemination of the results will be led by the authors and will include presentations at international conferences and publications in scientific peer-reviewed journals and the creation of best practice guidance for the development of technology for people with dementia. Results from the development and usability study will be published in 2023. A larger evaluation study will also be conducted. After evaluation and further adaptation where needed, the ACP website will be made freely available as a resource for people with dementia and their family caregivers, if it is evaluated as acceptable and useful by users, and no negative effects are noticed. The website will be disseminated via the dementia organizations that were involved in our advisory group and is expected to be publicly launched in 2024.

Discussion

Principal Findings

User involvement and PPI are recognized as critical components in the development of eHealth and digital solutions, as they can help ensure that interventions meet user needs [41,42]. Involving users in the development of technology has been suggested as an important component for improving technology acceptance, especially for older people [43]. The involvement of people

XSL•FO
RenderX

living with dementia in particular has been highly advocated for in the development of technology both in research and by groups such as Alzheimer Europe [24,26,44]. Yet, studies providing a detailed description of user involvement in technology development are scarce. A particular strength of this protocol relates to the step-by-step description of our development process and how we approached the involvement of multiple key stakeholders in all phases of the website development. We particularly emphasize the combination of PPI input and user-centered development methods, leading to a transparent and reliable development process. The development process of the ACP website brings together researchers, regional stakeholders in the fields of dementia and palliative care, as well as people living with dementia and family caregivers to support people with dementia and their families in engaging in ACP.

Furthermore, this protocol describes in detail a unique combination of approaches consisting of the MRC framework for the development of complex interventions [23], the process map for the development of web-based decision support interventions [22], and an agile development approach rooted in user-centered design. The findings of the content specification phase, which are based on rich and extensive input from people with dementia, family caregivers, and dementia experts, as well as up-to-date research evidence on ACP in the field of dementia, have informed the design and content of the ACP website. The iterative development process adopted in the creative design phase facilitated the provision of feedback from the end users. This combination of methods can support researchers and designers in the development of web-based technologies, as well as understanding and considering user needs early on and throughout the development process. We hope that our efforts to describe this research approach will inspire researchers to integrate PPI and user-centered approaches in their own studies.

We strongly encourage the active participation of people with dementia, their caregivers, and regional stakeholders in research on the development of web-based technologies for dementia care.

One of the challenges anticipated in the study described in this protocol is that our sample may not be very heterogeneous. In particular, one of the inclusion criteria was to have an interest in testing a website regarding ACP; thus, our sample may be composed of people with generally higher computer skills and who are already familiar with the topic of ACP. Therefore, we may lack different types of perspectives, which could influence the content and design of the ACP website. This study is the first step before a larger evaluation study, which will involve a larger sample and where we will aim for variability in the sample in terms of age, gender, type of dementia, and dyad composition (eg, partners or a parent and child). Additionally, continuous technical support should be organized to encourage the participation of people with lower computer skills.

Conclusions

The methods put forth in this protocol describe a feasible and inclusive approach to the development of an ACP website. The results from this study will be used to refine the design of the ACP website for a future larger evaluation study to assess the ACP website's acceptability by people living with dementia and their family caregivers and the effects on people with dementia and family caregivers' knowledge of ACP, attitudes toward ACP, and intention to engage in ACP. We hope that the findings of the development and usability of the ACP website for people with dementia and their family caregivers will contribute to the design and development of future studies involving the development of web-based technologies for people with dementia.

Acknowledgments

The authors would like to thank all study participants who took part in the usability testing of the different prototypes. We also thank the members of our advisory group as well as the team at Mindbytes for their efforts to develop, build, and refine the advance care planning (ACP) website. This study is part of DISTINCT: "Dementia: Intersectorial Strategy for Training and Innovation Network for Current Technology," which has received funding from the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement 813196. It is also part of the project "CAPACITY: Flanders Project to Develop Capacity in Palliative Care Across Society," a collaboration between the Vrije Universiteit Brussel, Ghent University, and the Catholic University Leuven, Belgium, which is supported by a grant from the Research Foundation—Flanders, file S002219N. LP is a senior postdoctoral fellow of the Research Foundation-Flanders. LVdB is a Francqui research professor (2020-2023).

Abstract

Background: Co-design is one of the human-centered design approaches that allows end users to significantly and positively impact the design of mental health technologies. It is a promising approach to foster user acceptance and engagement in digital mental health solutions. Surprisingly, there is a lack of understanding of what co-design is in this field. In this paper, co-design is approached as a cocreation process involving persons with a lived experience of mental health problems, health professionals, and design experts who lead and facilitate the overall creative process.

Objective: This paper describes an initial co-design research protocol for the development of a mobile app that aims to improve access to mental health care. It highlights the characteristics of a co-design approach in e–mental health rooted in human-centered design and led by design experts alongside health experts. The paper focuses on the first steps (phase 1) of the co-design process of the ongoing Mentallys project.

Methods: This Mentallys project will be located in Montréal (Quebec, Canada). The method approach will be based on the "method stories," depicting the "making of" this project and reflecting adjustments needed to the protocol throughout the project in specific situations. Phase 1 of the process will focus on the desirability of the app. Targeted participants will include people with a lived experience of mental health problems, peer support workers and clinicians, and 3 facilitators (all design experts or researchers). Web-based sessions will be organized because of the COVID-19 pandemic, using Miro (RealtimeBoard Inc) and Zoom (Zoom Video Communications, Inc). Data collection will be based on the comments, thoughts, and new ideas of participants around the imaginary prototypes. Thematic analysis will be carried out after each session to inform a new version of the prototype.

Results: We conducted 2 stages in phase 1 of the process. During stage 1, we explored ideas through group co-design workshops (divergent thinking). Six co-design workshops were held: 2 with only clinicians (n=7), 2 with peer support workers (n=5) and people with a lived experience of mental health problems (n=2), and 2 with all of them (n=14). A total of 6 facilitators participated in conducting activities in subgroups. During stage 2, ideas were refined through 10 dyad co-design sessions (convergent thinking). Stage 2 involved 3 participants (n=3) and 1 facilitator. Thematic analysis was performed after stage 1, while analytic questioning is being performed for stage 2. Both stages allowed several iterations of the prototypes.

Conclusions: The design of the co-design process, the leadership of the design expertise throughout the process, and the different forms of co-design activities are key elements in this project. We highly recommend that health researchers partner with professional designers or design researchers who are familiar with co-design.

Introduction

Background

Digital mental health technologies promise greater access to services, improved quality of care, reduced cost, reduced distance and isolation, and enhanced data quality and accessibility [1-3]. However, there are few examples of successful implementation [2], and 2 systematic reviews reveal that few users are using mental health apps for a long period of time [4,5]. One of the reasons for low user engagement is the lack of user perspective in the design of eHealth solutions [6-8]. In the design of sustainable solutions in health care, we should embrace a human-centered design approach at every level of the design process [9].

Human-centered design refers to a wide range of creative approaches that do not belong to engineering design and that allow end users to significantly and positively impact the design of technologies [10,11]. Co-design is one of them [12]. In co-design, end users are not only considered; they also take part in the creation of solutions alongside researchers, designers, and stakeholders [13]. By engaging them in the creative process, co-design can better address end users' needs and potentially improve user engagement [7,14]. Co-design can also contribute significantly to social change and social innovation [15].

Yet co-design remains an umbrella term, as evidenced by the diversity of initiatives in the scientific literature [16]. There is even a broad range of relationships between actors, from denigration to learning as one [17]. First, it is important to distinguish co-design and participatory design from collaborative design. In collaborative design, participants are "experts operating in their own domain of expertise on a shared problem" [18]. Even if the team is composed of a broad range of expertise, the activities are typically carried out in design teams [19]. The distinction between participatory design and co-design is harder to find in the scientific community, with both terms often being used as synonyms. However, participatory design is a term used in various disciplines to refer to a wide range of participatory activities that are not necessarily related to human-centered design principles and in which there is an irregular and sporadic involvement of end users during the design process. Halskov and Hansen [20] identified fundamental aspects of participatory design: people who are affected by a decision should have an opportunity to influence it; people play critical roles in design by being experts in their own lives; the use situation is the fundamental starting point for the design process; participatory methods are means for users to gain influence in design processes; the goal of participation is to design alternatives to improve quality of life [20]. These aspects also apply to co-design.

In a previous study, we suggested differentiating the 2 terms and reserving the term co-design for a specific form of participatory design rooted in human-centered design [11]. We need to define exactly what it consists of from a research protocol perspective. We consider co-design as a co-creation process at the center of 3 dimensions: collaboration, design, and participation [16]. Potential users are an essential component of any co-design approach, and the quality of the participatory experience offered to them is crucial [14]. Few studies in mental health report using co-design in the development of their applications [11,21], and even fewer embrace its principles [7,22,23]. Most studies in digital mental health simply conduct participatory workshops at specific points during development [24]. Participants usually have the opportunity to provide feedback on the developed solutions, but real cooperation and co-creation remain a challenge [22,25]. Moreover, the role of the expert designers in the development process is often unclear, and in most studies, there is no explicit mention of the presence of designers in the "design" team [11].

However, we have identified a small number of e–mental health studies, still very rare, that assign design and designers an important role in their team, with promising and effective results [26-28]. Co-design requires design. Following the perspective of Manzini, "expert design" (design that comes from people trained in design) is as much a part of a co-design process as "diffuse design" (design that comes from people not trained in design) [29]. The role of the design experts is to design the co-design experience and, as co-design facilitators, to provide conditions conducive to expanding the capabilities of nondesign-trained participants to fully contribute to the co-creation of the solution. People not trained in design bring their natural creativity and experiential knowledge, while design experts bring original ideas and visions, practical design tools, and a structured human-centered design approach derived from their experience [29].

We need to understand what co-design is in e–mental health and how we can implement it. For instance, people not trained in design can be people with a lived experience of mental health problems, families, peer support workers, clinicians, and health professionals. All of them can have their say in the creation process of a digital mental health solution. Therefore, in this paper, we will use this working definition of co-design in e–mental health: a 2-sided human-centered design approach in which (1) end users are engaged from day 1 as partners in the design of the solution and (2) design experts, alongside health researchers, play a key role as facilitators of the overall process and activities.

Objective

This paper describes an initial co-design research protocol for the development of a mobile app that aims to improve access to mental health care. This protocol highlights the characteristics of a co-design approach in e–mental health rooted in human-centered design and led by design experts alongside health experts. This paper focuses on the first steps of the co-design process for the Mentallys project.

Methods

Study Context

Methodological Approach and Principles

We want to position this paper in line with the approach of "method stories" in co-design [30,31]. Method stories focus on what the designers actually did with methods in particular circumstances [31]. It focuses not only on the results of co-design sessions but also on the way a method has been used and adjusted in a specific situation [30]. Thus, we will first depict the "making of" the method to be used in this project (see section Study Preparation). In addition, our research protocol for co-design claims a certain flexibility that is directly related to design thinking as a cognitive style [32-35]. Designers alternate between phases of divergent thinking (generating multiple ideas in an exploratory way) and convergent thinking (choosing the best ideas and making choices) [36]. They investigate the problem space more for new possibilities and are more open to a variety of prototyping materials and tools [37]. This leads to adjusting the process several times and adapting it to new creative insights that arise, especially in the early stages. Therefore, the protocol we present in this paper shows the basic structure of our co-design process but, since it is led by design, assumes that adjustments along the way can take place to support flexibility in ideation.

Setting

Our study is based on the Mentallys project, located in Montréal (Quebec, Canada). The aim of this project is to improve access to mental health care on a large scale through a mobile app (Mentallys) intended to be distributed for free to the population of a given territory. It is developed from the outset using a co-design process that involves persons with a lived experience of mental health problems, peer support workers, health care professionals (eg, social workers, nurses, psychologists, psychiatrists, and health managers), researchers, design experts, and design students. The Mentallys app will gradually take shape through several steps of co-design, prototyping, and real-world testing in an iterative loop of continuous improvement.

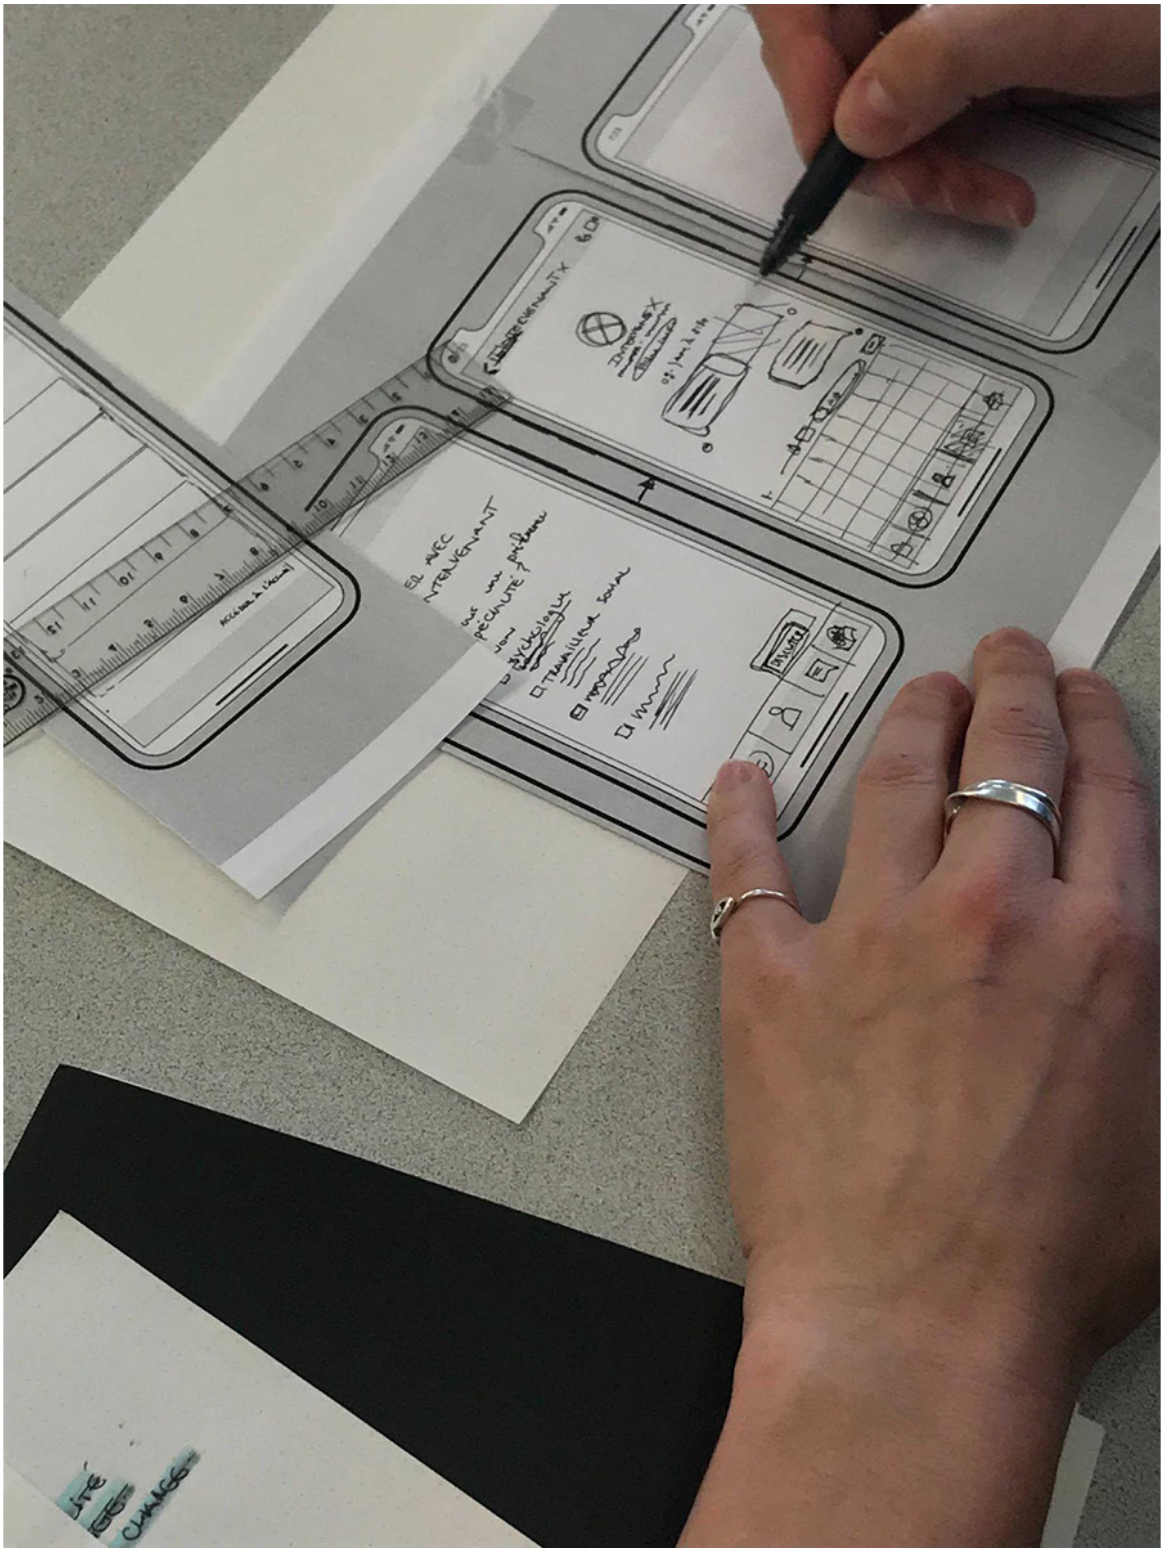
Study Preparation

The Mentallys project officially took shape in 2019, prior to the COVID-19 pandemic, and funding and ethics approval were obtained in 2020. Because of the lockdowns and remote work, we had to develop a system of 100% web-based workshops. To this end, we partnered with a design studio specialized in service design and co-design. Due to health restrictions, they had already started this type of practice. One designer (SR) from their team joined us and helped us prepare and initiate stage 1 of the co-design.

First, we set the objective: to explore ideas and desirable features for the Mentallys app. Second, we designed and implemented the co-design experience. The following design experts participated in this step: (1) one social design researcher from another university, (2) one service designer (SR) from the design studio we partnered with, and (3) 5 design researchers and students from our internal co-design team. Their contributions are detailed below.

1. The external social design researcher was Prof Philippe Gauthier, who is highly experienced in co-design practice for Montreal public libraries. We conducted an unstructured interview with him to gather his feedback and advice, particularly on how to initiate the co-design process in the most engaging way possible for participants. The interview highlighted the importance of what Dr Gauthier and his colleagues call "imaginary prototypes," "starting fictions," or "possible concepts," which they have shown to play a structuring role in fostering collective ideation, engagement in co-creation, and the organization of co-design workshops [38]. Gauthier and colleagues sometimes refer to these imaginary prototypes as "martyr concepts" to emphasize that they are typically inadequate concepts that participants are invited to criticize [39]. We prefer to think of them as provocative concepts or heuristic provocations, in the sense that they provoke reactions and promote the discovery of new ideas. This led us to build our co-design workshops with imaginary prototypes of the Mentallys app screens, presented as low-fidelity wireframes (having the appearance of being quickly drawn by hand). Workshop participants would then discuss and comment on these imaginary prototypes.
2. The service designer (SR) from the design studio we partnered with is one of the studio's founders and is the fifth author of this paper. When we contacted her in June 2020, she was already experienced in web-based co-design workshops, which was something relatively new in the early days of the COVID-19 pandemic. With her and thanks to her, we considered a structured co-design process able to take place entirely on the internet via a visual collaboration platform. As part of this process, each co-design workshop will have its own visual dashboard in which collaborative spaces will be organized, allowing each participant to comment on an imaginary prototype using web-based post-it notes (Figure 1). The process will rely on the role of several design experts acting as facilitators of co-creation with the participants. These designer-facilitators will act on several levels: stimulating individual and collective ideation, inspiring and moderating the conversation, supporting the visual formatting of ideas, and helping with the use of the software. Our partner service designer (SR) will participate as a cofacilitator in the first 2 co-design workshops to help us fine-tune the method, and our internal co-design team will then conduct the rest of the workshops alone.
3. Our internal co-design team was initially composed of 3 people (SV, SB, and SR) and then evolved to 5 people to meet the expected needs for facilitation (4 facilitators on

XSL•FO
RenderX



average per workshop): 1 design researcher (SV) experienced in interaction design with a background in clinical psychology and philosophy (principal investigator); 1 postdoctoral researcher (SB) with a background in industrial design and research expertise in co-design; 1 researcher in occupational therapy (MD) familiar with new technologies and participatory design; 1 doctoral student in service design with expertise in interaction design; and 1 master's student in design with expertise in graphic design and with personal experience of mental health problems. Highly experienced in design and familiar with the subject of mental health, our team will adopt the co-design method from the first workshops and then develop, adapt, and customize it through subsequent workshops. This will include the continuous design work of the co-design experience between workshops (Figure 2).

Figure 2. A preliminary sketch of an imaginary prototype in between 2 workshops.

Study Design

Our study is based on the core concepts of design thinking. Originally described as a cognitive style [33,34,40], design thinking is now widely recognized as an organizational resource for innovation [41]. It was popularized by American design agency IDEO, especially its former CEO Tim Brown, and defined as a methodology for innovation with a human-centered design ethos [42]. Our study design is inspired by design thinking as integrating thinking composed of 3 dimensions: desirability, feasibility, and viability [43]. Desirability relates to "what is desirable from a human point of view," that is, people's needs; feasibility relates to "what is technologically feasible," and viability relates to "what is economically viable" [44].

In an e–mental health context, we assume that (1) desirability relates to what is desirable and acceptable for people with a lived experience of mental health problems, families, peer

XSL•FO
RenderX

support workers, clinicians, and health professionals, which takes into account their needs, expectations, frustrations, and concerns; (2) feasibility relates to what is digitally and organizationally feasible within the health system; and (3) viability relates to what is economically acceptable for all stakeholders (business model) and environmentally sustainable.

Based on these 3 dimensions, we are planning 3 design phases: phase 1, focusing on exploring desirability, phase 2 exploring feasibility, and phase 3 exploring viability. In this study, we present only phase 1, desirability, since it will be entirely focused on co-design.

Recruitment

After obtaining an ethical certificate for the Mentallys project, we will launch a call for participation through our channels for the 3 types of participants: persons with a lived experience of mental health problems (n=10), peer support workers (n=10), and health professionals (n=10). Eligibility criteria in terms of age and language will be the same for all participants: Age (18-65 years) and being able to communicate in French. A diverse representation of ages, genders, and ethnicities will be sought.

For those with lived experience, additional eligibility criteria will be added: having experienced at least one anxiety or depressive episode in adulthood and within the past 2 years that has fully resolved or is currently at the mild to moderate level.

Ethics Approval

This project has been approved by the Institutional Human Research Ethics Committee of the Université du Québec à Montréal (No. 4425_e_2020).

Participants will sign an information and consent form, giving their free and informed consent to the research and publication, including their participation. They will be well informed that all personal information collected about them during the study will be coded to ensure confidentiality. This data will be kept under lock and key by the study leader for a period of 5 years after the end of the validity period of the research grant obtained, after which it will be destroyed. During this period, only members of the research team will have access to them. If the results of this research are presented or published, they will not be identified. All participants will receive monetary compensation (ranging from US $55 to US $75) for each time they participate.

Data Collection and Analysis

Textbox 1 shows the initial data collection and analysis strategy.

Participants will be divided into subgroups of 4 or 5 participants (1 subgroup per facilitator) and led by the facilitators to comment freely, generate thoughts, and share new ideas around the imaginary prototypes while being asked reflective questions by the facilitator. Imaginary prototypes will be delivered to participants in the form of wireframes. Well-known in the web industry, wireframes are visual schematics or screen blueprints that help represent and communicate the content and features of an app or website. Most often, wireframes are made with a low-fidelity design, that is, imitating a quick drawing by hand or a simple design with minimal graphic details (Figure 3).

Participants will directly comment on wireframes through the collaborative visual platform, mostly using web-based post-its (a different color for each participant; Figure 3). If necessary, a designer-facilitator with expertise in interaction design will be able to create a wireframe in real time based on the ideas shared by the participants using other annotation tools (Figure 4).

All the collected data will be analyzed through a thematic analysis. Thematic analysis is essentially a method for identifying and synthesizing the themes present in a corpus. In accordance with Paillé and Mucchielli [45], themes will be assigned to ideas, questions, and challenges that emerge from the workshop. They will then be grouped into categories. The process will be conducted jointly by the second author (SB) and a research assistant (a doctoral student) familiar with this process. The differences will be discussed between analysts in order to reach an interrater agreement.

Results

Overview

Our study received funding on June 2, 2020, from the Fonds de recherche du Québec (#2021-AUDC-283359). It received ethical approval on December 1, 2020, from the "Comité institutionnel d'éthique de la recherche avec des êtres humains" at the Université du Québec à Montréal (certificate number: 4425_e_2020). Recruitment began immediately, in December 2020, and lasted until the end of January 2021.

Here, we present the status of the co-design process for the Mentallys project. Consistent with the flexible methodology principle, the co-design activities have been conducted in 2 stages so far: one stage in group co-design workshops (February 2021 to June 2021) and one stage in dyad co-design sessions (April 2022 to July 2022). Only some of the participants from stage 1 participated in stage 2, since stage 2 required a very small number of people (Table 1).

Table 1. Sociodemographic data of the participants in both stages.

Variable	People with a lived experience of a mental health problem (n=2)	Peer support workers[a] (n=5)	Clinicians (n=7)
Gender, n (%)			
Women	2 (100)	4 (80)	4 (57)
Men	0 (0)	1 (20)	3 (43)
Age range (years), n (%)			
18-24	0 (0)	0 (0)	0 (0)
25-34	0 (0)	0 (0)	0 (0)
35-44	1 (50)	0 (0)	1 (14)
45-54	1 (50)	4 (80)	2 (28)
55-65	0 (0)	1 (20)	4 (58)
Geographical distribution, n (%)			
Montréal	1 (50)	2 (40)	4 (58)
Other regions in Quebec	1 (50)	3 (60)	1 (14)
France	0 (0)	0 (0)	2 (28)

[a]Peer support workers are also people with a lived experience of a mental health problem.

Stage 1: Exploring Ideas Through Group Co-Design Workshops

Stage 1 took place from February 2021 to June 21, 2021. We recruited 14 end users (see table 1). Participants have been divided into 2 groups. Group A included 7 clinicians (5 psychologists and 2 psychiatrists), and group B included 7 people with lived experience of a mental health disorder and peer support workers. We conducted 6 co-design workshops (rather than 5, as planned). Two workshops were held with group A, 2 workshops were held with group B, and 2 workshops were held simultaneously with both groups (Textbox 2).

Data analysis

- Thematic analysis [45]

This stage encouraged divergent thinking with the goal of generating ideas and identifying desirable features for the Mentallys app through imaginary prototypes and social conversations with different types of end users. Six facilitators were involved in the co-design activities, as it turned out that small groups were more appropriate for web-based workshops.

As planned, audio feedback from participants on the prototypes was collected and analyzed using thematic analysis. Moreover, visual data were eventually collected during a workshop with group B as we realized that we did not sufficiently understand their reality, which hindered the co-design process. Participants were invited to create care pathway maps (Figure 5), adjusting the initial protocol according to our flexible methodological approach. Those data have been analyzed using qualitative and quantitative content analysis [46].

Figure 5. Sample of a care pathway map.

Stage 2: Refining Ideas Through Dyad Co-Design Sessions

Stage 2 ran from April to July 2022. Two participants continued their involvement (1 peer support worker and 1 person with a lived experience of a mental disorder), and 1 health professional was recruited (a medical resident). The co-design activities did not take the usual form of group workshops but were rather conducted as dyad sessions, again adjusting for specific situations according to our flexible methodological approach (Textbox 3). This was necessary in order to explore sensitive and confidential topics while respecting the privacy of the participants and building trust. A total of 10 dyad co-design sessions were conducted for 3 months: 5 web-based sessions with the person with lived experience of a mental health problem, 2 web-based sessions with the peer support worker, and 3 in-person sessions with the medical resident.

Data analysis

- Analytic questioning [45]

XSL•FO
RenderX

This stage encouraged convergent thinking with the goal of validating ideas that can satisfy end users in the real world through real prototypes. One facilitator (SV) was involved in all sessions. For each session, the objective was to refine and validate a set of features through real, clickable, and testable prototypes shared on screen using a collaborative design and prototyping tool. End users could either verbally comment on the features or suggest new features in real time (Figure 6) or think about it at home and bring ideas to the next session (Figure 7).

Audio feedback from participants on the prototypes was collected and is being analyzed using an analytic questioning method inspired by Paillé and Mucchielli [45]. In this method, research questions are further developed and used as a framework to analyze the data. This is the most suitable approach when answers to a certain number of explicit questions are sought [45], which is the case for this convergent stage.

Discussion

Principal Findings

In this study, we described the characteristics of a co-design research protocol in e–mental health rooted in human-centered design and led by design experts alongside health experts. This protocol focused on initializing the co-design process and centered on exploring the desirability of a mobile app that aims to improve access to mental health care by collecting data on the needs, expectations, frustrations, and concerns of people with lived experience of mental health problems, peer support workers, and clinicians. We successfully implemented a 2-stage protocol, with group co-design workshops in the first stage and dyad co-design sessions in the second. For both stages, the role of expert design facilitators was crucial. In this discussion, we want to highlight a few challenges and lessons learned.

Initiating the Co-Design

Our preliminary design work on the co-design experience was critical to the implementation and success of the process, especially partnering with a design studio specialized in service design to help us structure the approach and become familiar with the best-suited tools. This allowed us to prepare and conduct the first workshops according to the best practices in human-centered design and, afterward, to continue doing so independently. We now have the full capacity to devise and manage further co-design stages thanks to the skills our team has acquired. These skills are necessary to create a positive group dynamic that encourages each participant's creativity. In co-design, co-designers participate with different perspectives, which can lead to frustration and conflicts among participants who do not always understand each other [47-49]. By structuring activities using a human-centered design perspective, optimizing collaboration by orienting the process toward positive and constructive interactions among participants, and leading participants into a creative design thinking mode, facilitators can create this positive dynamic and foster creativity [14]. Expert design skills are also needed to ground the co-design process in concrete prototypes from the start, which become mediators of conversation and ideation. Prototypes are a useful co-design tool to engage participants in the design conversation. Prototypes allow opposite opinions to exist and are socio-material, welcoming a neutral space and facilitating the negotiation of issues [50]. In this project, where the subjects discussed were often very sensitive, prototypes played a significant mediator role to ensure constructive conversation.

Adapting the Process Along the Way

Even when highly organized and structured, co-design is a creative process that inevitably involves unforeseen ideas and insights. Unique to each design process, this characteristic is known as the "creative leap" [51]. To facilitate a co-design process, one must be attentive to these creative leaps, be able to welcome them, and integrate them into the process along the way. This involves moving away from the rigidity of traditional methodological protocols in research in order to be able to adapt the protocol as it unfolds. The difficulty lies in maintaining a balance between following the planned protocol and making the necessary adjustments resulting from creative leaps. In this study, creative leaps led us to focus first on 1 major phase (desirability) instead of tackling all 3 phases from the outset (desirability, feasibility, and viability), which were itself divided into 2 stages (group co-design and dyad co-design). Therefore, we could only study the desirability dimension, as it turned out to require much more time. Indeed, rather than the 3 months planned, this study lasted a total of 8 months (5 months for stage 1 and 3 months for stage 2). Other similar studies also mentioned that some stages of the co-design process took longer than expected [52].

Doing Co-Design in Dyads

Our study suggests that co-design can be dyadic. During stage 2, we organized the co-design sessions in dyads, that is, one-to-one meetings, instead of the standard group workshops. Even if it was not a group activity, it was true collective creativity. Since co-design is a collaboration between diffuse design and expert design [29], it can start with 2 people, provided one of them is a design expert. As a specific point of co-creation, co-design is collective creativity that can be shared "by two or more people" [53]. In our protocol, each dyad session was a conversation between a person not trained in design (the end user) and a member of our team with design expertise (the principal investigator). Both were equal speakers, each able to bring his or her points to the table. The 3 main aspects of co-design, that is, collaboration, design, and participation [16], were present but manifested dyadically. Through the accumulation of dyadic sessions, a mass effect in data collection occurs that is comparable to that of a larger group. In-depth analysis of the results will provide a better understanding of the contribution of dyadic sessions to the design process.

Leading Co-Design Thanks to Design Expertise

Our co-design research protocol focused on a close and effective collaboration between experts in design and end users throughout the process. While other e–mental health research projects have shown less involvement on the part of the designers in their process, we aimed at creating a continuous collaboration environment between designers and users. In fact, very few studies mention the presence of designers on their teams and mostly focus on involving end users [11]. The challenge in these types of projects is how to properly incorporate users' needs into the project, redefine them properly, and bridge them while the project evolves. Design expertise leadership is a key component in achieving that goal since design practice and research focus on users' unmet needs through well-understood and applied inclusive design approaches coming from design expertise [54]. Designers are sensitive to how care is received through user-centered practices [55] and can use a variety of flexible methods and tools to enhance communication about the project.

Limitations and Future Work

While co-design is central to our approach, we recognize that other elements must be taken into account to ensure the development of a mental health app that meets the needs of users and is likely to be adopted. Close collaboration with the software development team is important, as is usability testing of the app [56] or user experience design [57]. One should also

XSL•FO
RenderX

assess the viability of the solution, develop a business model for the app, and plan the implementation of the technology [42,58]. This points to the importance of transdisciplinary work in the development of e–mental health solutions from a human-centered design perspective [59]. This is why the Mentallys project relies on other research and development activities complementary to co-design: a full design team, including branding design experts and user experience and user interface designers; a business accelerator program and business model definition coaching; a partner technology company that cosupervises the software development; and several partner health institutions to conduct real-world testing.

Conclusions

This paper presented a research protocol rooted in human-centered design related to the Mentallys project. More precisely, we sought to present how a co-design approach can be used to initiate the design and development of a mental health mobile app. The preliminary design of the co-design process, the leadership of the design expertise throughout the process, and the different forms of co-design activities are key elements in this project. We expect that this process can lead to the development of an app that is more engaging and better meets the important needs of people seeking access to mental health services. Overall, this research protocol may inspire other research teams that want to integrate co-design as a more user-centered approach to the development of e–mental health solutions. For this purpose, we highly recommend that health researchers partner with professional designers or design researchers who are familiar with co-design.

Acknowledgments

We would like to thank the following organizations: Fonds de recherche du Québec, Conseil de recherche en sciences humaines du Canada, Centre de recherche de l'Institut universitaire en santé mentale de Montréal, Fondation de l'Institut universitaire en santé mentale, and Université du Québec à Montréal. We would also like to extend our gratitude to our design experts, researchers, colleagues, and collaborators, Ariane Lecavalier, Laurence Paquette, Laury Martel, Philippe Gauthier, and Gabrielle Denault.

Data Availability

The data sets generated during this study are not publicly available since the research is still ongoing, but they are available from the corresponding author on reasonable request.

Abstract

Background: Early identification of mental disorder symptoms is crucial for timely treatment and reduction of recurring symptoms and disabilities. A tool to help individuals recognize warning signs is important. We posit that such a tool would have to rely on longitudinal analysis of patterns and trends in the individual's daily activities and mood, which can now be captured through data from wearable activity trackers, speech recordings from mobile devices, and the individual's own description of their mental state. In this paper, we describe such a tool developed by our team to detect early signs of depression, anxiety, and stress.

Objective: This study aims to examine three questions about the effectiveness of machine learning models constructed based on multimodal data from wearables, speech, and self-reports: (1) How does speech about issues of personal context differ from speech while reading a neutral text, what type of speech data are more helpful in detecting mental health indicators, and how is the quality of the machine learning models influenced by multilanguage data? (2) Does accuracy improve with longitudinal data collection and how, and what are the most important features? and (3) How do personalized machine learning models compare against population-level models?

Methods: We collect longitudinal data to aid machine learning in accurately identifying patterns of mental disorder symptoms. We developed an app that collects voice, physiological, and activity data. Physiological and activity data are provided by a variety of off-the-shelf fitness trackers, that record steps, active minutes, duration of sleeping stages (rapid eye movement, deep, and light sleep), calories consumed, distance walked, heart rate, and speed. We also collect voice recordings of users reading specific texts and answering open-ended questions chosen randomly from a set of questions without repetition. Finally, the app collects users' answers to the Depression, Anxiety, and Stress Scale. The collected data from wearable devices and voice recordings will be used to train machine learning models to predict the levels of anxiety, stress, and depression in participants.

Results: The study is ongoing, and data collection will be completed by November 2023. We expect to recruit at least 50 participants attending 2 major universities (in Canada and Mexico) fluent in English or Spanish. The study will include participants aged between 18 and 35 years, with no communication disorders, acute neurological diseases, or history of brain damage. Data collection complied with ethical and privacy requirements.

Conclusions: The study aims to advance personalized machine learning for mental health; generate a data set to predict Depression, Anxiety, and Stress Scale results; and deploy a framework for early detection of depression, anxiety, and stress. Our long-term goal is to develop a noninvasive and objective method for collecting mental health data and promptly detecting mental disorder symptoms.

Introduction

Overview

The Quantified Self movement proposes that self-tracking, measurement, and quantification of one's daily life using technology can lead to personal insights that can help individuals improve their behaviors and health. Recent advances in sensors and their embedding in many wearables and mobile devices have made this idea extremely easy to adopt [1]. Currently, affordable consumer devices contain sensors that continuously and unobtrusively track one's activity, sleep, heart rate, and stress levels. Furthermore, many mobile apps enable individuals to record multimedia throughout their day, such as media, images, audio, and video. Hundreds of MBs of data can be collected from an individual every day [2], thus creating a data stream amenable to machine learning algorithms that can capture patterns related to different behavioral, cognitive, and mental states. In this project, we investigate the usefulness of activity trackers and voice recordings as data sources through which models of mental health indicators can be extracted. More specifically, we are interested in examining how personalized models, constructed from long-term individual data streams, compared with population-level models, learned from population-level data in terms of their ability to predict mental health conditions accurately.

We developed a special-purpose app to collect voice, physiological, and activity data for this study. Physiological and activity data are provided by various off-the-shelf fitness trackers, which record steps, active minutes, duration of sleeping stages (rapid eye movement, deep, and light sleep), calories consumed, distance walked, heart rate, and speed. In addition, our study app collects 2 types of voice recordings: the former is a recording of the user reading a specific text, and the latter is a recording of the user responding to an open prompting question, chosen randomly from a set of open questions, without repetition. Finally, the app collects the users' answers to a standard psychological instrument, the Depression, Anxiety, and Stress Scale (DASS21) [3], which quantifies the severity of these 3 mental disorders based on the emotional states during the past week, and the results allow us to set the dependent variable of the machine learning algorithm for its classification.

The data collected through our study have already been used for detecting depression, anxiety, and stress [4]. Smartwatch activity data [5-8] and voice [9-11] have been demonstrated to predict depression, anxiety, and stress with high levels of accuracy. The novelty of our study lies in three pillars:

1. First, our study is designed to collect longitudinal data from each participant. In contrast, previous studies about detecting depression from voice relied on data sets consisting of a single data point per participant for a one-size-fits-all model. In addition, each data point includes 2 different voice samples, 1 text reading and 1 personal response to a prompt. This design enables us to analyze the complete data set to train the classifiers of the DASS21 scores and construct personalized models from each participant's data.
2. Second, besides voice data, our study includes physiological and activity data collected by any number of off-the-shelf fitness trackers, relying on the core subset of common data collected by most such devices today. So far, no study has fused these 2 types of data streams.
3. Third, we are recruiting both English-speaking and Spanish-speaking participants because we aim to develop a language-agnostic, data processing and analysis pipeline.

This paper aims to describe the design of the experiment to capture data from participants and define the study's objectives for analysis to advance research in mental health disorder detection and personalized machine learning in computing science.

Background

Personalized machine learning involves using algorithms trained on user data to automatically learn models and use this knowledge to make predictions from new data. Unlike traditional machine learning methods, the results of these models are tailored to an individual and not to a population [12].

Applications of personalized machine learning include heart rate profiling [13], personalized sleep monitoring [14], personalized chronotherapy [13], and studies that predict risk factors for a particular illness [15,16]. A similarity among the previous applications is that the studies have been longitudinal. Longitudinal studies are particularly useful in personalized machine learning, as they permit researchers to track individual data over time and gather data from various factors affecting the changes observed in the results. In these studies, multidimensional data are collected from individuals, and a model is created for each individual.

Typically, models are constructed for predicting one among a set of alternative future states of interest using a classification technique. For example, Feng et al [17] used binary classification to predict whether a specific drug combination would result in a therapeutic response. Webb et al [18] analyzed data from individuals with major depressive disorders and built a model to predict their likelihood of response to antidepressants. Regression models may be developed to forecast a variable's specific interest value. For example, Bertsimas et al [19] used a k-nearest neighbors regression model to predict blood sugar levels based on individual data from patients with type 2 diabetes. By leveraging the user's features, the learning

XSL•FO
RenderX

algorithms capture specific behaviors of the individual, and their performance is optimized for that particular person.

Early indicators of mental health disorders could motivate early treatment, potentially preventing more severe symptoms that could affect the quality of life of an individual. Preventing these diseases could reduce the symptoms' recurrence and associated disabilities [20]. These indicators could motivate people to seek the advice of a health professional and receive a prompt and correct diagnosis that could prevent severe depression symptoms in the future. Symptoms are usually diagnosed based on the patient's description and mental state. Hence, creating a tool to detect early signs of mental diseases is essential to take the necessary measures to prevent major onsets of these diseases.

Therefore, one must address two key questions: (1) *What types of data convey information relevant to extracting indicators of mental-health conditions?* and (2) *How can one collect ground truth on whether the individual is experiencing mental-health challenges?* There is substantial evidence to support the idea that the onset of mental health disorders often coincides with changes in the individual's daily activity patterns [21]. This information can be realistically captured by the data collected through activity trackers. Although significant studies have been conducted about extracting mental health indicators from activity trackers [4,8], our study aims to use this information without considering the brand, as we strive to compare traditional machine learning methods with personalized modeling. This approach may allow more widespread and accessible data collection, providing more comprehensive insights into mental health. Furthermore, recent studies have established that sound features and content from speech capture relevant information that can be exploited to recognize mental health conditions. This is why our study envisions a regular collection of 2 types of voice recordings: one recording of the users reading a standard text and a second recording of the user responding to a prompting question. To collect the ground truth about our participants' mental health status, we used the DASS21 instrument, validated for depression, anxiety, and stress [22]. Finally, recognizing that activity data and voice features may exhibit different patterns across individuals, our study is designed to construct personalized models in addition to cohort-based models. We anticipate that these personalized models could improve the accuracy of detecting mental health disorders.

Related Studies

Machine learning algorithms have been increasingly used for detecting depression, anxiety, and stress in recent years. Several studies have explored machine learning techniques, including deep learning and parametric and nonparametric techniques, to identify patterns in data from physiological measures, self-reported symptoms, and social media posts [23-25]. These studies have shown promising results in accurately predicting mental health outcomes, indicating the potential for machine learning to improve the detection and management of depression, anxiety, and stress.

Personalized machine learning has been increasingly used in health care to provide tailored interventions to individuals based on their unique characteristics and health status. Several studies have demonstrated the potential of personalized machine learning in improving health outcomes, such as predicting patient outcomes, personalized treatment recommendations, and identifying at-risk populations [26,27]. In mental health care, customized machine learning has been used to identify individuals at high risk for suicide and to provide personalized interventions based on individual characteristics and needs [28].

Wearable devices, such as smartwatches and fitness trackers, have emerged as a promising tool for detecting mental health conditions. Several studies have investigated wearables data in combination with machine learning algorithms to detect various mental health conditions, such as depression, anxiety, and bipolar disorder, by analyzing physiological data, such as heart rate and sleep patterns [29,30]. These studies have shown that wearables can provide a discreet and objective way to monitor mental health, allowing for early detection and personalized treatment. However, most studies are performed in clinical setups or with specific features found only with unique equipment. We address this issue by acquiring the core subset of common features among 3 major brands (Fitbit, Samsung, and Garmin) of fitness trackers for framework flexibility.

Using voice and machine learning to detect mental health issues is an active research area. Dematties et al [31] used speech features extracted from recorded interviews to distinguish between individuals with and those without major depressive disorder. Chen et al [32] analyzed the speech of patients with schizophrenia and found that certain speech features indicated the severity of their symptoms. Wang et al [33] used a machine learning algorithm to predict depression and anxiety from speech data obtained during therapy sessions. These studies suggest that voice and machine learning can potentially be valuable tools for the early detection and management of mental health issues. However, the analyzed data consist of a single data point per participant and language. Thus, the resulting data set could provide great insight into multilingual machine learning models and a deep analysis of mood over time.

Hypothesis and Research Questions

Our study is designed to investigate the following hypothesis: basic activity tracking, in combination with regularly and consistently captured speech data, can provide the basis for extracting accurate indicators of several prevalent mental health conditions, in this case, depression, anxiety, and stress.

Our focus is to comprehend the relative usefulness of the 2 data streams. We aim to investigate the significance of speech data when the user is reading a neutral text versus reflecting about their daily life experiences. In addition, we aim to compare the accuracy of personalized machine learning models with population-level models and evaluate the robustness of these models across various languages.

Our study will answer the following research questions:

1. How does voice modality affect predictive machine learning models, specifically comparing the impact of voice from a neutral text reading against that of voice from open questions about life experiences?
2. What critical predictive features exhibit strong association with DASS21 responses from participants?

XSL•FO
RenderX

3. To what extent does personalized machine learning demonstrate superior predictive power in mental health compared with traditional, one-size-fits-all models in the context of DASS21 responses?

Methods

Study Overview and Design

The study analyzes and applies machine learning models to behavioral data extracted from sensors embedded in wearable devices and voice to predict DASS21 results in participants. The data consist of two principal components: (1) sensors embedded in standard smartwatch devices (brands: Samsung, Fitbit, and Garmin) and (2) voice recordings.

Modern sensing technologies in wearable devices continuously measure the body's autonomic response. These responses include continuous heart rate, daily steps, speed, burned calories, and sleeping patterns (minutes in rapid eye movement sleep, deep sleep, and light sleep) and are monitored daily for the duration of the study. The voice data are collected using 2 methods: the first one is a text reading, which stays consistent with all participants, and the second one is a free-form speech (1 open question is asked). For 2 months, every third day, the participant submits voice samples and DASS21 answers.

The data will show variational patterns that could explain the DASS21 results, and machine learning algorithms can capture these consistent patterns that allow us to predict depression, anxiety, and stress.

Data Collection

Overview

Data collection for this study is ongoing. We expect to collect multidimensional data from at least 50 participants attending 2 major universities—the University of Alberta and Tecnológico de Monterrey, the former from the campus in Edmonton, Alberta, Canada, and the latter from 2 campuses in Mexico, Monterrey and State of Mexico campuses.

The selection criteria considered students aged between 18 and 35 years, with no chronic physical illnesses, high levels of chronic pain, or motor disability and who confirmed not being pregnant. Given that informed consent was required, the study excluded individuals with communication disorders, acute neurological diseases, or a history of brain damage.

Each participant contributes data over 2 months. Participants are assigned an alias as an identification number and are asked to download a mobile app on their mobile phones. The app was developed by the researchers in this study and included the mechanisms to collect the voice recordings and DASS21 questionnaires. Once collected, all data are stored in a repository inside the servers of the University of Alberta associated with this ID. Activity data are collected using Fitbit, Samsung, and Garmin smartwatches, and the app was made available only for Android mobile devices to collect voice and DASS21 answers and upload the smartwatch data.

After this initial assessment, the app regularly (every 3 d) prompts the participants to perform the following tasks. We have chosen 3 days as the app use period to collect samples on different days of the week; this could aid in reflecting the effect of day-to-day stress and workload.

Guided Reading

The participants are prompted to read out a paragraph. This task aims to capture as much phonetic variety as possible. For this task, we considered using established English and Spanish text snippets for speech analysis, such as the Calling Stella passage [34].

Free-Form Speech

In this task, the participants are asked 2 questions, randomly selected from a list of questions, to answer freely. This includes describing their hobby, city, favorite person, or memorable event. In addition to intonation, these data will enable us to analyze speech-to-pause ratio and durational features, which may correlate with their psychological condition.

Smartwatch Data

The participant downloads the data from the smartwatch (we provide the instructions depending on the model and brand) and then uploads the data to the app. The number of attributes and amount of data varies depending on the model and brand of the participant's smartwatch. However, we have identified and selected common base attributes of each smartwatch model.

Finally, once the abovementioned recordings are complete, participants are prompted to complete a mental health questionnaire (DASS21). The questionnaire gives us a valid indicator of their anxiety, depression, and stress levels to label the audio recordings.

The app lists the mental health resources available to the students of the University of Alberta and encourages them to seek help if they feel stressed, anxious, or depressed. For participants of Tecnológico de Monterrey, it provides a list of mental health resources available at their campus in Mexico.

Ethical Considerations

The protocol was reviewed and approved by the Research Ethics Office of the University of Alberta (Pro00116909). All participants provided written informed consent after being briefed about the study's goals. The data are collected using secure transfer mechanisms to comply with ethical and personal data privacy requirements.

Data Analysis

Overview

One of the first steps in data analysis is data exploration. Exploratory analysis is a crucial step in data science, as it helps uncover insights and patterns in the data that can inform subsequent analyses and models. It involves summarizing and visualizing the data, identifying relationships between variables, detecting outliers and missing values, and checking for data quality issues. It also helps to identify potential biases or confounding factors that may influence the results of subsequent analyses.

XSL•FO
RenderX

The purpose of our investigation is to address the abovementioned research inquiries. This section presents our analysis and approaches to examine each question.

Question 1

What is the effect of voice modality on predictive machine learning models, specifically comparing the impact of voice from a neutral text reading against that of voice while answering open questions about life experiences?

This question aims to perform a comparative analysis between 2 different voice data sets. These data sets include 2 recordings taken every third day and the answers to the DASS21 questionnaire. The DASS21 questionnaire result is the independent variable we want to predict. DASS21 adopts a dimensional perspective of a psychological disorder rather than a definite one, and it is designed to measure the severity of depression, anxiety, and stress. The scale consists of a numerical value ranging from 0 to 63. The higher the value, the higher the severity of depression, anxiety, and stress.

For this objective, we aim to train 2 machine learning models: one containing the data of a neutral text reading and the other with the voice while answering open questions. We must extract numerical features that quantitatively represent the audio to train the models. These features include but are not limited to language-agnostic linguistic features (eg, number of words, words/min, lemma/token ratio, and verbs/utterance) and perceptual features such as loudness, brightness, pitch, timbre, and rhythm. We will use ensemble methods, such as random forest and support vector machine for the machine learning algorithms that have been demonstrated to have good performance to detect mood disorders using these features [10], and deep learning methods, such as convolutional neural networks and recurrent neural networks [10,35]. We will test both approaches of machine learning tasks, binary classification and regression. For the classification task, the cutoff points are defined based on the DASS21 scale. All scores above mild scores are considered to be indicative of depression, anxiety, or stress for the classification task.

To validate our results, we will use leave-one-out, stratified cross-validation. This method assures us that by tuning the hyperparameters of our model, these will help to avoid overfitting the models. Several metrics can be used to compare the results, and for evaluating the task as a regressor, we use root mean squared error and R^2. For the classification task, we compare area under the curve and F_1-scores.

Question 2

Overview

What are the key predictive features that exhibit strong association with DASS21 responses from participants?

We aim to perform a feature selection process to identify the variables with the strongest association with the result of DASS21. This step involves selecting a subset of the most relevant features from a large set of potential predictors. It aims to simplify the model and reduce the risk of overfitting. Our data set will contain 3 different variable types: audio, text, and numeric variables. We will use other methods for each variable type to extract features and select the most significant ones.

Audio Features

In the case of audio features, this step will involve feature extraction techniques such as mel-frequency cepstral coefficients and discrete wavelet transform to extract the applicable features from the recordings. These techniques will help us transform the audio signal into a more meaningful representation that can be used as input for our machine learning model.

Text Features

In addition to extracting the audio signal, we aim to extract the transcript from the audio recordings and identify relevant semantic text features using word embeddings. The idea behind using word embeddings is to group similar words in a high-dimensional space, where words with similar meanings and emotional tones are close to each other. Our approach is to input the word vectors as sentences to the machine learning model to classify the emotional tone of the individuals' responses to the open questions.

Numeric Features

We will use wrapper methods to select the most relevant features in our numeric attributes subset, such as recursive feature elimination. This method will evaluate the performance of our machine learning model with different subsets of features by considering the interaction between the distinct variables and their relationship with the target variable.

Finally, after extracting meaningful representations of the audio and text columns in our data set and compressing the numeric features, we will use dimensional reduction techniques such as principal component analysis to reduce the number of features further, while preserving the most critical information, allowing us to visualize the data in 2 or 3 dimensions.

Question 3

To what extent does personalized machine learning demonstrate superior predictive efficacy in mental health compared with traditional, one-size-fits-all models in the context of DASS21 responses?

Personalized machine learning aims to fill the gap of one-size-fits-all models when assessing mental health disorders in people. The collected features could have significant variability among individuals with equal DASS21 assessment. Hence, we aim to supply individual machine learning models trained with personal data to provide personal activity and a baseline to assess whether personalized models outperform cohort-trained models.

We should consider careful preprocessing to clean the data to train a machine learning model. First, we need to consider the presence of outliers. Outliers could bias or influence the decision of our trained algorithms. Hence, applying Mahalanobis distance to our numerical attributes obtained from the activity tracker can aid us in identifying abnormal points of data and treating them. We could cap the score to treat the outliers at a particular value above the 90th or below the 10th percentile. The imbalanced data set is another issue while applying machine

XSL•FO
RenderX

learning for classification tasks. If the number of instances where one class label is significantly lower than the others, it could bias the model toward the majority class. Therefore, we should consider oversampling or undersampling techniques to remove this bias. Finally, we will consider removing background noise for voice analysis.

For personalized modeling, we should consider using multitasking learning techniques. These techniques leverage data from across the population with deep neural networks and hierarchical Bayesian models [36]. We could also consider implementing ensemble learning, such as random forest and gradient boosting, by training the models with the different data types for each person and using a voting regressor performance to select the most accurate model. The more data we obtain through time from the individual, the more the model will capture the patterns of the individual by retraining the models to adjust to the new data.

After training the models with the leave-one-out technique, we will compare the performance of the regression or classification models to draw our conclusions.

Results

The data collection process started in June 2022. So far, 67% (29/43) of the participants have completed the study protocol, and 33% (14/43) are in the process. The study results will be available at the end of 2023 and published in scientific journals.

Discussion

Expected Findings

This study aims to describe the data collection experiment to capture the mood and activity of students in Canada and Mexico. This data set will consist of longitudinal data from each participant, allowing us to observe our participants' behavior extensively. Each data set entry is labeled with the DASS21 questionnaire, enabling us to apply machine learning algorithms for prediction or classification. The data set includes physiological and activity data from some popular fitness trackers. This allows us to identify a subset of the common underlying data from these trackers. In addition, as we recruit English-speaking and Spanish-speaking participants, the data set will include 2 significant languages, allowing for rich analysis and comparison.

Overall, the high-level objective of this study aims to advance state-of-the-art personalized machine learning for mental health; generate a valuable data set that could be used to predict DASS21 results by applying algorithms of machine learning; and finally, deploy a framework that detects the onset of depression, anxiety, and stress to alert the user and prompt them to consult a professional. Moreover, we aim to compare traditional, cohort, machine learning methods against personalized methods and propose a methodology to detect multiple mood disorders not limited to depression, stress, and anxiety. Finally, we will compare the relative value of 2 speech data sources, free speech and simple text reading, for mood analysis.

Limitations

When interpreting the results of the study, various limitations need to be taken into account. Our experiments are exclusively conducted on students within graduate and undergraduate environments. This decision was mainly based on the available resources and will narrow the conclusions of our study for this specific group.

Another limitation is the challenge regarding the participant's adherence to the protocol and consistency of the data. The periodicity of the data might not be consistent for all the participants; thus, we require them to deliver 20 full days of complete data. However, we are planning to consider these gaps as part of the behavioral information that could lead us to the objective of personalized machine learning for DASS21 predictions.

Our methodology relies on the assumption that participants will provide true signals about their daily behavior and mental status. In principle, it is possible that they will remove their wearable devices during the study or that they may not respond truthfully to the DASS21 questionnaire. This is a potential flaw with all studies collecting and analyzing self-reported data, and it is almost impossible to eliminate. Nevertheless, we believe that our study protocol is designed in a manner that diminishes the likelihood of this problem. First, participation in our study is voluntary, and the monetary incentive was calculated to recognize the time that participants spend in following our protocol. Second, all data outside the consent form are anonymous and associated only with a nickname, which should alleviate any concerns that participants may have about being associated with the "stigma" of mental health challenges that might lead them to not answer truthfully. Furthermore, it is important to note that the DASS21 questionnaire has been extensively used and validated for Spanish-speaking and English-speaking users and adopted for depression, anxiety, and stress diagnosis.

Conclusions

In this paper, we have described a protocol for collecting physiological data using wearable and mobile devices, which will be used in a subsequent study to predict depression using machine learning algorithms. The project is designed to collect physiological signals, such as heart rate variability, sleeping patterns, voice, and activity levels, which are reliable indicators of depression, anxiety, or stress. The noninvasive protocol consists of simple steps for the participants to follow. In this paper, we have outlined the procedures to ensure informed consent and data collection in a standardized and secure manner.

With the increasing prevalence of anxiety and depression disorders, this study has significant implications for developing a noninvasive and objective method for collecting and joining DASS21 results and data from wearables and mobile devices. The availability of the data set for the scientific community could motivate new and better ways for prompt detection of mood disorders. The proposed methods emphasize the importance of proper participant recruitment and data storage, collection, and processing. However, we recognize the limitations of our study, including the small sample size and

XSL•FO
RenderX

need for further validations using more extensive and diverse populations, adherence of the participants to the study, and fidelity of the provided data. Further studies will be conducted to validate these findings and explore this technology's potential for predicting other mental health disorders.

Acknowledgments

This study was supported by the Natural Sciences and Engineering Research Council of Canada–Collaborative Research and Training Experience Program in Dependable Internet of Things Applications.

Data Availability

The data are not publicly available because the collection is ongoing and it has not been appropriately formatted. However, the data collection tools are available upon request from the corresponding author.

Protocol

Implications of Agile Values in Software Engineering for Agility in Breast Cancer Treatment: Protocol for a Comparative Study

Abstract

Background: Breast cancer treatment has been described as a dynamic and patient-centered approach that emphasizes adaptability and flexibility throughout the treatment process. Breast cancer is complex, with varying subtypes and stages, making it important to tailor treatment plans to each patient's unique circumstances. Breast cancer treatment delivery relies on a multidisciplinary team of health care professionals who collaborate to provide personalized care and quick adaptation to changing conditions to optimize outcomes while minimizing side effects and maintaining the patient's quality of life. However, agility in breast cancer treatment has not been defined according to common agile values and described in language comprehensible to breast cancer professionals. In the rapidly evolving landscape of breast cancer treatment, the incorporation of agile values from software engineering promises to enhance patient care.

Objective: Our objective is to propose agile values for breast cancer treatment adopted and adapted from software engineering. We also aim to validate how these values conform to the concept of agility in the breast cancer context through referencing past work.

Methods: We applied a structured research methodology to identify and validate 4 agile values for breast cancer treatment. In the elicitation phase, through 2 interviews, we identified 4 agile values and described them in language that resonates with breast cancer treatment professionals. The values were then validated by a domain expert and discussed in the context of supporting work from the literature. Final validation entailed a domain expert conducting a walkthrough of the 4 identified agile values to adjust them as per the reported literature.

Results: Four agile values were identified for breast cancer treatment, and among them, we validated 3 that conformed to the concept of agility. The fourth value, documentation and the quality of documentation, is vital for breast cancer treatment planning and management. This does not conform to agility. However, its nonagility is vital for the agility of the other values. None of the identified agile values were validated as partially conforming to the concept of agility.

Conclusions: This work makes a novel contribution to knowledge in identifying the first set of agile values in breast cancer treatment through multidisciplinary research. Three of these values were evaluated as conforming to the concept of agility, and although 1 value did not meet the concept of agility, it enhanced the agility of the other values. It is anticipated that these 4 agile values can drive oncology practice, strategies, policies, protocols, and procedures to enhance delivery of care. Moreover, the identified values contribute to identifying quality assurance and control practices to assess the concept of agility in oncology practice and breast cancer treatment and adjust corresponding actions. We conclude that breast cancer treatment agile values are not limited to 4.

Introduction

Background

Breast cancer is the most frequent cancer diagnosis and the main cause of cancer mortality in women globally [1]. Through the 2 past decades, traditional breast cancer treatment (BCT) has been the standard of care and has led to significant improvements in patient outcomes [2]. However, the lack of consideration of the unique characteristics of each patient's cancer can lead to ineffective and nontargeted therapy with adverse and toxic side effects, reduced quality of life, and, in some cases, a resulting delay in detecting progression [2-4]. Thus, today, BCT is shifting toward more personalized approaches that enhance the patient experience while considering their diverse characteristics and evolving conditions [3,5-7].

Different treatment strategies may be required for each subtype of breast cancer, and genetic variation within tumors may complicate aspects of treatment. Developing tailored medicines that target certain genetic alterations or molecular subtypes is one of the main challenges in BCT [8]. Treatment planning has become more difficult as a result of the increased emphasis on personalized medicine, which calls for adjusting plans depending on a patient's genetic profile [8]. Optimizing therapeutic results and reducing the risk of treatment resistance require customizing therapies to fit the genetic features of each patient's tumor [9]. A patient's values and preferences must be taken into account in addition to clinical factors while deciding on the best course of action [10].

Further complication arises from managing treatment side effects and maintaining a patient's quality of life, particularly with regard to the level of depression both before and after treatment, as highlighted in the work of Salibasic and Delibegovic [11] and Breidenbach et al [12]. It can be difficult to strike a balance between a treatment's effectiveness and possible effects on the patient's well-being. Additionally, there are obstacles associated with the timing and order of various treatment modalities, including radiation therapy, hormone therapy, immunotherapy, chemotherapy, and surgery. A multidisciplinary approach to care is necessary to determine the most effective sequence and combination of therapies, which necessitates a comprehensive evaluation of the tumor characteristics, patient's overall health, and adverse side effects [13].

In the literature, all these reported treatment challenges, efforts, and strategies lack consideration and identification of their respective agility values. According to the *Oxford Dictionary*, the word *agility* means "the ability to move quickly and easily" [14]. *Value* means "the quality of being useful or important" or "beliefs about what is right and wrong and what is important in life" as a meaning related to *principle* or *standard* [15]. Thus, to improve BCT approaches and strategies and to overcome these challenges, it should be assessed whether they meet agility values and to what extent. This calls for identifying standards for the ability to move quickly, easily, and effectively in this complex disease, that is, defining *agility values* for BCT. Although the literature emphasizes addressing some agility values, such as patient-centric processes, personalization, and a multidisciplinary approach to decision-making and treatment plan design, there is still no validated definition of agility values for BCT. The complexity of BCT, shaped by factors ranging from tumor characteristics to patient preferences, highlights the need to identify common agile values to help in overcoming the above challenges. By identifying and promoting these values, health care organizations can create an agile culture of interactions, continuous learning, and improvement.

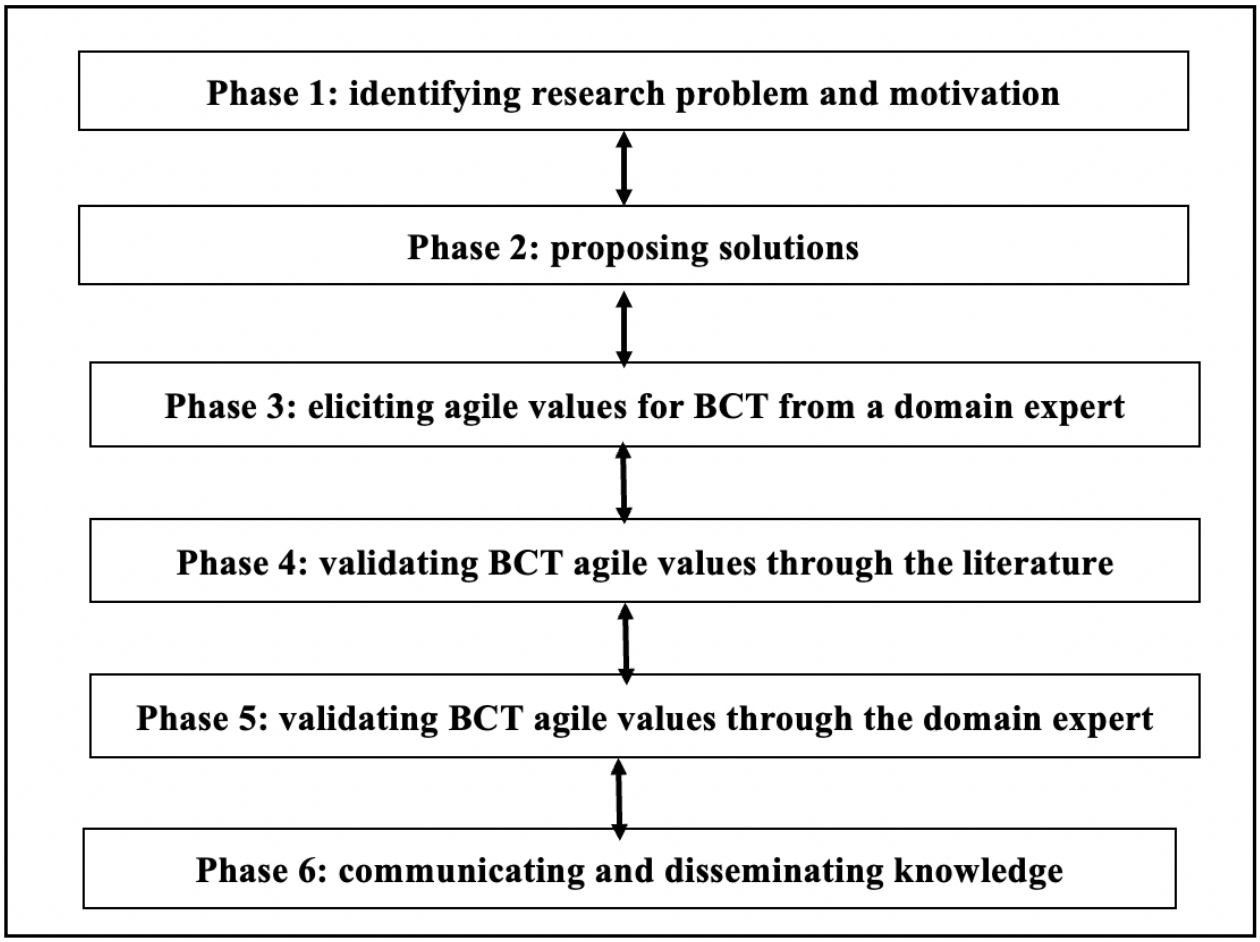
Multidisciplinary research has inspired individuals and communities, offered knowledge returns to individuals, and improved environment outcomes. In order to improve BCT and research, the different domains of software engineering and BCT may complement each other in a number of ways. Recent software development projects are adopting the agile approach to produce high-quality, useful software, in contrast to the traditional approach, which has limited flexibility, low user involvement, a long and delayed time-to-market cycle, late detection of errors, and high cost [16,17]

The concept of agility has been successfully described in the software engineering field over decades [17]. In software engineering, agility is a mindset, and its 4 values are not solid rules to follow [18]. In this context, it is possible to use the 4 agile values of software engineering for providing a shared framework for BCT teams to work together effectively and deliver value to their stakeholders while adapting to changing circumstances in complex environments and improving collaboration for better decision-making through a human-centric approach. Agile values emphasize the importance of individuals and interactions. This human-centered approach helps in building collaborative and motivated teams. The 4 agile values in software engineering are "individuals and interactions over processes and tools," "working software over comprehensive documentation," "customer collaboration over contract negotiation," and "responding to change over following a plan" [18]. The agile approach has enhanced value delivery to customers when user-centered experience and design are considered in the work of agile teams [19-21]. The agile approach has been used in the health care sector to translate the delivery of care from traditional methods into personalized ones, making care patient-centric, involving the patient in decision-making, enhancing continuous improvement and learning, and encouraging collaboration [22-26].

The creators of the agile values and principles have placed collaboration and people front and center, as the success or failure of a software project is highly dependent on them and not on the processes, tools, or the technology invested in it. Similarly, in the BCT process, the patient can be placed at the center of care by developing a personalized treatment plan considering the patient's preferences, values, and circumstances

XSL•FO
RenderX

and engaging their families to develop accurate and well-conceived plans [18].



Aim of the Study

In this paper, we aim at identifying agility values in BCT to drive the BCT journey and ensure that patients receive appropriate and responsive care that considers their unique needs and preferences, ultimately leading to improving the effectiveness and efficiency of BCT strategies and approaches. The 4 identified agile values are adopted and adapted for BCT from the software engineering field. Also, we aim to investigate and validate how these values conform to the concept of agility in the breast cancer context through work reported in the literature. This should allow us to assess how they conform to the concept of agility in comparison with agile values in the field of software engineering. The reason behind adopting and adapting agility values from software engineering is that this discipline was founded to engineer effective solutions for complex problems while considering different aspects of continuous change. According to a domain expert, this is a noted similarity to the BCT discipline.

Methods

Here, the applied research methodology has 6 overlapping phases (Figure 1). This encourages researchers to actively engage with the problem-solving process, resulting in outcomes that align with the identified and validated agile values for BCT; this is anticipated to have a direct impact on BCT, health care, and society. As the methodology is described as a problem-solving process, it starts by identifying the research problem and the associated motivation. This leads to identifying the desired solution, which allows identifying the corresponding BCT agile values. Then, an elicitation phase is conducted to elicit the agile values for BCT from the domain expert after reviewing and amending the software engineering agile values into language that is reasonable for BCT professionals. In the fourth phase, we review the literature to provide references with the aim of validating these values. In the fifth phase, the domain expert conducts a walkthrough of the 4 BCT agile values as a final validation before communicating them to the research community in phase 6.

Figure 1. Research methodology.

Phase 1: Identifying Research Problem and Motivation

According to a literature review, there is a gap in promoting the agility of BCT with respect to well-identified values, although the literature reports huge efforts in patient-centered and personalized BCT. It is essential for patients to have open, transparent, and personalized communication with their care team professionals and health providers about their treatment approach and whether it is agile or not. Patients are empowered when they are aware of how BCT is delivered, particularly if agile mindsets are leading the journey. This encourages them to take an active role in making decisions about their care, ask

XSL•FO
RenderX

pertinent questions, and advocate for the appropriate treatment options that meet their individual needs and circumstances. Having initial BCT agile values would pave the way to more flexible and personalized protocols, polices, and procedures to move closer to deliver patient-centric care. This also motivates policymakers to specify quality assurance processes that measure and indicate the extent of compliance to agility. Overall, this motivates health care providers to improve their care outcomes and increases patient satisfaction.

Phase 2: Proposing Solutions

To our knowledge, there is a lack of a validated definition of agile values for BCT, although BCT professionals strive to adhere to agility, as reported in the literature. The authors seek to propose and identify BCT agile values that are adopted and adapted from the software engineering field.

Phase 3: Eliciting Agile Values for BCT From a Domain Expert

The 4 agile values of software engineering were reviewed and rearticulated into language that is tailored to BCT professionals through 2 interview elicitation sessions conducted with a BC oncologist. The outcome here was the 4 identified BCT agile values, which are discussed below in phase 4 through work referenced from the literature. The outcomes of this phase are the following:

- Value 1: Individuals and interactions over processes and tools
- Value 2: Documentation and quality of documentation is as high priority as delivering an appropriate patient-centered treatment plan
- Value 3: Patient collaboration over treatment plan design agreement
- Value 4: Responding to change over following a plan

Phase 4: Validating Breast Cancer Treatment Agile Values Through the Literature

In this phase, we aim to reference work from literature that supports the articulation of the BCT agile values, as defined in phase 3. Below, each of the 4 BCT agile values is supported with work reported in the literature to enhance the validation.

Value 1: Individuals and Interactions Over Processes and Tools

In software engineering, this agile value highlights the fact that people and the communication behind developed processes and tools for achieving software development success are more important than these processes and tools themselves. Even if the team has the best, most appropriate tools, having the right people along with effective communication is still of greater importance. Regarding language for BCT professionals, this value is maintained as it is, without changing any of its wording [18,20].

In the BCT context, “working together is much more than policies, strategies, structures and processes” [27]. This can be seen in the shared decision-making (SDM) process for BCT, where the patient and everyone else is involved in delivering valuable information and reducing any mismatch between information that is delivered and the information that is needed in the complex treatment process [28]. When a patient is involved in SDM, it permits consideration of the patient’s preferences in the treatment, increasing their satisfaction and transforming the treatment process into a patient-centered one [29]. Improving patients’ engagement skills, using elicitation, performing clarification exercises for their preferences, and using formal and informal coaching are recommended to increase patients’ engagement in SDM in the BCT lifecycle. However, lack of time and resources are the biggest barriers mentioned regarding SDM [29]. This would prioritize individuals and their interactions over the tools [26,28,29]. Patient-centered communication and education, as well as coordination of care, are vital components for achieving the triple aims defined by the Institute for Healthcare Improvement that aim to improve the care experience for patient and family, improve the population’s overall health, and reduce health care capital costs [30]. According to research findings, the effectiveness of communication changes depending on the stage of the disease, and, for it to be effective, it must be adapted to the changing requirements and preferences of breast cancer patients [31,32]. Even after cancer treatment, regardless of the channel used, communications and interactions are still necessary. For example, a storytelling support group was run over the internet to break the social isolation that follows cancer [33,34].

In cancer care, the multidisciplinary team is a core central point of communication and collaboration. The National Health Service in the United Kingdom defines the multidisciplinary team (MDT) as “a group of health and care staff who are members of different organizations and professions (e.g. GPs, social workers, nurses, anesthesiologist, radiologist, pathologist, etc.,) that work together to make treatment and related services decisions of individual patients. MDTs are used in both health and care settings” [35]. In BCT planning, individuals in the MDT and their interventions can optimize care planning. For example, a nurse can stimulate interdisciplinary strategic planning that satisfies the clinical setting and improves outcomes through playing a key role in assessing the patient’s holistic needs [36]. A breast radiologist plays a vital role in the assessment and management of pain while leveraging patient communication and education, can add significant value to the care delivery process and patient care, and can improve outcomes [37]. Breast cancer patients who participated in a well-organized MDT contributed to facilitating a clear definition of their needs related to diagnosis, treatment, surveillance, and monitoring. This significantly enhanced breast cancer care planning, clarifying SDM in terms of booking appointments, referring procedures, and allocating respective roles and their responsibilities for patient care [38-40]. As a result, this MDT communication approach with the patient enhances survival rates and improves quality of life [40-44]. Although the research community reports that the MDT and patient interaction are prioritized over processes, some barriers may still hinder the effectiveness of these interactions; these are reported to include absence of leadership, individual personalities, cultural and belief systems, the need for regular clinical meetings, health care workers with double positions, availability of the workforce, specific goals of care, implementation in national

XSL•FO
RenderX

health insurance, hospital bureaucracy, issues with hospital infrastructure, patients themselves, and high turnover [44-46]. In the BCT context, collaborative decision-making constitutes far more than relying on factual information, as patient communication may generate a decision that contradicts the evidence; the evidence may suggest a different plan. This highlights the reality that communication between the MDT and patient allows for the consideration of all factors [47].

Effective tools and processes, such as value-based breast cancer care, cannot be effectively addressed without interactions [48]. This does not neglect the role of tools and processes in the BCT context. Tools and processes should be used to improve the provision of patient-centered BCT planning and interactions [18]. The National Coalition for Cancer Survivorship (NCCS) provides the Cancer Survival Toolbox, a tool that aids cancer patients to learn how to communicate, obtain information, make decisions, negotiate, and speak up for their patient rights as they manage their cancer treatment [49].

When a person is diagnosed with breast cancer, it not only affects the individual but also has a significant impact on their family members. According to some studies, it is viable and beneficial to shift care delivery toward person- and family-centered care to clarify and address patient preferences, legitimize care-partner contributions, and grant appropriate access to information for family members and other care partners who are key players in enacting high-quality cancer care [50]. Research indicates that involving family members as care partners in communication intervention at the point of care increases patient understanding of illness, patient access to and use of the patient portal, and viewing of clinician visit notes among patients with more actively engaged care partners [50].

In conclusion, the agility of this BCT value fully conforms to the corresponding software engineering value. This leads us to classify this BCT value as achieving agility.

Value 2: Documentation and Quality of Documentation is as High Priority as Delivering an Appropriate Patient-Centered Treatment Plan

This software engineering agile value places "working software over comprehensive documentation." This indicates that it is a higher priority to rapidly deliver functioning software than to spend great attention and effort on documentation tasks [18]. This does not neglect the importance of documentation. The aim is to improve future software releases through obtaining feedback quickly [18]. This value is translated into BCT language as follows: "Documentation and quality of documentation is as high priority as delivering an appropriate patient-centered treatment plan."

Documentation is vital for medical records and legal purposes in parallel to the patient's health and immediate needs. Patient-centered treatment planning's main objective is to involve patients and their families in meaningful and in-depth conversations with their medical professionals to develop an accurate, well-thought-out treatment plan that appropriately uses all available medical information while also taking the medical, social, and cultural needs and preferences of the patient and family into account [26]. The treatment plan is designed, developed, communicated, and executed based on the patient's individual characteristics, preferences, and responses to treatment in collaboration with an MDT that includes members with different specialties, thus ensuring that their best interests are considered and the best benefits are delivered. Therefore, all this necessary information should be documented as required by the MDT [26].

The documentation of a breast cancer patient may require up to 20 distinct professional groups. Across these different professions, most of this paperwork is normally completed by resident doctors [51]. Across different medical specialties, most of the documentation is carried out by gynecologists or gynecological staff. Most of the time dedicated to paperwork is required for therapy [51]. All this necessary information from different resources is required to be documented for organization, doctor-patient communication, quality assurance and management, managing future changes (as changes are inevitable during BCT), and, mostly, for diagnostic needs and follow-up after each therapy [51].

In a study carried out by the American Society of Clinical Oncology (ASCO), a treatment plan and summary template increased communication between patients and their health care providers among almost 90% of assessed patients and health care professionals [52]. This highlights the importance of documentation for communication and demonstrates not only the need to prioritize documentation but also the need to prioritize documentation quality requirements [51].

Thus, the agility of this BCT value does not conform with the corresponding agile value in software engineering.

Value 3: Patient Collaboration Over Treatment Plan Design Agreement

In software engineering, this agile value places "customer collaboration over contract negotiation." It highlights that contracts do not clearly detail customer needs; rather, customers themselves do. Thus, continuous feedback loops are a priority in this agile value to ensure that the developed product is effective and useful as per the customer's needs. This indicates that agile development is customer-centric. However, this does not neglect the role of contracts. This value can be translated into BCT language as follows: "patient collaboration over treatment plan design agreement."

BCT professionals interpret patients' collaboration based on continuous feedback from them. This is observed in patient collaboration and in visits that begin early in the BCT process and should happen frequently. This close collaboration culture with patients has been reported to lead to significant benefits for them, particularly when they are unable to make decisions [44]. Close collaboration helps oncologists and their teams ensure they are delivering an effective, useful treatment solution to patients. When they talk to patients and their families, they build feedback into the treatment cycle and reduce risks [28,29,41].

Encouraging patient collaboration can be achieved through providing them the care and information they need according to their stage of breast cancer, as each stage varies in the aspects of information and associated delivery of care [31,32]. What

XSL•FO
RenderX

was effective at one stage may not produce similar effectiveness in another stage. Therefore, it is highly recommended to look for communication alternatives that meet needs and preferences at each stage [53]. Sharing a treatment plan and summary template enhances patients' and their families' collaboration [52].

In conclusion, this leads us to classify this BCT value as achieving agility.

Value 4: Responding to Change Over Following a Plan

The world is not static. Therefore, a workable plan should never be static. This software engineering agile value highlights that changes in software development happen due to changes in the market, customer preferences, priorities, project management conditions, and business needs [18]. Thus, the agile mindset encourages reviewing and readjusting the plan based on new, emerging information. Regarding the BCT context, this value can be maintained as it is without changing any of its wording.

Changes in a BCT plan are inevitable and can occur for several reasons. Changes involve but are not limited to diagnosis results, follow-up assessments, surgical outcomes, health conditions, tumor characteristics, treatment response, side effects and tolerance, structural changes, resources, policies, disease recurrence, drug resistance, monitoring assessments, new research, and others. All these alert us to the need for a personalized response to the changes as a priority over following a static plan. For example, changing the sequence of treatment, in terms of radiotherapy and surgery, could improve outcomes and reduce side effects in terms of treatment complications and address safety and technical feasibility [54]. Lifestyle changes that involve exercise, diet, smoking, and alcohol have empowered patients psychologically and reduced the risk of recurrence and death [55-57].

Breast cancer is a complex disease in which not all patients can benefit from the same treatment. Thus, it is essential to go beyond conventional BCTs [58]. Changes in BCT may require developing a novel treatment that could be described as personalized [58]. Changes to the treatment plan could happen if the aim has changed. Aims could include preventing cancer recurrence, slowing growth of cancer, and managing symptoms of incurable cancer [59]. Accordingly, changes entail allocating roles that are put into place to address the aim of BCT and provide referral to clinical trials that are regulated to effectively address the desired treatment aim with minimum side effects [60]. Furthermore, a change may require halting the treatment to recover from adverse side effects [60].

Managing BCT entails evaluating the patient's response to treatment from the perspectives of surgery, imaging, and medical oncology. Adjuvant treatment is guided by an appropriate surgical and pathological assessment and follow-up care that concentrates on identifying recurring illness with the goal of enhancing long-term survival [61]. Whatever the change that requires a response, the BCT team will strive to improve the patient's quality of life.

Magnetic resonance imaging (MRI) is used to accurately identify stages of breast cancer by assessing the size and extent of the tumor within the breast and evaluating if it has spread to nearby lymph nodes or other structures [62]. This information is essential in determining an appropriate treatment approach that is ready to respond to changes. A major change in the treatment plan may involve the need for surgery and additional treatment [62-64].

In BCT, personalized treatment is a means of responding to a change and delivering patient-centric medicine. Knowing the molecular characteristics of breast cancer subtypes is necessary to create a tailored therapy and diagnosis [65]. It is necessary to establish molecular profiles and metrics for tailoring the appropriate treatment and evaluating its benefits and risks. Dose ratios and regimens are likely to change according to an identified combination therapy [66]. BCT decisions are based not only on the assessment of prognostic factors but also on the assessment of pathological and clinical findings. A multitopic-based integrated data approach to address many breast cancer risk variables can bring tremendous insight and promises to change treatment for the better [67].

In conclusion, this BCT agile value shows how change is necessary for the benefit of the patient.

Phase 5: Validating Breast Cancer Treatment Agile Values Through the Domain Expert

In this phase, the domain expert conducted a walkthrough of the output generated from the previous phase as a form of final validation. This was to ensure that the BCT agile values identified in phase 3 are consistent with the respective reported literature as shown in phase 4.

Phase 6: Communicating and Disseminating Knowledge

The research knowledge obtained from this paper is disseminated in this open access journal to increase its availability and accessibility to the scientific community, policymakers, practitioners, and the public. In addition, the article is published to enhance collaboration between multidisciplinary fields for better BCT strategies. The authors also aim to deliver a public seminar about the ideas delivered in this article to increase community awareness of promoting agility in BCT for better care values, strategies, and delivery.

Ethical Considerations

No ethical considerations are required for this study, as it does not involve human subjects. The statements for human subject research ethics review, exemptions, and approvals, as well as descriptions of informed consent (for the institutional review board), privacy and confidentiality protection, and compensation type and amount are not applicable. The study does not include any clinical setting for recruitment, not even recruitment procedures.

Results

In this study, we have identified BCT agility values and showed how they conform to the concept of agility in the field of software engineering. Our validation was conducted through a comprehensive review of the existing literature and interviews

XSL•FO
RenderX

with a breast cancer oncologist. This work has resulted in 4 BCT agility values, which are specified below:

1. Individuals and interactions over processes and tools (conforms)
2. Documentation and quality of documentation is as high priority as delivering an appropriate patient-centered treatment plan (does not conform)
3. Patient collaboration over treatment plan design agreement (conforms)
4. Responding to change over following a plan (conforms)

In summary, our analysis indicates that BCT has made significant strides in aligning with the concept of agility through the identification of the 4 values that were reconfigured from the software engineering field. These values focus on how individuals interact, collaborate, and welcome changes. However, the quality of documentation is as high priority as delivering a patient-centered treatment plan. These values have been integrated into various aspects of breast cancer care, from treatment planning and delivery to ongoing support and survivorship care. However, there is still room for improvement, and ongoing efforts to enhance these values in BCT will continue to benefit patients, families, BCT professionals, and health care providers.

Discussion

The work has delivered a novel contribution to knowledge in identifying the first set of agile values in the BCT context adopted from the software engineering field. We conclude that only 3 of the 4 identified agile values in BCT conform, in terms of agility, with the 4 agile values in software engineering. The 3 BCT agility values are "individuals and interactions over processes and tools," "patient collaboration over treatment plan design agreement," and "responding to change over following a plan." However, the second BCT agile value did not conform to agility, as it is vital that documentation not only be comprehensive but also have high quality and have high priority for delivering an appropriate patient-centered plan. None of the agile values were recorded as partially conforming to agility; this addresses the aim of this paper to identify BCT agile values and compare their conformance to agile values in the software engineering field.

In the first BCT agility value, the priority of collaboration has emerged as a fundamental aspect of BCT that is interpreted in the SDM and MDT approaches. MDTs consisting of oncologists, radiologists, surgeons, nurses, and other health care professionals work closely together to ensure comprehensive patient care. Furthermore, the involvement of patients in SDM has promoted collaboration between health care providers, patients, and those managing the treatment. Collaboration and ongoing interactions appear early in the BCT lifecycle and continue even after survival, emphasizing the significance of these interactions and implying that quality of life requirements are increasing and leading to more patient-centric processes. For the second BCT agility value, the design of BCT plans respects the personalized characteristics of each patient. All kinds of collaborations and interactions between the patient and the MDT to discuss and design an effective and safe BCT plan should be based on high-quality documentation. Therefore, it is a priority to allocate enough time to facilitate documentation work to attain agility in the remaining values. In the third agile value, patient collaboration is a higher priority than following a rigid treatment plan; this leads to better treatment decisions via continuous feedback throughout the BCT lifecycle. Regarding the fourth agile value, effective and safe changes are always welcomed to interrupt a BCT plan for the patient's benefit, with or without minimizing impacts on quality of life, thereby leading to closer, patient-centric, and better treatment outcomes, as well as minimized side effects.

Attempts to address BCT agile values are limited and constrained by cultural mindsets, the availability of resources for implementation, the availability of quality standards that support agility, and interoperability of health care systems. Patients' efficient participation is constrained by the quality of their education and their health literacy in terms of understanding risks, benefits, overall quality of life, and adherence to their treatment plans and medication regimens.

The authors do not claim that these are the only BCT agile values, as they are not limited to 4. Instead, the values proposed here constitute the first version of a BCT agile values manifesto. The implication of having BCT agile values shared among administration and BCT professionals is broader than the specific interpretation behind each identified BCT agile value. The identified agile values focus on effective and efficient collaboration between the patient and MDT in SDM, with consideration to continuous response to change, which will contribute to increasing the patient's activity level and forming a more personalized BCT process that drives patient-centric therapy decisions. Moreover, this contributes to eliminating waste, in other words, unneeded activities or tasks that may involve tests, procedures, and treatments. Hence, this contributes to more cost-effective, time-saving, and efficient care. Rather than just following strict protocols, BCT agile values increase the flexibility of these protocols, allowing for more personalized care with respect to patients' characteristics, preferences, and needs. The identified BCT agile values highlight the necessity of specifying quality assurance processes that aim at investigating the extent to which they conform to the concept of BCT agility. Health care systems are anticipated to become more flexible, patient-focused, and efficient by adopting agile values in BCT and care. This will eventually enhance patient outcomes and experiences and promote a change from inflexible, one-size-fits-all methods of care to ones that are tailored to the specific requirements of each patient and the rapidly advancing fields of medicine and technology. Finally, this holds the potential to revolutionize the way we approach oncological care. This endeavor reflects a commitment to embracing innovation, collaboration, and patient-centeredness, mirroring the very essence of the agile philosophy.

Abstract

Background: Information concerning the impact of the COVID-19 health crisis on populations most affected by HIV and hepatitis C virus (HCV; or key populations [KP]), and those working with these populations in community settings, is limited. Community-based organizations working in the field of HIV and viral hepatitis are well placed to identify and meet the new needs of KP owing to the health crisis.

XSL•FO
RenderX

Objective: This study aims to describe the development and implementation of an exploratory and descriptive multicountry, community-based research program, EPIC (*Enquêtes Pour évaluer l'Impact de la crise sanitaire covid en milieu Communautaire*), within an international network of community-based organizations involved in the response to HIV and viral hepatitis. The EPIC program aimed to study the impact of the COVID-19 health crisis on KP or people living with HIV or HCV and people working with these populations at the community level (community health workers [CHWs]) and to identify the key innovations and adaptations in HIV and HCV services.

Methods: A general protocol and study documents were developed and shared within the Coalition PLUS network. The protocol had a built-in flexibility that allowed participating organizations to adapt the study to local needs in terms of the target population and specific themes of interest. Data were collected using surveys or interviews.

Results: From July 2020 to May 2022, a total of 79 organizations participated in the EPIC program. Across 32 countries, 118 studies were conducted: 66 quantitative (n=12,060 among KP or people living with HIV or people living with HCV and n=811 among CHWs) and 52 qualitative (n=766 among KP or people living with HIV or people living with HCV and n=136 among CHWs).

Conclusions: The results of the EPIC program will provide data to describe the impact of the health crisis on KP and CHWs and identify their emerging needs. Documentation of innovative solutions that were put into place in this context may help improve the provision of services after COVID-19 and for future health crises.

Introduction

Context

Numerous COVID-19 research and epidemiological surveillance data have shown that certain populations are disproportionately affected by the COVID-19 health crisis not only in terms of mortality and morbidity but also in terms of the social and economic consequences of the crisis [1-4]. This is notably the case among the homeless and people living in inadequate or poor housing conditions, which makes the implementation of prevention measures such as social distancing and frequent hand washing difficult or unfeasible [5]. In addition, key populations (KP; such as men who have sex with men [MSM], people who inject drugs, sex workers [SWs], transgender women, and migrants) who are exposed or living with HIV or hepatitis C virus (HCV) may also experience compounding effects of the health crisis in terms of infringement on their human rights and exacerbation of preexisting health inequalities.

International organizations and community-based associations have alerted public authorities to the susceptibility of these marginalized groups in the early phase of the COVID-19 pandemic and the consequences on the HIV response [6]. The HIV epidemic is largely concentrated within KP: MSM, people who inject drugs, SWs and their clients, and transgender women [7]. The lack of consideration or consultation with KP has resulted in further social exclusion [3] and greater susceptibility to violence and human rights abuses [6]. For example, governmental measures such as lockdowns have exposed SWs to great economic instability, forcing them to put their health in danger [8]. The crisis may also have an important impact among transgender populations in terms of reinforcing preexisting inequalities with regard to access to health care, including gender affirming care and social and mental support [9]. Disruptions in access to drug services and clean drug consumption-related equipment were experienced early in the pandemic, possibly increasing the risk of infection with SARS-CoV-2 in addition to HIV and hepatitis B and C among people who use drugs [10-12]. Increased alcohol and drug consumption because of distress may also be a consequence of the crisis, and whether this persists after COVID-19 is of concern [5,13]. Among MSM, and likely other KP, a reduction in sexual activity was observed early in the pandemic owing to lockdowns and distancing measures, which may have resulted in a lower uptake of prevention tools such as preexposure prophylaxis and HIV testing [14,15]. It is thus important to ensure the necessary support and access to services when sexual activity resumes. Finally, disruptions in treatment and other services for people living with HIV and people living with HCV could lead to significant increases in new infections and mortality in the coming years, hindering global elimination efforts [16-18].

The COVID-19 crisis thereby represents a threat to the global progress against HIV and viral hepatitis and has consequently highlighted the importance of engaging or re-engaging and maintaining KPs, people living with HIV and people living with HCV in the HIV and HCV prevention and care pathway. The crisis has in many ways served as a catalyst for the development of innovative solutions for health service delivery since the beginning of the COVID-19 pandemic. For example, many in-person services moved to the web [19], and although this may be a viable solution for some individuals, there remains a concern that remote delivery of care will further exacerbate social gradients of health owing to limited or no access to internet, technological resources, and technological literacy [20]. Efforts to maintain harm reduction services despite lockdowns and other restrictions created an opportunity in some countries to develop or expand multimonth dispensing of opioid agonist treatment, unsupervised dosing and diversification of points of dispensation (pharmacy, vending machines), and

XSL•FO
RenderX

take-home naloxone, where they were previously not permitted [21,22]. Similarly, home delivery, multimonth dispensing, and "fast track" antiretroviral therapy refills were solutions put into place in some countries to maintain antiretroviral therapy services [23].

Many of these innovative solutions were put into place by community-based organizations (CBOs), who were notably at the forefront in the early days of the pandemic [21,24-26]. However, studies of the other epidemics have shown a negative impact (depression and stigmatization) of health crises on health workers [27,28]. Given their proximity to KP, and their essential role in the provision of support, prevention, and treatment for these populations, it is equally important to study the impact of the COVID-19 health crisis on community health workers (CHWs) [29].

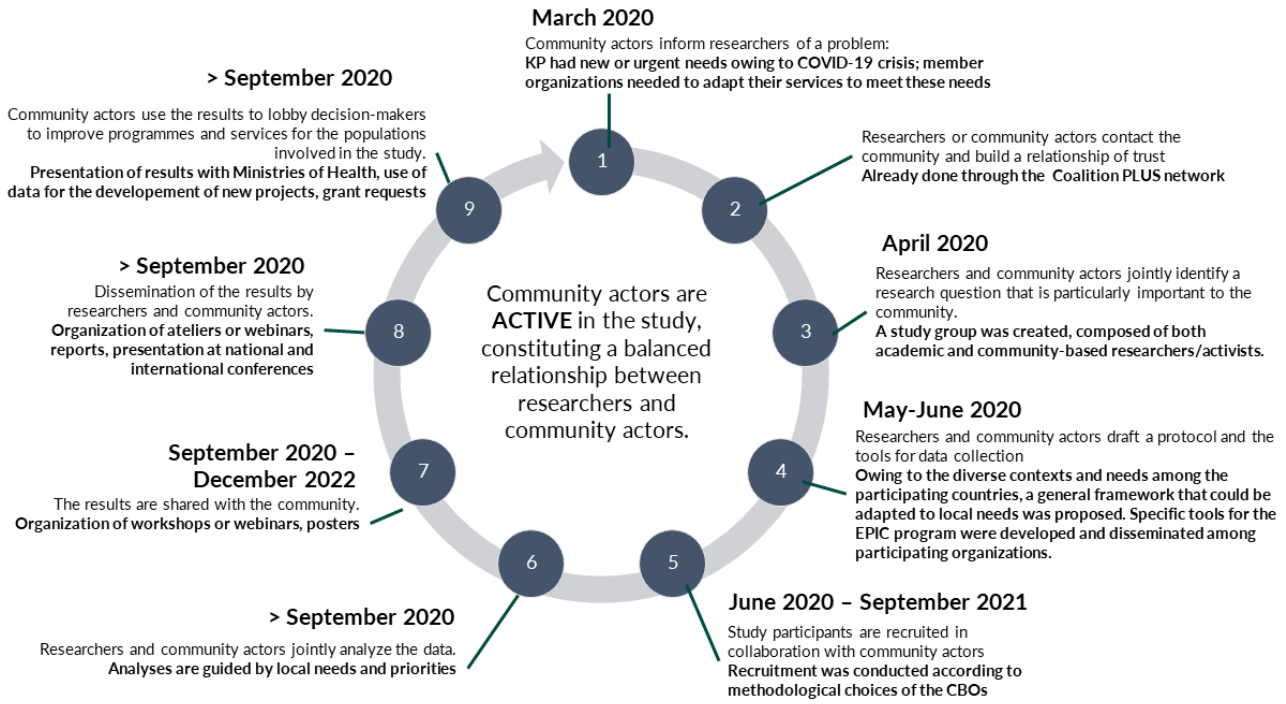
The COVID-19 pandemic has thus reinforced the necessity of community engagement to provide adapted responses to the specific needs of KP. Community organizations worldwide have effectively led initiatives to provide COVID-19 information and share expertise [24]; however, data regarding these initiatives are limited. Therefore, it is important to document the new solutions put in place during the COVID-19 health crisis and to document the perceptions and experiences of CHWs.

Objectives

The EPIC (*Enquêtes Pour évaluer l'Impact de la crise sanitaire covid en milieu Communautaire*) community-based research program aimed to understand how the COVID-19 health crisis affected the populations at higher risk for, or living with, HIV and viral hepatitis and the people working with these populations at the community level, and to identify the key innovations and adaptations in HIV- and hepatitis-related services. In the following sections, we describe the general framework of the EPIC program, which was implemented in 32 countries across the world in partnership with local CBOs involved in the fight against HIV and viral hepatitis. The program was developed by Coalition PLUS, an international union of CBOs involved in the fight against HIV and viral hepatitis, in partnership with external scientific partners. Founded in 2008, Coalition PLUS unites 16 member organizations and >100 partner organizations in 52 countries. These organizations are grouped into 6 regional networks (Middle East and North Africa [MENA], West Africa, Central and East Africa, Indian Ocean, Americas-Caribbean, and Europe), 2 thematic networks (RIGHT PLUS [research] and AGCS PLUS [advocacy]), and a linguistic (Lusophone) network.

Methods

General Design and Study Development



EPIC is an exploratory and descriptive multicountry, cross-sectional, and community-based program that uses mixed methods: qualitative and quantitative. To accommodate the diverse themes of interest and target populations, as well as the exceptional circumstances, the study was customizable at the local level, and there was a common basis for all organizations implementing EPIC. However, data collection tools were adjustable depending on the target population or populations and specific themes of interest, which were determined by the implementing organizations. Other considerations such as human and financial resources and technical capacity of the implementing organizations were also taken into consideration. The adaptative methods of the EPIC program thus resulted from an urgent need to document the COVID-19 crisis within the Coalition PLUS network and adapt to the realities of the field within the context of an ongoing pandemic. This decision was in line with the community-based approach and with Allport [30] when he postulated that "we should adapt our methods so far as we can to the object, and not define the object in terms of our faulty methods." Following the community-based approach [31], many CBOs, members or partners of Coalition PLUS, actively participated at all stages of this research project (Figure 1).

Starting in March 2020, Coalition PLUS members and partners mobilized to respond to the COVID-19 crisis within their organizations and countries. These CBOs were confronted with new needs such as supplying CHWs and beneficiaries with protective equipment and information regarding prevention measures, adapting services to respect governmental measures (lockdowns, distancing, and mobility restrictions), and provision of basic needs such as food for beneficiaries. In this context, there was a growing concern that KP at higher risk for HIV or HCV, and people living with HIV or HCV, were likely to have the greatest difficulty adapting to public health measures and most likely to experience negative impacts of the COVID-19 crisis.

On April 23, 2020, the Community-based Research Laboratory (CBRL) at Coalition PLUS organized a web-based Zoom (Zoom Video Communications, Inc) meeting with representatives from each of the regional, thematic, and linguistic networks as well as external scientific partners (hereafter, the EPIC study working group). A total of 18 people participated in this meeting and an additional meeting was held on April 28, 2020, with 5 people who were unable to join the first meeting. The aim of these meetings was to set the objectives of the project and the methodology that was best adapted to the current context and timeline. To better identify the needs within the various Coalition PLUS networks, the working group then consulted with the member and partner organizations of their respective networks to identify common themes. The feedback of these consultations informed the draft proposal of the research project, which was shared at a web-based Zoom meeting held on May 13, 2020. A total of 24 people participated in this meeting. Following this meeting, and individual exchanges with the working group members, the final study documents were finalized and shared on June 12, 2020.

XSL•FO
RenderX

Figure 1. Stages of a community-based research project adapted to the EPIC (*Enquêtes Pour évaluer l'Impact de la crise sanitaire covid en milieu Communautaire*) program. CBO: community-based organization; KP: key populations.

Objectives

The EPIC program had 3 main objectives:

1. To study the impact of the COVID-19 health crisis on KP at higher risk for, or living with, HIV or HCV (people who use or inject drugs, SWs, MSM, transgender people, and migrants)
2. To study the impact of the COVID-19 health crisis on people working with these populations at the community level (peer educators, CHWs)
3. To identify the key innovations and adaptations in HIV and HCV services that could be maintained and extended beyond the COVID-19 health crisis.

Study Population and Inclusion Criteria

The inclusion and exclusion criteria of the EPIC program are presented in Textbox 1.

Textbox 1. EPIC (Enquêtes Pour évaluer l'Impact de la crise sanitaire covid en milieu Communautaire) program inclusion and exclusion criteria.

Inclusion criteria

- Part of at least one of the eligible study populations: people living with HIV or hepatitis C virus, people who use or inject drugs, sex workers, men who have sex with men, transgender people, migrants, community health workers
- Above the age of the majority in the recruitment country
- Accept to participate and provide informed consent

Exclusion criteria

- Not a part of one of the eligible study populations
- Below the age of the majority in the recruitment country
- Refuse to participate or provide informed consent

Nomenclature

As the implementation of the EPIC protocol varied among the participating countries, based on target population, themes of interest, and methodology used, the overall project is referred to as the EPIC program. EPIC study or studies refer to the local implementation of the program among a specific target population. Therefore, in countries with multiple target populations, the studies were referred to as EPIC-(Methodology) (Country name) (Target Population).

Data Collection Tools

Quantitative Data

Two structured questionnaires were designed to collect quantitative data: one questionnaire targeted KP and the other targeted CHWs. Both questionnaires were organized into

XSL•FO
RenderX

different modules so that each organization had the option to implement modules corresponding to their specific interests and target populations. Textbox 2 describes the modules of each questionnaire. There was one mandatory module in the KP questionnaire and 3 mandatory modules in the CHWs questionnaire. Additional questions could be added by each participating organization to collect information on a specific topic that was not already covered by the questionnaire or questionnaires. It was not possible to change the wording of the questions or the proposed responses.

To centralize all the quantitative EPIC data, both questionnaires were created in the Voxco survey software, offering not only web-based but also offline data collection (via a tablet or smartphone app). Organizations that collected data using paper questionnaires entered the data into the Voxco software.

Textbox 2. Modules of the key populations and community health workers questionnaires.

Key populations

- Sociodemographic, general impact of COVID-19 and intention to vaccinate against COVID-19 (mandatory module)
- Sexual activity and prevention strategies for HIV and other sexually transmitted infections
- Experience and application of lockdown or barrier measures
- Socioeconomic needs and responses in relation to the COVID-19 health crisis
- Representations and perception of the COVID-19 risk
- Well-being and resilience
- Access to health care
- COVID-19 impact on pre-exposure prophylaxis
- People who use or inject drugs
- People living with hepatitis C virus
- People living with HIV
- Sex workers
- Migrant

Community health workers

- Sociodemographic, general impact of COVID-19 and intention to vaccinate against COVID-19 (mandatory module)
- Experience of the COVID-19 crisis at work (mandatory module)
- Experience and application of lockdown or barrier measures
- Relationship with beneficiaries (mandatory module)
- Representation and perception of COVID-19 risk
- Well-being and resilience

Qualitative Data

Two semistructured interview guides were designed to conduct individual interviews with the KP of member and partner organizations and with the CHWs of these organizations. An additional interview guide was designed for CHWs who also belonged to or identified with a KP group. Individual interviews aimed to explore in greater detail the experiences and needs of KP communities during the COVID-19 crisis. Textbox 3 describes the main areas of interest covered by the interview guides.

Interviews were conducted in different ways to accommodate the local restrictions in effect during the data collection period: face to face, on the web (with or without video), or by phone.

All interviews were conducted by trained CHWs, members of the Coalition PLUS community-based research team, or by a local consultant. The interview guides were translated into local language or languages in collaboration with local partners. Interviews were conducted in the local language or languages and recorded using a voice recorder. Voice recordings were transcribed verbatim and translated into French or Spanish, if necessary, for analysis. To guarantee the confidentiality and the anonymity of the interview, external consultants conducted all the interviews among CHWs.

XSL•FO
RenderX

Textbox 3. Main topics covered by the interview guides for key populations, community health workers, and community health workers who identify with a key population.

Key populations

- COVID-19 knowledge, risk perception, and experience of the COVID-19 crisis (in terms of stigma, emerging needs)
- Attitudes toward COVID-19 vaccination
- Experience of lockdown and other governmental measures
- Overall health care access
- Relations with the Coalition PLUS member or partner structure

Community health workers

- Personal experience of the COVID-19 crisis within the professional sphere
- Attitudes toward COVID-19 vaccination
- Impact of the COVID-19 health crisis on the beneficiaries

Community health workers who identify with a key population

- Personal experience of the COVID-19 crisis within the professional sphere
- Attitudes toward COVID-19 vaccination
- Impact of the COVID-19 health crisis on the beneficiaries
- Experience of lockdown and other governmental measures

Complementary Data

A country information sheet concerning local policies, government measures taken during the health crisis, and COVID-19–related data (eg, incidence at study launch) was created to gather information about the context in which the quantitative or qualitative data were collected. Similarly, an organizational information sheet was created to collect general information about organizations that implemented EPIC among CHWs (eg, size of the organization, KP reached, and regular and COVID-19–related activities).

Sample Size

Given the COVID-19 context and the exploratory and descriptive aims of the project, convenience samples were more adapted to the uncertain pandemic context than samples based on statistical criteria. Indeed, the aim was to gather information about the impact of the COVID-19 crisis on KP and CHW in many Coalition PLUS members and partner organizations. Each organization has its own specificities regarding the COVID-19 crisis at the local level, number of beneficiaries or users reached, and number of CHWs involved. However, before the implementation of the EPIC study, each organization provided an estimation of the sample size to be recruited on the basis of their context and their experience with the target populations to be included in the qualitative or qualitative studies. This sample size estimation was important to orientate or validate the methodological choices through technical support from the Coalition PLUS research team. As a general guide, a minimum of 100 respondents was recommended for quantitative studies and 10 for qualitative studies. Organizations that targeted <100 persons for quantitative studies were encouraged to switch to a qualitative methodology.

Ethical Considerations

Regarding data protection regulations, the EPIC protocol was registered at the French National Commission of Informatics and Liberties (registration #2218347 v 0).

Local ethics approval was obtained in each participating country before study implementation (Multimedia Appendix 1).

Before taking part in the study, participants were provided information regarding the research objectives, how the data were collected, managed, and by whom, as well as the participant's rights. For web-based participation, this information was available on the landing page of the EPIC questionnaire in Voxco. Participants had access to the questionnaire once they provided their consent to participate. For face-to-face participation, oral consent was obtained after this information was delivered and before starting the questionnaire or the interview. Face-to-face interviews were conducted in places that guaranteed anonymity and privacy.

All participating organizations signed a cooperation agreement to guarantee the security of the data collected in compliance with both French data protection regulations and local ethics and data protection requirements. The cooperation agreement also detailed collaborative research guidelines and operating rules for teams involved in the study, such as guaranteeing the place of communities in the research process, use of Voxco software, and the EPIC program logo.

General Coordination of the EPIC Program

The overall coordination of the EPIC program was assured by the Coalition PLUS CBRL, which initially comprised 7 people in 2020, including the principal investigator of the EPIC program and the Director of the Laboratory, 1 research manager, 4 research officers, and 1 biostatistician. By 2021, the team expanded to include an additional research manager, 6 research

XSL•FO
RenderX

officers, and 1 data manager for a total of 15 team members. One research officer was dedicated full-time to the coordination of the EPIC program, whereas the other team members worked on the EPIC program in addition to other studies. The follow-up of all participating organizations, in terms of presentation of the study protocol and other documents, development of local adaptation of the study tools, and overall technical support throughout the entire research process was provided by the CBRL team. In 2020, each participating organization was followed through regular Zoom calls and email exchanges by 2 members of the initial team. The addition of the new members in 2021 allowed a more local follow-up of participating organizations as 5 research officers were based in 5 Coalition PLUS regional networks (MENA, West Africa, Central and East Africa, Indian Ocean, and Americas-Caribbean).

Local Implementation and Data Collection

Following the community-based approach, and within the framework of the capacity-building mission of Coalition PLUS, each member or partner organization willing to locally implement EPIC was assisted by at least one person of the CBRL to guide, check, and validate all steps of the study implementation. Regarding quantitative data collection, each participating member or partner organization was trained on the Voxco software from the CBRL to learn the basic functionalities of the software, for example, how to modify a questionnaire, make it available on the web, and follow-up recruitment. All questionnaires were checked and validated by a member of the CBRL before the survey was launched. Regarding qualitative data collection, all CHWs who conducted interviews received training through a video conference from a qualitative researcher from the CBRL. Each local organization that used qualitative methods sent the first audio interviews and transcriptions to CBRL to check the quality of the interviews. If needed, additional support was provided by the CBRL to improve the quality.

It was crucial that the implementation of the research study did not become a barrier to the continuity of member and partner organizations' services during the health crisis. Therefore, implementation had to match the organization's needs in terms of data collection and topics of main interest while considering their local constraints (available human resources, contact with KP, COVID-19 prevention measures, etc). The local design and implementation of the EPIC protocol was documented in the EPIC implementation document. Textbox 4 describes the main sections of the implementation document and its content. The completed implementation document was used as a basis for the local EPIC protocol and was submitted to the local ethics committee in addition to the general protocol.

Once the implementation document was completed, the participating organizations translated all the EPIC study tools into the local language when necessary. The CBRL provided the EPIC main study documents (questionnaires, including web-based questionnaire in Voxco, interview guide, informed consent, etc) in 4 languages: English, French, Portuguese, and Spanish. The study documents were shared with external scientific partners upon request.

Each participating organization was responsible for the survey promotion and the entire data collection process, including data storage when not using the Voxco software (pen-and-paper questionnaires, voice recordings, etc).

XSL•FO
RenderX

Textbox 4. Content of the EPIC (Enquêtes Pour évaluer l'Impact de la crise sanitaire covid en milieu Communautaire) implementation document.

Section and main information of the section

1. Collaborators

- Local reference person responsible for the local implementation of the EPIC study
- Name and roles of all involved collaborators
- Budget (if any)

2. Local context

- General introduction and rationale of the project: COVID-19 situation, affected population, etc
- Brief presentation of the organization: history, key populations, etc
- Reasons for implementing EPIC, target populations, etc

3. Objectives

- Selection of the objectives to be used by the organization

4. Study population: List of all key populations to be surveyed by the organization, among

- People who use or inject drugs
- Sex workers
- Men who have sex with men
- Transgender people
- People living with HIV
- People living with hepatitis C virus
- Migrant people
- Community health workers

5. Inclusion criteria

- Be a part of the study population, above the national age of majority, and accept to participate and provide informed consent

6. Ethics committees

- French National Commission of Informatics and Liberties and local ethics committee approvals

7. Survey methods

- Quantitative surveys:
  - Study population or populations
  - Modules of the questionnaire to be used and additional questions (if any)
  - Administration of the questionnaire: face-to-face (pen-and-paper and tablet offline), self-administered (pen-and-paper, tablet offline, and web-based questionnaire)
  - Recruitment strategies: promotion (specific venues and on the web), key persons to be contacted and involved, places of recruitment, other channels for promotion or recruitment
  - Estimated time of recruitment and expected sample sizes
- Qualitative surveys
  - Target population or populations
  - Expected sample sizes
  - Recruitment strategies
  - Interview characteristics: who will conduct the interviews, where, face-to-face or remotely, etc

8. Informed consent

-

XSL•FO
RenderX

Brief note presenting the survey and participants' legal rights (voluntary participation, right to drop out at any moment, anonymity and privacy, and data storage)

- Ways to obtain consent: oral, voice recorded, or tick box

9. Data management

- Places where the data will be stored
- People granted with access to these data

Data Management

Overview

All data (quantitative, qualitative, and complementary) were centralized at Coalition PLUS and were securely stored and transferred. No personal data were collected to ensure anonymity of the study participants. The European General Data Protection Regulation requirements in terms of data protection are complied with regard to data processing and storage.

Quantitative Data

Quantitative data that were not collected through Voxco (ie, pen-and-paper questionnaires) were entered into Voxco by the corresponding organization, and hard copies of the questionnaires were stored in a secure place with restricted access. All databases generated by Voxco were then cleaned by the CBRL and shared with each participating organization. All databases are stored on a secured server with access restricted to the CBRL biostatistician and data manager. Each participating organization had access to its own data. The global or subset of the global database may be accessed if a formal demand to perform multicountry analyses is approved by the EPIC study group team.

Qualitative Data

Voice recordings, verbatim transcripts, and translations (when necessary) were sent by a secure link to the CBRL and stored.

Analyses

Overview

In general, local level analyses are prioritized as the overall aim of this study was to collect information regarding the impact of the COVID-19 crisis on KP and to identify specific needs to inform local or national interventions or adaptation of services. Analyses at the global and regional levels, and within specific populations, will also be conducted.

Quantitative Analyses

All participating organizations were provided with a cleaned database and descriptive tables of all their data, which were prepared by the CBRL. Technical assistance may also be proposed for conducting more in-depth analyses. Participating organizations are also encouraged to seek partnerships with local universities if support is needed for the analyses.

Country-level analyses will be conducted so that participating organizations can build on national results. When possible, multicountry analyses will be conducted, grouping countries by language, geographical region, key issues (eg, health care access), or targeted KP.

Descriptive analyses will be conducted to first characterize the needs of the participants. Three validated scales were used in this study: Patient Health Questionnaire-9 for depression [32] and the Generalized Anxiety Disorder-7 for anxiety [33] and the 6-item Brief Resilience Scale (BRS) for resilience.

Qualitative Analyses

According to the quality of qualitative data collected, 2 analysis methods are planned:

1. For corpus with a good quality of data collection, a thematic content analysis will be conducted on the transcripts of the interviews by the local consultant or consultants or CBRL in close collaboration with the local partners. The objective of the analysis will be to identify most relevant themes to describe the impact and experiences of the COVID-19 crisis in collaboration with the partners. The validity of the analysis will be checked with the interviewers or local consultant or consultants.
2. For corpus with difficulties in qualitative data collection (concerning several local organizations for which this was their first time using qualitative methods), a descriptive of the results will be provided by the CBRL based on quotes and summary themes. In addition, this experience will be used to strengthen partners' abilities in qualitative methods through working sessions to discuss the lessons learned and identify points of improvement.

The quality of the interviews was evaluated by the CBRL based on the transcriptions received. The criteria used were (1) the respect of the interview guide, (2) the quality of the exchanges (interviewers follow the semistructured method and had nonjudgmental and nondirective attitude during the interview), and (3) the quality of the transcription (all the interactions were transcribed).

Publications and Scientific Dissemination

All participating organizations are strongly encouraged to disseminate the results of the EPIC studies through various formats and channels of communication that are best adapted to the local context and target audience (including but not limited to the concerned communities and other stakeholders). EPIC data will be disseminated through webinars, in-person workshops, national reports (eg, detailed study reports and infographics), and scientific publications (article and conference presentations). Knowledge management documents that explore the EPIC program as an example of the community-based

XSL•FO
RenderX

research approach, and its implementation, during this health crisis are also under development.

Results

General Results

The first EPIC surveys were deployed by the CBOs AIDES (France), the Association de lutte contre le Sida (ALCS; Morocco), Asocia ia Română Anti-SIDA (ARAS; Romania), and Grupo de Ativistas em Tratamentos (GAT; Portugal) in the summer of 2020. To date, the EPIC program has been implemented by 79 organizations in 32 countries worldwide. In total, 118 country-level surveys were conducted, including 66 quantitative studies and 52 qualitative studies. The details on the number of participants, studies, and countries per target population are described in Tables 1-3.

In addition to Coalition PLUS member and partner organizations, external scientific partners (n=2) integrated specific questions or entire modules from the EPIC questionnaires into dedicated or follow-up questionnaires within the framework of ongoing studies. The data from one of these studies may or may not be included in the global database (and the global analyses) depending on the ability to fusion this specific database with the global database and confirmation that there is no risk of duplication. The study, which was implemented in Togo, Burkina Faso, Mali, and the Ivory Coast, has therefore been excluded from the numbers presented here (Tables 1 and 3).

Quantitative data collection completed on March 15, 2022, and qualitative studies completed on May 31, 2022. A total of 13,773 participants participated in the EPIC program (n=12,871, 93.5% participants for the quantitative studies and n=902, 6.5% participants for the qualitative studies).

To date, all participating organizations have received their cleaned database and descriptive tables. Although some countries have already started to disseminate initial results and work on more advanced analyses, many are starting to conduct or discuss the preliminary analyses. Regarding the diffusion of the results, at least 27 organizations have created infographics with a selection of descriptive data from their EPIC studies, which have also served as a basis for feedback to the concerned communities during dedicated meetings. Organizations are also working on national reports or other documents that will summarize the collected data at the national level. The EPIC data have also been used as an evidence base for discussions with local ministries of health or other governmental institutions.

Description of the EPIC program structure and preliminary global results have been presented at regional or international conferences (n=7). Reflections on the development of the EPIC program as a community-based research study in the context of a pandemic have been published [34].

Table 1. Distribution of collected quantitative data by targeted study population (N=12,871 respondents; 66 studies in 29 countries)[a].

Targeted study population[b]	Respondents (n=12,871), n (%)	Different studies (n=66), n (%)	Countries implicated, n	Countries (n=29)
Community health workers	811 (6.3)	10 (15.2)	9	Benin, Burkina Faso, Burundi, Colombia, Guatemala, Malaysia, Mali, Senegal, Spain
People living with HIV	3923 (30.5)	15 (22.7)	15	Brazil, Burkina Faso, Burundi, Canada (Quebec), Cape Verde, Chile, Guinea-Bissau, Mali, Mauritania, Mauritius, Mozambique, Portugal, Romania, São Tomé and Príncipe, Senegal
Men who have sex with men	2965 (23)	11 (16.7)	10	Algeria, Benin, Burkina Faso, Guatemala, Lebanon, Mali, Peru, Portugal, Senegal, Tunisia
Sex workers	2589 (20.1)	15[c] (22.7)	15[c]	Argentina, Algeria, Angola, Brazil, Burkina Faso, Cape Verde, France, Guinea-Bissau, Mali, Morocco, Mozambique, Portugal, São Tomé and Príncipe, Senegal, Spain
People who use drugs	1364 (10.6)	10 (15.2)	9	Algeria, Burkina Faso, Cape Verde, Colombia, France, Malaysia, Mozambique, Portugal, Senegal
Migrants	554 (4.3)	2 (3)	2	Colombia, Portugal
Transgender people	324 (2.5)	2 (3)	2	Benin, Timor
Key populations (including sex workers, people living with HIV, men who have sex with men, migrants)[d]	341 (2.7)	1 (1.5)	1	Colombia

[a]Excludes participants from 4 countries (Togo, Burkina Faso, Mali, and Ivory Coast) who participated in the EPIC program within the framework of an ongoing cohort study (CohMSM PrEP). The integration of the data from this study with a global database must be determined. Associations in Mali and Burkina Faso also implemented EPIC studies outside the cohort study and were therefore included in this study.

[b]None of the participating organizations specifically targeted people living with hepatitis C virus for their studies.

[c]Includes study (HIVITS-TS-COVID) conducted in Spain.

[d]No specified target population within the key populations.

Table 3. Distribution of collected quantitative and qualitative data by country[a].

Countries	Quantitative data (N=12,871), n (%)	Qualitative data (N=902), n (%)
Algeria	481 (3.74)	57 (6.32)
Angola	101 (0.78)	50 (5.54)
Argentina	256 (1.99)	N/A[b]
Benin	888 (6.9)	48 (5.32)
Bolivia	N/A	29 (3.22)
Brazil	246 (1.91)	60 (6.65)
Burkina Faso	838 (6.51)	60 (6.65)
Burundi	432 (3.36)	30 (3.32)
Canada (Quebec)	182 (1.41)	19 (2.11)
Cape Verde	292 (2.27)	30 (3.32)
Chile	300 (2.33)	N/A
Colombia	842 (6.54)	54 (6)
France	347 (2.69)	10 (1.11)
Guatemala	436 (3.39)	49 (5.43)
Guinea-Bissau	533 (4.14)	40 (4.43)
Lebanon	118 (0.92)	30 (3.32)
Malaysia	305 (2.37)	30 (3.32)
Mali	1168 (9.07)	N/A
Mauritania	151 (1.17)	10 (1.11)
Mauritius	260 (2.02)	N/A
Morocco	119 (0.92)	40 (4.43)
Mozambique	705 (5.48)	30 (3.32)
Peru	476 (3.7)	19 (2.11)
Portugal	1381 (10.73)	49 (5.43)
Romania	103 (0.8)	N/A
São Tomé and Príncipe	599 (4.65)	40 (4.43)
Senegal	623 (4.84)	45 (5)
Spain	437 (3.4)	29 (3.22)
Timor	100 (0.78)	10 (1.11)
Tunisia	152 (1.18)	34 (3.77)

[a]Excludes participants from 4 countries (Togo, Burkina Faso, Mali, and Ivory Coast) who participated in the EPIC program within the framework of an ongoing cohort study (CohMSM PrEP). The integration of the data from this study with a global database must be determined. Associations in Mali and Burkina Faso also implemented EPIC studies outside the cohort study and were therefore included in this study.

[b]N/A: not applicable.

Capacity Building Through the EPIC Program

A total of 139 people were trained during 38 training sessions, amounting to 54 hours of training. Specifically, 29 sessions concerned training on the Voxco platform and the use of its offline functionality, and 2 quantitative data analysis trainings were conducted. Three qualitative training sessions were conducted among 7 associations with 11 people.

Furthermore, several webinars have been organized to encourage sharing of experiences and mutual capacity building between the organizations implementing EPIC such as a webinar among all Spanish-speaking organizations to share experiences and tips regarding practical implementation and recruitment and another webinar for participating organizations in the MENA region, which focused on qualitative methodology and data collection. During the 11th Francophone Conference on HIV/AIDS, AFRAVIH, which was held in Marseille from April 6 to 9, 2022, a round table was organized for participating organizations and academic and community-based researchers to discuss the EPIC program, its implications, and the lessons learned.

XSL•FO
RenderX

Discussion

Principal Findings

In response to the COVID-19 health crisis, a general community-based research protocol was rapidly developed and made available to CBOs within the Coalition PLUS network. The research protocol was also adapted by external scientific partners to document the impact of the crisis among their ongoing studies. The aims of the global EPIC program were to identify and respond to the specific needs of KP at higher risk for, or living with, HIV or HCV, as well as those who work with these populations.

With a total of 66 surveys (12,871 respondents) and 52 qualitative studies (902 respondents), the EPIC program may largely be considered a success because of the mobilization of an unprecedented number of member and partner organizations across different networks within Coalition PLUS. The EPIC research program will contribute to wider reflections on developing and implementing research projects that respect the community-based research principles within a pandemic context [35]. Furthermore, the program has collected a consequential amount of data among populations who are not represented in general population survey data, who are often not adequately reached by traditional health structures, and who have specific needs [1,25,36].

Although the analysis of the study data is ongoing, we can reflect on some key elements and lessons learned from the implementation of the EPIC program.

Community-Based Research

Following the community-based research approach [31], the EPIC program was initiated based on information from CBOs of the emerging and urgent needs of KP at the start of the COVID-19 health crisis. CBOs were, and continue to be, involved at every step of the research study process as detailed in Figure 1.

Although the development and implementation of the EPIC program followed the stages of a community-based research project, this process was accelerated owing to the urgency of the COVID-19 health crisis (7 weeks between the initial meeting of the EPIC study working group and the validation and availability of the final study documents). The experience of the stakeholders involved in the project, regarding the specificities of EPIC as a community-based research project and the context of a global health crisis, will be explored in a knowledge management project led by the knowledge management department at Coalition PLUS.

Mobilization, Capacity Building, and Coordination

Several key factors related to the structure of Coalition PLUS and its mission may explain the reach and the anticipated breadth of the EPIC program data. The established geographic, thematic, and linguistic networks were advantageous to efficiently channel and coordinate information from the field. Through 2 programs (*convention programs*) that aim to structure and reinforce the local capacities of 5 geographical networks in terms of services, research, and advocacy, and cofunded by the Agence Française de Développement (AFD), local coordinators, and CBRL team members, had a key role in centralizing and communicating information regarding the EPIC program. The CBRL team members based in the 5 geographical regions were able to closely follow the local implementation with the participating organizations. The CBRL also provided support for member organizations that are not part of these 5 geographical networks, including the research network, RIGHT PLUS, and the (linguistic) Lusophone network.

Although most of the organizations have previously participated in research studies, or have had a coordinating role, for some organizations, EPIC was a first-time experience having an active and lead role in the implementation of a research study. This is the case for the association Bésyp in Benin, which collected quantitative data from >200 transgender people, >600 MSM, and >50 CHWs through EPIC surveys. However, it is important to note that most of the participating organizations had extensive experience in conducting research and were instrumental in sharing their experiences and good practices within their regional networks. Such exchanges among the partner and member organizations are fundamental to knowledge sharing and capacity building within and across the Coalition PLUS networks. As the coordinating organization of the Lusophone network, Grupo de Ativistas em Tratamentos in Portugal, had a lead role in training and providing technical support for the organizations and overall coordination of the EPIC studies within the network. Importantly, the EPIC program represented not only a first experience with community-based research for many of the Lusophone network organizations but also an opportunity to collectively work on a research project, and in turn reinforce the structuration of the new network (created in 2019) and collaboration with Coalition PLUS. The ALCS in Morocco, one of the founding members of Coalition PLUS and coordinating organization of the MENA geographical network, was the first to conduct an EPIC study in the region. The ALCS was therefore able to share first-hand experience regarding study implementation during the webinar on qualitative methods with the other partners who were still in the preparatory phase of the study.

A project to capitalize on the EPIC program is currently underway to study and document the achievements and results obtained, lessons learned and good practices, the specificity of this research project compared with an academic research project, and to identify the key factors that contributed to the success of the project at the level of the association, at the level of the regional, thematic, or linguistic networks as well as within Coalition PLUS.

Innovation but Not Without a Cost

For the CBRL, this was the first experience in developing a community-based study within the context of a pandemic as well as developing a general study protocol that was made available to the members and partners of Coalition PLUS. As described elsewhere [34], the EPIC program was launched without a clear idea of how many organizations would implement the study or the human resources and financing needed to assure the technical support and follow-up generated from the high demand. Although the flexibility of the EPIC's

XSL•FO
RenderX

methodology likely explains, in part, its high uptake within the Coalition PLUS network, it also adds complexity to the overall study coordination and follow-up. The global coordination of the study necessitated the mobilization of all 15 members of the research team, in addition to the coordinating organizations of the Coalition PLUS networks. Depending on the level of experience of the participating organizations, customized support regarding training on good study practices, data collection and management, and analysis were provided. The technical support provided by the Coalition PLUS CBRL will continue as participating organizations prepare to disseminate the results. Other Coalition PLUS departments, such as advocacy, knowledge management, and services, will have greater roles as results are used to inform recommendations and better practices.

Another significant factor to be considered is the fact that the development of the study protocol and its implementation in 2020 was possible largely because of the Coalition PLUS' or partner organizations' own funds. The number of participating countries greatly expanded in 2021 thanks to a reallocation of funds to pandemic efforts within the context of the *convention-programs* financed by the AFD [34]. Although 4 attempts were made to obtain research grants, success was limited because of the innovative methodology and the fact that research funding bodies were reluctant to fund studies that had already been launched at the time of the grant application. Research funding bodies also insisted on a justification for the choice of participating countries, the study populations, and sample sizes. This community-based research study was therefore evaluated within the framework of traditional research studies and not within the context of an ongoing pandemic, which explained the necessity to implement a flexible methodology and certain choices regarding the study population and size. The balance between keeping the research focus on responding to local needs during the health crisis and limiting local implementers' potential exposure to COVID-19 while assuring scientific rigor has been touched upon elsewhere [35]. In addition to cofunding from the AFD, funding from the French Agency for Research on AIDS and Viral Hepatitis (*ANRS-Maladies infectieuses émergentes*) was secured to cofinance the qualitative data collection, analysis, and scientific dissemination of the EPIC program in the MENA region. Finally, funding was also secured from the Robert Carr Fund for the organization of 3 workshops for the presentation and discussion of the EPIC results from the West African and MENA regions. Minor local financing or other support for the EPIC program was obtained by some participating organizations through national institutions or through the contribution of resources from universities.

Strengths and Limitations

Impelled by the urgency to identify and document emerging needs among KP at the start of the COVID-19 health crisis, the EPIC research program was developed following alerts from Coalition PLUS member and partner organizations. It was a research program guided by the principles of community-based research at its start and will continue to be throughout the research process. In line with the community-based research approach, the study populations and themes covered in the questionnaire or interviews were determined by the partner organizations in accordance with local needs. Therefore, the major strength of this program is the relevance of the study results to the local context. In addition, data regarding the impact of the COVID-19 crisis among KP at the local, regional, and global levels are particularly important to provide visibility to populations that are rarely represented in general population surveys. Furthermore, the EPIC data will capture precious information regarding the innovations or solutions that were put into place to maintain services during the crisis. This information could help support the sustainability of these solutions outside the COVID-19 crisis. The Coalition PLUS geographical and thematic networks aided in the (regional) coordination and implementation of the study. The collection of quantitative and qualitative data will provide more robust data to explore the experiences of KP and CHWs. Finally, implementation of this study, particularly by organizations that had little or no prior experience leading the local implementation of a research study, provided an opportunity for capacity building in research among the Coalition PLUS member and partner organizations.

The development and implementation of the EPIC program during a global pandemic has created several limitations that should be considered. COVID-19–related restrictions resulted in delays for ethics approvals and complicated data collection for some partners, sometimes resulting in a data collection period that spanned several months. Information regarding the state of the COVID-19 pandemic (eg, the epidemiological situation and governmental measures in place) at the time of data collection will be considered in the analyses to minimize potential bias. As each participating organization was able to construct their questionnaire or questionnaires according to local needs, there may be some limitations regarding the themes that can be explored in the global analyses. Thematic, regional, and global analyses will be performed whenever possible. Finally, some analyses will be limited owing to the sample size. Although it may not be possible to perform advanced data analyses in such situations, descriptive analyses will be performed and nonetheless will contribute important contextual information to broader common themes [37]. Analysis may also be limited owing to the quality of the collected data, particularly for qualitative data collection as it was a first-time experience in qualitative methods for many participating organizations. Although the literature on the implementation of multicountry qualitative research studies by previously untrained local implementors is limited, previous work suggests that implication of the local agents at the start of the study and continued support through the research process (including analysis) will help bolster the quality of the results [38]. In situations where the quality of EPIC data is not sufficient for in-depth analysis, efforts will be made to provide detailed feedback to the participating organizations to identify better practices.

Conclusions

The multicountry community-based EPIC program was developed by various stakeholders, including and with the continued engagement of communities at all stages of the research process. With the challenge of documenting the impact of the global health crisis among KP and the CHWs who work

XSL•FO
RenderX

with these populations, a general protocol was developed with a built-in flexibility that allowed the adaptation of the study to meet local needs. The deployment of this community-based research program within the Coalition PLUS network created the opportunity to not only collect data on the COVID-19 crisis but also to develop or reinforce capacity-building initiatives among the participating organizations through trainings, experience sharing, and continued technical support.

The EPIC program will provide essential information regarding the impact of the health crisis on KP at higher risk for HIV who are still little or not represented, depending on the geographical area, in the scientific literature. These results will therefore enhance community responses by capitalizing on new adaptations and innovations to HIV and viral hepatitis prevention and care services that may be pertinent beyond the current health crisis.

Finally, these data will also be essential to carry out national and international advocacy to ensure that KP are not forgotten in public responses to the current and future health crises. Thanks to the community expertise acquired in the field of HIV and hepatitis, it is anticipated that these data will show that the community-based response can be complementary to the public health response in a pandemic context and can continue to provide pertinent solutions for KP.

Acknowledgments

The authors would like to thank the participants of the EPIC program. The authors would also like to thank the organizations that participated in the EPIC program: Association de Protection Contre le Sida (APCS; Algeria); Amigos positivos (Colombia); Association African Solidarité (AAS; Burkina Faso); Abevamo (Mozambique); Ajuda de Desenvolvimento de Povo para Povo (ADPP; Guinea-Bissau); AIDES (France); Association de Lutte Contre le Sida (ALCS; Morocco); Asociación de Mujeres Meretrices de Argentina (AMAR; Argentina); Alliance Nationale Contre le Sida (ANCS; Senegal); Association “AnisS” de Lutte Contre le SIDA et de Promotion de la Santé (Algeria); Association Nationale de Soutien aux Séropositifs et malades du sida (ANSS; Burundi); Asocia ia Română Anti-SIDA (ARAS; Romania); Association pour la Résilience des Communautés pour l’Accès au Développement et à la Santé (Arcad Santé PLUS; Mali); Articulação Nacional das Profissionais do Sexo (ANPROSEX; Brazil); Associação São-tomense para Promoção de Planeamento Familiar (ASPF; Sao Tomé); Ass vida (Sao Tomé); Associação Brasileira de Gays, Lésbicas, Bissexuais, Travestis, Transexuais e Intersexos (ABGLT; Brazil); Associação das Profissionais do Sexo da Bahia (APROSBA; Brazil); Associação das Prostitutas de Minas Gerais (APROSMIG; Brazil); Associação Mulheres Guerreiras (Brazil); Association Tunisienne de Lutte contre les Maladies Sexuellement Transmissibles et le SIDA (ATL MST SIDA; Tunisia); Association Tunisienne de Prévention Positive (ATP+, Tunisia); Asociación de Travestis Transexuales y Transgéneros de Argentina (ATTTA; Argentina); Benin Synergies Plus (BéSyP, Benin); Colectivo Amigos Contra el SIDA (CAS; Guatemala); Casa trans (Argentina); CDR-CHU Annaba (Algeria); Centre d’estudis epidemiològic de les ITS i la sida de Catalunya (CEEISCAT; Spain); Central Única das Trabalhadoras e Trabalhadores Sexuais (CUTS; Brazil); Centro de investigación interdisciplinar en sexualidad, sida y sociedad (CIISSS; Peru); Cimientos de Luz (Colombia); Coalition des organismes communautaires québécois de lutte contre le sida (COCQ-SIDA) and the members of the COCQ-SIDA network (Québec); Coisa de Puta (Brazil); Coletivo Por Elas Empoderadas (Brazil); Coletivo de Pesquisa em Antropologia e Saúde-CPaS-FSP/USP (Brazil); Corporación El Faro (Colombia); Escuela de Salud Pública de la Universidad de Chile (Chile); Espace Confiance (Ivory Coast); Espoir Vie Togo (Togo); Fórum das ONG/Aids do Estado de São Paulo (FOaesp; Brazil); FUDAVIDA (Colombia); Fundación Huésped (Argentina); Fundación Organización Acción Humanista (OAH; Colombia); Fundación SAVIA (Chile); Fundación Shaddai (Colombia); Fundaroma (Colombia); Fundación Semillas de Cauca (FUNSEC; Colombia); Grupo de Ativistas em Tratamentos (GAT; Portugal); Grupo de mulheres prostitutas do Estado do Para (GEMPAC; Brazil); Hatutan (East-Timor); Fundación IFARMA (Colombia); Instituto para el Desarrollo Humano (IpDH; Bolivia); Jovens Unidos por Direitos Iguais e Humanos (Brazil); Kindlimuka (Mozambique); Kuyakana (Mozambique); Malaysian AIDS Council (MAC; Malaysia); Marsa Sexual Health Center (Lebanon); Movimento para o Acesso ao Tratamento em Mocambique (MATRAM, Mozambique); Montréal sans sida (Québec); Movimento de Prostitutas no Brasil (Brazil); MWENHO (Angola); Núcleo de Pesquisa em Direitos Humanos e Saúde da População LGBT+ (NHUDES; Brazil); Núcleo de Estudos da Prostituição (NEP; Brazil); Prévention Information Lutte contre le Sida (PILS, Mauritius); Prodihogar (Colombia); Recolvih (Colombia); Corporación Red Somos (Colombia); Rede Brasileira de Prostitutas (RBP; Brazil); Rede Nacional das Associações de Pessoas com HIV (RENAP; Guinea-Bissau); Responsabilité Espoir Vie Solidarité (REVS PLUS; Burkina Faso); SOS Pairs Educateurs (SOS PE, Mauritania); Stop. Correction of: https://www.researchprotocols.org/2022/5/e30496

(JMIR Res Protoc 2023;12:e47929) doi:10.2196/47929

In "Impact of a Postintensive Care Unit Multidisciplinary Follow-up on the Quality of Life (SUIVI-REA): Protocol for a Multicenter Randomized Controlled Trial" (JMIR Res Protoc 2022;11(5):e30496) the authors made three clarifications.

In the sample size section of the manuscript, the passage:

Therefore, we estimated that at least 50% had a very poor outcome, combining death and moderate to severe impairment of at least one EQ5D dimension

has been corrected to:

XSL•FO
RenderX

Therefore, we estimated that at least 50% had a very poor outcome, combining death and severe to extreme impairment of at least one EQ5D dimension.

In the sample size section of the manuscript, the passage:

The study was then powered to detect a decrease from 50% to 37% of patients with very unfavorable outcome with a power of 90% and a 2-sided 5% alpha risk, assuming this rate would be 50% in the control arm.

has been corrected to:

The study was then powered to detect a decrease from 50% to 37% of patients with very unfavorable outcome with a power of 80% and a 2-sided 5% alpha risk, assuming this rate would be 50% in the control arm.

In the "statistical methods" section of the manuscript, the passage:

The 1-year survival rate without major deterioration in QoL (main endpoint, defined as reporting of an extreme problem" level in 1 of the 5 dimensions studied) will be compared between both arms using a piecewise exponential model considering any censorship and the repeated nature of observations, prohibiting the use of conventional methods of analysis of censored data

has been corrected to:

The 1-year survival rate without major deterioration in QoL (main endpoint, defined as reporting of death or a severe to extreme problem" level in 1 of the 5 dimensions studied) will be compared between both arms using a piecewise exponential model considering any censorship and the repeated nature of observations, prohibiting the use of conventional methods of analysis of censored data.

The correction will appear in the online version of the paper on the JMIR Publications website on April 14, 2023, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 05.04.23; this is a non–peer-reviewed article;accepted 10.04.23; published 14.04.23.

Abstract

Background: Food allergy in children is increasing in prevalence in the western world and appears to become an important health problem. Parents of children at risk of food allergy live with the fear of allergic reaction, especially when the children are very young. The paradigm shift in allergy prevention in the last decade—away from allergen avoidance toward a tolerance induction approach—challenges both parents and health care professionals, as they have to deal with changing information and new evidence that often contradicts previous assumptions. Yet, research on health information–seeking behavior and needs of parents on primary prevention of food allergy in children as well as on prediction and prevention strategies of German health care professionals is lacking.

Objective: The aim of the study is to explore and understand parents' and health care professionals' perspectives on the prediction and prevention of food allergies. We are particularly interested in information needs, information seeking, and health care usage and place a special focus on families' experiences when their child is at risk or diagnosed with food allergies. Furthermore, food allergy prediction and prevention strategies of health care professionals will be explored.

Methods: This study is part of the NAMIBIO (food allergy biomarker) app consortium, which aims to identify early predictors for the development of food allergy in children and develop apps to guide health care professionals and parents of children with a high risk of food allergy toward prevention and timely tolerance induction. The study uses a qualitative approach with topic-guided interviews and focus groups with parents of children (0-3 years) and health care professionals. Data collection will continue until theoretical saturation is reached. The qualitative content analysis will be used according to Kuckartz to identify overarching themes toward information needs and seeking behavior as well as usage of health care and health care professionals' predictive and preventive strategies. In addition, a constructivist grounded theory approach will be used to explore and understand parents' experiences, interactions, and social processes in families in daily life.

Results: Recruitment and data collection started in February 2022 and is still ongoing.

Conclusions: The qualitative study will provide insight into parents' information-seeking behavior and needs regarding the prevention of food allergy in children, parents' use of pediatric primary care, and health care professionals strategies for the prediction and prevention of food allergies in children. We assume that our results will highlight the challenges associated with the paradigm shift in allergy prevention for both parents and health care professionals. The results will be used to make practical recommendations from the user's perspective and inform the development of the NAMIBIO apps.

Introduction

Background

Food allergies (FAs) are an important public health issue affecting children and adults and have been increasing in prevalence in the last 2 to 3 decades [1-3]. The estimated prevalence of food allergy in children (FAIC) in the western world is around 6%-8% [4]. The symptoms can vary from mild to severe, and in extreme cases, FA can lead to a life-threatening allergic reaction (anaphylaxis) [1]. Therefore, it is important to identify children at increased risk before the onset of clinical symptoms and prevent the development of FA. Genetic, epigenetic, and environmental risk factors are increasingly being clarified. This offers a potential for improved prevention and treatment strategies for at-risk groups and possibly all children [2,5]. Insights on pathophysiology reveal a complex interplay of the epithelial barrier, mucosal and systemic immune response, route of exposure, and microbiome among other influences resulting in allergy or in tolerance [6].

Currently, there is no cure for FAs [2]. Avoidance of allergens is the mainstay of management, along with patient education and provision of emergency medication (adrenaline auto-injectors) [2,7]. Prevention approaches based on new research highlight that a strict diet avoiding allergenic foods such as milk, egg, fish, or nuts is not a sensible allergy prevention intervention during pregnancy, breastfeeding, and complementary feeding. The aim is rather to introduce potentially allergenic foods at an early stage in order to promote tolerance induction [4,8].

This paradigm shift in allergy prevention—away from allergen avoidance toward a tolerance-induction approach [8-10]—challenges both parents and health care professionals (HCPs) as they have to deal with changing information and new evidence that often contradicts previous assumptions. Thus, different knowledge of (changing) guidelines, attitudes, and beliefs about FA may result in heterogeneous counseling practices [11] and prevention strategies [12] in pediatricians.

In Germany, pediatricians and midwives are an important source of information on newborn care and allergy prevention for parents [13]. However, parents also seek information from other sources, for example, websites and social media, which can lead to confusion when deciding which recommendation to follow [14,15]. In particular, those with limited access and information-seeking skills, as well as a lack of critical evaluation skills, have been identified as being disadvantaged when searching for health information on the internet [16,17].

Previous studies from other countries (the United Kingdom, Canada, and Australia) showed that parents' information needs regarding FA are often not met [18-20]. Hu et al [20] found that information needs and information-seeking behavior of parents with a child diagnosed with FA changed over the course of the disease. In particular, in the period after the diagnosis, parents wanted extensive information [20]. Other studies identified a strong parental need for recommendations on how to manage FA and on how to cope with fear and anxiety associated with the disease [18,19].

Chang et al [12] studied the beliefs and practices of general pediatricians from the United States regarding early peanut introduction. Physicians perceived important barriers to the implementation of the recommendations of the guideline. Among other things, they did not fully agree with the content of the guideline and also anticipated that parents would be skeptical. This corresponds to surveys from the United States, Brazil, and Canada, which revealed that awareness and implementation of guidelines on FA prevention varied widely among physicians [21-23].

Until now, there is no research on information-seeking behavior and needs of parents regarding the primary, early childhood prevention of FA as well as on FA prediction and prevention strategies of German HCPs.

Objectives

The objectives of the study are to (1) identify, conceptualize, and systematically describe (a) parental information needs, information seeking, and health care usage regarding prediction and prevention of FAIC and (b) HCPs' strategies on prediction and prevention of FAIC and (2) explore and understand how parents experience family life with children at risk of FA or with an existing FA.

Methods

Research Context

The study is a subproject of the Nahrungsmittelallergie biomarker (NAMIBIO) app consortium, funded by the German Federal Ministry of Education and Research (01EA2108A-E). The consortium aims to identify early predictors for the development of FAIC and to develop 2 applications to guide HCPs and parents of children at high risk of FA toward prevention and timely tolerance induction. NAMIBIO is a German acronym for Nahrungsmittelallergie biomarker ("food allergy biomarker"). The planned NAMIBIO digital health apps, "Parent app" and "Professional app," will provide an algorithm for individual prediction of children's FA risk and help parents of children at high risk of FA and their HCPs to manage their information needs and prevention efforts [24]. While there is an increasing availability of mobile health technology that focuses on FA management [25], to the best of our knowledge, until now, there is no app that focuses on the prediction and prevention of FAIC.

The results of this study will inform the development of the NAMIBIO apps.

Research Team and Reflexivity

Our subproject is jointly led and conducted by members of the Otto von Guericke University Magdeburg, Faculty of Medicine, Institute of Social Medicine and Health Systems Research and the University Children's Hospital Regensburg (KUNO) at the St. Hedwig Clinic, Hospital of the Order of St. John, University of Regensburg.

The project team consists of 2 leads (CA and SB), 4 research assistants with master's degrees (Public Health, Psychology, Sociology, and Social Work in the Aging Society, female), 1 postdoctoral researcher (Nursing Science, female), and 2 student research assistants (female). All team members have previous research experience and training in conducting qualitative research. In order to develop a common understanding of qualitative methods, we shared our prior qualitative research experience in a joint workshop during the elaboration of the study protocol. In this process, interviewing skills were further discussed and practiced as well as prejudices and preassumptions with regard to recruitment, data collection, and results were exchanged and recorded.

We are aware that qualitative research interviewers influence the interaction of the interviews. As interviewers, we want to display self-confidence in what we do, trust in the interview situation and what the participants will share with us, as well as inner tranquility that communicates interest and attention [26]. The participants will be informed about the reasons and aims of this study. We will also inform them that we (the interviewers) are part of the research team and where we are located (institute or university). We will not actively disclose personal information such as professional and research background and family situation (eg, children). Our credibility comes from active listening and asking relevant questions which are meaningful to our participants [26].

Study Design

The study uses a qualitative approach with topic-guided interviews and focus groups (Table 1). The qualitative content analysis approach according to Kuckartz will be used [27,28] and Charmaz constructivist grounded theory will be followed to develop a theory [29] of family life with children at risk of or diagnosed with FA.

Table 1. Study design.

Characteristics	Parent group	Health care professionals group

Participants	• Parents of children (0-3 years)
	  • Diagnosed with a FA[a]
	  • At risk of FA
	  • Without a known risk of FA
		• Health care professionals
		  • Pediatricians
		  • Allergists
		  • Pediatric dermatologists
		  • Gynecologists or obstetricians
		  • Midwives
		  • Nurses

Study design	• Qualitative approach	• Qualitative approach
Data collection	• Topic-guided interviews • Approximately 30 interviews	• Topic-guided interviews and focus groups • Approximately 15 interviews and 2-4 focus groups
Data analysis	• Qualitative content analysis according to Kuckartz [27,28] • Constructivist grounded theory according to Charmaz [29]	• Qualitative content analysis according to Kuckartz [27,28]
Dissemination	• Recommendations for the development of the NAMIBIO[b] apps	• Recommendations for the development of the NAMIBIO apps

[a]FA: food allergy.

[b]NAMIBIO: Nahrungsmittelallergie biomarker/food allergy biomarker.

Theoretical Framework

Within the social constructivist perspective, we work with sensitizing concepts from the social sciences, for example, "doing family" [30-32], "health literacy" [33], "the social amplification and attenuation of risk framework" [34], "burden of illness" [35], "access to health care" [36,37], "peer support among patient communities" [38], and "guilt" [39].

These concepts are preliminary tools and repeatedly stimulate our thinking about the topic (eg, raising questions for the topic guides) and the generated data (eg, while analyzing processes and actions or interactions). We will dispense with particular sensitizing concepts, if they prove to be irrelevant [29].

Participants

We focus on 2 different target groups—parents and HCPs: (1) The parent group includes caregivers (mothers or fathers) of children between the ages of 0 and 3 years diagnosed with FA, at risk of FA, or without a known risk of FA (Textbox 1). Participating parents receive 30€ (US $32.7) to compensate for their time and efforts. (2) The HCP group includes pediatricians, allergists, pediatric dermatologists, gynecologists or obstetricians, midwives, and nurses. Participation is remunerated with 80€ (US $87.2; Textbox 2).

XSL•FO
RenderX

Textbox 1. Inclusion criteria (parent group).

- Parents of children (0-3 years) diagnosed with a food allergy
- Parents of children (0-3 years) at risk of food allergy
  - Risk factors for food allergy in children
    - Preexisting allergies or allergic diseases, for example, allergic asthma and hay fever
    - Preexisting atopic eczema, especially one that starts early in life and is severe
    - Genetic or environmental risk factors for food allergy, for example, food allergy, atopic eczema, allergic asthma, or hay fever in the family history (first generation)
- Parents of children (0-3 years) without a known risk of food allergy
- Living in Germany
- Written consent form

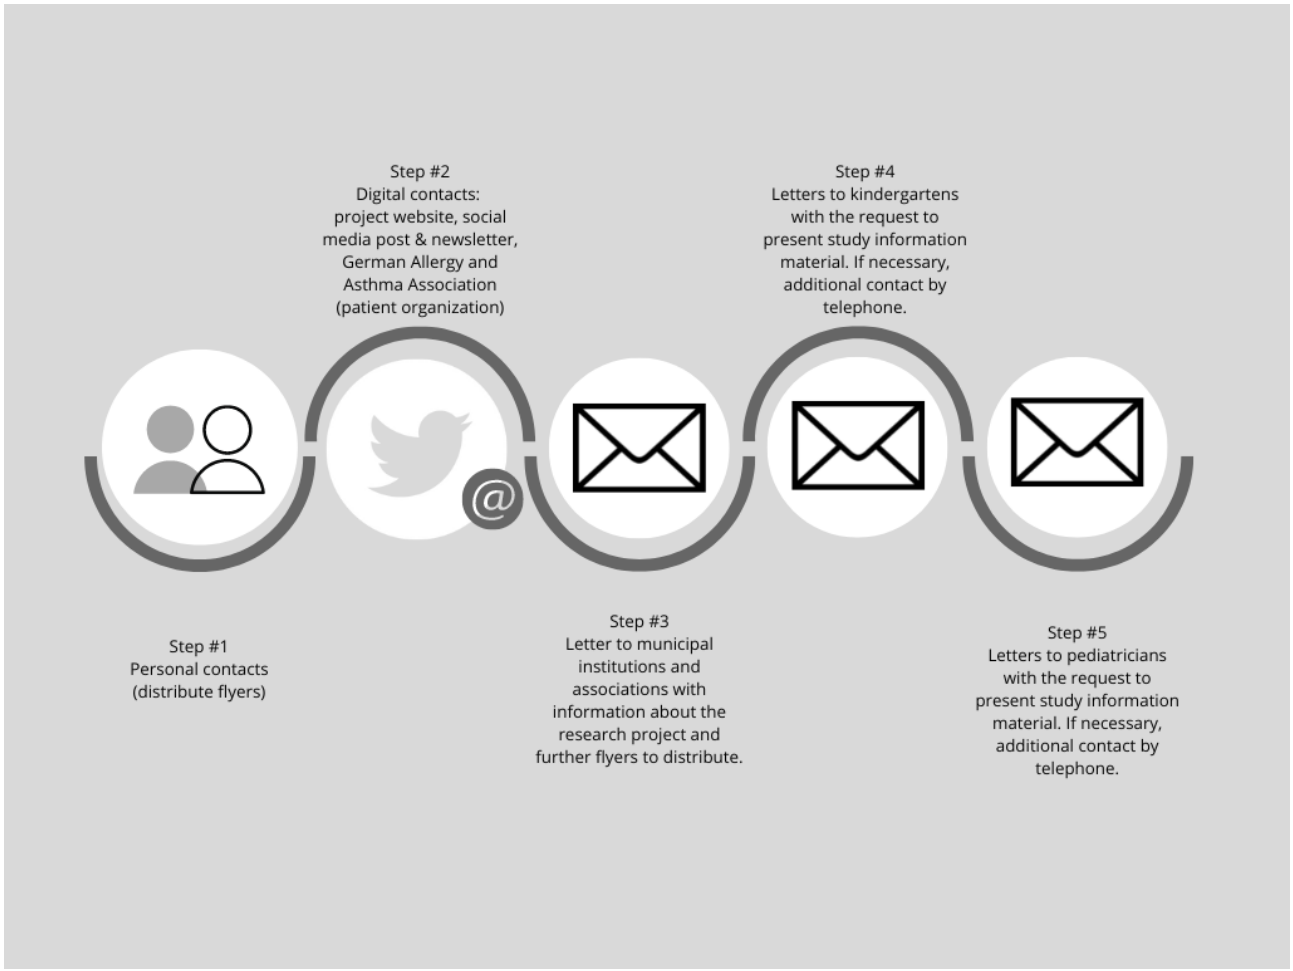
Textbox 2. Inclusion criteria (health care professionals group).

- Health care professionals: Pediatricians, allergists, pediatric dermatologists, gynecologists or obstetricians, midwives, and nurses
- Working in an inpatient or outpatient setting in Germany
- Written consent form

Recruitment Process

Figures 1 and 2 display the strategies for the recruitment of participants for the parents and the HCPs group.

We first established field access through personal contacts (in our families and professional environment) at the 2 projects sites in Germany—Magdeburg and Northern Saxony-Anhalt and Regensburg and Eastern Bavaria—which differ in sociodemographic and structural characteristics [40]. It was ensured that there is no personal relationship between the interviewer and the interviewee.



Afterward, we recruited through a snowball sampling, followed by theoretical sampling.

The snowball sampling provides a point of departure to find relevant material for the study. This offers first insights into different (perhaps opposing) perspectives of the field, for example, parents of children without known risk of FA and parents of children diagnosed with FA or pediatricians and allergists. In addition, snowball sampling can prepare the theoretical sampling in a narrower sense [41]. The selection of further “cases” (theoretical sampling) is primarily concerned with the elaboration and contrasting of the phenomena found. Accordingly, the criteria for initial sampling may differ from those we use while sampling theoretically. The goal is to collect information from different perspectives in order to arrive at a vivid and comprehensive representation of the phenomenon of interest [42].

The size and composition of the 2 target groups (parents and HCPs) are not precisely defined. We anticipate about 30 interviews with parents, as well as about 15 interviews with HCPs and 2-4 focus groups. We aim for theoretical saturation of our data. “Saturation” means that collecting fresh data no longer leads to new theoretical insights and does not reveal new characteristics of the core theoretical categories [29].

Figure 1. Recruitment strategy parents.

XSL•FO
RenderX

Figure 2. Recruitment strategy health care professionals.

Setting

Interviews and focus groups are conducted in person, by telephone, or via privacy-compliant videoconferencing systems (Webex, Cisco), and in light of applicable COVID-19 regulations. Parent interviews are conducted individually (mother or father) or as a parent or family interview according to participants' preferences.

Data Collection

The topic guides were developed for the interviews with parents and focus groups [43] with HCPs (Multimedia Appendices 1 and 2). The questions were phrased openly to provide only as much guidance in the narrative flow as is needed [44] and yet support the interviewers in data collection. In the focus groups, case vignettes were used (Multimedia Appendix 2) to stimulate narratives at the beginning. The short presentations represent hypothetical case descriptions to foster discussion among the participants.

The German Allergy and Asthma Association (patient organization) provided feedback on themes and questions. We will adapt the guiding questions as needed during data collection, for example, to check hunches about categories, clarify relationships between emerging categories, or identify variations within a process (theoretical sampling) [29].

Audio data are recorded as mp3 files. To better contextualize the insights gained from the interviews and focus groups, parents' sociodemographic data (year of birth, sex, nationality, marital status, country of birth, living situation, highest school or university degree, and employment or occupational status) as well as information on the HCPs' career (qualification and professional experience) were gathered. In addition, field notes were written after the interviews and focus groups, which provide space for the researchers' observations, perceptions, and further information.

Data Analysis and Reporting

The interviews and focus groups are transcribed verbatim. MAXQDA Analytic Pro 2022 (VERBI software for qualitative and mixed methods research) is used to support us in managing and coding the data.

For answering our first research question, we will identify, conceptualize, and systematically describe relevant themes on parental information needs and seeking as well as health care usage and HCPs' strategies on prediction and prevention of FAIC. A qualitative content analysis according to Kuckartz [27,28,45] will be applied. Kuckartz [27,28,45] describes different phases of data analysis that will be performed (Textbox 3). The procedure is rule governed and thus intersubjectively verifiable [27,45].

XSL•FO
RenderX

Textbox 3. Qualitative content analysis approach according to Kuckartz [27,45].

Step 1: Preparing the data, initiating text work, including attentive reading and marking interesting parts of the text, noting special features and evaluation thoughts, and creating initial case summaries
Step 2: Forming main categories corresponding to the research questions
Step 3: Coding data with the main categories
Step 4: Compiling text passages of the main categories and forming subcategories inductively on the data material; assigning text passages to subcategories
Step 5: Category-based analyses and presenting results
Step 6: Reporting and documentation

The second research question (investigating the family's experiences with children at risk of or diagnosed with FA) will be answered by using grounded theory methodology, which focuses on social processes and actions and interactions. Constructivist grounded theory [29] highlights shared meaning constructed by both participants and researchers. We use the 2 main types of coding of grounded theory: (1) initial coding, a strategy that helps us to conceptualize our ideas and (2) focused coding, which allows us to separate, sort, and synthesize our data. During initial coding, we study our transcripts line-by-line, (inter)action-to-(inter)action, or we adopt the narratives of our participants from time to time as in vivo codes [29]. Memoing on the interpretation and constant comparative analysis within and between interviews are used to confirm similarities and differences and push the analysis forward [29].

Weekly interpretative meetings including all researchers ensure an iterative process of data collection and analysis. Interpretations in groups are a discursive form (communicative validation) to establish intersubjectivity and comprehensibility [46,47]. At present, no respondent validation is planned.

Reportings will be based on COREQ checklist—consolidated criteria for reporting qualitative research [48]—that also guides the structure of this protocol.

Ethics Approval and Data Protection

The ethics approval was obtained for the study from the Ethics Committee of the University Medicine Magdeburg (184/21). Participation in the interviews and focus groups is voluntary. Participants receive information about the aims and contents of the study as well as data protection at the time of initial contact and afterward by email or post. They provide written informed consent prior to participation. All study activities are conducted in strict compliance with the European Union's General Data Protection Regulation and in accordance with the Declaration of Helsinki [49].

We are storing the data from the interviews and focus groups in a pseudonymized way. An independent trusted third party at the Medical Faculty of the Otto von Guericke University of Magdeburg manages data containing personally identifiable information (consent forms) and stores these data separately from the study data.

Results

The project was funded from June 2021. Data collection started in February 2022. Depending on theoretical sampling, data analysis will continue until spring 2023.

Discussion

The qualitative study will provide an in-depth insight into parents' information-seeking behavior and needs regarding the prevention of FAIC, how parents use pediatric primary care, and what strategies HCPs' use for prediction and prevention toward FAIC. The research team anticipates that the results will reveal challenges associated with the paradigm shift in allergy prevention for both parents and HCPs. We hope to be able to derive practical recommendations for the development of the NAMIBIO apps. Only by understanding the users' perspective and the family's experience with children who are at risk or diagnosed with FA, apps can be developed that correspond to the users' everyday needs and accepted by them.

The results will be disseminated through scientific publications, social media (Instagram and Twitter), and at national and international conferences of health services research and allergy.

When we started the recruitment for our study, it was assumed that potential participants might have difficulties understanding the overall goal of the NAMIBIO app consortium. Since there is no direct objective-added value from participating in the study, we expected that it would be easier to recruit informed and engaged people to participate in the study. We assumed that mothers with a high level of education would be more likely to feel addressed in the recruitment process. In addition, we also anticipated difficulties in recruiting HCPs, especially because of both a lack of time and interest.

By now, we were able to recruit a diverse sample of parents and pediatricians in terms of age and personal or occupational experiences, capturing a variety of different perspectives. Our in-depth interviews and focus groups lasted up to 90 minutes. We followed all the steps of the recruitment strategies. Currently, it appears very difficult to recruit parents with a migration history and low level of education, especially fathers.

For this reason, the recruitment process is still ongoing. While we may not be able to overcome these challenges completely, we have launched a social media channel (Instagram: namibioapp) and ensured that we address organizations that have special access to the groups relevant to our study, in

XSL•FO
RenderX

particular family and childcare institutions. Furthermore, we have adjusted the recruitment material. To gain better access to parents whose child has no known risk of FA, a broader approach focusing on general child health is used. In a preliminary contact, we inform about our study and ask about the risk factors for FAIC. In addition to German, the flyers are now also available in English, Turkish, Arabic, and Russian.

Abstract

Background: There has been significant interest in global health in low- and middle-income countries (LMICs) among individuals living in high-income countries (HICs) over the past 30 years. Much of the literature on global health engagements (GHEs) has been presented from the perspective of individuals from high-income countries. Local stakeholders such as health care workers and health care administrators represent critical constituencies for global health activities, yet their perspectives are underrepresented in the literature. The purpose of this study is to examine the experiences of local health care workers and administrators with GHEs in Kenya. We will explore the perceived role GHEs play in preparing the health system to address a public health crisis, as well as their role in pandemic recovery and its aftermath.

Objective: The aims of this study are to (1) examine how Kenyan health care workers and administrators interpret experiences with GHEs as having advantaged or hindered them and the local health system to provide care during an acute public health crisis and (2) to explore recommendations to reimagine GHEs in a postpandemic Kenya.

Methods: This study will be conducted at a large teaching and referral hospital in western Kenya with a long history of hosting GHEs in support of its tripartite mission of providing care, training, and research. This qualitative study will be conducted in 3 phases. In phase 1, in-depth interviews will be conducted to capture participants' lived experience in relation to their unique understandings of the pandemic, GHEs, and the local health system. In phase 2, group discussions using nominal group techniques will be conducted to determine potential priority areas to reimagine future GHEs. In phase 3, in-depth interviews will be conducted to explore these priority areas in greater detail to explore recommendations for potential strategies, policies, and other actions that might be used to achieve the priorities determined to be of highest importance.

Results: The study activities commenced in late summer 2022, with findings to be published in 2023. It is anticipated that the findings from this study will provide insight into the role GHEs play in a local health system in Kenya and provide critical stakeholder and partner input from persons hitherto ignored in the design, implementation, and management of GHEs.

Conclusions: This qualitative study will examine the perspectives of GHEs in relation to the COVID-19 pandemic among Kenyan health care workers and health care administrators in western Kenya using a multistage protocol. Using a combination

XSL•FO
RenderX

of in-depth interviews and nominal group techniques, this study aims to shed light on the roles global health activities are perceived to play in preparing health care professionals and the health system to address an acute public health crisis.

Introduction

Background

Over the past 30 years, there has been growing interest in global health volunteering and service-learning trips in low- and middle-income countries (LMICs) among individuals living in high-income countries (HICs) [1,2]. This is reflected in a large increase in the number of colleges, universities, and medical schools that offer programs of study and experiences in global health to their students. Across the United States, educational institutions of all sizes have begun offering global health programs to undergraduates and graduate students [3,4]. The desire for global health experiences is also observed among American medical students, 31% of whom reported having a global health experience in medical school in 2015, up from just 15% in 1998 [5].

Global health activities taking place in LMICs vary widely, with short-term clinical services being among the most commonly described in the literature, particularly among medical trainees [6,7]. The terminology used to describe these programs also varies considerably, with "international medical electives," "short-term medical missions," and "short-term experiences in global health" being just a few terms used to describe these activities [8-13]. The term "global health engagements" (GHEs) perhaps describes these activities in more comprehensive and inclusive terms and provides consideration to the fact that interest in global health has not been limited to the boundaries of higher education, or to those with specialized clinical skills. Religious organizations, civic clubs, nongovernmental organizations, corporate groups, and even for-profit volunteer placement companies have offered GHEs for those without specialized skillsets to participate in global health volunteering abroad [14]. As such, opportunities abound for both skilled health professionals and nonskilled lay people to travel to LMICs to participate in global health activities, including medical missions, service-learning projects, and a wide range of volunteer service activities [15,16]. Ranging from a few days to several weeks, GHEs take place in LMICs around the world with varying degrees of coordination with local stakeholders [7,11,14]. A core challenge of GHEs is that traveling volunteers often lack adequate training and preparation to work in the environment, regardless of their educational background or prior training, and are frequently sent into LMIC settings without formal needs assessments having been conducted nor adequate consultation with in-country stakeholders regarding local needs. This implies that many global health interventions may be subjective solutions posed by HIC participants rather than bidirectional efforts to address local needs and priorities [17-20].

GHEs are big business. Fueled by a growing awareness of global issues and participant motivations of "giving back" and "doing good," annual expenditures on GHEs have been estimated to be well in excess of US $3 billion from the United States alone [10]. A significantly increased interest in GHEs in recent years has prompted increased scientific inquiry and academic analysis on the subject. GHEs have been generally portrayed as providing value to the health care systems of LMICs, although objective assessments of these activities are infrequent [11]. A common critique of GHEs focuses on ethical concerns, in that they might allow an opportunity for students and nonskilled volunteers to "practice on the poor" by providing care beyond their skillset [21]. Recently, experienced global health practitioners have sought to bring greater awareness of this and other ethical concerns and have called for the development of guidelines for ethics training, predeparture preparation, and management of participants to improve the otherwise largely unregulated activities in GHEs [4,11,22,23]. Recent critiques of these questionable practices have also brought attention to inequities in global health activities. It has been argued that GHEs perpetuate colonial mindsets and power asymmetries between HIC and LMIC individuals and organizations [24,25]. In recent years, there has been growing awareness to examine these inequities in an effort to "decolonize" global health practices in favor of more equitable practices, including greater decision-making regarding the management of GHEs. Despite increased interest to critically evaluate global health practices through the lens of decoloniality, much of the scientific literature on global health efforts and GHEs has been presented in overwhelmingly positive terms, and largely from the perspective of HIC participants [11,14].

Examples of recent studies focused on HIC individuals participating in GHEs include those examining satisfaction and motivations for participation among volunteers; the impact on long-term career paths for students; and cultural competency skills development [26-29]. In addition to allowing HIC individuals to build their resumes, engagement in GHEs provides participants (particularly medical trainees) the ability to see tropical diseases firsthand or to develop cross-cultural communications skills in an effort to promote themselves as well-rounded and experienced candidates in the job market [4,15]. HIC participation in GHEs has also been shown to influence career choices, leading participants to choose careers in public service [30-32]. Although examining GHEs from the perspective of HIC participants is important, these individuals make up only a small portion of the total number of stakeholders

XSL•FO
RenderX

involved with global health activities occurring in LMICs. Local stakeholders, such as health care workers and health care administrators, represent a critical component of GHE activities, yet research focused on their perspectives is far less common. A recent literature review revealed only 31 studies reporting local stakeholder perspectives from LMICs, mostly consisting of multicountry surveys from LMICs around the world, although none focused solely on Kenya, despite the regular occurrence of GHEs in this setting. Studies of GHEs have shown that LMICs are often recipients of GHEs due in part to longstanding social, cultural, and political ties between institutions and communities within the host country and the sending country [6,14,15]. Since 1964, Kenya has maintained favorable and consistent diplomatic relations with the United States following its independence from Britain in December 1963 [33]. This long history has no doubt contributed, at least in part, to many Americans' perception of Kenya as a safe and stable country—a factor also known to attract GHEs [14]. Kenya's status as an English-speaking country and a top-notch safari destination are possible considerations that make Kenya an attractive location for some individuals pursuing GHEs, while others may be drawn to global health "hotspots" on the African continent due to (perhaps misguided) perceptions of needs related to poverty or health crises [15]. Whatever the motivations, Americans and other HIC individuals pursuing GHEs have maintained a notable and sustained presence in Kenya in recent decades.

COVID-19 Global Pandemic

The advent of the COVID-19 global pandemic significantly disrupted day-to-day activities around the world, including global health activities in Kenya [34]. This unprecedented shift has impacted local health care workers, health care administrators, and the health systems in which they work. Like in many other countries, health care workers in Kenya have experienced increased stressors, anxiety, insomnia, depression, and burnout [35-37]. Although occupational challenges are being increasingly well documented, far less is known about the potential new understandings health care workers and health care administrators are gaining as they make meaning of their work, the health care system, and the role of global health activities in relation to the COVID-19 pandemic in Kenya. We developed our study protocol to leverage the unique and unprecedented opportunity to explore how health care workers and health care administrators understand their new reality working in an environment where GHEs, which were previously ubiquitous, have greatly declined over a significant period of time. In this study, we will ask participants to reflect on their history with GHEs and consider how prior experience with these activities may have shaped them professionally, and the health system broadly, to provide care in the face of the COVID-19 pandemic. Findings from this study may contribute to the field of global health research by providing a more nuanced understanding of the roles—expected or actual—GHEs play in the professional lives of those working within LMIC health systems, as well as their perceptions of the functioning of the system itself. The paucity of current research on local LMIC stakeholder perceptions of GHEs means that far less is known about how individuals make meaning of these activities in comparison to their HIC colleagues. Understanding the local perspectives of GHEs and global health inequities is of increased importance in the era of the COVID-19 pandemic. Further research to examine GHEs from the local perspective is necessary to paint a more complete picture of how these activities are perceived by those who host and manage global health activities in Kenya, particularly in the context of the pandemic.

Study Aims and Objectives

The purpose of this study is to examine local health care workers' and administrators' experiences with GHEs in Kenya and the role they are perceived to play in preparing individuals and the health system to address the COVID-19 public health crisis and their unfolding role in pandemic recovery and its aftermath. The primary aim of this study is to examine how Kenyan health care workers and administrators interpret experiences with GHEs as having advantaged or hindered them and the local health system to provide care during the COVID-19 pandemic.

Our study protocol is guided by the following research questions: (1) In what ways have GHEs affected health care workers' and administrators' professional lives and their perceptions of the local health system? (2) How have previous experiences hosting GHEs positioned these individuals and the health system to deliver care during the COVID-19 crisis? and (3) What are stakeholder priorities with regard to the design, implementation, and management of GHEs in Kenya in the future?

To achieve the primary aim of our study, one-on-one in-depth interviews will be conducted among health care workers and administrators in the fields of pediatrics, adult medicine, and mental health care. Interviews will explore how participants make meaning of prior experiences of GHEs in relation to their work in a health system under the stress of a public health crisis. Their reflections may reveal new insight into the role GHEs may play in strengthening the capacity of the health care system as well as those who work within it.

A secondary aim of this study is to identify stakeholder priorities and explore recommendations for future GHEs to achieve maximum benefit in the health care system after the COVID-19 pandemic. We will achieve this aim by using a group consultation process, nominal group techniques (NGTs), followed by one-on-one in-depth interviews. NGTs use a highly prescriptive, multistep process that engages each group participant individually and gives equal voice across the group, thereby minimizing opportunities for stronger personalities to dominate conversations and influence group dynamics. NGTs were chosen in lieu of focus group discussions for several reasons. Primarily, NGTs offer a high level of efficiency in achieving group consensus in comparison to focus groups, which can be significantly impacted by group dynamics, dominant personalities, and biases of participants and researchers [38]. Equally important in the selection of NGTs is their proven use in research in health care research, including among individuals working in health care in the African context [39-43]. In our study, NGTs will be used to generate a prioritized list of recommendations among health care workers and administrators, which will be examined further in subsequent in-depth

XSL•FO
RenderX

interviews. In-depth interviews will identify potential strategies to implement recommendations generated during NGT activities. Together, these methods will result in stakeholder-identified priorities as well as actionable strategies necessary to implement recommended innovations for future GHEs in Kenya.

Methods

Study Design

Qualitative methods are particularly well-suited to understanding disruptive social events, including disasters and crises, to explore meaning-making and the experiences of those living through these events [44]. Using 2 qualitative methods, our study will explore the perceptions of GHEs among individuals and groups from 2 key stakeholder groups who were particularly impacted by the COVID-19 public health crisis: health care workers and health care administrators. Conducted in 3 phases, our study will ask participants to reflect on their experiences working in the health care system prior to and during the COVID-19 pandemic to examine how their understandings of GHEs have shifted. Participants will be asked to consider how the presence of GHEs or lack thereof may have benefited, or disadvantaged, them to provide care during an acute public health crisis. Our research will also explore participants' opinions, views, and perspectives on the essential elements of GHEs that are beneficial, as well as identify the aspects of these activities in which innovations can be made to improve their design, implementation, and management in the future.

Using in-depth interviews, phase 1 of the study will explore perceptions of, and experiences with, GHEs among frontline health care workers (eg, nurses and physicians) and health care administrators (eg, individuals responsible for decision-making and the day-to-day management of health care facilities). The research team will use NGTs in phase 2 to develop a stakeholder-prioritized list of actions and recommendations that can be used in future GHEs in Kenya. Similar to focus groups, NGTs are used to gather input from stakeholder groups regarding a specific topic of interest. Unlike focus groups, which rely on group discussions guided by a facilitator, NGTs use a highly structured protocol where participants are individually asked to generate ideas, discuss them as a group, and rank or score those ideas. This results in building consensus on the discussion topics, which can be used to determine priorities for action to solve problems. This is a useful method to compare the viewpoints and priorities of stakeholder groups. Two NGTs will be conducted in this study, 1 for each of the 2 stakeholder groups (ie, health care workers and health care administrators). Phase 3 will use another set of in-depth interviews to further explore potential recommendations identified in phase 2 regarding the design, implementation, and management of GHEs in pandemic recovery and beyond. The findings will offer insight from the local perspective regarding the role GHEs play in local health systems in Kenya and provide critical stakeholder input on the management of future GHEs.

Study Setting

Participants will be recruited from the flagship hospital of a network of health care facilities, which regularly hosts a wide variety of global health activities, headquartered in the Kenyan city of Eldoret, in Uasin Gishu county [45,46]. The network of health care facilities began with a single facility through a partnership of universities in Kenya and the United States. Established in the early 1990s in response to the HIV/AIDS crisis in Kenya, it now comprises a network of more than 800 care facilities across western Kenya. Today, this system provides primary and specialized health care to more than 8 million people, including more than 150,000 in its flagship HIV/AIDS program, and pursues a tripartite mission of providing health care and training and conducting research in partnership with many universities across North America [47]. For the past 30 years, this health system has had a consistent flow of North American faculty, researchers, clinicians, students, and affiliated personnel to participate in global health service and learning opportunities in the fields of medicine, pharmacy, dentistry, nursing, child health, and myriad other health professions. The constant presence of these HIC individuals over the past 3 decades makes this setting ideal to study local perspectives on GHEs and perceived impact of the COVID-19 pandemic on the health system.

Ethics Approval

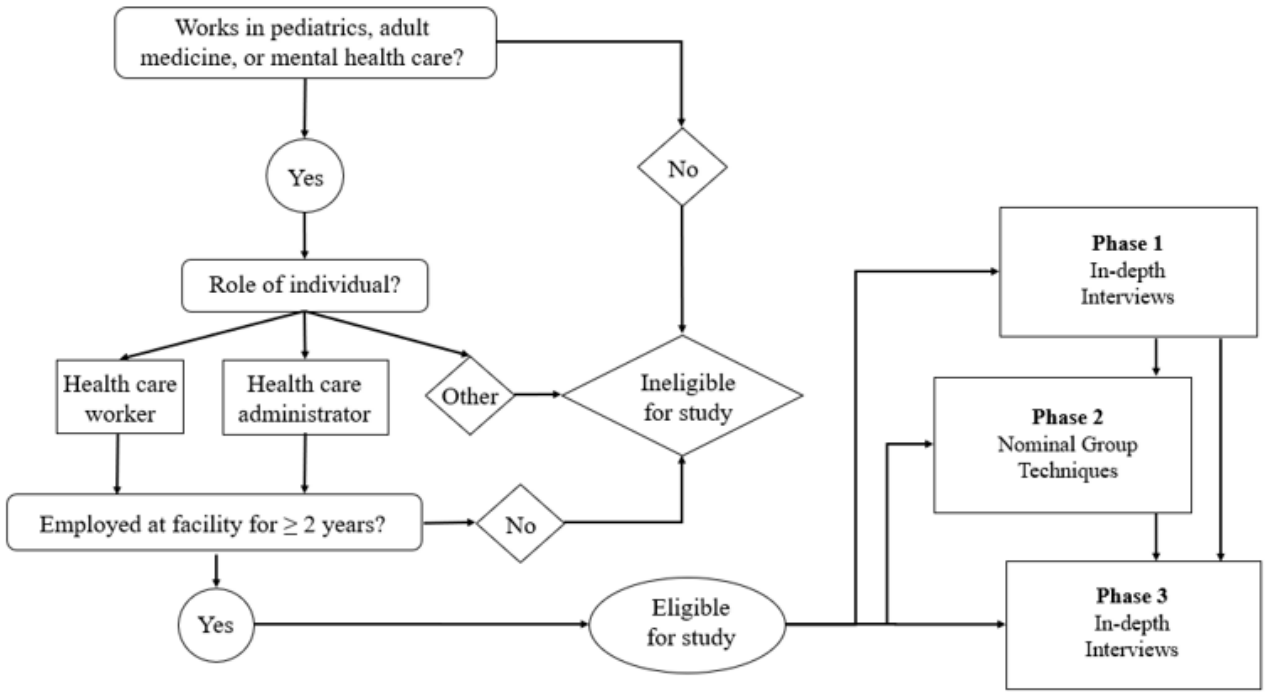
The research procedures presented in this study protocol have been approved by the Northern Illinois University Institutional Review Board (HS21-0286) and Moi University's Institutional Review and Ethics Committee (IREC059/2021). Protocols were also reviewed by the study site's research working groups, which are responsible for vetting research conducted at the network's facilities prior to ethics reviews. Protocols have been approved by the behavioral and social science and public health and primary care working groups for primary and secondary review, respectively. A national research permit was also secured from Kenya's National Commission for Science, Technology, and Innovation (NACOSTI/P22/16944).

Study Participants

Health care workers and health care administrators were selected as the 2 primary categories of stakeholders of interest for this study because they offer 2 very important, yet potentially different perspectives, on GHE activities at health care facilities in western Kenya. This cross-sectional approach has been commonly used in health science research in African settings, including Kenya, and was chosen because it creates opportunities for a more comprehensive exploration of a broad range of perspectives than otherwise possible from a singular cadre of stakeholders [48,49]. First, as decision-makers and managers, health care administrators stand to offer viewpoints rooted in leadership and organizational perspectives, particularly in relation to carrying out activities and achieving the health care network's tripartite mission. Their "30,000-foot view" can provide insight into the design and implementation of GHEs as well as the "how and why" decisions are made regarding them. In contrast, health care workers and other frontline staff offer different, much more granular perspectives of GHEs and can provide an up close and personal look at these activities. Frequently working alongside individuals pursuing GHEs, individuals in this stakeholder category have firsthand knowledge of the challenges and opportunities created by these activities and understand how they influence clinical

XSL•FO
RenderX

environments for both patients and local providers. Collectively, both of these stakeholder groups offer an opportunity to explore perceptions on GHEs in Kenya during the COVID-19 pandemic.



We will recruit participants aged 18 years or older who are proficient in English, have worked at target facilities for a minimum of 2 years, and have either direct interaction with global health activities or have firsthand knowledge of their impact on their clinical facility and wider network's system. Inclusion criteria include being a health care worker (eg, nurse, physician, and other clinical staff) or a health care administrator (eg, "in-charge" staff, facility leadership and management, other administrative staff) working in facilities providing pediatric, adult medicine, or mental health care services. Exclusion criteria include those aged younger than 18 years; those without the ability to speak English; individuals working at the target health facilities for less than 2 years; those without direct experience with, or knowledge of, global health activities in the facility; individuals who do not fall into the 2 stakeholder categories (ie, health care workers and health care administrators); and those working outside of pediatrics, adult medicine, and mental health care services.

Recruitment Procedures

To elicit a range of perspectives, participants will be recruited from among individuals working in the fields of pediatrics, adult medicine, and mental health care. Recruitment flyers will be posted in staff areas of targeted facilities and at selected staff gatherings (eg, staff meetings), where members of the research team will briefly share information on the purpose of the study and provide contact details. Interested parties will be invited to contact members of the research team to arrange eligibility screenings and to discuss study activities. Once eligibility has been established, potential participants can be recruited into 1 or more phases of the study based on the individual's interest and the study's ongoing recruitment needs. Simultaneous recruitment for all 3 study phases is intended to provide greater flexibility, improve efficiencies, and counterbalance potential challenges due to the attrition of participants over the course of study activities. Purposive sampling will be used to achieve a balanced range of perspectives of participants across stakeholder categories as well as gender [50]. As such, male and female participants will be recruited into the study in roughly equal numbers into each of the 2 stakeholder categories (ie, health care administrators and health care workers).

Figure 1 shows the recruitment eligibility decision tree for basic recruitment and eligibility guidelines for study participation.

Figure 1. Recruitment eligibility decision tree.

Informed Consent

All research activities, including the informed consent process, will take place in a private room and informed consent will be obtained prior to eligible individuals' engagement in any study activity. A member of the research team will provide eligible individuals with an overview of the nature of the study including that their participation is voluntary. Potential participants will be provided with all pertinent information including the study's purpose, procedures, risks, and benefits. A member of the research team will explain how confidentiality will be maintained, including the management and storage of data for future use. The individual will be provided with information on their rights as a study participant, including that their participation in the research study is entirely voluntary and that participation can be withdrawn at any point during study activities.

After being given the overview of the study and their rights as a participant, the individual will be given ample opportunity to ask questions and to seek clarification on any points that require

XSL•FO
RenderX

additional information. The potential participant will then be assessed to determine whether they understand the study. The research team member will assess the individual's understanding of the goals of the study by asking "Can you tell me what this study is about?" The individual will then be asked (1) to name things they will be expected to do during the study; (2) to explain what they would do if they no longer wished to participate in the study; and (3) to identify potential risks and benefits of participating in the study. Respondents will be enrolled only if they are able to provide clear and correct answers to each item.

The individual will then be given a copy of the informed consent document to read in full. After the person is done reading the document, they will be asked if they understand the form and will be given the opportunity to ask clarification questions. After satisfying any remaining questions, the individual will be asked if they would like to participate in the study. The individual will be enrolled in the study by signing, dating, and returning the informed consent document to the research team member. The participant will be given the option to have a copy of the informed consent form to keep for their own records.

Compensation

Eligible Kenyan health care workers and health care administrators will receive compensation for their time. Participants will receive 550 Kenyan shillings (approximately US $5) for each study component (ie, interviews and NGTs) in which they participate. Cash payments will be made at the completion of each interview or group activity.

Data Collection Procedures

Overview

All data collection activities will be administered by a team of trained Kenyan research assistants experienced in qualitative research methods. All one-on-one interviews and NGTs will be audio-recorded and transcribed verbatim. Transcripts will then be verified and deidentified by members of the research team. All study records will be assigned a unique identification number and will be uploaded and stored in password-protected files on a cloud-based encrypted file storage service.

Phase 1

One-on-one in-depth interviews will be conducted to capture participants' lived experience in relation to their unique histories and perspectives regarding GHEs and the local health system. Interviews will be conducted by Kenyan research assistants in order to facilitate an environment conducive to elucidating candid responses from participants. This is of particular importance given that previous research on stakeholder perspectives on GHEs suggests that participants are reluctant to make overly critical statements, particularly among HIC partners, for fear of losing access to resources and opportunities [51,52].

In-depth interviews will be conducted for the 2 stakeholder categories of interest: health care workers (target sample size: n=5) and health care administrators (target sample size: n=5). All in-depth interviews will be conducted in a private setting within the research areas of the study site, which is a teaching and referral hospital. In-depth interviews will be audio-recorded and will last approximately 1 hour. Interviews will conclude when questions or talking points (as outlined in research protocols) have been exhausted. Textbox 1 below outlines sample interview questions. Participants will be queried about their past experiences with GHEs and will be asked to provide their perspectives (beliefs, opinions, and viewpoints) on GHEs in Kenya. Participants will also be asked to reflect on how these activities have professionally shaped them, as well as the health system, to provide care during the COVID-19 pandemic (Textbox 1).

Textbox 1. Phase 1: sample interview questions.

- What have you learned about the Kenyan health system during the COVID-19 pandemic?
  - Probe: Strengths?
  - Probe: Weaknesses?
- In your view, how has the prior history of global health activities shaped the local health system to face events such as the COVID-19 pandemic?
  - Probe: Prepared the health system?
  - Probe: Hindered the health system?
- How has your own prior history with global health activities shaped you professionally to face events such as the COVID-19 pandemic?
  - Probe: Prepared you?
  - Probe: Hindered you?

Phase 2

Group discussions using NGTs will be conducted in phase 2 of the study. NGTs are administered through a structured, multistep process in which participants are asked to (1) generate ideas, (2) share ideas in round-robin format, (3) clarify ideas presented, and (4) rank the ideas presented. This consensus-building research method is used to determine stakeholder priorities for action to solve problems among communities of interest. NGTs are similar to focus group discussions; however, they have unique strengths, namely the ability to equalize groups of participants and minimize opportunities for individual participants from dominating or influencing the group dynamic. Using the round-robin format, NGT facilitators engage each

XSL•FO
RenderX

participant to speak one by one, creating an equal voice across the group and minimizing opportunities for stronger personalities to dominate the conversation [53]. Additionally, NGTs are noted for their usability and outputs, typically prioritized lists of actions, and can be a useful method to compare viewpoints and priorities of stakeholder groups [39]. NGT methods have also been shown to reduce researcher bias and have been applied frequently in health research, particularly among health care workers—including in sub-Saharan Africa [39-43,54].

A total of 2 NGTs will be conducted, 1 for health care workers (target sample size: n=8) and 1 for health care administrators (target sample size: n=8). Each NGT is anticipated to last between 2 and 3 hours and will be audio-recorded. NGTs will conclude after completing the steps of nominal group activities. The 8 steps outlined below describe the NGT process developed for this study:

1. Explain the process for NGTs: In the first step, facilitators will outlay expectations and answer questions participants may have regarding the process.
2. Silent idea generation: Participants will be asked to recall their past experiences with global health activities prior to the COVID-19 pandemic to reflect on aspects (eg, characteristics, policies, and management) to recall how these activities impacted them and their work, both positively and negatively. Participants will then be presented with the following prompt: "What changes do you feel are necessary for global health activities after the COVID-19 pandemic is over?" and will be asked to silently and independently generate ideas for 5 minutes.
3. Round-robin idea sharing: Participants share their ideas one at a time, 1 participant at a time. Participants may think of new ideas during this phase but can only share them at their designated turn. Ideas are recorded on a flip chart until no new ideas are uncovered.
4. Clarification: A brief discussion of ideas may follow for clarity of purpose for the ideas presented. Participants may ask questions of facilitators and other participants to clarify the ideas presented. Similar or overlapping ideas are grouped together and are discussed until all participants understand each concept presented.
5. Idea ranking: Participants are then asked to consider all the ideas presented and to vote in rank order based on their subjective determinations of importance. Participants are given a piece of paper to anonymously assign scores to the top 5 ideas according to their preferences. Scores will then be tallied by the facilitators and presented to the group for discussion. The number of ideas to be discussed will vary depending on how many ideas were generated in the second and third stages.
6. Discussion: Tallied scores are then presented to the group for a detailed discussion regarding the results. Participants will be invited to share their thoughts on the results. Participants can provide additional context to why certain ideas may have received higher scores and may ask questions of one another for clarification and to foster robust discussion. No new ideas will be introduced or discussed at this stage.
7. Reranking: After discussing results, participants will be asked to anonymously rank the ideas once more based on the discussion of the results from ranking in step 5. Participants will again assign scores to their top 5 ideas according to their preference in light of the recent discussion. Participants may remain consistent with their ranking selections or can change their selections according to changes in their opinions based on the discussion.
8. Sharing of results: Final scores will be tallied and presented to the group. The top-scoring ideas will be used as themes to explore in more detail through one-on-one in-depth interviews in phase 3.

Conventionally, NGTs are drawn to a close after a single round of ranking or voting and scores have been tallied (corresponding to step 5 in this study) [39]. Our study adds additional steps to include participants in a peer-to-peer discussion to further explore potential motivations behind their selections. The additional step for discussion (step 6) was added to this study to allow participants to engage with one another in dialogue similar to that of focus groups to share greater detail regarding their preferences for certain ideas over others. A second round of ranking (step 7) will provide participants with the opportunity to reassess their individual priorities in consultation with their peers. Collectively, these additional steps are intended to gather robust data to provide further insight into the groups' interests in prioritizing key areas of action in relation to GHEs.

Phase 3

One-on-one in-depth interviews will be conducted based on the ranked priorities identified in phase 2. A semistructured interview guide will be used to further explore the priority areas identified in NGTs. These in-depth interviews will serve as a means to closely examine the similarities and differences of ranked priorities between health care workers and health care administrators, as well as to explore the contextual nuances of NGT discussions. Phase 3 participants will be recruited into groups of key informants, health care workers (target sample size: n=5), and health care administrators (target sample size: n=5). All in-depth interviews will be conducted in a private setting, will be audio-recorded, and last approximately 1 hour. Interviews will conclude when questions and talking points have been exhausted. Participants will be asked to share their perspectives on potential innovations identified in phase 2 regarding the implementation and management of global health activities in the future. Data collected in phase 3 will provide insight into recommendations for potential strategies, policies, and other actions that might be used to achieve the priorities ranked with highest importance among the 2 stakeholder groups.

Data Analysis

The analytical plan will be conducted in 2 steps. First, trained qualitative researchers will conduct open coding of transcripts to identify emergent themes. Members of the research team will read all transcripts and develop an initial list of codes independently. In the open coding process, researchers will identify broad categorical themes that emerge among frequently used words and key phrases in the data. The researchers will then compare emergent codes during regular research meetings to eliminate duplicates and collapse overlapping codes.

XSL•FO
RenderX

Discrepancies in coding decisions will be discussed to determine consensus. Upon reaching a consensus, a codebook will be developed, which will be used to purposefully analyze the data. Qualitative analysis will be conducted by independent coders to explore the nuances of the data to develop themes and examine phenomena of interest to generate new concepts [55]. This approach is ideal for studies, such as this one, exploring under-researched areas of inquiry such as local perspectives on GHEs in Kenya [56]. Researchers will independently code approximately 20% of the transcripts and then compare the independently coded data. Interrater reliability will be established by achieving Cohen κ coefficient ≥80%. All qualitative analyses will be conducted using qualitative analysis software (NVivo; QSR International).

Results

The study activities commenced in late summer 2022, with the recruitment of participants began in August 2022. All 3 phases of this study, including 10 in-depth, one-on-one interviews in phase 1, 2 nominal group activities in phase 2, and 10 in-depth, one-on-one interviews in phase 3 were conducted between September 2022 and February 2023. In each phase, data collection and analysis were conducted concomitantly. The results are expected to be published in 2023.

Discussion

This qualitative study examines the perceptions of GHEs in relation to the COVID-19 pandemic among Kenyan health care workers and health care administrators working at a facility with a long history of hosting global health activities. It is one of the small but growing number of studies that examine the perceptions of GHEs in LMICs from the local host perspective, and this is the first study to our knowledge to do so in relation to the COVID-19 pandemic. The purpose of this study is to examine participants' experiences with GHEs in Kenya and the role they are perceived to play in preparing individuals and the health system to address the COVID-19 crisis and their unfolding role in pandemic recovery and its aftermath.

Data collected in this study will be critical to understanding participants' current and evolving perspectives on GHEs in relation to their work against the backdrop COVID-19 pandemic. Our multiphase study will examine how participants interpret their experiences with GHEs as having advantaged or disadvantaged them and the health system to provide care during a public health crisis, using one-on-one in-depth interviews in phase 1. The second and third phases of the study aim to identify stakeholder priorities and explore recommendations for future GHEs to achieve maximum benefit in the health care system going forward, using NGTs in phase 2, followed by one-on-one in-depth interviews in phase 3, respectively.

Applying a lens of decoloniality to global health research, our study elevates the voices of 2 stakeholder groups that are frequently involved in management and hosting activities associated with GHEs yet are currently underrepresented in global health perceptions literature [11,52]. The findings may reveal areas of strength and potential areas of growth for global health approaches in Kenya and perhaps other LMIC settings. Furthermore, the findings may provide critical data that can inform improved practices to overcome well-documented challenges in global health activities, including issues of equity in global health collaborations as well as sustainability and the effectiveness of programs [20,25].

This study has several strengths and limitations. A key strength of this study is its data collection methodology, which will use highly experienced Kenyan qualitative researchers for data collection to reduce potential bias. Another strength is the inclusion of 2 additional steps in the NGT process. Steps 6 and 7 in phase 2 of this study aim to elicit additional data to garner greater insight into reasoning and decision-making with regard to prioritizing key recommendations to be explored in phase 3. Limitations of this study relate to the contextual aspects of the study setting and its participants, which may limit the generalizability of study findings to other settings. The study site is the flagship hospital of a large, fairly well-resourced network of health facilities, which is not reflective of the wider Kenyan health care system. This could influence the perspectives shared by participants in this study. Likewise, participants will be recruited into 2 broad categories (ie, health care workers and administrators) from among individuals working in disciplines of mental health care, adult medicine, and pediatrics—it is unclear how individuals' professional views or occupational environments might influence the data. Therefore, the findings from this study may be specific to the local reality and may not be generalizable to other contexts elsewhere in Kenya, sub-Saharan Africa, or other LMICs.

In summary, this exploratory qualitative study will engage 2 key groups of Kenyan stakeholders to gain insight into the role GHEs are perceived to have played in preparing the health care system, and those who work within it, to provide care in an acute public health crisis. Informed by calls to decolonize global health, this study will provide valuable stakeholder-identified priorities and insight into improved practices for the management and accountability of GHEs going forward. The implications of which may provide greater clarity regarding the expected roles and intended purpose of GHEs in Kenya among those who are frequently involved in hosting these activities. A better understanding the role that GHEs play in the professional lives of LMIC stakeholders may shed light on the challenges inherent in hosting GHEs, ultimately informing the development of models for more equitable engagement of LMIC partners.

Acknowledgments

This study has been supported in part by research funds from Northern Illinois University College of Health and Human Sciences (EA); Indiana University's Emergency Equity Fund for Research (SB; Indiana University Office of the Vice President for Research); and Northern Illinois University's Open Access Publishing Fund (BWH).

Abstract

Background: Voluntary self-exclusion from gambling is a common but underdeveloped harm reduction tool in the management of gambling problems or gambling disorders. Large-scale, multi-operator, and operator-independent self-exclusion services are needed. A recent nationwide multi-operator self-exclusion service in Sweden (Spelpaus), involving both land- and web-based gambling sites, is promising, but recent data have revealed limitations to this system and possibilities to breach one's self-exclusion through overseas web-based gambling. More knowledge is needed about the benefits and challenges of such an extensive self-exclusion service, and its effects as perceived by gamblers.

Objective: This study protocol describes the rationale and design of a qualitative interview study addressing the effects and limitations perceived by individuals with gambling problems and their concerned significant others. The study aims to provide an in-depth experience of this novel self-exclusion service and to inform stakeholders and policymakers in order to further improve harm reduction tools against gambling problems.

Methods: Individuals with gambling problems will be recruited primarily through social media and also from a treatment unit, if needed, for a qualitative interview study. Recorded interview material will be analyzed through content analysis, and recruitment will continue until saturation in the material is reached. This study will provide in-depth information about a harm reduction tool that is promising and commonly used, but which has proven to be breached by a significant number of users, potentially limiting its efficiency. The aim is to interview a sufficient number of gamblers until saturation has been obtained in the interview material. Saturation will be considered through a continuous analysis, comparing recently collected data to previously collected data.

Results: Results will be reported as the themes and subthemes identified after the thorough analysis and coding of the transcribed text material and will be accompanied by citations representing relevant themes and subthemes. Results are planned to be provided before the end of 2023.

Conclusions: This study will likely provide new insights into user perspectives on a multi-operator self-exclusion service that involves both web- and land-based gambling operators, and which according to previous literature attracts many gamblers but also appears to have limitations and challenges in the target group of individuals with gambling problems. Policy and legislation implications, as well as clinical implications for treatment providers, will be discussed. Results and conclusions will be disseminated to policy makers in Sweden and internationally, as well as to peer organizations, treatment providers, and the research community.

Introduction

Gambling disorder (GD) is an addictive condition known to cause overindebtedness, mental health consequences, and psychosocial problems in affected individuals and their concerned significant others. GD is the first addictive condition not involving a substance, and it is defined both in the diagnostic manual of the American Psychiatric Association, the DSM-5 (the *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition) [1], and in the International Classification of Diseases (ICD) manual of the World Health Organization [2]. GD typically involves problematic gambling on either chance-based gambling modalities such as land- or web-based casinos, bingo or lotteries, sports or horse race betting, and poker or other card gambling. Severe consequences for family relationships are common [3], and psychiatric comorbidity is very common in individuals suffering from GD [4]. Likewise, GD is associated with overindebtedness [5] and with an increased risk of suicidal behavior including completed suicide [6,7]. GD can be treated using a psychotherapeutic approach, typically involving cognitive behavioral therapy, or through brief or more extensive motivational interventions or normative feedback interventions. Furthermore, pharmacological treatment strategies are applied, most commonly involving opioid antagonists. In addition, psychiatric comorbidities are fundamental to identify and treat [3]. However, treatment-seeking is typically low, and many patients with GD experience barriers against seeking treatment [8].

Voluntary self-exclusion from gambling venues or from web-based gambling sites is one preventive or harm-reducing strategy often applied. The concept behind this is the desire of individuals with gambling problems to control or discontinue their gambling behavior, that is, the voluntary choice to apply external control on gambling, in individuals who perceive a lack of control in their own behavior. Voluntary self-exclusion from gambling can be chosen by individuals regardless of whether they seek treatment or not. In addition, although people who choose self-exclusion typically may experience a gambling problem that they wish to control, self-exclusion may theoretically also be chosen by individuals without gambling problems. Previous data have revealed that individuals who choose to self-exclude have—in most but not all cases—gambling problems [9]. Thus, it is theoretically possible, although hitherto poorly demonstrated, that individuals without any gambling problems may wish to prevent themselves from developing potential gambling problems.

In many cases, self-exclusion services involve only one or a few land-based gambling venues or involve one or a few web pages of web-based gambling operators. Thus, a typical scenario is that a person with a GD chooses to self-exclude from that individual's most common gambling sites or as many sites as possible but may relapse into gambling on other gambling sites. One part of this challenge is the fact that self-exclusion services are often operator-based and therefore involve only the gambling services of a specific gambling operator. Thus, breaching one's own voluntary self-exclusion historically has been a challenge strongly limiting the efficacy of this harm reduction tool [10-13]. The highly diverse designs of such programs across countries and settings have been pointed out as a major limitation of this type of harm-reducing intervention [14]. In recent years, more transparent self-exclusion programs, easier to access, have been called for [15].

Based on these limitations, a new type of self-exclusion service, the Spelpaus service (literally "gambling break") was introduced in Sweden in 2019, as part of the introduction of a new gambling market. The new gambling legislation allowed for a large number of gambling operators, previously often operating over the internet from overseas settings, to obtain a license to operate in Sweden, provided they adhere to this national self-exclusion system and other responsible gambling practices [16]. Spelpaus is a unique self-exclusion service, as it (1) is nationwide; (2) involves all licensed gambling operators, both web- and land-based (currently around 80 different operators are licensed to operate in Sweden); and (3) is independent of the operators themselves, administered by a governmental institution and therefore possible to access without any contact with gambling operators.

The actual effects of the Spelpaus service have not been assessed in research. However, it has been documented that Spelpaus attracts a large number of people; around 95,000 people on a given day are reported to be self-excluded from gambling through this system [17]. Thereby, the number of people self-excluded through this service clearly surpasses the number of people believed to experience a GD at a given time (which may, despite discrepancies between methods of measure, reach a number in the order of 30,000) [18]. Thus, this service appears to attract many people [19,20], both in the general population and among people attending a GD treatment unit [21].

However, one experience of Spelpaus is the emerging data indicating that despite the multi-operator, nationwide nature of this service, breaching the self-exclusion appears to be common in individuals with a GD. This type of breaching typically involves access to overseas, unlicensed web-based gambling operators [21]. In one web-based survey study, 38 percent of self-excluded individuals reported that they had continued to gamble during the self-exclusion period, and web-based casinos were the most common gambling type reported by individuals who relapsed in that context [22]. Furthermore, in patients with a GD, gambling under another person's identity has been reported as a different way of breaching one's self-exclusion [21].

Thus, Spelpaus appears to be a potentially effective harm reduction tool in order to prevent gambling in patients with GD

XSL•FO
RenderX

or in people at risk of such problems, but major challenges regarding gambling outside of the jurisdiction appear to potentially limit the value of this service. However, given the popularity of this service, and the need to optimize harm-reducing interventions against GD, there is reason to study the effects and limitations of the self-exclusion service further. Hitherto, the experience of this new, unique self-exclusion tool is primarily based on quantitative research [19-22], whereas qualitative research may provide deeper knowledge about the lived experience of Spelpaus self-exclusion in individuals affected. Furthermore, the experience of concerned significant others has been little understood so far, and there is reason to suspect that the relationship of gamblers with their concerned significant others may change if they self-exclude in order to discontinue a problematic gambling pattern. Theoretically, the negative experience of concerned significant others from the gambling of their loved ones may be partly relieved if an external barrier can prevent the gambler from gambling further. In line with this, previous research has demonstrated that the choice of a person to self-exclude often involves the communication of this decision to the person's loved ones, or sometimes is even part of measures required by the family [9].

The study aims to describe the experience of the Spelpaus service in gamblers, in order to deepen the understanding of the utility and challenges of this harm reduction tool. The study will use a semistructured interview design, in order to obtain a deeper knowledge than can be achieved in quantitative survey studies.

Methods

Study Procedure

This is a semistructured, qualitative interview study including individuals who gamble and who have an experience of Spelpaus self-exclusion. Interviews will be carried out primarily over the internet (or in exceptional cases face-to-face). Interviews will be recorded and transcribed verbatim, and the text will be analyzed using a content analysis on a descriptive level [23]. Interviews will be carried out by the second author of this paper, who has extensive clinical experience in psychiatric nursing and experience in qualitative research interviewing. The interview structure has been tested, and thereafter adapted (Textbox 1), in a pilot interview conducted with a respondent with a history of gambling problems and involved in peer support of patients with GD.

XSL•FO
RenderX

Textbox 1. Semistructured interview guide. The interview guide is meant to guide the qualitative interview, and therefore, the conversation is likely to move away slightly from the exact wording of the questions, based on the responses and associations made by the interviewee. Closed-ended questions will be asked as if they introduce a potential topic into the interview, and will not be handled, in the interview situation, as dichotomous quantitative study items.

General introduction to one another, introduction to the topic of the research, etc.

- How old are you?
- Your gender (male, female, or other)?
- Your marital status (married, cohabitating, partner, or unmarried living alone)?
- What is your occupation?
- Which gambling types has/have been problematic for you? On how many gambling operators?
- Have you ever been in treatment for gambling problems? Which type of treatment?
- Have you ever had any problems related to the misuse of alcohol or drugs?
- Have you ever been in treatment (therapy or medication) for any kind of poor mental health?
- Tell me a little bit about your gambling problem. Why did you start gambling, and for how long have you had a problem? Which types of gambling have been involved, and on how many operators? Have you ever sought treatment, now or before? What type?
- How has your gamble influenced your concerned significant others (CSOs)?
- Tell me about your choice to self-exclude through Spelpaus? Which factors led to that?
- Did any of your CSOs have any influence on your decision to self-exclude?
- Do you have previous experience of other self-exclusion from gambling, before Spelpaus existed?
- How many times have you self-excluded, and for how long periods? Why did you choose those periods of time? Are you self-excluded right now, and for what duration?
- Tell me about your experience of Spelpaus. What has it meant to you, and to your CSOs? Do you believe it changed something for you? Did it reduce the inflow of gambling advertising, and how did that affect you? Which factors of Spelpaus have been favorable, and unfavorable, respectively?
- If you have received treatment for gambling problems, how has the Spelpaus self-exclusion affected that?
- Has your relationship with other people changed after your self-exclusion? How?
- Have you gambled during the Spelpaus self-exclusion? If no, which factors prevented you from that?
- After how long time of self-exclusion did you relapse into gambling? In what gambling types? Which were the factors in life that led to this gambling or which made it more difficult? In what way?
- Were you able to tell people that you had relapsed into gambling? How did that affect your relationship with these people?
- What's your general impression of Spelpaus? What works and what does not? What could be improved in this system?
- Is there anything you feel we have forgotten to ask, and that you would like to add when it comes to your own and your CSO's impressions of Spelpaus?

The analysis will be a content analysis, more specifically involving a text analysis of transcribed text, in order to interpret and provide an understanding of the narrative of the study participants. The analysis will be conducted according to the following sequence: (1) repeated reading of the entire transcribed text material, (2) coding of meaning units, (3) categorization of identified themes and subthemes, (4) provision of citations describing the categories, (5) calculation of the number of times a theme appears in the transcribed material, (6) comparison of interviews and identification of differences and similarities between them, and (7) the search for explanations to such differences. Analyses will be carried out by the second and third authors of this paper. The analytic procedure and discussions within the study group will aim to optimize trustworthiness in the analyses [24].

Study Questions

What is the lived experience of users who have been self-excluded through the Spelpaus service? Which have been the major advantages and the major disadvantages of self-exclusion in gamblers, and in which way has this been affected by the possibility of breaching one's self-exclusion through gambling on overseas gambling sites? Which potential improvements can be made to the Spelpaus self-exclusion service, according to users? What is the lived experience of gamblers who have self-excluded at Spelpaus, regarding how this has changed their relationship with their concerned significant others?

Study Participants

Study participants will be recruited through purposeful sampling. Individuals will be recruited because they are either (1) individuals recruited from social media advertising and who

XSL•FO
RenderX

have a gambling problem and experience of the Spelpaus self-exclusion service or (2) patients with a GD at the Gambling Disorder Unit of Region Skåne and who have experience of the Spelpaus self-exclusion service. Participants will primarily be recruited through social media recruitment. In case of a slow recruitment procedure, patients at the treatment unit will also be addressed with a question about their interest in taking part in the study. Participants receive a smaller economic compensation, in the format of cinema ticket gift cards. The study aims to recruit a sufficient number of gamblers for saturation to be obtained in the data material. This will include the aim to include participants with a wide variety of experiences concerning the Spelpaus service, including different reasons for self-excluding, and involving both women and men.

Saturation will be considered through a continuous analytic procedure, where collected data material is compared to previously collected data. Thus, no exact number of expected interviews can be decided and reported beforehand, and given the continuous process of assessing saturation, this may require the research group to add additional participants during ongoing analysis. However, based on our experience from previous studies, and based on the intention to assess potentially diverse experience and potentially experience in women and men, it has been reported in the ethics application that the final number of included clients may reach 20. Thus, despite this uncertainty, we expect the final number of participants to be in the range of 12-20.

Setting

The outpatient Gambling Disorder Unit in Region Skåne, Sweden, from which a minority of participants may be recruited, is one of very few units treating GD in a health care setting in Sweden, and has been described previously [21,25]. The unit is part of the Region Skåne Competence Center Addiction, which is a research and development unit closely related to an addiction medicine research group. This treatment unit welcomes patients aged 18 years and older, who experience gambling problems (typically diagnosed with GD [25]) and who live in the Skåne county, a region with a population of 1.4 million inhabitants. The facility is located in the city of Malmö, which is the most urban center of the region.

Ethical Considerations

The study has been approved by the Swedish Ethical Review Authority (overall project approved, file number 2022/06933-01, and amendment number 2023/01684-02 regarding change of interview guide and social media route of recruitment).

Study Preregistration

The study has been preregistered at ClinicalTrials.gov (NCT05693155).

Results

Results from this study are scheduled to be presented before the end of 2023. Findings will be reported as themes and subthemes, which will be identified after transcribing and coding the text material. Results will be accompanied by citations which will be selected to represent relevant themes and subthemes.

Discussion

Principal Findings

This study will be the first to examine, in a qualitative in-depth research design, the experiences of the present self-exclusion system, which is novel and relatively unique in international comparison. Given the novelty of the service, the study may have the potential to guide improvements in this self-exclusion service and the regulations around it.

Findings from this study will be disseminated both within the research community and to peer organizations addressing individuals with GD and their concerned significant others. In addition, findings will be discussed formally and informally with policymakers in government settings, public authorities, and with treatment providers and organizations involved in the prevention and early detection of addictive disorders. Furthermore, findings from this qualitative study are likely to inspire upcoming quantitative studies that can quantify and follow, over time, key aspects of gambling self-exclusion identified through this research.

Strengths

The possibility to address more detailed aspects of different reasons for self-excluding, other than what can be obtained through closed-ended quantitative study items, is one advantage of the qualitative study design. Another strength of this study is that it is the first to assess the present type of nationwide, multi-operator system which involves both land-based, traditional gambling types, and web-based gambling sites. In addition, it is conducted in a situation where web-based gambling, either within or without the jurisdiction in which the system is introduced, is likely a larger challenge than ever. Therefore, this study has the potential to add updated information about a novel type of system that meets challenges that have been less significant in older similar systems.

Limitations

Limitations of the study may be related to the recruitment procedure. As it is hitherto largely unknown which features may characterize individuals who self-exclude from the present type of self-exclusion service, other than people with manifest gambling problems, it is a challenge to reach the full variety of reasons for self-excluding or types of self-exclusion–related experiences. Therefore, wide social media recruitment has been chosen, although patients with a known GD at a treatment facility may also be added, in case of a slow recruitment procedure through the open social media channel. Thus, given the lack of knowledge so far, we have chosen a wide recruitment method but still, the inclusion of participants may potentially be biased by features of social media users and users who are specifically attracted by this type of study advertising. These aspects will be of importance to discuss in the analyses and the results reported in upcoming publications.
