Gaming technologies have displayed a high level of adherence and engagement characteristics, and this has led to the gamification of telehealth interventions. Gamification refers to the use of game design elements in nongame contexts and is being used across a variety of telehealth interventions to promote treatment adherence [15]. Within telehealth intervention, gamification elements provide immediate feedback, continuous progress reporting, points, badges, levels, challenges, competitive components, and avatar and profile functionality [15]. There is a broad appeal to including gamification elements in telehealth studies for multiple reasons, such as (1) supporting transition to increased levels of intrinsic motivation, (2) deliverability through multiple technology streams, (3) appeal across different audiences, and (4) appeal in health and fitness industries [15]. However, the impact of gamification features on redeemable rewards is unclear [26]. More specifically, it is unknown how individuals' intrinsic motivation will be affected by redeemable rewards. Within this study, participants will receive either gamified rewards or flat rewards. For those receiving gamified rewards, there will be an increase in the number of redeemable points the longer adherence and participation are maintained. Those receiving flat rewards will receive a fixed number of points for regular participation in the intervention. Elements of participation include but are not limited to logging in to the platform, interacting with the educational content, and watching multimedia content. These variations in rewards will inform whether gamification features alone promote a shift from extrinsic to more intrinsic motivation and whether this is associated with increased adherence and engagement or whether financial incentives are necessary to promote study adherence.

MOST Framework

Telehealth intervention studies typically use randomized controlled trial designs. However, telehealth interventions are comprehensive packages that include components such as coaching calls, educational content, texting, email, and mobile apps. Randomized controlled trials fail to reveal which components are responsible for any behavior change elicited during the intervention; rather, they only show whether the intervention package as a whole had any effect. Therefore, it is necessary to know which elements of telehealth interventions are needed or should be removed for a more efficient telehealth intervention. To optimize the My Health, My Life, My Way program, the MOST framework will be used to assess which study elements (coaching calls and gamification) elicit behavior change. The MOST framework, derived from engineering principles, is an efficient method to gather information on each intervention component or package and investigate whether the presence or absence of a component has an impact on the performance of other components [20,21,27]. Within this study, we will assess coaching calls (scheduled or on demand) and gamification (scaled rewards or flat rewards).

Intervention Design

The My Health, My Life, My Way study is a 2 × 2 randomized factorial experiment. By using the MOST framework, we can evaluate the effectiveness of different combinations of features within the My Health, My Life, My Way program, such as fixed versus gamified rewards and scheduled versus on-demand coaching calls. Eligible participants will be randomly assigned to one of four groups: (1) scheduled coaching calls with gamified rewards, (2) scheduled coaching calls with rewards independent of gamification, (3) no scheduled coaching calls with gamified rewards, and (4) no scheduled coaching calls with rewards independent of gamification (Table 1). For the study, 4 weeks is considered a month, thereby making the study duration 24 weeks. Study activities involving participants with disabilities will be conducted primarily on the web nationally in the United States.

XSL•FO
RenderX

Table 1. Research design.

Gamified rewards	Coaching calls	
	Scheduled coaching calls	No scheduled coaching calls
Gamification-based rewards	Scheduled coaching calls with gamified rewards	No scheduled coaching calls with gamified rewards
Rewards independent of gamification	Scheduled coaching calls with rewards independent of gamification	No scheduled coaching calls with rewards independent of gamification

Sample Size

We will use a 2 × 2 factorial design for this MOST trial (detailed in the Intervention Design subsection). Our sample size and power calculations for the primary outcome (health-related quality of life) assume an overall 2-sided type I error rate of 5%, 80% power, and an analysis of covariance–based approach with 2 independent dichotomous factors (ie, each factor has 2 levels). We will assume an attrition rate of 20%, with 160 (80%) participants completing the study (referred to as completers) from 200 participants enrolled. Under these assumptions, we will have 80% power to detect at least a minimally detectable difference (Cohen *d*) of 0.36 for the main effect or 0.18 in terms of the standardized regression coefficient. In these calculations, we assume a conservative correlation of 0.6 between the baseline covariate and outcome, which is similar to that in a previous study by Froehlich-Grobe et al [4]. In addition, 12 participants will be enrolled for pilot-testing the My Health, My Life, My Way program [28].

Recruitment

Recruitment will be conducted on the web nationally through the National Center on Health, Physical Activity and Disability (NCHPAD) website and its associated social media. The NCHPAD website has approximately 45,000 site visits per month, with most of the internet traffic flowing from the United States (74%). Through these mechanisms, interested individuals will be directed to a website landing page that will have promotional media content and information about the study. From here, participants will be directed to a separate link through the Health Insurance Portability and Accountability Act (HIPAA)–compliant REDCap (Research Electronic Data Capture; Vanderbilt University) platform [29,30] and complete a screening eligibility form. If deemed eligible, the participants will be sent an electronic consent form to be completed using REDCap. On the basis of our recruitment methods, we expect that approximately 400 individuals will be screened for eligibility.

Allocation

Participants will be randomized into 1 of 4 study arms in a 1:1:1:1 allocation ratio using a computer-generated randomization procedure. The allocation sequence will be implemented after the baseline survey is completed. The computer-generated randomization process will be implemented in REDCap after the data from the baseline survey are completed using REDCap. This will trigger the allocation procedure to randomly assign participants to 1 of the 4 study arms. The health coach will be notified about the randomization through the telecoaching dashboard and will inform the participants about their randomization into the My Health, My Life, My Way intervention or the attention control arm during the orientation call.

Blinding (Masking)

The principal investigator and primary statistician will be blinded to the randomization of the participants into the study arms. All other study staff will be unblinded for purposes of recruitment, consent, orientation calls, welcome calls, and coaching calls. There are no circumstances in which the principal investigator or statistician will become unblinded during this protocol.

Eligibility Criteria

Eligible participants must meet the following inclusion criteria: (1) aged ≥18 years; (2) self-reported diagnosis of heart disease, chronic lung disease, hypertension, or type 2 diabetes; (3) living with a permanent physical disability such as spinal cord injury, spina bifida, multiple sclerosis, or stroke; (4) speak and read English; and (5) availability of a smartphone or computer. To screen for permanently impaired mobility, we will use the National Health and Nutrition Examination Survey (NHANES; physical functioning) [31].

The exclusion criteria are as follows: (1) current enrollment in any structured intervention, (2) severe cognitive impairment, (3) major cardiac event in the past 12 months, (4) resting tachycardia, (5) renal failure, (6) severe peripheral neuropathy, (7) active treatment for cancer in the past 12 months, and (8) having both visual and hearing impairments (either is acceptable).

Participant Timelines and Intervention Duration

The study duration for those enrolled in the study will be 6 months (24 weeks), regardless of study arm allocation. Participants assigned to groups with scheduled coaching calls will receive scheduled weekly coaching calls. Those assigned to a group without scheduled coaching calls will have access to health coaches during the study and be able to communicate with the health coaches as needed.

Study Survey Packets

After enrolling in the study, participants will automatically be electronically delivered a REDCap link to a survey packet. This survey packet will include demographics and outcome measures (Table 2). Participants will be asked to complete this survey packet 3 times during the 6-month study period (excluding the demographics in the first survey packet). The surveys should take approximately 20 minutes to complete at each time point. The time points include baseline, 3 months, and 6 months.

XSL•FO
RenderX

Table 2. Measures of effectiveness.

Variables[a]	Instruments	Time points
Health-related quality of life	Enabled version of 36-item Short Form Health Survey (primary outcome)	Baseline, 3 months, and 6 months
Physical activity	Godin Leisure-Time Exercise Questionnaire	Baseline, 3 months, and 6 months
Physical activity	Minutes, steps, and related data from Fitbit	Continuous
SE[b] for managing symptoms	PROMIS[c] Item Bank v1.0–Self-Efficacy for Managing Chronic Conditions–Managing Symptoms–Short Form 4a	Baseline, 3 months, and 6 months
SE for managing daily activities	PROMIS Item Bank v1.0–Self-Efficacy for Chronic Conditions–Managing Daily Activities–Short Form 4a	Baseline, 3 months, and 6 months
SE for managing sleep disturbance	PROMIS Item Bank v1.0–Sleep Disturbance–Short Form 4a	Baseline, 3 months, and 6 months
Psychosocial Illness	PROMIS Item Bank v1.0–Psychosocial Illness Impact-Positive–Short Form 8a	Baseline, 3 months, and 6 months
SE for managing emotions	PROMIS Item Bank v1.0–Self-Efficacy for Managing Chronic Conditions–Managing Emotions–Short Form 4a	Baseline, 3 months, and 6 months
SE for managing social interactions	PROMIS Item Bank v1.0–Self-Efficacy for Managing Chronic Conditions–Managing Social Interactions–Short Form 4a	Baseline, 3 months, and 6 months
Emotional distress	PROMIS Item Bank v1.0–Emotional Distress-Depression–Short Form 4a	Baseline, 3 months, and 6 months
SE for managing medications and treatments	PROMIS Item Bank v1.0–Self-Efficacy for Managing Chronic Conditions–Managing Medication and Treatment–Short Form 4a	Baseline, 3 months, and 6 months
SE for managing sleep-related impairments	PROMIS Short Form v1.0–Sleep-Related Impairment–Short Form 4a	Baseline, 3 months, and 6 months
Dietary intake	Short Healthy Eating Index	Baseline, 3 months, and 6 months
Medication adherence	Medication Adherence Rating Scale and Beliefs About Medication Questionnaire	Baseline, 3 months, and 6 months
Usability	Health Information Usability Evaluation Scale and System Usability Scale	Three months and 6 months

[a]In addition to the variables listed in the table, primary care visits, pharmacy visits, physical therapy and occupational therapy visits, emergency visits, and hospitalizations in the last 3 months (self-reported) will also be taken into account.

[b]SE: self-efficacy.

[c]PROMIS: Patient-Reported Outcomes Measurement Information System.

Welcome Call

After the first survey packet is electronically delivered to participants, study team members will contact the participants by telephone. The purpose of this call is to welcome them into the program and explain the program elements. During the call, the staff will inform the participants that they will receive a technology package in the upcoming days.

Randomization

A randomization sequence will be generated and stored within REDCap, which assigns a participant to 1 of the 4 study arms of the My Health, My Life, My Way study. Randomization will occur only after the baseline survey packet is complete.

Overview of the Intervention

Orientation Call

After the welcome call and randomization, a study health coach will be notified through REDCap that a participant has been randomized to one of the study arms and will conduct an orientation call with the participant. The purpose of this call by the health coach is to introduce themselves to the participants as their primary health coach and to schedule the first weekly coaching call. For those not receiving scheduled coaching calls, the health coach will inform participants that they can contact the coaching staff during the study to ask questions related to the educational content provided on the platform.

Intervention Package

All participants, regardless of study arm allocation, will receive an intervention package that will include a PA tracker (Fitbit; Google LLC) and access to a telehealth platform. The Fitbit tracker will be shipped to the participants after randomization. The telehealth platform will be a central location for educational content (videos, articles, etc) for participants to access during the study. Those with conversational agents (eg, Amazon Echo) will be provided access to a My Health, My Life, My Way specific program that can operate with their home device. This package will be used for intervention delivery and not for outcome measurements.

XSL•FO
RenderX

Educational Content and Health Coaching for the Study Arms

The study arms for the My Health, My Life, My Way study with the coaching calls for all groups will be guided by a prepared outline of inclusive educational content that will be delivered to the participants through the telehealth platform. This content will be delivered at the beginning of each week. The educational content will be created and adapted for individuals with physical disabilities by experts and delivered to the participants as multimedia content. There will be generalized educational content applicable to all participants. On the basis of a specific physical disability as well as specific health conditions, education-specific content will be tailored to each individual. For those receiving scheduled coaching calls, the content discussed will include nutrition and eating habits, exercise and PA, and medication adherence. Questions outside the scope of the health coaching content will be dealt with by the study clinician. If the study team determines that the questions indicate that it is necessary to collect a participant's detailed medical profile, the participant will be guided to communicate with their primary care physician. Finally, the health coach will address other health-related questions that the participant may have. For each call, the health coach will be able to record notes on the telehealth platform regarding topics discussed with the participant for future calls, as needed.

Telehealth Platform

The My Health, My Life, My Way telehealth platform will be used by participants throughout the duration of the study. On the platform, participants will be able to access educational multimedia content (videos and articles), track and log medication use, create and track health-related goals, and access food- and nutrition-related information. In addition, participants will be able to view upcoming health coaching calls and contact the health coaching team using the messaging feature of the platform.

Participant Study Activities

Gamification Component

All participants, regardless of gamification variation, will be able to obtain points and badges on the platform. Participants can check their points status at any time during the study by logging in to the platform to view an itemized list for all badges and points. In addition, participants will be provided email notifications for all gamification updates. All activities, such as viewing and reading educational content and logging in to the platform, will automatically be updated on the platform. Health coaches will encourage participants to engage on the platform regularly. Those not receiving scheduled coaching calls who exercise the on-demand coaching option will be encouraged by a health coach to use the platform regularly.

Health Coaching Component

Those receiving scheduled health coaching calls will be able to view upcoming calls on the platform. In addition, email and SMS text messaging notifications will be provided to remind participants of all scheduled coaching calls. Scheduled coaching calls will occur once per week and are expected to last up to 60 minutes. Those who will not receive scheduled coaching calls will still have access to the study platform. Within the platform, participants will be able to contact health coaching staff if they desire on-demand coaching. With this on-demand coaching function, participants can discuss any questions regarding educational content on the platform.

Exit Interviews

After the study duration, up to 30 participants from the My Health, My Life, My Way program will be contacted for a follow-up interview to obtain their experiences and feedback with the My Health, My Life, My Way telehealth platform. These interviews will be conducted on the web.

Data Collection Methods

Outcome Measures

Primary and secondary outcome measures will be assessed at baseline, 3 months, and 6 months (after the intervention). The primary clinical outcome measure is health-related quality of life; the secondary outcome measures are described in Table 2 along with the primary outcome measure.

Health-Related Quality of Life

The primary outcome measure is health-related quality of life. This will be measured by using the 36-item Short Form Health Survey, enabled version (SF-36E). More specifically, the physical functioning section of the SF-36E has been modified, which uses disability-friendly inclusive language for individuals with mobility impairments [4].

All other measures, including demographic data and secondary outcome measures, will be retrieved and automatically stored through electronic surveys delivered by REDCap. All self-reported items within the questionnaires will be mandatory to prevent missing data. The questionnaire packet will be delivered electronically to the participants during the study.

PA Measurements

To measure PA, participants will complete the Godin Leisure-Time Exercise Questionnaire. This 3-item questionnaire asks questions related to strenuous, moderate, and light exercises performed during the past 7 days [32]. In addition, activity counts and time spent in PA will be collected from the participant's Fitbit device.

Self-efficacy for Managing Symptoms

Participants will complete the Patient-Reported Outcomes Measurement Information System (PROMIS) Item Bank v1.0–Self-Efficacy for Managing Chronic Conditions–Managing Symptoms–Short Form 4a, which is a 4-item survey that assesses confidence in managing symptoms associated with their chronic health condition [33].

Self-efficacy for Managing Daily Activities

To assess confidence in handling daily activities, participants will complete the 4-item PROMIS Item Bank v1.0–Self-Efficacy for Chronic Conditions–Managing Daily Activities–Short Form 4a [33].

XSL•FO
RenderX

Self-efficacy for Managing Sleep Disturbances

Participants will complete the PROMIS Item Bank v1.0–Sleep Disturbance–Short Form 4a, which is a 4-item survey that evaluates sleeping habits during the previous 7 days [33].

Psychosocial Illness

To assess self-efficacy for managing psychosocial illness, participants will complete the PROMIS Psychosocial Illness Impact-Positive–Short Form 8a [33]. This questionnaire includes 8 items that evaluate psychosocial illness before and after an illness.

Self-efficacy for Managing Emotions

To assess the ability to manage emotions, participants will complete the PROMIS Item Bank v1.0–Self-Efficacy for Managing Chronic Conditions–Managing Emotions–Short Form 4a [33]. This survey includes 4 items regarding the ability to manage emotions while experiencing chronic health conditions.

Self-efficacy for Managing Social Interactions

Participants will complete the PROMIS Item Bank v1.0–Self-Efficacy for Managing Chronic Conditions–Managing Social Interactions–Short Form 4a [33]. This 4-item survey will assess an individual's perceived ability to engage in meaningful social interactions.

Emotional Distress

To assess self-efficacy for managing depression, participants will complete the PROMIS Item Bank v1.0–Emotional Distress-Depression–Short Form 4a [33]. This survey includes 4 questions about participants' emotions within the past week.

Self-efficacy for Managing Medications and Treatment

To assess confidence in managing medications and treatment, participants will complete the 4-item PROMIS Item Bank v1.0–Self-Efficacy for Managing Chronic Conditions–Managing Medications and Treatment–Short Form 4a [33].

Self-efficacy for Managing Sleep-Related Impairments

Participants will complete the PROMIS Short Form v1.0–Sleep-Related Impairment 4a to evaluate overall sleep quality during the previous 7-day period [33].

Dietary Intake

Participants will complete the Short Healthy Eating Index (sHEI) survey, which is a 23-item survey that evaluates nutritional habits, such as fruit and vegetable consumption, water intake, and sugar consumption [34].

Medication Adherence

To measure medication adherence, participants will complete the Medication Adherence Rating Scale (MARS). The MARS is a general, 10-item binary questionnaire that asks questions related to regularly taking medication [35]. Medication adherence will also be measured using the Beliefs About Medication Questionnaire (BMQ). The BMQ is an 18-item questionnaire that includes Likert-style questions regarding personal beliefs about how medications influence daily living [36].

Telehealth Dashboard Usability

To measure the usability of the telehealth dashboard, participants will complete the System Usability Scale (SUS) and the Health Information Technology Usability Evaluation Scale (Health-ITUES). These Likert scales include items asking about the dashboard's effectiveness (ability to complete tasks), efficiency (level of dashboard use), and satisfaction (subjective reactions to the dashboard) [37,38].

Medication and Dosage

Participants will be asked to provide current medications and dosages throughout the study duration to control medication data during the statistical analysis.

Feasibility Measures

This study will obtain measures related to the feasibility and acceptability of the My Health, My Life, My Way intervention on self-management for individuals with disabilities who also experience chronic conditions. Measures will include process, resource, scientific, and management feasibility outcomes. All elements of intervention delivery will be collected, including but not limited to adherence, retention, attrition, coach and participant communication needs, staff preparation, and adverse events. Obtaining these measures will inform future considerations in the delivery of a web-based self-management program for people with disabilities.

Data Management

All data collected will be entered directly into REDCap and stored. Participants will be assigned a participant number upon enrollment in the study. Only approved study personnel will have access to the REDCap program, where data will be stored. Data checking will involve confirming that surveys, questionnaires, and health coaching calls are completed.

Statistical Methods

All statistical analyses will be conducted in an intent-to-treat manner at the individual level taking into account the correlated nature of data (multiple time points for every participant). Statistical significance will be evaluated at a type I error rate of 5%. Quality control will include descriptive and graphical approaches to summarize baseline characteristics of all key variables. With respect to data, we will begin by systematically cleaning and verifying all collected data, as well as examining ranges, missing values, and provenance. The significance tests conducted for the primary outcome are all specified a priori and modest in number. Consistent with published guidelines for statistical reporting, exact *P* values (rather than, eg, "$P<.05$" or "NS" [not significant]) will be reported [39]. This allows readers who may have their own opinions about multiple testing corrections, configurations of a family of hypotheses, and costs of type I errors to set the significance level to know the raw, uncorrected result and make their own judgments about statistical significance [40,41]. As Saville [42] noted, in multiple comparison issues, there is no right answer, and each investigator must ultimately "cut the Gordian knot" themselves. To evaluate the potential systematic variation among the study arms, key variables such as age, race, sex, disability type, and physical function at baseline will be examined and compared

XSL•FO
RenderX

for relationships with study arms. If a potential confounder is found to differ meaningfully among the groups and if we find that the inclusion of the covariate improves the corrected Akaike information criterion (AIC), it will be included as a covariate in our analyses. We will estimate and test the effects of the 4 individual intervention components by means of a full factorial experiment. First, we will fit a linear mixed model to account for correlated data, to check whether each factor has a significant effect on outcome change across the time points (baseline and 6 months). For each of the 2 components, we will determine whether there is a difference in change across time using baseline as the reference cell (ie, 6 months vs baseline). This would be considered the main effect of each component on the pre-post difference. However, statistically, these effects will be modeled as component-by-time interactions, with the 6-month outcome as the primary end point. We will also include interactions among the components (eg, factor 1 × factor 2 × time interaction). In terms of multiple testing, given that this is a pilot project (ie, an exploratory and not confirmatory trial), we will estimate the false discovery rate and false discovery proportion based on the *P* values for all outcomes.

Our 3-pronged approach involves minimizing missing data, leveraging the maximum likelihood–based approach or the multiple imputation approach under the assumptions of ignorability (ie, missing-at-random [MAR] assumption), and conducting multiple sensitivity analyses assuming MAR as well as missing not at random [43,44]. Analytically, our choice of mixed models to account for the repeated nature of the data will allow us to handle missing data for the primary and secondary outcomes under the assumptions of MAR. The MAR mechanism is ignorable when mild regularity conditions are satisfied. Such inferences can proceed by analyzing the observed data only, without explicitly addressing a form of the MAR mechanism. Missing data in other independent variables (mediators or other covariates) will be handled through the expectation-maximization algorithm coupled with bootstrapping for SEs, which will give maximum likelihood–based imputation under the MAR assumption [43].

Data Monitoring

This project is a pilot feasibility and efficacy study that has a duration of 6 months and only involves minimal risks. Therefore, we believe that a data monitoring committee is not necessary. The principal investigator will be responsible for protocol fidelity and data collection throughout the study. The biostatistician will oversee data analysis in preparation for publication.

Harms

The My Health, My Life, My Way study will monitor all adverse events. Adverse events will be assessed for severity and causality and reported to the institutional review board and all other relevant regulatory bodies as needed.

Auditing

All elements of the study protocol will be evaluated at regular intervals (ie, weekly, monthly, or quarterly) to ensure proper and consistent adherence to the study design and implementation. Elements of auditing will include checklists; coaching call logs; audio recordings or coaching calls; content resource banks; telehealth platform reviews and event logs; review of participant food, PA, and medication, as well as time spent on the platform and in regular team meetings to discuss participant progress; educational content provided during health coaching calls; and protocol adherence.

Protocol Amendments

Any protocol changes deemed necessary by the principal investigator or study team will be submitted as amendments to the university's institutional review board, and we will only apply changes after approval.

Ethics Approval

This protocol has been approved by the institutional review board of the University of Alabama at Birmingham (IRB-300009485).

Consent or Assent

All consent processes will be conducted on the web through predetermined screening questionnaires provided through the website landing page and REDCap link. If a participant is deemed eligible through the web-based process, an electronic consent form will be sent to the participant to complete. Only approved study staff will have access to completed records of the consent form.

Confidentiality

Personal information will be collected in this study. All personal information shared, such as demographic details, will be collected and stored through REDCap. Only approved study staff will have access to securely stored personal information. All information will be subject to the university's institutional review board and the policies of affiliated entities surrounding confidentiality.

Results

Overview

The My Health, My Life, My Way protocol was funded in September 2020 and has been approved by the university's institutional review board and registered at ClinicalTrials.gov (NCT05481593). The telehealth platform (dashboard and educational content) and website landing page are being developed by the study technical support team. Research personnel are developing the database (REDCap) that will store data and communication mechanisms (ie, emails and SMS text messaging notifications). We project that enrollment for the study will begin in May 2023, with data analysis being completed within 6 months of completing data collection.

Dissemination Policy

The results of this study will be disseminated publicly through publication in peer-reviewed journals and presented at regional and national conferences.

Discussion

Many Important Implications

The aim of this paper was to detail the study protocol used to develop a web-based self-management program for individuals with physical disabilities who also experience chronic conditions by using artificial intelligence techniques. The incorporation of variations in coaching calls and gamification will be evaluated to determine which combination of intervention components is the most effective for personal self-management. As the My Health, My Life, My Way program will be implementing a 4-arm protocol using the MOST design, many important implications can be drawn based on the findings of this study. The findings will assess what resources are required by self-management programs to maintain high levels of adherence and engagement. For coaching calls, if scheduled coaching calls are not as effective at promoting self-management as on-demand coaching calls, this would result in a reduced demand for excess resources, including the number of health coaches, monetary expenses, training, and daily availability of health coaches. If scheduled coaching calls are shown to be more effective than on-demand coaching calls, future web-based self-management programs should consider bolstering the resources to provide appropriate health coaching with qualified health coaches. Within the gamification context, the results from this study will inform future programming for individuals with physical disabilities who also experience chronic conditions. If gamified rewards are shown to be more effective than the fixed rewards model, self-management programs should consider using appropriate methods to promote extrinsic motivation by providing desirable incentives for behavior change. If fixed rewards are shown to be more effective than gamified rewards, this could indicate that a participant's intrinsic motivation to improve their self-management is more important than extrinsic rewards such as redeeming increasing monetary incentives to promote behavior change.

As multiple barriers hinder a person's ability to successfully manage chronic conditions, My Health, My Life, My Way aims to create a sustainable, scalable, accessible, implementable, sustainable, and inclusive self-management program for people with disabilities, which currently does not exist. This study will examine the feasibility and preliminary efficacy of My Health, My Life, My Way for individuals with physical disabilities who also experience chronic conditions using mobile apps and web-based applications, telehealth coaching sessions, and educational multimedia material. As part of the development process of My Health, My Life, My Way, we have conducted extensive focus groups with stakeholders with physical disabilities who also experience chronic conditions to obtain their perspectives on the proposed program and plan to implement relevant changes during further development. In addition, in line with the protocol, My Health, My Life, My Way is built upon a prior protocol evaluating the effectiveness of a web-based diabetes management program for individuals with physical disabilities [45]. The My Health, My Life, My Way study will also focus on quality-of-life measures during the intervention and will include qualitative interviews conducted after the intervention to provide a holistic evaluation of the program as a viable mode for self-management of chronic conditions. Next, to reduce barriers experienced by people with disabilities, the My Health, My Life, My Way program will be conducted completely on the web, with all coaching sessions taking place over the telephone, thereby allowing all participants to engage in the program and manage their health conditions in a home environment.

Limitations and Strengths

This protocol includes limitations. First, we are using self-reported measures to collect data on participant perceptions about their physical and mental health. Therefore, we are relying on participants' responses to be truthful when they answer all the surveys. The surveys we will use in this study have been shown to be reliable and valid in assessing physical and mental health outcomes. Second, My Health, My Life, My Way is using a web-based platform that participants will use to access multimedia content; therefore, those without internet capabilities will be unable to participate.

This study will add to the current literature to improve the quality of web-based self-management programs. In addition, not only will My Health, My Life, My Way determine how coaching calls and gamification variations affect behavior, but this program is also designed to be inclusive for those who experience physical disabilities, considered an underserved population. Finally, the findings from this study will inform how future self-management programs can be created and tailored to populations consisting of individuals with disabilities.

Abstract

Background: Heart failure (HF) is the leading cause of hospitalization among older adults in the United States. There are substantial racial and geographic disparities in HF outcomes, with patients living in southern US states having a mortality rate 69% higher than the national average. Self-management behaviors, particularly daily weight monitoring and physical activity, are extremely important in improving HF outcomes; however, patients typically have particularly low adherence to these behaviors. With the rise of digital technologies to improve health outcomes and motivate health behaviors, sensor-controlled digital games (SCDGs) have become a promising approach. SCDGs, which leverage sensor-connected technologies, offer the benefits of being portable and scalable and allowing for continuous observation and motivation of health behaviors in their real-world contexts. They are also becoming increasingly popular among older adults and offer an immersive and accessible way to measure self-management behaviors and improve adherence. No SCDGs have been designed for older adults or evaluated to test their outcomes.

Objective: This randomized clinical trial aims to assess the efficacy of a SCDG in integrating the behavioral data of participants with HF from weight scale and activity tracker sensors to activate game progress, rewards, and feedback and, ultimately, to improve adherence to important self-management behaviors.

Methods: A total of 200 participants with HF, aged ≥45 years, will be recruited and randomized into 2 groups: the SCDG playing group (intervention group) and sensor-only group (control group). Both groups will receive a weight scale, physical activity tracker, and accompanying app, whereas only the intervention group will play the SCDG. This design, thereby, assesses the contributions of the game. All participants will complete a baseline survey as well as posttests at 6 and 12 weeks to assess the immediate effect of the intervention. They will also complete a third posttest at 24 weeks to assess the maintenance of behavioral changes. Efficacy and benefits will be assessed by measuring improvements in HF-related proximal outcomes (self-management behaviors of daily weight monitoring and physical activity) and distal outcomes (HF hospitalization, quality of life, and functional status) between baseline and weeks 6, 12, and 24. The primary outcome measured will be days with weight monitoring, for which this design provides at least 80% power to detect differences between the 2 groups.

Results: Recruitment began in the fall of 2022, and the first patient was enrolled in the study on November 7, 2022. Recruitment of the last participant is expected in quarter 1 of 2025. Publication of complete results and data from this study is expected in 2026.

heart failure; digital game; self-management; mobile phone; older adults

Introduction

Background

More than 6 million adults in the United States live with heart failure (HF), a condition that is the leading cause of hospitalization among older adults in the United States [1]. Despite substantial advances in treatment and management, the current estimated annual cost is US $32 billion, which is projected to rise to US $69 billion by 2030 [2]. There are major regional disparities among individuals diagnosed with HF in the southern United States, with a mortality rate 69% higher than the national average [3,4].

Self-management behaviors are important for patients with HF to help reduce serious adverse sequelae and outcomes [5]. For example, weight gain is an initial warning sign of volume overload in patients with HF; by monitoring their weight daily, patients may receive prompt treatment for their weight gain, which can help avoid clinically significant exacerbations (odds ratio 0.42, 95% CI 0.23-0.76) [6,7]. Similarly, physical activity is linked to clinically significant improvements, such as improved myocardial function (P=.02) and functional capacity (P<.001) [8] and reduced depressive symptoms [9]. By self-managing these 2 critical elements, patients with HF experienced improved quality of life (QoL) and reduced health care use and cost in high-quality research studies [10,11]. Conversely, poor HF self-management may delay recognition of severe HF symptoms and result in more frequent hospitalizations, impaired functional status, and poorer QoL [12].

Despite its importance, persistent adherence to critical self-management behaviors continues to remain a challenge for patients with HF [13,14]. Patients have poorer adherence to weight monitoring and physical activity than to other self-management behaviors [15]. Thus, there is a need for novel approaches to support and motivate patients with HF to self-manage these critical behaviors. Interventions that are remote, resource conservative, and can be used in home may help address the widening geographical [3,4] and racial [16] health disparities in HF outcomes. Wearable technologies, mobile health apps, and sensor devices offer substantial promise in that they are portable, scalable, and allow for continuous observation and motivation of health behaviors in real-world contexts. Despite these benefits, the adoption of these technologies is low; abandonment is common [17], and longitudinal studies, especially in the context of chronic health conditions, are rare. Although the potential of wearables and digital sensor technologies for HF to improve care and outcomes has been acknowledged [18] and proven [19,20], the studies exploring their use in practice have largely been limited in size and scale [21].

Objectives

One promising approach to increasing adherence to self-management behaviors in patients with HF is to leverage the use of digital technologies such as sensor-controlled digital games (SCDGs). SCDGs synchronize data on behaviors from sensors, such as wearable devices, with a mobile gaming app, allowing game progress, rewards, incentives, and personalized feedback (eg, reduce fluid intake or contact a physician) based on real-time contextual information (eg, weight gain or concerning symptoms) [22]. To promote change and its maintenance, SCDGs can also incorporate immersive stories [23], active learning [24], and social connections [25]. SCDGs are not only affordable, portable, and scalable, but they are also enjoyable and easy to use. Furthermore, prior research has indicated that they can also contextualize health behaviors [26], motivate behavioral changes, and improve health outcomes [27]. Thus, SCDGs offer an immersive and accessible way to objectively measure self-management behaviors and improve adherence [28]. Our previous research [29] conducting an SCDG intervention with 38 adults (aged ≥55 years) with HF from Texas and Oklahoma demonstrated improvements in weight monitoring and physical activity, and the intervention showed a high rate of acceptability (92%) from participants.

In this clinical trial, we have updated the SCDG intervention and will evaluate its efficacy for improving HF outcomes by integrating behavioral data of participants with HF from weight scale and activity tracker sensors to activate game progress, rewards, and feedback.

Methods

Study Design

This study is an efficacy clinical trial, using a prospective, 2-group randomized (1:1) controlled design in which an SCDG playing group with sensors and tracking apps (intervention group [IG]) will be compared with a sensor-only group (control group [CG]) that receives only the app that tracks weight monitoring and physical activity. In a sample of 200 individuals with HF, who are aged ≥45 years (n=100 per arm), benefits will be assessed by measuring improvements in HF-related proximal outcomes (self-management behaviors of daily weight monitoring and daily physical activity) and distal outcomes (HF hospitalization, QoL, and functional status) between baseline and weeks 6, 12, and 24. We will also apply mixed methods to

XSL•FO
RenderX

assess IG and CG participants' perceptions of intervention and behavior adherence.

Study Setting

We will enroll 200 patients in this study, 100 each in the IG and CG. To recruit patients, we are contracting with Trialfacts [30], a web-based recruiting company. Participants will be recruited from 7 southern states of the United States to address prominent geographic health disparities in HF [3,4]. These states are Alabama, Arkansas, Georgia, Louisiana, Mississippi, Oklahoma, and Texas, where people experience higher HF rates than the rest of the country.

Eligibility Criteria

Participants must be aged ≥45 years (lifetime risk for HF is high for the age group of 45-95 years) [1]; have been hospitalized for HF in the last 12 months (to reduce the variance in recovery from a recent HF hospitalization); and be classified as class I, II, or III per the New York Heart Association's HF classes [31] (thus ensuring recruitment of those who would benefit the most from self-management interventions). They must also be fluent in English, able to pass a mini–cognitive screening assessment [32], and able to walk independently without using a walker or other assistance. Exclusion criteria include (1) having severe visual or tactile impairments (eg, legal blindness or severe arthritis), which might make using smartphones and sensor devices difficult; (2) having undergone a heart transplantation or implantation of a durable mechanical circulatory support device in the past; (3) having a history of renal failure (which adversely affects HF prognosis); or (4) being diagnosed with an end-stage or terminal illness (eg, cancer). The study is registered at ClinicalTrials.gov (NCT05056129).

Ethics Approval and Informed Consent

The protocol was approved by the Institutional Review Board of the University of Texas, Austin (STUDY00001438), on February 18, 2022. Informed consent will be obtained from all eligible participants through a phone call before baseline surveys are sent and data collection begins. After a member of the research team reads the consent form and solicits questions, participants will receive the consent form via email and be requested to provide their digitally signed consent form through the REDCap (Research Electronic Data Capture; Vanderbilt University) web-based survey database. Participants who prefer to sign a physical copy will be mailed a consent form. This approach will allow participants sufficient time to follow-up with questions and discuss the study with their family or friends before officially signing the consent form. Our team will make it clear to participants that they may decline to answer specific questions or terminate their involvement in the study at any time.

Enrollment and Randomization Procedures

Participants will be assigned to either the IG or CG through computer-automated randomization. These assignments will be stratified based on sex (male, female, or other) and age (45-64 years or ≥64 years) to ensure balance in the study design. The allocation sequence for permuted block randomization with random block sizes of 4 and 6 was created by a statistical analyst who is not connected to the participant enrollment process. The allocation sequence will be uploaded to REDCap, which will automatically assign the participants to groups when they are enrolled in the study. The research team will be blinded to assignment group or maintained in a way that ensures the separation of intervention implementation from evaluation, thus reducing any potential bias (eg, ascertainment bias) in the collection and analysis of outcome data. For example, data collectors will not be a part of the intervention delivery team. Similarly, participants will be blinded to their group assignment, as both groups use digital tools. All participants will be provided with the same informed consent form that includes general terms such as *digital health tools* to enable blinding of participants to their group assignment.

Intervention Description

The SCDG, which will be used by the IG in this study, is a smartphone app called Heart Health Mountain, which is available on both iOS and Android platforms. The design of the game was guided by behavioral change mechanisms using the concepts of motivation, ability, and trigger from the Fogg behavioral model and self-determination theoretical frameworks, as described in detail in a previous study [33]. This app has already been developed by a multidisciplinary team and tested through initial usability and feasibility studies and is described in detail elsewhere [28,29]. Several screenshots from the SCDG are pictured in Figure 1.

Figure 1. Screenshots from the different interfaces that make up the different levels within the sensor-controlled digital game.

XSL•FO
RenderX

The SCDG fosters relatedness by involving a narrative, the goal of which is to help the game avatar avoid rehospitalization using game points, earned via the participants' demonstration of competence or ability in real-time behaviors, in game tasks that help maintain the avatar's optimal HF health status. The participants' real-time behaviors of weight monitoring and physical activity will be tracked by off-the-shelf sensors and an app (Withings Pulse HR tracker, Body scale, and Health Mate app; Withings app). The data from the Withings sensors will then be routed to our SCDG app.

The digital game paired with sensors will enable objective tracking of real-time behaviors such as physical activity and weight monitoring and provide personalized, contextually relevant feedback (eg, reduce fluid intake or call a physician for weight gain) as triggers to motivate engagement in and generate habit formation of HF-related self-management behaviors. The game is adaptive to real-time behaviors; for example, participants' step goals automatically adapt each week to encourage a tolerable physical activity level based on a rank-ordered algorithm [34].

Control Description

The CG will use the same Withings devices over the same period but will not have access to the SCDG. Real-time behaviors of weight monitoring and physical activity will be tracked by the Withings Pulse heart rate tracker, Body scale, and Health Mate app. However, the data from the Withings sensors will not be routed to the SCDG. Instead, the CG will receive the same educational content that is presented in the SCDG in a paper format by mail. This study design feature will allow us to isolate the SCDG effect from the other features of behavioral motivation.

Remote Study Procedures

All research activities will be conducted at participants' homes. Participants will be directed to engage in research activities through remote means (email, phone call, or video calls). Participants will be asked to provide a convenient time for a research team member to contact them.

Participants in both the IG and CG will receive their Withings devices by mail, along with information on how to install the HealthMate app and connect the devices. The IG will also receive instructions on how to install the SCDG app (Table 1).

Table 1. Components of interventions received by the intervention group (IG) and control group (CG) participants.

Devices and apps	IG	CG
Withings weight scale and activity tracker	✓	✓
Withings HealthMate app for sensor data tracking	✓	✓
SCDG[a] app with progress of game, messages, and incentives tailored to participant's real-time HF[b] self-management behaviors	✓	
Standard evidence-based HF educational content [35,36] embedded in SCDG	✓	
Standard evidence-based HF educational content [35,36] provided in paper format		✓

[a]SCDG: sensor-controlled digital game.

[b]HF: heart failure.

Participants in both groups will receive remote training from a member of the study team on how to install and use the devices. This remote training (ie, over Zoom [Zoom Video Communications] or FaceTime [Apple iOS]) was also successfully provided in our feasibility study [29]. After 3 days, both the groups will receive a follow-up email from the interventionist to summarize participants' study tasks and provide contact information in case of troubleshooting needed while using the devices and apps.

Both groups will use the devices for 24 weeks. A dashboard was developed to track the time stamps of behavior data that were last synced by the participants to identify participants without any behavior data for >3 days. On a different page, the dashboard also shows the time stamps of the last time each participant in the IG opened the SCDG app. An unblinded team member aware of troubleshooting procedures and following a protocol to communicate similarly with participants in both groups will reach out to participants in both groups who have not had any behavior data from their devices synced in 3 days. This member would follow-up with participants in both groups daily for 3 business days. In case of no response, they will reach out to the alternative contact person listed by the participant.

Randomized Controlled Trial Data Collection

All the survey data will be collected using the REDCap web-based survey system. After completing the baseline survey, all participants will complete the first and second posttests at 6 and 12 weeks for assessment of the *immediate effect of the intervention* and will complete the *third* posttest at 24 weeks after the first week for assessment of the *maintenance of behavioral changes*. Survey links will be sent via text messages to participants at 4 time points through automated events programmed in the REDCap survey system. In addition, daily sensor data will be obtained from the Withings server, and the game playing data will be obtained from a backend server hosted on Amazon Web Services. The steps, weight, and game state data will also be stored in a MongoDB database. All variables will be measured at all follow-ups using the instruments described in detail in Table 2.

Table 2. Data collected and operationally defined, with time points.

Variables	Instrument or measure	Time point (weeks)
Baseline characteristics		
Sociodemographic	Sociodemographic and Upstream Risk Questionnaire [37,38]	Baseline
Clinical	Hospital discharge summary (medications, comorbidities, and ejection fraction)	Baseline
Weight monitoring frequency in the past week	1-item question using Likert scale	Baseline
Depressive symptoms	Patient Health Questionnaire-2 [39,40][a,b]	Baseline and 6, 12, and 24
Ability		
HF[c] self-management knowledge	30-item Atlanta Heart Failure Knowledge Test (Cronbach α=.84) [41][d]	Baseline and 6, 12, and 24
HF self-efficacy	6-item Section C Self-Care of HF Index (Cronbach α=.88) [42][d]	Baseline and 6, 12, and 24
Trigger		
Engagement with SCDG[e] and features	Backend game state logs of IG[f] participants; Intrinsic Motivation Inventory [43] and Qualitative Interviews	6, 12, and 24; 12
Motivation or behavior outcomes		
Number of days of weight monitoring (primary)[g]	HealthMate app logs [44] in IG and CG[h]	6, 12, and 24
Daily physical activity steps	HealthMate app logs [44] in IG and CG	6, 12, and 24
Daily physical activity intensity (light, moderate, or intense)	HealthMate app logs [44] in IG and CG	6, 12, and 24
HF self-management behaviors	9-item European Heart Failure Self-care Behavior Scale (Cronbach α=.80) [45][b,d]	Baseline, 6, 12, and 24
Patient outcomes		
Functional status	23-item Kansas City Cardiomyopathy Questionnaire [46][b,d]; functional status (Cronbach α=.93) [46]; QoL[i] (Cronbach α=.78) [46]	Baseline and 6, 12, and 24
QoL	Participant self-report	Baseline and 6, 12, and 24
HF hospitalization	Participant self-report and confirmed through hospitalization discharge summary and health care provider	Baseline and 6, 12, and 24

[a]A total of 90% sensitivity in patients with HF and reliable prognostic prediction of mortality and rehospitalization.

[b]Established validity using correlation with other instruments or clinical ratings in known groups.

[c]HF: heart failure.

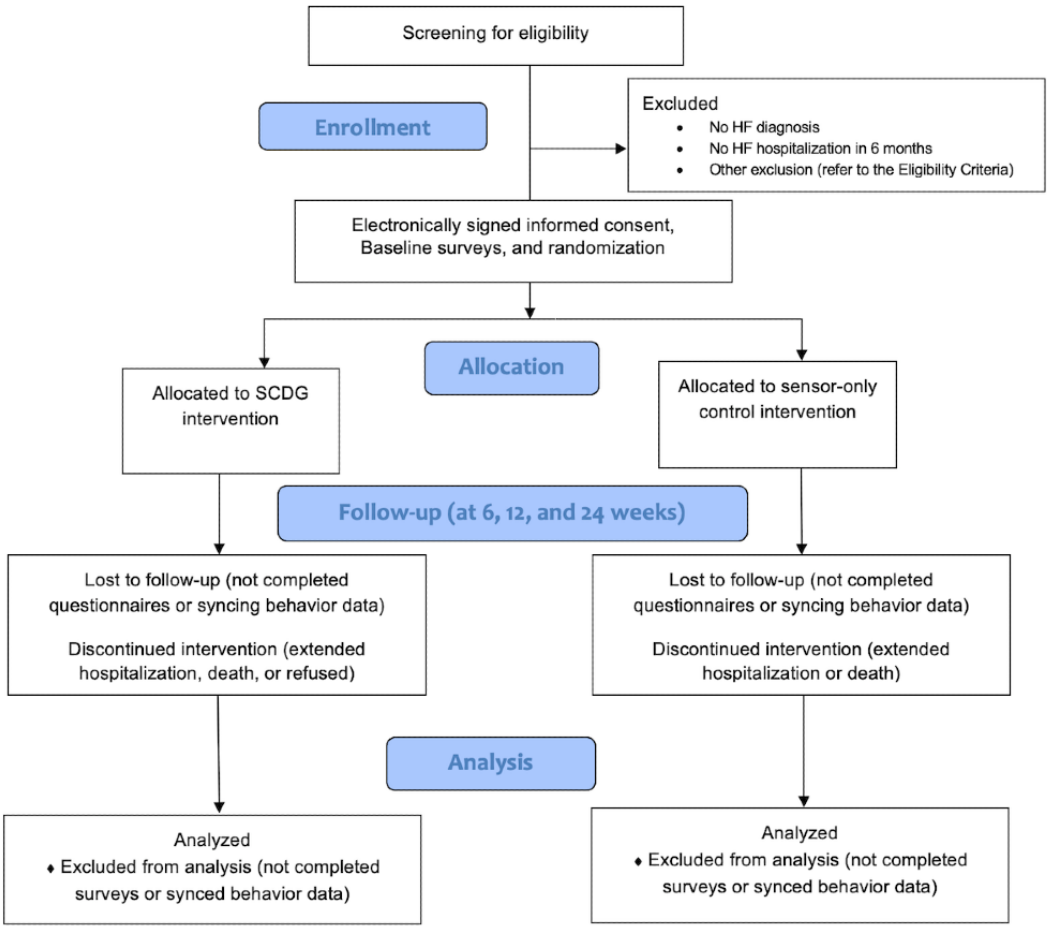
[d]Established reliability using interitem correlations and test-retest. Instruments take 30-55 minutes to complete when administered together.

[e]SCDG: sensor-controlled digital game.

[f]IG: intervention group.

[g]Outcome measure.

[h]CG: control group.



[i]QoL: quality of life.

The incentive of a gift card worth US $10 will be provided for the completion of surveys at each data collection time point (baseline and 6, 12, and 24 weeks) through Tango, a digital gift card disbursement system [47], as a reward for their effort. All participants will retain the scale and tracker till the end of the study.

An overview of the study's phases is mapped in Figure 2.

Figure 2. Study flow diagram. HF: heart failure; SCDG: sensor-controlled digital game.

Participant Data Protection

We will take measures to ensure the best possible protection of participant data. Each participant will receive a unique identifier as well as a pseudonym identifier to use for their Withings account so that no personal or identifying information is connected to the account. The option to share contacts, location data, or photos from the game and the Withings app will be disabled. Withings is also subject to the European Union General Data Protection Regulation, which include strict policies against sharing of data or other misuse of data without participant knowledge or consent. Participants' unique identifiers, rather than their personal information, will be connected to their behavioral and survey data as well as any data shared or presented externally. To protect participants' privacy, a 6-digit unique identification number and dummy email addresses will be generated for the profile information required by the HealthMate app.

Baseline demographic and clinical data will include sex (male, female, or other), race and ethnicity, marital status, age, level of education, medications, depressive symptoms, hospitalizations, and HF-relevant phenotype data such as ejection fraction and comorbidities.

Outcomes Measured

The outcome measures that we will use in the study are delineated and described in the following subsections.

Primary Outcome

The primary outcome assessed will be the *number of days reporting the HF self-management behavior of weight monitoring*: The data collection time frame will be 6, 12, and 24 weeks. This outcome will be measured by collecting the number of days with weight-monitoring data. These measures will be collected from the sensor logs within the Withings server from the HealthMate app [44] for the IG and CG.

Secondary Outcomes

We will assess a variety of secondary outcomes in the study. These outcomes are listed below.

1. *Daily physical activity steps*: The data collection time frame will be 6, 12, and 24 weeks. This outcome will be measured by collecting the number of daily cumulative steps days. Daily average total will be calculated weekly for 6, 12, and 24 weeks. These measures will be collected from the sensor logs within the Health Mate app [44] for the IG and CG.
2. *Daily physical activity intensity*: The data collection time frame will be 6, 12, and 24 weeks. This outcome will be measured by collecting the intensity level of daily physical activity. Averages will be calculated weekly for 6, 12, and 24 weeks. These measures will be collected from the sensor logs within the Health Mate app [44] for the IG and CG.
3. *Self-report HF self-management behaviors*: The data collection time frame will be baseline and 6, 12, and 24

XSL•FO
RenderX

weeks. This instrument will be the 9-item European Heart Failure Self-care Behavior Scale, which gives a standardized score from 0 to 100 (every item is given an equal weight), with a higher score indicating better self-care. Items are rated on a Likert scale ranging from 1 to 5. For calculating the standardized score, each item is reverse coded and then computed using the following formula: *(sum of all ever-coded items − 9) × 2.7777*. Cronbach α was .80 for the European Heart Failure Self-care Behavior Scale-9 and showed convergent validity with routine self-care behaviors and symptom response behaviors in the Self-Care of Heart Failure Index instrument [45].

4. *HF-related QoL*: The data collection time frame will be baseline and 6, 12, and 24 weeks. The instrument used will be items 13 to 15 from the Kansas City Cardiomyopathy Questionnaire (KCCQ). Values for the QoL domain range from 0 to 100, with higher scores indicating better QoL. The domain score will be transformed to a 0 to 100 range by subtracting the lowest possible scale score, dividing by the range of the scale, and multiplying by 100. Cronbach α was .78. The KCCQ is sensitive to clinical changes in HF compared with similar QoL instruments and had a significant, high correlation with the New York Heart Association HF classification (P<.001).
5. *HF-related functional status*: The data collection time frame will be baseline and 6, 12, and 24 weeks. Items 1 to 12 on the KCCQ will be used. Values for the functional status summary score ranged from 0 to 100, with higher scores indicating a better QoL. Summary score will be transformed to a 0 to 100 range by subtracting the lowest possible scale score, dividing by the range of the scale, and multiplying by 100. Cronbach α of the KCCQ for measuring functional status was excellent at .93. The scale demonstrated criterion validity with a high correlation with the New York Heart Association HF classification and the 6-minute walk test [46].
6. *Number of cardiac hospitalizations*: The data collection time frame will be baseline and 6, 12, and 24 weeks. This measure will be obtained through participant self-report through REDCap surveys and will be confirmed by hospitalization discharge summary and health care provider.
7. *HF self-management knowledge*: The data collection time frame will be baseline and 6, 12, and 24 weeks. The instrument used will be the 30-item Atlanta Heart Failure Knowledge Test [41]. Each correct answer is scored as 1 point, with no additional weighting of items; correct responses are then summed. Incorrect or skipped questions are awarded 0 points. Total scores range from 0 to 30. Higher scores indicate better knowledge of HF. Content validity ratings on relevance and clarity ranged from 0.55 to 1.0, with 81% of the items rated from 0.88 to 1.0. Reliability by Cronbach α was .84 for patients. Construct validity was demonstrated by directly correlating knowledge with clinical and self-care outcomes including dietary sodium consumption, medication adherence, and health care use.
8. *HF self-efficacy*: The data collection time frame will be baseline and 6, 12, and 24 weeks. The instrument used will be the 6-item Section C Self-efficacy section of the Self-Care of Heart Failure Index [42]. Scores on the self-efficacy scale will range from 0 to 100, with higher scores reflecting better self-efficacy. To standardize scores, the following formula will be used: *(sum of Section C items − 6) × 5.56*. Cronbach α was .88, with good evidence of construct validity and contrasting group validity.

To assess the facilitators and barriers impacting engagement of IG and CG participants with the SCDG and sensor-only interventions for HF self-management behavior adherence, we will use the convergence triangulation mixed methods design (including both quantitative and qualitative components) [48]. We will collect a survey informed by the Intrinsic Motivation Inventory [43] from all 200 participants at the 12-week follow-up assessment. In parallel, we will use random sampling to invite a subset (n=40) of IG and CG participants (20 per group) to participate in qualitative phone interviews at the end of 12 weeks. Interviews will be conducted by trained study staff, audio taped, and thematically coded by participant number to protect confidentiality. Participants will receive US $10 as an incentive to participate in the qualitative interview.

Adverse Event Collection and Handling

Participants will be monitored for anticipated and unanticipated adverse events from the time they sign the study consent until 30 days after the final study visit. Participants will be provided with contact information of a research team member to inform them of any adverse events that occur. In addition, the study team will monitor the adverse events that arise during data collection. A communication protocol was developed to report adverse events to appropriate research personnel, including the development of a phone tree. Serious adverse events will be reported to the Institutional Review Board associated with the University of Texas Austin within 24 hours of being informed of the incident. Unanticipated problems will be reported by the principal investigator (KR) to the Data Safety Monitoring Committee, the funding agency, and the Institutional Review Board within 15 days of the event. The Data Safety Monitoring Committee will meet the principal investigator and study staff to review adverse events once a year and as needed to address any adverse events that need to be addressed immediately.

Should any conditions present harm to the participant if they continue with the intervention, they will either be withdrawn from the intervention or asked to take a break from the intervention until the condition subsides. These conditions will be assessed on a case-by-case basis, with the principal investigator (KR) making the final decision. All adverse events, protocol deviations, and reportable information will be entered into the REDCap database.

Statistical Analysis

We have estimated the sample size for the primary outcome in our feasibility study for the 12 weeks study duration. All secondary outcomes will be examined on an exploratory basis. Analyses will be performed in an intent-to-treat manner.

General Considerations

Cronbach α coefficients will be computed for each multi-item scale, with Cronbach α≥.70 denoting acceptable consistency.

XSL•FO
RenderX

In outcome analyses, we will control for the possible effects of the biological variables of age and sex, prespecified as potentially strong predictors of outcomes. Statistical significance will be Cronbach α=.05 for primary and secondary analyses. Descriptive statistics will be computed for study variables to assess missingness, out-of-range values, and features of variable distributions including floor and ceiling effects. For testing and quantification of treatment effect with respect to primary and secondary outcomes, the IG and CG will be compared following the intention-to-treat principle.

Missing Data

We expect missingness of items and other data to be minimal at baseline. Follow-up measures may be missing either because of formal dropout or failure to respond to contact from our research team. In all cases, we will assume missingness at random. For missing values at baseline, single (when <5%) or multiple (when ≥5%) imputation will be used. For more extensive missing data, especially at follow-up, we will use multiple imputation strategies when the analyses are based on generalized estimating equations [49] with sensitivity analyses to determine the effects of imputation. Sensitivity analyses will focus on which variables are used in imputation and on deviations from the missingness at random assumption (which must be parameterized, as this statistical assumption is not formally testable with the data) [50]. For missing outcomes in linear mixed models, imputation is not required because the analysis is based on maximum likelihood. However, missing predictors in mixed models will require single or multiple imputation.

Measuring Outcomes

For the primary outcome of days with weight monitoring, binary weight-monitoring data (yes or no) will be summed over days for each of the 24 weeks during which data are collected. Data will be analyzed with a linear model for binomial-like data with an effect of time (ranging from 1 to 24) and a time-by-treatment effect. We do not need a treatment main effect owing to randomization, which implies no treatment effect at time=0. Primary outcome treatment effect at 12 weeks can then be estimated from the model as a difference in mean weight-monitoring days (out of 7) comparing the IG with the CG. The model will be fitted with generalized estimating equations [51], using the matrix-adjusted estimating equations method to estimate model correlation over repeated measures within a subject and using a bias-corrected sandwich variance estimator [52]. The model will allow for overdispersion relative to the binomial variance, yielding correct statistical descriptions of the data and inference. We will consider exchangeable, exponential decay and a combination of the 2 correlation structures. Finally, (1) we mention that the linear (vs the logistic) model is valid for binomial data, especially when the binomial parameter is not near 0 or 1 and yields an interpretable treatment effect on the scale of "number of weight-monitoring days," and (2) we will maximize power by analyzing all 24 weeks of data, although we aim to extract the 12-week mean difference as the primary contrast of interest.

For the secondary outcome of physical activity, as measured by the number of steps, data will again be aggregated (summed) by week. As the measures are counts, we will use a log link and variance proportional to the mean (as with the Poisson distribution), allowing for an overdispersion parameter. Analysis will then emulate that for the number of weight-monitoring days. The log link will yield coefficients that, when exponentiated, will be interpreted as relative mean numbers of steps, which, given the expected between-person variability, will be more interpretable than a mean difference on the natural scale. For secondary outcome measures of HF self-management knowledge, self-efficacy, HF-related functional status, and QoL measured 4 times over the multiple data collection time points, we will use linear mixed effects models [53] with random slopes and intercepts to capture the association over time in the repeated measures within participant, estimating the treatment effect from the model at each of 6, 12, and 24 weeks.

Sample Size and Statistical Power

For a 1:1 randomization scheme (IG:CG), we aim to recruit 100 participants per group and allow for 25% attrition (some of which will be recovered through the treatment of missing data). We would like to detect a weight-monitoring rate of at least 80% (5.6/7) of days per week, as patients with HF who completed ≥80% of weight diaries were found to have significantly reduced odds for HF-related hospitalizations compared with patients who completed <80% of weight diaries [7]. In our planned analysis, we aim to use weekly data for weeks 1 through 24, fitting a flexible (eg, df=2) trend for the mean number of days (out of 7) in which participants complete weight monitoring, and thereby extracting the estimate at 12 weeks for each of the IG and CG. Using all 24 weeks of data represents an efficient use of data by exploiting a smooth time trend, by leveraging the positive correlation among the repeated measures on a given individual, and by offering the opportunity to handle missing time points through imputation or weighting of the nonmissing longitudinal data. For power estimation, because we are not sure about the form of the model based only on pilot data and because pilot data are relatively sparse for purposes of estimating within-subject correlation, we *conservatively* (in the sense that true power is expected to be greater) use aggregated pilot data just across weeks 7 to 12 (42 days) to estimate the mean and variance of $\hat{a}$, where a is the average within-group probability of engaging in weight monitoring on any given day. Owing to the strong day-to-day correlation within subject, the total number Y of weight-monitoring days is considerably overdispersed relative to the binomial distribution, such that for a given subject in a given group, the mean of Y is $42a$ and the variance of Y is $42Øa(1 - a)$, where $Ø$ is an overdispersion parameter. In our pilot data, we estimated $Ø$=17.5; these values yield 2-group power calculations comparing IG weight-monitoring rate, a_{IG}, with CG weight-monitoring rate, a_{CG}, under within-group sample size n=75. If a_{IG}=0.80, then we will have 90% power to detect differences between a_{IG} and a_{CG}, as small as 0.14 (SD 0.12; ie, a_{CG} as big as 0.66, SD 0.68), yielding strong power from our longitudinal design. Owing to the need to estimate the overdispersion parameter, these calculations were custom coded by our team in R (R Foundation for Statistical Computing) [54].

XSL•FO
RenderX

Qualitative Coding and Analysis

Survey analysis will include descriptive statistics of counts and frequencies for the scale items and thematic analysis for the open-ended survey responses [55,56]. Verbatim transcripts will be created; they will be coded and examined using thematic analysis and Dedoose (SocioCultural Research Consultants) [57] software to enable examination of themes overall. Finally, the quantitative and qualitative results will be merged [48] to provide insights on the weight monitoring, physical activity, sensor use, and SCDG-playing behaviors of participants with HF; facilitators and barriers affecting participant engagement with sensors or SCDG for HF self-management behavior adherence; as well as future improvements and design modifications of the SCDG. The facilitators and barriers affecting engagement in sensor-based digital health interventions will be published in a secondary analysis publication.

Results

A CONSORT (Consolidated Standards of Reporting Trials) flow diagram will be reported. The clinical trial was initiated on October 24, 2022, and the first participant was enrolled on November 7, 2022. Recruitment of the last participant is anticipated in quarter 1 of 2025. Full trial results are planned to be published by 2026.

Discussion

Principal Findings

Our SCDG intervention addresses a substantial challenge, that is, to develop an affordable and scalable technology-assisted intervention to facilitate persistent adherence to self-management behaviors by adults with HF to improve QoL, functional status, and health outcomes and, ultimately, to reduce the burden of HF worldwide. We hypothesize that 12 weeks of playing the SCDG will result in greater behavioral changes in key self-management indicators of HF outcomes in adults aged >45 years compared with a CG that uses only sensors.

The recent rapid rise in the use of smartphones across demographic groups has enabled the scalability of innovative digital health interventions to promote HF self-management behaviors across diverse groups [58]. Although interventions such as digital games for health can be easily deployed to address geographic disparities in HF outcomes experienced by populations in southern US states, there is a lack of systematic research on the effectiveness of digital game interventions to promote evidence-based self-management behaviors of individuals with HF with conflicting priorities or in unsupportive environments. Current digital health interventions with unobtrusive monitoring capabilities allow the gathering of relevant contextual data to tailor and adapt interventions without overburdening participants through cumbersome data collection [59]. This study protocol was informed by our feasibility randomized controlled trial study, in which we demonstrated the remote implementation of a smartphone-based intervention using a digital game and sensors among participants in 18 counties in Texas and Oklahoma [29]. Combining digital games and sensors holds the potential to offer a powerful way to improve treatment adherence [60,61]; sustain healthy behaviors; and make health care more participatory, personalized, predictive, and preventive, as defined by precision medicine [62]. The lessons from this initial study provide a strong foundation to test our intervention with individuals with HF in 7 southern US states. Therefore, we hypothesize that 12 weeks of playing the SCDG will result in greater behavioral changes in key self-management indicators of HF outcomes in adults aged >45 years compared with a CG that uses only the sensors.

Strengths

Developing a dashboard that will allow easier visualization of behavioral data from all participants will provide us with the opportunity to intervene immediately in the event of absent or unsafe levels of behavioral data. In addition, fully remote study procedures will enhance the accessibility of HF research to participants living in rural or remote areas that are far from large HF centers in cities.

Limitations

Self-selection bias may be a limitation of this study as participation is voluntary, and participants already comfortable with using technology might be especially motivated to participate in digital intervention studies.

Dissemination Plan

We will disseminate our study findings to target an audience that cares for patients with HF and will benefit from the lessons learned through our study. This includes disseminating our findings through (1) peer-reviewed health technology–related journals such as *Games for Health Journal* or *Journal of Medical Internet Research* and clinical journals such as *Journal of Cardiovascular Nursing* or *Journal of Cardiac Failure*; (2) annual research conferences conducted by the Heart Failure Society of America, American Heart Association, Society of Behavioral Medicine, American Medical Informatics Association, and Gerontological Society of America; (3) local and regional nursing organizations such as Texas Public Health Association's monthly webinars and similar organizations in other southern US states; (4) scheduled continuing education sessions or monthly meetings conducted by HF clinics for their staff; and (5) local and regional support groups for patients with HF. In addition, all peer-reviewed and accepted manuscripts will be uploaded either by the investigator or by the journal (for those journals that perform this function) to the National Library of Medicine's PubMed Central in accordance with the National Institutes of Health Public Access Policy.

Conclusions

Nevertheless, this project will generate insight and guidance for scalable and easy-to-use digital gaming solutions to motivate persistent adherence to HF self-management behaviors and improve health outcomes among individuals with HF.

Acknowledgments

This research was supported by the National Heart, Lung, and Blood Institute of the National Institutes of Health under award R01HL160692. The content is the sole responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

Although the final data set comprising questionnaire and qualitative data will be stripped of identifiers, we believe that there remains the possibility of deductive disclosure of participants with unusual characteristics. Thus, we will make the data and associated documentation available to users only under a data-sharing agreement that provides for (1) a commitment to using the data only for research purposes and not to identify any individual participant, (2) a commitment to securing the data using appropriate computer technology, and (3) a commitment to destroying or returning the data after analyses are completed. After reviewing the purpose of the data request to ensure that it is consistent with the original project goals and verifying that the request meets approval from the Institutional Review Board, deidentified data may be shared with researchers as soon as possible but no later than within 1 year from the completion of the funded project period for the parent award or upon acceptance of the data for publication, whichever is earlier.

Conflicts of Interest

MO is the owner of Good Life Games, Inc, a company that develops health games for hire, which provided the prototype game images for this study.

Abstract

Background: Bipolar disorder (BD) is a highly prevalent psychiatric condition that can significantly impact every aspect of a person's life if left untreated. A subtype of BD, bipolar disorder type II (BD-II), is characterized by long depressive episodes and residual depression symptoms, with short-lived hypomanic episodes. Medication and psychotherapy, such as cognitive behavioral therapy (CBT), are the main treatment options for BD-II. CBT specific for BD-II involves the recognition of warning signs, potentially triggering stimuli, and the development of coping skills to increase euthymic periods and improve global functioning. However, access to in-person CBT may be limited by several barriers, including low availability, high costs, and geographical limitations. Thus, web-based adaptations of CBT (e-CBT) have become a promising solution to address these treatment barriers. Nevertheless, e-CBT for the treatment of BD-II remains understudied.

Objective: The proposed study aims to establish the first e-CBT program specific for the treatment of BD-II with residual depressive symptoms. The primary objective of this study will be to determine the effect of e-CBT in managing BD symptomatology. The secondary objective will be to assess the effects of this e-CBT program on quality of life and resilience. The tertiary objective will involve gathering user feedback using a posttreatment survey to support the continuous improvement and optimization of the proposed program.

Methods: Adult participants (N=170) with a confirmed diagnosis of BD-II experiencing residual depressive symptoms will be randomly assigned to either the e-CBT and treatment as usual (TAU; n=85) group or the TAU (n=85) control group. Participants in the control group will be able to participate in the web-based program after the first 13 weeks. The e-CBT program will consist of 13 weekly web-based modules designed following a validated CBT framework. Participants will complete module-related homework and receive asynchronous personalized feedback from a therapist. TAU will consist of standard treatment services conducted outside of this research study. Depression and manic symptoms, quality of life, and resiliency will be assessed using clinically validated symptomatology questionnaires at baseline, week 6, and week 13.

XSL•FO
RenderX

Results: The study received ethics approval in March 2020, and participant recruitment is expected to begin in February 2023 through targeted advertisements and physician referrals. Data collection and analysis are expected to conclude by December 2024. Linear and binomial regression (continuous and categorical outcomes, respectively) will be conducted along with qualitative interpretive methods.

Conclusions: The findings will be the first on the effectiveness of delivering e-CBT for patients with BD-II with residual depressive symptoms. This approach can provide an innovative method to address barriers to in-person psychotherapy by increasing accessibility and decreasing costs.

Introduction

Bipolar disorder (BD) is a highly prevalent affective psychiatric condition that affects nearly 2% of the global population [1-5]. It is characterized by chronic mood swings fluctuating from mania or hypomania to depression, which often cause significant impairment both socially and occupationally. The manic or hypomanic component involves 3 days or more of persistently elevated mood, recklessness, grandiosity, decreased need for sleep, reduced ability to concentrate, and irritability [2,4,6-8]. The depressive component involves 2 weeks or more of persistently low mood, anhedonia, poor appetite and sleep, reduced ability to concentrate, agitation or motor slowness, and suicidal ideation [4,8]. There are 4 main types of BD that are differentiated by the type, frequency, and severity of the mood episodes. Bipolar I disorder requires at least one manic episode, whereas bipolar disorder type II (BD-II) is characterized by depressive and hypomanic episodes. Cyclothymic disorder involves the presence of depressive and hypomanic states that do not meet diagnostic criteria and last a minimum of 2 years. Lastly, BD with mixed features is characterized by depressive and elevated moods simultaneously [2,4]. Unlike other types of BD, individuals with BD-II tend to experience longer and more persistent depressive episodes, sometimes with residual depressive symptoms, which are further exacerbated by the negative consequences of their hypomanic episodes [8].

Misdiagnosis and delayed treatment are common for individuals with BD, which can result in serious and sometimes irreversible outcomes. These outcomes can include more frequent and severe mood episodes, intellectual disability, loss of independence, and loss of ability to function [2,4,6,7,9-12]. Although mood-stabilizing medication remains the first line of treatment for BD, the beneficial effects of psychosocial treatments, particularly cognitive behavioral therapy (CBT), are now widely recognized [13]. Furthermore, the use of psychotherapy for the management of BD-II has evolved significantly over the past few decades [8]. CBT targets negative or dysfunctional thought patterns and behaviors through cognitive and behavioral restructuring techniques. These techniques aim to help the individual develop healthier or more balanced thought patterns (cognitive restructuration), which can then be applied in day-to-day life (behavioral restructuration). This can help with reducing psychiatric symptomatology and decreasing depressive episode duration along with increasing euthymic periods and improving global functioning and quality of life [14-20]. Furthermore, CBT specific for BD-II often includes techniques to practice acceptance, recognize warning signs of an upcoming mood episode, recognize potentially triggering stimuli, and develop an action plan with helpful steps and considerations to follow before, during, and after a mood episode [8,14,16,17,19,21,22].

However, several barriers prevent the broader uptake of CBT and other in-person psychotherapy options, including high costs, low availability, long waitlists, stigma against psychiatric interventions, and geographical and physical limitations [11]. Thus, web-based adaptations of traditional in-person CBT (e-CBT) have become promising alternatives due to their lowered cost, time effectiveness, flexibility, privacy, and convenience [14,23-25]. Additionally, e-CBT has been shown to increase help-seeking behaviors among patients and to have similar effectiveness at reducing psychiatric symptomatology as in-person CBT [11,14,26-28]. e-CBT programs often include weekly assignments for the participants and may be either fully self-guided or guided with asynchronous support from an assigned therapist [14]. Despite these benefits over in-person CBT, e-CBT options specific to BD remain significantly understudied and underdeveloped, and very few e-CBT programs have focused on BD-II [15-19,29].

To supplement this gap in the literature and guide clinical practice, this will be an open-label randomized controlled trial studying the effectiveness of a novel e-CBT program specific for BD-II in addition to treatment as usual (TAU; e-CBT + TAU). This program will be developed with the help of individuals with lived experience of BD-II to ensure applicability and accuracy. Thus, the primary objective of this study will be to determine the changes in BD symptomatology (hypomanic and depressive symptoms) of participants receiving e-CBT + TAU compared to participants receiving only TAU. Based on the evidence comparing e-CBT specific for BD to psychoeducation, attention controls, and TAU [16,17,19], this study hypothesizes that adding this e-CBT program to TAU will result in better symptom management than TAU by itself. The secondary objective will be to assess the effects of this

XSL•FO
RenderX

e-CBT program on quality of life and resilience. The tertiary objective will involve gathering user feedback using a posttreatment survey to support the continuous improvement and optimization of the proposed program.

Methods

Participants

This is the protocol for a randomized controlled trial studying the efficacy of a novel e-CBT program. Participants (N=170) diagnosed with BD-II experiencing residual depressive symptoms will be recruited from the Mood and Anxiety Clinic at Providence Care Hospital, Kingston Health Sciences Center, family physicians, other health care professionals, and self-referrals within Ontario, Canada. Additionally, recruitment efforts will be carried out through flyers in social gathering areas (eg, coffee shops, college campuses), media advertisements, and expert end user referrals. After providing consent to participate in the study, the participants will complete a Mini International Neuropsychiatric Interview 7.0.2 (MINI) with a trained research assistant [30]. The MINI assesses 17 common psychiatric conditions following the diagnostic criteria of the Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) [30]. Inclusion criteria include being 18 years or older at the start of the study, a diagnosis of BD-II based on the MINI assessment, a Montgomery-Åsberg Depressive Rating Scale (MADRS) score of mild to moderate depression symptomatology (MADRS score 7-34), competence to consent and participate, ability to speak and read English, and consistent and reliable access to the internet [14,31-33]. Exclusion criteria include acute hypomanic or manic episodes, acute psychosis, severe alcohol or substance use disorder, and active suicidal or homicidal ideation. Additionally, individuals who are currently receiving or have received CBT in the past 6 months will be ineligible to avoid confounding treatment effects.

Procedures

Eligible participants will be randomly assigned to either a 13-week e-CBT program in addition to TAU (n=85; e-CBT + TAU group) or TAU only (control group; n=85). If interested, participants in the control group will be offered access to the e-CBT program after completing 13 weeks as part of the control group. The e-CBT program will be delivered as an augmentation to TAU through the Online Psychotherapy Tool (OPTT), a secure and interactive platform developed by the principal investigator (PI) [14,34]. TAU will consist of medications, regular physician or clinician visits, referrals, or consultations that are conducted outside of this research study.

e-CBT Specific for BD-II

Participants in the e-CBT group will receive weekly predesigned web-based modules for 13 weeks. Each module will consist of approximately 30 slides and should take an estimated 45 minutes to complete. Each participant will be assigned a therapist to communicate with them asynchronously through the OPTT platform. In addition, the modules include weekly homework for the participants, which will be submitted directly through OPTT to the assigned therapists. The therapists will then use the OPTT platform to provide personalized feedback using session-specific therapy feedback templates. These feedback templates were developed under the guidance of the PI (NA) to standardize the quality and content of the feedback across different patients and therapists. Furthermore, in previous studies conducted by the PI, these feedback templates have been used to prepare personalized feedback in approximately 15-20 minutes [14,33,35,36].

The proposed e-CBT program will be developed to teach core CBT concepts (ie, the 5-part model, automatic thoughts, the thought record, cognitive and behavioral restructuration) and concepts specific to the management of BD-II [8,14,35,37]. These BD-II–specific concepts include techniques to practice acceptance, recognize warning signs of an upcoming mood episode, recognize potentially triggering stimuli, and develop an action plan with helpful steps and considerations to follow before, during, and after a mood episode [8,14,16,17,19,21]. Additionally, individuals with lived experience of BD-II will be recruited to help in module development and review the modules for applicability and accuracy.

Training

Research assistants trained in the delivery of CBT and writing feedback will be assigned as therapists for the e-CBT group. The PI, who is an expert in the web-based delivery of psychotherapy and CBT [14,33,35-37], is involved in the training of the therapists to ensure the quality and reliability of the treatment programs. Training will involve weekly workshops and a CBT training video with a quiz at the end. To further ensure that the therapists are well prepared, the co-PI (MY) will closely guide the therapists through their first patient (assigning modules, reviewing homework, writing feedback, and answering questions using the OPTT platform). Furthermore, all therapists will use predesigned session-specific feedback templates to secure the quality of the feedback, which will be reviewed by the co-PI before being sent to the participants. To avoid a conflict of interest, the PI will not be involved in writing or supervising feedback.

Outcome Evaluation

The primary outcome of this study will be to determine the change in BD symptomatology (hypomanic and depressive symptoms) of participants receiving e-CBT + TAU compared to participants receiving TAU only. This will be measured through clinically validated symptomatology questionnaires, including the MADRS and the Young Mania Rating Scale (YMRS) [31,32]. The secondary outcome will be to assess the effects of this e-CBT program on quality of life and resilience. These metrics will be assessed using the Quality-of-Life Enjoyment and Satisfaction Questionnaire-Short Form (Q-LES-Q-SF) [38] and the 14-item Resilience Scale (RS-14) [39]. All questionnaires will be completed through OPTT at baseline, week 6, and week 13. Subsequent to the treatment period, follow-up assessments will be conducted for all the outcome measures at 3, 6, and 12 months. The tertiary outcome will involve gathering user feedback using a posttreatment survey. This posttreatment survey will be sent to all participants who completed the e-CBT program and will consist of questions related to their experience going through the modules and using

XSL•FO
RenderX

the OPTT platform. Also, it will collect any additional feedback and suggestions to support the continuous improvement and optimization of the proposed program.

Ethics Approval

This study has been reviewed for ethical compliance by the Queen's University Health Sciences and Affiliated Teaching Hospitals Research Ethics Board (File Number 6028658) in March 2020. Participant data is only accessible to the health care professionals; otherwise, participants will only be identified by their study ID, and all records will be stored on a secure platform. As part of the consent process, participants are informed that they can withdraw from the study at any time and request for their data to be removed from the analysis. The research team will safeguard the data and privacy of the participants to the extent permitted by the applicable laws and duty to report.

OPTT is compliant with the Health Insurance Portability and Accountability Act, Personal Information Protection and Electronic Documents Act, and Service Organization Control-2. Also, to assure provincial and federal privacy and security regulations are met, all servers and databases are hosted in the Amazon Web Service Canada cloud infrastructure. OPTT only collects anonymized metadata used in service quality analysis; no identifiable personal information or IP addresses are collected.

Data Analysis

Initially, all data will be examined for missing, nonsensical, and outlying variables. Missing data will be treated as missing and not imputed (ie, will be analyzed on a per-protocol basis). However, an intention-to-treat analysis will be conducted to determine the clinical effects of the e-CBT program on participants who dropped out. Based on previous experience with CBT and e-CBT in similar patient populations, the anticipated dropout rate is up to 30% by the end of the treatment or TAU phases [14,33,35,37,40]. Given the likelihood of participant dropout or withdrawal, the study sample has been purposely oversampled to obtain meaningful and statistically significant results at the end of the study. Considering the effect size for e-CBT reported by Todd et al [19] for the reduction of depression symptomatology (effect size=0.44), a significance of $P<.05$ and a power of 0.80, a sample size of 170 (85 per arm) would be sufficient to detect significant changes from this intervention [14,19,33,35,40,41]. As this is the first study aiming to establish an e-CBT program specific for BD-II, this sample size calculation relies on data from e-CBT specific for BD (all types). It takes into account the established effectiveness of web-based psychotherapy [14].

A 2-tailed significance level of $\alpha=.05$ will be used for all calculations, except when a Bonferroni correction is needed. Possible differences between program completers and noncompleters will be determined by comparing the respective demographic information using independent sample *t* tests. A 2-by-3 repeated measures ANOVA of the primary (BD symptomatology: MADRS and YMRS) and secondary (Q-LES-Q-SF and RS-14) outcomes will be conducted to compare the effects of e-CBT + TAU to TAU only throughout the 13-week treatment course (0-, 6-, and 13-week assessment points). Variables associated with outcome measures will be determined using linear regression (continuous outcomes) and binomial regression analysis (categorical outcomes). The data collected from the posttreatment survey will be analyzed qualitatively with 2 reviewers to identify common themes and specific areas for improvement. All statistical analyses will be conducted using SPSS Statistics for Mac, version 28 (IBM Corp).

Results

The literature comparing the efficacy of e-CBT specific for BD to psychoeducation, attention controls, and TAU has shown that e-CBT specific for BD is effective at reducing BD symptomatology (depression and mania or hypomania symptoms) and improving quality of life [16,17,19]. Thus, this study hypothesizes that adding this e-CBT program to TAU will result in better symptom management (reduction of BD symptomatology and improvement of quality of life) than TAU by itself. The study received notice of funding acceptance through the Queen's University Department of Psychiatry Internal grant in December 2019. Participant recruitment will begin in February 2023 using targeted advertisements and physician referrals (see Methods). Complete data collection and analysis from all phases are expected to conclude by December 2024. All procedures and outcomes have been and will be reported using the CONSORT (Consolidated Standards of Reporting Trials) and TIDieR (Template for Intervention Description and Replication) Report Guidelines [42]. This study has been registered through the ClinicalTrials.gov system (NCT04664257).

Discussion

This is a protocol for an RCT that aims to establish the first e-CBT program for the management of BD-II with residual depressive symptoms. This program will cover helpful coping techniques to increase euthymic periods and improve global functioning by applying the widely validated principles of CBT [14-20]. Based on literature evidence, previous clinical trials conducted by NA, and the use of a validated therapy approach, this study hypothesizes that this novel e-CBT program will have similar effectiveness as face-to-face CBT for the management of BD-II with residual depressive symptoms [14,33,35-37].

The management of BD-II involves the use of mood-stabilizing medications and psychosocial interventions [13]. Thus, given the proven efficacy of CBT for a variety of psychiatric conditions, the development of CBT for the management of BD-II has become a growing area of research [8]. CBT for BD-II usually involves face-to-face sessions with a therapist and covers techniques to practice acceptance, recognize warning signs of an upcoming mood episode, recognize potentially triggering stimuli, and develop an action plan [14-20]. However, access to in-person CBT faces significant barriers, including high costs, low availability, long waitlists, stigma against psychiatric interventions, and geographical and physical limitations [11]. Also, despite advances in the development and validation of web-based adaptations of CBT for other psychiatric conditions

XSL•FO
RenderX

[14,15,20], e-CBT options specific for the treatment of BD-II remain understudied [15-19]. This presents an important gap in the literature with potentially detrimental consequences for individuals with this condition.

The strengths of this novel e-CBT program and of this study include the use of a validated approach for the delivery of interactive, predesigned web-based modules with the asynchronous guidance of a therapist through the OPTT platform [14,33,35-37]. Also, by taking advantage of the web-based medium, this program has the potential to improve accessibility, cost, time effectiveness, flexibility, privacy, and convenience. For instance, previous studies have shown that asynchronous psychotherapy, through the use of predesigned web-based modules, allows therapists to deliver care to 3-4 patients in the same time as a traditional hour-long in-person session [14,33,35-37]. Furthermore, using the OPTT platform, this study will be able to reliably collect user analytics, which allows for the improvement and continuous optimization of e-CBT program delivery. Additionally, by comparing this proposed program to a validated therapeutic approach (face-to-face CBT for the management of BD-II) [14-20], the design of this study should provide helpful evidence for the validation of e-CBT for the management of BD-II with residual depressive symptoms.

Moreover, the knowledge dissemination plan for this study includes the publication of the findings in a peer-reviewed academic journal. The findings will also be presented broadly through academic meetings and conferences. Thus, this plan ensures the commitment to continuing education in the relevant research areas. Also, collaboration with the Canadian enterprise OPTT Inc. will enhance the dissemination and application of knowledge. Additionally, by providing this service to clinicians, the care capacity for accessible, affordable, and high-quality mental health care could be more rapidly scaled across Canada.

Though this study has some potential limitations that mainly stem from the web-based mode of delivery of this program, the main limiting factor is that participants would need a reliable internet connection and sufficient technology literacy to participate. In turn, this could introduce biases in participant demographic characteristics. To account for this, this study will analyze demographic factors through multiple sample *t* tests to identify the impact of these factors on treatment outcomes. Additionally, the design of this study is limited by the lack of therapist and client blinding. However, due to the delivery mode and design of the program, it is not possible to conceal client allocation. Furthermore, web-based psychotherapy is often characterized by significant dropout rates, with some studies reporting a dropout rate of up to 30% by the end of the treatment or TAU phases [14,33,35,37,40]. Hence, this study is intentionally oversampling to account for this potential high dropout rate without compromising the statistical power of this study.

In conclusion, this study recognizes the significant potential of web-based psychotherapy as a tool that can lower costs and increase capacity and accessibility in mental health care, as well as the lack of available web-based psychotherapy options for individuals with BD-II. Therefore, the results of this study aim to fill an important gap in the literature through the development, implementation, and validation of a novel e-CBT program for the management of BD-II with residual depressive symptoms. Additionally, these results aim to inform clinical practice and health care policy to support the widespread implementation of web-based psychotherapy, with potential benefits to the care capacity and performance of the health care system.

Acknowledgments

This study was funded by a 2020 Queen's University Department of Psychiatry Internal Grant. The funding agency has no role in the study design, execution, data collection, analysis, or interpretation.

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed yet for the preparation of this protocol manuscript. Though, the data sets generated and analyzed in the randomized controlled trial will be available from the corresponding author on reasonable request.

Conflicts of Interest

NA and MO have cofounded the care delivery platform in use (ie, OPTT) and have ownership stakes in OPTT Inc. NA will be involved in web-based modules design, therapist training, and study design and methodology. MO will oversee the study design and methodology. RM has received consulting and speaking honoraria from AbbVie, Eisai, Janssen, Lallemand, Lundbeck, Neonmind, and Otsuka, and research grants from CAN-BIND, CIHR, Janssen, Nubiyota, OBI and OMHF.

Abstract

Background: Law enforcement officers are routinely exposed to hazardous, disturbing events that can impose severe stress and long-term psychological trauma. As a result, police and other public safety personnel (PSP) are at increased risk of developing posttraumatic stress injuries (PTSIs) and disruptions to the autonomic nervous system (ANS). ANS functioning can be objectively and noninvasively measured by heart rate (HR), heart rate variability (HRV), and respiratory sinus arrhythmia (RSA). Traditional interventions aimed at building resilience among PSP have not adequately addressed the physiological ANS dysregulations that lead to mental and physical health conditions, as well as burnout and fatigue following potential psychological trauma.

Objective: In this study, we will investigate the efficacy of a web-based Autonomic Modulation Training (AMT) intervention on the following outcomes: (1) reducing self-reported symptoms of PTSI, (2) strengthening ANS physiological resilience and wellness capacity, and (3) exploring how sex and gender are related to baseline differences in psychological and biological PTSI symptoms and response to the AMT intervention.

Methods: The study is comprised of 2 phases. Phase 1 involves the development of the web-based AMT intervention, which includes 1 session of baseline survey measures, 6 weekly sessions that integrate HRV biofeedback (HRVBF) training with meta-cognitive skill practice, and 1 session of follow-up survey measures. Phase 2 will use a cluster randomized control design to test the effectiveness of AMT on the following prepost outcomes: (1) self-report symptoms of PTSI and other wellness measures; (2) physiological indicators of health and resilience including resting HR, HRV, and RSA; and (3) the influence of sex and gender on other outcomes. Participants will be recruited for an 8-week study across Canada in rolling cohorts.

Results: The study received grant funding in March 2020 and ethics approval in February 2021. Due to delays related to COVID-19, phase 1 was completed in December 2022, and phase 2 pilot testing began in February 2023. Cohorts of 10 participants in the experimental (AMT) and control (prepost assessment only) groups will continue until a total of 250 participants are tested.

XSL•FO
RenderX

Data collection from all phases is expected to conclude in December 2025 but may be extended until the intended sample size is reached. Quantitative analyses of psychological and physiological data will be conducted in conjunction with expert coinvestigators.

Conclusions: There is an urgent need to provide police and PSP with effective training that improves physical and psychological functioning. Given that help-seeking for PTSI is reduced among these occupational groups, AMT is a promising intervention that can be completed in the privacy of one's home. Importantly, AMT is a novel program that uniquely addresses the underlying physiological mechanisms that support resilience and wellness promotion and is tailored to the occupational demands of PSP.

Introduction

Background

Law enforcement officers are routinely exposed to hazardous, disturbing events that can impose severe stress and long-term psychological trauma. Upward of 42% of public safety personnel (PSP) report one or more mental health symptoms [1]. Accumulated stress and posttraumatic stress injuries (PTSIs) result in chronic physical and mental health disorders, including anxiety, depression, substance abuse, and cardiovascular disease [2,3]. PTSI is also related to reduced occupational performance, absenteeism, and risky behavior, with implications for both police and public safety [4,5]. Recent empirical research and government reports have highlighted a mental health and suicide crisis among various PSP sectors in Canada [6-8]. The accumulated evidence forms an urgent call for evidence-based programs that build resilience and wellness capacity in order to prevent PTSI symptoms before they manifest as severe, chronic, diagnosable disorders in PSP.

Biological Resilience: The Missing Piece

Existing PTSI prevention and resilience promotion interventions tailored to PSP not only show limited effectiveness but also do not consider sex and gender as central determinants of health and variables of importance [5,9,10]. Further, most traditional interventions are focused on addressing cognitive, emotional, and behavioral components without addressing the underlying neurophysiological mechanisms that erode resilience [2,11-14]. Typically, when a person encounters stress (either real or imagined), they will experience characteristic changes in the autonomic nervous system (ANS), including increased sympathetic nervous system (SNS) activation that elevates heart rate (HR) and respiration and a withdrawal of parasympathetic nervous system (PNS) activation. When stress has abated, PNS activation will lower heart and breathing rates and blood pressure, helping the body to return to reparative and restorative functioning [15].

Advances in physiology and neuroscience demonstrate that resilience is maintained by healthy ANS functioning. Disruptions in ANS functioning can be observed by objectively and noninvasively measuring 2 biological indices [13,14,16]: heart rate variability (HRV) and respiratory sinus arrhythmia (RSA). HRV is the variation in the time between successive heartbeats and depends primarily on the extrinsic regulation of HR by the balance between the SNS and PNS branches of the ANS [17,18]. If the time between heartbeats is rather constant, HRV will be low, whereas if the time varies, HRV will be higher. When a person is at rest, a high HRV signals good health because it represents a physical indicator of autonomic flexibility in responding to challenges [18,19]. In contrast, low resting HRV signals an imbalance in autonomic function, such as in clinical cases of anxiety and psychopathology, where there is an overactivation of the sympathetic branch and a weakening of parasympathetic influence over the heart [20]. RSA refers to the synchronization of HRV with breathing such that HR speeds up during inhalation (shortening the time between heartbeats) and slows during exhalation (lengthening the time between heartbeats) [21,22]. Increasing RSA builds physical wellness capacity by strengthening an individual's long-term reserves, which is theorized to occur via multiple pathways (ie, baroreflex control, blood pressure regulation, and efficiency of pulmonary gas exchange) [21,23].

There is evidence to suggest sex can influence ANS functioning, as indicated by differences in HRV and RSA at rest [24]. These findings have direct implications for evaluating and understanding biological resilience and the effectiveness of psychophysiological interventions. Policing is known to be both intensely stressful [25] and a hypermasculinized profession [26,27], both of which have significant consequences for women's professional experiences of stress and health. What remains to be seen is whether sociocultural gender and related occupational stressors (eg, gender discrimination and harassment) might contribute to differences in biological functioning and the effectiveness of physiologically focused wellness interventions.

Biological Resilience Training: Heart Rate Variability Biofeedback

Research reveals a connection between respiration, arousal, and emotional control, such that how a person breathes sends signals to regions in the brainstem and forebrain that modulate arousal [28]. For example, periods of slow breathing are associated with SNS suppression and PNS stimulation, which may underlie the anxiety- and stress-reducing effects of RSA [28]. For nearly 3 decades, Lehrer and Gevirtz [21] have pioneered and refined a

XSL•FO
RenderX

cardiorespiratory intervention called heart rate variability biofeedback (HRVBF). During HRVBF, a person is shown visual feedback of their beat-by-beat HR data while engaging in slow breathing with the goal of maximizing RSA. For clinically effective treatment, it is not sufficient to simply instruct a person to breathe slowly. Rather, HRVBF technology is required to identify the precise breathing rate for maximizing individual RSA and to condition this rate through training [29,30].

In collaboration with expert police practitioners as well as medical and academic experts in psychophysiological risk and resilience, the lead author developed the International Performance Resilience and Efficiency Program (iPREP), an in-person resilience program that improves occupational health and performance by addressing the unique acute and chronic stressors faced by police [31-33]. This program has been refined across 6 grant-funded multimethod studies with over 300 police participants measuring objective psychophysiological and behavioral data [31-40]. The components of the currently proposed intervention are based upon the same core scientific principles and validated intervention methods as iPREP, including mental health awareness and support [2] and psychophysiological techniques (ie, HRVBF) to promote resilience by conditioning adaptive HRV, RSA, and HR functioning [30,41,42]. Research has shown that the autonomic modulation techniques instructed during iPREP result in significant, long-term reductions in occupational errors and improvements in officers' ability to recover quickly from acutely stressful events when completed during scenario-based, in-person training [31-33].

Objectives

The aim of the proposed study is to develop (phase 1) and test (phase 2) if a web-based delivery of autonomic modulation training (AMT) can reduce symptoms of PTSI and build psychological wellness capacity and physiological resilience in police officers with similar effectiveness as in-person training. An additional novel scientific contribution of this protocol includes an examination of sex and gender in baseline biological and psychological presentations of PTSI among police and in response to a resilience-building intervention.

Hypotheses

Self-reported PTSI Symptoms and Resilience

The following 3 hypotheses were proposed:

- H1: Symptoms of PTSI will be significantly reduced following the completion of the AMT intervention.
- H2: Functional wellness capacity and resilience will be significantly improved following the completion of the AMT intervention.
- H3: Sex and gender differences in PTSI will be observed at baseline and postintervention assessments.

Specifically, we expect that self-identified females will report more symptoms of PTSI and lower resilience at baseline, a greater reduction of PTSI symptoms, and a greater increase in resilience at follow-up than self-identified males. Gender role stress, discrimination, and harassment will be explored as moderators of PTSI symptoms at baseline and in response to the AMT intervention.

Objective Biological Indicators of PTSI Symptoms and Resilience

The following 4 hypotheses were proposed:

- H4: Resting HRV will significantly increase following the completion of the AMT intervention.
- H5: RSA will significantly increase following the completion of the AMT intervention.
- H6: Recovery from acute stress will significantly improve following the completion of the AMT intervention.
- H7: Based on inconsistencies in the extant literature, we will conduct exploratory analyses of any potential sex and gender differences in HRV, RSA, and acute stress recovery at baseline and postintervention assessments.

Methods

Ethics Approval

This protocol has been approved by the University of Toronto's Social Sciences, Humanities, and Education Research Ethics Board (Protocol #39478).

Design

Capitalizing on the numerous long-standing professional relationships between study coinvestigators and police populations of interest, phase 1—development of the AMT intervention—will use an integrated knowledge translation (iKT) approach to generate user-informed content [42]. To test the effectiveness of the AMT intervention (phase 2), a cluster randomized control trial with parallel assignment will be used on several cohort samples of active-duty Canadian police officers. This study has been registered with ClinicalTrials.gov (NCT05521360).

Recruitment

We aim to test the AMT intervention on a sample of approximately 250 frontline police officers in rolling cohorts of 10-15 participants (half AMT, half waitlist control) from geographically representative police services across Canada. A power analysis was conducted using G*Power software [43] and found that a minimum total sample size of 128 participants was required (effect size f=0.25, α=.05, power=0.80, number of groups=2, number of repeated measures=2). However, we plan to oversample officers by sex and mitigate possible attrition based on the principal investigator's previous experience with conducting longitudinal research on police officers [31-33]. A small laboratory-based prepilot sample (n=10) will test equipment reliability, accuracy, and integration of HR monitors with HRVBF and learning management system (LMS) platforms. An initial pilot cohort 1 (n=30) will then test the AMT intervention in the population of interest (ie, law enforcement officers) using a combined laboratory-remote paradigm to validate the implementation of study procedures. These participants will also be invited to participate in a poststudy focus group as per the study protocol (see iKT Focus Groups in Procedures) to optimize the intervention (ie, content and delivery) and overall study procedures to provide

XSL•FO
RenderX

stakeholder- and user-informed feedback. When all user feedback has been incorporated, all subsequent participants will be tested fully remotely and in accordance with the randomized control trial procedures and group allocation.

Participants will be recruited in several ways: (1) partnering police services will provide a link to the web-based study hosted on the confidential University of Toronto (ie, not police-related) servers to members via email, announcements, and internal media postings with encouragement to participate; (2) the research team will visit police services and other related fora (eg, industry meetings and conferences) to hold recruitment and information days where eligible officers may sign up for the study; (3) our knowledge user (MLV) and expert police practitioner collaborator (PS) will facilitate recruitment of law enforcement officers through targeted media attention, networking, and professional outreach activities; (4) supporting stakeholder groups will facilitate communication and recruitment with users and law enforcement officers. Based on delays due to the COVID-19 pandemic, the order in which partner organizations are recruited and tested is subject to change based on availability and current public health guidelines.

Interested participants will be directed to a web-based consent form on a secure site that will detail the study aims, eligibility criteria, intervention protocol, allocation and procedures for experimental and control groups, risks and benefits, and other information related to their rights as a research participant (ie, confidentiality and contact information for PIs and the institutional ethics board). Participants will provide their informed consent by clicking on a link that will take them to an eligibility screening survey that will collect the following identifiable information: full name, mailing address (for equipment shipping and incentive payment), personal email address (for correspondence with the research team that is not monitored or accessible by the participants' police agency), and demographics including sex at birth, gender, age, ethnicity, police service (to verify active duty status against publicly available directories), role, years of service as a police officer, and confirmation that they are not currently on extended medical leave. Participants deemed eligible for the study will be provided with deidentified usernames and passwords to access the preintervention assessment (see phase 2 procedures).

Inclusion and Exclusion Criteria

Inclusion criteria included adults (aged 18 years or older) currently employed as active duty (ie, not retired or on an extended medical or disability leave) frontline law enforcement officers fluent in English. Exclusion criteria include non-Canadian law enforcement officers, police administrators, civilian employees (ie, nonsworn members), and officers that do not have regular access to a computer with internet access to complete the web-based AMT intervention. Scores on self-reported mental health screening tools completed during the preintervention sessions will be used to match the assignment of participants to experimental or control groups but will not be used to exclude participants based on established cutoff scores for high or severe PTSI symptoms.

Procedures

Phase 1: AMT Development

Using an iKT approach, the multidisciplinary research team will consult with police practitioners to tailor AMT content (ie, graphics and recruitment materials) and promote participation and adherence to the AMT intervention by advising on procedural aspects of the research study (ie, feasibility, accessibility, understandability, and relevance). The AMT intervention is comprised of 2 components—HRVBF training and meta-cognitive coping skills.

HRVBF Training

Based on an established and publicly available protocol [30], HRVBF has shown significant efficacy in treating a wide variety of disorders, including general anxiety disorder [44-46], major depressive disorder [47-51], hypertension [52-54], asthma [29,55,56], pain [57-61], and posttraumatic stress disorder (PTSD) [62]. Recent meta-analyses revealed a large effect size for HRVBF on reducing symptoms of self-reported anxiety and stress [63] and a moderate effect for HRVBF and paced breathing across targeted physical symptoms and measures of functioning [64]. The original protocol is intended for in-person delivery, and this project will test the effectiveness of web-based HRVBF delivery among police officers. Therefore, the protocol will be formatted for web-based delivery and presented on an LMS using a commercially available HRVBF app paired with a wearable HR monitor.

Meta-cognitive Coping Skills

Integrated with HRVBF training, psychoeducational modules will be developed to help individuals cultivate meta-cognitive coping skills, defined as the awareness and understanding of one's own thought processes and learning how to manage the assessment of one's own experiences, correctly identify demands and resources, and regulate the appraisal of experiences using attentional and cognitive techniques [2]. Participants will also receive training on developing effective coping skills, including the ability to garner social support from family or friends, engage in positive relationships, and seek professional help when needed. Further, participants will receive training on emotion regulation, such as directing thoughts in the service of reducing demands or increasing resources, the ability to express emotions appropriately and keep them in perspective, and the ability to stay aware of policy and procedures under stress. These meta-cognitive coping skills are rooted in cognitive behavioral therapy principles that have been tested digitally [2] and will be developed in consultation with licensed psychiatrists and clinical coinvestigators (NA).

Research ethics approvals, data sharing agreements with partner institutions, and the procurement of equipment to record HRV and HRVBF will also be finalized during this phase of the study.

Phase 2: Testing the Efficacy of the AMT Intervention

Overview

The ention assessment, 6 weeks of AMT sessions, and a postintervention assessment. Once participants are deemed eligible for the study, they will be issued a unique deidentified

XSL•FO
RenderX

username to access the web-based study, which will be hosted on secure LMS and survey platforms (eg, Qualtrics).

Session 1: Preintervention Assessment (1.5 Hours)

During this session participants will complete self-reported baseline measures of: (1) PTSI, including the Personal Health Questionnaire (PHQ-8) for major depressive disorder, General Anxiety Disorder Scale (GAD-7), Depression, Anxiety, and Stress Scale (DASS-42), PTSD checklist (PCL-5), Alcohol Use Disorder Identification Test (AUDIT), Perceived Stress Scale (PSS), and Personal Burnout Subscale of the Copenhagen Burnout Inventory (CBI) [65-71]; (2) resilience and well-being using the Brief Coping Orientation to Problems Experienced Inventory (Brief-COPE), Resilience Scale for Adults (RSA-33), Brief Resilience Scale (BRS), White Bear Suppression Inventory (WBSI), Perseverative Thinking Questionnaire (PTQ), Ultra Brief-Penn State Worry Questionnaire (UB-PSWQ), and Ultra Brief-Rumination Response Styles (UB-RRS) Questionnaire [72-78]; (3) functional wellness and occupational stress using the Sheehan Disability Scale (SDS), Good Health Practices Scale (GHPS), COVID-19 adapted version of the Holmes Rahe Stress Inventory (COVID-19 HRSI), World Health Organization Disability Assessment Scale (WHODAS 2.0) [79-82], operational and organizational subscales of the Police Stress Questionnaire (PSQ) [83], and Lam Employment Absence and Productivity Scale (LEAPS) [84]; and (4) sex and gender-relevant data using the Workplace Gender Discrimination Scale (WGDS) and Gender Experiences Questionnaire (GEQ) [85,86]. Global ratings of stress will be asked at the beginning of each AMT session using a sliding visual analog scale of 0 (not at all stressful) to 10 (extremely stressful) in response to 2 questions: “How stressful was this past week?” and “How stressed are you right now?.” Data will be immediately tabulated to randomly assign participants matched on demographic and outcome variables to either the experimental AMT intervention group that will continue with sessions 2-8 of the protocol or to the waitlist control group that will only be responsible for the first part of session 2 and all of session 8 (postintervention assessment).

Upon completion of session 1, participants will be asked if they want to continue in the study. This secondary “reconsent” is designed to conserve shipment of expensive study equipment (approximately USD $550 total) and retain eligible participants that demonstrate commitment to adhering to the study protocol. If participants agree to continue, they will receive a notification in their personal email confirming their mailing address and will be shipped necessary study materials, including compensation for completing session 1, a wearable HR monitor and chest band, a device equipped with the HRVBF app (an iPad), and a prepaid envelope to return all equipment at the end of the study. Once participants confirm receipt of their equipment in the mail, they will gain access to session 2.

Session 2: Baseline Physiological Assessment and Introduction to AMT (40-60 Minutes)

All participants will be taught via web-based video modules how to apply the wearable HR monitor and configure the HRVBF app. The wearable HR monitor will automatically record date and time-stamped physiological data upon contact with the skin via the chest band and will communicate with the HRVBF app via Bluetooth. All HRV data will be stored locally on the HRVBF app and study device, which will be mailed back to the research team at the end of the study period. In the first part of this session, both experimental and control participants will provide baseline resting HRV and RSA data that will be recorded while participants engage in a 7-minute neutral activity (eg, listening to prerecorded sounds) that does not stimulate arousal or relaxation (N Quigley, unpublished data, 2019). To assess recovery from an acute stressor, participants will perform web-based versions of the Paced Auditory Serial Addition Test (PASAT) [87] and the emotional Stroop task [88], both of which have been shown to induce significant sympathetic arousal but do not simulate traumatic material [28].

Following these baseline physiological assessments, participants in the experimental group will continue with the rest of their session (15-20 min) and begin the AMT intervention. Participants in the control group will not have any programming until session 8 (postintervention assessment).

AMT Intervention Sessions 3-7 (45-60 Minutes Each)

These sessions will be completed by participants in the experimental group only. The content of each AMT session will be modified from the Lehrer et al [30] HRVBF protocol and informed by practitioner, knowledge user, and stakeholder-informed design workshops to adhere to iKT principles and fit a web-based format [42]. Participants will use the HRVBF app linked via Bluetooth to their HR monitor to engage in paced breathing exercises, view their RSA progress and live HRVBF data, engage with psychoeducational content on the LMS, and complete their homework assignments (ie, paced breathing practice at least twice a day as per protocol) [30]. Participants will also view short video lectures, text, and educational content, and engage in practical exercises during each session. Participants will receive weekly emails with practice reminders and links to useful resources, including links to YouTube videos of their preferred breathing pace. Participants will learn about meta-cognitive and coping skills as they can help mitigate stress in operational, organizational, and personal contexts to foster holistic resilience and well-being.

Session 8: Postintervention Assessment (2 Hours)

All participants will receive an email reminder 1 week before the final session, which will be completed by both experimental and control participants. It will begin by obtaining objective physiological measures at rest, including HRV (7-minute neutral task), RSA (paced breathing), and recovery from acute stress (PASAT and Stroop tasks). Next, participants will complete the same self-reported questionnaires as in session 1 to assess changes in self-reported PTSI, resilience and well-being, occupational and operational stress exposure, and sex and gender-relevant data (see hypotheses). Participants in the control group will be asked if they would like to complete the AMT intervention. If so, they will be provided access to sessions 3 to 7 and will be asked to complete a second postintervention assessment (session 8) after completing the AMT intervention. Incentive payments will be processed as participants drop out or complete study assessments.

XSL•FO
RenderX

iKT Focus Groups

Following cohort 1, we will invite participants to take part in iKT Focus Groups to generate user-informed feedback on the web-based AMT intervention and identify potential sex and gender differences in the user experience. Focus groups will be led by our sex and gender expert (RR) and use a semistructured, purposive, snowball sampling design. Half-day focus groups will be held in person, with dedicated focus groups for female and male participants to provide sex-stratified samples. We will limit focus groups to 5 participants, as previous research shows groups of 4-6 ameliorate the effects of "over sharing" or domineering participants, as well as participants who may feel intimidated and become silent within larger groups [89,90]. Groups will also include officers of the same rank, a sampling stratification strategy designed to help ensure interaction with others that are not perceived as threatening and with whom an individual's experience may also resonate [90,91]. Focus group discussions will last between 60 and 120 minutes and will be voice-recorded to preserve their accuracy during transcription.

Outcomes

In accordance with our hypotheses, PTSI (H1) will be measured by the PHQ-8, GAD-7, DASS-42, PCL-5, AUDIT, PSS, CBI, and self-reported stress visual analog scale. Self-reported resilience and well-being (H2) will be measured by the Brief COPE, RSA-33, BRS, WBSI, PTQ, UB-PSWQ, and UB-RRS. Functional wellness capacity and occupational stress will be measured by the SDS, GHPS, COVID-19 HRSI, WHODAS 2.0, PSQ, and LEAPS. Sex will be measured by self-reported sex at birth (male, female, or other); gender is measured by self-identification as male, female, nonbinary, or other (with the option to self-report) or "prefer not to disclose." Sex and gender-related experiences will be measured by the WGDS and GEQ (H3 and H7). Changes in resting HRV (H4) will be measured by time and frequency domain parameters based on data collected from the wearable HR monitors (eg, high- and low-frequency HRV, low- or high- frequency ratio, and the Root Mean Square of Successive Differences, [RMSSD]) as recommended in the standards of practice for HRV analysis [17]. RSA (H5) will be measured by obtaining respiratory frequency. Greater power at the respiratory frequency indicates a higher level of RSA and will be analyzed using the gold standard HRV analysis program, Kubios [92]. Recovery from acute stress (H6) will be measured following completion of the web-based PASAT and emotional Stroop Tasks. Acute stress recovery will be assessed via a time-domain measure of HRV (RMSSD) [17].

Data Security and Analyses

Any personally identifiable information provided in the eligibility questionnaire will be downloaded and immediately deleted from web-based platforms, stored offline in encrypted files on password-protected computers at the University of Toronto accessible only by members of the primary research team approved by the lead principal investigator (JPA), and will not be shared with collaborators or participating police organizations. Data collected on the LMS and secure survey platforms (ie, pre- and postintervention assessments and responses to intervention exercises) will be matched to a deidentified user ID. Physiological data gathered by the wearable HR monitor and HRVBF app will be stored locally and will not be transferred to publicly accessible third-party cloud-based servers. Rather, participants will mail the equipment back to the research team, which will match the deidentified data offline. The key code linking participants' personal information and deidentified user IDs will only be stored on secure servers at the University of Toronto and will be destroyed once the participant completes or withdraws from the study, has received their compensation, and all deidentified data files have been matched.

Physiological data will be transferred to a 2-time Canada Research Chair in Health Informatics and Big Data expert coinvestigator (CM) via a secure virtual private network (VPN) tunnel and housed on a private cloud-based Big Data analytics platform located within the *Compute Ontario Advanced Research Computing* equipment at the Centre for Advanced Computing (Queen's University). CM will design the data management, cleaning, and analysis protocols necessary to construct the big data pipeline to process the large amount of continuous data, including matching the time stamps on the physiological data to significant event markers in the AMT intervention (eg, questionnaires, PASAT, and emotional Stroop tasks) and on the HRVBF app (eg, paced breathing exercise). Preprocessed data will then be sent back to the primary research team (JPA, PMD, and SCS) via a secure VPN tunnel and housed on the secure internal University of Toronto server (RES-NAS) for the statistical analyses described below using bespoke syntax and code on various software platforms (eg, Kubios, MatLab, and SPSS). Data from iKT focus groups will be stored in RR's secure data web-based Al Fresco space and hard copies in her triple-locking filing cabinet in her office at the Memorial University of Newfoundland.

To test the effectiveness of the AMT intervention on reducing PTSI symptoms and improving resilience, we will conduct prepost analyses of the self-reported PTSI (H1) and resilience measures (H2) using separate repeated measures analyses of covariance (ANCOVAs) accounting for demographic covariates for normally distributed data, and ranked repeated measures ANCOVAs for nonnormally distributed data [93]. Variables including sex, gender (H3), age, years of service, and geographic service region (eg, urban or rural; East, Central, or West) will be included as covariates.

To test the effectiveness of the AMT intervention on improving biological indicators of resilience, prepost analyses of resting HRV parameters (H4), RSA (H5), and recovery from acute stress (H6) will be separately assessed using repeated measures ANCOVAs with sex, gender (H7), age, years of service, and geographic service region as covariates. To determine which factors significantly predict greater changes in biological outcome measures, hierarchical linear regression analyses will be undertaken with self-reported measures and demographic variables entered as predictors in the models. We will also compare weekly changes in HRV and RSA as measured during AMT module exercises with repeated measures ANCOVAs. A main effects analysis of the "time" variable will explore the potential incremental benefit of AMT training and identify at what point during the 6-week intervention significant biological

XSL•FO
RenderX

changes occur. Computational approaches to analyzing and visualizing biological indices of resilience will be led by CM, including integration of cardiac (eg, HRV) and respiratory (eg, RSA) rhythms to elucidate patterns of desynchronization before, during, and following AMT.

To explore sex and gender-based contributions to self-report (H3) and objective indices (H7) of PTSI and resilience, the above analyses will include sex and gender as covariates or predictor variables with sex-stratified samples. These findings will clarify any sex-related differences in baseline and postintervention rates of PTSI and resilience among law enforcement officers and whether there are any sex-related differences in the magnitude of treatment effects (H3). Moderated regression analyses will test whether the AMT intervention affects the relationship between sex and PTSI symptoms and resilience. Multiple comparisons will be adjusted with Bonferroni corrections, where applicable.

Qualitative analyses of the transcribed data obtained from the iKT focus groups will be led by the sex and gender coinvestigator (RR) with the assistance of graduate students and postdoctoral fellows, with the aim of identifying sex- and gender-based considerations for developing effective occupational health interventions tailored to police officers and other PSP groups. Qualitative data analysis will use an inductive, comparative approach without initially arriving at any definitive, substantive, or theoretical conclusions about what the data reflect interpretatively with a lens on sociology and criminology [94]. Themes will emerge through the dynamic interaction of participants. Coding will be performed using NVivo qualitative analysis software (Lumivero), allowing for comparison across sessions [89] and the emergence of prominent themes through the tracking of coding “nodes” both across and within groups. Regular research team meetings will ensure that thematic development emerges in a consistent and reliable manner and help to ensure the hermeneutically attuned validity of the data [90].

Results

The study received notice of funding acceptance in March 2020. In February 2021, ethics approval was obtained from the University of Toronto’s Social Sciences, Humanities, and Education Research Ethics Board (Protocol #39478) and was renewed in February 2023. Phase 1 of the study (AMT Development) was completed in December 2022. Participant recruitment for phase 2 began with the pilot cohort in February 2023 via advertisements through partnering stakeholders (see Recruitment section). As of April 2023, 7 pilot participants were actively registered for the AMT intervention. Knowledge dissemination for phase 1 was completed in March 2023 at an annual meeting of the public safety wellness team grant holders and is planned for 1 scientific (May 2023) and 1 practitioner (October 2023) conference. iKT focus groups will take place following the completion of each sufficient cohort (see the iKT Focus Groups section above).

Discussion

Based on the extant and precedent literature, we predict that the stated hypotheses will be confirmed following the execution of the proposed protocol. Specifically, we anticipate significant reductions in PTSI symptoms and improvements in physiological indicators of health and resilience following the completion of the 6-week web-based AMT intervention. We also anticipate sex- and gender-based differences in pre- and postintervention outcomes, such that self-identified females will report higher PTSI symptoms and lower resilience at baseline and a greater reduction of PTSI symptoms and greater increase in resilience at follow-up than self-identified males. The direction and magnitude of sex- and gender-based differences in physiological outcomes are not currently specified, given the novelty of these analyses. Insights derived from iKT focus groups will supplement the quantitative sex- and gender-based analyses (H3 and H7).

AMT fills an existing gap in the applied research literature supporting evidence-informed prevention and intervention programs for PSP exposed to PTSI, such that AMT aims to measure and strengthen objective biological resilience [12]. Specifically, we are developing a tool that integrates wearable technology, real-time app-based visualized biofeedback tailored to an individual’s biological rhythms, and confidential web-based resources that meet the needs of accessibility and availability expressed by PSP organizations and governmental agencies [16]. Furthermore, our project addresses population-specific needs, including stigma reduction and gendered perspectives on occupational and organizational stress from female officers. By delivering our program on an LMS platform that can be accessed remotely in the privacy of one’s own home, we are providing officers with a secure and accessible wellness promotion intervention and resources that they might not otherwise seek out. This project will also contribute substantial new knowledge to the scarce literature about how sex and gender are related to biological indicators of PTSI and resilience (ie, HRV and RSA). Specifically, analyses will reveal the directionality and strength of interactions between sex and gender and physiological resilience outcomes (eg, what was thought to be sex-based differences in HRV may be related to gender norms and gender stress; see [95]). Our study provides a well-powered design to sufficiently address the persistent knowledge gap in this area.

AMT techniques have previously garnered high “buy-in” from participating police officers because the intervention provides tangible, real-time, biological evidence of occupational and health improvement from the very first HRVBF session [31-34]. Buy-in is further promoted by potentially relieving some symptoms early on without having to wait until the end of the intervention. Further, AMT directs focus on more “physical” rather than “psychological” symptoms to reduce the association of PTSI with potential weakness or occupational inadequacy among police, which has been previously noted [33,96].

Pending significant results, AMT can be delivered alone or in tandem with other psychotherapeutic treatments, such as cognitive behavioral therapy, to provide PSP services with an

XSL•FO
RenderX

attractive suite of resilience and wellness capacity interventions that reduce PTSI symptoms and save operating costs (eg, maintenance fees for multiple participant licenses) [97]. The intervention, if found to be effective, can be implemented on a larger scale with affordable, commercially available wearable technology (eg, FitBit and Apple iWatch) and apps (eg, HRV Trace and HRV Train) [98].

Rapid and direct knowledge dissemination to various stakeholders (eg, police organizations, unions, and professional and nonprofit first responder organizations such as The Haven, Badge of Life Canada, Ontario Women in Law Enforcement, and Wounded Warrior) will be facilitated by knowledge users' (MLV and PS) capacities as retired PSP, board members, and English-French bilingual contributors to police periodicals including "The Blue Line." In addition to this protocol, several research articles will be prepared based on the planned objectives and analyses identified above. High-impact peer-reviewed journals in relevant fields (eg, Psychophysiology, International Journal of Environmental Research and Public Health, and Policing) that provide open access options will be prioritized. Research findings on the pilot (n=30) and complete data sets (n=250) will be disseminated at scientific (Association for Applied Psychophysiology and Biofeedback, Society for Psychophysiological Research) and applied practitioner conferences (Law Enforcement and Public Health, Canadian Institute for Military and Veteran Health Research, Canadian Association of Chiefs of Police, Canadian Association of Police Educators) to distribute new knowledge generated to the widest audience possible.

Acknowledgments

This study was funded by the Canadian Institutes of Health Research's priority fund for public safety wellness. The funding agency has no role in the study design and will not impact the study execution, data collection, analysis, or interpretation. We would also like to acknowledge our academic, clinical, and practitioner partners, collaborators, and stakeholders, including Dr Joseph Arpaia, Paul Lehrer, Karen Quigley, Julian Thayer, Lissa Ruocco, and Juha-Matti Huhta. We would also like to thank the police services that offered letters of support at the grant writing stage and the Canadian Institute for Public Safety Research and Treatment for their support, media promotion, and knowledge dissemination. We also acknowledge the efforts of research associates and student volunteers at the University of Toronto (Dina Hejazi) and Ontario Tech University (Tina Cloutier).

Data Availability

To protect the privacy and confidentiality of participants, which are comprised of active-duty Canadian police officers, the data sets generated or analyzed during this study are not publicly available, but deidentified or aggregated data may be available from the principal investigator (JPA) on reasonable request.

Authors' Contributions

All authors have read and approved the submitted version of this manuscript. JPA, PMD, RR, and CM wrote the first draft of the manuscript. JPA, PMD, SCS, and CM wrote the final draft of the manuscript. JPA was responsible for conceptualization. NA, GA, CB, CM, RR, PS, and MLV were involved in consultation, coinvestigation, and final manuscript edits.

Conflicts of Interest

None declared.

Abstract

Background: Despite pharmacological treatment, individuals with inflammatory bowel disease (IBD) experience a variety of symptoms, including abdominal pain, fatigue, anxiety, and depression. Few nonmedical self-management interventions are available for people with IBD. A validated comprehensive self-management (CSM) intervention is effective for patients with irritable bowel syndrome who can have symptoms similar to those of individuals with IBD. We created a modified CSM intervention tailored to individuals with IBD (CSM-IBD). The CSM-IBD is an 8-session program delivered over 8-12 weeks with check-ins with a registered nurse.

Objective: The primary objective of this pilot study is to determine the feasibility and acceptability of study procedures and the CSM-IBD intervention and to evaluate preliminary efficacy on quality of life and daily symptoms for a future randomized controlled trial. Additionally, we will examine the association of socioecological, clinical, and biological factors with symptoms at baseline and response to intervention.

Methods: We are conducting a pilot randomized controlled trial of the CSM-IBD intervention. Participants aged 18-75 years who are experiencing at least 2 symptoms are eligible for inclusion. We plan to enroll 54 participants who will be randomized (2:1) into the CSM-IBD program or usual care. Patients in the CSM-IBD program will have 8 intervention sessions. Primary study outcomes include the feasibility of recruitment, randomization, and data or sample collection, as well as the acceptability of study procedures and interventions. Preliminary efficacy outcome variables include quality of life and symptoms. Outcomes data will be assessed at baseline, immediately post intervention, and 3 months post intervention. Participants in the usual care group will have access to the intervention after study participation.

Results: This project is funded by the National Institutes of Nursing Research and reviewed by the University of Washington's institutional review board. Recruitment began in February 2023. As of April 2023, we have enrolled 4 participants. We expect the study to be completed by March 2025.

Conclusions: This pilot study will evaluate the feasibility and efficacy of a self-management intervention (a web-based program with weekly check-ins with a registered nurse) that aims to improve symptom management in individuals with IBD. In the long term, we aim to validate a self-management intervention to improve patient quality of life, reduce direct and indirect costs related to IBD, and be culturally appropriate and accessible, particularly in rural and underserved communities.

KEYWORDS

inflammatory bowel disease; self-management; symptom management; pilot; intervention; randomized controlled trial

Introduction

Background and Rationale

Inflammatory bowel disease (IBD; including ulcerative colitis and Crohn disease) is a chronic immune-mediated disease of the gastrointestinal system that impacts individuals worldwide. Patients with IBD are often diagnosed at a young age and experience a lifetime of disease management, with symptoms including diarrhea, pain, fatigue, urgency, anxiety, and depression [1,2]. These symptoms result in suffering, substantial health care costs, and indirect costs related to work and school impairment, with fatigue being the most common reason for work absenteeism [3]. Health care providers are often not trained to manage noninflammatory symptoms, and with improved medications such as biologics and small molecule therapy, the disconnect between patient symptoms and management is widening [4,5]. Our team has a comprehensive solution to help patients with irritable bowel syndrome manage symptoms and improve self-management skills that can be adapted for an IBD population to address the urgent need for symptom management.

Within the United States, approximately 3.1 million individuals have a diagnosis of IBD [6]. As societies become more westernized, IBD incidence and prevalence have increased worldwide [7]. IBD affects men and women equally, although ulcerative colitis is slightly more common in males and Crohn disease is slightly more frequent in females [8]. In the past, it was thought that IBD occurred less frequently in racial and ethnic minorities compared with whites; however, this gap is narrowing with an increased incidence of IBD among African American and Asian individuals [9]. Therefore, with growing incidence and prevalence worldwide and among racial and ethnic minority populations, IBD represents a growing health problem demanding tailored, culturally appropriate, and effective interventions.

Immunosuppressive therapy can be effective in achieving control of endoscopic inflammation from IBD; yet, patients can experience symptoms while they await response to therapy or in the setting of refractory disease [10,11]. Patients can also have chronic symptoms, even after achieving remission, due to damage from chronic disease, altered surgical anatomy, or co-occurring functional symptoms [12]. While immunosuppression is essential in achieving and maintaining endoscopic remission for patients with moderate-severe IBD, other interventions are needed to improve symptom management and quality of life.

Symptom-directed medical therapies (eg, antidiarrheals, antiemetics, antispasmodics, and neuromodulators) offer symptom relief for some but are not effective for everyone and offer limited benefit for symptoms such as pain and fatigue. Nonpharmacological interventions such as dietary modification, relaxation techniques, and cognitive behavioral therapy (CBT) have been shown to improve symptoms [13,14], but teaching patients how to implement these interventions is time-consuming and impractical to achieve in a routine clinic visit. Some clinics have used an IBD specialty medical home model, which can reduce hospitalizations and emergency department visits as well as increase the quality of life [15]. Yet, patient access to providers who are experienced in these interventions and care delivery systems can be limited, especially in rural and underserved communities [16,17].

As the majority of a patient's time is spent outside of the clinic, there is a need to empower patients with the skills to manage their disease. Self-management refers to the day-to-day management that individuals must engage in while living with a chronic condition [18,19]. Among individuals with other chronic conditions, self-management programs are effective in reducing hospitalizations, days in the hospital, and fatigue while increasing self-reported health [20,21]. Despite the effectiveness of self-management programs among other chronic condition populations, few effective self-management interventions exist for individuals with IBD [22]. A systematic review identified 6 self-management randomized controlled trials conducted among individuals with IBD (representing 1715 patients) [22]. However, only half of the interventions improved health-related quality of life or reduced disease activity at 12 months. Psychological outcomes were reported by 2 studies, and 1, which used a written self-management plan developed with a clinician, failed to demonstrate an improvement in depression and anxiety [23,24].

An existing comprehensive self-management (CSM) intervention that provides patient education on nonmedical interventions for symptom management (eg, dietary modification, stress reduction, and CBT) has been shown to improve quality of life and decrease abdominal pain in patients with irritable bowel syndrome [25-27]. Furthermore, the intervention reduced anxiety, depression, fatigue, and extraintestinal pain and improved self-reported sleep compared to usual care [28,29]. To date, CSM interventions have not been routinely used in patients with IBD. Because there is a significant overlap between symptoms of irritable bowel syndrome and those of IBD, we hypothesized that adapting the CSM intervention to a population of individuals with IBD may also be effective (CSM-IBD). However, this remains to be tested.

Objectives

The objectives of this pilot randomized controlled trial are to (1) determine the feasibility and acceptability of study procedures (recruitment, randomization, and data and sample collection) and CSM-IBD; (2) compare CSM-IBD to usual care on changes from baseline to 3 months post intervention in

XSL•FO
RenderX

quality of life and daily symptoms (fatigue, sleep disturbance, psychological distress, gastrointestinal symptoms) among IBD patients and (3) explore the association of socioecological factors (age, sex, race, ethnicity, or diet), clinical phenotype (medications, disease distribution, and disease activity), and biological signatures (microbiome and calprotectin) with symptoms at baseline and response to intervention (post intervention).

Methods

Study Design

The proposed study is a 2-arm pilot randomized controlled trial that follows the Consolidated Standards of Reporting Trials and Standard Protocol Items: Recommendations for Interventional Trials guidelines [30,31]. In a 2:1 ratio, 54 participants will be randomized (intervention=36 participants; usual care=18 participants). This randomization scheme was selected to maximize data collection and information regarding the intervention group. The intervention will take place over 8 sessions. The participants will be blinded to the study hypotheses. Web-based self-reported questionnaires will be used to reduce detection bias.

Theoretical Framework

This study is guided by the Individual and Family Self-Management Theory (IFSMT) [32]. The IFSMT has 3 dimensions: context, process, and outcomes. It posits that interventions can influence the context and process (Figure 1). The context includes not only the individuals with IBD but also the complexity of the condition or treatment, individual factors (eg, age and sex), and social determinants of health such as food access and environmental settings, which can influence self-management skills and the ability to self-manage. In the IFMST, the process includes knowledge and beliefs (patient activation), self-regulation skills and abilities, and social facilitation and support (see Table 1 for the IFSMT process and CSM-IBD content). The IFSMT process of knowledge and beliefs includes Bandura self-efficacy theory, in which the intervention enhances self-efficacy (an individual's belief in their capacity to execute behaviors) and thus improves self-management [33,34]. Specific strategies and approaches used within the intervention are based on the expansive literature on CBT [35,36]. By impacting both the context and process, the intervention can influence the outcome to decrease symptoms and improve quality of life.

Figure 1. Individual and Family Self-Management Theory.

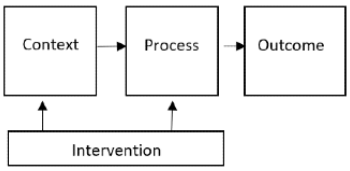

Table 1. IFSMT[a] self-management processes and CSM-IBD[b] content.

IFSMT process	IFSMT description	CSM-IBD content
Knowledge and beliefs	• Factual information • Self-efficacy • Goal congruence	• "When to contact your provider" • Introduction to strategies • Explanation of self-management • Personalized goals
Self-regulation skills and abilities	• Goal-setting, self-monitoring, reflective thinking • Decision-making, planning and action • Self-evaluation • Patient activation	• Abdominal breathing • Alternative thinking • Passive or active progressive muscle relaxation • Cognitive distortions • Sleep patterns, sleep hygiene • Pain management
Social facilitation	• Social influence • Support	• Eating out • Travel

[a]IFSMT: Individual and Family Self-Management Theory.

[b]CSM-IBD: comprehensive self-management for inflammatory bowel disease.

Study Population

Participants are individuals seeking care for their IBD at the University of Washington (UW). Inclusion criteria include participants who (1) have a health care provider diagnosis of IBD as reported in the electronic medical record, (2) report at least 2 current, active symptoms (Short Inflammatory Bowel Disease Questionnaire [SIBDQ] equal or less than 4 ["some of the time"] on any 2 items), (3) are 18 to 75 years old, and (4) are able to read and write in English. Participant exclusion criteria include (1) pregnant individuals, (2) significant co-occurring mental or physical conditions that would impact study participation, (3) surgery or hospitalization within the past month, or (4) living outside of Washington State.

CSM Intervention

The 8-session CSM includes patient education about self-management of symptoms using CBT, relaxation training,

XSL•FO
RenderX

and diet counseling. The intervention will be delivered digitally with skill videos, readings, and homework, as well as a weekly phone call or Zoom check-in with a nurse trained in CBT. For each session, participants will review information and practice skills on the session topic. The content for each session is outlined in Table 2. The weekly phone calls are designed to provide accountability and support for achieving the session goals and to enable individuals to ask questions about the content. The estimated time of completion is 8 weeks; however, participants will have 12 weeks to complete the sessions to allow for unexpected events. Intervention fidelity will be monitored using fidelity checklists and through the evaluation of a random selection of 20% of participants.

Also of note, the original CSM intervention was administered as a paper workbook with weekly hour-long sessions with a trained advanced practice nurse. To improve accessibility and feasibility, we have adapted the intervention to be administered as a web-based intervention with weekly phone call check-ins with a CBT-trained nurse. This unique approach expands the feasibility and reach of the intervention by enabling patients who may live in rural or underserved areas to access the intervention content. To be appropriate for the IBD population, the session 1 disease content was modified to include the role of inflammation, the importance of endoscopic remission, and information on when to contact their health care provider. The intervention content was reviewed by patients and health care providers.

Table 2. Comprehensive self-management for inflammatory bowel disease (CSM-IBD) by session.

Session	Content
Introduction and tracking symptoms session	• "When to contact your provider" • Introduction to IBD[a] • Introduction to strategies and self-management • Personalized goals and social support
Abdominal breathing and stress session	• Role of stress • Abdominal breathing
Problem-solving and travelling session	• Alternative thinking or problem-solving • Travelling
Healthy thought patterns session	• Healthy thought patterns • Automatic thoughts
Sleep and physical intimacy session	• Sleep tracking • Sleep hygiene • Physical intimacy
Pain management and quick relaxation session	• Pain management • Passive or active progressive muscle relaxation
Healthy eating, tracking, and trigger foods session	• Tips for healthy eating • Eating out
Comprehensive plan session	• Developing a comprehensive plan

[a]IBD: inflammatory bowel disease.

Usual Care

The intervention group will be compared to a usual care group of participants who meet the same eligibility criteria. Due to a current lack of standardization in managing IBD within the clinic setting, a usual care patient group most accurately reflects current practice.

Study Outcomes

Feasibility Outcomes

Feasibility will be evaluated for study procedures (recruitment, randomization, and data and sample collection) and the CSM-IBD intervention.

1. Recruitment: the number and percentage of participants prescreened, approached, screened, and enrolled.
2. Randomization: we will assess dropout rates between the CSM-IBD and usual care.
3. Data collection: the quality of data will focus on the data completeness of questionnaires; missing data will be reported as a percentage of missing data and the time point at which missing data occurred. Bivariate comparisons will be made between individuals with and without missing data. Information on sample collection time, transit time, and processing time will be obtained.
4. Sample collection: we will report how many participants collected biological samples on the planned date and the length of time from sample collection to arrival at the laboratory.
5. Intervention feasibility: measured with the Feasibility of Intervention Measure, in which participants respond to 4 questions on a 5-point Likert scale from 1=completely

XSL•FO
RenderX

disagree to 5=completely agree at the end of the intervention [37].

Acceptability Outcomes

A semistructured interview guide will be used to assess the acceptability of study procedures as well as the acceptability and satisfaction with the CSM-IBD. For instance, questions will probe for clarity of instructions, the burden of study procedures, and satisfaction with intervention content and delivery. Transcripts from participant interviews will be coded by 2 individuals using open coding methods to evaluate intervention acceptability. The use of CSM-IBD strategies will be assessed at 3 months post intervention by asking participants how often they use each strategy, with response options as: not at all or rarely, occasionally (at least 1 day a week), often (at least 2 days a week), very often (at least 4 days a week), or almost always [38]. Participants will complete the Acceptability of Intervention Measure, which includes 4 questions rated on a 5-point Likert scale from 1=completely disagree to 5=completely agree [37]. Satisfaction will also be measured with the 8-item Client Satisfaction Questionnaire [39].

Primary Outcomes

Quality of Life

The SIBDQ is a 10-item questionnaire that evaluates the quality of life. Participants respond on a 7-item Likert scale from all the time to none of the time. Total score range: 10 to 70 [40].

Symptoms

Symptoms are measured using a numeric rating scale where participants report the severity of the symptom from 0=not present to 10=worst possible. Symptoms include abdominal pain, anxiety, bloating, constipation, depression, diarrhea, fatigue or tiredness, passing gas, sleepiness during the day, stress, and urgency. See Multimedia Appendix 1 for a copy of the IBD Symptom Scale.

Secondary Outcomes

1. Process variables [41,42]
   - Self-Efficacy for Managing Chronic Disease: a 6-item self-report scale. Participants report ranging from not at all confident to totally confident [21].
   - Index of Self-Regulation: a 9-item scale to measure an individual's level of self-regulation [43].
   - Patient Activation Measure: a 13-item scale that assesses patients' beliefs, knowledge, and confidence in managing their health [44,45].
2. Biological signatures: stool samples will be collected by participants and stored immediately in home freezers (–20 °C) before transport to the UW School of Nursing Biobehavioral Laboratory. Samples will be stored at –80 °C until batch processing.
   - Gut microbiome: fecal microbial communities will be characterized using metagenomic shotgun sequencing on the Illumina MiniSeq or NextSeq platforms (Illumina, Inc) [46,47].
   - Fecal calprotectin: fecal calprotectin is a biomarker used to measure inflammation in the gut and will be assessed using an enzyme-linked immunosorbent assay [48].
3. Socioecological factors were selected based on the National Institute for Nursing Research's common data elements and include sex, gender, age, race or ethnicity, education level, employment, marital or partner status, household size, and neighborhood (urban or rural, zip code). Dietary intake can influence the composition of the gut microbiome and symptoms [49]. At the time of the stool collection, subjects will complete a detailed 3-day food record (Fred Hutchinson Cancer Research Center Nutrition Assessment).
4. The clinical phenotype will be obtained from the electronic medical record: type of disease, time since diagnosis, history of bowel surgery, disease distribution (measured by the Montreal Classification), medications, and disease activity (Harvey Bradshaw Index for Crohn Disease [50] and Simple Colitis Activity Index for Ulcerative Colitis [51]; <5 indicates remission).
5. Health care use will be evaluated from the electronic medical record and patient self-report, including emergency department use, hospitalizations, outpatient visits, laboratory tests, imaging, and procedures, as well as providers' nonclinical time spent managing patients.

Participant Timeline

Multimedia Appendix 2 presents the schedule of enrollment, interventions, and assessments based on the Standard Protocol Items: Recommendations for Interventional Trials guidelines. All procedures will occur remotely; data collection will occur digitally through REDCap (Research Electronic Data Capture; Vanderbilt University), a secure Health Insurance Portability and Accountability Act (HIPAA)–compliant database [52,53]. Individuals meeting eligibility criteria and interested in the study will be asked to sign a consent form and HIPAA form prior to participating in the study. All participants will complete baseline questionnaires (socioecological factors and disease information). Participants will collect a stool sample at home using a stool sample collection kit (instructions and researcher contact information will be provided); a 3-day food record will be collected starting 2 days before the stool sample collection. The stool samples will be placed in home freezers and returned to the School of Nursing Biobehavioral Laboratory. Participants will be provided with ice packs, a Styrofoam mailing box, and return labels. Stool samples will be stored at –80 °C until batch processing.

Following baseline data collection, participants will be randomly assigned to the 8-session CSM-IBD or usual care. Immediately post intervention, participants will complete questionnaires, collect a stool sample, and report a 3-day food record. Three months post intervention, participants will complete questionnaires and participate in a qualitative data collection interview. In addition, participants will report whether or not they are continuing the self-management skills learned in the intervention. Semistructured interviews will be conducted to understand the participants' perspective on procedural burden and suggestions to improve the intervention, including satisfaction with the intervention (see Multimedia Appendix 3). Interviews will be recorded and transcribed. Participants will

XSL•FO
RenderX

be compensated for each assessment completed (baseline, immediately post intervention, and 3 months post intervention). To increase retention, participants in the usual care group will be provided access to the intervention upon study completion. Participants can continue the study despite not completing all data collection assessments and all intervention sessions.

Sample Size

Based on recommendations for preliminary studies [54], we aim for data on 54 participants (36 intervention and 18 usual care). The sample size is appropriate for assessing feasibility and acceptability (aim 1). For aim 2, we will be able to detect fairly large effect sizes of 0.81 with 80% power. For aim 3, there will be 80% power to detect a correlation of 0.45. As a pilot study, the project is not powered to detect differences or correlations unless they are large.

Recruitment

Overview

Participant recruitment will take place at the UW Inflammatory Bowel Disease Clinics. The UW sees a large number of patients with IBD and serves as a tertiary care clinic for patients with IBD in the Washington, Oregon, Alaska, Montana, and Idaho regions. Recruitment may occur in three different settings: (1) in a clinic, (2) virtually (via telephone, email, or mail), and (3) by posting on the Institute of Translational Health Sciences website. All individuals will be informed that participating or not participating will not influence the care that they receive.

In a Clinic

Weekly prescreening will occur to determine if participants with scheduled IBD clinic appointments may be eligible for the study. The goal of prescreening is to enable purposeful sampling of patients based on demographic (eg, age and race) and disease characteristics (eg, disease activity). Individuals who are eligible will receive a flyer containing the study purpose and contact information from either their health care provider or study staff (depending on feasibility and current COVID-19 restrictions). Individuals will have time to review the study information. Participants can call study staff or complete a REDCap survey to express their interest and complete screening questions.

Virtually

The team may contact potential participants via phone, email, or mail if in-person recruitment becomes difficult or not feasible. All contact will follow the UW's institutional review board guidelines for cold contact recruitment. Those expressing interest in the study will call study staff for more information and then complete additional screening questions.

Institute of Translational Health Sciences Website

Information regarding the study will be posted on the UW Institute of Translational Health Sciences website. Interested individuals can complete the contact form to be contacted by study staff and can complete screening questions digitally.

In all instances, the purpose of the study, study design, and length of time to complete the study will be discussed. To assess participants' understanding of study procedures, individuals will be asked to briefly describe the study. Interested individuals will complete additional screening questions to confirm whether patients meet the specified inclusion and exclusion criteria. Screening questionnaires may be completed over the phone or electronically via REDCap, based on patient preference. Those meeting inclusion or exclusion criteria will be invited to participate in the study, sign a consent form, and begin data collection. Throughout the entire process of informed consent, from the first contact with the patient, the potential participants are able to ask any questions or delay making a decision. This screening and recruitment process will continue until the target sample size has been reached.

Intervention Allocation

A computer adaptive randomization procedure using a modification of the minimization method proposed by Pocock and Simon [55] will be used to balance groups based on SIBDQ at baseline. Once the data are entered into the computer, the computer program will return the participants' group assignment.

Statistical Analysis

Feasibility

The number and percentage will be calculated for participants who were prescreened, approached, screened, and enrolled (recruitment). We will assess dropout rates between the CSM-IBD and usual care (randomization). Quality of data will focus on the data completeness of questionnaires; missing data will be reported, and bivariate comparisons will be made between individuals with and those without missing data (data collection). We will report how many participants collected biological samples within the desired timeframe (sample collection). The mean and SD will be reported for the Feasibility of Intervention Measure (intervention feasibility).

Acceptability

Transcripts from participant interviews will be coded by 2 individuals using open coding methods (acceptability and satisfaction). In addition, numbers and percentages will be reported for participants who continue to use self-management strategies 3 months post intervention.

Primary Outcomes

Data from the 2 follow-up time points (immediate and 3 months post intervention) will be analyzed together using linear mixed models for each of the outcomes. For example, one model will have a change in the quality of life from baseline to immediate and 3 months post intervention as the outcomes, subject as a random effect, time (immediate or 3 months) as a within-subject fixed factor, and treatment group as an across-subject fixed factor. Baseline quality of life will be included as a covariate in the model, as will any baseline variables that differ between the 2 treatment groups. The parameter for the treatment group factor will provide an estimate of the treatment effect, that is, the difference between the treatment groups in mean change in the quality of life, and a 95% CI on the estimated difference will be computed. We hypothesize participants in the CSM-IBD will report a greater reduction in symptoms compared to those in usual care. A second model will also include an interaction between group and time to test whether the treatment effect is

XSL•FO
RenderX

different at the 2 post intervention times. Additional analyses will estimate treatment effects separately for men and women.

Secondary Outcomes

Analyses of microbiome data will use 3 summary measures—Shannon diversity, richness, and *Firmicutes/Bacteroidetes* ratio—as well as the relative abundance of bacterial families (eg, family Ruminococcaceae) and genera and will control for the read count. For diet, we will focus on protein and fiber intake, as our previous work has indicated these may be important dietary intake components related to the gut microbiome. First, we will examine the associations between socioecological, clinical phenotype, and biological signatures with symptoms at baseline in the total sample using Pearson correlation or Spearman rank correlation based on measure distributions. Scatter plots will be used to visually display these associations. Second, we will examine associations between socioecological, clinical phenotypes, and biological signatures at baseline and response to intervention in the intervention group. Response to intervention is conceptualized as an increase of 8 points on the SIBDQ scale (quality of life) [40] or a 50% decrease from baseline in the GI symptom score [27]. Among the intervention group, we will use the *t* test and chi-square test to compare socioecological factors, clinical phenotypes, and biological signatures among patients with and without a response to treatment.

Monitoring

This study has been classified as a minimal-risk study. The principal investigator has the responsibility for study oversight, including patient safety and data quality, as well as submitting reports to the funder and the institutional review board. Due to the low-risk nature of the CSM-IBD, we do not anticipate any adverse events or serious adverse events. The data safety and monitoring team will meet quarterly to review the study. The team will monitor accrual, withdrawals, data quality, timeliness of data submission, protocol compliance, and the types and frequency of adverse events and serious adverse events. No interim analysis or stopping rules are currently planned. However, if any adverse events or serious adverse events are reported, the data safety and monitoring team will meet within a week to discuss the event and any potential changes needed to the study procedures.

Ethics and Dissemination

Data Management

Study data will be collected and stored on REDCap. Participants will be assigned a unique study identification number. Only study members will have access to the data through a password-protected system and will have access to the least amount of data required for their position using limitations in REDCap user rights. The study will use ongoing quality control procedures during data collection, storage, and processing, including the use of the REDCap data quality module.

Ethics Approval

The institutional review board at the UW approved this protocol (STUDY 00015210) and determined the study to be minimal risk. This study is registered in ClinicalTrials.gov (NCT05651542). Any amendments to the study will be reviewed by the institutional review board and subsequently updated in the ClinicalTrials.gov registry. Participants in the usual care group will be offered access to the CSM-IBD intervention after they complete the 6-month data collection.

Dissemination

Study findings will be disseminated through presentations and publications to clinicians and researchers. Findings will be reported to the community through lay presentations and social media. Individuals will be eligible for authorship based on the International Committee of Medical Journal Editors' recommendations. The study will provide the basis for future research on self-management interventions. The findings of the study will be used to refine the intervention and develop a full-scale trial with additional recruitment sites throughout diverse geographical regions.

Patient Involvement

This study is informed by a patient advisory group that was convened for the purpose of providing advice and oversight for the study.

Results

This pilot randomized controlled trial was funded by the National Institute of Nursing Research (K23NR020044) in April 2022. Recruitment began on February 20, 2023. As of April 2023, we have enrolled 4 participants. We expect the study to be completed by March 2025.

Discussion

Expected Findings

This project is focused on evaluating the feasibility, acceptability, and preliminary efficacy of a CSM intervention for improving the quality of life and symptoms among individuals with IBD. We expect that overall participants will find the intervention acceptable and feasible, as mixed methods systematic review reported that greater than 75% of participants in IBD-related telehealth and mobile health interventions reported satisfaction with the intervention [56]. We also anticipate receiving feedback from participants on ways to improve the intervention.

Further, we expect to find preliminary signals of efficacy. A similar CSM intervention implemented in individuals with IBS showed reductions in anxiety, depression, abdominal pain, fatigue, and extraintestinal pain and improvements in sleep and quality of life [25-29]. A recently published study of a digital health program in IBD reported promising improvements in stress and energy levels, with a participant retention rate of 40% [57]. We hope that our approach of incorporating weekly check-ins will lead to higher retention rates. Findings from the study will be used to refine the intervention and develop a full-scale trial that will incorporate additional recruitment sites from diverse geographical regions. In future trials, we plan to collaborate with a variety of clinical practice settings, including community-based and academic settings.

XSL•FO
RenderX

Strengths and Limitations

Individuals participating in a pilot self-management intervention may be more interested in or engaged in research and self-management than a general clinic population. Additionally, recruitment is currently focused on an academic medical setting, which may have a more medically refractory group of patients. Thus, expanding recruitment to other sites (eg, community sites) may assist with generalizability. To enhance its feasibility and reach, the intervention has been adapted into a web-based format.

Future Directions

If CSM-IBD proves effective, further research into predictors of response to CSM would be warranted, including assessing the correlation with the microbiome, histology, or co-occurring illness (eg, depression and anxiety). Other future directions include consideration for implementation barriers and facilitators. Future work may consider multilevel interventions that can impact the health care system level to promote self-management and quality of life.

Conclusions

The results of this study will inform the development of a full-scale clinical trial to examine the impact of CSM-IBD compared to usual care. If the intervention demonstrates acceptability and efficacy, it could be deployed in a variety of practice settings to improve patient self-management of IBD.

Acknowledgments

KK is supported, in part, by the National Institutes of Nursing Research (K23NR020044). LY and SW are supported, in part, by the National Institutes of Nursing Research (T32NR016913). We thank Dr John Inadomi for support throughout the process.

Data Availability

The data sets generated during this study will be deposited in a publicly available repository at study completion.

Conflicts of Interest

SL receives grant and research support from the following: AbbVie Pharmaceuticals, Janssen Pharmaceuticals, Inc, Takeda Pharmaceuticals, Inc, Bristol Myers Squibb Pharmaceuticals, Inc, Pfizer Pharmaceuticals, Inc, Atlantic Pharmaceuticals, Ltd, Gilead Sciences, Inc, Tetherex Pharmaceuticals, Arena Pharmaceuticals, and Shield Therapeutics PLC, and is a consultant for UCB Pharma, Cornerstones, Janssen Pharmaceuticals, Inc, Takeda Pharmaceuticals, Inc, and Eli Lilly Company. KC-S has been a consultant for Pfizer Pharmaceuticals, Inc, Takeda Pharmaceuticals, Inc, AbbVie Pharmaceuticals, and Bristol Myers Squibb Pharmaceuticals, Inc. LK is co-founder and equity owner of Trellus Health and a consultant to Pfizer, Eli Lilly, Takeda, and Ardelyx. For the remaining authors, no conflicts of interest were declared.

Abstract

Background: Adverse pregnancy outcomes (APOs) identify cardiovascular disease risk, but few effective interventions are available. High sedentary behavior (SED) has recently been associated with APOs, but very few randomized controlled trials (RCTs) have tested SED reduction in pregnancy.

Objective: The Sedentary Behavior Reduction in Pregnancy Intervention (SPRING) pilot and feasibility RCT addresses this gap by testing the feasibility, acceptability, and preliminary pregnancy health effects of an intervention to reduce SED in pregnant women. The objective of this manuscript is to describe the rationale and design of SPRING.

Methods: Pregnant participants (n=53) in their first trimester, who are at risk for high SED and APO and without contraindications, are randomized in a 2:1 ratio to an intervention or control group. SED (primary outcome) and standing durations, and steps per day, are measured objectively in each trimester for 1 week with a thigh-mounted activPAL3 accelerometer. SPRING also seeks to demonstrate feasibility and acceptability while estimating preliminary effects on maternal-fetal health outcomes assessed during study visits and abstracted from medical records. The pregnancy-customized intervention promotes daily behavioral targets of less than 9 hours of SED and at least 7500 steps, achieved via increased standing and incorporating light-intensity movement breaks each hour. The multicomponent intervention provides a height-adjustable workstation, a wearable activity monitor, behavioral counseling every 2 weeks (through videoconference), and membership in a private social media group. Herein, we review the rationale, describe recruitment and screening processes, and detail the intervention, assessment protocols, and planned statistical analyses.

Results: This study was funded by the American Heart Association (20TPA3549099), with a funding period of January 1, 2021, and until December 31, 2023. Institutional review board approval was obtained on February 24, 2021. Participants were randomized between October 2021 and September 2022, with final data collection planned for May 2023. Analyses and submission of results are expected for winter of 2023.

Conclusions: The SPRING RCT will provide initial evidence on the feasibility and acceptability of an SED-reduction intervention to decrease SED in pregnant women. These data will inform the design of a large clinical trial testing SED reduction as a strategy to reduce APO risk.

Introduction

Background

Cardiovascular disease (CVD) remains the number one health threat in women [1]. Adverse pregnancy outcomes (APOs), such as hypertensive disorders of pregnancy, gestational diabetes, and preterm birth, affect up to 20% of pregnant women and are recognized as major risk factors for latent and future CVD [2,3]. Though research to disentangle the contributions of prepregnancy risk factors from APOs on future CVD risk is ongoing, interventions that prevent APOs as a target for reducing CVD offer immediate and possibly long-term benefits. Effective preventative therapies, however, remain elusive [4]. Moderate- to vigorous-intensity physical activity reduces APO risk [5,6], but less than 1 in 4 pregnant women achieve guidelines [7]. This likely reflects that pregnant women report unique exercise barriers such as fatigue, pain, medical restriction, and concern for the baby [8].Therefore, more feasible lifestyle strategies to prevent APOs are needed.

One such strategy could be reducing sedentary behavior (SED), which is defined as low-intensity behavior that occurs in a seated, reclined, or lying posture [9]. Considering barriers to more intensive physical activity during pregnancy, replacing SED across the day with standing and light-intensity physical activities may be more achievable. Excessive SED has been related to an increased risk of CVD and mortality in general populations, even after accounting for moderate- to vigorous-intensity physical activity [10]. Though sparse data on SED during pregnancy exist, our laboratory recently completed a small cohort study among 120 pregnant women that objectively measured SED and physical activity during each trimester [11]. We found that, on average, pregnant women had approximately 9.5 hours per day of SED, which is higher than the general population [12]. Further, using trajectory analysis, women with a pattern of very high SED across pregnancy (approximately 11 hours per day) versus low SED (approximately 8 hours per day) had 6.76 (95% CI 1.20-38.14) higher odds of experiencing an APO [11]. Of interest, women in the low and medium SED groups (approximately 8 and 9 hours per day, respectively) had no excess risk of APO, indicated a possible threshold effect. Similar threshold effects were observed for time spent standing and in the number of steps per day such that only women in the very low trajectory groups had excess risk. Importantly, moderate- to vigorous-intensity activity was not associated with APO outcomes, bolstering support for a strategy of reducing SED by increasing standing and daily steps as a novel intervention target to improve pregnancy health. Yet, few randomized clinical trials (RCTs) testing SED reduction interventions are available, especially in pregnant women.

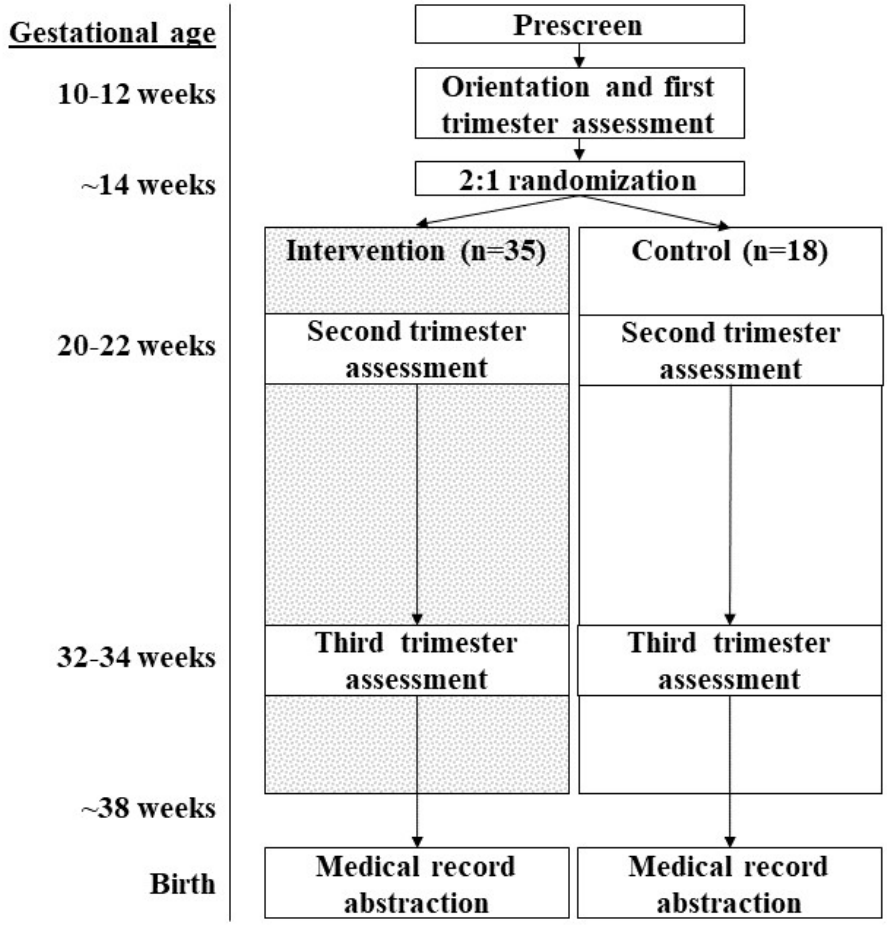
The Sedentary Behavior Reduction in Pregnancy Intervention (SPRING) pilot and feasibility study, funded by the American Heart Association (20TPA3549099), seeks to address these research gaps. SPRING is an RCT that tests the feasibility, acceptability, and preliminary effects of a novel intervention designed to reduce SED and improve all-day activity patterns among pregnant women at high risk for APOs.

Objectives

The SPRING study's specific aims are to (1) evaluate the effect of SPRING versus control on objectively measured SED (*primary outcome*, *hypothesized to decrease*), standing (*hypothesized to increase*), and steps per day (*hypothesized to increase*); (2) evaluate the feasibility and acceptability of SPRING, including recruitment, retention, outcome assessment rates, intervention fidelity, and program evaluation; and (3) estimate the preliminary effects of SPRING versus control on maternal-fetal health outcomes including composite APOs (hypertensive disorders of pregnancy, gestational diabetes, and preterm birth), maternal blood pressure and glucose, psychosocial outcomes, gestational age at birth, and infant birth anthropometrics.

Methods

Study Design Overview



In the absence of established SED-reduction interventions or guidelines in pregnant women, a pilot and feasibility RCT among pregnant women with higher risk for SED and APOs was chosen as the first logical step to determine if the intervention could successfully reduce SED by increasing standing and steps per day across pregnancy. Figure 1 describes the timeline of study assessments and intervention procedures (SPIRIT [Standard Protocol Items: Recommendations for Intervention Trials] checklist [13] available in Multimedia Appendix 1). The SPRING pilot and feasibility trial is registered on ClincialTrials.gov (NCT05093842).

Potential participants complete baseline assessments and begin the 1-week baseline activity monitoring protocol between 10 weeks 0 days (10^0 weeks) and 12 weeks 6 days (12^6 weeks) of gestation. Upon receipt of valid activity monitoring data with a completed time-use diary and clearance to participate from the participant's prenatal care provider, pregnant women are randomized in a 2:1 ratio to either a multicomponent SED-reduction intervention or a usual care control group. Beginning at approximately 14 weeks of gestation, participants randomized to the intervention group begin the active intervention, which lasts through 38 weeks of gestation or until the participant gives birth, whichever occurs first. Participants randomized to the usual care control arm do not receive the intervention but are mailed a Fitbit Luxe after giving birth.

XSL•FO
RenderX

Participants in both groups complete assessments in each trimester and are remunerated US $40 for completing the first trimester (baseline) assessment between 10^0 and 12^6 weeks, US $50 for completing the second-trimester assessment between 20^0 and 22^6 weeks of gestation, and US $60 for completing the third-trimester assessment between 32^0 and 34^6 weeks of gestation. After participants give birth, maternal-fetal outcomes are abstracted from medical records by trained clinical staff.

Figure 1. Participant flowchart across the study protocol.

Ethics Approval

All research procedures were approved by the University of Pittsburgh Human Research Protection Office (STUDY20110193).

Eligibility Criteria

Eligibility criteria for the SPRING Study are listed in Textbox 1. We recruit participants in their first trimester of pregnancy who are at risk for high levels of SED and who have at least 1 risk factor for APO. These criteria reflect an early gestational age when we can intervene meaningfully across pregnancy and higher SED appropriate for modification (ie, reduction) to reach the levels that we have found to be associated with better pregnancy outcomes [11]. The criteria of having at least 1 risk factor for APO relate to our long-term goal to test whether our intervention can reduce APO risk; therefore, we sought to evaluate feasibility and preliminary effects in this specific population. Lastly, to allow for our exploratory outcome assessment using prenatal records of maternal-fetal outcomes, participants are required to consent to abstraction either through our affiliation with the University of Pittsburgh Medical Center or through separate medical record release if they are receiving prenatal care elsewhere.

Participants younger than 18 years or older than 45 years are excluded to avoid an inability to provide consent and more complicated pregnancies with advanced age, respectively. Those with preexisting hypertension or diabetes are excluded because existing management of these conditions could affect our study outcomes (eg, prenatal blood pressure and glucose test results). Any other contraindications to exercise during pregnancy or severe mobility limitation are also exclusionary since the intervention asks participants to increase standing and daily steps. We also require participants to receive clearance for participation in the intervention from their prenatal care provider as an additional safety precaution. Lastly, those participating in other interventional research that could confound our study outcomes are excluded to reduce bias or contamination.

XSL•FO
RenderX

Textbox 1. Eligibility criteria.

Inclusion criteria

- Gestational age:
  - Between 10 weeks 0 days and 12 weeks 6 days of gestation
- At risk for high sedentary behavior (meets at least one of the following criteria):
  - Primarily sitting, full-time desk job (more than 30 hours per week)
  - Primarily sitting, part-time desk job (less than 30 hours per week) and reports sitting at least half of the time during nonwork days
  - Does not work and reports sitting at least three-fourths of the time
  - Reports no more than 6000 steps per day from a wearable activity monitor
- Risk factor for adverse pregnancy outcome (APO; meets one of the following criteria):
  - Nulliparity
  - History of APO
  - Prepregnancy BMI of 30 kg/m^2 or greater
  - Age of 35 years or older
- Medical record access:
  - Plans to deliver at the University of Pittsburgh facility or willing to provide consent for medical record release of prenatal care and birth records

Exclusion criteria

- Young or advanced maternal age:
  - Younger than 18 years; older than 45 years
- Chronic hypertension:
  - Resting blood pressure of 140/90 mm Hg or greater or antihypertensive medication use
- Pregestational diabetes:
  - Type 1 or type 2 diabetes, prior to pregnancy
- Contraindication to exercise:
  - Serious medical conditions such as underlying cardiac disease, severe anemia, chronic bronchitis, poorly controlled hyperthyroidism, or seizure disorder
- Severe mobility limitation:
  - Self-report of inability to walk 2 blocks or climb a flight of stairs
- No prenatal care provider clearance:
  - Unable to obtain a signed permission form from a prenatal care provider to participate in the intervention
- Other research intervention:
  - Participating in another health-related intervention study that could affect study outcomes
- Travel plans restricting participation:
  - Plans to travel that limit ability to fully participate in the study protocol

XSL•FO
RenderX

Recruitment and Screening

Recruitment Methods

Participants are recruited from within approximately 50 miles of the University of Pittsburgh's main campus in Pittsburgh, Pennsylvania. A variety of recruitment methods are used, including the University of Pittsburgh Clinical and Translational Science Institute's Pitt+Me research registry and targeted emails sent to the university community. In addition, recruitment messages from the study physician are sent to patients at the University of Pittsburgh Medical Center's (UPMC) Maternal Fetal Medicine clinic who meet eligibility requirements through the MyUPMC mobile app. Finally, flyers are placed in patient-facing areas of Magee-Womens Hospital of UPMC, the largest birthing hospital in the Pittsburgh region.

Screening, Orientation, and Informed Consent

Interested participants are directed to complete a web-based screening questionnaire using Research Electronic Data Capture (REDCap) [14,15]. The screening questionnaire contains a detailed summary of the study, a request for electronic consent to answer screening questions, and specific questions about the candidate's current pregnancy, risk factors for APO, SED exposure and habits, chronic diseases, medications, and contact information. Trained study staff assess initial eligibility based on the answers to the screening questionnaire and, if a candidate is deemed ineligible, they are informed at that time. Candidates who appear to be eligible during initial screening are invited to a web-based videoconference orientation where the study is described in detail, verbal informed consent is obtained, and then an electronic informed consent document is signed by the participant and study personnel conducting the informed consent. Finally, a detailed medical and reproductive history questionnaire is administered to determine final eligibility.

Randomization

A randomization ratio of 2:1 (2 intervention to 1 control) was chosen to provide more robust data to evaluate the feasibility and acceptability of our intervention and assessment protocols [16]. To help achieve balance over time, blocks of 6 were selected, and 9 blocks of computer-generated, randomly ordered sets were placed sequentially into sealed, numbered envelopes by a blinded study personnel. These envelopes were then provided to the unblinded study personnel (principal investigator and interventionist) and kept in a secure location.

Participant randomization begins with the blinded study coordinator notifying the principal investigator that a participant is eligible and has completed all baseline assessment procedures. The study investigator then opens the next sequential envelope and records the randomization assignment and date in the randomization log. The principal investigator then contacts the participant to inform her regarding her randomization assignment, describe next steps, ensure that the participant comprehends that the intervention and assessment study procedures are separate, and reinforce the importance of continued participation in either group.

Outcome Assessments

Study outcome assessments are conducted by trained, blinded study personnel and occur via web-based videoconference once per trimester of pregnancy (Table 1). Any necessary assessment materials are mailed to participants prior to study visits.

SED and physical activity are measured in each trimester. Objective assessment of activity patterns is conducted using a thigh-mounted activPAL3 monitor (PAL Technologies, Glasgow) worn for 24 hours over 8 days. This protocol is the best-practice methodology for field monitoring of SED and standing [17], and we have shown it to be a valid measure of moderate- to vigorous-intensity physical activity in pregnant women [18]. Participants wear the monitor on the anterior upper thigh for 8 days, with removal only for swimming activities. Concurrently, participants are asked to record periods of work, nonwork, sleep, and nonwear in a diary for accurate data processing. Participants are verbally instructed regarding procedures for correct monitor wear at each virtual assessment visit, including visual verification of correct placement. Detailed written instructions on monitor wear and diary completion are also provided. The activPAL3 24-hour event data are downloaded and cleaned by removing periods of sleep and nonwear; remaining valid wear time is used to calculate average daily durations of time spent in SED (total and in prolonged bouts of at least 30 and 60 minutes), standing, and stepping. Daily frequency of steps and sit-stand transitions are also averaged across days. Lastly, to estimate moderate- to vigorous-intensity physical activity, time with a stepping frequency of at least 75 steps per minute and 100 steps per minute are averaged across valid wear days from daily summary data. Averages are calculated overall and during working times (if applicable). Data are considered valid with at least 5 days of at least 10 hours of waking wear time recorded [19].

Self-reported SED and physical activity are assessed using the Pregnancy Physical Activity Questionnaire [20], with questions regarding proportion of time spent in SED during work and nonworking times added to improve the accuracy of self-reported SED assessment [21].

Blood pressure is assessed virtually during study assessment visits in each trimester using a validated oscillometric monitor [22]. Either a UA-611 monitor (A&D Medical) that was provided as part of prenatal care at the University of Pittsburgh Magee-Womens Hospital or a study-provided BP7250 monitor (Omron Healthcare Inc) is used. Participants use the same monitor and cuff for all visits. During the virtual assessment, participants first provide verbal confirmation of abstention from caffeine and nicotine for 1 hour prior. Then, participants place the cuff on the left upper arm and complete a supervised 5-minute quiet rest with their arm supported at chest level, back supported against a chair, and feet flat on the floor or other support with ankles and knees uncrossed. After the rest, the participant initiates the measurement by pressing the start button with the blood pressure monitor facing the video camera and visible only to the assessor (to reduce participant reactivity). The assessor leads the participant through 3 measurements, taken with a 1-minute rest in between, and records blood pressures and heart rates in the database prior to informing the

XSL•FO
RenderX

participant of all values. The average of the second and third measurements is used for analysis.

Demographics, medical history, reproductive history, and medication use are collected at baseline using a standardized form. Anthropometry is assessed at baseline via self-reported height and prepregnancy weight, which are subsequently verified through medical record abstraction (described later). To capture changes that occurred following randomization, updates to demographics (eg, new employment) are reported in a questionnaire and changes to medical history or medication use (eg, a new diagnosis or starting, stopping, or changing dosage of medications) are assessed during an interval medical history review at each follow-up visit.

[a]SED: sedentary behavior.

[b]SPRING: Sedentary Behavior Reduction in Pregnancy Intervention.

Dietary intake is assessed at each visit using the Diet Screening Questionnaire, a semiquantitative questionnaire that measures typical dietary habits [23]. Psychosocial behavioral targets and outcomes are measured at baseline and each follow-up visit via web-based self-report questionnaires. Validated questionnaires assessing behavioral targets of the intervention include the Sitting during Pregnancy Barriers and Outcome Expectations Questionnaire [24], Expected Outcomes and Barriers for Habitual Physical Activity [25], the Multidimensional Scale of Perceived Social Support [26], and Social Support for Exercise [27]. Validated questionnaires assessing possible psychosocial effects of the intervention include the Profile of Mood States [28], the Centers for Epidemiologic Studies Depression Scale (CES-D) [29], the Perceived Stress Scale [30], Health-Related Quality of Life for Nausea and Vomiting during Pregnancy [31], and the Pittsburgh Sleep Quality Index [32].

Adverse events are collected systematically at follow-up assessment visits by blinded study personnel. Details of new or worsening medical conditions, including pregnancy-related adverse events, are recorded and classified regarding severity and relationship. In addition, ongoing assessment of adverse events in the intervention group is conducted by intervention staff. All adverse events are reviewed by the principal investigator and, if needed, the study physician for accuracy, possible relationship to the intervention, and to make any necessary modifications or terminate participation in the intervention.

Pregnancy health and maternal-fetal outcomes are abstracted from the participant's medical record of prenatal visits and labor and delivery notes. Maternal outcomes extracted include gestational weight gain, clinic-measured blood pressures, pregnancy complications including APOs, glucose screening values, and tolerance tests (if available), and labor and delivery details. Fetal outcomes include gestational age at birth, anthropometrics, and complications. All abstractions are reviewed by a second reviewer and discrepancies are resolved. The study's maternal-fetal medicine physician coinvestigator (AH) confirms all APOs and a random sample of healthy pregnancies for accuracy.

XSL•FO
RenderX

Feasibility and Acceptability

Feasibility and acceptability are also assessed through a variety of methods across the study period (Table 2). Screening outcomes are recorded prospectively including recruitment sources and yield, eligibility rates and ineligibility reasons, and rates of enrollment. We also administer a study-developed questionnaire at baseline (prior to randomization) to assess participant expectations, motivations, and experiences when enrolling in the SPRING RCT. Rates of valid assessment completion are also prospectively recorded. Intervention fidelity with respect to delivery, receipt, and enactment [33] is assessed at each intervention contact (see Intervention Content and Schedule section). A final web-based program evaluation assesses acceptability and includes 22 short-answer, ranking, and multiple-choice questions. The evaluation is distributed after the last intervention lesson to intervention participants only and aims to evaluate participants' perceptions regarding their health, usefulness of the intervention components, general satisfaction and acceptability of the intervention, and suggestions for improvement.

Table 2. Description of intervention components.

Component	Socioecological level	Description
Height-adjustable workstation [34]	Environment	A height-adjustable workstation is selected based on participant preference, occupational status, and the home or office setting. Study staff deliver and, if needed, install the workstation. This component supports the SPRING[a] study goals to alter posture frequently and increase standing time.
Facebook group [35]	Interpersonal	A private Facebook group for SPRING participants and intervention staff offers an opportunity to discuss shared experiences of reducing SED[b] during pregnancy and provide social support between participants. Participants are asked to join the private group after a web-based group social support lesson that includes a handful of other participants with a similar due date. Participants agree to community guidelines about respectful interaction on the page, and all activity is monitored by the intervention team. Study staff posts to the group twice per week with content aiming to provide information, engage members in discussion, and engender social support across participants.
Behavior coaching [36]	Individual or interpersonal	Participants engage in up to 13 videoconference contacts across the second and third trimesters of pregnancy. The interventionist delivers scripted lessons and check-ins (content described in more detail in Table 3) and uses motivational interviewing or problem-solving to help participants choose strategies for SED reduction and self-monitoring, set goals for standing, stepping, and movement breaks, and overcome barriers. Before each contact, the interventionist gathers the participants' objective activity data from the previous 14 days recorded by the wearable activity monitor (described below) to guide discussions. Most lessons are delivered one-on-one, except for 1 social support lesson during the fourth contact (~18th week of gestation) that includes a small group of 2-4 intervention participants with a similar due date.
Wearable activity monitor [37]	Individual	Participants are given the choice of receiving a new Fitbit Luxe or are allowed to continue the use of a personal Fitbit or Apple Watch. This flexibility of wearable choice reflects our previous experience that participants sometimes strongly preferred to continue use of their current wearable. Participants either share credentials (Fitbit) or grant shared access to their activity data (Apple Watch) so that the interventionist can review the participants' objective data. Participants are encouraged to wear the monitor during all waking hours and use the associated smartphone app to self-monitor their daily steps and adherence to daily movement break goals. The monitors are set up to alert participants if they have been inactive over the past hour during a participant-selected daytime interval. Participants are instructed to respond to an inactivity alert by taking a movement break, for example, a 2- to 3-minute walk or another light-intensity activity break. This component supports the study goals of breaking up prolonged SED and accumulating steps across the day.
Self-monitoring [37]	Individual	Participants are instructed to track the targeted behaviors to support behavior change and accurately report it to the interventionist during contacts. Participants are encouraged to use their wearable activity monitor app to track hourly movement breaks and daily step goals. To track standing, participants are offered paper or electronic diaries or are allowed to choose a preferred method, for example, smartphone app.

Table 3. Schedule and content of the SPRING[a] study behavioral intervention lessons.

Intervention contact	Gestational week	Intervention content
Lesson 1: Education (90 minutes)	14	• Orientation to SPRING study • Review of physical activity recommendations during pregnancy [36] • Education about the health risks of SED[b] with review of participant's objective SED and steps from the baseline assessment [38] • Introduction to SPRING behavioral targets • Height-adjustable workstation use and ergonomic safety • Use of wearable activity monitor for inactivity prompts and step tracking • Choose self-monitoring strategies • Goal setting for standing, movement breaks, and daily steps [39]
Check-in (15 minutes)	16	• Check for contraindications • Evaluation of fidelity (delivery, receipt, and enactment) [33] • Discuss goal attainment and, if needed, problem-solving [40,41] • Goal setting for the next 2 weeks
Lesson 2: Social support (30 minutes)	18	• The only behavioral lesson that occurs as a group, including 2-4 intervention participants with a similar due date (ie, "due date group") • Discussion of social support for behavior change at the individual and community level • Introduction to community-level support via the private Facebook group [35] • Goal setting for community-level engagement
Check-in	20	• Described in gestational week 16
Lesson 3: Know your cues (45 minutes)	22	• Check-in (described above) • Discuss stimulus control and environmental re-engineering [42] • Evaluate daily activity patterns using the activity tracker app and apply concepts to identify inactivity patterns or creating barriers to achievement • Goal setting for pregnancy-specific stimulus control strategies
Check-in	24	• Described above
Lesson 4: Progress review (45 minutes)	26	• Check-in (described above) • Guided self-reflection on progress for standing, movement breaks, and step goals [38,43] • Review of progress comparing the objective SED and steps data from second-trimester assessment to baseline levels • Goal setting for improvement or maintenance of standing, movement breaks, and daily step goals in the third trimester
Check-in	24	• Described above
Lesson 5: Motivation (45 minutes)	30	• Check-in (described above) • Introduction to concepts of internal motivation and behavior change adherence [44,45] • Guided activity to identify study-specific values • Goal setting and reflection on intrinsic motivation
Check-in	32	• Described above
Lesson 6: Lapses do not have to be collapses (45 minutes)	34	• Check-in (described above) • Discussion of behavior change maintenance, relapse theory, and prevention [39] • Goal setting for strategies to improve long-term maintenance of SED reduction or change
Check-in	36	• Described above
Check-in	38	• Described above

[a]SPRING: Sedentary Behavior Reduction in Pregnancy Intervention.

[b]SED: sedentary behavior.

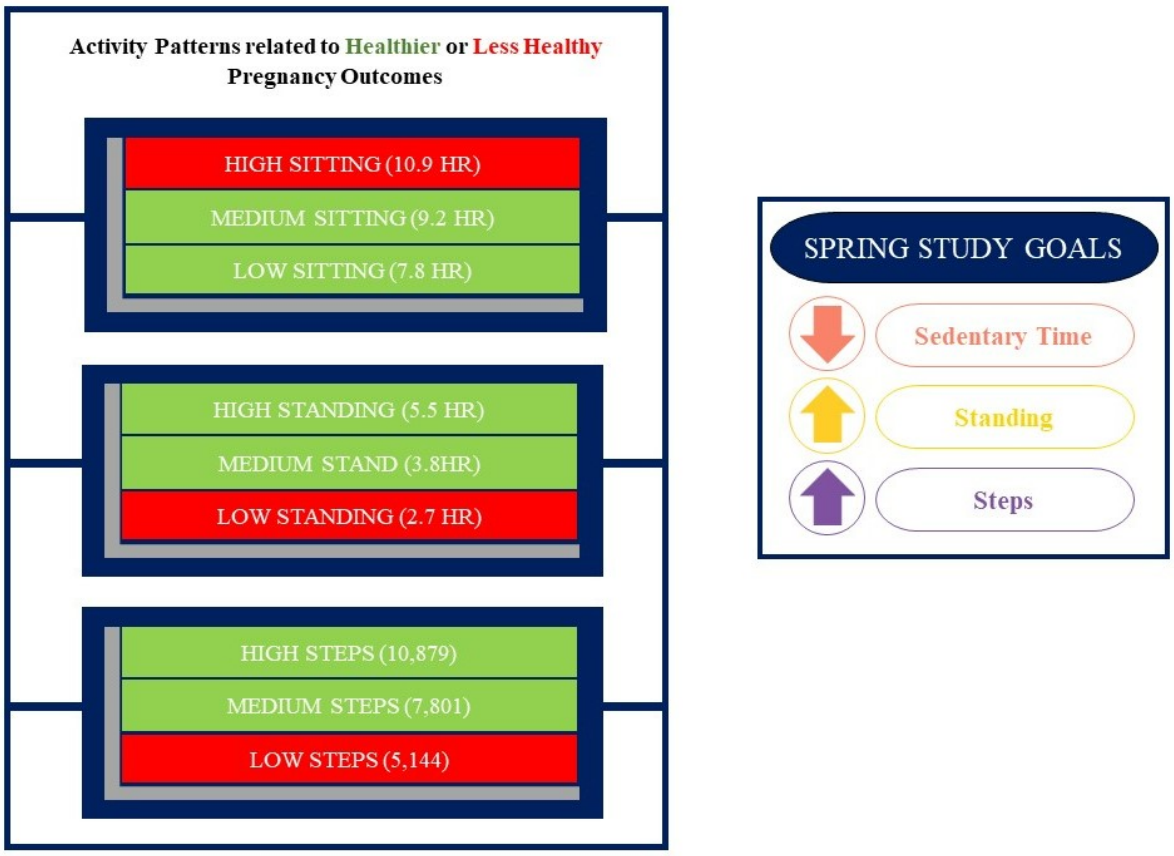
Intervention



Intervention Content and Schedule

SPRING developed behavioral targets informed by the specific patterns of SED, standing, and daily steps that were associated with lower APO risk in our observation cohort of pregnant women [11]. Specifically, we observed threshold effects whereby engaging in SED for approximately 9.2 hours per day or less, standing for approximately 3.8 hours per day or more, and accumulating approximately 7801 steps per day or more were the activity patterns associated with a significantly lower risk of an APO [11] along with other maternal and fetal health benefits [46-48]. We also considered additional data from our observational research regarding determinants, barriers, attitudes, and outcome expectations related to SED during pregnancy. Findings from these studies suggested that pregnancy-related physical symptoms such as nausea and fatigue along with work-related sitting were the most commonly reported barriers to reducing SED [24]. Using objectively measured SED data, we also found that desk jobs and fewer children aged 5 years or younger in the home emerged as the factors that are most strongly associated with SED during pregnancy [49]. We then used these data to adapt our existing SED-reduction interventions in nonpregnant adults [50-52] to the new population of pregnant women at high risk for SED and APOs.

Thus, with the overall goal of reducing SED to less than 9 hours per day, we set evidence-based behavioral targets for our intervention as follows: (1) increase standing time by 2-3 hours per day with a daily total target of at least 4 hours per day; (2) increase light-intensity movement across the day, achieving at least 7500 steps per day; and (3) increase steps by at least 250 per hour (up to 8 hours per day). An example of the graphics used to convey these behavioral targets in the participant-facing intervention materials is presented in Figure 2. To facilitate behavior change toward these standing and step targets in our intervention group, we developed an evidence- and theory-based, multicomponent intervention strategy across 3 levels of the socioecological model (Table 2) [34,35,37,40].

The schedule and content of the behavioral coaching lessons are described in Table 3. Safety and fidelity of the intervention are assessed at each contact by measuring contraindications [36], delivery (provision of intervention components), receipt (self-report of intervention components working properly), and enactment (self-report of self-monitoring and goal achievement) [33].

Figure 2. Intervention behavioral targets.

Control Group

Participants assigned to the control group are asked to continue their typical behavior for the duration of their pregnancy and are provided with a general handout regarding recommended physical activity during pregnancy [36] but received no further intervention materials. After delivery, control participants are mailed a report of their objective activity levels that were previously measured during the study assessments and a Fitbit Luxe.

Statistical Analysis

Analytic Strategy for Aim 1 and the Exploratory Aim

We will use Stata (StataCorp) for all analyses with an intention-to-treat philosophy. First, participant flow will be summarized using a Consolidated Standards of Reporting Trials diagram for randomized trials [53]. Second, descriptive statistics will be computed for variables by treatment group and time point. Third, the baseline measures will be compared between the 2 groups using independent samples *t* tests, Wilcoxon rank sum, chi-square, or Fisher exact tests, as appropriate. While significant differences are not expected, any found will be considered in sensitivity analyses. Next, main analyses will fit a series of linear mixed models with follow-up continuous outcomes as the dependent variable (eg, SED); intervention group (intervention or control), follow-up time (eg, second and third trimester), and group × time as fixed effects; baseline value of outcomes as fixed-effect covariates; and a participant random effect to account for multiple observations from the same participant over time. Mean contrasts will estimate the between-group difference at each follow-up time point. Similar methods will be used for the other activity variables (eg, standing and steps). Analysis of the exploratory aim will use similar methods, with logistic regression for dichotomous outcomes (eg, APOs). We will first consider the use of multiple imputation to account for missing data, but we will perform additional sensitivity or exploratory analyses to ensure robustness and extend our findings, for example, complete-data-only or last-value-carried forward strategies for missing data.

Analytic Strategy Aim 2

For the recruitment feasibility outcomes, we will calculate frequencies of recruitment method use and yields; rates of screening contacts, consent, eligibility, and randomization; reasons for ineligibility; and characteristics of enrolled participants. Benchmarks will be 42 (80%) for retention and 40 (95%) of the retained participants for valid outcome assessments. Intervention fidelity will be calculated based on intervention contacts with an overall average benchmark of 30 (85%) of each intervention contact competed. Quantitative or semiquantitative acceptability and program evaluation data will be summarized descriptively. Open-ended questionnaires will be analyzed using a constant comparison method to identify salient categories, themes, and patterns via open coding, iterative review and codebook generation, code linking into similar categories, and final integration into themes [54].

Sample Size Considerations

The primary outcome of this study is a change in SED. Based on our pilot data that suggest lower SED protects women from APOs [11], we calculated sample size requirements assuming the following: a between-group SED difference of 1 hour (SD 56 minutes) per day, a 2:1 randomization ratio to enhance recruitment and increase program evaluation and feasibility data, 90% power, and α=.05. This yielded a required sample size of 42 (28 intervention and 14 control). A final sample size of up to 53 (35 intervention and 18 control), inflated by 20%, was adopted to account for attrition.

Results

The SPRING study was funded as an American Heart Association Transformational Project Award, which began on January 1, 2021, and ends on December 31, 2023 (20TPA3549099; Principal Investigator: BBG). Institutional review board approval was obtained on February 24, 2021. Participants were recruited over approximately 1 year, with the first subject being randomized on October 4, 2021, and the final participant being randomized on September 9, 2022. The last research assessment visit occurred on January 20, 2023. Abstraction of maternal-fetal health outcomes has a planned completion date of May 31, 2023, data analysis is planned to be completed by June 30, 2023, and submission of primary outcomes to a scientific journal is planned for September 30, 2023.

Discussion

In summary, the SPRING pilot and feasibility RCT is testing the effects of our evidence-based SED-reduction intervention to modify SED, standing, and steps as well as determining whether our approach is feasible and acceptable among pregnant women at risk for high levels of SED and APOs. The multilevel intervention targets an activity pattern that we have found to be associated with a lower risk of APOs in observational research. To achieve these targets, our intervention approach synthesized our previous findings on determinants of SED during pregnancy with successful strategies for SED reduction intervention in nonpregnant adults. Our final exploratory aim will begin to assess the effects of our intervention on pregnancy health outcomes, including APOs. These data, including our planned in-depth feasibility, acceptability, and intervention program evaluation and clinical outcomes, will be critical for designing a fully powered RCT where we can test an optimized SED-reduction intervention for pregnant individuals. This next trial will importantly have maternal-fetal health measures (eg, APOs) as the primary outcomes so that we can understand whether our approach should be recommended as an alternative to standard moderate- to vigorous-intensity physical activity recommendations of 20-30 minutes per day. If ultimately successful, our intervention that targets reducing SED through an increase in standing and daily steps during pregnancy could offer a novel, more feasible strategy for preventing APOs and improving immediate and long-term cardiovascular health in women.

Acknowledgments

This study was funded by the American Heart Association (grant 20TPA3549099). This research was also assisted for recruitment by the University of Pittsburgh's Clinical and Translational Science Institute funded by the National Institutes of Health (grant UL1TR001857).

Abstract

Background: Even before the onset of the COVID-19 pandemic, children and adolescents were experiencing a mental health crisis, partly due to a lack of quality mental health services. The rate of suicide for Black youth has increased by 80%. By 2025, the health care system will be short of 225,000 therapists, further exacerbating the current crisis. Therefore, it is of utmost importance for providers, schools, youth mental health, and pediatric medical providers to integrate innovation in digital mental health to identify problems proactively and rapidly for effective collaboration with other health care providers. Such approaches can help identify robust, reproducible, and generalizable predictors and digital biomarkers of treatment response in psychiatry. Among the multitude of digital innovations to identify a biomarker for psychiatric diseases currently, as part of the macrolevel digital health transformation, speech stands out as an attractive candidate with features such as affordability, noninvasive, and nonintrusive.

Objective: The protocol aims to develop speech-emotion recognition algorithms leveraging artificial intelligence/machine learning, which can establish a link between trauma, stress, and voice types, including disrupting speech-based characteristics, and detect clinically relevant emotional distress and functional impairments in children and adolescents.

Methods: Informed by theoretical foundations (the Theory of Psychological Trauma Biomarkers and Archetypal Voice Categories), we developed our methodology to focus on 5 emotions: anger, happiness, fear, neutral, and sadness. Participants will be recruited from 2 local mental health centers that serve urban youths. Speech samples, along with responses to the Symptom and Functioning Severity Scale, Patient Health Questionnaire 9, and Adverse Childhood Experiences scales, will be collected using an Android mobile app. Our model development pipeline is informed by Gaussian mixture model (GMM), recurrent neural network, and long short-term memory.

Results: We tested our model with a public data set. The GMM with 128 clusters showed an evenly distributed accuracy across all 5 emotions. Using utterance-level features, GMM achieved an accuracy of 79.15% overall, while frame selection increased accuracy to 85.35%. This demonstrates that GMM is a robust model for emotion classification of all 5 emotions and that emotion frame selection enhances accuracy, which is significant for scientific evaluation. Recruitment and data collection for the study were initiated in August 2021 and are currently underway. The study results are likely to be available and published in 2024.

Conclusions: This study contributes to the literature as it addresses the need for speech-focused digital health tools to detect clinically relevant emotional distress and functional impairments in children and adolescents. The preliminary results show that our algorithm has the potential to improve outcomes. The findings will contribute to the broader digital health transformation.

Introduction

Background

The increase in the rates of mental health problems among the pediatric population predates COVID-19. According to the Substance Abuse and Mental Health Services Administration and US Department of Health and Human Services Centers for Disease Control and Prevention [1]:

> *Between 2016 and 2020, the number of children ages 3-17 years diagnosed with anxiety grew by 29% and those with depression by 27%. In 2020, suicide was the second leading cause of death for young people aged 10-14 and 25-34, and among the top 9 leading causes of death for people ages 10-64.*

There has been an increase in suicide rates among children and adolescents [2], especially in low-income communities [3]. The meta-analysis of 29 studies with a total of more than 80,000 participants indicated an increase in emergency room visits by 22.3% and reported that 1 out of every 4 adolescents is experiencing clinically relevant depressive and anxiety symptoms, which was double the rate of prepandemic levels [4].

The need to focus on young people is partly related to the onset of mental disorders, which usually starts during a person's early developmental stages, and almost half of all mental health conditions are present before 14 years of age. Trauma plays a role in more than three-quarters of youth experiencing mental health disorders [5]. The early onset of the disease for Black, Indigenous, people of color, and other marginalized communities is related to the high rate of the experience of trauma, which is generational, and partly due to a history of discrimination, poverty, and poor access to quality mental health care. One way to account for the incidents and the severity of trauma is the use of Adverse Childhood Experiences (ACE). ACE scores tend to be higher for families from lower socioeconomic status [6]. ACE identifies a more expensive account of trauma, including the role of divorce and parental incarceration, and substance abuse. ACE score of 4 or more is likely related to symptoms of trauma, including aggression, self-harm behavior, posttraumatic arousal, and inattention, as well as neurobiological, developmental, and social delays [7]. Consequences across the lifespan include disrupted neurodevelopment and socioemotional and cognitive impairment. ACE also exacerbates the chances of future drug abuse, poor physical health, and early chronic disease, disability, and mortality [8].

The current behavioral health care system is falling short in addressing the crisis in the mental health needs of children and adolescents. In addition to the shortage of health care providers, the accurate diagnosis of mental disorders by humans requires extensive training, experience, and resources. Therefore, low-resourced communities have been experiencing a severe lack of experienced mental health providers, while the need for mental health services and the severity of patients remains disproportionately high. There is a need for technology-based and accessible tools for early intervention mechanisms for emotional distress in children and adolescents [9]. As a marker of emotional distress, speech or voice indicators have been used to understand the state of the mood and condition in health care [10]. Previous studies have already underlined the value of speech-based detection mechanisms in mental health. In earlier works, Scherer et al [11] followed 379 patients. They found that acoustic and linguistic measurements from voice samples achieved 85%-93% accuracy in classifying patients as suicidal, mentally ill but not suicidal, or neither. Mota et al [12] used a 2- to 5-minute free speech session and voice analysis method to predict (with 100% accuracy) whether an individual is at risk of first-episode depression. These examples and literature show the potential of speech analysis in detecting psychological distress and mental health issues [13-15]. Speech-based digital health technologies can assist health care providers in identifying children in need and aid in the delivery of appropriate and timely services to families in the community [16]. Specifically, such mechanisms can be used for early intervention, which can delay the onset and reduce the probability of developing the disorder [17]. Such prevention and mental health interventions can divert this population from future mental health issues and other high-risk behaviors [18].

In this study, we aim to develop and test a speech analysis algorithm to detect clinically relevant emotional distress and functional impairments in children and adolescents with diagnosable mental health disorders.

Theoretical Background

Archetypal Voice Categories

A significant problem for identifying speech emotions is the need to classify a collection of appropriate emotions to be identified as automatic emotion recognizers. Linguists have identified inventories of the emotional states that are occurring the most in our lives [19]. Several scholars agree with the "palette principle," which states that any emotion can be broken down into primary emotions, such as how each color is a mixture of simple colors. In this framework, the primary emotions are anger, happiness, fear, neutral, and sadness. These are the most visible and distinct feelings in our lives, and therefore, these emotions are called archetypal [20]. Given the role of emotions in human communication and decision-making, intelligent human-machine interfaces must respond appropriately to human emotions [20].

Automated emotion recognizers can be seen as devices assigning emotional states to category labels. The detection and identification of emotions in speech involve not only signal processing and interpretation methods but also psychological, linguistic, and emotional interpretation [20]. As a result of the

XSL•FO
RenderX

rich voice data that can be identified, the focus on archetypal emotions—anger, happiness, fear, neutral, and sadness—is usually justified as a way of making finer distinctions [21]. On this premise, 2 forms of knowledge are included in the communication structure of human speech. The first type is more direct and communicates using spoken sentences. The second type is more passive and uses implicit, nonverbal signals to convey the message. We focus on understanding negative and nonnegative emotions from implicit and nondirect voice signals. This form of communication represents emotional distress and can help identify human emotions at a deeper level.

Theory of Psychological Trauma Biomarkers in Speech

Among all the biomarkers under development, speech stands out as an attractive candidate because it is affordable, noninvasive, and nonintrusive. Speech has the potential for applicability to a cohort of patients with various emotional or behavioral disorders from multiple cultural and linguistic backgrounds [20]. This capability is achieved by selecting only prosodic and acoustic features commonly existing in human speech and using them for predicting everyone's emotional distress and negative emotion [19]. This speech clustering emotion is assisted initially by traditional clinical diagnosis and at least 3 scientifically validated surveys: ACE, Patient Health Questionnaire 9 (PHQ-9), and Symptom and Functioning Severity Scale (SFSS) [22].

The link between trauma or stress and voice types is related to changes in the autonomic nervous system, including the disruption of speech-based characteristics partly due to muscle tensions. For example, evidence points to a connection between neural activity in the gamma-aminobutyric acid neurotransmitter, susceptibility to depression, and changes in muscle tonality [23]. Changes related to muscle tonality produce distinct utterances, thereby indicating the presence of negative mood or depressive symptoms [24]. Additionally, emotional states have a temporal structure. For example, people with bipolar depression or chronic anxiety may be in intense emotional states for months or years or have negative emotions for weeks [25]. On the other hand, emotions such as anger and excitement may be transient and last only for a few minutes. Emotions, therefore, have a broad meaning and a narrow sense. Overall, meaning reflects the long-term emotions underlying it, and the narrow sense applies to the mental stimulation that motivates people to behave in the short term [26]. To correctly identify the level of emotional distress, the algorithm needs to identify the underlying emotions of the behavioral/emotional disorder severity.

Methods

Participants

Participants are recruited from 2 mental health care centers that focused primarily on children and adolescents from low-income communities. The participants receive mental health services paid for by Medicaid, the Children's Health Institute Program, and the Department of Children and Family Services. The participants are children aged 5-18 years and those who have been referred for behavioral health services through schools, DJJ, and child protective agencies.

Ethical Considerations

The study received ethical board approval for a multisite pilot involving children and adolescents. We will receive written and informed consent from participants. The activities for patients enrolled in the study include data collected using multiple surveys and a voice sample. The surveys include structured and unstructured voice samples based on a reading selected by the research team. All the study contents are approved by the ethical board.

Data Collection

Using a software application, we use the TQI app [27] to collect voice samples from youth receiving mental health and family preservation services at the point of care. The app and data collection process include the concurrent administration of a scientifically validated, SFSS [28]. The patient's emotional disorder severity is confirmed based on the scores of the SFSS, ACE, and PHQ-9, as well as the patient's diagnosis and other clinical information from the patient's treatment history. For every voice sample collected, the pilot has a diagnosis or multiple, current procedural terminology code, and the therapist's clinical input. These data serve to categorize voice sample data into distinct categories and train voice-based machine learning (ML) algorithms to distinguish children in need and at high risk. The innovation is focused on families with low socioeconomic status, in whom ACE are common.

Data are collected by trained therapists (n=15). An Android mobile app is used to collect speech samples, SFSS, PHQ-9, and ACE scale responses. Each therapist receives a 5-hour in-person training about app installation and access, data (SFSS, voice sample) collection using the app, compliance and parameters, the process of the reward program, communication, and real-time technical support. Data are collected from patients every week as part of the mental health or other family-based intervention visits. Visits occur in a suitable (private) location at home (including foster and group homes) or school as part of a state's commitment to access services. Data are collected virtually as part of the shift in services secondary to the COVID-19 pandemic. Initially, identified target patient group demographics are shared in Table 1.

Voice samples are collected using the TQI app. To elicit speech for recording and analysis, patients are asked to choose from a subset of readings. Patients' reading is recorded for up to 90 seconds—a clock feature in the app signals when the time is up. Voice samples are stored in a separate deidentified database that will allow 3 to 4 psychologists to label the voice sample independently. SFSS, PHQ-9, and ACE responses are collected using the same app. The app scores the surveys immediately and makes the results available to the therapist to share with their patients if it is clinically appropriate; the availability of the data in real time is intended to close the gap in transparency, accountability, and family engagement.

Table 1. Identified target patient group demographics.

Characteristics	Values (N=420), n (%)
Gender	
Female	136 (32)
Male	147 (35)
No gender disclosed	137 (33)
Ethnicity	
Hispanic	115 (27)
Caucasian	66 (16)
Black	93 (22)
Asian	2 (0.5)
No ethnicity disclosed	144 (34)

Data Processing

Data Preparation

Preprocessing speech samples, that is, segregating the voiced region from the silent and unvoiced portion of an utterance, is a crucial step in developing reliable voice analysis. Most of the speech-specific attributes are present in the voiced part of speech, and our algorithm learns emotion only based on the voiced portion as opposed to the whole segment. To extract the active voice from our samples, an open-source voice activity detection (VAD) algorithm called "WebRTC VAD" [29] is used in preprocessing. WebRTC VAD is a power-based VAD algorithm that extracts the features such as spectral energy and zero crossing rate during a short time frame of 30 milliseconds and feeds them into a decision tree trained by a large voice data set to decide the voice activity. As the clinical data collected from the app contains different levels of noise, we chose a high aggressiveness for our VAD in order to clean the data into voiced utterances.

Feature Extraction

Feature analysis is made by applying a shifting Hamming window of 25.6-minute length frames of the speech signal. Within each frame, the signal is approximately stationary. We then estimate the spectrum by calculating the discrete Fourier transform for each segment with N-point FFT (Fast Fourier transform) of 256 samples. For each analysis frame, we extract time domain feature, spectral features, and Mel-frequency cepstrum coefficient.

The time domain features extracted are zero crossing rate, energy, and entropy. Pitch and energy information are the most prominent features, as they can identify emotion based on the tension of vocal folds and subglottal air pressure. The time elapsed between 2 successive vocal fold openings is called a pitch period, while the vibration rate of the vocal folds is the fundamental frequency. Smaller pitch periods, that is, higher velocities of airflow, are associated with emotions like happiness, while longer pitch periods are linked to harsher emotions like anger. The spectral features extracted are entropy, spread, flux, and roll-off. The alterations in estimations of spectral spread over the frequency range and entropy in speech have been proven to be strongly linked to the diagnoses of clinical depression [30].

The Mel-frequency cepstrum coefficient extracted from the speech is a representation of linear cosine transform of a short-term log power spectrum of the speech signal on a nonlinear Mel scale of frequency. The incorporation of these coefficients in the feature vector is useful in the identification of paralinguistic content in speech. This extraction is of the type where all the characteristics of the speech signal are concentrated on the first few coefficients. A probability model algorithm is used to classify speech and to derive a prediction of the speaker's emotions.

Emotional Frame Selection

Feature extraction procedures produce a quantified collection of attributes. However, emotion recognition is still challenging as we do not understand the correlation between certain features and certain emotions. To better analyze and understand the correlation, we use a Gaussian mixture model (GMM) to perform frame selections. The key intuition is that emotions are usually more concentrated on certain words. While we are not studying emotion from a semantics perspective, it does help us to locate emotionally rich frames and study their features.

We perform GMM clustering on frame features in an utterance. The cluster means are visualized with multidimensional scaling, projecting the Euclidean distance between all clusters onto 2D map. We repeat the process for all emotion categories except neutral. Drawing inspiration from intuition, we deem frames close to the origin on the projection map to be less discriminative and frames on the outer ring to be more discriminative. By using the selected frames, inputs become more condensed hence boosting the classification accuracy.

Machine Learning Models

Gaussian Mixture Model

Our first model takes an unsupervised parametric clustering approach. The GMM is a parametric probability density function consisting of several single Gaussian distributions [31]. It is an unsupervised soft clustering technique that is widely used for speech and speaker classification, audio classification, audio segmentation, and so forth. A GMM approach was used, where

XSL•FO
RenderX

speech emotions were modeled as a mixture of Gaussian densities. The model is parameterized by 2 types of values: the mixture component weights and the component mean and variances or covariances. For a model with K components, the kth component has a mean vector of length k and k × k dimensional covariance matrix. The mixture component weights are defined such that the total probability distribution normalizes to 1. If the component weights are not learned, they are viewed as an a priori distribution over components. If they are learned, they are the a posteriori estimates of the component probabilities given the data.

In the first step (expectation or E), the expectation of the component assignments for each data point is calculated. In the second step (maximization or M), the expectations calculated in the E step are maximized. This iterative process repeats until the algorithm converges, giving a maximum likelihood estimate. Alternating between which values are assumed fixed or known, maximum likelihood estimates of the nonfixed values can be calculated efficiently.

To ensure GMM's performance, we extract features from audio samples that have a satisfying discriminate capacity. We apply Fisher discriminant ratio [32] for the feature selection process. Fisher discriminant ratio is a significant measure for features to be used in classification. For our task, Fisher discriminant ratio indicates how separable the clusters for different emotions are. The top features include energy below 250 Hz, median and minimum of F1 formant frequency, a median of F0 formant frequency, and the variation of the duration of energy plateaus (represents speech rate). Other features used in our analysis include linear predictive coding coefficients and Mel-frequency cepstrum coefficients. Linear predictive coding coefficients is a robust, reliable, and accurate linear representation of speech that takes into consideration the vocal tract and glottal pulse characteristics of voiced speech [33]. Mel-frequency cepstrum coefficients is extracted on a nonlinear scale of frequencies that are altered to closely resemble human hearing capabilities [34]. As we are aiming at children's stress detection with varying age differences across all children patients, it is important to note the difference in the vocal cord between gender and age groups.

There are 2 general approaches for GMM parameter estimation methods: the maximum likelihood approach and expectation-maximization (EM) estimation [35]. The ML method constructs a most likely model to fit for all of the current observations. Since there is no way to ensure unbiased data collection regarding mental health, the ML method poses an unrealistic assumption on the data set. Comparatively, EM is a far superior method to cope with this so-called missing data problem, where we assume only a subset of the features is observed. The EM algorithm consists of 2 iterative steps. Expectation or the E-step made an initial guess for the model parameter concerning missing data, using current estimates, and conditioned upon observed data. The maximization (M-step) then provides a new estimate increasing the above expectation.

The entire iterative process repeats until the algorithm converges, giving a maximum likelihood estimate. Intuitively, the algorithm works because knowing the component assignment Ck for each xi makes solving for model parameters easy while knowing the model parameters and makes inferring the probability of point xi belonging to component Ck easy. The expectation step corresponds to the latter case, while the maximization step corresponds to the former. Thus, alternating between which values are assumed fixed or known, maximum likelihood estimates of the nonfixed values can be calculated efficiently.

Recurrent Neural Network and Long Short-Term Memory

Our second model takes on a different approach to learning, where it employs a supervised learning scheme. The primary motivation for using a recurrent neural network is the idea that they can connect previous information to the present, such as using features extracted from previous frames of the signal to understand the present frame [30]. A long short-term memory network is a special kind of recurrent neural network (RNN) capable of learning long-term dependencies. It uses memory cells and gates to control whether the information is memorized, output, or forgotten [30]. The gating mechanism is used to control information flow by pointwise multiplication. There is a cell to memorize information within the unit. The long short-term memory (LSTM) incorporates cell states at several different time points prior to the current frame using a linear combination, which is computed using an attention mechanism where the weights of data points are learned. This configuration implies an assumption that the current state depends on the state of the previous time step. Thus, emotion patterns are learned by not only correlating the features to the labels independently but also taking the change in features in time into consideration.

Recurrent neural network is a potent tool to extract features in speech recognition, audio scene detection, and so forth. Unlike artificial neural networks, RNN forms a directional graph along a temporal sequence, which registers temporal information throughout the learning process. RNN has proven to be extremely powerful in speech- or audio-related tasks [20,21,23,24] due to the temporal nature of speech. Emotion poses a similar temporal feature to speech, so we wish to create an RNN-based neural network for our task. There has been some research using RNN/LSTM networks for emotion classification. LSTM units are capable of learning long-term dependencies and avoid vanishing gradient problems. With more and more clinical data flooding our database, we are quite positive about what RNN can achieve for our task.

Results

Overview

The institutional review board approved the study in July 2021. Recruitment and data collection for the study were initiated in August 2021 and are currently underway. The study results are likely to be available and published in 2024.

Testing With a Public Data Set

The proposed models are first trained and tested on large public voice data sets to validate the model's ability of emotion classification. These data sets are the Toronto emotion speech set, Ryerson audio-visual database of emotional speech and song, and Surrey audio-visual expressed emotion, which have

XSL•FO
RenderX

simulated emotions provided by professional actors [36]. The voice samples are split into training and testing sets, with a ratio of 85:15 for each of the 5 emotions. The models are trained both with utterance level features and with emotion frame selection to demonstrate the effectiveness.

Based on the results (Table 2), GMM with 128 clusters shows an evenly distributed accuracy across 5 emotions. With utterance level features, GMM achieves an accuracy of 79.15% in total and with frame selection of 85.35%. This demonstrates that GMM is a robust model for emotion classification of all 5 emotions, and emotion frame selection enhances the accuracy of all emotions, which is significant for scientific evaluation. The RNN-LSTM model also shows an evenly distributed accuracy over the emotions, with 79.6% overall accuracy on utterance level and 86% overall accuracy on emotional frames. With emotion frame selection, accuracy on emotions is enhanced but for fear.

Table 2. Accuracy testing results (%) for emotions with the public data set.

Emotions	GMM[a] utterance (%)	GMM frame selection (%)	RNN[b] utterance (%)	RNN frame selection (%)
Neutral	81.68	89.97	86	87
Happy	75.77	82.50	76	88
Sad	73.61	80.10	73	88
Angry	82.52	87.27	84	96
Fear	81.6	85.89	79	71
Overall	79.15	85.35	80	86

[a]GMM: Gaussian mixture model.

[b]RNN: recurrent neural network.

Clinical Data

During this study, we plan to collect and test our model with a clinical data set. Due to the potential variance of the sample size of available clinical data and the richness of emotions that may differ in the pediatric population, training with clinical data is necessary with GMM. For the public data set, our models yield unbiased classification accuracy across all emotion categories. GMM and RNN results are on par, and both could take advantage of the frame selection process to boost accuracy by 6.2% and 6.4%, respectively. Yet, GMM and RNN-LSTM approaches traditionally require a large amount of training data to achieve the best results. Therefore, the clinical data set is aimed to be diverse and large enough to meet the requirement for the training data set. Nevertheless, the results show that our approach is effective for adult human emotion recognition.

For the clinic data set, the performance drop in children's emotion recognition is expected, especially for the data trained on adult speech and tested on children's speech. It may demonstrate the difference between adults' and children's vocal quality. For models trained on clinical data sets, the performance depends on data sample size and quality. In addition, children's voice quality between 6 and 18 years of age is different across gender as well as age groups. It indicates that the training data set is required to be clustered into separate groups. Another parameter to consider is the natural bias in the data set. Since voice samples are collected from patients, they could be biased toward negative emotions, especially fear, anger, and sad categories.

Discussion

Principal Findings

Our study aims to develop and test a speech analysis algorithm to detect clinically relevant emotional distress and functional impairments in children and adolescents with diagnosable mental health disorders. More specifically, the study proposal focused on developing an ML model for a feature extraction that is used for discriminating clinically relevant emotions from speech utterances. The ML model we built also achieved its goal of emotion classification and frame selection for pediatric patients with mental health disorders.

The clinical voice samples provided a wealth of information that can indicate mental status and overall emotional functioning [10], and our study is building on top of earlier evidence on predicting mental conditions [11], including depression and emotional distress [13-15]. Therefore, we anticipate that our study findings will contribute to the literature in terms of understanding the current landscape and building evidence to develop an automated speech analysis algorithm to detect emotional distress and functional impairment.

Even though the study data collection is ongoing, preliminary testing with a public data set showed promising results. The study developed a robust emotion recognition algorithm for 5 classes of emotion based on open-source data sets with 79.14% accuracy using probabilistic models. Compared to the literature, we have promising scores in terms of accuracy with the public data set [11]. A GMM-based speech emotion classification algorithm is used with 3 public adult speech corpora.

Developing a more accurate model requires addressing the problem of biased samples; currently, all the voice samples are collected from youth in mental health services with known mental health diagnoses. The average score of ACE for this sample population (N=420) is 5 out of 10; less than 13% of the US population has an ACE score of 4 or higher [37]. Furthermore, some of the youths display regional Southern American accents, African American Vernacular English, as well as accents related to the fact that English is not their first language. While this gives us the opportunity to build a unique

XSL•FO
RenderX

clinical data set from youth from low-income communities, a skewed data set may decrease the accuracy of the algorithm to detect and score the severity of negative emotions.

Limitations

The study presents several limitations. First, the quality and variability of speech data, including background noise and speech disorders, can affect the accuracy and reliability of biomarkers. Second, the sample population may not be representative to the greater US population, limiting the generalizability of findings. Finally, legal and regulatory considerations, including privacy rules and compliance with regulations, must be reviewed based on the state and jurisdictions, and may limit the use of the algorithm. The latter must be considered to protect participants and ensure the lawful use of data.

Implications and Future Work

In the United States, there are several bottlenecks in the current system of mental health care that technology can address immediately. First is a quick and accurate measurement of the severity of the mental health problem, keeping in mind that all planned interventions depend on the accuracy of symptom severity. Technology, like voice and artificial intelligence, that can make objective measurements of severity can be integrated with limited disruption to the workflow. They can play a significant role in triaging youth to the appropriate level of services proactively and effectively. As we transition to a knowledge-based economy and adjust to the digital industrial revolution, the mental health system of care can no longer afford to resist technology as one part of improving treatment outcomes While automation is routinely adopted in other sectors of the economy, the semimanual workflow of the current mental health system of care accounts for inefficiency in care and provider burnout. For example, mental health providers spend 40% of their time documenting, equivalent to 2 days out of the 5-day workweek that they cannot provide patient services.

Artificial intelligence, automation, and data analytics will be an integral part of the future of mental health services. Adoption of this technology will require the design of user-friendly interfaces, such as the TQI app, that can help mitigate clinician technophobia [38]. Because of the anticipated lack of qualified providers, health care organizations and school systems need to adopt innovation to address quality and cost. As a result, we expect to see the prevalence of innovative technologies continue to rise as payers and other stakeholders demand evidence-based services and data demonstrating treatment outcomes. The shift to value-based care is from payment based on service provided to payment based on outcomes. The providers that will thrive in this new service landscape must use technologies to improve clinical accuracy, workflow productivity, and efficiency. This will help service organizations not only to identify and track high-risk children but also to improve treatment outcomes. A significant percentage of patients in child protective services and covered by Medicaid and other state expenditures come from low-resourced communities. Such solutions will mitigate the severe shortage of highly trained mental health providers in these communities and address health outcome disparities.

The current student-to–school counselor ratio for most school systems is 300 students to 1 counselor. Some schools have a contractual agreement with virtual behavioral health providers to lessen this burden for their staff. The technology could play an influential role in integrating services and breaking down silos. Collaboration between mental health care providers, pediatric primary care, schools, and other stakeholders has been shown to be effective in the early identification and treatment of mental health conditions.

Conclusions

The integration of digital mental health innovations is crucial in addressing the ongoing mental health crisis among children and adolescents. Speech-based digital biomarkers that can be collected via a user-friendly interface hold promise for identifying emotional distress and functional impairments in this population. The findings will contribute to the broader digital health transformation and pave the way for proactive and collaborative mental health care practices.

Acknowledgments

The research reported in this publication was supported by the National Science Foundation Phase I SBIR grant under award number 1938206 and a grant from The Google Black Founders Fund. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Science Foundation or Google. We are grateful for the support of our pilot sites.

Data Availability

Data sharing is not applicable to this study as no data sets were generated or analyzed during this study. Preliminary work was completed using a public data set, and the data set is cited in the manuscript.

Conflicts of Interest

YA is the founder and CEO of TQIntelligence and the principal investigator for the NSF SBIR Phase I grant. The company, TQIntelligence, has also been the recipient of an award from the Google Black Founders Fund that partially funded this research. The company was also awarded a patent for this technology (serial No. 17/550,544) a year and a half after this study.

Protocol

A Smartphone-Delivered Program (Anathema) to Promote the Sexual Health of Older Adults, Colorectal Cancer Survivors, and Stroke Survivors: Protocol for a Feasibility Pilot Randomized Controlled Trial

Abstract

Background: Despite the prevalence of sexual distress and dysfunction in older adults in general and stroke and colorectal cancer survivors in particular, access to specialized care is limited by organizational barriers and stigma, embarrassment, and discrimination. The internet allows reaching services that would otherwise be difficult or impossible to reach, and as smartphones are personal (intimate) technologies, they are a promising vehicle to close this gap. However, research focusing on smartphone-delivered sexual health promotion programs is scarce.

Objective: This study aims to assess the acceptability, feasibility, and preliminary efficacy of Anathema, an 8-week, iOS/Android smartphone–delivered, individually tailored, cognitive-behavioral sexual health promotion program developed to improve relationship and sexual satisfaction, sexual functioning, sexual distress, sexual pleasure, and health-related quality of life (HRQoL) in older adults, colorectal cancer survivors, and stroke survivors compared to treatment as usual in a waiting-list control condition.

Methods: Two-arm, parallel, open-label, waiting list, feasibility, pilot randomized controlled trials (RCTs) will be conducted involving older adults, stroke survivors, and colorectal cancer survivors. The primary outcomes are the acceptability, usability, and feasibility of Anathema. Sexual function, relationship and sexual satisfaction, sexual pleasure, sexual distress, anxiety, depression, and HRQoL are the secondary outcomes. This study has been reviewed and approved by the ethics committees of Instituto Português de Oncologia do Porto Francisco Gentil, Europacolon Portugal, Faculty of Psychology and Educational Sciences, University of Porto, and Sigmund Freud University (approval numbers: CES218R/021, CES19/023, and 2022/01-05b).

Results: This project is funded by the European Commission through the Active and Assisted Living (AAL) Programme (reference: AAL-2020-7-133-CP) from April 2021 to December 2023. Recruitment for the pilot RCTs started on January 2023 in Portugal, Austria, and the Netherlands and is currently ongoing. As of May 2023, we randomized 49 participants in the trials. We expect to complete the RCTs in September 2023. The results on the acceptability, feasibility, and preliminary efficacy of Anathema are expected in the second semester of 2023. We expect Anathema to be highly accepted by the populations under study; to prove feasible to scale up to parent RCTs; and to be potentially efficacious in improving sexual functioning, relationship and sexual satisfaction, sexual distress, sexual pleasure, and HRQoL in older adults, colorectal cancer survivors, and stroke survivors compared to treatment as usual in a waiting-list control condition. The study results will be published in open-access venues according to COREQ (Consolidated Criteria for Reporting Qualitative Research) and CONSORT EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines.

Conclusions: The study results will inform the refinement and scale-up of Anathema. Anathema's wider-scale implementation can potentially promote the sexual health of largely neglected user groups such as older adults, colorectal cancer survivors, and stroke survivors.

Introduction

Background

Sexual health is an integral component of general health [1]. It is significantly related to physical and psychological health, as well as to the perception of well-being and health-related quality of life (HRQoL) [1-3]. Being sexually active has been reported to be associated with improved mental health, increased heart rate variability, and lower risk of certain cancers and coronary events, resulting in lower annual death rates [4]. However, the aging process frequently threatens the experience of a positive, healthy, and fulfilling sex life [5].

Due to physiological and psychosocial changes, older adults are at higher risk of developing sexual difficulties when compared to the general population [6,7]. Frequent problems affecting older women include decreased libido, lack of vaginal lubrication, and orgasmic difficulties. Among older men, erection problems, reduced sexual desire, and an inability to reach climax are the most reported sexual difficulties [5-7]. Previous studies focusing on the predictors of such conditions in both sex groups [5] have identified interpersonal and attitudinal factors, mental health conditions (eg, depression), and physical health conditions as being strongly associated with sexual problems. In this regard, colorectal cancer [8] and stroke [9] are examples of prevalent acquired medical conditions highly associated with older age, which may result in significant impairments in sexual functioning and satisfaction [10,11].

Studies targeting colorectal cancer survivors [12,13] often reported a decrease in the frequency of sexual intercourse, a high incidence of sexual problems (ie, low sexual desire, and arousal and orgasm difficulties), and a significant decrease in survivors' sexual satisfaction after cancer treatment. Identified risk factors for sexual dysfunction include being diagnosed with low rectal cancers, undergoing abdominoperineal resection, having a stoma, and prior treatment with radiotherapy [13]. Moreover, male sex, older age, individual and partner distress, and comorbidities have been reported to be associated with increased sexual disorders in colon cancer survivors [12]. The literature also suggests that sexual difficulties in colorectal cancer survivors span the continuum of care [14].

Among stroke survivors, research reports a high prevalence of sexual dysfunction [15]. The etiology of poststroke sexual dysfunction is multifactorial, and it includes organic (eg, lesion site, comorbidities, medication, etc) and psychosocial factors (eg, anxiety, depression, fear of recurrence, etc) [15]. Common clinical presentations of sexual dysfunction in female survivors include decreased libido, lack of vaginal lubrication, arousal problems, and orgasmic dysfunction [11,15,16]. Male survivors often report decreased libido, sexual activity, and coitus frequency, as well as erectile and ejaculatory dysfunctions [11,15,16]. These difficulties also manifest in stroke survivors with an absent or mild physical impairment, with nearly half experiencing decreased libido, coitus frequency, sexual arousal, orgasm, and sexual satisfaction [11,16]. This finding suggests that changes to prestroke relationships and roles, communication difficulties between partners, taboo and stigma, negative beliefs and attitudes toward sexuality, and perceived social norms may disrupt sexual expression in stroke survivors, leading to decreased sexual satisfaction and poor HRQoL outcomes [11,17].

Despite the prevalence of sexual distress and dysfunction in older adults in general and stroke and colorectal cancer survivors in particular, access to specialized care is limited, and sexual health remains a largely neglected component of treatment [18]. Recent reviews [19-21] have identified a lack of available information concerning sexual issues, a lack of education and training of health care professionals on sexual health, poor quality of the relationship between patients and health professionals, and misalignment between their perspectives on the importance of sexual health as important barriers to accessing sexual health support. Negative societal views and beliefs toward sexual health, stigma, embarrassment, and discrimination were also identified as major factors hindering access to sexual health support and treatment among older adults and other chronic disease groups [19-21]. Finding alternative ways of facilitating access to evidence-based sexual health support that is tailored to the unmet needs of older adults, colorectal cancer survivors, and stroke survivors in a nonstigmatizing manner is, therefore, critical to overcome barriers to treatment-seeking and promote their sexual health.

Because smartphones are personal (intimate) technologies that, augmented with internet connections, allow reaching services that would otherwise be difficult or impossible to reach, they are a promising vehicle to close this gap. However, research focusing on internet-delivered interventions for sexual health is scarce [22]. Most studies addressing such programs focused on male and female sexual dysfunctions in adult populations [23], and only a few targeted sexual difficulties related to chronic conditions. A recent systematic review [24] of mobile health interventions for sexual health among adults with chronic diseases reported no studies with interventions delivered through smartphones. All analyzed studies used a website for intervention delivery, failing to leverage the advantages of mobile devices in this context, namely, "convenience, privacy, anonymity, and more interactive treatment for sexual dysfunction" [24]. Still, the evidence suggests that internet-delivered sex therapy is effective in improving psychosexual outcomes in chronic patients [24].

XSL•FO
RenderX

Among these, cancer is the most frequently researched condition [25-27], with studies including patients with gynecological [28,29], breast [29-32], prostate [33], and colorectal cancers [28]. The findings of these studies suggest that internet-delivered interventions for sexual health are feasible, acceptable, and potentially effective in improving sexual health in cancer survivors [25,27]. Reviewed studies have reported improvements in sexual function and activity [28,29,31]; sexual arousal and pleasure [30]; sexual, intimacy, and relationship satisfaction [34,35]; and sexual distress [28,30]. Furthermore, the positive effects of these interventions in cancer survivors are likely to persist in the long term [34].

However, previously conducted studies vary greatly in sample size, intensity, and program length, and further research is necessary to attest the feasibility and efficacy of internet-delivered interventions for sexual health among different target cancer populations, including colorectal cancer populations, and the use of digital technologies like smartphones.

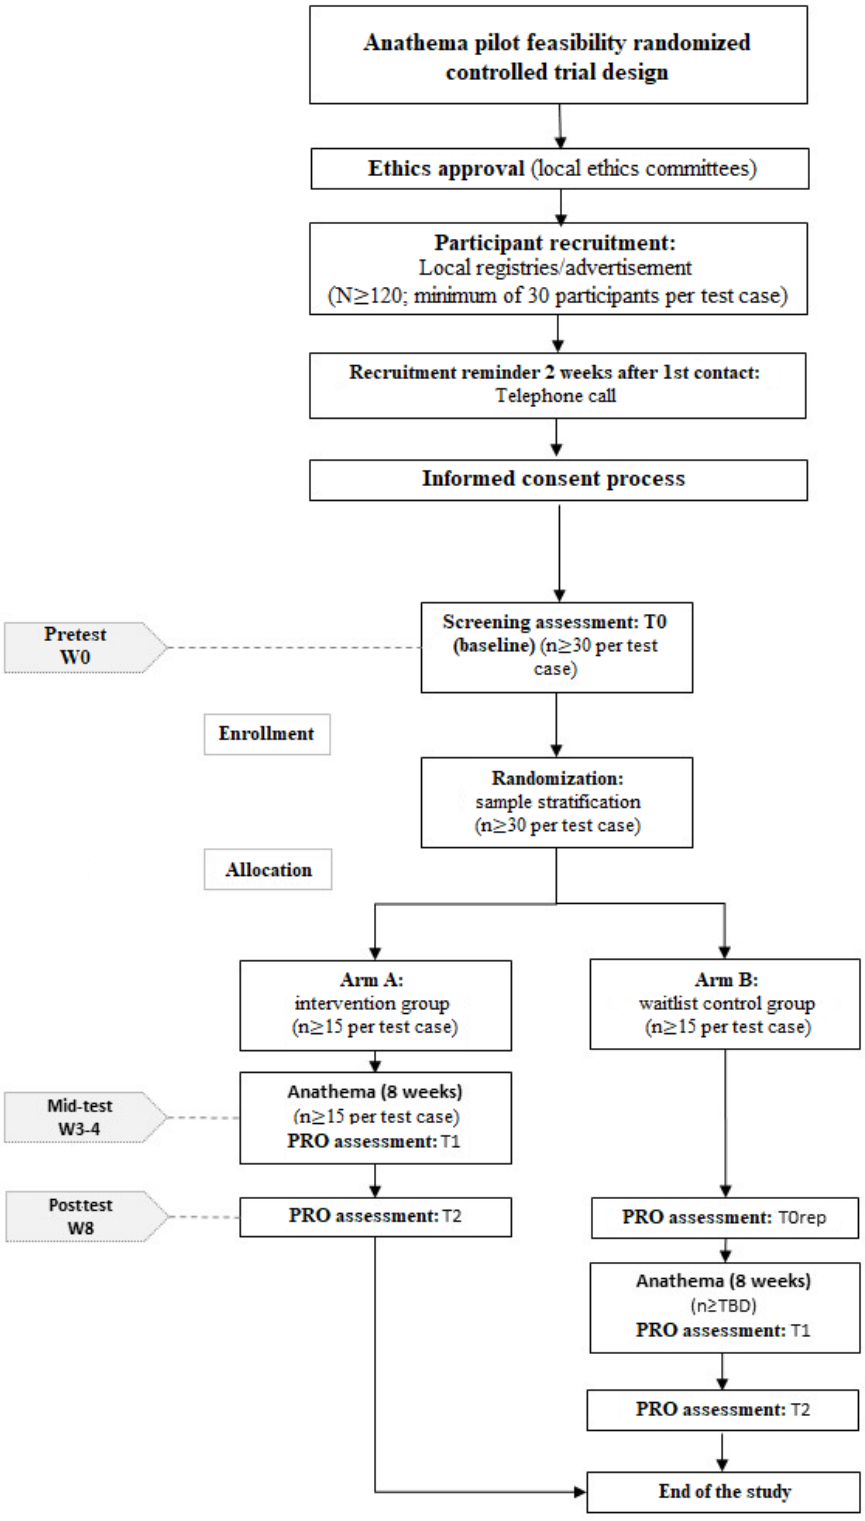
To the best of our knowledge, no study has yet assessed the efficacy of internet-delivered interventions to promote sexual health in stroke survivors or older adults. Nevertheless, professionally guided online sexual rehabilitation programs were identified as highly consensual in a recent Delphi study involving stroke survivors, their partners, clinicians, and researchers [36], underlining the pertinence of developing and testing internet-delivered sexual health promotion programs targeting stroke survivors.

To address the research and supportive care gaps mentioned above, we developed, in the context of a European project named *Anathema – Technology for ageless sexual health*, an 8-week, iOS/Android smartphone–delivered, individually tailored, cognitive-behavioral, sexual health promotion program to improve relationship and sexual satisfaction, sexual function, sexual distress, sexual pleasure, and HRQoL in older adults, colorectal cancer survivors, and stroke survivors (for further details on Anathema's development and structure, please see [37]). This project is funded by the European Commission through the Active and Assisted Living (AAL) Programme. This report presents the research protocol that will support the assessment of Anathema's acceptability, feasibility, and preliminary efficacy in the 3 target populations compared to treatment as usual (TAU) in a waiting-list control (WLC) condition. The findings of this study will support Anathema's future scale-up, implementation, and commercialization, and ultimately facilitate access of older adults, colorectal cancer survivors, and stroke survivors to sexual health support.

Objectives and Hypothesis

This study aims to assess the acceptability, usability, feasibility, and preliminary efficacy of Anathema in older adults, colorectal cancer survivors, and stroke survivors compared to TAU in a WLC condition.

We hypothesize that Anathema will be highly accepted by study participants and prove feasible to scale up. We also expect Anathema to preliminarily show more efficacy in improving relationship and sexual satisfaction, sexual functioning, sexual distress, sexual pleasure, and HRQoL in the study populations compared to TAU in a WLC condition.



Methods

Study Design

Two-arm, parallel, open-label, waiting list, feasibility, pilot randomized controlled trials (RCTs) (Figure 1) will be conducted with older adults, stroke survivors, and colorectal cancer survivors. We will have 1 test case per target population, where different service models (unguided, guided, or blended care) will be tested. The feasibility pilot trials will be performed to identify weaknesses in the study design, test the data collection process, estimate sample sizes, and assess the feasibility of the parent RCTs. The acceptability of Anathema by study participants; the structure, format (ie, unguided, guided, and blended), and content of the study intervention; and between-group differences will also be preliminarily evaluated through this design.

Ethics Approval

This study has been reviewed and approved by the ethics committees of Instituto Português de Oncologia do Porto Francisco Gentil (IPO-Porto) (approval number: CES218R/021, and CES19/023), Europacolon Portugal, Faculty of Psychology and Educational Sciences, University of Porto (approval number: 2022/01-05b), and Sigmund Freud University.

Study Population and Research Sites

This research will target 3 study populations: older adults, colorectal cancer survivors, and stroke survivors. Older adults will be recruited in the Netherlands and Austria. Colorectal cancer survivors and stroke survivors will be recruited in Portugal. A minimum of 30 participants [38,39] per target group is expected to participate in the study trials.

The criteria presented in Textbox 1 will be used to check eligibility for participation in the study:

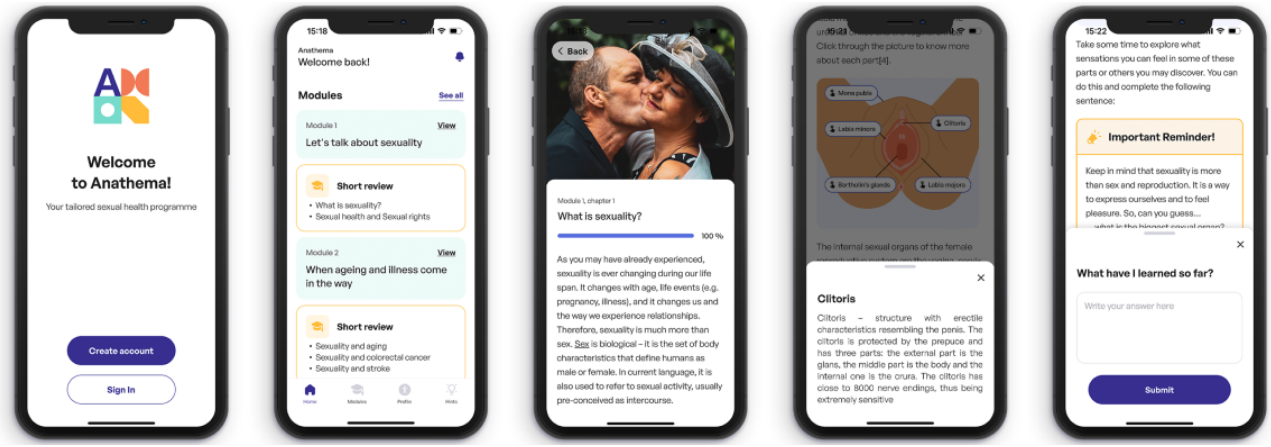
XSL•FO
RenderX

The study will be conducted at 5 different research sites: Unie KBO in the Netherlands; Instahelp in Austria; and IPO-Porto, Europacolon Portugal, and Centro de Reabilitação Profissional de Gaia in Portugal. Sites invited to participate were selected owing to their working standards and resources.

Textbox 1. Eligibility criteria for Anathema's feasibility randomized controlled trials.

Inclusion criteria

- All target groups: Ability to provide informed consent; age ≥55 years; all gender identities, sexual orientations, relationship statuses, and sexual practices at the time of the study; absence of severe psychiatric comorbidity (psychotic or bipolar disorders, severe depression, and substance abuse); single or partnered; no unstable medical conditions precluding participation in a sexual health promotion program; no concurrent therapy to alleviate problems with sexuality or intimacy, or cognitive-behavioral therapy for other psychological issues; ongoing regular psychoactive medication accepted if the dosage has been stable during the last 3 months; daily access to the internet and ability to perform basic use of a smartphone; and no concurrent participation in any other interventional study or clinical trial.
- Specific for colorectal cancer survivors: History of histologically confirmed colorectal cancer; an interval of ≥6 months from primary adjuvant treatment completion (surgery, chemotherapy, or radiotherapy); no previous treatment for another type of cancer (except for cervix carcinoma in situ or basal cell carcinoma); and disease-free at the time of study entry.
- Specific for stroke survivors: Confirmed diagnosis of stroke (hemorrhagic or ischemic) based on clinical examination and imaging, as assessed by a neurologist; and absence of severe cognitive issues or dementia.



Exclusion criteria

- All target groups: Age <55 years; inability to co-operate and provide informed consent; current severe, uncontrolled systemic disease or mental disorder; parallel ongoing psychological treatment; ongoing regular psychoactive medication if the dosage has been changed during the last 3 months; no access to the internet; inability to use a smartphone and the internet; parallel ongoing participation in another interventional study or clinical trial; and assessment by the investigator to be unable or unwilling to comply with the requirements of the protocol.
- Specific for colorectal cancer survivors: Colorectal cancer not histologically or cytologically confirmed; history of other malignancy within the last 5 years; and metastasized colorectal cancer.
- Specific for stroke survivors: Unconfirmed stroke diagnosis; and severe cognitive impairment or dementia.

Study Intervention and TAU

Anathema (Figure 2) is an 8-week, iOS/Android smartphone–delivered, individually tailored, cognitive-behavioral sexual health promotion program developed to improve relationship and sexual satisfaction, sexual functioning, sexual distress, sexual pleasure, and HRQoL in older adults, colorectal cancer survivors, and stroke survivors.

Figure 2. Anathema app overview.

The program was created using a participatory design approach [40], involving its primary (older adults, colorectal cancer survivors, and stroke survivors), secondary (psychologists and sexologists), and tertiary end users (managers of care homes, day-care centers, or clinics). Anathema's development followed an agile development framework [41] and was based on peer-review sources (eg, [12,42-49]) and user research insights (eg, [37]). The program adopts a transdiagnostic structure, featuring sexual health promotion strategies considered appropriate for the different populations under study. Its central components are psychoeducation, cognitive restructuring, mindfulness, communication skills training, exercises to promote sexual sensation awareness and erotic repertoire, and masturbatory and sensate focus exercises. Anathema is structured into 5 modules to be completed for up to 8 weeks. A detailed description of Anathema's structure and content is provided in Table 1.

Regarding human support, Anathema may be delivered using 3 service models. The subtypes are as follows: unguided or self-guided (the primary end user follows all the intervention programs on her/his own with no support from a clinical psychologist), guided (the intervention program incorporates

XSL•FO
RenderX

clinical psychologists' synchronous or asynchronous support, guidance, and feedback via email, chat, etc), and blended (treatment programs that combine face-to-face or videoconference sessions with online treatment modules in an integrated and sequential format). An iOS/Android app co-developed in the context of this project will be used to deliver the self-guided version of the intervention to older adults in the Netherlands. In this approach, no clinical psychologist-participant contact is foreseen. This app will also guide colorectal cancer and stroke survivors throughout the program in Portugal. Synchronous (eg, voice and chat) and asynchronous (eg, email) communication channels will be available to provide participants with guidance and support weekly and upon request. The blended-care format intervention will be delivered to older adults in Austria via an iFrame to be made available on the Instahelp platform [50]. In this case, the developed modules will be combined with 3 videoconference sessions (at the onset, mid, and conclusion of the intervention) focusing on the clarification of the intervention's content and strategies to be implemented. Upon request, sessions are also possible for participants requiring additional support from clinical psychologists.

In this research, TAU refers to the routine sexual health care participants would receive at the recruitment sites. Therefore, the type of TAU received may vary and include pharmacologic treatment or psychosocial support. WLC participants will be informed that they are free to access any form of support during the study and encouraged to seek professional help in case they experience symptomatic deterioration or other difficulties. WLC participants will be offered the same treatment protocol applied to the experimental group after completion of the program (approximately 8 weeks from baseline).

Table 1. Anathema's structure and content.

Module	Intervention components	Content
Let's talk about sexuality? (week 1)	• Psychoeducation	• Concepts underlying sexuality • Male and female anatomies and erogenous zones • Sexual response and sexual pleasure • Sexual health, sexual rights, and their importance • Activities: Setting my personal goals within Anathema, and I get pleasure from…
When aging and illness come in the way (week 2)	• Psychoeducation (tailored to each study population)	• Successful aging • Sexual expression in older age • Physiological, cognitive, and emotional changes in older age • Sexual problems and sexual dysfunction in older age • Biopsychosocial changes associated with colorectal cancer (CRC) and stroke, and their impact on survivors' sexual health • Activities: Practicing self-compassion, and identifying and classifying the changes I experience in my sexual life due to aging, CRC, or stroke
Emotional and physical intimacy (weeks 3-6)	• Psychoeducation • Cognitive restructuring • Mindfulness • Communication skills training • Sensate focus	• Sexual beliefs, thoughts, and emotions, and their impact on sexuality • Identifying, evaluating, and modifying maladaptive thinking • Interpersonal relationship and communication issues commonly associated with aging, CRC, and stroke • Restoring interpersonal relationships and intimacy • Activities: Rational disputation, diary of thoughts and emotions, practicing mindfulness, identifying and overcoming relationship stressors, improving communication, and sensate focus
Exploring one's sexuality (week 7)	• Psychoeducation • Mindfulness exercises • Sexual skills training	• Giving and receiving pleasure: eroticism, masturbation, and intercourse • Sex aids and strategies to enhance sexual pleasure and satisfaction • Activities: Practicing mindfulness and identifying treatment options
Planning for a long-term fulfilling sex life (week 8)	• Relapse prevention	• Overview of Anathema and progress evaluation • Strategies to maintain progress and prevent setbacks • Promotion of a healthy lifestyle as key to better sexual health • Activities: Managing therapeutic progress, and strategies to enhance sexual pleasure and satisfaction

Measures

Primary Outcome Measures

The primary outcomes in this study are the acceptability, usability, and feasibility of Anathema. To assess Anathema's acceptability, participants will self-report on the appropriateness and usefulness of the intervention's content, length, usability, and service delivery model, using a self-developed 5-point Likert scale and the System Usability Scale [51].

Anathema's feasibility-specific measures include recruitment, randomization, retention, and adherence rates (Table 2). Postintervention semistructured interviews will also be conducted to gather further data on Anathema's usefulness, usability, and feasibility, as perceived by participants.

XSL•FO
RenderX

Table 2. Primary outcome measures.

Outcome	Metrics
Acceptability	• Self-developed 5-point Likert scale assessing the appropriateness and usefulness of the intervention's content, length, usability, and service delivery model • Postintervention semistructured interviews
Usability	• System Usability Scale [51]
Feasibility	Recruitment: • Number of participants screened per week • Number of screening failures • Number of participants enrolled per week • Proportion of recruited participants opting to enroll Randomization: • Proportion of eligible participants who access Anathema following randomization • Proportion of eligible participants who complete at least one module of Anathema Retention: • Proportion of participants who complete T0 (baseline) measures • Condition-specific completion rates following randomization (completion is defined as ≥50% of modules accessed at least once) • Proportion of participants initiating baseline measures who complete T1 (midtest) and T2 (posttest) measures Adherence: • Proportion of participant dropouts from each intervention condition • Proportion of participant withdrawals from the study • Postintervention semistructured interviews

Secondary Outcome Measures

Sexual function, relationship and sexual satisfaction, sexual pleasure, sexual distress, anxiety, depression, and HRQoL are secondary outcome variables in this research. A summary of the secondary outcome measures to be used in this study is presented in Table 3. Participants will not be invited to fill in all the listed measures, since secondary outcome measures will be tailored to participants' gender, sexual orientation, and condition.

XSL•FO
RenderX

Table 3. Secondary outcome measures.

Measure	Construct	Number of items	Dimensions	Rating scale	Cutoff points	Psychometric properties	Translation/adaptation to the target populations
Sociodemographic and clinical background questionnaires tailored to each target group	N/A[a]	11	N/A	N/A	N/A	N/A	Original version developed in Portuguese (Portugal) by the research team and translated to Dutch and German.
Mini-International Neuropsychiatric Interview (MINI) [52]	Mental disorders	16 modules (branching tree logic items)	Multidimensional	Dichotomous rating scale	N/A	Cohen k=0.7	Translated and adapted to Portuguese (Portugal), Dutch, and German.
Patient Health Questionnaire (PHQ-9) [53]	Depression	9	Unidimensional	4-point Likert scale	Mild depression (<5), moderate depression (6-10), moderately severe depression (11-15), and severe depression (>15)	α=.86	Translated and adapted to Portuguese (Portugal), Dutch, and German.
Generalized Anxiety Disorder Screener (GAD-7) [54]	Anxiety	7	Unidimensional	4-point Likert scale	Normal anxiety (<5), mild anxiety (5-9), moderate anxiety (10-15), and severe anxiety (15-21)	Primary care setting (α=.92); general population (α=.89)	Translated and adapted to Portuguese (Portugal), Dutch, and German.
World Health Organization Quality of Life: Brief Version (WHO-QoL-BREF) [55]	Quality of life	26	Multidimensional	5-point Likert scale	N/A	.66<α<.84	Translated and adapted to Portuguese (Portugal), Dutch, and German.
Global Measure of Sexual Satisfaction (GMSEX) [56]	Sexual satisfaction	5	Unidimensional	7-point Likert scale	N/A	α=.94	To be translated and adapted to Dutch and German in the context of this research.
Global Measure of Relationship Satisfaction (GMREL) [56]	Relationship satisfaction	5	Unidimensional	7-point Likert scale	N/A	α=.95	To be translated and adapted to Dutch and German in the context of this research.
Sexual Pleasure Scale (SPS) [57]	Sexual pleasure	3	Unidimensional	7-point Likert scale	N/A	α=.84	To be translated and adapted to Dutch and German in the context of this research.
International Index of Erectile Function (IIEF) [58]	Sexual function	15	Multidimensional	0-5 or 1-5 numeric rating scale	≤25 expresses risk of sexual dysfunction	α>.70 for all domains	Translated and adapted to Portuguese (Portugal), Dutch, and German.
Female Sexual Function Index (FSFI) [59]	Sexual function	19	Multidimensional	0-5 or 1-5 numeric rating scale	≤26 expresses risk of sexual dysfunction	α>.9 for all domains	Translated and adapted to Portuguese (Portugal), Dutch, and German.
Sexual Distress Scale (SDS-R) [60]	Sexual distress	13	Unidimensional	5-point Likert scale	N/A	α>.85	Translated and adapted to Portuguese (Portugal), Dutch, and German.

[a]N/A: not applicable.

Study Procedures

Compliance With Laws, Regulations, and Ethical Standards

The study will comply with the following laws, regulations, and ethical standards: the International Conference on Harmonisation (ICH) E6 Guideline for Good Clinical Practice (GCP), the Declaration of Helsinki (October 1996), Regulation (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46/EC (General Data Protection Regulation), as well as the following Portuguese Decree-laws: Lei n.º 58/2019 (Assegura a execução, na ordem jurídica nacional, do Regulamento (UE) 2016/679 do Parlamento e do Conselho, de 27 de abril de 2016, relativo à proteção das pessoas singulares no que diz respeito ao tratamento de dados pessoais e à livre circulação desses dados); Lei n.º 21/2014 (Lei da Investigação Clínica), de 16 de Abril; Lei n.º 73/2015, de 27 de julho (Primeira alteração à Lei n.º 21/2014, de 16 de abril, que aprova a lei da investigação clínica, no sentido de fixar as condições em que os monitores, auditores e inspetores podem aceder ao registo dos participantes em estudos clínicos); Regulamento n.º 258/2011 (nos termos do artigo 77.º do Estatuto

XSL•FO
RenderX

da Ordem dos Psicólogos Portugueses, aprovado pela Lei n.º 57/2008, de 4 de Setembro, a Ordem elabora, mantém e atualiza o Código Deontológico da Ordem dos Psicólogos Portugueses); and Linhas de Orientação para a Prestação de Serviços de Psicologia Mediados por Tecnologias da Informação e da Comunicação (TIC) da Ordem dos Psicólogos Portugueses.

In Austria, clinical psychologists will follow the Ethics Guideline from the Federal Ministry of Labour, Social Affairs, Health, and Consumer Protection. The practice of the profession of clinical psychology and health psychology in Austria is regulated by the Psychologists Act 2013, Federal Law Gazette I No. 182/2013. The Code of Professional Conduct, in the form of an ethics guideline, supplements and concretizes the professional duties laid down in the Psychologists Act 2013 and serves to safeguard and promote the professional ethics of the members of the profession. The professional and ethical principles are based on the Meta Code of Ethics of the European Federation of Psychologists' Associations (EFPA) as follows: (1) respect for the dignity and rights of the person, (2) competence, (3) responsibility, and (4) integrity. The most recent version (as of May 21, 2021) was updated in February 2020.

The study will follow ISO standards TC314 (Ageing committees) and 82304-2 (Health and wellness apps), as noted in the AAL Guidelines for Ethics, Data Privacy, and Security, as they are also relevant.

However, due to the openness that a participatory design approach brings to research projects, fixed regulations and ethics guidelines may not suffice for Anathema. Therefore, an in-action ethics [61] approach, whereby the entire consortium is called to define the project ethos, eliciting values that the project should stand for and that should guide decisions in case the answer to ethical dilemmas falls outside normative ethics principles, is being adopted.

Study Initiation

The pilot feasibility trials will be initiated in February 2023. The study duration will be approximately 12 months. A study initiation visit will be performed to present the research protocol, train the local study teams, and adjust the study procedures to site specificities. A training course targeting the study psychologists will be delivered before the onset of the recruitment period to train them on Anathema's key components, structure, and delivery, as well as on the study procedures. This course will be delivered online by certified psychologists and sex therapists.

Recruitment

Recruitment procedures will follow a multicenter strategy, as different consortium partners have access to different study populations. Unie KBO in the Netherlands, and Instahelp and Sigmund Freud University in Austria will be responsible for recruiting older adults. In Portugal, IPO-Porto and Europacolon will be responsible for recruiting colorectal cancer survivors. Centro de Reabilitação Profissional de Gaia will be responsible for recruiting stroke survivors in Portugal. With the support of local study team members, potential study participants will be identified by reviewing patient files at each site or following advertisements of the studies in institutional newsletters, social networks, or newspapers.

Consent Process

All participants will provide informed consent before any study-specific assessments and procedures are performed. Regardless of the implemented recruitment strategy, a local study team member will perform the first contact to secure the participants' permission to be approached by the researchers. Copies of the study information sheet and informed consent forms will be provided for analysis and discussion. Subjects self-referring to participate (eg, following the study's advertisement) will be directly contacted by the study team to provide any required clarifications before giving their consent. After informed consent is obtained, screening and baseline assessment procedures may occur.

Screening and Baseline Assessments

Screening and baseline assessments will be conducted by certified psychologists or psychology students supervised by the study team. The abovementioned outcome measures will be used for this purpose (Table 3). Participants fulfilling the eligibility criteria for the study will then be further assessed via a diagnostic interview. The Mini-International Neuropsychiatric Interview (MINI) [52] will structure this process. Participants with severe mental disorders will be referred to psychology departments at study sites or community mental health services.

Enrollment and Randomization

Participants fulfilling all eligibility criteria will be registered and randomized. Simple randomization will be performed by an independent statistician, using a computerized program. Older adults in Austria, and colorectal cancer and stroke survivors in Portugal will be submitted to subsequent simple randomization so that they are randomly assigned to one of the study psychologists. Colorectal and stroke survivors will be guided by study psychologists from SexLab, and older adults in Austria will have access to blended support provided by clinical psychologists from Instahelp. Older adults in the Netherlands will not be submitted to this second randomization procedure, given that they will get access to the self-guided version of the program. Participants randomized to Arm A (experimental condition) will receive immediate access to Anathema. Participants assigned to the WLC condition will gain access to the program approximately 8 weeks after randomization and after being submitted to a second baseline assessment to confirm their eligibility for the study.

Study Intervention Delivery and Assessment

After randomization, participants will gain access to Anathema either via the co-developed app (older adults in the Netherlands, and colorectal cancer and stroke survivors in Portugal) or the Instahelp platform (older adults in Austria). At this stage, the 3 abovementioned service models will be tested for acceptability, feasibility, and preliminary efficacy.

The self-guided model will be tested with older adults in the Netherlands. Participants will gain access to the treatment modules every week, being prompted to complete the modules in approximately 1 week. If participants fail to complete the

XSL•FO
RenderX

modules in the specified time frame, a reminder will be sent. Upon completion, participants will receive access to the following module. The preliminary efficacy of the intervention will be assessed at midtest (T2) and after the completion of the program at posttest (T3), using the measures listed above.

The guided model will be trialed by colorectal cancer and stroke survivors in Portugal. Participants will gain access to the intervention after a preliminary online or telephone appointment is conducted with their assigned study psychologist. This first e-appointment aims to discuss the program's structure, report the baseline findings, and tailor the intervention according to participants' needs and preferences. Once clinical psychologists and participants reach an agreement, the selected modules will be prescribed and made available weekly to the participants. Participants will be prompted to complete the modules in approximately 1 week. Within 24 hours of module completion, the study psychologists, based on the reported outcomes, will assess participants' progress and determine whether it is appropriate or not for the participants to proceed to the next module. If so, participants will receive access to the following module. If not, study psychologists will instruct participants on what needs to be completed to advance to the next module. The preliminary efficacy of the intervention will be assessed at midtest (T2) and after the completion of the program at posttest (T3), using the measures listed above.

The blended model will be assessed by older adults in Austria. Participants will gain access to the intervention after a preliminary 60-minute videoconference appointment is conducted with their assigned study psychologist. This first appointment aims to discuss the program's structure and tailor the intervention according to participants' needs and preferences. Once clinical psychologists and participants reach an agreement, the selected modules will be prescribed and made available every week to the participants. Participants will be prompted to complete the modules weekly. Within 24 hours of module completion, the study psychologists, based on the reported outcomes, will assess participants' progress and determine whether it is appropriate or not for the participants to proceed to the next module. If so, the participants will receive access to the subsequent module. If not, clinical psychologists will instruct participants on what needs to be completed to advance to the next module. Online videoconference appointments will be conducted at the onset of the program (session 1), at week 3/4 (session 2), and at the end of the program (session 3) to blend self-care work and asynchronous support with therapeutic videoconference synchronous support. During the videoconference appointments, study psychologists will assess participants' progress, instruct participants on how to implement treatment strategies, and determine whether it is appropriate or not for participants to proceed with the program. Upon request, sessions are also possible for participants requiring additional support from clinical psychologists. Still, they are limited to 5 extra sessions, at a maximum of 1 per week and for approximately 40 to 50 minutes. If an extra videoconference session is requested, it will replace the scheduled asynchronous session to avoid redundancy. The preliminary efficacy of the intervention will be assessed at midtest (T2) and after the completion of the program at posttest (T3), using the measures listed above (Table 3).

Discontinuation of Participation

Participants may withdraw from the study at any time and for any reason, without any consequences, or be dropped from the study by the research team if a severe aggravation of baseline measures occurs. In this case, the participant will be referred to psychology services at study sites or specialized resources in the community. The main reason for withdrawal will be registered, and a final assessment will be performed whenever the participant agrees with it. Participants who are lost to follow-up may be replaced to ensure a balanced number of participants in each study arm.

Data Handling and Storage

All data to be collected within the scope of Anathema will be completed by participants via the Anathema app and through regular outcome assessments. Questionnaire data will be collected through LimeSurvey [62] and Microsoft Office Forms. These surveys will exclude personal information and IP storage, so that confidentiality and anonymity are ensured. Each participant will be assigned a random user, and this will be used by researchers to identify the participants and their survey responses during the study. Feasibility and trial-related data will be monitored via TrialMonitor [63], a software tool that scaffolds the creation of personalized web dashboards for monitoring participants in technology-enabled field trials. Data will be kept confidential and will be stored in compliance with physical infrastructure and software requirements imposed by the European Union (EU), namely the EU Regulation 2016/679 of The European Parliament and of the Council of April 27, 2016, on the protection of natural persons with regard to the processing of personal data and on the free movement of such data. The questionnaire responses and data from the application will be stored in a secure database that is not accessible from the outside world without proper authorization. The data will be protected by multiple layers of security to ensure that it remains confidential and can only be accessed by authorized personnel. The database will be regularly backed up to ensure that the data are not lost in case of any unforeseen events. Additionally, strict protocols will be in place to track and monitor any access to the data, to ensure that the data are only being used for authorized purposes. All communication related to Anathema will take place within the developed platform, so no confidential information is sent unencrypted and via third-party programs.

Regarding physical infrastructure, data will be stored in servers that are physically located on the premises of Associação Fraunhofer Portugal Research in Porto, Portugal. These servers are situated in a locked server room that is equipped with a key and card-keypad access control system, and is accessible to only authorized personnel. A dedicated division of IT technicians, working at Associação Fraunhofer Portugal Research, is responsible for the maintenance of the hardware equipment (servers and network), ensuring that all equipment is constantly running and is redundant (various hardware backups ensure continuity if one system fails). The software on the servers is updated constantly. Additionally, full backups of the system

XSL•FO
RenderX

are performed on a daily basis and stored at a different location than the live servers. These backups are encrypted. The server operating system is Linux-based, and the operating system installation is dedicated only to the platform services. Encrypted (https/Transport Layer Security) protocols will be used in all data communication between the servers and the users, as well as in peer-to-peer audio/video chat. The key to produce the code that allows the indirect identification of the participants will be deleted 5 years after the end of the study, as mandated by Deliberação n. 1704/2015 (Deliberação da Comissão Nacional de Proteção de Dados Aplicável aos tratamentos de dados pessoais efectuados no âmbito de Investigação Clínica).

Instahelp uses 3 different security mechanisms to protect data from external access: (1) encryption of data before transmission (end-to-end encryption), (2) secure data transmission (Transport Layer Security), and (3) 2-factor authentication. The widely used and recognized LibSodium cryptography library is used to encrypt the data. Each individual chat message is encrypted with a symmetric space key based on the Salsa20 (64-bit) method. In addition, each message is checked for tampering after transmission using message authentication via Poly 1305MAC. The hosting of the web server (including the implementation on the server side) and the database are provided by the IT service provider 1&1 in Frankfurt (Germany).

Analysis

Descriptive statistics (ie, means, percentages, frequencies, etc) will be used to characterize the study sample and report on acceptability, usability, and feasibility quantitative measures. Acceptability and feasibility assessments will also be based on the qualitative data collected during the postintervention interviews. Qualitative data will be thematically analyzed [64].

To evaluate Anathema's preliminary efficacy, we will first perform independent sample *t* tests and chi-square analysis to assess potential baseline differences between participants randomized to the experimental and control arms. Second, we will calculate the differences between the experimental group and the control condition for secondary outcomes. Data analysis will be performed according to the intention-to-treat principle and resorting to a mixed-models approach [65]. Effect sizes (Cohen *d*) [66] and the 95% CI will be calculated to measure the treatment magnitude for continuous outcomes. Finally, clinical significance will be assessed using the Jacobson & Truax method [67]. All statistical analyses will be conducted in IBM SPSS for Windows (IBM Corp).

Results

The European Commission funds the project Anathema through the AAL Programme (reference: AAL-2020-7-133-CP) from April 2021 to December 2023. Recruitment for the pilot RCTs started on January 2023 in Portugal, Austria, and the Netherlands, and is currently ongoing. As of May 2023, we randomized 49 participants in the trials. We expect to complete the RCTs in September 2023. The results on the acceptability, feasibility, and preliminary efficacy of Anathema are expected in the second semester of 2023.

Considering that the development of Anathema involved a participatory design approach [40] and included primary, secondary, and tertiary end users, we expect it to be highly accepted by older adults, colorectal cancer survivors, stroke survivors, mental health professionals, and sexual health experts. We also expect it to prove feasible to scale up to parent RCTs and to be potentially efficacious in improving the relationship and sexual satisfaction, sexual pleasure, and HRQoL of older adults, colorectal cancer survivors, and stroke survivors compared to TAU in a WLC condition. Study results will be published in open-access venues according to COREQ (Consolidated Criteria for Reporting Qualitative Research) [68] and CONSORT EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) [69] guidelines.

Discussion

This study is designed to assess the acceptability, usability, feasibility, and preliminary efficacy of Anathema in decreasing sexual distress and improving sexual function, relationship and sexual satisfaction, sexual pleasure, and HRQoL in older adults, colorectal cancer survivors, and stroke survivors when compared to TAU in a WLC condition. We expect this feasibility study to prove that the adopted methodology is sound, feasible, and coherent with participants' expectations and needs. We also expect Anathema to be potentially efficacious in improving the relationship and sexual satisfaction, sexual pleasure, and HRQoL of older adults, colorectal cancer survivors, and stroke survivors compared to TAU in a WLC condition.

To our knowledge, this is the first study evaluating the acceptability, feasibility, and preliminary efficacy of a smartphone-delivered sexual health promotion program targeting older adults that also caters to the unmet specific sexual health needs of colorectal cancer and stroke survivors, and is an important contribution to this knowledge field. Furthermore, the obtained results will add to the evidence on the acceptability, feasibility, and effectiveness of internet-delivered sex therapy in cancer [25-27] and chronic disease patients [24]. The results will also inform Anathema's refinement and the methodology used in future parent RCTs testing the effectiveness of the sexual health promotion program in the 3 target populations.

If proven acceptable, feasible, and preliminarily effective, Anathema will be made available to participants, and health care and research organizations to be used free of charge in health care and future research. Anathema is expected to be an important self-care tool to be used autonomously and with the support of sexual health experts, contributing to close the sexual health care gap experienced by older adults, colorectal cancer survivors, and stroke survivors.

The strengths of this study include the inclusive, participatory, and multicountry design approach used in Anathema's development. This approach will ensure Anathema is culturally sensitive in the Netherlands, Austria, and Portugal, facilitating the program's acceptance and use in these countries. The fact that the program is inclusive and made available in English also enables the opportunity of conducting future research targeting other populations and countries. Regarding the study design,

XSL•FO
RenderX

the multicentric feasibility RCT design to be used in the pilot phase is of utmost relevance, as it will provide information on Anathema's feasibility and preliminary efficacy, and increase the chances of the generalizability of the results. The assessment of 3 different service delivery models for Anathema in comparison with TAU is also an advantage, as it will provide data on their relevance and preliminary impact in the target populations, informing the design of future sexual health care services. Finally, the combination of the RCT design with the qualitative insights emerging from the posttest interviews will warrant deeper exploration of Anathema's acceptance and future use, facilitating its future implementation.

The potential limitations include challenges in the recruitment and retention of participants. The limited research conducted to assess the acceptability, feasibility, and efficacy of smartphone-delivered sexual health promotion programs in older adults, colorectal cancer survivors, and stroke survivors makes it difficult to estimate recruitment, retention, and adherence rates for Anathema. To overcome this limitation, a multicountry participatory design approach was used to design Anathema, and diversified recruitment strategies were defined (eg, local recruitment by clinical teams at each site, and advertisements of the studies in institutional newsletters, social networks, or newspapers).

Acknowledgments

We thank Gerhard Andersson, Noëlle Sant, and Patrícia Pascoal for providing scientific and technical advice to the research team. The authors wish to acknowledge the European Commission through the Active and Assisted Living (AAL) Programme (reference: AAL-2020-7-133-CP) and the Member States: Fundação para a Ciência e a Tecnologia in Portugal, the Austrian Research Promotion Agency (FFG) in Austria, and ZonMw (The Netherlands Organisation for Health Research and Development) in the Netherlands for funding this project.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

ACB and CMS conceptualized and designed the study. ALQG, RP, PV, and PN developed the sexual health promotion program and provided important feedback regarding the study design. CMS wrote the manuscript. ACB, ALQG, RP, PV, and PN revised the article for important intellectual content. ACB secured funding for this research. The authors alone are responsible for the views expressed in this article, and they do not necessarily represent the decisions, policy, or views of their affiliated institutions.

Conflicts of Interest

None declared.

Abstract

Background: The prevalence of smoking remains high in many low- and middle-income countries (LMICs), including the Southeast Asian nation of Cambodia. Smoking is especially hazardous for people with HIV. In Cambodia, approximately 43%-65% of men with HIV and 3%-5% of women with HIV smoke cigarettes. Thus, there is a critical need for cost-effective smoking cessation interventions for Cambodian people with HIV. This paper describes the design, methods, and data analysis plans for a randomized controlled trial assessing the efficacy of a theory-based mobile health smoking cessation intervention in Cambodian people with HIV.

Objective: This 2-group randomized controlled trial compares the efficacy of a mobile health–based automated messaging (AM) intervention versus standard care (SC) in facilitating smoking cessation among Cambodian people with HIV.

Methods: Cambodian people with HIV who currently smoke and are receiving antiretroviral treatment (target, N=800) will be randomized to (1) SC or (2) the AM intervention. SC participants will receive brief advice to quit smoking, written self-help materials, nicotine patches, and will complete weekly app-delivered dietary assessments for 26 weeks. AM participants will receive all SC components (but will complete smoking-related weekly assessments instead of dietary assessments), in addition to a fully automated tailored messaging program driven by the weekly assessments to facilitate smoking cessation. In the Phase-Based Model of smoking cessation, the cessation process is partitioned into 4 phases: motivation, preparation (precessation),

XSL•FO
RenderX

cessation (quit date to 2 weeks post quit), and maintenance (up to 6 months post quit). Our AM program targets processes within these phases, including increasing motivation to quit, enhancing self-efficacy, obtaining social support, skills to cope with nicotine withdrawal symptoms and stress, and skills to maintain abstinence. All participants will complete baseline and 3-, 6-, and 12-month in-person follow-up assessments. The primary outcome is biochemically confirmed abstinence at 12 months, with 3- and 6-month abstinence as secondary outcomes. Potential mediators and moderators underlying treatment effects will be explored, and cost-effectiveness will be assessed.

Results: This study was approved by all relevant domestic and international institutional and ethical review boards. Participant recruitment commenced in January 2023. Data collection is expected to conclude by the end of 2025.

Conclusions: By demonstrating the greater efficacy and cost-effectiveness of AM relative to SC, this study has the potential to transform HIV care in Cambodia and prevent tobacco-related diseases. Furthermore, it may be adapted for use in other Cambodian populations and in other low- and middle-income countries. Ultimately, the AM approach to smoking cessation could greatly improve public health in the developing world and beyond.

Introduction

Tobacco use remains the leading cause of preventable morbidity and mortality worldwide [1]. Although the prevalence of tobacco use has declined in high-income nations in recent decades, the prevalence of smoking remains strikingly high in many low- and middle-income countries (LMICs) [2]. In Cambodia, for example, national surveys have indicated that 33%-43% of adult men and 3% of adult women smoke cigarettes [3,4]. Thus, the development and evaluation of sustainable tobacco cessation interventions suitable for widespread implementation in Cambodia are pressing public health needs.

Certain special populations, such as people with HIV, are confronted with disproportionately high tobacco-related health risks. Data from high-income nations indicate that tobacco use represents a leading cause of mortality among people with HIV [5-10]. Nonetheless, there are few efficacious tobacco cessation interventions for people with HIV. The problem of tobacco use among people with HIV appears to be even more critical in Cambodia: available estimates indicate that 43%-65% of men with HIV and 3%-5% of women with HIV smoke cigarettes [11,12]. Although Cambodia has widespread coverage for antiretroviral treatment (ART), no known efforts have been made to provide tobacco treatment to ART recipients who smoke. Thus, complementing ART with efficacious tobacco cessation treatment offers tremendous potential to improve HIV care and prolong life for people with HIV.

This paper describes the design, methods, and analysis plans for an ongoing intervention trial with pharmacological and behavioral treatment components, including a fully automated, smartphone-delivered intervention. Mobile health (mHealth) interventions are proliferating in the United States, but efforts to use similar approaches in Cambodia are extremely limited. The World Health Organization (WHO) acknowledges that the use of mobile and wireless technologies for health promotion is cost-effective, scalable, and sustainable for the least developed countries [13]. In addition, text messaging interventions for smoking cessation have been shown to be effective [14,15], cost-effective [16], and very affordable for tobacco control globally [17-19].

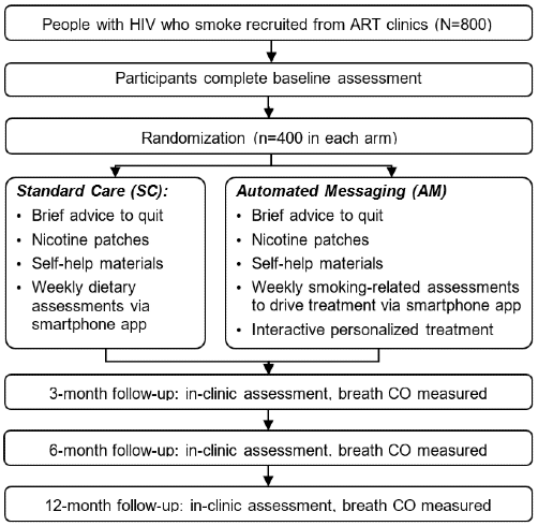
We previously developed the mHealth-based intervention approach discussed in this paper and completed a pilot study with 50 Cambodian people with HIV who smoked and received care at an ART clinic. The results indicated that the biochemically confirmed, 7-day point prevalence abstinence rates at the 2-month follow-up were 40% in the group receiving the mHealth intervention versus 8% in the standard care (SC) control group (relative risk 5.0, 95% CI 1.2-20.5) [20]. This study will evaluate the long-term efficacy of this intervention with a fully powered sample size.

In this study, we are conducting a 2-group randomized controlled trial (RCT) to fully evaluate our mHealth-based automated messaging (AM) intervention versus an SC approach among Cambodian people with HIV who smoke. Specifically, we will assess the long-term (12 months) efficacy of AM, and we will conduct an economic evaluation to compare its cost-effectiveness to that of SC. We will also explore potential mediators and moderators underlying the associations between AM treatment and smoking abstinence (Multimedia Appendix 1).

Methods

Ethics Approval

Funding for this study was provided by the National Cancer Institute in 2021 (U01 CA261598-01). It was approved by Moffitt Cancer Center's institutional review board (IRB; Advarra), which was selected to serve as the single IRB of record for the research described in this protocol by all participating domestic institutions (#00000971), while the IRB of the Ministry of Health of Cambodia—the Cambodian



XSL•FO
RenderX

National Ethics Committee for Health Research—approved the research conducted at sites in Cambodia (NECHR #092).

Study Design

We are using a 2-group RCT to compare the efficacy of 2 smoking cessation interventions: our already-developed smartphone-delivered AM intervention versus SC. Participants are people with HIV recruited through ART clinics in Phnom Penh. Following consent, participants will be randomly assigned to 1 of the 2 study groups: SC (n=400) or AM (n=400). Participants will be asked to complete in-clinic assessments at baseline, and at 3-, 6-, and 12 months following study enrollment (Figure 1). All participants also will complete brief weekly assessments via smartphone. All staff-participant interactions will be conducted to mitigate the potential spread of SARS-CoV-2 and other infections. Should COVID-19–related risks increase in Phnom Penh, we will adapt our procedures by conducting all assessments and follow-ups remotely.

Figure 1. Trial schema. CO: carbon monoxide.

Conceptual Framework for AM

Our AM intervention is based on the Phase-Based Model (PBM), a theoretical framework that is specific to smoking cessation [21]. The PBM partitions the cessation process into 4 phases: motivation, preparation (precessation), cessation (quit date to 2 weeks post quit), and maintenance (up to 6 months post quit); our project focuses on the 3 latter phases. The PBM helps to identify challenges and opportunities that smokers face at each phase, explains underlying phase-specific mechanisms, and facilitates the selection of intervention components and measures. Several putative mechanisms are relevant across phases and have been empirically shown to be reliably associated with long-term abstinence. These include withdrawal or craving, motivation to quit, positive or negative affect, coping with stress and urges, self-efficacy, and perceived support [21-25]. As such, the AM intervention specifically targets these mechanisms.

Participants and Eligibility

There are currently 12 ART clinics or hospitals in Phnom Penh that serve approximately 18,800 registered ART patients [26]. We will begin recruitment at sites that serve larger volumes of patients but may add additional clinic sites as needed to reach our accrual goals. Services provided include ART, ART adherence and risk-reduction counseling, nutrition education, and treatments for comorbidities other than tobacco use. Of the ART patients seen at these clinics or hospitals, >90% are of Khmer ethnicity, 49% of them are men, and 93% of them are aged ≥18 years [12,26,27]. The mean levels of education are seventh grade for men and fourth grade for women [28]. The mean duration of ART is 5.7 years. Registered patients at the clinics have periodic prescheduled appointments (about once per month for ART), further facilitating screening and tracking. Study inclusion criteria are: (1) aged ≥18 years; (2) HIV positive; (3) self-report of current combustible cigarette smoking (smoked ≥100 cigarettes in a lifetime and currently smoke ≥1 cigarette per day); (4) willing to set a quit date within 2 weeks of study enrollment; (5) able to provide written informed consent; and (6) able to read Khmer (score ≥4 points on the Rapid Estimate of Adult Literacy in Medicine—Short Form [29]). Exclusion criteria are (1) history of a medical condition that precludes the use of nicotine replacement therapy (NRT), (2) physician or clinician deemed ineligible to participate based on medical or psychiatric condition, or (3) enrolled in another cessation program or use of other cessation medications.

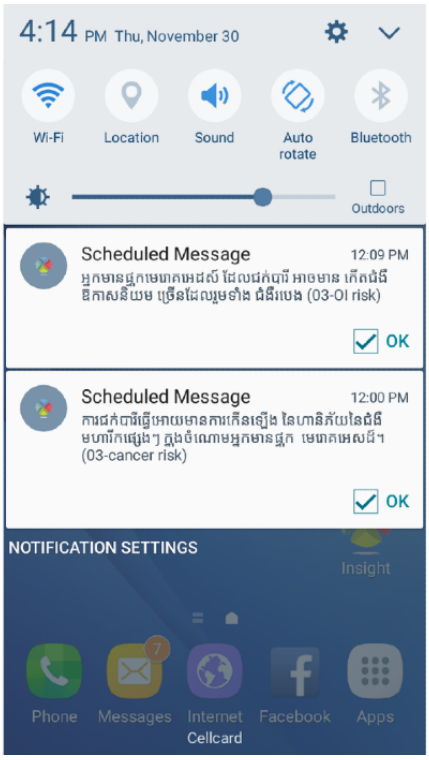
Baseline Assessment and Randomization

All eligible individuals will be invited to participate. Individuals interested in participating in the study will complete the informed consent process. Enrolled participants will be instructed to complete a tablet-delivered baseline computer-assisted self-interview (CASI), which is managed and delivered by an electronic data capture platform [30-32]. The use of an electronic data capture system that contains programmed logic checks and skip patterns enhances both accurate data collection across sites and timely and secure data transmission. Research staff will help participants complete the assessment if needed. The baseline assessment will take approximately 40 minutes to complete. Enrollees will be randomized to SC or AM via stratified randomization, with sex assigned at birth serving as the stratification variable. All participants will subsequently complete a brief training session

XSL•FO
RenderX

on smartphone use and the smartphone app. Smartphones will be loaned to participants who need them. These procedures were followed in our pilot and were found to be feasible in the ART setting.

Intervention Conditions



Standard Care

Participants randomized to SC receive brief advice to quit smoking delivered by trained research staff and self-help materials, including 2 fliers and a 32-page booklet. These self-help materials are from Khmer Quit Now, a national smoking cessation campaign in Cambodia, and are based on the WHO's "A guide for tobacco users to quit [33]." Participants also receive an 8-week supply of NRT in the form of nicotine patches, which is consistent with US Food and Drug Administration recommendations and has been found to double cessation rates in meta-analyses [34,35]. SC participants complete brief weekly smartphone assessments (4 items) about their diet for a 26-week period. The dietary assessments are included to approximately equate the 2 conditions on the number and frequency of assessments.

Automated Messaging

Participants in the AM group receive the SC components (with the exception of the dietary assessments) plus proactive personalized messages for smoking cessation. The AM content was adapted from the team's previous efforts and designed to tap the theoretical mechanisms described in the PBM (see Conceptual Framework for AM) [20,36,37]. That is, treatment content is designed to increase motivation, self-efficacy, use of coping skills, and social support and to reduce nicotine withdrawal symptoms and stress. The AM treatment begins immediately after enrollment and continues for a 26-week period. The Insight platform is used to manage and deliver the AM intervention and all weekly assessments [38]. The AM intervention approach allows for several levels of personalization for each participant, as it leverages the adaptive capabilities of the Insight platform. First, at baseline, participants are asked several questions about past quit attempts, preferred coping skills, and the presence or fear of specific health conditions. Messages tailored to these responses are delivered automatically throughout the treatment period. Second, there are different messages for different cessation phases to ensure that the AM intervention targets critical mechanisms of each phase. Phase identification is based on modified PBM definitions; specifically, preparation (enrollment to quit date), cessation (quit date to week 4 post quit date), and maintenance (weeks 4-26 post quit date) [39]. Third, participants are asked to complete brief (4-8 items) smartphone-delivered assessments during each week of the AM treatment course. Some questions vary depending on the phase (eg, current level of intrinsic motivation for preparation or maintenance phases) and other questions are asked in all phases (eg, smoking status in the past week and self-efficacy level). Intervention content (eg, types and frequencies of messages) is based on responses to these weekly assessments and participant phases. Our EndIT-Pilot results demonstrated that the app (Figure 2) worked very well, including being compatible with the 3 largest Cambodian cellular networks, properly delivering messages and weekly assessments, and reliably collecting and transferring data to our encrypted server [20].

Figure 2. Insight app user interface example.

Measures

Overview

CASI assessments occur in-clinic at baseline and at 3, 6, and 12 months. Participants also complete brief, weekly assessments via smartphone for the first 6 months of the study. Table 1 summarizes study measures at each assessment.

Table 1. Study assessments.

Variable type and measure	Baseline	Weekly[a]	In-clinic follow-up (3, 6, and 12 months)
Descriptors or potential moderators			
Demographics; health literacy [40]	✓		✓[b]
Alcohol and drug use [41,42]	✓		✓

In-Clinic Assessments at Baseline, 3-, 6-, and 12-Month Follow-Ups

Three forms of data are collected at these time points: CASI, expired carbon monoxide (CO) assessed with a CO monitor (CoVita Breath CO) to verify smoking status biochemically, and medical record data. The CASI assessment is administered at baseline (requires approximately 40 minutes to complete) and at each in-clinic follow-up visit (requires approximately 20 minutes to complete). Medical records are used to collect participants' clinical information (with participants' consent), including most recent CD4 counts, viral loads, medication, tuberculosis diagnosis or treatment, and other HIV-related or health conditions. Currently, ART patients at the selected clinics have CD4 lymphocyte count and viral load tests every 3-6 months. However, if participants' medical records do not contain their CD4 lymphocyte count and viral load test results collected within the last 90 days, participants will be asked to provide a blood sample for these tests, following the current testing protocols at the ART clinics. At the final 12-month follow-up, we also will ask AM participants open-ended questions regarding usability, factors or features that helped them quit, barriers to cessation and how to overcome these barriers, and areas for improvement to the AM treatment program. Participants are compensated US $15 (~60,000 Cambodian riels) for each in-clinic visit.

XSL•FO
RenderX

Brief Weekly Smartphone Assessments

Participants are asked to complete brief weekly assessments via smartphones for 6 months, delivered by the Insight app (University of Oklahoma). Participants in AM receive 4-8 questions as described in the Automated Messaging section. Although completion of these brief treatment-driving assessments could be conceptualized as part of the AM treatment, we will attempt to balance the effects of these weekly contacts between the treatment groups. Therefore, participants in SC are also asked to complete a brief 4-item weekly assessment via the app. However, questions for SC participants are about diet. Participants' responses are encrypted and stored on smartphones and synced to our secure server whenever a connection is active. Thus, our team has near real-time access to responses and we are able to track adherence carefully.

Primary Outcome

The primary outcome is smoking status 12 months post enrollment. Abstinence is defined as biochemically confirmed self-reported 7-day point prevalence abstinence with expired CO <6 ppm [54]. Secondary outcomes include 3- and 6-month biochemically confirmed abstinence. We will consider several other common outcomes, such as self-reported abstinence, length of abstinence, and number of quit attempts.

Data Analysis Plan

Aim 1: Conduct an RCT to Evaluate the Efficacy of AM for Cambodian People With HIV Who Smoke

H1: At the 12-Month Follow-Up, Smoking Abstinence Will Be Higher in the AM (vs SC) Group

The primary outcome is biochemically verified 7-day point prevalence abstinence at the 12-month follow-up. The primary abstinence analysis will be intention-to-treat, with patients who do not complete the follow-up assessments considered to be smokers; however, we will explore other approaches for dealing with missing data (see Missing Data and Dropouts below).

To estimate the effect of AM on abstinence rates while accounting for the potential clustering of participants recruited from multiple clinic sites, we will use generalized linear mixed models (GLMM) analyses in which intervention groups (AM vs SC) will be estimated as a fixed effect, while the clinic will be modeled as a random effect nested within the treatment condition. Specifically, log binomial mixed models will be used to estimate the relative risk of quitting in the AM (vs SC) group. Although groups should be similar in baseline characteristics due to randomization, we will explore models that control for any demographic or clinical variables that differ between groups at baseline. We will also use GLMM to examine changes in abstinence rates over time while accounting for relevant baseline covariates. Similar GLMM or methodology, as appropriate for each outcome variable, will be used to examine other smoking-related variables, such as continuous abstinence, prolonged abstinence, and quit attempts. Statistical analyses will be performed using SAS (version 9.4; SAS Institute, Inc).

Missing Data and Dropouts

Although treating participants lost to follow-up as "not abstinent" has been a widely used analytical strategy in smoking cessation studies, some researchers have pointed to potential problems with this "intent to treat" approach, especially when comparing treatment arms with differential dropout rates [55]. Thus, we will conduct sensitivity analyses to test for treatment differences assuming different missing data mechanisms. For example, we will consider a multiple imputation approach based on smoking-related patient characteristics at baseline as well as demographics to account for potential missing-at-random mechanisms. We also will explore pattern-mixture and selection models to account for potential (and likely) missing-not-at-random mechanisms [56]. Similar findings based on these sensitivity analyses will strengthen our study conclusions.

Aim 2: Conduct an Economic Evaluation to Compare the Cost-Effectiveness of the 2 Smoking Cessation Interventions (AM vs SC)

H2: AM Will Be More Cost-Effective Than SC

Information on costs and cost-effectiveness is especially important for decision makers in LMICs, as these countries are particularly resource constrained. Evidence of cost-effectiveness is critical for our partners in government agencies to implement and ultimately to scale up the AM program at ART clinics throughout Cambodia. To facilitate decision-making of stakeholders in the public sector, the cost-effectiveness analysis (CEA) will be conducted from the perspective of the governmental service providers.

Measures of Costs and Collection of Cost Data

For AM and SC, the costs associated with implementation will come from 4 sources: study personnel, capital costs, production of materials, and distribution of materials. If existing resources are used without charge (eg, office space or computers), we will estimate these costs, given that they would be required for implementation. We will not include the cost of the smartphones because once the efficacy of AM is established, implementation will capitalize on the wide availability of mobile devices in the community and will not involve the distribution of these devices.

Measures of Effectiveness

Two commonly used measures of effectiveness, number of quitters and years of life saved (YOLS) [57], will be used to compare with other CEAs of smoking cessation interventions published in the literature. The number of quitters in each arm will be extracted from the 12-month abstinence assessment. We will extrapolate from abstinence to YOLS using a published algorithm that models YOLS per quitter [58]. We will revise the algorithm using more current estimates of age-specific smoking-attributable deaths from tobacco [59], adjusting for reduction in survival for people with HIV. We also will include quality-adjusted life years, which will be calculated based on the five-level EQ-5D (EQ-5D-5L). The EQ-5D-5L is the latest version of the EQ-5D health–related quality of life questionnaire and has been translated into Khmer [53].

Analysis

We will summarize findings from the CEA in terms of the incremental cost-effectiveness ratio, calculated as the difference in mean costs between the AM and SC treatments divided by

XSL•FO
RenderX

the difference in mean effectiveness between the 2. The incremental cost-effectiveness ratio estimates additional resources needed to achieve an increase in 1 unit of effectiveness and is compared with a commonly published threshold value, which is 3 times the gross domestic product per capita for LMICs according to WHO recommendations [60]. We will assess both short-term and long-term economic impacts of the interventions. To obtain the 95% CIs, we will apply nonparametric bootstrapping methods to the person-level data [61]. We will conduct 1-way sensitivity analyses to examine the impact of alternative measures of cost and outcomes or key assumptions. We will then apply the Bayesian approach to construct the cost-effectiveness acceptability curve and conduct probabilistic sensitivity analysis [62,63]. We will conduct the Bayesian analysis using WinBUGS (BUGS Project), with costs modeled as a gamma or lognormal distribution and abstinence as a binomial distribution [64].

Aim 3 (Exploratory): Explore Potential Mediators and Moderators Underlying the Associations Between Treatment Group and Abstinence

We will explore potential mediators and moderators underlying the associations between treatment group and abstinence, as informed by the PBM. We will compare the magnitude of the mediated effects of AM treatment on the outcome of abstinence. Potential mediators include NRT adherence, nicotine withdrawal, motivation, self-efficacy, social support, coping with stress, and positive or negative affect. We also will investigate moderators of the relationship between the treatment group and abstinence to determine the types of participants who may benefit most from AM treatment. We will explore biological sex, HIV stage (as measured by CD4 count and viral load), ART adherence, presence and treatments of common comorbidities (eg, tuberculosis), illicit substance use, and nicotine dependence level as possible moderators. Although we anticipate a small proportion of women in our study, we will make every effort to explore the potential moderating effect of biological sex on the association between treatment arm and abstinence.

Results

Participant recruitment commenced in January 2023, with all data expected to be collected by the end of 2025. Frequent data analyses to monitor participant performance will occur during the recruitment and follow-up periods, with final data analysis to occur after data collection concludes.

Discussion

This project capitalizes on a strong, collaborative partnership among researchers at Moffitt Cancer Center, University of Oklahoma Health Sciences Center, The University of Texas MD Anderson Cancer Center, and 3 national governmental agencies that are comprehensively responsible for HIV/AIDS control and care in Cambodia. The investigative team consists of US and Cambodian experts in tobacco, HIV, economic evaluation, mHealth, and health care administration. If our findings indicate that AM is efficacious and cost-effective, our collaboration with influential Cambodian governmental agencies will facilitate wide-scale implementation to HIV clinics across the country. Thus, the project has the potential to transform HIV care delivery throughout the country and to reduce tobacco-induced morbidity and mortality significantly.

Cigarette smoking among people with HIV represents a global public health problem. This issue is even more striking in Cambodia due to a high smoking prevalence in people with HIV and a lack of cessation treatment efforts for this population. Available data (ie, high smartphone ownership rates in Cambodia and high ART coverage) suggest that our approach, which involves recruiting participants from ART clinics and using smartphones to deliver a cessation intervention, represents an ideal and highly feasible way to address this public health problem. Existing data also suggest that Cambodians are receptive to mHealth interventions, and our promising data from the EndIT-Pilot support the feasibility, acceptability, and preliminary efficacy of our approach [20]. This project will provide valuable long-term efficacy data for the AM intervention in a large population of Cambodian people with HIV. Given AM's potential as a feasible, scalable, highly affordable, and cost-effective standalone intervention, the proposed work has the potential to transform HIV care delivery throughout Cambodia. Sustainability and widespread adoption potential are further enhanced by the direct involvement of Cambodian governmental health agencies. In addition, AM could potentially be integrated with other mHealth services for HIV/AIDS care, such as ART adherence and tuberculosis prevention or treatment. AM also has the potential to be broadly adapted for other populations in Cambodia and other LMICs to address the critical need for tobacco treatment. Finally, very little evidence to support the efficacy and cost-effectiveness of smartphone-based tobacco cessation treatment is available in LMICs [65], and it is largely unknown whether effective cessation interventions from high-income countries are transferable and applicable to LMICs. Therefore, our work will help to answer critical questions including what types of tobacco cessation interventions can be effectively introduced to LMICs and whether this type of mHealth intervention is more cost-effective than alternative treatments in settings with low-cost mobile phone services.

Acknowledgments

This study is supported by a grant from the National Cancer Institute (U01CA261598-01) awarded to DJV and TCB. TCB, MSB, and SK are also supported in part by a National Cancer Institute Cancer Center Support Grant (P30CA225520, awarded to the University of Oklahoma Stephenson Cancer Center) and a grant from the Oklahoma Tobacco Settlement Endowment Trust (R23-02). DJV also received support via a National Cancer Institute Cancer Center Support Grant (P30CA076292, awarded to

XSL•FO

Abstract

Background: Counseling support for HIV self-testing (HIVST) users is essential to ensure support and linkage to care among men who have sex with men (MSM). An HIVST service with web-based real-time instruction, pretest, and posttest counseling provided by trained administrators (HIVST-OIC) was developed by previous projects. Although the HIVST-OIC was highly effective in increasing HIVST uptake and the proportion of HIVST users receiving counseling along with testing, it required intensive resources to implement and sustain. The service capacity of HIVST-OIC cannot meet the increasing demands of HIVST.

Objective: This randomized controlled trial primarily aims to establish whether HIVST-chatbot, an innovative HIVST service with web-based real-time instruction and counseling provided by a fully automated chatbot, would produce effects that are similar to HIVST-OIC in increasing HIVST uptake and the proportion of HIVST users receiving counseling alongside testing among MSM within a 6-month follow-up period.

Methods: A parallel-group, noninferiority randomized controlled trial will be conducted with Chinese-speaking MSM aged ≥18 years with access to live-chat applications. A total of 528 participants will be recruited through multiple sources, including outreach in gay venues, web-based advertisement, and peer referral. After completing the baseline telephone survey, participants will be randomized evenly into the intervention or control groups. Intervention group participants will watch a web-based video promoting HIVST-chatbot and receive a free HIVST kit. The chatbot will contact the participant to implement HIVST and provide standard-of-care, real-time pretest and posttest counseling and instructions on how to use the HIVST kit through WhatsApp. Control group participants will watch a web-based video promoting HIVST-OIC and receive a free HIVST kit in the same manner. Upon appointment, a trained testing administrator will implement HIVST and provide standard-of-care, real-time pretest and posttest counseling and instructions on how to use the HIVST kit through live-chat applications. All participants will complete a telephone follow-up survey 6 months after the baseline. The primary outcomes are HIVST uptake and the proportion of HIVST users receiving counseling support along with testing in the past 6 months, measured at month 6. Secondary outcomes include sexual risk behaviors and uptake of HIV testing other than HIVST during the follow-up period. Intention-to-treat analysis will be used.

Results: Recruitment and enrollment of participants started in April 2023.

XSL•FO
RenderX

Conclusions: This study will generate important research and policy implications regarding chatbot use in HIVST services. If HIVST-chatbot is proven noninferior to HIVST-OIC, it can be easily integrated into existing HIVST services in Hong Kong, given its relatively low resource requirements for implementation and maintenance. HIVST-chatbot can potentially overcome the barriers to using HIVST. Therefore, the coverage of HIV testing, the level of support, and the linkage to care for MSM HIVST users will be increased.

Introduction

Background

Globally, the HIV epidemic among men who have sex with men (MSM) remains out of control [1]. High coverage of HIV testing among the at-risk population is the first and crucial step to achieving the 90-90-90 targets set by the joint United Nations Program on HIV/AIDS [2]. Therefore, international health authorities recommend that MSM take up HIV testing every 6 months [3,4]. However, despite the high risk of HIV infection among MSM in the Hong Kong Special Administrative Region of China (HIV prevalence: 6.54% in 2017), their HIV testing rate remained inadequate (65% in the past year) [5].

HIV self-testing (HIVST) could remove the obstacles of HIV testing faced by MSM, such as inconvenience and perceived stigma from service providers [6]. A systematic review and meta-analysis suggested that HIVST could significantly increase the frequency and coverage of HIV testing among MSM [7]. Therefore, the World Health Organization (WHO) strongly recommends that HIVST should be offered as an additional approach to existing HIV testing services [8]. MSM in Hong Kong mainly relied on facility-based HIV testing and counseling provided by community-based organizations (CBO) and governmental clinics [9]. During the COVID-19 pandemic, facility-based HIV testing services provided by CBOs and governmental clinics were suspended or closed in Hong Kong [10]. However, the availability of HIVST kits in Hong Kong was not affected by the pandemic. An increasing demand for HIVST among MSM was observed in Hong Kong [11].

Pretest and posttest counseling is essential for HIVST, facilitating linkage to care, and behavioral change among HIVST users. In standard-of-care HIV testing and counseling, the pretest counseling involves assessing the individual's risks, providing information about HIV testing, asserting the user's right to refuse the test, and informing the user about the possibility of beneficial disclosure of serostatus status, as well as providing preventive information and material [12]. Posttest counseling entails interpreting testing results, offering psychological support to individuals with positive results, facilitating beneficial disclosure of positive serostatus, and referring individuals for further care, treatment, and support services. Additionally, preventive information and material are provided for those with negative test results [12]. Despite the advantages of HIVST, HIVST users may skip pretest or posttest counseling. There are concerns about incorrect procedures, inadequate support for users, and potential issues related to the linkage of care [13]. A meta-analysis study examined that HIVST reduced linkage to care by 47% comparing facility-based HIV testing due to the lack of counseling support [14].

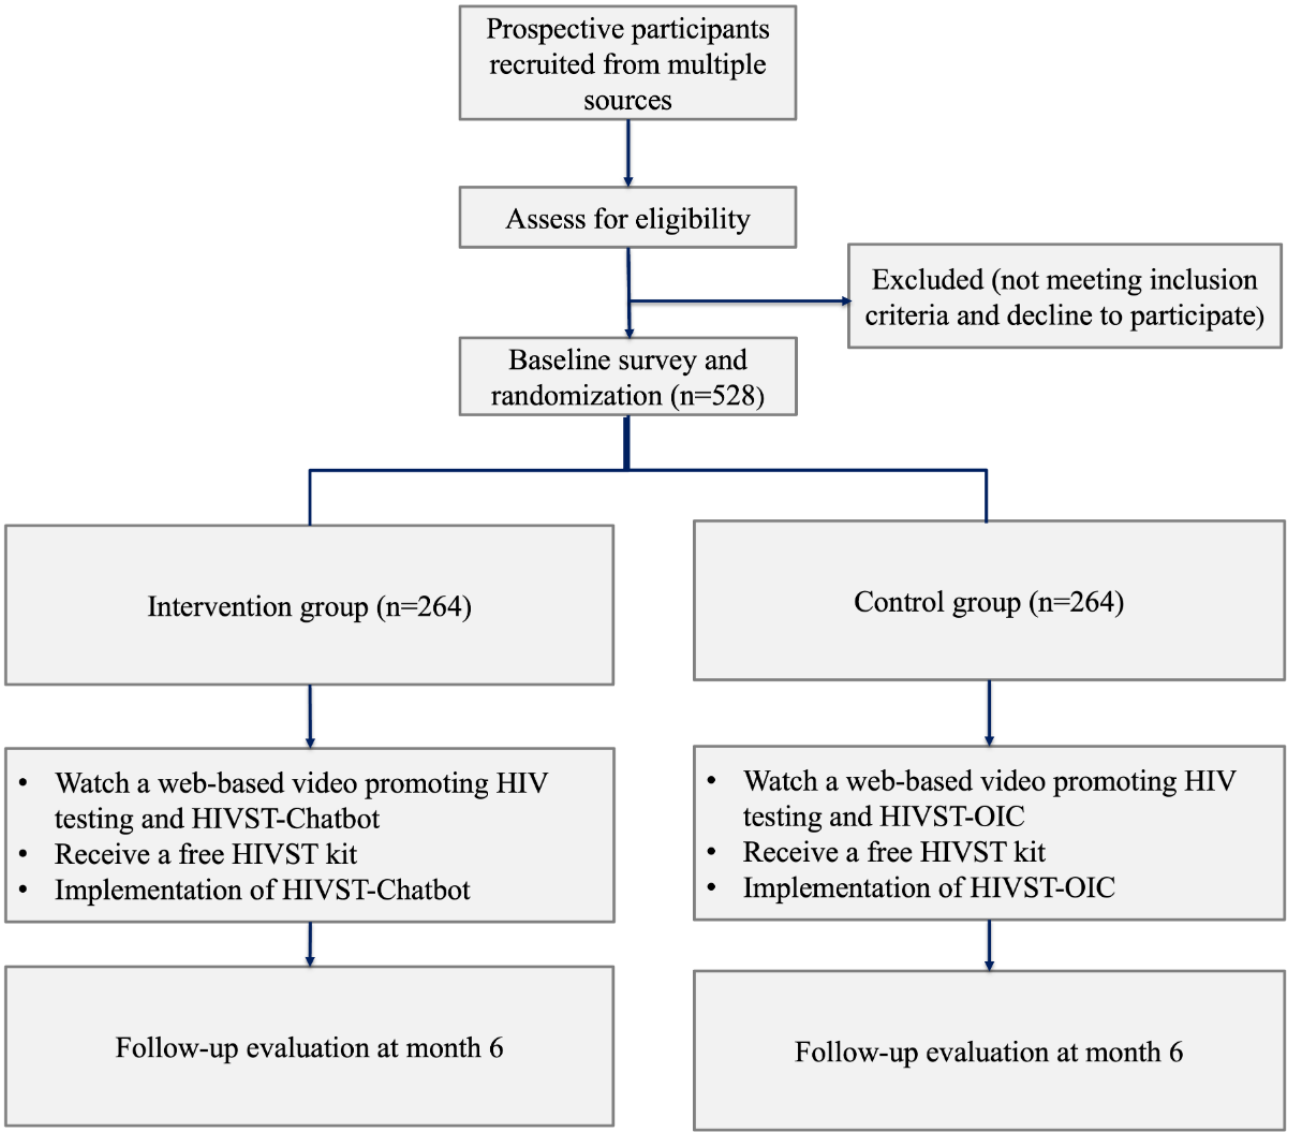
In previous projects, an evidence-based HIVST service was developed for MSM in Hong Kong, which included web-based promotion of HIVST, delivery of free HIVST kits, and provision of web-based, real-time instruction and standard-of-care pretest and posttest counseling through live chat application (HIVST-OIC) [15]. The HIVST-OIC is highly effective in increasing HIVST uptake and the proportion of HIVST users receiving counseling along with testing. A randomized controlled trial showed that after being offered HIVST-OIC, 87.9% of participants took up HIVST, and all HIVST users received counseling. Moreover, the HIVST-OIC was effective in reducing sexual risk behaviors among users. The Centers for Disease Control and Prevention listed HIVST-OIC as an evidence-based intervention and best practice [16]. However, there are issues during the implementation, as HIVST-OIC requires intensive resources. Therefore, it is difficult to increase the service capacity of HIVST-OIC, resulting in a significant gap in implementation.

A chatbot is a computerized program that can automatically select and provide different paths of intervention according to participants' responses. The chatbot can offer personalized, engaging, and on-demand health communication. With the advancement in artificial intelligence, a chatbot can learn from previous human-machine interactions to increase the accuracy and quality of future interactions [17]. A recent systematic review demonstrated the feasibility and effectiveness of chatbot in promoting healthy lifestyles, smoking cessation, treatment adherence, and substance misuse [18]. The chatbot is potentially useful for delivering real-time counseling to support HIVST users. To our knowledge, this approach is novel.

Objectives

This study aims to demonstrate whether an innovative HIVST service with web-based real-time instruction and counseling provided by a fully automated chatbot (HIVST-chatbot) is as efficacious, if not more efficacious, as HIVST-OIC in increasing HIVST uptake and the proportion of HIVST users receiving counseling alongside testing among MSM in Hong Kong.

XSL•FO
RenderX



The primary objective is to establish whether HIVST-chatbot would produce effects similar to HIVST-OIC in increasing HIVST uptake and the proportion of HIVST users receiving counseling alongside testing within a 6-month follow-up period. We hypothesize that HIVST-chatbot would be statistically noninferior to HIVST-OIC in increasing HIVST uptake and the proportion of HIVST users receiving counseling alongside testing. The noninferiority margin is set as 10% (HIVST-chatbot is no worse than 10% less than that of the HIVST-OIC). The secondary objectives are to compare HIVST-chatbot with HIVST-OIC on the prevalence of condomless anal intercourse, multiple male sex partnerships, and uptake of HIV testing other than HIVST at month 6.

Methods

Study Design

A parallel-group, noninferiority randomized controlled trial will be conducted. A total of 528 participants are randomized 1:1 to either the intervention group (n=264) or the control group (n=264). We will promote and implement HIVST-chatbot and HIVST-OIC in the intervention group and control group, respectively. A telephone follow-up evaluation will be conducted 6 months after the baseline survey by blinded interviewers. The study was registered at ClinicalTrials.gov (NCT05796622). A flowchart diagram is shown in Figure 1.

Figure 1. Flowchart diagram for the noninferiority randomized controlled trial. HIVST: HIV self-testing; HIVST-OIC: HIV self-testing service with web-based real-time instruction, pretest and posttest counseling provided by trained administrators.

Participants and Recruitments

Inclusion criteria are (1) Hong Kong–based Chinese-speaking men aged at least 18 years; (2) anal intercourse with at least 1 man within the past 6 months; (3) willingness to provide contact information for follow-up at month 6; (4) having access to WhatsApp; and (5) not having the intention to leave Hong Kong for 1 month consecutively in the next 6 months. Those who have been diagnosed as HIV-positive will be excluded.

Participants will be recruited through multiple sources. Upon obtaining the approval of the owners, trained and experienced fieldworkers will approach prospective MSM participants in gay bars and saunas at different time slots during weekdays and weekends. They will brief prospective participants about the

XSL•FO
RenderX

study details and give them an information sheet. The research team will also conduct web-based outreach by posting study information periodically as discussion topics on gay websites with the highest traffic in Hong Kong. If prospective participants are interested in this study, they can contact the research team through private messaging, WhatsApp, telephone, or email. Recruitment will be supplemented by peer referrals.

Ethics Approval

Participants will be guaranteed anonymity during the study, the right to quit at any time, and that refusal will have no consequences. Verbal instead of written informed consent will be obtained to allow participants to maintain anonymity. Field-workers will sign a form pledging that the participants have been fully informed about the study. Similar methods to obtain informed consent have been commonly used in interventional studies targeting MSM in Hong Kong [15,19-21]. Multiple forms of contact information will be obtained to make an appointment for a baseline telephone survey, which takes about 20 minutes to complete. Another telephone follow-up survey will be conducted 6 months after the completion of the baseline survey. A supermarket coupon (HK $50 [US $6.38]) will be mailed to an address provided by the participants upon completion of each survey. Ethics approval was obtained from the Survey and Behavioral Research Ethics Committee of the Chinese University of Hong Kong (SBRE-22-0488).

Sample Size Planning

The target sample size is 528 (n=264 per group) participants. Our previous study showed that about 90% of MSM used HIVST after exposure to HIVST-OIC promotion and implementation [15]. We conservatively assume that 80% of participants in the control group will take up HIVST during the project period. A noninferiority margin of between-group difference of this primary outcome is set at 10% (no worse than 10% less than that of the control group). A sample size of 198 per group will be sufficient to confer 80% power at the 1-sided significance level of .05 (PASS 11.0). Given the 25% dropout rate during the follow-up period [22], 264 participants per group (528 total) will be needed for the study.

The Baseline Survey and Random Allocation Process

Participants will be randomized evenly to either the intervention or control groups. Computer-generated random allocation codes will be produced and sealed in opaque envelopes by a research staff member without involvement in recruitment or baseline survey. One envelope will be drawn and opened by the fieldworkers. They will then inform the participant which group he is assigned to. Block randomization with a block size of 8 will be used.

The Control Group

Web-Based Promotion of HIVST-OIC

Participants will watch a 7-minute web-based video promoting HIV testing in general and HIVST-OIC developed by previous projects [15,20]. The web-based video is based on the constructs of perceived benefits and perceived barriers of the Health Belief Model [23]. The video has 2 parts. The first part is to promote HIV testing in general. A local MSM introduces the potential benefits of taking up HIV testing in general (eg, help to detect HIV infection earlier, increase trust between sex partners, and reduce psychological burdens) and the WHO recommendation for MSM with risk behaviors to take up HIV testing every 6 months. In the second part, the same MSM narratively discusses the benefits and barriers of HIVST-OIC, demonstrates its procedures, and emphasizes the availability of real-time web-based support.

Signing up for HIVST-OIC

After completing watching the web-based video, participants are asked to select their preferable HIVST kits (oral fluid-based or blood-based), choose a service model (comprehensive version with real-time instruction and pretest and posttest counseling or a simplified version with real-time posttest counseling only), and fill in their contact information and address to receive the HIVST kits. Participants can receive a free HIVST kit through rapid courier service, mail it in a plain envelope, or pick it up at collaborative CBO or the research office. Participants can make an appointment with trained HIV testing administrators to implement HIVST-OIC after receiving the HIVST kit. OraQuick in-home test kit (OraSure Technologies, Inc.; sensitivity: 91.7%; specificity: 99.9%) and BioSure HIV self-test kit (BioSure, Inc.; sensitivity: 99.7%; specificity: 99.9%) will be used in this study.

Implementation of HIVST-OIC

The implementation will follow the same procedures reported in previous studies [15,20]. Through live-chat applications (eg, Line, WhatsApp, and Skype), an experienced HIV testing administrator will guide the participants through self-test procedures on-screen and in real-time. Participants are guaranteed anonymity, and no taping will be made. Users may elect to refrain from displaying their faces on the screen. Standard-of-care pretest and posttest counseling will be provided if the user chooses the comprehensive version. The administrator will also explain how to use the HIVST kits and send the user a demonstration video if needed. The entire procedure of the comprehensive version takes about 60 minutes to complete, which is comparable to the time required for facility-based HIV testing and counseling. If the user prefers a simplified version, pretest counseling will be replaced by web-based pretest information (eg, window period of HIVST and types of sexual behaviors with a high risk of HIV transmission). Users can access the demonstration video and standard-of-care, real-time counseling. The simplified version will take about 20 minutes to complete. Users screened to be positive will be given immediate psychological support and explained about the need to take up free confirmatory HIV antibody testing offered by the Department of Health. If necessary, the collaborative CBO staff member will accompany them to the CBO or Department of Health.

The Intervention Group

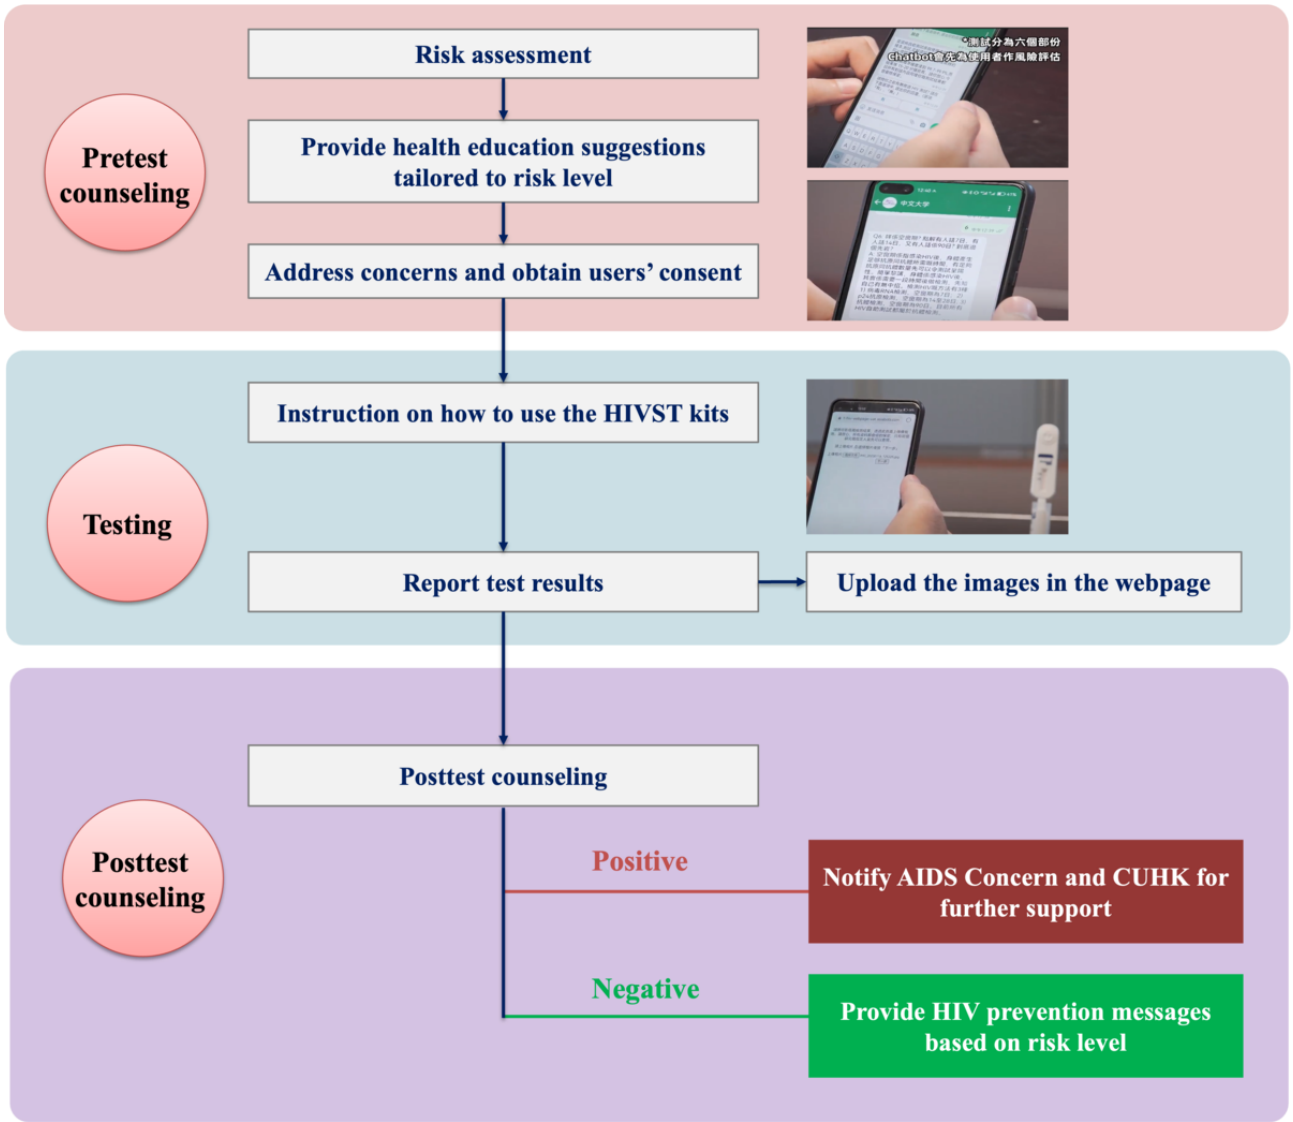
Web-Based Promotion of HIVST-Chatbot

Participants in the intervention group will watch a web-based video promoting HIV testing in general and HIVST-chatbot. The first part of the web-based video promoting HIV testing generally is the same as the one for the control group. In the

XSL•FO
RenderX

second part, the same MSM narratively discusses the advantages of HIVST-chatbot (no need to wait for an appointment, operates 24 hours a day, and artificial intelligence) and the availability of real-time support from chatbot and supporting staff (if users receive positive screening results). The video will also demonstrate the procedures of the HIVST-chatbot. Project staff will help the participants connect to the chatbot. Participants are guaranteed anonymity during the implementation.

Signing up for HIVST-Chatbot



Participants will receive a free HIVST kit in the same manner. The chatbot will contact the participants to confirm receipt of the kits. Participants can get the chatbot to implement HIVST without a previous appointment.

Implementation of HIVST-Chatbot

Pretest Counseling

When users contact the chatbot for implementation, the chatbot will provide standard-of-care pretest and posttest counseling covering key components listed in the Quality Assurance Guideline on HIV Testing and Counseling Services in the format of text messages or videos [24]. The workflow of the HIVST-chatbot is presented in Figure 2.

Figure 2. The workflow of the HIVST-chatbot. CUHK: The Chinese University of Hong Kong; HIVST: HIV self-testing.

1. Risk assessment: The chatbot will ask some standard questions to assess users' HIV risk (eg, injective drug use, use of condoms and alcohol or drug during sexual behaviors, and use of preexposure prophylaxis) and show the response categories. After users complete the questions, the chatbot will interpret their responses and define their risk level. The questions and definition of risk level are identical to those used by facility-based HIV testing and counseling services in Hong Kong (Multimedia Appendix 1).
2. Providing health education advice tailored to risk level: The chatbot will inform users about their risk level and explain the rationale. For high-risk users, the chatbot will prepare them for potential positive results. It will explain the implication of positive screening results and follow-up procedures and emphasize that the staff of collaborative CBO will provide immediate support for users receiving positive testing results from 10 AM to 9 PM (Monday to Friday). These users are advised to perform HIVST within such a time frame. For users without high risk, advice on

XSL•FO
RenderX

maintaining safe sex practices is provided. Users can skip parts (1) and (2). If they prefer to skip these parts, standard pretest information will be sent to them (eg, window period of HIVST or types of sexual behaviors with a high risk of HIV transmission).

3. Addressing concerns and obtaining consent for HIVST: Users can choose one or more references from a list of common concerns identified by literature review and interviews of local MSM and service providers. In case their problems are not included in the list, the participant can raise them verbally or in written text. The chatbot will interpret users' input, extract keywords, retrieve relevant information from the knowledge graph, and prepare a response in the text to the participants. Ultimately, the chatbot will ask whether users are ready to perform HIVST.

Instruction on How to Use the HIVST Kit

The chatbot will play a prerecorded web-based demonstration video showing the procedures of using an oral fluid-based or blood-based HIVST kit. Users can watch the demonstration video repeatedly. They can also skip it if they are familiar with the procedures.

Reporting Testing Results

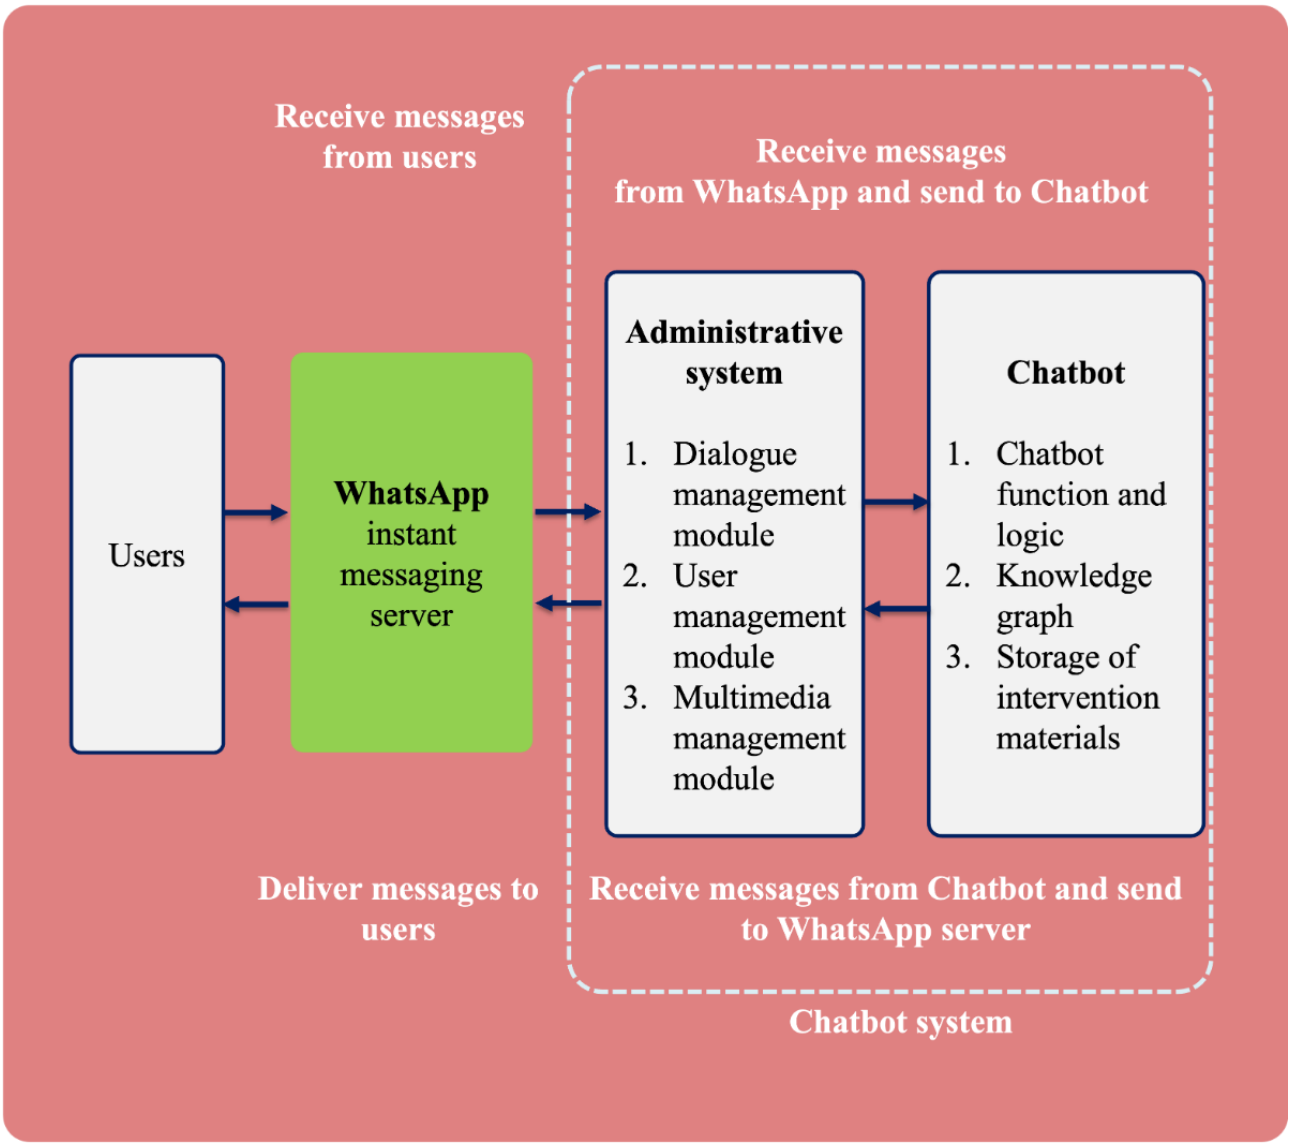
The chatbot will show examples of positive, negative, and invalid results to help the users interpret them. Users will report their results by answering a multiple-choice question.

The chatbot will ask the users to take a photo of their testing result and upload it to a secure web page for verification.

Posttest Counseling

For users receiving negative testing results, the chatbot will explain that the user is not infected unless the test was taken within the window period, remind them about the risk of HIV infection, and provide advice for safe sex practices. Ultimately, the chatbot will emphasize the need for regular HIV testing.

For users receiving positive testing results, the chatbot will automatically notify a designated supporting staff from the collaborative CBO after obtaining users' consent. The supporting staff will follow up with the user as soon as possible. The chatbot will explain (1) this is a preliminary positive test result, (2) further confirmatory testing in the Department of Health is required, (3) a staff member from collaborative CBO is already notified and will follow up with them as soon as possible, and (4) emphasize that HIV treatment is very effective. Hotline numbers for 24-hour emotional support and the collaborative CBO will also be provided. Our project staff may accompany them to visit the collaborative CBO or the Department of Health if desired.



Development of the HIVST-Chatbot

The Architecture of the Chatbot System

We adopted the WhatsApp platform to implement the chatbot. The chatbot is integrated with WhatsApp through its public Web API services. Participants' messages are sent to WhatsApp's instant messaging server and a separately constructed chatbot system (an administrative system and the chatbot). The chatbot system processes and sends a message back to the WhatsApp instant messaging server. Finally, the users can view the message sent by the chatbot. The entire process spans less than a second without a sluggish feel for users. The architecture of the chatbot system is presented in Figure 3.

XSL•FO
RenderX

Figure 3. Architecture of the chatbot system.

The chatbot system contains 3 modules:

1. Dialogue management module: The dialogue system records all conversations between users and the chatbot. The system can extract context information, such as basic statistics of users' activities and previous interactions between a user and the chatbot. The natural language processing module analyzes the text content of each message. Then, the message is forwarded to trigger specific actions based on preprogrammed rules. For example, when a user sends a message containing a specific keyword, the chatbot immediately responds with information that corresponds to that keyword. In addition, the module initiates new conversations based on the preprogrammed intervention plan.
2. User management module: This module records detailed information about user conversations. Administrators can link users' WhatsApp numbers with the chatbot and review the progress of the intervention delivery (eg, number of completed sessions or disconnection between users and the chatbot).
3. Multimedia management module: The chatbot system supports image uploading, sending, and updating through this module to allow image and video exchange.

Preparation of Knowledge Graph

To build a system that addresses various personal and relevant concerns related to HIV, HIV testing, and HIVST, we created a knowledge graph linking questions and responses. We conducted in-depth interviews with 10 local MSM to crowdsource concerns related to HIV, HIV testing, and HIVST. We also interviewed experienced HIV testing administrators, CBO workers, and experts in HIV prevention to obtain responses addressing these concerns. The knowledge graph will be used to set rules for the chatbot and train it to get familiar with and identify commonly encountered concerns or misinformation and how to address them through machine learning. The knowledge graph will evolve with more previous interactions during the intervention period.

Conversation Mechanism

1. The chatbot uses a mixture of techniques so that a dialogue is not merely rule-based, but it can also learn from a big

XSL•FO
RenderX

pool of previous conversation patterns through machine learning. The chatbot resolves the recent conversation to create a plan for a suitable response. Relevant information is retrieved and used for the preparation of a reply. A persuasion template is selected in accordance with the current stance of the conversation and the perceived user characteristics by the chatbot. The pool of previous conversation patterns will grow bigger after extended usage, and the variety of responses will increase accordingly.

2. In case there is no relevant response to participants' input, the chatbot will respond by saying, "I am not confident about an answer to your question." The chatbot will suggest a new conversation topic after 3 off-topic inputs from the user.
3. In case the participants want to know more about 1 topic. The chatbot will respond differently within the knowledge graph to the same topic. Upon request, the chatbot can also repeat the response.
4. In case the conversation between the chatbot and the participants is interrupted. The chatbot will cancel participants' incomplete input and invite them to input again.
5. The chatbot will document previous conversations with the users and avoid responding repetitively to users' questions.

Pilot Testing and Refinement

We purposely recruited 30 MSM who were HIV-negative or unknown serostatus to use the HIVST-chatbot. With informed consent, the research team retrieved and reviewed users' interactions with the chatbot. Feedback was also collected from these users. The pilot study showed that the chatbot was running smoothly. Users were satisfied with the performance and interface of the chatbot.

Measurements

Primary Outcomes

The primary outcomes of this study are self-reported uptake of any HIVST at month 6 and the proportion of HIVST users self-reported having received counseling along with HIVST during the follow-up period. The chatbot will accurately document the number of HIVST-chatbot use, while HIV testing administrators will record the number of HIVST-OIC performed.

Secondary Outcomes

The secondary outcomes of this study are as follows:

1. Condomless anal intercourse with men and multiple male sex partnerships in the past 6 months measured at month 6.
2. Uptake of other types of HIV testing in the past 6 months measured at month 6. They are (1) HIV testing at CBOs in Hong Kong, (2) HIV testing at public hospitals or clinics in Hong Kong, (3) HIV testing at private hospitals or clinics in Hong Kong, (4) HIV testing at other organizations in Hong Kong, and (5) HIV testing in places other than Hong Kong.

Baseline Background Characteristics

Information on social demographics (eg, age, current relationship status, education level, and income), sexual orientation, history of HIV testing, COVID-19, and other sexually transmitted infections will be collected. In addition, participants are asked to report the use of preexposure prophylaxis and different HIV or sexually transmitted infection prevention services (receiving free condoms, peer education and pamphlets, and attending workshops).

Process Evaluation

At month 6, participants will be asked about their level of satisfaction with the promotion and implementation of HIVST-chatbot and HIVST-OIC.

Statistical Analysis

Intention-to-treat analysis will be performed. Multiple imputations will handle missing values at month 6. Markov Chain Monte Carlo method will be used to impute data with an arbitrary pattern of missing values, while monotone methods will be used to impute data having a monotone pattern of missing values. Predictors included baseline background characteristics and baseline values of these outcomes. The relative risk reduction, absolute risk reduction, and number needed to treat, and their 95% CIs will be calculated using Excel. The chi-square tests will inspect between-group balances of potential confounders at baseline. Adjustments will be made if any potential confounders show $P<.05$ in the comparisons. SPSS 26.0 for Windows (SPSS Inc) will be used for all analyses; statistical significance is set at the $P<.05$ level (1-sided).

Results

Study recruitment started in April 2023, and data collection is expected to be concluded in January 2024. No results are available as of manuscript preparation.

Discussion

The COVID-19 pandemic and its control measures (eg, lockdown, closure of business, and physical distancing) have direct and negative impacts on HIV testing service use among MSM, especially for facility-based HIV testing services [25-28]. Across countries, health authorities have been actively promoting HIVST to mitigate such negative impacts [29-31]. As a result, there was an increase in HIVST use among MSM [11]. Such growth may continue even in the postpandemic era. Therefore, ensuring sufficient support and linkage to care for the increasing number of MSM, HIVST users becomes more important. Although evidence-based HIVST services existed (eg, HIVST-OIC), most required intensive resources to implement and maintain. Such constraints limited their public health impacts. To our knowledge, this is the first attempt to apply an artificial intelligence chatbot to deliver real-time instruction and counseling support to HIVST users. This randomized controlled trial will compare the efficacy of the HIVST-chatbot with an evidence-based HIVST service, the HIVST-OIC, in increasing HIVST uptake and the proportion of HIVST users receiving counseling along with the testing. If HIVST-chatbot is proven noninferior to HIVST-OIC in improving HIVST uptake and coverage of counseling among users, it may address the existing HIVST service gaps. Since HIVST-chatbot is fully-automated and requires fewer resources

XSL•FO
RenderX

to implement and maintain, it can be promoted and implemented by governmental organizations and CBOs in Hong Kong as an alternative approach to HIVST-OIC. The HIVST-chatbot has the potential to overcome the barriers to using HIVST (eg, concerns about lack of support and missing linkage to care), improve overall HIV testing coverage, and reduce the HIV burden among MSM.

Although the trial will yield essential insights for HIVST program planning and policy making, it has some limitations. First, the use of HIV testing other than HIVST-chatbot or HIVST-OIC is self-reported. Such responses may be over-reported due to social desirability. Second, similar to most interventional studies [15,19-21], participants will be recruited through convenient sampling. Cautions should be taken when generalizing the findings to MSM in Hong Kong. Third, collecting characteristics of MSM who refuse to participate in the study is difficult. Selection bias may exist.

In conclusion, this study will generate important research and policy implications regarding using chatbot in HIVST services. If HIVST-chatbot is proven noninferior to HIVST-OIC, it can be easily integrated into existing HIVST services in Hong Kong, given its relatively low resource requirement for implementation and maintenance. HIVST-chatbot holds the potential to overcome the barriers to using HIVST. Therefore, the coverage of HIV testing, the level of support, and the linkage to care for MSM HIVST users will be increased.

Acknowledgments

This study was supported by AIDS Trust Fund (MSS349R; Multimedia Appendices 2 and 3).

Authors' Contributions

SC, QZ, CC, AC, PKHM, and ZW initiated the research plan and designed this protocol. SC, FY, YF, and ZW designed the measurements. SC, QZ, JC, FY, AC, and ZW developed the interventions. QZ, AC, PKHM, and ZW acquired the funding for this study. All authors edited the protocol and agreed with the final version of the manuscript.

Conflicts of Interest

None declared.

Protocol

A Trauma-Informed HIV Intervention (LinkPositively) to Improve HIV Care Among Black Women Affected by Interpersonal Violence: Protocol for a Pilot Randomized Controlled Trial

Abstract

Background: Black women bear a disproportionate burden of HIV, accounting for nearly 60% of new diagnoses among US women. Black women living with HIV often experience mutually reinforcing epidemics, known as syndemics, including interpersonal violence and substance use. Syndemics are associated with decreased HIV care engagement and treatment adherence and worsening HIV outcomes. Few HIV services and resources are tailored to be culturally and gender-responsive and trauma informed for Black women living with HIV. Technology-based, psychoeducational, and peer navigation programs offer promising pathways to tailored HIV support and improved HIV care outcomes. Therefore, the web-based, trauma-informed intervention LinkPositively was developed in collaboration with Black women living with HIV to promote uptake of HIV care and ancillary support services.

Objective: This study primarily determines the feasibility and acceptability of the LinkPositively intervention among Black women living with HIV affected by interpersonal violence. The secondary aim is to examine the preliminary impact of the LinkPositively intervention on retention in HIV care, antiretroviral therapy adherence, and viral suppression while evaluating the role of mechanism of change variables (eg, social support) in the associations.

Methods: The LinkPositively trial is a pilot randomized controlled trial conducted in California, United States, among 80 adult Black women living with HIV who have experienced interpersonal violence. Core components of LinkPositively include one-on-one peer navigation with phone and SMS text message check-ins; 5 weekly one-on-one video sessions to build coping and care navigation skills; and a mobile app that contains a peer support social networking platform, an educational database with healthy living and self-care tips, a GPS-enabled HIV and ancillary care resource locator, and a medication self-monitoring and reminder system. Participants are randomly assigned to the intervention (n=40) or control (Ryan White standard of care; n=40) arm, with follow-up at 3 and 6 months. At each assessment, participants complete an interviewer-administered survey and submit hair samples for the assessment of HIV medication adherence. All research staff and investigators adhere to ethical principles and guidelines for conducting research activities. Data will be analyzed using generalized estimating equations.

Results: Final development and testing of the LinkPositively app were completed in July 2021. As of May 2023, we have screened 97 women for eligibility. Of the 97 women screened, 27 (28%) were eligible and have been enrolled in the study. The dissemination of preliminary results will occur in 2024.

XSL•FO
RenderX

Conclusions: This trial will advance HIV prevention science by harnessing technology to promote engagement in HIV care while improving social support through peers and social networking—all while being trauma informed for Black women living with HIV with experiences of interpersonal violence. If shown to be feasible and acceptable, LinkPositively has the potential to improve HIV care outcomes among Black women, a marginalized key population.

Introduction

Background

The United States has seen a reduction in HIV infections in recent years, yet Black women continue to bear a disproportionate burden of diagnoses [1-3]. In 2019, Black women comprised 13% of the US female population yet accounted for nearly 60% of new HIV diagnoses; by comparison, White women represented 62% of the female population but 22% of HIV diagnoses [4]. HIV incidence among Black women is 11 times that among White women (18.9 vs 1.8) [4]. Women living with HIV, in particular Black women, often experience HIV with mutually reinforcing epidemics known as syndemics. The substance use, violence, and HIV/AIDS syndemic is the overlapping and synergistic intersection of these conditions [5]; in addition, mental health coincides with the substance use, violence, and HIV/AIDS syndemic [6,7]. These mutually reinforcing conditions of violence, substance use, and adverse mental health among people living with HIV [6,7] are more prevalent among women than men [5,8-13]. Among women living with HIV, approximately 55% experience lifetime intimate partner violence (IPV) [14,15], 27% experience past-year IPV [16], and 67% experience lifetime interpersonal violence more broadly [17]. Black women generally face 35% higher lifetime IPV victimization than White women [18]. Women experiencing violence are more likely to experience adverse mental health [10,19], whereas women living with HIV have worse mental health outcomes than men living with HIV and women without HIV. Furthermore, women living with HIV experiencing IPV have worse mental health outcomes than those who do not experience IPV [19]. Black women living with HIV have 3-fold higher rates of prevalence of posttraumatic stress disorder (PTSD) and major depressive disorder compared with Black women without HIV regardless of substance use category [20]. Compared with women without HIV, women living with HIV have reported higher use of cigarettes, nonprescribed cannabis, cocaine, speed, and heroin in North American settings [21], and women living with HIV who have recently experienced violence have higher odds of using substances [22]. Together, these findings show that women living with HIV, especially Black women, are at a substantially increased risk of a variety of mental and physical health problems.

In addition to syndemic factors among women living with HIV, Black women continue to face worse HIV care outcomes than other people living with HIV, including non-Black women; these outcomes are exacerbated by syndemic experiences. Once diagnosed, Black women are significantly less likely than White women to be linked to care within 90 days of diagnosis [23], and once in care, only 56% of Black women are retained [23]. As a result, Black women are significantly less likely to be virally suppressed than White women [24,25]. Violence, substance use, and adverse mental health are associated with low or suboptimal antiretroviral therapy (ART) adherence, reduced viral suppression [10,14,15,17,22,26-29], and low retention in HIV care [30] among women living with HIV. Lifetime experiences of violence in particular are associated with an 8 times lower likelihood of being virally suppressed among women living with HIV compared with women not exposed to violence [31]. In studies that account for syndemic conditions among women living with HIV, more co-occurring conditions (IPV, substance abuse, and adverse mental health) was associated with worse ART adherence [32] and, among racial and ethnic minoritized women, reduced viral suppression [5].

Black women living with HIV lack services that are responsive to their syndemic needs, which likely contributes to suboptimal HIV outcomes. Syndemic experiences and the lack of trauma-informed care services may act as barriers to HIV care, complicating both the receipt of services logistically and the acceptability of services. People living with HIV with adverse mental health (PTSD and depression) have lower odds of retention in HIV care [30]. Furthermore, Black women living with HIV face sociostructural barriers to care (HIV stigma, medical mistrust, and unmet housing and transportation needs) at higher rates than HIV-negative and male HIV-positive individuals [33-35], affecting retention in care and ART adherence; racial and ethnic minoritized women are the most affected [34,36-42]. HIV stigma is the most noted barrier to care and ART adherence among women living with HIV [37,43-47]. Conversely, formal and informal social support networks may mitigate the effects of syndemic and sociostructural barriers on HIV care outcomes. Increased social support is associated with fewer depressive symptoms; less HIV stigma [48-50]; and improved HIV-related health symptoms [51], ART adherence [41,52-54], perceived ability to engage in HIV care [42], and HIV self-management [55].

Trauma-informed services offer a pathway to more acceptable care for syndemic-affected women living with HIV, particularly in the setting of peer navigation. Trauma-informed care is a strength-based approach that aims to meet the unique needs of trauma survivors. Trauma-informed care increases the

XSL•FO
RenderX

acceptability and comfort of services while minimizing barriers to care. Although trauma-informed care has been studied and practiced in the context of addiction treatment, mental health, and health care, it has been less extensively practiced in terms of HIV prevention and treatment [56-61]. Peer navigators—medication-adherent role models with shared lived experiences with their clients—provide social support and modeling of engagement-supportive behaviors to their clients [62]. Peer navigators help build self-efficacy in patient-provider communication and decrease medical mistrust, offsetting the impact of syndemic factors affecting HIV care (eg, violence, substance use, and adverse mental health) [62]. Peer navigation for improving linkage to and retention in care among women living with HIV is feasible, acceptable, and efficacious in the United States and other countries [63-68]. Peer navigation can improve ART adherence [69,70] and viral suppression [63,71], although some studies have found no effect [72], perhaps because of the small samples or the lack of informal social support. The addition of informal social support may help reduce social isolation, build community, and share strategies for addressing barriers to ART adherence. Among women living with HIV, social support group participation with HIV-positive peers has demonstrated benefits related to mental health, relationships, and sociostructural barriers [73-76].

With increased internet access and smartphone ownership, technology-based interventions have become an increasingly feasible option for improving health [77] and demonstrate significant potential for trauma-informed interventions using peer navigation. Technology-based interventions related to HIV are primarily mobile app– or SMS text messaging–based and have been developed for women living with HIV who are outside the United States [78-81], older in the United States [82], and pregnant [83-85]; people living with HIV regardless of gender [86]; transgender women living with HIV [87,88]; and HIV prevention [89,90]. The results include decreased viral load and improved engagement in care and ART adherence [91-93]. Women report that technology-based interventions feel more confidential, lead to more efficient and perceived-safer care, and feel more empowering to women with a history of interpersonal violence than nontechnology interventions [94-98]. Overall, technology-based interventions among women living with HIV in the United States have been limited and, to our knowledge, nonexistent for Black women living with HIV or women who have experienced interpersonal violence, although most US women (91%) use the internet, including 78% of Black women [99]. Few of those that do exist have not considered the syndemic conditions and unique barriers faced by women living with HIV [100,101] despite interest in, advantages, and acceptability of technology-based interventions, particularly for increasing social support [102-105].

Given the unique needs and significant disparities faced by Black women living with HIV in the United States and the lack of services and interventions that are syndemically responsive and culturally tailored to Black women, we undertook the development of a trauma-informed HIV intervention for Black women living with HIV that uses a culturally and gender-tailored mobile app, LinkPositively, combined with one-on-one peer navigation.

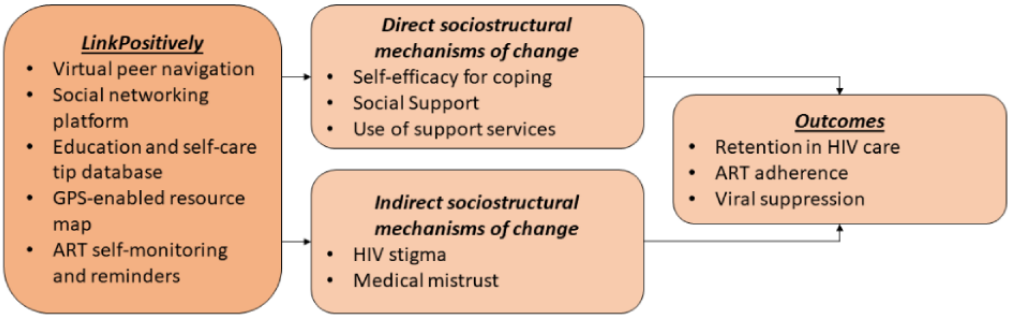
Theoretical Foundations

LinkPositively is grounded in the theory of triadic influences and syndemic theory and informed by trauma-informed care as a derivative of trauma theory. The theory of triadic influence is a multilevel social cognitive theory that understands 3 streams of influence—individual, social, and structural—that act in combination to affect health behaviors [106]. This study considers individual-level influences, such as racial or ethnic minority identity and experiences of interpersonal violence, and indirect sociostructural influences, such as medical mistrust, HIV-related stigma, and limited access to resources. In consonance, LinkPositively was created under the framework of syndemic theory, which understands HIV as co-occurring and mutually exacerbating with other comorbidities in disadvantaged populations [107]. These synergistic conditions are influenced by the social, economic, environmental, and political settings in which a population exists [107]. Within the population of interest (Black women living with HIV who have experienced interpersonal violence), these other syndemic conditions or experiences include violence, mental health disorders, and substance use, which, in combination, negatively and synergistically affect HIV care outcomes. Finally, trauma-informed care is a service delivery model that aims to be responsive to the impacts of trauma by emphasizing physical, psychological, and emotional safety; empowerment; and healing for survivors of trauma and their care providers [108]. According to trauma theory, unprocessed trauma is stored as physiological reactions to circumstances that recall the initial trauma [109]; health care interactions in particular may elicit trauma responses [110]. Evidence from mental health, substance use, and social service settings finds that adopting trauma-informed care practices improves patient outcomes and enhances patient satisfaction and engagement with clinic staff [111]. Simultaneously, there have been calls to integrate trauma-informed care practices within HIV care settings [112,113].

Objectives

The primary aim of this study is to determine the feasibility and acceptability of the LinkPositively intervention and mobile app among Black women living with HIV affected by interpersonal violence. The secondary aim is to examine the preliminary impact of the LinkPositively intervention on retention in HIV care, ART adherence, and viral suppression while evaluating the role of mechanism of change variables (ie, social support, activation of social support networks, self-efficacy, and the use of ancillary support services) in the associations. Collectively, both aims serve as preparation for a large-scale R01 randomized controlled trial.

Methods



Study Design

The LinkPositively trial is a pilot randomized controlled trial of 80 Black women living with HIV who have experienced lifetime interpersonal violence, with 6 months of follow-up after enrollment. Women are randomized to the LinkPositively intervention (intervention arm; n=40) or Ryan White standard of care (control arm; n=40) groups. Survey and biological

XSL•FO
RenderX

assessments occur at baseline and 3 and 6 months after randomization to evaluate improvement in primary and secondary outcomes. Feasibility and acceptability measures are assessed using a combination of self-reported surveys, intervention paradata, and study process measures (eg, retention rates). The primary outcomes are retention in HIV care, ART adherence, and viral suppression. Secondary outcomes are hypothesized direct and indirect mechanisms of change, including self-efficacy for coping, social support, the use of ancillary support services, HIV stigma, and medical mistrust (Figure 1).

Figure 1. LinkPositively conceptual model. ART: antiretroviral therapy.

Study Population

The inclusion criteria for LinkPositively are self-reported (1) self-identification as a woman; (2) Black or African American racial and ethnic background; (3) age of ≥18 years; (4) HIV-positive status; (5) current residence in the San Diego, Los Angeles, or Alameda counties in California, United States; (6) linked to HIV care but having fallen out of care; (7) lifetime experience of physical (ie, hitting, slapping, kicking, assault with a weapon, or threats thereof), sexual (ie, attempted, forced, or threatened sexual activities, including unwanted touching), or psychological (ie, yelling or insulting, controlling behavior, and fear of violence) abuse by a current or former partner or nonpartner (eg, relative, friend, or stranger); (8) ownership of a smartphone with internet-browsing capabilities; and (9) ability to speak English. Being out of care is defined as not having had a blood test while taking HIV medication for at least 3 months or within the past year, not having had a medical appointment with an HIV care provider, not having had an ART prescription filled, or not having had blood tests to monitor HIV (CD4 counts and HIV viral load). The exclusion criteria are (1) unwillingness to participate in the study and (2) cognitive impairment that would limit participation in study procedures. The study staff assess cognitive impairment through direct observation. Specifically, if during the consent process a participant appears to be experiencing paranoia or auditory hallucinations, has sporadic outbursts, or is not capable of comprehending the interview or materials, the participant is excluded from the trial.

Study Procedures

Recruitment and Screening

The recruitment methods for LinkPositively include 3 main approaches. First, we partnered with the San Diego Center for AIDS Research Health Equity Sociobehavioral Science Core to distribute flyers to community-based agencies. We also used the recruitment and retention subcommittee of the San Diego Center for AIDS Research Health Equity Sociobehavioral Science Core Community Advisory Board to promote and advertise the study. We partnered with local health care clinics and HIV service organizations within the community to passively recruit through flyer distribution. Los Angeles–based recruitment used the Los Angeles County Service Planning Area provider meetings; Commission on HIV caucus and work group meetings; and local community advisory board meetings, support groups, and education forums. Alameda County–based recruitment used the Collaborative Community Planning Council of the Oakland Transitional Grant Area and local HIV service agencies to disseminate study flyers. Second, we used social media platforms to maximize outreach and recruitment in the 3 California counties. Social media platforms included Facebook, Instagram, and Twitter. Paid advertisements, promotions, and web banner advertisements will be used to target populations based on demographic characteristics, including gender, age, race, ethnicity, and location of residence. Finally, we distributed advertisements, newspaper advertisements, and flyers at bus stops, libraries, transitional housing facilities, social service agencies, and businesses located in San Diego, Los Angeles, and Alameda County communities with at least 10% Black residents. Recruitment and screening for the study are ongoing to facilitate the development of a study cohort consisting of approximately 80 eligible women.

Enrollment and Randomization

Women interested in participating in LinkPositively provide consent to be screened and complete a screening survey that includes questions regarding age, gender, self-reported HIV status, HIV care status, and violence exposure history. The screening survey is self-administered or staff-administered depending on the preference of the potential participant and will be housed in REDCap (Research Electronic Data Capture; Vanderbilt University). Eligible participants are invited to enroll in LinkPositively and scheduled for an in-person or on the web (via Zoom [Zoom Video Communications]) baseline enrollment visit. At the baseline study visit, the participant provides documented informed consent and completes a 45-minute interviewer-administered, computer-assisted personal interview hosted on REDCap on topics including sociodemographic characteristics, HIV care, treatment history, substance use, mental health status, interpersonal violence, care interactions, medical mistrust, coping self-efficacy, social support, stigma, COVID-19, and technology use (Table 1). Participants also provide a hair sample in person or via mail to assess for

XSL•FO
RenderX

tenofovir and emtricitabine concentrations as an objective measure of ART adherence. The hair sample collection kits include 1 piece of aluminum foil, 2 white adhesive labels, 2 alcohol swabs, 1 small freshness packet, and scissors. Hair sample collection involves the following steps: (1) cleaning the blades of a pair of scissors with an alcohol pad, (2) lifting up the top layer of hair from the occipital region of the scalp to isolate a small thatch of hair (approximately 100 fibers of hair) from underneath the top layer, (3) cutting the small hair sample as close to the scalp as possible, (4) keeping fingers on the part of the hair that was furthest away from the scalp and placing the hair sample down on an unfolded piece of tin foil, (5) placing a thin label over the end of the hair sample that was furthest away from the scalp, (6) refolding the foil over to completely enclose the hair and placing a study identification number label on the folded piece of foil, and (7) placing the folded piece of foil inside the plastic bag and sealing the bag. All hair samples are securely shipped to the University of California, San Francisco Hair Analytical Laboratory, where liquid chromatography or tandem mass spectrometry will be used to assess antiretroviral concentrations in hair samples over the past 3 months, requiring 3 cm of hair. Participants are compensated with US $25 upon the completion of the survey and US $25 upon the provision of the hair sample.

Following the completion of the baseline survey, participants are randomized at a 1:1 ratio into the LinkPositively intervention group or the control group, stratified by perpetrator of violent experience (intimate partner vs nonintimate partner). Randomization is conducted using a randomly permuted block randomization design by a study staff member with no participant contact. Participants are informed of their group assignment, and participants assigned to the LinkPositively intervention arm are shown how to download the LinkPositively app and given a demonstration of LinkPositively features. Follow-up assessments occur at the 3- and 6-month follow-up visits, requiring a survey and hair sample collection (Figure 2).

Table 1. Exposure and outcome measures.

Measure category	Measures
Evaluation outcomes	
Feasibility	Number of participants recruited, number of participants enrolled, number of participants retained, and number of intervention group sessions completed
Acceptability	CSQ-8[a] and System Usability Scale [114]
Individual-level factors (survey)	
Sociodemographic characteristics	Age, education, employment, living situation, income, relationship status, household composition, medical insurance status, and food insecurity (6 items) [115]
HIV care and treatment history	Year first diagnosed with HIV, year they first started medical care for HIV, usual place for HIV treatment (yes or no), frequency of seeing an HIV care provider, period of intermittent care (yes or no), taking antiretroviral medication (yes or no), HIV medication adherence [116] (3 items), and barriers to HIV treatment since diagnosis [117] (14 items)
Interpersonal violence	Intimate partner violence (12 items), revised Conflict Tactics Scale (ever and since last visit) [118]; non–intimate partner violence (physical, sexual, or psychological abuse by a relative, friend, or stranger [ever and since last visit]); ACEs[b] (10 items); mental health coercion (3 items); substance use coercion (3 items); and DA-5[c] (5 items)
Co-occurring syndemic conditions (survey)	
Mental health	Depression (10 items), PHQ-9[d] [119]; PTSD[e] (9 items), NSESS[f]-PTSD [120]; anxiety (7 items), GAD-7[g] [121]; stressful life experiences (20 items), PCL-5[h] [122], and traumatic life events (17 items), LEC-5[i] [123]; resilience (10 items), PLHIV[j] Resilience Scale [124]; and suicidality (4 items), SBQ-R[k] [125]
Substance use	Alcohol use (10 items), AUDIT-10[l] [126], and drug use, NIDA[m]-modified ASSIST[n] 2.0 [127]
Direct sociostructural mechanisms of change measures (survey)	
Coping self-efficacy	Self-Efficacy Scale (CSE[o], 26 items) [128]
Social support	MMOS-SS[p] (20 items) [129]
Ancillary support use	Use and met need of ancillary support services (eg, transportation, housing, mental health care, domestic violence services, and substance use treatment)
Indirect sociostructural mechanisms of change measures (survey)	
HIV stigma	Chronic Illness Anticipated Stigma Scale (30 items) [130]
Medical mistrust	GBMMS[q] (12 items) [131]
COVID-19–specific PTSD	5 items, adapted PC-PTSD-5[r] [132]
Outcome measures	
Retention in HIV care	Having ≥2 laboratory tests (CD4[s] or VL[t]) dated at least 90 days apart [133]
ART[u] adherence	Self-reported 3-item measure, dichotomized (>90% adherent vs <90% adherent) [116]
ART adherence (objective measure)	Tenofovir and emtricitabine concentrations in hair sample [134]
Viral suppression	Undetectable or <200 copies of viral DNA per mL vs detectable or ≥200 copies of viral DNA per mL [135]

Intervention Group

LinkPositively is a trauma-informed peer navigation intervention using a mobile-optimized web application that aims to improve retention in HIV care and ART adherence and promote reaching or maintaining viral suppression among Black women living with HIV who have experienced interpersonal violence. The development of the LinkPositively app with Black women living with HIV has been previously described [136]. In brief, the app comprises a social networking platform to facilitate connections among Black women living with HIV and information sharing, with the option to do so anonymously; an educational and self-care tip database; a self-monitoring and reminder system to promote ART adherence and other health behaviors; and a GPS-enabled resource locator for local and national HIV and ancillary care services (Table 2). Women assigned to the LinkPositively intervention group have access to all components of the LinkPositively app and one-on-one peer navigation. At the baseline visit, the women are introduced to the LinkPositively app. The study staff conduct onboarding, which involves training participants on how to download the app onto their smartphone, explaining the 5 components, and using each component, with an emphasis on contacting their assigned peer navigator. Within the first week of participants being assigned to this group, peer navigators schedule and complete a one-on-one video intake session with the participant. During this one-on-one intake session, the peer navigator conducts a thorough participant needs assessment to connect the participant to HIV medical care via local health clinics and identify other areas of need, services of need, and assisted referrals. These areas include but are not limited to domestic violence services, mental health care, substance abuse treatment, and housing and legal support. Peer navigators provide trauma-informed, intensive emotional and informational support, including guidance on accessing information (eg, agency name, address, website, and contact information) about referred services. Participants attend five 60-minute web-based one-on-one peer navigation sessions over a 5-week period, covering a variety of topics: building coping skills for syndemic conditions, activating social support networks, and addressing medical mistrust (Table 3). In addition, participants text or call their peer navigators during and after the 5-week period if they have questions or seek to debrief after sessions or appointments. In the back end of the web application, peer navigators enter case notes on peer navigation sessions and check-ins, set notifications and appointment reminders, and send their assigned participants direct messages that show up only on that participant's profile. Peer navigators can also view the women's responses in real time and data on medication and appointment outcomes to inform their upcoming session or check-in. In addition to

XSL•FO
RenderX

videoconference or phone sessions and check-ins, participants receive automated daily medication reminder SMS text messages, scheduled appointment alerts, and access to daily postings in the education and self-care tip component of the app.

Table 2. LinkPositively app components, features, and mechanisms of change.

App element	Features	Hypothesized mechanism of change influenced
Profile page	• Option to customize avatar from a variety of preloaded options or upload photo[a] • Option to share information in the "about me" section • Option to customize profile page background using preloaded optionsa	N/A[b]
Social networking	• Ability to post text, images, or videos to a "timeline"[a] • Ability to react to content using emoticons • Ability to comment on others' postsa	• Social support • HIV stigma
Education and self-care tips	• Rotating tip featured daily on the timeline • Searchable database of tips categorized using tags • Integrated external resources	• Coping self-efficacy • Ancillary support use • HIV stigma • Medical mistrust
ART[c] self-monitoring and reminders	• Pre-established monitoring of ART adherence and mood • Ability to create customized reminders • Option to receive reminders at the time of their choosing • Option to receive reminders via in-app notifications or SMS text message • Ability to view responses to tracked activity in a past-month calendar depiction	• Coping self-efficacy
Resource locator	• Searchable database of services related to HIV and non-HIV medical and social support services • Up-to-date information on location, hours, and contact information • Information on insurance acceptance when available	• Coping self-efficacy • Ancillary support use • Medical mistrust

[a]Indicates features that may require *unlocking* through continued app use.

[b]N/A: not applicable.

[c]ART: antiretroviral therapy.

Table 3. LinkPositively intervention content delivered via one-on-one peer navigation sessions.

Session number	Topic	Objectives
1	Emotional awareness	• Understanding how trauma and other co-occurring conditions (eg, substance use) affect emotions • Learn ways in which social environments influence how we experience emotions (social influences on our emotional experience exercise) • Introduce and practice labeling feeling states • Introduce and practice focused breathing
2	Emotional regulation and distress tolerance	• Introduce the benefits of emotion regulation (common unhealthy coping skills exercise and handout) • Learn the 3 ways in which we experience emotion (the 3 areas of emotion exercise or handout) • Explain why we tolerate unpleasant emotions and how to know whether to tolerate the unpleasant emotions or not • Learn how to assess the pros and cons of distress tolerance (pros and cons list) • Introduce different methods for healthy coping (with distress) with 3 ways in which we experience emotions (positive self-statements, pleasurable activities, and formal time-out)
3	Relationship patterns and activating social support networks	• Introduce interpersonal or relationship patterns (exercise—what are interpersonal patterns? The self-fulfilling prophecy) • Identify feelings and interpersonal or relationship patterns (how to identify your interpersonal patterns exercise and common interpersonal patterns exercise) • Learn what assertive communication and behavior are (exercise in defining assertive, nonassertive, and aggressive communication and behavior) • Understand how assertive behavior works in healthy relationships (healthy boundaries) • Learn how to make requests and ask for help clearly and in an assertive manner • Understand when and how to say “no” • Introduce basic personal rights (exercise and handout)
4	Interpersonal violence and the impact on existing sociostructural barriers	• Identify ways in which power and control dynamics, disclosure of violence, and interpersonal violence influence HIV stigma and medical mistrust • Explain the 3 types of power balances in relationships (exercise and handout) • Identify personal relationship patterns • Explore flexibility in relationships • Understand the role compassion and respect play in how we view ourselves and others
5	Medical mistrust and review	• Understand the relationship between discrimination and medical mistrust • Review conspiracy theories and HIV treatment • Learn skills for effective patient-provider communication • Review material covered in all 5 sessions

Control Group

Women assigned to the control arm are connected with and receive self-directed (not peer navigation–supported) treatment as usual at agencies and institutions in the San Diego, Los Angeles, or Alameda counties following the Ryan White HIV/AIDS Program standard of care (ie, referrals to physical, dental, and mental health care services; medical case management; and ancillary services [eg, alcohol/substance use recovery and family support]). Women who are not already receiving services and do not have other means of receiving services or are not under medical case management elsewhere are referred to care. Alternatively, women may request case management services via the Ryan White HIV/AIDS Program elsewhere in the counties.

Using the Ryan White standard of care, goals are set to create an individual care plan related to medical care, housing, financial, and other resources as needed. Referrals are made to appropriate services (eg, primary care, housing, benefits counseling, transportation, food, legal services, and support services) based on an intake interview. Women who require a higher level of care (eg, significant mental health concern, at risk, or falling out of care) and do not have other means of receiving services or are not under medical case management elsewhere may request case management services via the Ryan White HIV/AIDS Program.

Participants requiring medical case management have a case file that provides appropriate participant follow-up and tracking information. Case managers have in-person contact with all participants at least every 90 days to assess the further need for services. Either the participant or the case manager initiates a given contact. The case manager has in-person or phone contact with participants at least every 30 days to discuss changes and progress toward meeting the goals of the individual care plan and an in-person meeting with each participant at least once every 90 days. Participants are reassessed at least once every 120 days. It is important to note that the medical case management approach is self-guided versus intense peer

XSL•FO
RenderX

navigation assistance, meaning that participants learn the responsibility to move toward autonomy in their HIV care.

Follow-Up

Participants enrolled in LinkPositively have 2 follow-up visits at 3 and 6 months after their baseline visit. Although follow-up visits occur virtually through Zoom, participants still follow the same activities from their baseline visit. Activities include a 45-minute computer-assisted follow-up survey and a self-collected hair sample. Participants are compensated with US $25 upon the completion of the survey and US $25 upon the provision of the hair sample.

Safety Protocols

Given that LinkPositively's focus is on women who have experienced interpersonal violence, we took additional measures to ensure the safety of participants in the study. This included the creation of a safety protocol, wherein all participants are screened for current IPV and risk of homicide by a current partner using the Danger Assessment [137] and are provided with violence-related resources, which are integrated both within the LinkPositively app and on the LinkPositively website. Furthermore, participants are asked about safety information when the study staff contacts them, such as the use of a different name or only contacting the participant through certain means or at certain times, and hair sample collection is conducted at a safe location of the participant's choosing. For participants who indicate current experiences of violence, the study team offers a warm handoff to violence services and follows up with the participant to ensure their safety. Finally, safety elements are integrated into the LinkPositively app itself, including an automatic log-out feature when the app is swiped away from and an ambiguous app icon and home screen that disclose no information about the purpose of the app and do not reference HIV. Study staff also monitor the social networking feed on the app to identify posts that suggest potential harm to the self or others. These posts are flagged, and a study staff member follows up with the participant, activating the safety protocol and reporting this as an adverse event to the University of California, San Diego (UCSD) Human Research Protection Program (HRPP). To date, no adverse events have been reported to the UCSD HRPP.

Ethics Approval, Informed Consent, and Data Privacy

All study procedures were reviewed and approved by the UCSD HRPP (UCSD HRPP project 191398), and a reliance agreement was executed for San Diego State University and Charles R. Drew University of Medicine and Science to rely upon the UCSD HRPP determination. Before engaging with research participants, all study staff members completed training in the ethical conduct of human participant research, data management and compliance, and the Health Insurance Portability and Accountability Act (HIPAA). All women enrolled in LinkPositively provide written informed consent and are asked to sign a HIPAA authorization form. This study was issued a certificate of confidentiality by the National Institutes of Health.

Data Management and Quality Assurance

In compliance with National Institute of Mental Health policies, LinkPositively operates under a data and safety monitoring plan, which details methods for secure data collection, management, and monitoring. Under the data and safety monitoring plan, all digital data collected are stored on a password-protected encrypted server, whereas physical copies of data are retained in a locked filing cabinet in a locked office within a restricted-access research building. Identifying information is stored separately from the study data, with study records associated via a participant identification number. Data for linkage between participant identification number and identifying information are stored in a HIPAA-compliant secure web application designed for participant management and tracking (Ripple Science). Study staff members are only provided with data access commensurate with their study role and specifically the lowest level of access needed. Access to study data is not granted until after the completion of full ethical training. Deidentified quantitative data are downloaded on a weekly basis by the study data manager. Hair samples are associated with participant identification numbers and stored in a locked cabinet within a locked office until they are batch shipped for analysis at the University of California, San Francisco. Following completion of the analyses, the results are transmitted deidentified via secure email to UCSD.

The study staff actively monitor adverse events and serious adverse events, which are reported immediately to the principal investigator and within 24 hours to the UCSD HRPP. Finally, study activities are monitored by a Data and Safety Monitoring Board (DSMB). The DSMB convenes twice annually, at which time the study team provides updates on study activities and the DSMB provides recommendations for participant safety and data security. The DSMB comprises (1) a professor of social work and licensed social worker with substantial experience in the development and implementation of interventions for gender-based violence and HIV, (2) a professor of disease prevention and health promotion and board-certified registered nurse with substantial research experience in health information use among people living with and at risk of HIV, and (3) a biostatistician with substantial experience in randomized controlled trials in public health research.

Analysis

Aim 1

The first aim is to determine the feasibility and acceptability of LinkPositively. We will assess the feasibility of the intervention by computing the percentage of participants retained at each follow-up visit and chi-square tests or Fisher exact tests to compare the intervention and control groups. Retention cutoff percentages will be used to determine the level of feasibility as follows: (1) ≥90%=strong feasibility, (2) 80% to 89%=acceptable feasibility, (3) 70% to 79%=modest feasibility with a need for improvement, and (4) <70%=unacceptable. We will assess the acceptability of the intervention by computing the percentage of participants endorsing a particular level of satisfaction on a Likert scale from questions on the Client Satisfaction Questionnaire–8 [138] and System Usability Scale [139]. We will obtain these percentages at the 3- and 6-month follow-up assessments. Responses from women in the intervention and control groups will be compared using 2-tailed *t* tests (for continuous acceptability measures) and chi-square

XSL•FO
RenderX

tests (for dichotomous acceptability measures). We will also compute similar percentages based on responses from the peer navigators at the 6-month follow-up time point.

Aim 2

The second aim is to examine the preliminary impact of LinkPositively. Self-reported dichotomous outcomes of retention in HIV care, ART adherence, and viral suppression will be evaluated. Outcomes will be past–3-month measures assessed at each time point (3- and 6-month follow-ups). The primary independent variable will be intervention group. Chi-square tests will be used to test for significant differences in self-reported outcomes by intervention group. We will use generalized estimating equations to generate 3 independent repeated-measure logistic regressions to model retention in care, self-reported ART adherence, and viral suppression. We will also examine an objective biological outcome measure of ART adherence based on tenofovir and emtricitabine hair concentrations. We will use univariable random-intercept linear regression models to model tenofovir and emtricitabine hair concentrations, with the final model based on a generalized estimating equation repeated-measure linear regression model with a time variable (3 and 6 months). Aligned with the theory of triadic influence and syndemic theory, we will assess the impact of individual- (eg, sociodemographics, HIV treatment history, and social support), syndemic- (eg, PTSD and substance use), social- (eg, medical mistrust and HIV-related stigma), and structural-level (eg, unstable housing and insurance coverage for HIV services) factors on dependent variables. During model building, we will consider variables associated with outcome variables (univariate: $P<.10$; bivariate: $P<.10$). For the final models, adjusting for type-I error, the significance level will be set at $P<.05$.

Secondary analyses will be conducted among the 40 women randomized to the intervention group. We will estimate the association between the individual features of the LinkPositively app and retention in care, ART adherence, and viral suppression. Individual features of the LinkPositively app will include (1) the frequency of participant initiation of peer navigation through texting or calling the peer navigator, (2) number of messages sent and viewed to or by peers using the social networking platform, (3) frequency of viewing educational and self-care tips, (4) number of times the GPS-enabled resource locator was accessed, and (5) number of points earned through gamification features. Individual features of the LinkPositively app will be independent variables, and retention in care and ART adherence measures will be dependent variables. The regression models will follow those outlined for the primary analyses.

Results

LinkPositively was approved by the institutional review board in October 2019 and funded in December 2019. The LinkPositively app was designed and developed between February 2020 and January 2021. Beta testing and refinement of the app were completed in July 2021. Recruitment began in February 2022, with the goal of enrolling 3 participants per month. As of April 2023, we have screened 97 women for eligibility and enrolled 27 (28%) eligible participants. We anticipate the dissemination of preliminary results in early 2024.

Discussion

Anticipated Main Findings

LinkPositively is the first intervention that combines a tailored mobile app and peer navigation to address HIV care outcomes among Black women living with HIV who have a lifetime history of interpersonal violence. The anticipated main finding of this intervention study is that LinkPositively will be feasible and acceptable for Black women living with HIV. It is also anticipated that Black women living with HIV randomized to the LinkPositively arm will demonstrate improvements in retention in HIV care, ART adherence, and viral suppression compared with Black women living with HIV randomized to the control arm.

The use of a virtual intervention overcomes a number of structural- (eg, stigma) and individual-level (eg, access to transportation) barriers to intervention engagement. This is particularly important as our study population—Black women living with HIV—experience structural barriers (eg, medical mistrust and discrimination) to engagement with HIV health services [140,141]. In addition, social support provided by both the peer navigators and other study participants target interpersonal-level facilitators, reinforcing resilience and connectedness, which have been shown to be associated with improved HIV care outcomes. In addition, the peer navigators help disseminate and change behavioral norms that are conducive to achieving viral suppression. The integration of peer navigation, an evidence-based practice, may support further improvements in Black women's overall health and well-being outcomes beyond the HIV care continuum.

Future Research

If shown to be feasible and acceptable, LinkPositively has the potential to serve as an alternative for this marginalized, key population. We will test it further in a larger efficacy trial among a broader sample of Black women living with HIV. Although LinkPositively may not be accessible to all Black women living with HIV who experience interpersonal violence as some may not have access to a smartphone, it represents a critical avenue for intervention to improve HIV care among a large and growing group of women and has the potential for scale-up.

Abstract

Background: Chronic obstructive pulmonary disease (COPD) is a progressive condition associated with physical and cognitive impairments contributing to difficulty in performing activities of daily living (ADLs) that require dual tasking (eg, walking and talking). Despite evidence showing that cognitive decline occurs among patients with COPD and may contribute to functional limitations and decreased health-related quality of life (HRQL), pulmonary rehabilitation continues to focus mainly on physical training (ie, aerobic and strength exercises). An integrated cognitive and physical training program compared to physical training alone may be more effective in increasing dual-tasking ability among people living with COPD, leading to greater improvements in performance of ADLs and HRQL.

Objective: The aims of this study are to evaluate the feasibility of an 8-week randomized controlled trial of home-based, cognitive-physical training versus physical training for patients with moderate to severe COPD and derive preliminary estimates of cognitive-physical training intervention efficacy on measures of physical and cognitive function, dual task performance, ADLs, and HRQL.

Methods: A total of 24 participants with moderate to severe COPD will be recruited and randomized into cognitive-physical training or physical training. All participants will be prescribed an individualized home physical exercise program comprising 5 days of moderate-intensity aerobic exercise (30-50 minutes/session) and 2 days of whole-body strength training per week. The cognitive-physical training group will also perform cognitive training for approximately 60 minutes, 5 days per week via the BrainHQ platform (Posit Science Corporation). Participants will meet once weekly with an exercise professional (via

XSL•FO
RenderX

videoconference) who will provide support by reviewing the progression of their training and addressing any queries. Feasibility will be assessed through the recruitment rate, program adherence, satisfaction, attrition, and safety. The intervention efficacy regarding dual task performance, physical function, ADLs, and HRQL will be evaluated at baseline and at 4 and 8 weeks. Descriptive statistics will be used to summarize intervention feasibility. Paired 2-tailed *t* tests and 2-tailed *t* tests will be used to compare the changes in the outcome measures over the 8-week study period within and between the 2 randomized groups, respectively.

Results: Enrollment started in January 2022. It is estimated that the enrollment period will be 24 months long, with data collection to be completed by December 2023.

Conclusions: A supervised home-based cognitive-physical training program may be an accessible intervention to improve dual-tasking ability in people living with COPD. Evaluating the feasibility and effect estimates is a critical first step to inform future clinical trials evaluating this approach and its effects on physical and cognitive function, ADL performance, and HRQL.

Introduction

Background

Chronic obstructive pulmonary disease (COPD) is a progressive respiratory condition characterized by chronic bronchitis and emphysema [1]. It is the third-leading cause of death worldwide [2] and is responsible for high levels of health care use because of frequent respiratory exacerbations [3]. Individuals with COPD experience significant airflow obstruction and dynamic hyperinflation of the lungs, leading to symptoms of dyspnea, sputum production, chronic cough, and fatigue [1]. Skeletal muscle dysfunction, comprising decreased muscular strength and endurance, is also a common consequence of COPD and is driven by a combination of several mechanisms, including muscle atrophy, altered fiber type, and impaired metabolism [4]. Collectively, these changes contribute to diminished exercise capacity, limitations in activities of daily living (ADLs), and reduced health-related quality of life (HRQL) among individuals with COPD [5].

Cognitive Impairment in COPD

A growing body of research has demonstrated the presence of limitations across several domains of cognition among individuals with COPD [6]. Decreases in attention, memory, and visual-motor processing have been commonly reported [6-8]. The underlying mechanisms of cognitive impairment among individuals with COPD are complex and have been attributed in part to neural tissue hypoxemia and systemic inflammation [9,10].

Recent studies have indicated that COPD is associated with impaired dual-tasking performance [11,12]. Dual tasking, the performance of 2 tasks simultaneously, is an important aspect of executive function and is often required for the performance of routine daily activities, such as walking and talking. The performance of a cognitive task (eg, spelling words backward) while carrying out a physical task (ie, usual-paced walking) can result in decrements in cognitive or physical performance (eg, walking speed or distance) owing to competing attentional demands. Dual task decrements (difference between dual and single task performance) are often more pronounced in those with existing cognitive impairments or neurological conditions compared with those without these disorders [13,14]. Indeed, increased dual task decrements for both motor [12,15] and cognitive [16] performance have been found among people with COPD compared with healthy individuals [17]. There is emerging evidence indicating that cognitive-motor dual task performance impairment among patients with COPD is related to alterations in markers of prefrontal cortex neural activity and inefficiency, which may impede the executive function needed to *plan one's day* [11,12,17]. Thus, combined cognitive-physical training may be a good strategy to improve neural efficiency in patients with COPD who may have a range of executive functional capacities. Cognitive training targeting attention, memory, executive functioning, and speed of processing when combined with physical exercise training may provide the neuroplasticity to derive synergistic benefits on the performance of ADLs and physical function [18-20].

Traditional Pulmonary Rehabilitation

Pulmonary rehabilitation is considered a primary management approach for moderate to severe COPD and has been shown to reduce dyspnea and increase exercise capacity, leading to improvements in daily function and HRQL among individuals with COPD [21]. To date, pulmonary rehabilitation strategies have typically focused on education (eg, medication management, breathing techniques, and stress reduction) and physical training (ie, aerobic and strength exercises) [21,22]. Currently, cognitive training is not included in most pulmonary rehabilitation programs despite evidence that cognitive impairments are common among individuals with COPD and are associated with greater functional limitations, decreased HRQL, and increased health care use in this population [8,23].

XSL•FO
RenderX

Home-Based Pulmonary Rehabilitation

Several barriers limit engagement in pulmonary rehabilitation for people with COPD, including factors related to the environment (eg, travel and wait times), knowledge (eg, referral processes), and beliefs (eg, perceived benefits) [24]. Recently, accessibility has been further complicated by the COVID-19 pandemic. For these reasons, there is increasing interest in home-based pulmonary rehabilitation programs as an alternative strategy for COPD management compared with center-based pulmonary rehabilitation programs [25-27]. Several studies have demonstrated the safety and feasibility of remote telerehabilitation interventions for patients with COPD, with high levels of compliance with home training and no adverse events [28-30]. There is meta-analytic evidence from systematic reviews also indicating that the effects of home-based pulmonary rehabilitation interventions are similar to those of traditional outpatient programs for outcomes including dyspnea [26,27], exercise capacity [26,31], and HRQL [26,31], potentially offering increased accessibility to those with travel restrictions [32]. However, most studies on telerehabilitation for COPD have required study assessments to be conducted in person, and none have included remote assessment of functional testing, cognitive assessments, or dual task performance, a knowledge gap that this study hopes to address [27].

Study Purpose

The specific aims of this study are to evaluate the feasibility (ie, recruitment rate, program adherence, attrition, safety, and participant satisfaction) of an 8-week individualized, home-based cognitive-physical training program for patients with moderate to severe COPD and derive preliminary estimates of cognitive-physical training intervention efficacy on measures of cognitive and physical function, dual task performance, ADL, and HRQL. We hypothesize that it will be feasible to safely recruit patients with COPD into a home-based cognitive-physical training program with 75% adherence and high satisfaction ratings with the prescribed training. We also hypothesize that the cognitive-physical training group will demonstrate greater beneficial effects on cognitive function, dual task performance, ADL, and HRQL compared with the physical training group.

Methods

Design

This is a pilot randomized controlled trial (RCT) to assess the feasibility of a full-scale, adequately powered RCT evaluating a home-based combined cognitive-physical training program for patients with moderate to severe COPD. The study takes place at the University Health Network (UHN) in Toronto, Ontario, Canada, but has been expanded to include recruitment from community respirology clinics not affiliated with the UHN.

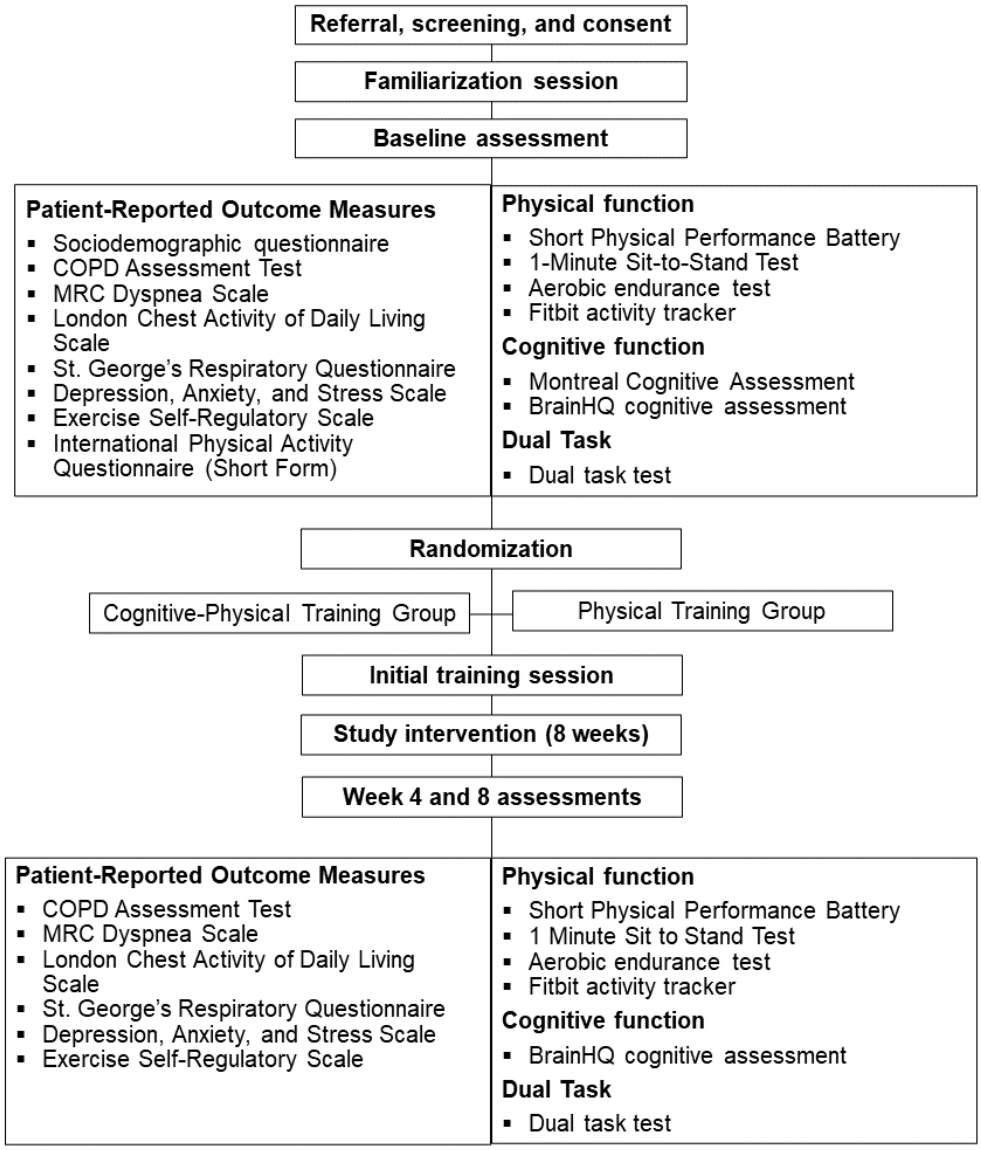
Ethics Approval and Informed Consent

Research ethics approval was obtained through the research ethics board of the UHN (study ID: 21-5336), and the study has been registered at ClinicalTrials.gov (NCT05140226). Informed consent will be obtained from participants before study enrollment.

Participants

The study sample will consist of older adults (aged ≥50 years) with a clinical and spirometric diagnosis of moderate to severe COPD (postbronchodilator forced expiratory volume in the first second [FEV_1]/forced vital capacity of <0.70 [or lower limit of normal of FEV1/forced vital capacity] and FEV_1=30%-79%). Participants will be required to have access to a reliable internet connection and be able to mobilize independently and safely with or without a walking aid. Exclusion criteria include the following: (1) current participation in supervised in-person or an internet-based pulmonary rehabilitation program; (2) COPD exacerbation in the previous 3 months to ensure clinical stability; (3) presence of cardiovascular, neurological, or musculoskeletal conditions that could interfere with the safe performance of study procedures (eg, unstable coronary artery disease, heart failure, stroke, myopathy, or moderate to severe arthritis); (4) severe cognitive impairment ascertained through chart review or self-report (eg, severe dementia or inability to perform ADLs independently); (5) medical instability (eg, hepatic dysfunction, metabolic abnormality, or active infection); (6) overt psychiatric disorder or substance abuse; (7) current use of home oxygen therapy; (8) insufficient English fluency to carry out testing and training; and (9) being listed for lung transplantation.

Recruitment and Screening



Participants will be recruited during routine visits to outpatient respirology clinics at UHN in Toronto, Ontario, Canada, and local respirology clinics. Clinic personnel within the circle of care will introduce the study to patients with COPD and ask if they are interested in participating. If interested, a member of the research team will then contact the potential participant to screen for eligibility criteria, review study procedures, and obtain informed consent. The study recruitment poster will also be provided to medical personnel at local respirology clinics who will introduce the study to patients with COPD and instruct them to contact the research team if they are interested in pursuing study participation.

Study Timeline

The study timeline is shown in Figure 1. After completing consent procedures, participants will receive a package by mail containing the following study equipment: Fitbit Charge 4 device (Fitbit Inc), foot peddler (VANGONA D2 pedal exerciser), pulse oximeter, resistance bands (Thera-Band), measuring tape, and exercise manual. They will also receive an email with instructions on how to access the internet-based appointment platform (Microsoft Teams; Microsoft Corp) on their devices. Following receipt of study materials, participants in both groups will be booked for a 45-minute videoconferencing familiarization session. During the familiarization session, participants will be introduced to the study equipment and software, their safety in performing remote physical testing will be assessed, and study assessment procedures will be explained. Furthermore, appropriate equipment setup for remote testing will be determined, and participants will have the opportunity to practice the physical assessment tests. After the familiarization session, participants will be booked for the *baseline assessment* session (1 hour) to complete the assessment measures described in the following sections.

XSL•FO
RenderX

Figure 1. Study timeline. COPD: chronic obstructive pulmonary disease; MRC: Medical Research Council.

Randomization

After the baseline assessment, participants will be randomized to either the cognitive-physical training (intervention) group or the physical training (control) group using a 1:1 ratio. Randomization will be performed using shuffled opaque envelopes containing the group assignment. Given the pilot stage of this research and the nature of exercise interventions, group allocation will be known to the research team, exercise professionals, and study participants.

Intervention Groups

Summary

After randomization, participants in both groups will complete an initial training session (1 hour) to introduce the intervention. The initial training session will consist of a health and exercise history assessment, tailored exercise prescription, goal setting, and software account setup, as described in the following sections. Both groups will also receive weekly videoconferencing calls (30-60 minutes) from the study team via Microsoft Teams. Weekly sessions will involve a review of training and any adverse events, progression or adaptation of the program as needed, and troubleshooting of any difficulties encountered by the participant. Participants will also have the option of scheduling additional sessions with the study team during the week if further support is needed.

Physical Training Group

Overview

Participants in the physical training group will perform 8 weeks of home-based physical exercise training as per the current standard of care for pulmonary rehabilitation [22,33]. The physical training program was developed according to established guidelines for pulmonary rehabilitation [22,33] and includes both aerobic and strength training exercises that will be individually tailored to the specific needs and physical condition of each participant. Table 1 summarizes the physical exercise training program parameters.

XSL•FO
RenderX

Table 1. Physical exercise training parameters.

Modality and frequency	Intensity	Time	Type	Progression
Aerobic: 5 days/week	• Moderate to vigorous (target Borg RPE[a] score of 4-6/10) • 60%-85% of symptom-limited maximum heart rate	• 30-50 minutes • Either continuous or interval training	• Foot peddler	• Gradual progression of training duration • Increase pedaling speed (revolutions/minute) or resistance • Increase target heart rate or RPE score
Strength: 2 days/week	• Target Borg RPE score of 4-6/10	• 6 exercises • 1-3 sets • 10-12 repetitions	• Resistance band exercises: band pull-aparts, seated bicep curls, seated rowing, and seated tricep kicks • Body weight exercises: chair sit-to-stand exercises and calf raises	• Resistance intensity will be increased when prescribed exercises can be completed without difficulty to maintain moderate exertion • Increase in resistance band tension • Increase in number of sets or repetitions

[a]RPE: Rating of Perceived Exertion.

Individualized progressive exercise prescriptions will be developed by an exercise professional and supported using a web application and mobile app (Physiotec) that allows for customizable exercise prescriptions with written instructions, video tutorials, and self-reported tracking of exercise completion. The exercise program will be reviewed, revised, and progressed as appropriate based on participants' needs during the weekly check-ins with the exercise professional. This will involve reviewing available data from Fitbit and self-report records from the participant, including pulse oximeter recordings.

Participants will be encouraged to include a warm-up and a cooldown period as part of their exercise training sessions. The warm-up will be a 5-minute routine consisting of mobility and breathing exercises to be implemented before starting physical activity. The cooldown at the end of each training session will comprise neck, shoulder, and leg stretches. See Table 2 for examples of warm-up and cooldown exercises.

Table 2. Summary of warm-up and cooldown exercises.

Exercise	Intensity	Time	Type
Warm-up (5 minutes)			
Breathing	• As tolerated • Gentle breathing exercises	• Approximately 3 minutes	• Pursed-lip breathing
Mobility	• Gentle mobility exercises as tolerated by the participants' range of motion while combining with the rhythm of breathing	• 5 exercises • 1 set of 10 repetitions	• Neck mobility (chin tuck and head to the sides) • Shoulder circles • Arms reach up and reach down (touch ankles) • Knee extension and flexion (performed while sitting in a chair)
Cool down (5 minutes)			
Stretching	• Gentle stretching exercises as tolerated by the participants' range of motion	• 3 exercises • 1 set of 2 repetitions for each exercise • Hold each exercise for 10 seconds	• Chest stretching in chair • Back stretching in chair • Leg stretching in chair

Aerobic Training

Aerobic training will consist of using a foot peddler (VANGONA D2 pedal exerciser) provided by the research team (Table 1). Participants will be asked to perform aerobic training 5 times per week for a minimum of 30 minutes (up to 50 minutes) at a moderate to vigorous intensity (level 4-6 out of 10 on the Borg Rating of Perceived Exertion [RPE] Scale). Aerobic exercise may be performed in intervals (eg, 5 minutes of pedaling and 2 minutes of rest) or completed in shorter bouts throughout the day if participants cannot tolerate 30 minutes continuously. Exercise duration and intensity will be adapted to the participants' level of dyspnea and fatigue. Aerobic training will progress under the guidance of the exercise professional by increasing duration, cycling speed, and resistance.

Strength Training

Strength training will be performed 2 times per week using resistance bands (provided by the research team), the participants' own body weight, and household items (eg, chairs).

XSL•FO
RenderX

Participants will be prescribed 1 to 3 sets of 10 to 12 repetitions for 6 strength exercises targeting large muscle groups such as the chest, back, arms, shoulders, and legs. Exercises may include band pull-aparts, seated rowing, bicep curls, triceps extensions, sit-to-stand exercises, and calf raises. Specific exercises and the number of sets and repetitions will be tailored to suit the individual needs of each participant, with a target intensity level of 4 to 6 on the Borg RPE Scale. Strength training will be performed under the guidance of the exercise professional by increasing the number of sets or repetitions or by increasing the tension in the resistance bands.

Safety Precautions for Remote Training

Participants will be given a personalized exercise program supervised by a qualified exercise professional. The exercise professional will review important considerations for home exercise, such as maintaining an open training environment free from tripping hazards (eg, rugs, clutter, and pets), the suitability of exercise equipment setup, and appropriate exercise attire (eg, footwear). Before beginning the remote exercise sessions, the exercise professional will perform a safety check to determine the appropriateness of proceeding with testing or training. The safety check will involve an objective assessment of oxygen saturation, heart rate, and blood pressure (if available) and a subjective assessment of self-reported symptoms (eg, breathlessness, dizziness, and chest pain). The research team will also collect participants' home addresses, telephone numbers, and emergency contact information to be used in the event of a medical emergency during internet-based interactions.

Participants will be instructed to monitor their oxygen saturation (pulse oximeter), heart rate (pulse oximeter or Fitbit), and subjective level of exertion (Borg RPE Scale) and breathlessness (Borg Dyspnea Scale) while exercising using printed scales. They will be advised to lower their intensity level (ie, decrease cycling speed or resistance) if they reach a score of ≥7 on the Borg Dyspnea or RPE Scales, if their oxygen saturation drops to <85%, or if they experience any other symptoms (eg, light-headedness). They will be asked to track any adverse events using the training diary and encouraged to contact a member of the research team immediately upon noticing any adverse events. If participants experience chest pain or discomfort (uncomfortable feeling of pressure, pain, squeezing, or heaviness in the chest spreading to the shoulder, arms, neck, and back), they will be instructed to immediately stop exercising, rest, and seek emergency medical assistance if the symptoms persist beyond 5 minutes. The training program will be monitored by the exercise professional via weekly internet-based appointments involving a review of physiological exercise parameters (heart rate and oxygen saturation) from the Fitbit data and participant self-reported records. Participants will also be able to contact the exercise professional and study team at any time if questions or concerns arise.

If a participant communicates a medically concerning adverse event or contraindication to exercise (eg, cardiovascular event), the program will be suspended until medical clearance to resume the exercise program is obtained from the participant's physician and approved by the principal investigator. Participants who experience a COPD exacerbation during the study will be instructed to temporarily discontinue their training program. They will be reassessed by the principal investigator and exercise professional within 2 weeks for their ability to resume the study.

Cognitive-Physical Training Group

Overview

Participants in the cognitive-physical training group will perform 8 weeks of home-based web-based cognitive training in addition to physical exercise training.

Physical Exercise Training

Physical training, including aerobic and strength exercises identical to those in the physical training group, will be performed a minimum of 5 days per week, as described previously.

Cognitive Training

Cognitive training will be performed using the web-based BrainHQ training platform (Posit Science Corporation) [34]. Participants will be instructed to train 5 days per week with a target of 24 levels per session (approximately 60 minutes). Cognitive training may be completed on a desktop computer, laptop, or tablet. A tablet device will be provided to any participants without access to a personal device for training. A customized training focus has been designed for this study based on areas of cognition known to be affected by COPD: attention, memory, speed of processing, and executive function [6-8]. These cognitive domains will be targeted using the following BrainHQ exercises: Double Decision, Hawk Eye, Visual Sweeps, Eye for Detail, Mind Bender, and Target Tracker [35,36]. The BrainHQ platform is designed to have training difficulty continuously adjusted to be performed "at threshold" of 70% to 80% accuracy, meaning that exercises become easier or more difficult based on the individual's performance. All participants in the cognitive-physical training group will have a similar training session initially, but training parameters will become more individualized as users progress and the algorithm considers their individual performance history. Previous research indicates that the proposed training schedule (8 weeks, 40 hours total) is sufficient to elicit cognitive improvements [35,37,38].

Data Collection

Primary Outcomes

Overview

The primary outcomes for this study include the following indicators of intervention feasibility: recruitment rate, retention, adherence, safety, and satisfaction. See Table 3 for an overview of the feasibility outcomes.

XSL•FO
RenderX

Table 3. Feasibility outcome measures.

Feasibility outcome	Assessment measure	Success criteria	Time point
Recruitment	Number of consented participants relative to the total number of eligible patients approached for consent	Recruitment rate of ≥30%	During study period
Retention	Number of participants who complete the final study assessment relative to the total number of participants enrolled and randomized	Retention rate of ≥80%	During study period
Adherence	Percentage of completion of physical and cognitive training intervention components according to training logs and BrainHQ records	Intervention adherence of ≥75%	During study period
Safety	Adverse events reported via exercise training logs and weekly check-in sessions	No study-related adverse events	During study period
Satisfaction	Participant satisfaction survey	≥80% reporting above-average or excellent satisfaction on a Likert scale	Weeks 1, 4, and 8

Recruitment

The recruitment rate will be defined as the percentage of consented patients relative to the total number of eligible patients who agreed to be approached by the study team for participation. Reasons for study participation and nonparticipation will also be collected. A recruitment rate of ≥30% has been established as our criterion to inform feasibility for a future study and help with modifications to recruitment for future studies.

Retention

Retention for the whole study and per group will be defined by the number of participants who complete the final study assessment compared with the number of participants enrolled and randomized. A retention rate of ≥80% (in each group) has been established as our criterion to determine feasibility for a future study.

Adherence

Adherence to the prescribed physical training and cognitive-physical training programs will be assessed via daily exercise training logs, the number of training levels completed in BrainHQ (displayed on a secure cloud-based group portal accessible by the study team), and weekly communications with participants. Adherence to the physical exercise training intervention will be expressed as the percentage of physical training days completed out of the total number of training days prescribed. Adherence to the cognitive training intervention will be expressed as (1) the number of cognitive training days completed out of the number of cognitive training days prescribed and (2) the number of cognitive training levels completed out of the total number of levels prescribed using the BrainHQ platform. Adherence to the interventions of ≥75% (ie, combination of physical training logs and cognitive training platform) is our criterion to determine feasibility for a future study.

Safety

Intervention safety will be monitored based on the occurrence and severity of adverse events. Participants will be instructed to log and report any side effects or adverse events during the intervention (ie, falls, injuries, and respiratory symptom worsening). Adverse events will also be reviewed by the exercise professional during weekly sessions.

Satisfaction

Participant satisfaction with the cognitive-physical training and physical training programs will be assessed at weeks 1, 4, and 8 using a Participant Evaluation Questionnaire developed for this study involving multiple-choice and open-ended questions. The results will be reviewed and analyzed by the study team at the end of the trial to determine overall satisfaction and any modifications required for future trials.

Secondary Outcomes

Overview

Effect size estimates will be evaluated using secondary outcome measures of physical and cognitive function, dual task performance, ADLs, and HRQL, as described in further detail in the following sections. These measures will be assessed at baseline and at 4 and 8 weeks after starting the intervention. See Table 4 for a summary of secondary outcome measures.

XSL•FO

Table 4. Secondary outcome measures by time point.

Outcome	Assessment measure	Time points
Characterization measures		
Sociodemographic information	• Sociodemographic questionnaire	• Baseline
Cognitive screening	• Montreal Cognitive Assessment Test	• Baseline
Disease impact	• COPD[a] Assessment Test	• Baseline, week 4, and week 8
Clinical characteristics	• Medical chart review	• During study period
Physical function		
Lower-body strength	• 1-Minute Sit-to-Stand Test	• Baseline, week 4, and week 8
Lower-body function	• Short Physical Performance Battery	• Baseline, week 4, and week 8
Aerobic endurance	• Foot peddler endurance test	• Baseline, week 4, and week 8
Cognitive performance	• BrainHQ assessment	• Baseline, week 4, and week 8
Dual-tasking performance	• Foot peddler dual task test	• Baseline, week 4, and week 8
Self-reported outcomes		
Dyspnea	• MRC[b] Dyspnea Scale • 18-item qualitative dyspnea scale • Borg Dyspnea and RPE[c] Scales	• Baseline, week 4, and week 8
Activities of daily living	• The London Chest Activity of Daily Living scale	• Baseline, week 4, and week 8
Health-related quality of life	• St. George's Respiratory Questionnaire	• Baseline, week 4, and week 8
Mood	• Depression, Anxiety, and Stress Scale (21 items)	• Baseline, week 4, and week 8
Exercise self-efficacy	• Exercise Self-Regulatory Efficacy Scale	• Baseline, week 4, and week 8
Physical activity		
Physical activity habits	• International Physical Activity Questionnaire–Short Form	• Baseline
Physical activity behaviors	• Fitbit activity tracker	• During study period
Health care use	• Medical chart review • Self-reported	• During study period and 1 year before study enrollment

[a]COPD: chronic obstructive pulmonary disease.

[b]MRC: Medical Research Council.

[c]RPE: Rating of Perceived Exertion.

Characterization Measures

Sociodemographic Information

Age, sex, ethnicity, employment status, educational level, and smoking history will be collected via chart review and self-report to characterize the sample and interpret findings from the cognitive assessments.

Montreal Cognitive Assessment

The Montreal Cognitive Assessment (MoCA) [39] is a 30-point screening test for mild cognitive impairment that has been previously applied in patients with COPD [12,40]. The MoCA specifically assesses short-term memory, visuospatial abilities, executive function, attention, concentration, working memory, language, and orientation to time and place. The MoCA will be administered only at the baseline assessment to help characterize the study population.

COPD Assessment Test

The COPD Assessment Test [41] is a short questionnaire for assessing and monitoring the impact of COPD. The COPD Assessment Test consists of 8 items that assess cough, the production of phlegm, chest tightness, breathlessness, activity limitation, confidence, sleep, and energy. Each item is rated on

XSL•FO
RenderX

a 6-point scale, and the overall score ranges from 0 to 40, with a higher score indicating greater disease impact.

Clinical Characteristics

Clinical characteristics, including FEV_1; medications (eg, inhaled medications, opioids, and prednisone); baseline 6-minute walk distance; Body Mass, Obstruction, Dyspnea, and Exercise index; and exacerbation history, will be ascertained from chart review up to 1 year before study enrollment. We will also capture anthropometric measures and BMI from pulmonary function tests if available from routine clinical evaluations. Comorbidities in our study participants will be assessed using the Charlson Comorbidity Index and through chart review using a comprehensive comorbidity questionnaire previously applied by our group [42].

Physical Function

Lower-Body Strength

The 1-Minute Sit-to-Stand Test [43] will be used to evaluate lower-body strength. This test involves participants completing as many sit-to-stand rises from a chair as possible in 1 minute. Participants will be instructed to stand fully upright and then sit down again immediately without delay, with arms crossed at the chest to avoid the use of the arms to rise from the chair. The research team will guide participants in selecting an appropriate chair (approximate height of 46 cm) with a flat, noncushioned bottom and no armrests. Participants will be prompted to report their Borg Dyspnea and Borg Leg RPE scores before and after the test.

Lower-Body Function

The Short Physical Performance Battery [44] will be used to assess lower-extremity performance, including balance (ability to stand with feet side by side, semitandem, and tandem), gait (usual-paced walking speed over 4 meters), and chair stand (time to rise from a chair 5 times). The Short Physical Performance Battery score is a summation of the scores on the 3 tests, each scored from 0 to 4, with a maximal cumulative score of 12.

Aerobic Endurance

Aerobic endurance will be measured using a foot peddler test developed by our research group for this study. Participants will pedal for as long as they can up to 15 minutes at a set speed of 50 revolutions per minute and a resistance setting that allows them to carry on a conversation (approximately 3-4 on the Borg RPE Scale). This intensity level is intended to be challenging but not exhausting. The primary endurance measure will be the number of minutes of testing completed. The reason for test termination will also be recorded. Oxygen saturation, qualitative dyspnea descriptors, Borg Dyspnea score, and Borg Leg RPE score will be measured before and after endurance testing. The complete aerobic endurance testing protocol is described in Textbox 1.

XSL•FO
RenderX

Textbox 1. Aerobic endurance foot peddler testing protocol.

Baseline measurements

- Oxygen saturation with pulse oximetry, qualitative dyspnea descriptors, Borg Leg Rating of Perceived Exertion score, and Borg Dyspnea score will be measured before testing.

Warm-up

- Participants will pedal for 1 minute at a self-selected speed as a warm-up in order to become familiar with the foot peddler.

Test period

- Participants will continue pedaling at a set speed of 50 revolutions/minute and a resistance setting that allows them to carry on a conversation (approximately 3-4 on the Borg Rating of Perceived Exertion Scale) for as long as they can up to a maximum of 15 minutes. Participants will be prompted every few minutes to monitor their heart rate and oxygen saturation using an oximeter and their Borg Dyspnea score. The test will be stopped based on any of the following stopping criteria:
  - 15 minutes have been completed.
  - Oxygen saturation drops to <85%.
  - Self-reported Borg Dyspnea score is >7.
  - The activity becomes unbearable (eg, severe leg pain or the participant is too tired to continue).
  - Heart rate reaches 85% of age-predicted maximum (calculated as 220 beats/minute–age).
  - Participant is unable to maintain a speed of 50 revolutions/minute.
  - The research team member decides to stop the test because of apparent breathlessness or discomfort of the participant.

Posttest measurements

- The reason for test termination will be recorded, and repeat measurements will be taken for oxygen saturation, qualitative dyspnea descriptors, Borg Leg Rating of Perceived Exertion score, and Borg Dyspnea score. We will also ascertain if participants have any additional comments regarding their test performance.

Cooldown

- Participants will be instructed to continue pedaling at a self-selected speed and resistance to cool down until heart rate drops to <110 beats/minute.

BrainHQ Cognitive Assessment

Cognitive performance will be evaluated via the BrainHQ assessment platform. A custom assessment battery modeled on the training exercises will be used, with a focus on evaluating changes in performance from training as a measure of target engagement [45]. These assessments were chosen in consultation with the scientific team at BrainHQ and coinvestigators with cognitive expertise (DG, RG, and JLC).

Dual Task Performance

Dual task performance will be evaluated through a dual task test on the foot peddler, as previously undertaken in other populations [46,47]. Participants will complete a motor, cognitive, and combined dual task (all of 1-minute duration) in random order: (1) the *cognitive task* involves spelling 5-letter words backward from a list of 100 words provided verbally (homonyms excluded), (2) the *motor task* involves pedaling on the foot peddler at a set speed of 50 revolutions per minute and a self-selected resistance corresponding to a moderate-intensity level allowing participants to hold a conversation (approximately level 4 on the Borg RPE Scale), and (3) the *dual task* involves spelling and pedaling at the same time. Participants will be instructed to prioritize both tasks equally. Spelling tasks (single and dual tasks) will be audio recorded using a Dictaphone to allow for precise scoring. The number of words correctly spelled backward and the distance covered while pedaling will be compared between the single and dual task conditions to calculate a dual task cost score for both the cognitive and physical performance tasks.

Patient-Reported Outcomes

Medical Research Council Dyspnea Scale

The Medical Research Council Dyspnea Scale [48] will be used to assess the degree of functional disability because of breathlessness. Participants will indicate the extent to which breathlessness limits their daily physical activities on a scale from 1 (only breathless with strenuous activity) to 5 (too breathless to leave the house or breathless when dressing or undressing).

ADL Outcomes

The London Chest Activity of Daily Living scale [49] will be used to assess limitations in performing ADLs because of dyspnea. It comprises 15 questions across 4 domains: self-care, domestic activities, physical activities, and leisure. Each question is rated on a scale from 0 to 5, with 5 representing the greatest dyspnea-related impairment. Total scores range from 0 to 75 points, with higher values indicating greater ADL limitations [50]. The London Chest Activity of Daily Living scale has been applied in patients with COPD with a minimally important difference of 4 points [49].

XSL•FO
RenderX

HRQL Outcomes

The St. George's Respiratory Questionnaire [51] will be administered to measure the impact of COPD on overall health, daily life, and perceived well-being. The questionnaire comprises 50 items. Scores range from 0 to 100, with higher scores indicating worse HRQL. A minimally clinically important difference of 4 points has been identified in patients with COPD [52].

Mood

The Depression, Anxiety, and Stress Scale–21 [53] is a 21-item questionnaire that measures the emotional states of depression, anxiety, and stress. It has acceptable to excellent internal consistency and normative data for the COPD population [54]. Scores are categorized as normal, mild, moderate, severe, and extremely severe for each of the 3 domains.

Self-Efficacy to Exercise

The Exercise Self-Regulatory Efficacy Scale (Ex-SRES) [55] will be administered to measure exercise self-regulatory efficacy among participants. The Ex-SRES consists of 16 items asking participants to indicate the degree to which they are confident that they could continue to exercise regularly (3 times/week for 20 minutes) when faced with various barriers. Ratings are provided from 0% (not at all confident) to 100% (highly confident). The validity and reliability of the Ex-SRES have been demonstrated in individuals with COPD [55].

Physical Activity Levels

The *International Physical Activity Questionnaire–Short Form* [56] will be used to characterize baseline physical activity levels among participants. The International Physical Activity Questionnaire–Short Form consists of 7 questions that capture average time spent sitting, walking, and engaging in moderate and vigorous physical activity over the previous 7 days to provide an estimate of overall activity levels based on metabolic equivalent of task minutes per week.

During the 8-week study period, physical activity levels will be measured via a wrist-worn activity tracker (Fitbit Charge), which will capture daily step count, sedentary time, and number of active minutes (minutes of activity classified as "moderate" or "vigorous" intensity based on heart rate) [57].

Health Care Use

Health care use over the course of the 8-week intervention and 1 year before study enrollment will be assessed through chart review. The following information will be collected: COPD exacerbation history, history of falls, emergency department visits, admissions to hospital (reasons and length of hospital stay), and mortality during the study period.

Statistical Procedures

Sample Size

A sample size of 12 participants per group is considered appropriate for a pilot study to assess feasibility [58], accounting for an estimated attrition rate of approximately 20% in each group. Power calculations were not performed for the secondary outcomes as the primary study purpose is to assess effect estimates for further program development and evaluation in a future RCT.

Data Analysis

Descriptive statistics will be used to summarize recruitment and retention rates, program adherence, participant satisfaction, and safety in both groups. Means and 95% CIs will be reported for the secondary outcomes at baseline, 4 weeks, and 8 weeks within and between groups to derive effect estimates for analysis and sample size calculations for a subsequent larger-scale RCT. Paired 2-tailed *t* tests and 2-tailed *t* tests will be used to compare the changes in the secondary outcome measures over the 8-week study period within and between the 2 randomized groups, respectively. All participants will be included in the analyses based on the intention-to-treat principle according to their group allocation from randomization.

We will explore the contribution of age and sex to feasibility end points and secondary outcomes. Given the modest sample size and importance of age for both cognitive and physical function, we limited our inclusion criteria to the age of ≥50 years to ensure a more homogenous study population. Other important clinical factors such as BMI and medications will be included for descriptive purposes.

Data Quality and Management

Our research team is trained in the study processes, measurement protocols, and institutional requirements. We have received peer review comments from the Canadian Lung Association (Multimedia Appendix 1) and incorporated this feedback into the study protocol. Standard operating procedures are in place for all study procedures. The research team will make every effort to have participants complete all study elements, and incomplete or missing data will not be imputed. All participants will be closely supervised by the exercise professional, who will support adherence and accurate data collection.

As per national and institutional research guidelines, all participants will be given a unique study ID to be used in place of their name for all study data. Physical data collection forms and data collected from questionnaires will be kept in a cabinet in the principal investigator's office under lock and key. Electronic data will be stored on a password-protected research server. Once data collection is complete, deidentified data will be exported to statistical software for analysis.

Results

Recruitment began in January 2022. It is estimated that the study period will be 30 months long, with data collection to be completed by December 2023. Study results will be submitted for publication in the summer of 2024.

Discussion

Study Summary

COPD is associated with several physical and cognitive impairments contributing to limitations in daily activities that often involve the simultaneous performance of a physical (eg, walking) and cognitive (eg, talking) task, known as dual tasking.

XSL•FO
RenderX

The benefits of pulmonary rehabilitation in reducing COPD symptoms and improving daily function are well established [21], and it is known to be feasible and effective when delivered remotely in the home environment via telehealth [26,27,31]. However, traditional pulmonary rehabilitation programs typically focus mainly on physical exercise training without addressing cognitive function despite evidence that many patients with COPD have some cognitive limitations, which can contribute to greater functional limitation, increased health care use, and decreased HRQL [6,23]. Patients with COPD with cognitive limitations are also at increased risk of noncompletion of pulmonary rehabilitation [59], suggesting that a better understanding of cognitive limitations and approaches to improve cognition may lead to better adherence and outcomes. However, to date, no studies have examined a pulmonary rehabilitation approach that specifically combines both physical and cognitive training. Therefore, this protocol describes a pilot RCT that is entirely internet based and home based and combines cognitive and physical training in patients with COPD with the aim of further improving daily function and HRQL beyond traditional pulmonary rehabilitation approaches.

Cognitive Training Mechanisms

Cortical activity is essential for all motor performance, ranging from complex activities to basic ADLs; thus, the benefits derived from cognitive training can be obtained even in those with normal cognition [60]. Cognitive training has been shown to be more effective in those completing a physical exercise intervention as the neural network is primed for neuroplasticity. Thus, cognitive training may be a complementary strategy in conjunction with physical exercise to improve dual tasking in patients with COPD, which is often required during routine daily activities (eg, talking or avoiding obstacles while walking). COPD is associated with impaired dual-tasking performance, manifested as changes in dual task gait properties, including reduced gait speed [12] and increased gait variability [15]. There is also evidence from our group that loss of neural automaticity may be an underlying mechanism contributing to slower gait speed among individuals with COPD [11]. Collectively, these changes suggest that cognitive limitations may arise from increased attentional demands and neural inefficiency, which may contribute to decreased cognitive and physical performance in COPD [17]. Although traditional pulmonary rehabilitation does not appear to improve dual task gait in patients with COPD [15], cognitive training is known to produce distinct benefits on dual task reaction time [61] and has been shown to independently improve measures of functional mobility among healthy older adults [62]. Therefore, the addition of cognitive training may help improve neural efficiency and attentional capacity in patients with COPD, leading to improvements in dual-tasking ability that may translate to better performance in daily activities and HRQL and reduction in the risk of falls.

Clinical practice guidelines established by several leading organizations recommend cognitive training as a strategy to decrease the risk of cognitive decline (World Health Organization; American Academy of Neurology; National Academies of Sciences, Engineering, and Medicine; and Agency for Healthcare Research and Quality) [63-66]. These recommendations were largely established based on strong scientific evidence in the form of meta-analyses showing both near and far transfer effects from cognitive training in older community-dwelling adults, those with mild cognitive impairment, and those with dementia [67-71]. BrainHQ by Posit Science is a computerized cognitive training platform offering game-based exercises that target the speed and accuracy of information processing across the domains of attention, memory, spatial navigation, executive function, and emotional processing. In the largest RCT on cognitive training to date involving 2832 healthy older adults, speed-of-processing training on BrainHQ was found to improve cognitive and functional performance to a greater extent than other forms of memory or reasoning training, which translated to a reduction in risk of impairments in daily activity performance and an increase in reported quality of life that remained at follow-up of 5 to 10 years [72]. BrainHQ training resulted in improved visual processing speed and accuracy, and these improvements were associated with improved balance and smaller decrements in dual task gait speed among older adults [73,74], which has important implications for patients with COPD who are at risk of falls [42]. To our knowledge, this study will be the first to explore BrainHQ cognitive training in a population of individuals with chronic lung disease.

Given the breadth of impairments associated with COPD and the complexity of routine daily activities, the rehabilitation approach described in this paper combining physical exercise with cognitive training targeting attention, memory, executive functioning, and speed of processing may offer the flexibility to further improve daily function and reduce the risk of falls in patients with COPD beyond physical training alone. Notably, the cognitive training modality to be implemented in this study is distinct from the proposed dual task outcome measure, supporting the potential transfer of gains to a variety of daily activities.

Strengths

There are several strengths to this study. The physical training program and assessments were specifically designed to support feasibility and safety in the home environment. All participants will be provided with exercise training equipment (foot peddler, resistance bands, Fitbit, and pulse oximeter), which will improve safety and accessibility and standardize physical training and assessments. This study is novel as it provides a new approach to remote assessments of aerobic endurance (ie, foot peddler), functional outcomes, and cognitive assessment and training as part of a home-based pulmonary rehabilitation program for patients with COPD [27]. Our protocol may optimize not only accessibility but also outcomes in home-based pulmonary rehabilitation programs. The use of commercially available software programs (Fitbit, Physiotec, and BrainHQ) supports the future clinical translation of this work as these and other similar programs may be used by clinicians and patients looking to integrate cognitive-physical training into pulmonary rehabilitation programs. Furthermore, the chosen cognitive training platform (BrainHQ) has the largest evidence base and, to our knowledge, is the only brain training program that meets all the National Academy of Medicine criteria for cognitive training [29,30]. Our specific cognitive training protocol was designed in consultation with neuropsychology and cognitive

XSL•FO
RenderX

science experts to specifically target common areas of deficit among individuals with COPD.

Limitations

We also acknowledge that there are limitations to the design of this study. Given the small sample size, we will be unable to adjust the analyses for potential confounders such as medications (opiates, sedatives, or corticosteroids) or COPD exacerbations; however, these factors will be tracked throughout the study period to explore their influence on selected outcomes. This study will be conducted entirely remotely, and therefore, we are unable to prospectively measure specific tests of outcomes such as pulmonary function (ie, spirometry) or neural activity (ie, functional near-infrared spectroscopy). However, some of this information will be derived from chart review or will require future study. Furthermore, cognitive assessments will be completed independently at home, and differences in device or screen size (ie, computer vs tablet) may influence the results. Participants who do not have access to a suitable device will be provided with a tablet for the duration of the study. Owing to the nature of the training intervention and internet-based environment, blinding of participants and the exercise professional is not possible, thus creating a risk of bias. Furthermore, most of the physical training measures and intensity will be ascertained through self-report, which may not be as accurate as if they were captured electronically from the training devices.

Conclusions

A partly supervised, home-based, telehealth cognitive-physical training program may be an accessible intervention to improve cognitive function and further address dual-tasking abilities in people living with COPD. Evaluating the feasibility and effect estimates is a critical first step to inform future clinical trials evaluating this approach and its effects on physical and cognitive function, ADL performance, and HRQL.

Acknowledgments

The research team would like to acknowledge the collaboration of study participants and the clinical staff at the University Health Network and referral centers. They also thank Dr Mouna Attarha from Posit Science for assistance in designing the cognitive training and assessment protocols. This research is funded by the Breathing as One–Boehringer Ingelheim Canada or Canadian Institute of Health Research (CIHR) Institute of Circulatory and Respiratory Health Chronic Obstructive Pulmonary Disease Catalyst Grant Award through the Canadian Lung Association (BAO 176004). The trial is also partly supported by the Sandra Faire and Ivan Fecan Professorship in Rehabilitation Medicine and the CIHR Project Grants (PJM 179846 and PJT 183640). This study is sponsored by the University Health Network. The study sponsors had no role in the design of the study protocol and will have no involvement in the data collection process, data analysis, interpretation of the results, or manuscript preparation.

Authors' Contributions

DR and WDR conceived the study and participated in the design of the protocol and development of the intervention. DR, DSM, JLC, MBS, and WDR are the grant holders. SN and MIM helped with the coordination of the study under the direct supervision of DR. JS is responsible for the implementation of the study. DR, JS, and WDR helped draft this manuscript. DR, JS, ECP, SN, MIM, DSM, JLC, EH, RG, MHK, AL, DG, MBS, and WDR provided expert advice and reviewed the protocol. All the authors approved the final manuscript for submission.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Peer review report from the Chronic Obstructive Pulmonary Disease Catalyst Grant Award.

Abstract

Background: Children managed for asthma in an emergency department (ED) may be less likely to be hospitalized if they receive intravenous magnesium sulfate (IVMg). Asthma guidelines recommend IVMg for severely sick children but note a lack of evidence to support this recommendation. All previous trials of IVMg in children with asthma have been too small to answer whether IVMg is effective and safe. A few major questions remain about IVMg. First, it has not been tested early in the course of ED treatment, when the impact on hospitalization would be greatest. Second, the clinical impact of hypotension, a known adverse effect of IVMg, has not been well characterized in previous research. Third, no trials have compared different IVMg doses or serial serum magnesium (total and ionized) concentrations to optimize dosing, so the most effective dose is unknown. A large, conclusive, randomized, placebo-controlled clinical trial of IVMg might be challenging due to the need to enroll and complete study procedures quickly, a lack of understanding of blood pressure changes after IVMg, and a lack of pharmacologic information to guide the optimal doses of IVMg to be tested. Therefore, a pilot study to inform the above gaps is warranted before conducting a definitive trial.

Objective: The objectives of this study are to (1) demonstrate the feasibility of enrolling children with severe acute asthma in the ED in a multicenter, randomized controlled trial of a placebo, low-dose IVMg, or high-dose IVMg; (2) demonstrate the feasibility of timely delivery of study medication, assessment of blood pressure, and evaluation of adverse events in a standardized protocol; and (3) externally validate a previously constructed pharmacokinetic model and develop a combined pharmacokinetic/pharmacodynamic model for IVMg using magnesium (total and ionized) serum concentrations and their correlation with measures of efficacy and safety.

Methods: This pilot trial tests procedures and gathers information to plan a definitive trial. The pilot trial will enroll as many as 90 children across 3 sites, randomize each child to 1 of 3 study arms, measure blood pressure frequently, and collect 3 blood samples from each participant with corresponding clinical asthma scores.

Results: The project was funded by the National Heart, Lung, and Blood Institute (1 R34HL152047-2) in March 2022. Enrollment began in September 2022, and 43 children have been enrolled as of April 2023. We will submit the results for publication in late 2023.

XSL•FO
RenderX

Conclusions: The results of this study will guide the planning of a large, definitive, multicenter trial powered to evaluate if IVMg reduces hospitalization. Blood pressure measurements will inform a monitoring plan for the larger trial, and blood samples and asthma scores will be used to validate pharmacologic models to select the optimal dose of IVMg to be evaluated in the definitive trial.

Introduction

Background

Asthma is the most common chronic illness in childhood and a leading cause of pediatric hospitalization, disability, and health care–related costs [1]. The current standard management of acute asthma in children is defined in guidelines published in 2007 by the National Heart, Lung, and Blood Institute (NHLBI) and includes inhaled bronchodilators (albuterol and ipratropium), systemic corticosteroids, oxygen, and further treatment depending on response [2]. Although these guidelines have been broadly implemented, hospitalization remains a common outcome for children with asthma after emergency department (ED) treatment, ranging from 13% to 50% of all asthma visits among pediatric EDs nationally [3].

Intravenous magnesium sulfate (IVMg) has been used to treat asthma for more than 70 years [4,5] and may reduce hospitalization in children with asthma. However, its specific role in treating pediatric acute asthma is still unclear [6]. NHLBI asthma guidelines suggest that clinicians consider a 20-minute infusion of IVMg in children or adults as an adjunct for life-threatening exacerbations, or for severe distress after an hour of initial therapy. These guidelines do not suggest a specific dose but rather provide a broad 3-fold dose range of 25-75 mg/kg. Conflicting evidence prevents a definitive recommendation or direction for clinical implementation [2]. In a review of care delivered to children with asthma over 6 years in 7 EDs, 5774 (25.7%) of 22,499 children hospitalized for asthma received IVMg in the ED [7]. A meta-analysis of previous small trials suggests that IVMg given in the ED may reduce hospitalization in children by 30% [8]. Applying a 30% reduction in hospitalization to the remaining hospitalized children who do not receive IVMg in the United States could potentially avoid 16,500 hospitalizations each year, each at an average cost of US $3600 [9], producing direct cost savings of US $65 million yearly in addition to avoiding indirect costs of missed school and work.

In this project, we are conducting a pilot trial that will address the following knowledge gaps needed to conduct a conclusive trial to assess the impact of IVMg on hospitalization.

First, previous trials evaluated IVMg for acute asthma only in children refractory to initial treatment. Though IVMg is currently infrequently used in clinical practice in the ED to prevent hospitalization [10], earlier administration could have a greater effect on this important outcome. Administration early in the treatment course would better align with the NHLBI recommendation that IVMg be considered after the first hour of treatment [2]. Only 1 previous trial of IVMg with hospitalization as an outcome attempted to enroll children on arrival to the ED [11]. Before a large trial can determine the effect of early administration of IVMg on hospitalization, protocols to support the administration in the first 90 minutes of treatment should be tested and refined in a pilot trial setting.

Second, the safety of IVMg has not been well characterized in previous trials. Earlier small trials reported no significant adverse events (AEs) after IVMg but included too few children to conclude adverse effects were rare. In a study of 100 children who received a single dose of 50 mg/kg in an ED, 11 had hypotension after IVMg, though only 7 received any intervention, limited to an intravenous (IV) fluid bolus with normalization of blood pressure [12]. In a multinational survey of ED physicians, 24% reported hesitancy about using IVMg in children because of the risk of hypotension [10]. Collection of safety outcomes in a trial environment, including data collected after discharge from the ED, will allow enhancement and refinement of safety monitoring procedures for the future trial.

Third, the optimal dosage of IVMg in pediatric acute asthma is unknown [8]. Our current pharmacologic understanding of IVMg is insufficient to define which doses should be tested in clinical trials to carefully strike a balance between avoiding potential adverse effects and exploring maximal clinical effect. To safely explore thresholds of efficacy and safety in a large trial, we must fill gaps in the pharmacologic understanding of IVMg. To define the optimal dose of IVMg, safety and efficacy outcomes must be correlated with serum concentrations of magnesium in children receiving a range of IVMg doses.

Informative pharmacodynamic (PD) analysis requires a marker of respiratory status that can be measured reliably and repeatedly in all patients. The use of spirometry as an inclusion criterion in most previous trials [13,14] excludes most older patients in severe respiratory distress and also excludes children 4 years and younger by design, as they can rarely cooperate sufficiently to perform adequate spirometry. The Pediatric Respiratory Assessment Measure (PRAM; Table 1) is a clinical respiratory score that has been validated in children to be predictive of hospitalization [15,16] and to show a change in respiratory status after a bronchodilator [17]. A respiratory score such as

XSL•FO
RenderX

the PRAM is valuable because it allows repeated measurement in every patient, allows comparison of respiratory status between treatment arms, and can serve as a measure of respiratory status for PD modeling.

Table 1. Pediatric respiratory assessment measure.

Score	Suprasternal retractions	Scalene muscle contraction	Air entry	Wheezing	O_2 saturation, %
0	Absent	Absent	Normal	Absent	≥95
1	N/A[a]	N/A	Decreased at bases	Expiratory only	92-94
2	Present	Present	Widespread decrease	Inspiratory and expiratory	<92
3	N/A	N/A	Absent or minimal	Audible without stethoscope or silent chest with minimal air entry	N/A

[a]N/A: not applicable.

Objectives

The objectives of this study are to (1) demonstrate the feasibility of enrolling children in the ED with severe acute asthma in a multicenter, randomized controlled trial (RCT) of a placebo, low-dose IVMg, or high-dose IVMg; (2) demonstrate the feasibility of timely delivery of study medication to enrolled patients and assessment of blood pressure and associated AEs in a standardized protocol; and (3) externally validate a previously constructed pharmacokinetic (PK) model [18] and develop a combined PK/PD model for IVMg using magnesium (total and ionized) serum concentrations and their correlation with measures of efficacy (improvement in respiratory distress) and safety in children with severe acute asthma.

Methods

Study Overview

This pilot trial is a prospective double-blind, placebo-controlled trial of children 2-17 years of age with severe acute asthma. It was endorsed by the Pediatric Emergency Care Applied Research Network (PECARN) and is being conducted at 3 PECARN sites in Utah, Pennsylvania, and Ohio. The goal is to evaluate study procedures and gather the data necessary to plan a larger trial.

Study Population

Eligible participants are identified among children presenting to the ED for treatment of acute asthma. Specific criteria are listed in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- 2-17 years old
- Emergency Severity Index Triage acuity of 1 or 2
- Albuterol ordered to be administered in the emergency department (ED)
- A previous physician diagnosis of asthma confirmed by a licensed independent practitioner (ED attending, fellow physician, nurse practitioner, or physician assistant) in the ED who has spoken with the patient and family and reviewed the medical record
- Severe acute asthma, defined as a PRAM (Pediatric Respiratory Assessment Measure) score of 7 or greater as assessed by a treating physician at the time of screening using the study scoring instrument

Exclusion criteria:

- Positive pregnancy test in females of child-bearing potential (performed in all female potential participants 12 years and older) or known pregnancy (by a patient or parent report)
- Age-adjusted hypotension at presentation using age-based Pediatric Advanced Life Support parameters for systolic blood pressure in millimeters of mercury (children 1-10 years of age, systolic blood pressure (70 + 2×age in years) mm Hg; >10 years, systolic blood pressure <90 mm Hg) [19]
- Application of assisted ventilation before enrollment assessment (intubated, bilevel positive airway pressure, continuous positive airway pressure)
- Received IVMg within 24 hours before screening (by a parent, patient report, or medical record review)
- Enrollment assessment is 60 minutes or more after the start of ED treatment (start of first albuterol treatment)
- Previous enrollment in the same trial (by research staff review of trial records)
- Known severe renal impairment (by parent or patient report)

XSL•FO

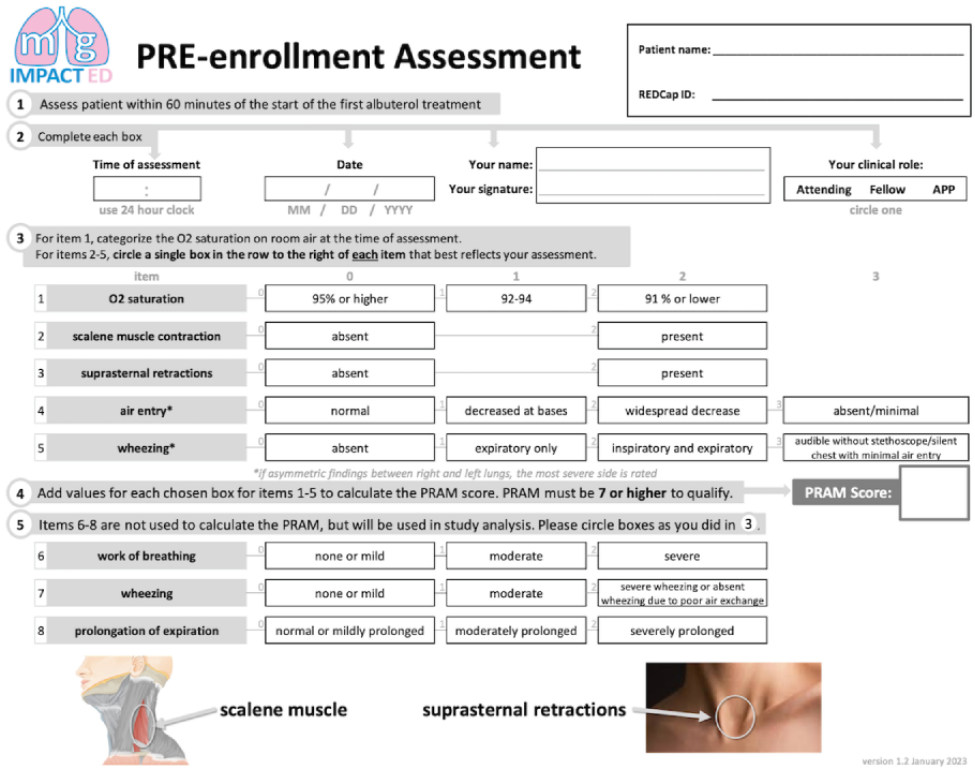
Study Procedures

Overview

Descriptions of protocol procedures in this paper reflect protocol specifications and do not reflect whether protocol deviations have occurred. Significant protocol deviations will be reported in future publications.

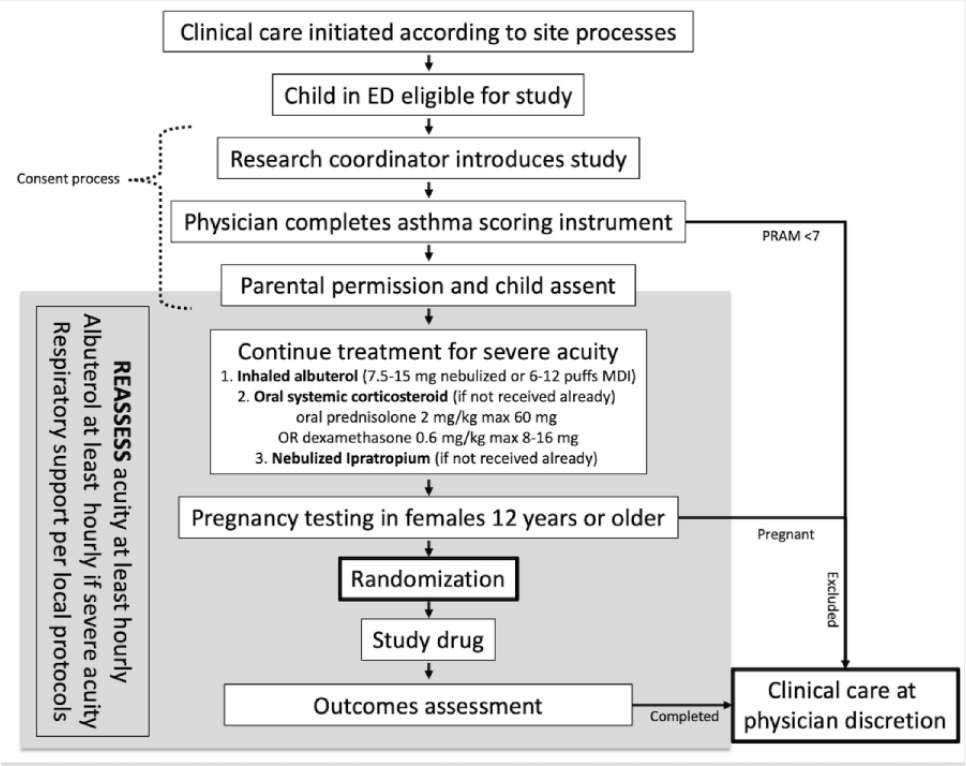
Screening Schedule



Research staff identifies children who present to the ED with acute asthma during screening hours maintained by each study site.

Screening and Enrollment

Research staff identifies children within the study age range who have physician orders to receive inhaled albuterol and are triaged at an Emergency Severity Index [20] acuity of 1 or 2. The research staff member approaches the treating physician to determine if the child is being treated for asthma, and if the child meets other inclusion criteria. The physician examines the child and completes an asthma scoring instrument that generates the PRAM score (Figure 1). If the PRAM is high enough, research staff review exclusions with the clinician, and if no exclusions apply, they introduce the study to the patient and family.



If the PRAM score is 7 or higher, the research staff approaches the family for consent (including parental permission for all children and child assent for children 7 years and older) and enrollment. Consent documents are prepared in Spanish and English, but patients whose primary language (or the language of their guardian) is not English or Spanish are included if a professional interpreter can communicate the content of consent documents to the family and discuss study consent. After consent is complete, the child receives standard asthma treatment according to the study protocol (Figure 2). After consent, females 12 years and older without a reported pregnancy provide a blood or urine sample for qualitative pregnancy testing and are excluded from receiving the study drug if positive. Clinical staff reports pregnancy results to patients and families following institutional policies and state regulations.

XSL•FO
RenderX

Figure 2. Study asthma treatment protocol. ED: emergency department; MDI: metered dose inhaler; PRAM: Pediatric Respiratory Assessment Measure.

Randomization

The investigational pharmacy at each institution prepares doses in a manner to maintain allocation concealment for all ED staff. A sequential randomization scheme with random-sized blocks stratified by each site was prepared in advance by a study statistician and entered into a Research Electronic Data Capture (REDCap) [22] database. After informed consent is completed, the physician requests the study drug from the pharmacy staff member, who then prepares and delivers the assigned dose for administration. The subject is considered enrolled when the earlier of 2 possible events occurs, that is, the REDCap randomization module is invoked to generate a randomization code for the patient, which code will then be relayed to the pharmacy, or the pharmacy dispenses a study drug dose based on the sequential randomization scheme. Nursing staff administers the dose regardless of the time since the initiation of treatment.

Study Drug Administration

Acquisition

The specific study agent used in this pilot trial is magnesium sulfate in water for injection, a sterile, nonpyrogenic solution of magnesium sulfate heptahydrate in water. The study agent is acquired by each hospital's research pharmacy from a common manufacturer as a solution of magnesium sulfate in water at 80 mg/mL. This agent is the commercially available preparation of IVMg and is shipped directly from the manufacturer to each study hospital pharmacy.

Preparation, Storage, and Labeling

Doses for each IVMg arm are prepared in an identical manner by drawing a specified volume of IVMg from the commercial container using a sterile technique and mixing it in a syringe or a polyvinylchloride container with a specified volume of sterile water. For the 50 mg/kg arm, this is accomplished by mixing 25 mL of IVMg (80 mg/mL) with 15 mL of sterile water for a final concentration of 50 mg/mL and a volume of 40 mL. For the 75 mg/kg arm, this is accomplished by mixing 37.5 mL of IVMg (80 mg/mL) with 2.5 mL of sterile water for a final concentration of 75 mg/mL and a volume of 40 mL. For the placebo arm, 40 mL of 0.9% sodium chloride solution are drawn into a polyvinylchloride container identical in appearance to the containers used for the IVMg arms.

Each prepared dose is labeled according to the sequential randomization scheme and stored according to the local pharmacy procedure. Either the pharmacist draws equivolumetric dosages (1 mL/kg, with maximum of 40 mL) from the prepared vials, or the pharmacist delivers the full dose to the bedside study team with instructions for the volume to be delivered.

Dosing Arms

Enrolled subjects are randomized to 1 of 3 arms:

1. IVMg 75 mg/kg arm: 75 mg/kg (maximum 3 gm, 40 mL) infused over 20 minutes through a peripheral IV catheter
2. IVMg 50 mg/kg arm: 50 mg/kg (maximum 2 gm, 40 mL) infused over 20 minutes through a peripheral IV catheter
3. Placebo arm: 1 mL/kg (maximum 40 ml) of normal saline over 20 minutes through a peripheral IV catheter

Dose Modification for Potential Toxicity

Clinicians are not to administer IVMg to enrolled subjects outside of the study protocol until study outcomes are determined 2 hours after the start of the infusion. The half-life of IVMg is approximately 2 hours [18]. Repeated-dose protocols

XSL•FO
RenderX

in an intensive care unit setting that gave as much as 125 mg/kg IVMg to children with asthma over 2 hours produced no hypotension or other serious adverse effects [23]. Because of this margin of safety, open-label IVMg 50 mg/kg can be administered safely 2 hours after the study infusion under strict study monitoring protocols without the need for unblinding.

Unblinding Procedures

If a patient's asthma symptoms deteriorate before 2 hours, clinicians are instructed to assume that the subject received the highest dose of active study drug and that they can give IVMg at a dose as high as 50 mg/kg open-label as soon as 120 minutes after the start of initial study infusion without unblinding, which would result in a maximum of 125 mg/kg over 2 hours if the patient is in the 75 mg/kg arm. Other interventions are given as needed in response to the patient's condition. If unblinding is considered necessary, allocation information can be obtained from the site pharmacist, and unblinding is considered a study protocol violation.

Discontinuation of Study Drug

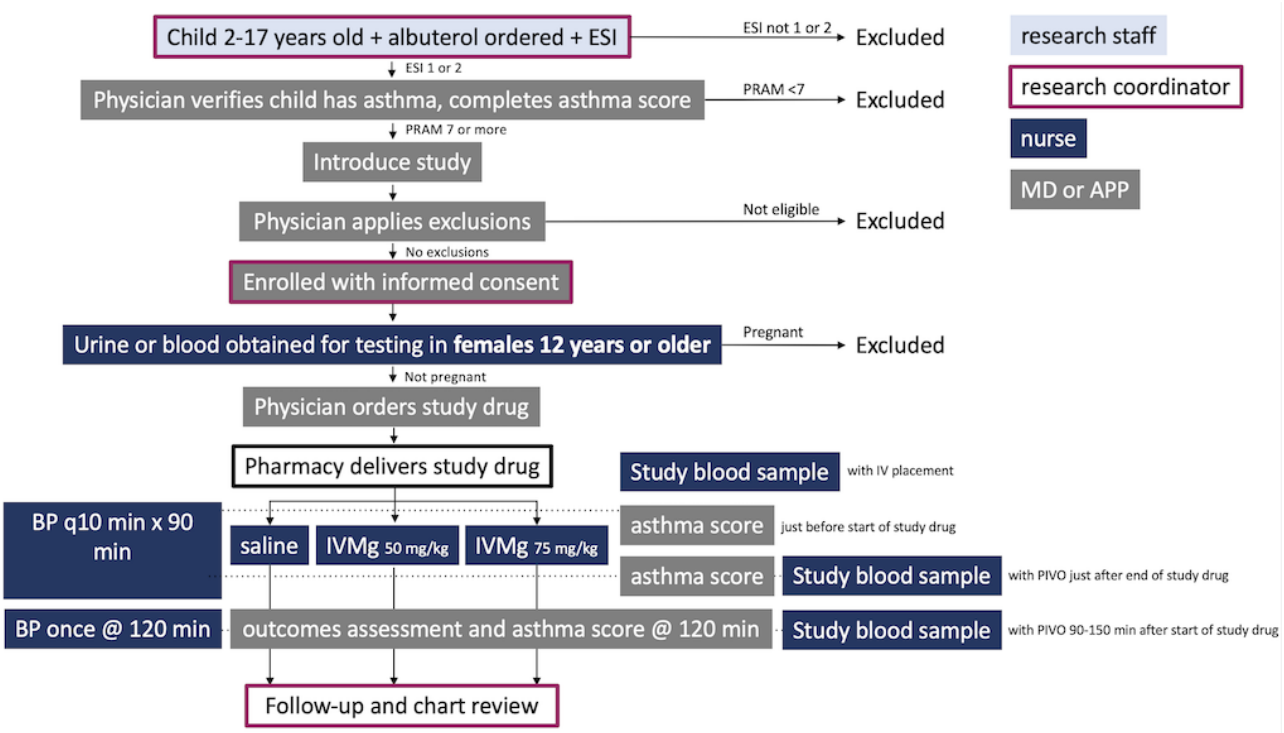
If hypotension is measured and perfusion is impaired (see Data Collection section), study infusion is stopped, clinicians give a 20 mL/kg bolus (maximum 1 L) of isotonic IV fluid and provide other interventions at the clinician's discretion. If perfusion is normal, study drug infusion is continued at the same rate.

Withdrawal From Study

Subjects are observed in the ED for a minimum of 2 hours after the start of study infusion unless they require transfer to the intensive care unit due to escalation of therapy. Parents can withdraw permission for their children to continue in the study at any time. If a parent or child chooses not to continue in the study during study infusion, the infusion of the study drug is stopped. All patients who withdraw are followed for AEs and other symptoms.

Data Collection

Baseline Data



The research staff who approaches the patient for enrollment gathers baseline information from the child's parent or guardian, including age, sex, race, ethnicity, chronic asthma control status and medications, treatments received for the current illness before ED presentation, and chronic medical conditions. The research staff member also collects data from the treating ED team, including the following items:

- Scoring: The treating physician completes a clinical asthma scoring instrument that includes the components of the PRAM immediately before, 20-40 minutes after, and 2 hours after the start of study infusion.
- Blood samples: They are drawn by clinical staff through the IV before the start of study infusion, then through the IV using a PIVO blood-drawing device (BD Medical) 20-40 minutes and 90-150 minutes after the start of study infusion. When the blood draw is not possible using PIVO, blood is drawn through the existing peripheral IV if possible.
- Blood pressure: It is measured by the study staff using an automated device just before the start of study infusion (within 10 minutes before the start of infusion), every 10 minutes (±4 minutes) for 90 minutes following the start of infusion, and once more 2 hours (±10 minutes) after the start of study infusion.
- Perfusion: If age-adjusted hypotension is detected, a treating clinician, which could be the treating nurse, completes a standardized assessment of perfusion based on World Health Organization criteria [24]. This assessment is then reviewed with the research staff. If perfusion is impaired during study drug infusion, study drug infusion is stopped.
- Timing: The research staff records time points of screening, identification, consent, and randomization, as well as times of infusion and blood draws, using the nurse's documentation.
- Disposition: The research staff approaches the treating physician 2 hours after the start of study infusion and collects the stated disposition for the patient (hospitalization, discharge home, or uncertain), at which point study procedures are finished for the ED visit (see Figure 3).

Plasma is separated by centrifugation, transferred to a separate vial, stored at -80 C, and shipped to the study laboratory at the University of California, Davis

XSL•FO
RenderX

Figure 3. Schedule of Activities. APP: Advanced Practice Provider; BP: blood pressure; ESI: Emergency Severity Index; IVMg: intravenous magnesium sulfate; MD: physician; PRAM: Pediatric Respiratory Assessment Measure.

Follow-Up Assessments

For patients discharged to home, study staff calls or texts the family in 12-48 hours and in 1 week (5-10 days) to determine if they returned to any ED, the outcomes of any return visit, and to assess for AEs. All data points initially recorded on paper forms are securely stored and then entered into a REDCap database created by the Emergency Medical Services for Children Data Center (EDC) at the University of Utah.

Medical Record Review

Study staff reviews the electronic medical records of all subjects 1 week after enrollment to determine the actual patient disposition and hospital course.

Instruments

The PRAM is outlined in Table 1 and section 3 of Figure 1.

Data Analysis

Specific Aim Analyses

Specific Aim 1

Demonstrate the feasibility of enrolling children in the ED with severe acute asthma in a multicenter RCT of a placebo, low-dose IVMg, or high-dose IVMg.

For the primary study hypothesis, we will identify, consent, and enroll 90 patients in 7 months or less. Our experience with previous trials within PECARN suggests a 7-month enrollment period is adequate to reach a stable rate of enrollment and demonstrate trial procedures. Because the future large RCT will need multiple sites for adequate enrollment, this pilot trial is testing trial procedures at 3 sites with various patient volumes, research infrastructures, and patient populations. Based on the projected 8% of asthma visits in the PECARN Registry that would qualify based on previous volumes at study sites, we anticipated that approximately 360 patients would qualify for the study during the 7-month study period, allowing for study completion even if only 25% of qualifying patients were enrolled. The study is expected to end once 90 patients are enrolled, even if this occurs in less than 7 months, but will not enroll for more than 9 months. An enrollment rate of 90 patients in 7 months for 3 sites would be sufficient to conduct a future trial powered to detect a difference in hospitalization, enrolling 800 patients in 23 months at 10 sites. A slower rate will prompt an adjustment of future trial length.

Specific Aim 2

Demonstrate the feasibility of timely delivery of study medication to enrolled patients and assessment of blood pressure and associated AEs in a standardized protocol.

Our first objective in this aim is to assess our ability to administer the study drug within 90 minutes after the start of asthma treatment. Timely delivery of study drug is considered feasible with current study procedures if 90% of study subjects received study medication within this time frame, giving time for study intervention to affect hospitalization and making hospitalization an outcome appropriate for the future trial. Delivery of study drug to less than 90% of study subjects indicates a need to further refine study procedures before the larger trial. We will optimize the delivery of study drug in the future trial by examining the impact of factors in the pilot trial that may influence study drug delivery. Factors associated with time to first study drug administration, administratively censored at 180 minutes, will be explored using Cox proportional hazards modeling. The Cox models are intended to identify features

XSL•FO
RenderX

requiring additional planning to promote timely delivery rather than to find statistical significance.

Our second objective in this aim is to inform a safety monitoring plan for the future trial that is focused, clinically feasible, and effectively protects patient safety. We intensively monitor blood pressure (every 10 minutes) during the pilot trial for 90 minutes after the start of study drug infusion (see Data Collection section) and record all AEs from the time of randomization until the follow-up call approximately 1 week after enrollment. All serious, unexpected, and related AEs that are unresolved at the time of the patient's termination from the study or discharge from the hospital will be followed by the Clinical Center investigators until the events are resolved, the subject is lost to follow-up, the AE is otherwise explained or has stabilized, or 12 months have passed from the time of last study dose.

We consider the procedures of the pilot trial feasible for the larger trial if we can collect 90% or more of planned data points related to blood pressure. This collection rate would indicate that this data gathering does not pose an undue burden on the teams providing clinical care to study patients. We will use the degree to which data points are collected in coordination with the frequency and timing of blood pressure changes, the frequency and degree of age-adjusted hypotension and poor perfusion, interventions delivered to patients with measured hypotension, and other recorded adverse effects to devise a monitoring plan for the future trial that captures all AEs and is maximally feasible.

Specific Aim 3

Externally validate a previously constructed PK model and develop a combined PK/PD model for IVMg using magnesium (total and ionized) serum concentrations and their correlation with measures of efficacy (respiratory distress) and safety (adverse effects) in children with asthma.

We will use these data to validate a PK/PD model that will guide dosing for the large trial. Ideal external validation of our previous PK model requires blood samples from a minimum of 30 patients who receive IVMg at sites outside of the site used to derive the PK model [18]. For an enrollment of 90 subjects, we anticipate approximately 40 subjects to meet this criterion. Data from the samples collected in this study will be used to externally validate our previously developed population PK model and, if needed (ie, median prediction error >15% or <−15%; median absolute prediction error >30%, calculated as the median of the values obtained from equations 2 and 3 for all collected samples), update the model with this larger sample size. Concentration analysis, PK model validation, and updating our previous PK model (if needed) will use similar approaches as we have previously described [25]. Notably, this includes accounting for endogenous magnesium concentrations (Equation 1) assumed to be at steady-state before IVMg administration.

Once the PK model has been confirmed (or refined, if necessary), we will incorporate PRAM scores and other measures of respiratory distress to develop a population PK/PD model describing the relationship between IVMg systemic exposure and clinical response. Additionally, we seek to construct a PK/PD model describing the association between IVMg systemic exposure and AEs, including hypotension. PK/PD modeling will use NONMEM software (version 7.3, ICON Development Software). The first-order conditional estimation with the interaction method will be used throughout model building and evaluation. Model selection will be based on parsimony, objective function value (OFV), and visual diagnostic plots. Direct and indirect approaches to incorporating PD will be tested. After determining the base model, covariates will be tested for impact on PD using a forward inclusion (P<.05) and backward exclusion (P<.01) method. Covariates will be added to the model in a stepwise fashion and allowed to remain in the model if covariate inclusion decreases the OFV by at least 3.84 and its exclusion increases the OFV by at least 6.63. Once the final PK/PD model is determined, we will evaluate model accuracy and robustness through bootstrapping methods and visual predictive checks.

Dose-exposure response data simulated (1000 data sets) from the PK/PD model will be used to select doses used in the future large trial. Specifically, we will use the simulated data sets to determine the dose at which 10% of participants are expected to have adverse effects (ie, hypotension) and establish an upper limit of dosing for the future trial. Importantly, this analysis will allow us to evaluate the role of an upper dose limit (ie, the 2 or 3 gm maximum dose, regardless of patient weight) in preventing hypotension. Similarly, we will use the simulated PK and PD data to define doses expected to yield 20%, 40%, and 60% reductions in PRAM and hospitalization, respectively. We plan to target the use of these doses in the future study as the doses that are expected to maximally reduce hospitalization.

If we are unable to build a robust population PK/PD model using NONMEM, we will evaluate correlations between PK and PD using Pearson correlation analyses in GraphPad Prism version 6.05 (or later) software. In this scenario, the population PK model will be used to identify doses that generate simulated concentration data within the target therapeutic range established by the correlation analyses.

Per the PECARN Registry, approximately one-fourth of children receiving IVMg for asthma weigh more than 40 kg, the weight at which a 2 gm (50 mg/kg) or 3 gm (75 mg/kg) dose is reached. As a result of this maximum, children weighing more than 80 kg (low-dose arm) or 120 kg (high-dose arm) would implicitly have an intended dose less than 25 mg/kg IVMg, below the lower end of the range of doses in the guidelines. As a drug that exhibits first-order kinetics, delivering IVMg with an arbitrary maximum may reduce the benefit of the drug in a substantial portion of children. We will use the newly developed PD model and validated PK model to determine if patients above 40 kg have less improvement in clinical score and if any associations found are related to changes in serum values.

Sample Size Calculations and Statistical Power

Sample size for this pilot trial was driven by the first aim, which is to demonstrate the ability to enroll children severely ill with asthma in an RCT. The second aim is focused on the feasibility of study drug delivery and the collection of safety data, and the third aim is focused on pharmacologic modeling for dose

XSL•FO
RenderX

estimation to be used in the large trial to follow this pilot trial. All 3 aims of the pilot trial are focused on generating data to inform the structure of the larger trial to follow, and accordingly, they do not have sample size calculations or associated calculations of statistical power.

Protection of Human Subjects

Ethics Approval

A single investigational review board (IRB) was used for this study. Study sites relied on the University of Utah IRB to act as the IRB of record (IRB #00104082). The EDC and each clinical center obtained IRB approval before participating in the study.

Risk Benefit Assessment

Asthma is a leading cause of hospitalization in children and incurs substantial costs for the health care system [1]. Previous trials of IVMg in children with asthma were too small to conclude whether IVMg can reduce hospitalization in children with asthma. To date, these small trials of IVMg in acute asthma have not been followed by larger, conclusive trials. Comparison to placebo in a large trial is needed to evaluate the effect of IVMg on hospitalization.

Risks of IVMg have been described in previous literature but not sufficiently to dismiss them as minor. This study will help ensure that monitoring for children enrolled in future trials is feasible and complete.

Considering the potential benefits and the anticipated risks, the research outlined in this proposal will provide important evidence to guide the care of children with asthma. By clarifying the efficacy, safety, and dose of IVMg for children with asthma, these results will influence the care provided to severely ill children with asthma nationally and globally through inclusion in NHLBI guidelines and other guidelines such as those developed by the Global Initiative for Asthma.

Population to Be Studied

The enrollment of patients in this trial is expected to reflect the population of children with severe acute asthma at each of the enrolling sites with respect to age, sex, race, and ethnicity.

Data and Safety Monitoring Plan

Data Safety Monitoring Board (DSMB)

Each clinician caring for a study patient had primary responsibility for the safety of the individual subjects under his or her care. A DSMB was established before the initiation of enrollment. The DSMB consisted of 3 members, 1 of whom had statistical expertise and 2 of whom had experience in emergency medicine. All individuals had experience in the conduct of randomized clinical trials and had no direct association with the clinical sites in the trial or other conflicts of interest that would interfere with their objectivity. We did not anticipate having sufficient interim data during the trial for the DSMB to reach conclusions regarding efficacy or safety, though safety data were considered in interim analysis. The DSMB is responsible for approval of the final study design, reviewing and analyzing the progress of the study, monitoring the safety of the study treatments (as outlined below), and reviewing reports of data quality. The DSMB met before the first site was activated for enrollment and again after approximately 30 subjects were enrolled. The DSMB, or study principal investigator (PI), had the power to request additional meetings. The DSMB has the power to halt the study if safety reasons exist.

Study-Specific AE definitions

Hypotension is defined as any systolic blood pressure (mm Hg) meeting the following age-specific norms [19]:

1. Children 1-10 years: <70 + (age in years × 2)
2. Children >10 years: <90

Measured hypotension without associated symptoms is categorized as a mild AE; the presence of symptoms is categorized appropriately based on the degree of impairment of activity.

A serious AE is defined as any experience that results in death, is life-threatening, results in prolongation of existing hospitalization, results in a permanent disability, results in congenital anomaly/birth defect, or any other event that, based upon appropriate medical judgment, may jeopardize the subject's health and may require medical or surgical intervention to prevent one of the other outcomes listed in this definition.

Investigational New Drug Application Information

Investigation of IVMg in this study is supported and supervised by the Food and Drug Administration (FDA) through Investigational New Drug Application No. 133781.

Study Training

A formal training program for investigators and research staff was held before the start of enrollment. The training covered regulatory topics, including applicable drug regulations and training in good clinical practice. The training provided in-depth explanations regarding study procedures, clinical care, AE reporting, data entry procedures, quality assurance, site monitoring, and the informed consent process. A manual of study operations was created and provided to each site investigator before the start of enrollment. The manual detailed specific information about the study procedures, regulatory information, safety reporting, and other necessary information. Updates and revisions to the manual were made available electronically. The EDC, in collaboration with the study PIs and clinical coinvestigator (MDJ, JJZ, and Dr Shihabuddin), was the main contact for study-related questions.

Before the start of enrollment, lead investigators and each site's research coordinator, along with EDC staff, met virtually or in person for a training session. Each site investigator instructed the ED physicians at their home institutions about the study procedures, provided training on the PRAM score, served as a local advocate and champion for the study, and answered questions as they arose. Throughout the study, the study investigators and research coordinators have at least monthly scheduled telephone conference calls or webinars for all study personnel and more frequent group communications, as necessary. BD Medical conducted training on the use of PIVO

XSL•FO
RenderX

with blood-collection staff before subject enrollment at each site.

Monitoring of the research activities conducted during the pilot trial is supported by quality assurance visits conducted regularly by the nodal administrators of the involved PECARN sites, including regular assessment of support and funding for study effort and preparation for monitoring by the EDC and other data regulatory bodies, including the Food and Drug Administration. Each quality assurance visit is followed by a joint discussion with the site PI and study staff to define isolated, structural, or study-related barriers to study success.

Public Use Data Set

After subject enrollment and follow-up have been completed, the EDC will prepare a final study database for analysis. A releasable database will be produced and completely deidentified in accordance with the definitions provided in the Health Insurance Portability and Accountability Act (HIPAA). Namely, all identifiers specified in HIPAA will be recorded in a manner that will make it impossible to deduce or impute the specific identity of any patient. The database will not contain any institutional identifiers.

The EDC will also prepare a data dictionary that provides a concise definition of every data element included in the database. If specific data elements have idiosyncrasies that might affect interpretation or analysis, this will be discussed in the dictionary document. In accordance with policies determined by the investigators and funding sponsors, the releasable database will be provided to users in electronic form.

Results

The project was funded in March 2022, began enrollment in September 2022, will stop enrollment no later than the end of May 2023, and we expect to submit results for publication in late 2023.

Discussion

Overview

The study design for this pilot trial mirrors the design that we expect to use in the larger, conclusive trial. The future trial will be powered to evaluate the effect of bolus IVMg on hospitalization and will be conducted at more sites, while the pilot trial is designed to demonstrate feasibility and collect safety and pharmacologic data needed to optimize the design of the future trial. In this pilot trial, we seek to shift current research paradigms regarding the application of pharmacologic principles to pediatric clinical trials. More pharmacologic rigor in trials which include children would result in improved pharmacotherapy for children. In this project, we incorporated 3 key related innovations that improve our ability to integrate pharmacologic principles into the future large trial, and pediatric clinical trials in general.

First, we implement improved collection of study blood samples with less pain using a clinical device, which circumvents the need for repeated venipuncture for blood samples. Medication dosages used in children generally rely on prescribing data derived from adults, in small trials, or by group consensus [26]. Even when medications are tested in children in a trial, inadequate consideration of dosing is the most common reason a trial fails [27]. Defining appropriate pediatric doses within a trial requires repeated serum samples. Historically these samples were collected using repeat venipuncture to measure serum concentrations to inform PK models. This was how samples were collected during routine clinical care to inform the model we previously constructed using retrospective clinical data [18]. Pain and distress are the most common reasons for a child to reject participation in a trial, and children commonly experience pain and distress during venipuncture [28]. As a result, many studies do not collect the PK data needed to define dosing, and most previous trials of IVMg in children did not obtain serum samples. The 3 trials that obtained samples obtained only 2 per subject [13,14,29], insufficient for robust pharmacologic analysis or modeling. This current state of dose planning in trials involving children presents a pressing need to identify innovative strategies to collect serum samples from children while avoiding the pain and distress of venipuncture. The PIVO device is currently used clinically to facilitate repeat blood draws without repeat venipuncture, but it is not widely used in clinical research aside from a prospective study we conducted to validate our PK model [25]. As expected from our previous single-site study, we expect that use of the PIVO device at all sites in the pilot trial will reduce harm to children who participate in the trial, increase acceptability to children and parents (35/50, 70% of eligible children were enrolled in our previous study), and result in higher sample collection rates than expected with repeat venipuncture or drawing blood from the existing IV (29/35, 83% with 3 samples in our previous study using PIVO vs 97/308, 31% in previous PECARN studies).

Second, we incorporate trial optimization and dose finding in pediatric asthma guided by PK/PD modeling. Previous trials of IVMg in children with asthma in the ED did not use pharmacologic principles to select an optimal dose for evaluation. Though pharmacologic principles have been used to select dosages for many trials in children and adults, our application of PK and PD methods to the study of pediatric asthma in the ED is novel. Our team's preliminary studies in the ED demonstrated our ability to collect and analyze pharmacologic data, and we used these data to select doses for the pilot trial with maximal rigor. We will use the PIVO device to enable the collection of repeat serum samples, and we will use the data from our samples to integrate and refine our PK and PD models to optimize the doses we select for the future large conclusive trial.

Third, we evaluate early administration of intensive asthma treatment in a trial setting. Previous trials did not attempt to deliver the study drug to children with asthma early in the ED treatment. This reflects an outdated clinical paradigm of pediatric acute asthma treatment based on administering intensive treatments only when initial treatments have been ineffective. Though this is generally how care delivery is outlined in clinical guidelines published in 2007 [2], subsequent evidence supports the administration of continuous beta-agonists [30], steroids [31], and IVMg [32] *as early as possible for patients with severe illness*. Improving the timeliness of

XSL•FO
RenderX

treatment delivery is a major focus of quality improvement in the ED care of children with asthma [33,34]. Early administration of intensive treatment to children with asthma in this project is a novel application of high-quality clinical care delivery in a trial setting.

Previous trials of IVMg are insufficient to guide the clinical use of IVMg. The equipoise needed to study the effect of IVMg versus placebo on hospitalization in a large clinical trial is illustrated by a combination of possible but uncertain clinical benefits for ill children, variation in clinical use, lack of consensus regarding clinical benefit, and evidence gaps from previous trials. IVMg is inexpensive, readily available, and widely used in current clinical settings, but it lacks evidence to guide its current use for children with asthma.

Limitations

A large trial in children severely ill with acute asthma, like other clinical trials in acutely ill children, is at risk of low patient accrual if not properly planned and conducted [26], including the risk that physicians may hesitate to enroll patients being randomized to either study therapy or placebo. With this trial, we will further the previous expertise of PECARN in conducting research on severely ill children. The trial outlined in this proposal represents a novel challenge for this network by requiring rapid enrollment after patient arrival, providing an opportunity to understand and manage these risks and challenges in the future trial.

Parental consent may be a barrier to enrollment, although consent in previous trials of children with acute respiratory illness conducted in PECARN has been obtained at rates of approximately 50% [35]. This pilot trial is structured to allow enrollment of our sample size during our 7-month study window even if only 25% of the estimated number of eligible patients consented and enrolled, though the number of patients eligible for enrollment could differ due to episodic variations in asthma illness that cannot be controlled or anticipated.

This pilot study anticipates 3 blood draws per patient: 1 with IV placement and 2 from the IV after infusion of study drug. Repeat blood draws from an IV avoid additional venipuncture but are at risk for failure or loss of the IV line, which would result in fewer than anticipated serum measurements. In a previous study of IV benzodiazepines conducted in PECARN [36], 64% (197/308) of patients successfully had multiple blood draws from a single IV (internal data). During preliminary study at 1 of the study sites [25], the PIVO vascular access device for IV blood draws allowed 2 consecutive blood draws from a peripheral IV in 90% of patients and 3 consecutive blood draws in 83%, which was adequate for trial procedures.

Conclusions

IVMg has the potential to improve the outcomes of ED treatment for children with severe acute asthma but requires further evaluation of its efficacy, safety, and optimal dosage in a robust pediatric trial setting. More broad and standardized use of IVMg, if effective, may reduce hospitalizations and related health care costs for children and would be cost-effective. An economic analysis of children with asthma at 2 hospitals concluded that the use of IVMg reduced costs by 28% and increased quality-adjusted life years [37]. If IVMg is found to not be effective in a well-powered clinical trial, its use could be appropriately guided and restricted by the trial's results, future investigations can focus on other therapies, and these findings should be included in institutional and national asthma guidelines. This pilot trial will provide important information to guide a larger, conclusive trial that can fully evaluate the effect of IVMg on hospitalization of children with severe acute asthma.

Acknowledgments

This study is supported by the grant awarded to the University of Utah (principal investigator MDJ) by the NHLBI in response to application 1 R34 HL152047-01.

PECARN is supported by the Health Resources and Services Administration (HRSA) of the US Department of Health and Human Services (HHS), in the Maternal and Child Health Bureau (MCHB), under the Emergency Medical Services for Children (EMSC) program, through the following cooperative agreements: EMSC Data Center (EDC)-University of Utah, GLEMSCRN- Nationwide Children's Hospital, PRIME-Primary Children's Hospital, Children's Hospital of Philadelphia and University of California at Davis Medical Center. This information or content and conclusions are those of the authors and should not be construed as the official position or policy of, nor should any endorsements be inferred by HRSA, HHS, or the US Government. Abstract

Background: The World Health Organization recommends pre-exposure prophylaxis (PrEP) for all populations at substantial risk of HIV infection. However, at-risk women very rarely use PrEP in France—this represents a critical issue among migrant women sex workers (MWSWs). Previous studies on PrEP use among women sex workers or migrants focused on individual or social determinants of motivation. However, operational studies in real-word settings using a holistic population approach to maximize PrEP adherence among MWSWs are lacking.

Objective: FASSETS (ie, "Favoriser l'Accès à la Santé Sexuelle des Travailleuses du Sexe"; English: "facilitate the access to Sexual Health in women sex workers") is a participative, multilevel, mixed methods study aiming to improve global knowledge of and access to sexual health care and PrEP among MWSWs through targeted empowerment strategies.

Methods: This study comprises several phases: (1) phase 1: an initial qualitative study combining semistructured interviews, informal interviews, and participative observations will be performed among MWSWs, local community nongovernmental organizations, and institutions providing sexual reproductive health services to identify the determinants of PrEP access among MWSWs and for respondent-driven sampling (RDS); (2) phase 2: the size of the hidden MWSW population is estimated in Marseille through capture-recapture (the RDS survey will serve as "recapture"); (3) phase 3: a longitudinal cohort will be formed through RDS to represent the MWSW population with a goal of 150 inclusions—this cohort will be followed up for 12 months, and sequential questionnaires exploring medical history; knowledge of sexual health, HIV, and sexually transmitted infections; migration route; and current living conditions will be administered at inclusion (month 0) and months 3, 6, and 12 to measure the following interventional phase's outcomes; and (4) phase 4: an interventional study with community empowerment actions

XSL•FO
RenderX

about sexual health and PrEP will be conducted with community health workers; standardized questionnaires and semistructured interviews, observations, and focus groups will highlight MWSWs' experiences with empowerment resources, concerns about sexual health, and especially PrEP use or uptake, and we will evaluate whether and how community-adapted empowerment actions conducted by community health workers are effective in increasing access to sexual health, prevention and screening of sexually transmitted infections, and PrEP knowledge and access among MWSWs.

Results: Recruitment commenced on March 1, 2022. We estimate the follow-up period to end on September 30, 2023.

Conclusions: This multiphase study will provide robust evidence about the magnitude of the MWSW population in Marseille (the second largest town in France) and their current conditions of living, access to and knowledge of sexual health, and PrEP access. Using a mixed methods analysis, we will investigate whether individual and collective community health empowerment approaches can facilitate access to PrEP and its initiation, use, and adherence in this vulnerable population.

Introduction

In contrast to the population of men who have sex with men, where HIV incidence has decreased owing to pre-exposure prophylaxis (PrEP—taking antiretroviral drugs to prevent HIV infection), estimates of HIV incidence have not decreased in migrant populations in France and other European countries [1,2]. Indeed, the highest incidence of HIV infection has been currently reported in migrants in France [2]. Moreover, when living with HIV, migrants also tend to be diagnosed later than nonmigrants [3,4]. In this context, a recent French study has shown that a majority of migrants (58%) contracted HIV within 6 years after arrival [5], confirming previous results showing that migrants living with HIV in Europe frequently contracted the virus post migration [6-8]. In this French study, HIV acquisition after migration was linked to short or transactional partnerships and the lack of a residence permit [5]. These results highlight the economic and social determinants of HIV exposure in this population. Another study showed that in France, the majority of migrants do not know about PrEP as a tool for HIV prevention [9].

HIV prevalence among cis- or transgender women engaged in transactional sex (women sex workers [WSWs]) is substantially higher than that in similarly aged women worldwide [10,11]. Consequently, migrant WSWs (MWSWs) are at a particularly high risk of HIV infection, and progress toward the global target of HIV elimination will not be possible without interventions and programs aimed at them.

Previous studies on HIV prevention programs have specifically targeted WSWs, and PrEP has emerged as a potentially effective option for HIV prevention in this population, with most studies being performed in transitional countries [12]. PrEP is highly effective in reducing HIV incidence in this population with appropriate individual compliance [13]. Unfortunately, 2 PrEP trials among cisgender women in Africa were stopped early due to suboptimal adherence [14,15]. The subject of adherence and its determinants is of tremendous importance in this population [12]. As with HIV risk factors, determinants of PrEP use in WSWs arise from multiple social and biological factors [9,14,16]. MWSWs face structural factors associated with a precarious immigration status, migration, and occupation-related marginalization [11]. A systematic review among WSWs has stressed the need for comprehensive care in order to increase the use of and adherence to PrEP [12,17]. However, few studies have investigated how to implement community-based interventions to promote PrEP access and health equity within this vulnerable population [11]. Indeed, there is a need to develop interventions with a holistic approach, including specific clinics and social services [12,18]. Another key element is to implement a prevention intervention based on community empowerment, in which MWSWs take collective ownership of knowledge of and resources about sexual health [19].

In France, as in other European countries and the United States, women represent a minority of PrEP users (less than 3%) [20-22]. Marseille is France's second largest city and one of the poorest (with 200,000 people living with less than €1000 [US $1086.26] per month) located on the Mediterranean coast [23]. In 2018, overall 12% of Marseille's population (192,330 inhabitants) was born abroad and statistically considered a migrant population with 28% of them born in northern Africa and 14% of them born in sub-Saharan Africa [24]. These figures do not take into account undocumented migrants. Among 2197 people consulting for PrEP at the 10 medical centers for sexual health and prevention (managed by the departmental council of the Bouches du Rhône—an area of Marseilles and its suburbs) between 2016 and 2022, only 7 were MWSWs [25].

The objectives of the FASSETS (Favoriser l'Accès à la Santé Sexuelle des Travailleuses du Sexe) study are to (1) analyze the individual and structural determinants of the access to sexual health care and notably PrEP among MWSWs working in Marseille, (2) estimate the size of the MWSW population in Marseille, and (3) follow up with a representative cohort of 150 MWSWs to evaluate the effectiveness of a holistic approach based on community empowerment interventions targeting MWSWs to improve PrEP use.

For this purpose, we designed a mixed methods study comprising the following: (1) a study in the field with community health workers (CHWs) evaluating the determinants

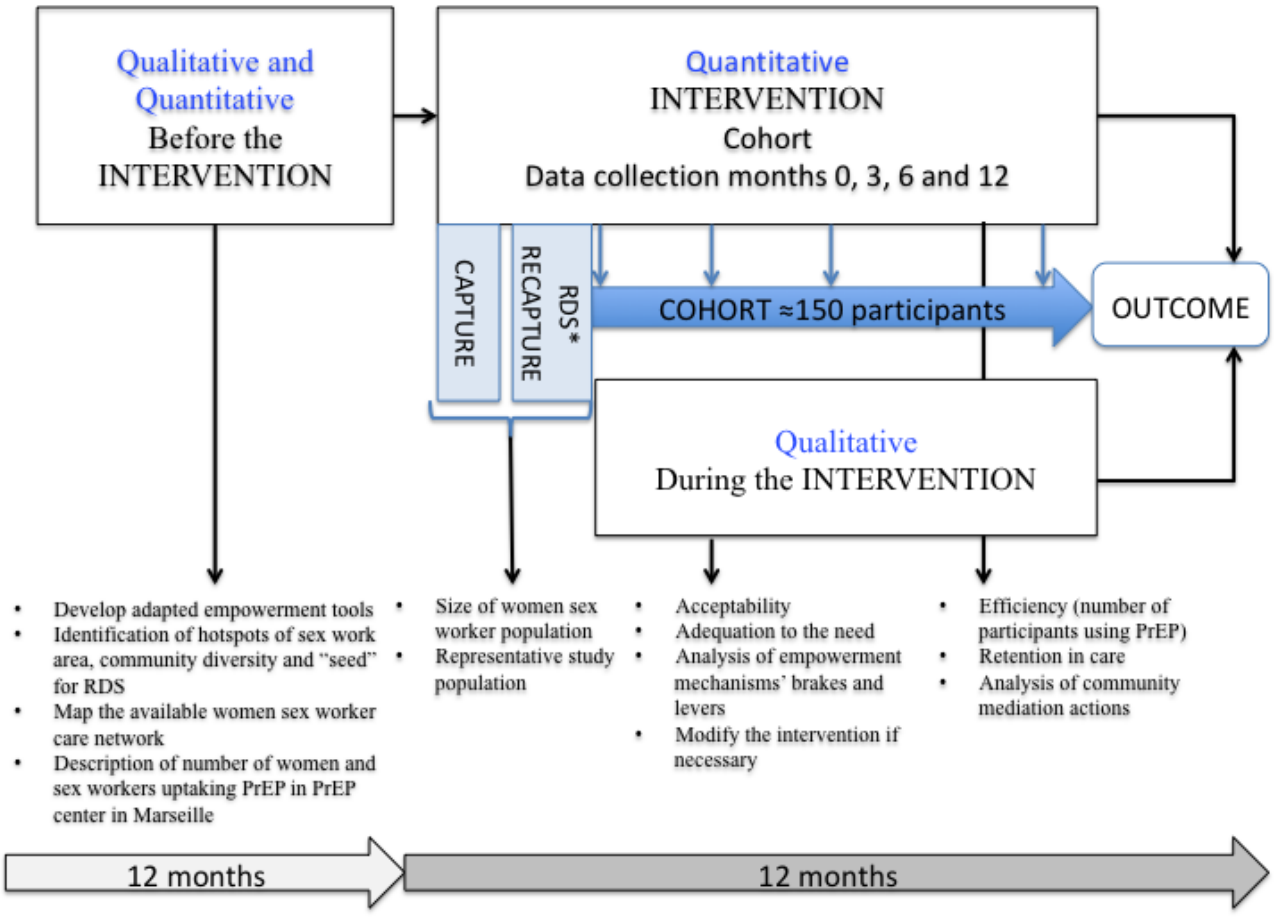
XSL•FO
RenderX

for the access to PrEP, (2) a capture-recapture method with respondent-driven sampling (RDS) to estimate the size and characteristics of a hidden and stigmatized population, (3) formation of a longitudinal cohort of MWSWs that will be followed up for 12 months, and (4) an intervention study involving CHWs to apply an empowerment strategy and evaluate its results with regard to the number of MWSWs taking PrEP at the end of the follow-up period.

Methods

Overview

Phase 1 of the FASSETS study is a qualitative multilevel evaluation of facilitators and barriers to PrEP access for MWSWs in Marseille, which will last 12 months before the intervention begins (Figure 1).



Phase 2 will be a capture-recapture study to evaluate the size of the MWSW population in Marseille (Figure 1).

Phase 3 will involve the formation and follow-up of a representative cohort of 150 MWSWs.

Phase 4 will be the community empowerment intervention by CHWs provided to the 150 MWSWs of the cohort recruited through RDS (Figure 1).

The intervention by CHWs will consist of facilitating knowledge and PrEP uptake but also more generally to facilitate access to health care and social services as needed, using an individual and longitudinal follow-up and collective empowerment actions.

Figure 1. Mixed methods model of intervention analysis. PrEP: pre-exposure prophylaxis; RDS: respondent-driven sampling.

Objectives of the Different Phases of the Study

Phase 1 will describe the determinants of PrEP uptake in MWSWs with a multilevel approach including individual, collective, and institutional analysis.

Phase 2 will determine the size of the MWSW population in Marseille.

Phase 3 will describe attitudes, knowledge, and practices of sexual and reproductive health (SRH) among MWSWs, health care pathways and mobility, testing for sexually transmitted infections, and prevalence and frequency of screening in the MWSW population at month 0 and their evolution during follow-up.

Phase 4's primary objective is to analyze access to PrEP and retention in care through a community empowerment follow-up of MWSWs. Secondary objectives will be to document individual and collective empowerment tools for MWSWs and to describe CHW interventions for MWSWs.

Key Outcomes for Each Phase of the Study

The key outcomes of phase 1 will be the analysis of the verbatim responses of MWSWs and institutional actors about the

XSL•FO
RenderX

determinants of PrEP use, those of phase 2 will be the estimated number of MWSWs in Marseille, those of phase 3 will be the number of MWSWs included in the longitudinal study and quantitative analysis of the questionnaire data, and those of phase 4 will be the number of consultations for sexual health, access to rights, and PrEP uptake among MWSWs before and after the interventional phase.

Study Population

The FASSETS study will take place in Marseille, which is the second largest city in France, and a significant proportion of its population has precarious living conditions [26]. The FASSETS study was developed in collaboration with the nongovernmental organization (NGO) AIDES and a Nigerian community NGO for women (The Truth), which provides HIV prevention and testing services to MWSWs.

Phase 1: Qualitative Assessment

Qualitative data collection will be carried out separately with a trained qualitative researcher. Qualitative interviews will be conducted following semistructured interview guides in private with selected participants representative of the cohort, in focus groups, and in a multilevel assessment with doctors and social workers in the field. These interviews will be carried out to document the determinants for PrEP access in MWSWs.

Phase 2: Estimation of the Sample Size of the Hidden Population of MWSWs by Capture-Recapture

Population size estimation is a challenge because the MWSWs are hidden and difficult to reach. Hence, capture-recapture is recommended to estimate the size of the MWSW population in Marseille [27,28]. The estimation will be based on the following equation:

$$N=(n1\times n2)/m$$

where $n1$ is the number of MWSWs who received a token (capture), $n2$ is the number of MWSWs included in the RDS study (recapture), and m is the number of participants common to both groups (MWSWs with a token). Tokens (safety whistle: a little emergency whistle with a flashlight) will be distributed over a period of 15 days by the NGOs and institutions but also directly to the MWSW network. Indeed, distribution of safety whistles will serve as a first "capture" and the RDS survey will serve as "recapture." When participants visit the center for RDS enrollment, they will be asked if they had received a safety whistle; if they answer yes, the research team will ask them to identify the safety whistles from a group of photographs depicting different safety whistles. If the participants correctly identify the safety whistles from the photographs, they will be included as having received a safety whistle.

Phase 3: Representative Cohort Formation Through RDS and Follow-up

The inclusion criteria are being a cis- or transgender woman older than 18 years, self-reporting as having changed their sex for money or other resources during the past 12 months, having been born outside of France, living or working in the city of Marseille, and agreeing to participate in the study.

Numerous studies have demonstrated the effectiveness of RDS to engage adults in HIV research, particularly in stigmatized communities [29,30]. Initial RDS participants (ie, "seeds") will be recruited for the study to achieve good representativeness in terms of the type of community or nationality, sex work (eg, indoor, outdoor, via the internet), place of residence in Marseille, and gender (cis- or transgender women). The prior qualitative study will make it possible to clearly define the characteristics of representativeness. Approximately 150 participants are expected to be enrolled in the cohort. At the beginning, participants will be offered 3 coupons. Participants who meet the eligibility criteria will be provided with a food coupon worth €10 (US $10.86) for completing each part of inclusion and follow-up (at months 3, 6, and 12), and another food coupon worth €10 (US $10.86) for each eligible and participating peer recruited. In addition, FASSETS study participants will be given public transport tickets, free condoms, and lubricating gel.

Phase 4: FASSETS Community Empowerment Intervention and Follow-up Program

Empowerment Framework

There are many definitions of participant empowerment in the literature [31]. In this study, empowerment intervention will be defined as a process by which MWSWs take collective action to achieve the most effective SRH outcomes and address social and structural barriers to their health and human rights [32]. Most effective SRH effects have been defined in accordance with national and international guidelines [33,34]. The main outcomes are related to a decrease in the number of sexually transmitted infections, unintended pregnancy and abortion, sexual violence, and an increase in the access to comprehensive, good-quality information about sex and sexuality and the ability to access sexual health care. The main goal is to mainstream migrant health access to include people-centered health services. Community empowerment programs conducted in many countries to reduce HIV risk among WSWs have previously proven their effectiveness [35]. In order to evaluate empowerment, 5 specific principles will be used, including improvement, democratic participation, community knowledge, evidence-based strategies, and capacity building [36].

Participant and Public Involvement

CHWs and peer workers were involved in the design of the structures survey, with special attention paid to the terms and methods of communication used during participant interviews.

Participants will be involved in the intervention phase in the design of individual and collective empowerment actions. CHWs will be involved in the dissemination plans of this study by communicating in public conferences and workshops with local and nationwide actors in the field.

Community-Based Participatory Research

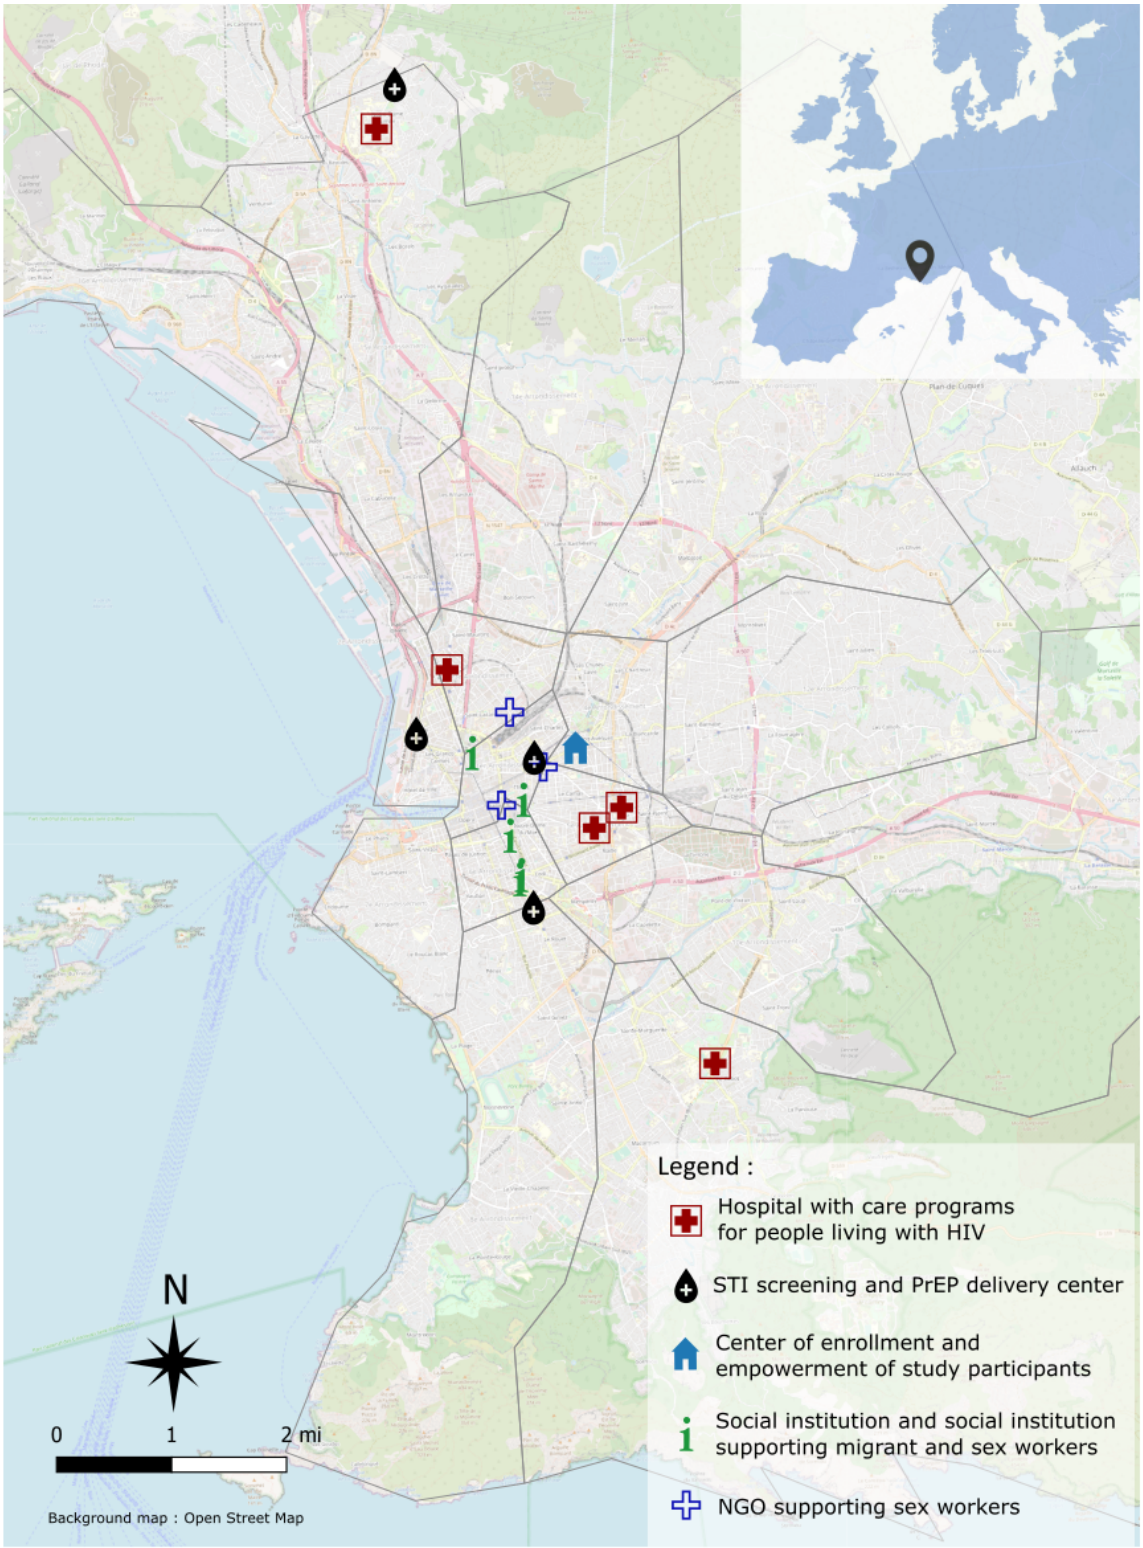
Community-based participatory research is an approach to research that involves a collective, reflective, and systematic study in which researcher and community stakeholders engage in all steps of the research process with the goal of improving practice [37]. This approach to research is recognized as particularly useful when working with populations that

XSL•FO
RenderX

experience marginalization—as is the case for MWSWs—because it supports the sharing of control over individual and group health and social conditions [37,38]. The FASSETS study was initially developed around 2 community NGOs, AIDES and The Truth, which provide SRH community interventions for MWSWs. In accordance with community-based participatory research principles, this study will involve partnership building, regular exchange among partners and community NGOs, and experience sharing among the researchers, CHW staff, and the MWSW community. A community-based participatory research approach could mitigate the intersecting forms of marginalization faced by MWSWs. Indeed, a participatory approach is of particular relevance in health equity research, in which cultural and socioeconomic differences among the community, health care givers, and researchers potentially impede the identification of problems and discovery of their causes [39]. Partnering with the community will by no means eliminate this barrier during the evaluation but can enhance understanding and increase insight into the social and physical conditions as well as policy environments that are impacting the health of the community [39,40]. During the program and results dissemination, researchers, community participants, partner NGOs, and CHWs could also participate in increasing the use of social and health service usage by MWSWs and in advocacy to improve the overall living conditions of MWSWs.

Implementation Study

The term “implementation research” describes the scientific study of the process used in the implementation of an initiative as well as the contextual factors that affect these processes [41]. This study aims to address the factors affecting the implementation of PrEP among MWSWs (such as health literacy, poverty, access to health, or traditional beliefs), the processes of implementation themselves (proposal, distribution, and follow-up of PrEP), and the outcome of the implementation under study. Indeed, the FASSETS study should be aligned with MWSWs’ needs and respond to the particularities of different communities. The study will be conducted in a real-world setting and will consider context and other factors that influence implementation. A qualitative study will help understand and document the PrEP empowerment actions in the FASSETS cohort and to describe the community mediation implementation with its positive or negative impact on MWSWs and their needs.



Field Implementation

The FASSETS intervention will take place at a center for enrollment and empowerment (Figure 2). The health care and social service network for MWSWs has already been mapped (Figure 2). Some NGOs and CHWs of the study are mobile and will visit some prostitution sites.

After inclusion, participants will be offered to be followed up at least every 3 months by CHWs, either in the mobile or fixed area, on the basis of their preference. Participants will also have access to health screening centers and other institutions or NGOs any time they need them, in addition to planned individual or collective meetings.

XSL•FO
RenderX

Figure 2. Mapping of the sexual health and social care and support network for migrant sex workers in Marseille. PrEP: pre-exposure prophylaxis; NGO: nongovernmental organization; STI: sexually transmitted infection.

Training of Community Health Workers and Intervention Implementers

The CHWs will be members of the communities to which the recruited MWSWs belong. They will be able to improve recruitment, accurately monitor the correct understanding of the questionnaires, and conduct and ensure participation in empowerment, prevention, and screening interventions. They will provide information about PrEP and assist with care and follow-up for participants who wish to receive the treatment. They will be uniformly trained to conduct the survey using a structured interview. All actions (type, date, and public) taken by the CHWs with MWSW participants (eg, access to care, prevention, and assistance in accessing social insurance) will be also collected.

XSL•FO
RenderX

The CHWs will be responsible for health education and individual and collective empowerment actions. They will receive rigorous prejob training and assessment, which include PrEP use and sexual health prevention and care, by caregivers (infectious disease physicians) and nationally recognized community-based NGOs working in the field of HIV prevention (including AIDES, Planning familial, and COREVIH [COordination REgionale de lute contre le Virus de l'Immunodéficience Humaine]). The training program will be conducted with the entire CHW group and will also include individualized follow-up. All CHWs will have a discussion platform via a social network to obtain real-time responses from physicians. Information or prevention tools, adapted to the MWSW populations, will be made available to the CHWs by the NGO's partners. Posttraining mentorship, supervision, and monitoring with regular training will take place every 3 months by the investigating physicians. CHWs' course evaluation feedback and posttraining monitoring visits will be provided by the study coordinator. Finally, a follow-up and psychological support will be set up to support the CHWs in their work with this vulnerable population.

Data Collection

Upon enrollment and at months 3, 6, and 12, participants will be asked to complete a structured survey administered by a CHW. The survey will include questions regarding network size for RDS weighting. These will include questions about the token given at the time of data capture. Individual data including sociodemographic characteristics; sexual practices; knowledge and behavior; HIV testing history; medical history; PrEP knowledge, adherence, and compliance; contraception; drug and alcohol use; mental health (including Perceived Stress Scale-10 scores); quality of life; literacy; social support; being subjected to racism; stigmatization or violence during the past 12 months; and mobility will be collected. Other more structural determinants will be collected as follows: residence permits, health insurance, housing conditions, and food security (Table 1). Indeed, such structural determinants are previously described to have a significant impact on health care access among sex workers [42]. The semistructured questionnaire will explore the barriers and levers to accessing PrEP among MWSWs. The instrument or interview guide will attempt to understand how PrEP fits into women's needs, care pathways, and mobility. Representation of MWSWs' PrEP uptake among caregivers and which mechanisms are (or are not) implemented by social institutions to facilitate access to prevention and care for MWSWs (Table 1).

Type, objective, and number of actions of mediation in terms of prevention, support, or access to health care or social services will be self-reported by CHWs.

CHWs will use encrypted and secure survey software to report the MWSWs' responses to the questionnaires and to monitor their actions of mediation. All electronic questionnaires will be forwarded to a database that is managed and hosted by SESSTIM (Inserm laboratory in Marseille). Each staff member will have a secure individual account.

Databases of all NGOs and institutional screening and PrEP centers of Marseille will be retrospectively analyzed to describe the HIV status and to assess PrEP characteristics among migrants and women in Marseille.

Table 1. Data collection tools and timing.

Method	Timing	Population	Data collected
Questionnaire	4 rounds: months 0, 3, 6, and 12	Randomized migrant woman sex worker cohort in Marseille	Sociodemographic data, knowledge of sexual health, results of tests for sexually transmitted diseases, medical treatment including pre-exposure prophylaxis (PrEP), retention time in care, health care pathway, residence permit, health insurance coverage, housing conditions, and food security
Questionnaire	Continuous	Community health workers	Type, number, and objective of actions
Semistructured interviews and focus groups	Continuous from September 2021 through January 2022	Migrant women sex workers	Perception of PrEP and sexual health, qualitative explanation of possible empowerment mechanisms, health needs, and care pathway
Semistructured interviews	Continuous from September 2021 through January 2022	Nongovernmental organizations (NGOs) and institutions in charge of the sexual health of sex workers in Marseille	Perception of PrEP and sexual health in migrant women sex workers, identification of available empowerment resources for migrant women, and health care offer
Observation	Continuous	NGOs and institutions in charge of the sexual health of sex workers and migrants in local and international territories	Social history of public sexual health strategies among migrant women sex workers

Data Analysis

Descriptive statistics will be applied to the characteristics of the survey population. Categorical variables will be reported as percentages and compared using the chi-square test (and the Fisher exact test for small numbers). Continuous variables will be expressed as mean (SD) or median (IQR) values, and compared using Student and Wilcoxon signed ranked tests in accordance with the variable distribution. A simple logistic regression analysis will be applied to select variables associated with the outcome, and all variables with a P value of <.10 will be entered into a multiple logistic regression model for each outcome. Statistical analysis will be performed using STATA

XSL•FO
RenderX

(version 11.2; StataCorp), and statistical significance will be defined as a *P* value of ≤.05.

Survival analysis will be used to analyze cumulative retention in care for 12 months after the beginning of the intervention. Differences between survival curves will be assessed at month 12 using the Kaplan-Meier estimate (log-rank test).

Ethics Approval and Consent to Participate

The protocol received approval from French Ethics Committee in October 2021 (2021—A01746-35). Prior informed consent of the participants will be collected by a member of the research team before data collection. All the participants are free to withdraw from the study at any moment without incurring any penalties or consequences with regard to future care or services they might rightfully expect.

The study protocol has also been reviewed and approved by an independent peer review for funding by Sidaction.

Planned dissemination of study findings includes manuscript publication, conference presentations, and community dissemination (eg, community meetings and social network).

Results

Recruitment commenced on March 1, 2022. We estimate that the follow-up period will end on September 30, 2023.

Discussion

Anticipated Findings

Community empowerment interventions that aim to reduce the risk of HIV acquisition using PrEP among MWSWs are scarce worldwide. To our knowledge, this is the first intervention of its kind in Europe. Innovative and community-based approaches to bring MWSWs closer to health and social services are required. The findings from the FASSETS study will prove useful for tailoring PrEP use, proposing PrEP use to MWSWs and ensuring its adherence among them, and developing a sustainable community-based intervention.

One of the main challenges of this study is to take into account all the barriers to access to care in this vulnerable population and possibly the low prioritization of PrEP in light of their vital needs. Indeed, MWSWs have to deal with many structural factors such as the criminalization of their work, stigmatization, racism, or their precariousness [17,42]. This project, through a holistic approach based on the needs of the participants, aims to work on the issue of empowerment in a transversal approach. CHWs will be trained in sexual health prevention and will help the participants better access their rights and basic needs, especially those of housing, civic rights (eg, resident permit and social insurance), and access to food. Regarding the fight against stigmatization and racism, this study aims to set up a collective empowerment program with the help of CHWs for better consideration of their difficulties. Partner NGOs such as The Truth and AIDES will participate in advocacy in accordance with the difficulties encountered by the participants. Moreover, CHWs' actions have been previously described as having a social transformation impact [43].

The FASSETS intervention team has the capacity to provide cohort follow-up and individual and collective empowerment actions through partnerships with local organizations interested in connecting with the population of MWSWs. This team includes CHWs from multiple countries and cultures. FASSETS participants will have greater access to services, and health organizations may be able to reach a wider segment of the population to propose the use of PrEP.

FASSETS is a comprehensive, interdisciplinary, participatory study that combines clinical, epidemiological, and social sciences. Research questions are not limited to the participants and they take the health care network and implementing staff into consideration, notably with health mediation descriptions.

Limitations

Operational challenges are numerous and are linked to the relationship with MWSW communities and their perception of the intervention, mobility of the participants, stigmatization and racism that they could face from institutions, decrease in preventive actions, and modification of the type of sex work due to health measures or restrictions linked to the COVID-19 pandemic. Documenting all these logistic and operational aspects should enable gathering of crucial information regarding the potential transferability of the intervention.

Regarding the FASSETS methodology of evaluation, we were unable to use a control group or a stepped wedge method because of ethical problems (benefit to participate) and the difficulty to implement empowerment in a sequential and reproducible way. However, exhaustive local data from all screening and delivery PrEP centers in Marseille are available for investigators at the beginning and at the end of the study and will permit them to evaluate, through pre- and postintervention comparisons and those between participants and nonparticipants, the access and adherence to PrEP among MWSWs.

Conclusions

The FASSETS intervention aims to understand whether the implementation of a specific community accompaniment for MWSWs regarding PrEP use with an adapted follow-up and wide access to health care and social services are sufficient to improve the uptake of PrEP in this vulnerable population.

Acknowledgments

The authors thank all participants, the operational team, and NGOs and especially Prospective Coopération, AIDES, and The Truth for their support and help. The authors also want to thank Ms. Sophie Gisclard for her photographs use here as a Table of Contents image. This work was supported by Sidaction (grant 2020-2-AEQ-12890), by ViiV HEALTHCARE, and by the Marseille city.

Abstract

Background: The high academic demands experienced by students will often have an impact on the quality of their mental and physical health. The most common health problems reported are gastrointestinal disorders. This condition tends to manifest in the emergence of generalized anxiety disorders (GADs) and reduces the quality of life and productivity. The population that experiences this disorder the most is female adolescents, and this condition occurs in both South African and Indonesian populations. The use of drugs, especially benzodiazepines, often causes psychological conditions as side effects. For this reason, it is necessary to have a solution in the form of a targeted and efficient approach to reduce psychological symptoms that arise from functional gastrointestinal disorders (FGIDs) in the form of anxiety.

Objective: The purpose of this study is to produce and implement a counseling intervention model to assist female students with GADs caused by FGID factors using an approach combining cognitive behavioral therapy (CBT), web-based counseling, and local wisdom in Indonesian and South African populations.

Methods: The research subjects will comprise 118 female adolescent students from Indonesia and 118 female adolescent students from South Africa, making a total sample of 236 participants, and the study will use a prospective, parallel randomized controlled trial design. The recruitment process will begin in July 2023, and the trial will begin in August 2023. The posttest assessment data gathering will take place by November 2023. Questionnaires that will be used in this study include the Functional Gastrointestinal Disorder Checklist (FGI-Checklist) to collect data related to FGIDs and the Generalized Anxiety Disorder 7-item (GAD-7) to measure the anxiety conditions experienced by respondents.

Results: By adopting the intention-to-treat principle, there will be significant mean changes in GAD scores and FGID scores after exposure to this combined approach in the Indonesian and South African populations. Implementing this comprehensive intervention will improve the students' psychological symptoms related to FGIDs and ultimately enhance their overall well-being.

Conclusions: This study will develop and implement a model of counseling intervention for female students with GADs obtained from FGIDs using a combination approach to CBT, web-based counseling, and local wisdom in both the Indonesian and South African populations. The trial findings will contribute to our understanding of the effects of CBT combined with local wisdom

KEYWORDS

adolescent college girls; cognitive behavioral therapy; CBT; functional gastrointestinal disorders; FGIDs; generalized anxiety disorders; GADs; local wisdom; web-based counseling

Introduction

Background

Students experience various changes and challenges over the period of their studies. The high academic demands that students must meet and the tendency for weak control over health impact students' conditions [1,2]. Various mental health disorders also tend to increase during an individual's time as a student [3-5]. This condition tends to cause health problems and affects students' quality of life and mental condition. Disorders that appear commonly in students are functional gastrointestinal disorders (FGIDs) [6,7], which are characterized by abdominal pain, dysphagia, dyspepsia, diarrhea, constipation, bloating, and acute gastrointestinal (GI) disturbances [7-9]. Based on data from the Ministry of Health of the Republic of Indonesia in 2020, FGIDs are included in the list of 10 diseases that affect adolescents the most in Indonesia, with a prevalence of up to 40.85% [10]. FGIDs appear in conditions without an organic basis and are more likely to occur due to impaired communication between the brain and the gut. In other words, disturbances in digestive function are reciprocal. Individuals with FGIDs tend to experience anxiety disorders, while individuals with dominant anxiety conditions will experience digestive disorders [8,11-14]. Treating FGIDs based on the latest findings generally still relies on drug therapy, but this therapy tends to produce other side effects subsequently experienced by the patient [15]. In addition, FGID treatment, which essentially does not produce organic conditions, is time-consuming and expensive. In addition, the patient's anxiety condition often does not subside and worsens [13,16].

When viewed from a demographic perspective, anxiety disorders as a result of FGIDs are often experienced by the female population during their reproductive years [17,18]. It has been found in population-based case-control studies that women with FGIDs experience a more negative impact on their daily functioning than their male counterparts and other women without this condition [12]. In the South African population, 8% of the total population experienced this; in the KwaZulu-Natal province of South Africa, it was found that among 201 rural patients who presented with one type of FGID (functional dyspepsia), most patients (74.13%) [19] reported anxiety disorders. The impact is that if anxiety conditions and FGIDs are not handled properly, this will decrease students' productivity and quality of life. Generally, this impact will result in a decrease in students' opportunities for achievement and learning outcomes to the point of being unable to continue their studies [9,13,16,20]. Anxiety resulting from FGIDs also contributes significantly to the decline in quality of life. It impacts both the student's college life in terms of their learning, social, and personal lives, and the condition of their future career. Various attempts to alleviate this problem have been made but have not yielded significant results. Among others, a pharmacotherapeutic approach relieves anxiety symptoms that arise [15,21]. However, the use of drugs, especially benzodiazepines, often causes side effects on psychological conditions. For this reason, it is necessary to have a solution in the form of a targeted and efficient approach to reduce psychological symptoms that arise from FGIDs in the form of anxiety [22-41]. With a specific target on anxiety sufferers in the female population of student age, it is deemed appropriate to provide a cognitive behavioral therapy (CBT) approach combined with the implementation of web-based counseling and local wisdom. The advantage of this approach is that the assessment process can be carried out in a remote setting using web-based counseling technology developed in the author's previous research, then combined with an approach that has proven effective in conducting behavioral change therapy and emphasizes the implementation of local wisdom. In addition, the combination of these 3 elements will be able to spur positive changes in the anxiety experienced by female students with FGID conditions.

Objective

The purpose of this study is to produce and implement a counseling intervention model to assist female students with generalized anxiety disorders (GADs) caused by FGID factors using an approach combining CBT, web-based counseling, and local wisdom in Indonesian and South African populations.

Hypothesis

Based on the understanding that students face various challenges and changes during their university studies, including the high academic demands and potential impact on their health, particularly in terms of mental health, it is important to address these issues effectively. One common disorder among students is FGIDs, which not only affect their physical well-being but also have an impact on their quality of life and mental state. Additionally, anxiety disorders often coexist with FGIDs, further exacerbating the negative effects on students' overall well-being. Considering the prevalence of FGIDs and anxiety disorders among female students, it is crucial to develop an intervention model that combines CBT, web-based counseling, and local wisdom. Thus, this study hypothesizes that there will be significant mean changes in GAD scores and FGID scores after exposure to this combined approach in the Indonesian and South

XSL•FO
RenderX

African populations. Implementing this comprehensive intervention is expected to improve the students' psychological symptoms related to FGIDs and ultimately enhance their overall well-being.

Methods

Research Design

This study is developmental research involving the systematic and conceptual design of a psychological treatment approach. The development model that will be used as the basis for this research activity is one adapted from the ADDIE (Analysis, Design, Development, Implementation, and Evaluation) model [42,43]. A prospective, parallel randomized controlled trial design involving pre- and posttesting of a treatment group and a control group will be used by the researchers [44]. At the end of a diagnostic interview conducted by the researchers, participants who are considered eligible for the study will be randomly assigned to 1 of 2 groups: the web-based CBT group or the usual care control group.

Research Subjects

The research subjects will consist of female adolescent students in Indonesia and South Africa (aged 15-17 years); 118 people from each country will be recruited from general practice or family medicine clinics as well as high schools within each study area to arrive at an overall sample of 236 participants for this study. An initial assessment will be conducted on 1000 potential participants (500 adolescent girls per country), who will be screened according to the research criteria so that a representative sample for the intervention may be obtained. The results of a recent study [45] found that 44.1% of participants were able to complete a CBT program using a web-based approach and that the average completion rate for the 12 sessions was 7.8 (65%). Therefore, we will take into account the attrition rate of 55.9% by including 55.9% extra participants in our initial sample for each group produced by the G*power (Heinrich-Heine-Universität Düsseldorf) sampling program [46]. To account for the potential effects of missed sessions in a standard web-based CBT program, as shown by recent research [45], 4.2 sessions (35%) will be added to the 12-session program, which will result in approximately 16 sessions (to be delivered over 4 months). Based on the G*power calculation, the required sample size is 38 participants per group (85% statistical power; medium effect size Cohen d=0.5; a priori probability level of 0.5) for a linear mixed model (LMM) analysis. Given the presumed attrition rate, we will recruit 59 participants per group in each country.

Randomization and Masking

This study will use a computer-generated random list obtained from Random Allocation Software [47] to randomize groups using a simple randomization technique by 2 biostatisticians (1 for each country) who are not part of the research team to ensure assignment concealment. Each country's research team is expected to have 59 research subjects in the treatment group and 59 research subjects in the control group, totaling 118 adolescent girl participants from each country. The group randomization process will be concealed from the study subjects. Thereafter, the researchers will notify subjects of their group membership through invitations to participate in the treatment intervention or usual care sessions.

Treatment Activities and Procedures

This research will be reported in line with the guidelines for the Consolidated Standards of Reporting Trials (CONSORT) [48]. The study was registered in a clinical trials registry before the recruitment of the first participant. A 16-session CBT manual incorporating web-based counseling techniques and principles and local wisdom approaches to the treatment of GAD among adolescent college girls with FGID symptoms will be developed by the research team for this study. The research team will adapt evidence-based techniques and procedures from existing CBT intervention manuals for GAD and FGID treatments with a focus on cultural components, traditions and values, and local wisdom, as well as web-based counseling techniques and processes, to address GAD and FGID symptoms among adolescent college girls. Each web-based session for the treatment group as well as the usual care session for the control group in each country (study site) is expected to last for 90 minutes each, once a week for 4 months. To assess the efficacy of CBT combined with local wisdom and web-based counseling approaches, we used the usual care as a comparison group. This study defines usual care as whichever treatment for GAD and FGIDs adolescents receive from their regular health care providers or therapists. This form of comparison group was selected to appraise the effects of CBT combined with local wisdom and web-based counseling approaches against the treatments that would normally be available without this intervention. The use of usual care as a comparison group also contributes to the viability of the trial since other clinicians are not required to be trained in a particular approach to comparator therapy. Due to this study's design, it is possible to compare the effects of CBT combined with local wisdom and web-based counseling methods with the usual practice in GAD treatment for adolescent girls with FGIDs. Three specialist raters in each country will evaluate the treatment's integrity. During the project, 2 postgraduate-level psychologists with a master's degree will serve as research assistants in each country. Two cognitive behavioral therapists with a doctorate in counseling psychology will provide the web-based CBT intervention for the treatment group, while the usual care intervention for the control group in each country will be provided by 2 CBT practitioners with doctorate degrees in psychology. The recruitment process will begin in July 2023, and the trial will begin in August 2023. The posttest assessment data gathering will be undertaken by November 2023. A summary of the treatment intervention is shown in Table 1.

XSL•FO
RenderX

Table 1. Summary of the intervention components.

Sessions	Integrated web-based counseling with local wisdom CBT[a]
Initial assessment (session 1)	In the first session, the counselor and clients will engage in an initial assessment to identify the presenting issues and set goals for therapy. This assessment typically takes 1 session. This stage involve the use of a web-based assessment system.
Sessions 2-3	Psychoeducation (2 sessions): Over 2 sessions, the counselor provides educational materials and resources to the clients through text, videos, or web-based sources. The counselor explains the concepts of CBT, the connection between thoughts, feelings, and behaviors, and introduces the techniques and strategies that will be used in therapy.
Sessions 4-5	Identification of negative thought patterns (2 sessions): This process involves self-observation, reflection, and discussion, taking into account the perspective of cultural values and local wisdom. By incorporating cultural perspectives and values, the counselor aims to create a culturally sensitive and inclusive environment that respects the clients' cultural background. The exploration and identification of these patterns typically take 2 sessions, allowing sufficient time for the client to reflect and discuss their experiences within the context of their cultural beliefs and values.
Sessions 6-9	Restructuring negative thoughts (4 sessions): Once negative thought patterns are identified, the counselor and clients collaborate to restructure these thoughts and replace them with more realistic, balanced, and positive thoughts, integrating the principle of "nature as the master teacher" from Minangkabau culture in Indonesia. This process involves techniques such as realistic thinking, thought replacement, and asking challenging questions while drawing inspiration from nature's wisdom. By incorporating local wisdom, the counselor helps the clients develop a deeper understanding and connection with their cultural roots. In this respect, the Ubuntu counseling model as a local wisdom approach will be integrated to assist the South African adolescents during the treatment sessions since it involves integrating African culture into the therapeutic process in that it recognizes the relevance of culture to patient mental health and self-identity. Several group processes are emphasized in the Ubuntu counseling model, including communality, cooperation, and oneness among others. Several traditions and values are also intrinsic to the Ubuntu counseling model, and they determine how mental disorders are understood and treated in South Africa.
Sessions 10-13	Development of coping skills (4 sessions): The counselor assists the clients in developing healthier coping skills. This includes stress management strategies, relaxation techniques, problem-solving skills, and fostering adaptive thinking patterns. It typically takes 4 sessions to introduce and practice these skills.
Sessions 14-15	Assignments and exercises (2 sessions): Throughout therapy, the counselor assigns tasks and exercises for the clients to apply the concepts and skills learned in sessions to their daily lives. The counselor may review progress and provide feedback in 2 dedicated sessions for discussing and reviewing assignments.
Session 16	Monitoring and feedback (1 session): The counselor uses web-based monitoring tools, such as questionnaires or web-based daily journals, to track changes in the clients' thoughts, feelings, and behaviors. In 1 session, the counselor provides constructive feedback based on the information gathered and the progress made.

[a]CBT: cognitive behavioral therapy.

Inclusion and Exclusion Criteria

To be considered eligible, participants must (1) be between the ages of 15 and 17 years, (2) be experiencing moderate to severe GAD and FGID symptoms at baseline, (3) speak and understand English to a reasonable level, (4) be willing to take part in the web-based CBT program or attend the usual care program, (5) have been taking continuous doses of anxiety medications for at least two months before the commencement of the program, (6) have a smartphone or tablet device that is capable of running Whatsapp, Zoom, or the Konselo counseling app and have access to the internet, which is necessary to participate in the program sessions, and (7) demonstrate the ability to commit to the expectations of the trial. Some conditions will exclude participants from the study. This includes (1) participants who cannot answer questions in the assessment tools on their own with a reasonable degree of English, (2) participants affected by psychiatric or medical comorbidities that would severely impact their ability to participate or adhere to the program schedule, (3) persons who are currently receiving CBT treatment, (4) individuals who have practiced meditation regularly or previously, (5) a lack of internet access or the inability to use a device that is capable of connecting to the internet, and (6) inability to commit to the expectations of the trial. In each country, 2 postgraduate-level research assistants with a master's degree in psychology will be trained to screen prospective participants using these inclusion and exclusion criteria by telephone. On completion of the screening process and after it has been determined that participants are eligible for the study, they will be invited to complete a diagnostic interview with the research investigators in each study area to additionally validate their eligibility for the study. Participants will be reached by phone in line with the schedule of the program as soon as it has been determined that they are eligible to participate in the research study.

Outcome Measures

Questionnaires that will be used in this study include the Functional Gastrointestinal Disorder Checklist (FGI-Checklist) [49] to collect data related to FGIDs and the Generalized Anxiety Disorder 7-item (GAD-7) screening tool [50] to measure the anxiety conditions experienced by respondents.

The FGI-Checklist includes the 20 most common FGID symptoms, which encompass a series of symptoms across the GI tract [49]. Five subscales contribute to the total score of the FGI-Checklist, including abdominal and bowel syndrome (7 items; Cronbach α=.86), functional dyspepsia syndrome (5 items; Cronbach α=.87), reflux syndrome (4 items; Cronbach α=.80), esophageal syndrome (3 items; Cronbach α=.69), and nausea and vomiting syndrome (2 items; Cronbach α=.73).

XSL•FO
RenderX

Several single items on the FGI-Checklist are used to ascertain the severity of global dyspeptic symptoms, abdominal symptoms, stool frequency, and stool form as per the Bristol stool scale. Thus, it is often seen as a comprehensive symptom assessment scale covering esophageal, epigastric, and abdominal symptoms. It is a self-administered outcome measure with a 7-day recall period [49]. Patients are required to rate the intensity of each symptom using 4 response options to indicate impairment in daily activities due to the symptom as follows: 0=none, 1=mild (not affecting daily activity), 2=moderate (some daily activities are affected), and 3=severe (almost all daily activities are affected). The FGI-Checklist total score, which ranges from 0 to 3, is calculated by averaging the scores of the 20 items. Patients with mild (monthly) to severe (weekly) symptoms can be identified with the FGI-Checklist. A higher score represents more severe symptoms [49].

It has been demonstrated that the GAD-7's internal consistency is excellent (Cronbach α=.92) and its test-retest reliability is adequate (intraclass correlation=0.83) [50]. The GAD-7 has a 4-point response scale ranging from 0 (not at all) to 3 (nearly every day). Scores between 0 and 4 indicate minimal GAD, 5 to 9 indicate mild GAD, 10 to 14 indicate moderate GAD, and 15 to 21 indicate severe GAD [50]. The GAD-7 also has a strong correlation with patients' mental health (r=0.75), social functioning (r=0.46), general perceptions of health (r=0.44), bodily pain (r=0.36), role functioning (r=0.33), and physical functioning (r=0.30) [50]. An invaluable feature of the GAD-7 is its ability to assess changes in anxiety symptoms severity over recent weeks (that is, over the previous 2 weeks).

Data Analyses

The analyses of the data in this study will include descriptive analysis, analysis of the coefficient of agreement between program raters (interrater reliability), and internal consistency analysis using Cronbach α and partial η^2 (effect size statistics). A sensitivity analysis will also be carried out to avert potential data dredging. The Mauchly sphericity test and Levene equality of variance test will be carried out to ensure that the assumptions of the chosen statistical test are met. LMM will be used to analyze the primary outcome measures statistically based on the principle of intention-to-treat to determine whether considerable changes have occurred over time [51]. By using LMM, participants with incomplete data will be included in the analyses so that treatment effects can be assessed over time (group time interaction) [51]. Using LMM, the treatment group, time, and interactions between the treatment group and time will be considered fixed factors; the covariance structure will be constructed in an unstructured manner. We will ascertain posttest outcomes in terms of mean changes in GAD-7 and FGI-Checklist scores from baseline to 4 months following the pretest. Complier-adjusted causal effect (CACE) analysis will be conducted based on the causal framework and estimation methods to account for variations in treatment effect due to variations in treatment adherence between the groups [51,52]. We will calculate CACE as the difference between the mean GAD-7 and FGI-Checklist scores of compliers in the treatment group as well as the control group. To be considered a complier, a participant must have attended 80% or more of the program sessions, which is a frequently used threshold [51,53]. A bootstrapping technique will be used to determine standard errors. Statistical analyses will be completed using R (R Core Team) to analyze the CACE data and SPSS (version 29; IBM Corp) for the rest of the analyses. P values of .05 or less will be considered statistically significant.

Ethics Approval

Each participant will be informed about their freedom to withdraw from the research project at any point in time without consequences. The research team will obtain web-based informed consent from the participating female adolescents, and their right to privacy will be respected. Parental consent will be sought. The project will be conducted in line with relevant ethical guidelines of the institutional review boards of the investigators; the research protocol has undergone ethical review approval (00402113712112520230227). Therefore, the project will comply with ethical research principles, including the issues of confidentiality, legality, professionalism, consent, privacy, and protection from harm. This research protocol has also been prospectively registered in the UMIN Clinical Trial Registry (UMIN000051386) on June 20, 2023.

Results

By adopting the intention-to-treat principle, there will be significant mean changes in GAD scores and FGID scores after exposure to this combined approach in the Indonesian and South African populations. Implementing this comprehensive intervention will improve the students' psychological symptoms related to FGIDs and ultimately enhance their overall well-being.

Discussion

Primary Findings

This study will aim to develop and implement a model of counseling intervention for female students with GAD obtained from FGIDs using a combination approach of CBT, web-based counseling, and local wisdom in Indonesian and South African populations. A substantial proportion of the South African population consists of adolescents, representing 17.4% of the population and accounting for 2.1% of the overall mortality rate [54]. Meanwhile, it is estimated that the Indonesian population consists of 46 million adolescents; this makes it vital for the nation to promote adolescents' health and well-being to fully take advantage of its demographic strength [55]. Adolescents are regarded as the potential workforce and contributors to national development and socioeconomic growth, which is why their health and well-being are paramount as they form a cornerstone of society [54]. However, the adolescent population may face some mental health challenges, such as GAD. Anxiety experienced by individuals (in this case, students) is closely related to the emergence of various health problems, especially digestive conditions [8,22-24]. This anxiety condition becomes psychopathological, which has a reasonably close and reciprocal correlation with the emergence of various GI problems. The problems most commonly experienced by students who experience anxiety are FGID symptoms, which are a group of disorders characterized by chronic GI symptoms (eg, abdominal

XSL•FO
RenderX

pain, dysphagia, dyspepsia, diarrhea, constipation, and bloating) without any pathology that can be proven in conventional testing [25-27]. When individuals experience FGIDs, they tend to also experience anxiety reactions. This is so recurrent that it is challenging to stop the cycle of problems between psychological and physical disorders[28,29].

Previous studies have also revealed the relationship between psychological problems (especially anxiety) and FGIDs. This condition tends to be experienced in the form of dyspeptic disorders, with a correlation prevalence of 0.48 [30,31]. In addition, other studies show a strong relationship between FGIDs and major depressive episodes and GADs [56]. As a form of reciprocity, studies have shown that the incidence of psychological disorders in patients with FGIDs is significantly higher than in non-FGID patients; symptoms of FGIDs are strongly associated with mental health disorders, especially anxiety and depression [49,50]. Pathophysiological studies of FGIDs have shown that psychosocial factors can influence FGIDs by regulating processing pathways and decreasing visceral signaling in the brain [29,32]. Analyses of interventions for irritable bowel syndrome have shown that psychological interventions, including web-based CBT, could treat irritable bowel syndrome effectively in patients [56,57].

This study hypothesizes that there will be significant mean changes in GAD scores and FGID scores after exposure to this combined approach of CBT, web-based counseling, and local wisdom in the Indonesian and South African populations. So far, pharmacotherapy and psychological interventions have undertaken the management of anxiety that results in FGIDs, and vice versa [25,28]. These psychological interventions include psychotherapy, psychodrama, CBT, relaxation therapy, and hypnosis [33-36]. Psychological intervention refers to psychotherapeutic methods designed to change a person's cognition, perception, or behavior. Psychodynamic psychotherapy focuses on how maladaptive thoughts and behaviors occur [35,36]. The psychodynamics of interpersonal psychotherapy are more concerned with the relationship between therapist and patient. This method emphasizes that the therapist and patient form a robust, cooperative working alliance. Meanwhile, CBT aims to improve the quality of life by changing the patient's thoughts or patterns of thinking and behavior. Relaxation therapy allows the patient to experience the physical and mental pleasure that relaxation brings to correct the psychological and physiological dysfunction caused by tension [12,37,38]. Hypnotherapy is the use of hypnosis to treat patients and improve their condition. For this reason, it is necessary to have a new approach that uses collaborative and cross-approach concepts to get more effective and efficient results. Following previous research, there are empirical results regarding the impact of psychological interventions on reducing anxiety symptoms and improving pain due to FGID; there is still no single fixed model with a combination of approaches to reduce anxiety conditions effectively. In addition, existing research has not shown an in-depth evaluation process of research results in the adolescent population. This study uses a CBT approach that has proven useful for clients with maladaptive disorders such as stress and anxiety. The study also uses the web-based counseling intervention approach as a way to evaluate and supervise the progress of counseling and also uses the implementation of local wisdom. The therapeutic model of local wisdom is added to this study, considering that behavioral change is closely related to the cultural values it carries [39-41]. In this respect, the Ubuntu counseling model as a local wisdom approach will be integrated to assist the South African adolescents during the treatment sessions since it involves integrating African culture into the therapeutic process in that it recognizes the relevance of culture to patient mental health and self-identity [58]. This study uses cross-cultural analysis with very different cultures, namely Indonesian and South African cultures. The cross-cultural analysis will show whether the intervention can be applied to 2 different cultures with almost the same indications of anxiety in terms of symptoms and aggravating factors. The results of this study will contribute to the literature on GAD and FGID treatment by informing clinicians about the potential benefits of CBT combined with local wisdom and web-based counseling approaches for adolescent girls with FGIDs experiencing GAD. However, in this study, there are some potential limitations, including that the treatment pattern does not allow for the blinding of therapists, the possibility that participants may use other interventions or treatments while taking part in the study, and a sample size that may make it impossible to generalize the study results to a larger population and spot subtler effects. While participating in the trial, participants will be required to speak frankly about their medications and treatments. In addition, they will be required to notify the researchers about any modifications to their medication doses throughout the study. In this way, the results can be taken into account with respect to any confounding variables.

Conclusions

This study will develop a model counseling intervention for female students with GAD caused by FGID using a combination approach to CBT, web-based counseling, and local wisdom in Indonesian and South African populations. The study proposes that there will be significant mean changes in GAD scores and FGID scores after exposure to this combined approach of CBT, web-based counseling, and local wisdom in the Indonesian and South African populations. The use of drugs, especially benzodiazepines, often causes side effects on psychological conditions. Thus, it is necessary to have a solution in the form of a targeted and efficient approach to reduce psychological symptoms that arise from FGID in the form of anxiety. With a specific target of anxiety sufferers in the female population of student age, it is deemed appropriate to provide a CBT approach combined with the implementation of web-based counseling and local wisdom. The trial findings will contribute to our understanding of the effects of CBT combined with local wisdom and web-based counseling approaches that mental health counselors can use to treat GAD-affected adolescent girls with FGIDs.

Abstract

Background: Children and adolescents with cancer may experience multiple disease- and treatment-related symptoms that negatively affect health-related quality of life. Routine symptom surveillance thus constitutes an important component of supportive care in pediatric oncology. The Symptom Monitoring and Systematic Assessment and Reporting System in Young Survivors (SyMon-SAYS) system will administer, score, interpret, and display the results of symptom assessments captured weekly using patient-reported outcomes presented via the electronic health record (EHR) portal between clinic visits in oncology ambulatory settings, when patients are likely to be more symptomatic. This study is testing a digital system for routine symptom surveillance that includes EHR-based reports to clinicians and alerts for severe symptoms.

Objective: In this randomized trial, we are examining the effects of the SyMon-SAYS system on perceived barriers to symptom management, self-efficacy, and symptom severity. Better self-management and timely clinical intervention to address symptoms promote adherence to treatment plans, strengthen child and parent self-efficacy, improve interactions between children, parents, and their clinical providers, and optimize clinical outcomes.

Methods: The SyMon-SAYS system is integrated into the EHR to streamline the presentation of symptom scores and delivery of alerts for severe symptoms to clinicians using EHR (Epic) messaging functionalities. Children (aged 8 to 17 years) complete the weekly symptom assessment and review the symptom report by logging into the patient portal (Epic MyChart). This single-institution waitlist randomized controlled trial is recruiting 200 children (aged 8-17 years) with cancer and their parents, guardians, or caregivers. Participating dyads are randomly assigned to receive the intervention over 16 weeks (Group A: 16-week SyMon-SAYS intervention; Group B: 8-week usual care and then an 8-week SyMon-SAYS intervention). Analyses will (1) evaluate the efficacy of SyMon-SAYS at week 8 and the maintenance of those effects at week 16; (2) evaluate factors associated with those efficacy outcomes, including contextual factors, adherence to the SyMon-SAYS intervention, demographic characteristics, and clinical factors; and (3) evaluate predictors of adherence to the SyMon-SAYS intervention and preference of SyMon-SAYS versus usual care.

Results: Data collection is currently in progress. We hypothesize that at 8 weeks, those receiving the SyMon-SAYS intervention will report decreased parent-perceived barriers to managing their children's symptoms, increased parent and child self-efficacy, decreased child symptom burden, and ultimately better child health-related quality of life, compared to waitlist controls. Feasibility,

XSL•FO
RenderX

acceptability, and engagement from the perspectives of the children with cancer, their parents, and their clinicians will be examined using mixed methods.

Conclusions: We anticipate that this system will facilitate prompt identification of problematic symptoms. Additionally, we hypothesize that with the availability of graphical symptom reports over time, and timely provider responses, children or parents will become better informed and take an active role in managing their symptoms, which will further improve clinical outcomes.

Introduction

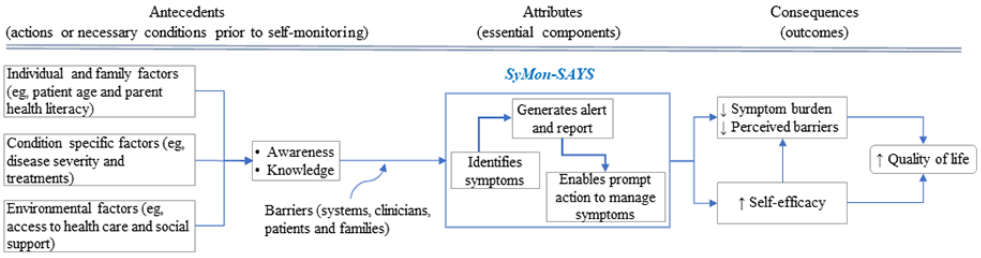
Background

Cancer can be distressing, in part, due to the unrelieved symptoms caused by aggressive therapy regimens implemented to treat the disease, which can last even after the completion of treatment [1]. Management of cancer-related symptoms in children has not kept pace with these advances in treatments. Children continue to experience distressing symptoms related to cancer and its treatment [2,3], as do childhood cancer survivors at all stages of survivorship. The unrelieved symptoms and side effects of often-aggressive cancer treatments can lead to poor psychosocial functioning and decreased health-related quality of life (HRQoL) for children with cancer and their families [4]. There is a need to improve child or family self-monitoring and self-management skills to better manage symptoms throughout the treatment continuum, from on-therapy to long-term survivorship, in order to provide timely intervention and lessen the adverse impacts of symptoms on HRQoL. Subsequently, it is recommended that children with cancer and their family should receive systematic assessments to identify their psychosocial health care needs [5].

Factors contributing to inadequate symptom management exist at the system, health care provider, and patient levels. Health care system barriers include the structure and organization of care, reimbursement, logistics, and resources [6,7]. Health care provider barriers include limited time available during a patient encounter [8], willingness to elicit information from patients [6,9], and challenges in obtaining systematic symptom assessment [10]. For very young patients, there is the added complexity regarding uncertainty about the accuracy of self-report. Patient-level barriers include failure to report symptoms to clinicians [11], desire to be a “good patient” to avoid conflict [12-14], concern over side effects of prescribed medications [12,15], and a perception that during cancer treatment symptoms are inevitable or untreatable [4]. A patient-centered approach to health care can minimize these barriers. Patient-related factors that facilitate self-management include: proactively seeking information and sharing their opinion about their self-management regimen with providers [16].

Improvements in the quality of communication between patients and health care providers can favorably affect symptom management, including improved information recall [17], satisfaction [18], overall HRQoL [19,20], and adherence to practitioners’ recommendations [21]. According to the IOM consensus report Cancer Care for the Whole Patient: Meeting Psychosocial Health Needs [22], inadequate communication and lack of patient involvement are particularly worrisome, as effective patient-clinician communication is linked to positive health outcomes. For patients and families, information is crucial to promote a sense of control, decrease emotional distress, support effective self-management, and eliminate disruptions to daily activities [23,24]. Research on adult oncology patients showed the average patient asks 5 or fewer questions during a 15-minute doctor’s office visit, with a high proportion asking no questions, suggesting that patients generally are not taking an active role in their care [25]. Previous literature suggests the clinician-patient relationship can be strengthened by the simple addition of a “prompt sheet,” encouraging patients to ask questions about treatment and prognosis; oncologists’ efforts to address the issues raised by the use of prompts promoted patient confidence to ask about prognosis, alleviated patient anxiety and reduced clinic visit length [26]. Yet, most literature examining interventions to strengthen patient-clinician communication about problematic issues has focused on adult patients and there has been limited research on children with cancer. Patients’ developmental ages are critical. Children’s less-developed verbal skills, along with parents’ and clinicians’ possibly conflicting communication styles and attitudes toward children, might prevent children from adequately communicating symptoms to providers [27]. Consequently, children are less likely than adults to discuss their symptoms with health care providers [28].

Health care delivery has shifted from inpatient to outpatient or home settings, leading investigators to focus on integrating technology into symptom monitoring and self-management support. The literature suggests that web-based symptom management programs in patients with pediatric cancer are feasible [29], may improve care, enhance patient and provider satisfaction, and lessen symptom burden, and generally do not increase provider time and effort. Tsimicalis et al [30] reviewed studies incorporating technology in pediatric oncology settings, identifying several benefits including surmounting logistical difficulties of distance, time, costs, and transport [31-34]; improving access to experienced and specialized health care professionals in rural and remote areas [35]; offering support



XSL•FO
RenderX

after hours; and avoiding unplanned hospital visits [36]. The scope of research exploring electronic symptom surveillance systems in pediatric oncology has been constrained, primarily concentrating on palliative care [29] and hospitalized children [37]. Both do not capture symptoms that occurred between clinical visits. This study fills a gap in knowledge about the feasibility, acceptability, and effects on self-efficacy and symptom burden of measurement-based symptom care delivered via the electronic health record (EHR) and explores implementation challenges and strategies that will need to be addressed to refine this intervention for optimal efficacy and adoption. The aim of this manuscript is to outline the study protocol (version 4; February 17, 2023) for this waitlist randomized controlled trial.

Purpose

In this trial, we are testing the efficacy of 8 weeks of Symptom Monitoring and Systematic Assessment and Reporting System in Young Survivors (SyMon-SAYS), an EHR-based system for routine symptom surveillance with self-management support to children and parents or caregivers, reports to clinicians and alerts for severe symptoms. The conceptual model of the SyMon-SAYS intervention is shown in Figure 1; the model was modified from a self-monitoring model [38], our SyMon-SAYS pilot study [39], as well as from literature. “Self-monitoring” is defined as awareness of symptoms or bodily sensations that are enhanced through periodic measurements, recordings, and observations to provide information for improved self-management [38]. The interplay among awareness, measurement, and observations can enhance self-management by improving how individuals monitor their health. SyMon-SAYS is designed to capture 2 major attribute components: (1) increased awareness of symptoms, and (2) accurate measurement and recording of symptoms. Adherence to the SyMon-SAYS intervention (ie, completion of weekly reports of symptoms by patients and parents) is hypothesized to be influenced by contextual factors (child or family, condition-specific, environmental factors) as well as barriers and facilitators. Through technology-based monitoring and reporting, the SyMon-SAYS program facilitates self-monitoring of symptoms via systematic symptom assessments and graphic reports based on these assessments and facilitates self-management by directing patients or parents to web-based resources developed by clinicians for appropriate strategies to manage the symptoms identified by the assessment. The resources site can be accessed directly through MyChart. Because the SyMon-SAYS system is designed to help patients and parents track symptoms on a consistent basis, it aims to lessen perceived barriers to managing symptoms and symptom burden, enhance self-efficacy of patients and parents, and ultimately improve HRQoL [23,40-45].

Figure 1. SyMon-SAYS conceptual model modified based on the "Model of the concept of the the self-monitoring" by Wilde and Garvin [38]. SyMon-SAYS: Symptom Monitoring and Systematic Assessment and Reporting System in Young Survivors.

Objectives and Study Aims

Overview

In this single institution modified waitlist control randomized trial, 200 children (aged 8-17 years) with cancer and their parents will participate for 16 weeks (group A: 16-week SyMon-SAYS intervention; Group B: 8-week usual care and then 8-week SyMon-SAYS intervention). Our study is addressing the following specific aims.

Aim 1

Evaluate the efficacy of SyMon-SAYS after 8 weeks and its maintenance effects at week 16. We hypothesize that group A (vs group B) will report decreased parent-perceived barriers to managing their children’s symptoms, decreased child symptom burden, increased child and parent self-efficacy, and ultimately increased child HRQoL at week-8. We expect that these differences between Groups A and B will be narrowed at week 16 when Group B completes the 8-week SyMon-SAYS intervention.

Aim 2

Evaluate factors associated with aim 1’s efficacy outcomes, including but not limited to (1) contextual factors, (2) adherence to the SyMon-SAYS intervention, and (3) symptom communication between clinicians and children or families.

Aim 3

Evaluate predictors of adherence to the SyMon-SAYS intervention and preference of SyMon-SAYS versus usual care. We will identify predictors of adherence and model their association by using ordinal regressions. Preference of SyMon-SAYS versus usual care will be evaluated using responses from SyMon-SAYS program evaluation. This understanding will help to develop individualized symptom management approaches for better quality and outcomes of care in pediatric oncology ambulatory settings.

Methods

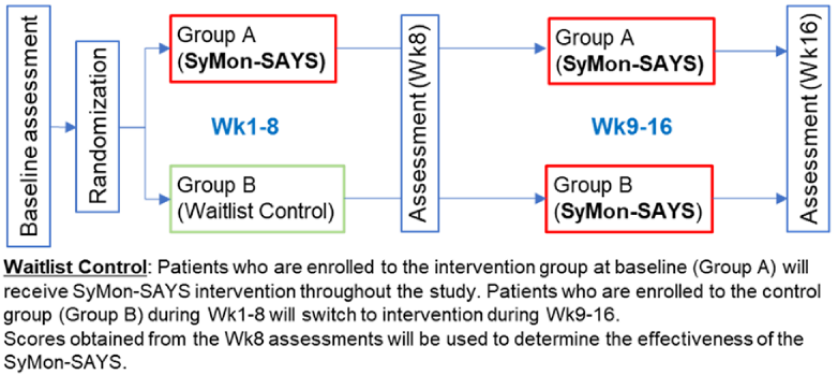
Ethics Approval

This study was approved by the Institutional Review Boards of Northwestern University (STU00210598) and Ann & Robert Lurie Children's Hospital of Chicago (IRB 2019-3018). Lurie Children's maintains records of the authorization and reliance agreements. All subsequent modifications to the protocol will be submitted for review and approval by the Ann & Robert Lurie Children's Hospital of Chicago. This trial is registered in ClinicalTrials.gov (NCT04789720). The Data and Safety Monitoring Board (DSMB) of the study provides oversight for data and safety monitoring for this trial. The DSMB consists of 3 members outside of Northwestern University and Ann & Robert Lurie Children's Hospital of Chicago, who have extensive experience in research with clinical trials, patient-centered outcomes, and pediatric oncology. DSMB and the study teams meet annually to review the data and any adverse events that occurred.

Study Design and Setting

The study design is shown in Figure 2. To increase the utility and compliance of clinicians, children, and parents, the SyMon-SAYS system was built within the Ann and Robert H. Lurie Children's Hospital of Chicago (Lurie) EHR (Epic). Participants (parents and children) complete assessments using an iPad or a device with internet access at baseline, week-8, and week-16. They are randomly assigned to Group A (weeks 1-16: SyMon-SAYS intervention) or Group B (weeks 1-8: usual care; weeks 9-16: SyMon-SAYS intervention) after the baseline assessment. During the intervention weeks (either weeks 1-16 or weeks 9-16), participants complete a weekly symptom assessment wherever they have internet access using their MyChart patient portal, accessible via smartphone, tablet, or computer. The SyMon-SAYS intervention schema is shown in Figure 3.

Figure 2. Overall study design. SyMon-SAYS: Symptom Monitoring and Systematic Assessment and Reporting System in Young Survivors. Wk: week.



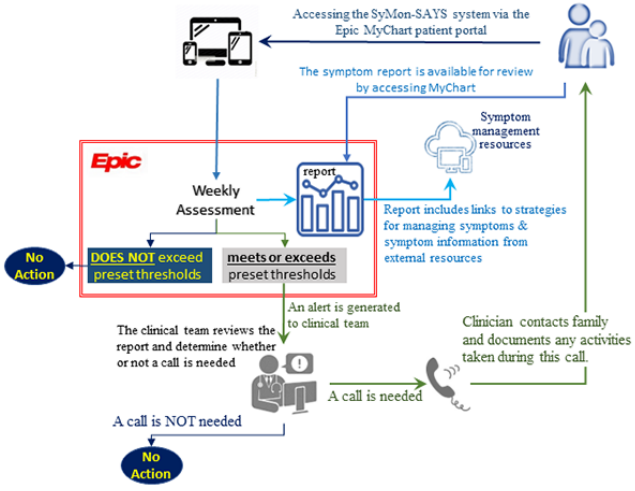


Figure 3. SyMon-SAYS intervention schema. SyMon-SAYS: Symptom Monitoring and Systematic Assessment and Reporting System in Young Survivors.

Participants

Overview

We are recruiting 200 children with cancer from hematology, oncology, and brain tumor clinics at Ann & Robert Lurie Children's Hospital, Chicago with an anticipated 20% attrition rate over a 16-week trial. In order to generalize our results to the entire pediatric cancer population and not exclude important patient subpopulations, we have broad inclusion criteria. Oncology clinical providers who treat participants are also enrolled in the study and provide informed consent as research participants per IRB's requirements at Lurie Children's Hospital. Our inclusion criteria are as follows.

XSL•FO
RenderX

Patients

Eligible participants are those with a diagnosis of malignancy (including children with primary brain tumors), who are currently receiving cancer-directed therapy or are within 6 months of completing cancer-directed therapy, and who are between 8 and 17 years old at the time of enrollment, English-speaking, have sufficient cognitive and motor abilities to complete surveys via an electronic device (eg, smartphone, iPAD, etc) or computer, and able and willing to sign assent forms (for those between 12-17 years of age). No formal cognitive testing is conducted; eligibility based on cognitive status is determined by the judgment of their clinicians. Usage of any assistive device to complete the assessment is acceptable and will be documented.

Parents

A parent of eligible children (father, mother, or legal guardians) is eligible for the study if she or he demonstrates sufficient fluency in English or Spanish to understand and provide informed consent (either in clinic or via remote recruitment), agrees to complete assessments at all time points, and has sufficient cognitive and motor abilities to complete surveys via an electronic device (eg, smartphone, iPAD, etc) or computer. Only one parent per child participates in the study.

Clinicians

Eligible clinicians are oncology attending physicians, fellows, nurse practitioners, and nurses who treat participating children at Ann & Robert Lurie Children's Hospital.

Informed Consent Procedures

Study personnel explain the aims of the study, what is involved in study participation, and the potential risks and benefits of the study to the potential participants (children, their parents, and providers) so that they can make an informed decision as to whether they wish to participate. This explanation is done in plain, nonexculpatory language that is easy for parents, patients, and providers to understand. Additionally, all participants who are approached for participation in this study are informed that participation in this study is voluntary, and that a decision to not participate will not jeopardize or affect their medical care or their employment status (for clinical providers) in any way. They are informed that they are also free to discontinue participation at any time during the study with no adverse impact on their treatment, overall care, or employment status. Clinical provider participants are also be informed that their decision to participate or discontinue participation will not impact their employment status, and the data they provide during the course of their participation will be used for the purpose of this research study only and will not be made available to the institution or any managing or supervisory personnel (eg, for their merit reviews).

Risks and Ethical Issues

There are no known social or legal risks to subjects who participate in this study. Our experience with data collection using similar questions has indicated that few (less than 1% of over 15,000 participants over more than 20 years) are distressed by the content of the questions posed to them. Participants are advised that if they become upset by the questions, they will have the option to talk with a trained mental health professional. The principal investigator (PI) will be notified of all requests for consultation with a mental health professional.

There is a slight possibility that enhanced monitoring of symptoms could lead to an increase in anxiety. Yet our feasibility study showed that SyMon-SAYS significantly decreased children's anxiety levels at week-4 (P=.046; unpublished data). Furthermore, in this study, children's emotional distress (worry and sadness) are included in the weekly assessments and are monitored closely. As with all symptoms being monitored, an alert is generated when children's reports of worry or sadness meet or exceed the preestablished threshold. Clinicians are notified within 24 hours and take appropriate actions to respond to these symptom experiences. In addition, in consultation with the site clinical team, the study team reserves the right to withdraw any participant for whom there is concern that the intervention is having an adverse effect.

Measures to Protect Privacy and Confidentiality of Participants

Study personnel enroll patients and their parents and assign each patient and parent participant their unique ID code, which is used for identifying and tracking participants throughout the study. Parent codes are linked to corresponding patient (child or adolescent) codes. Clinician participants are recruited by the study team and are also assigned a unique ID code. All data collected from all participants are linked with this unique identifier and not the participants. Information of linking IDs to participants is saved as a separate password-protected file that only the PI and the study coordinator can access.

Sample Size Consideration

An effect size of at least 0.33 has been shown to be clinically meaningful in the measurement of PROs in patients with cancer [46,47]. An effect size of 0.45 is relevant when using cancer treatment satisfaction as an end point [48,49]. Therefore, effect sizes between 0.33-0.45 are expected and will represent clinically meaningful differences for the barriers and self-efficacy end points. We anticipate intervention effects will be maintained in Group A over 16 weeks, and comparisons between groups will be made using both week-8 and week-16 data. We have calculated statistical power to detect differences between the study arms at both weeks 8 and 16, taking into consideration attrition. First, we consider a simple 2-group comparison at the primary 8-week follow-up visit for each end point in aim 1. For this comparison, we calculated that a sample size of 180 (90 per group) will provide 80% power to detect effects of 0.42 for the primary comparisons at week 8. Considering effects at week 16, a sample size of 160 (80 per group) will provide 75% power to detect an effect size of 0.42 but would provide 80% power to detect an effect size of 0.45.

Based on our symptom monitoring studies with more than 100 patients with advanced cancer, fewer than 15% of patients dropped out of a 12-week study because of death, disease progression, ineligibility to continue (eg, transfer care or move), or unwillingness to continue study participation. The dropout rate was 9.5% (6/63) in the SyMon-SAYS pilot (8-week). We

XSL•FO
RenderX

project a higher dropout rate (40/200, 20%) in the proposed 16-week study period, with approximately half of these dropouts (20/200, 10%) occurring by week 8. To accrue at least 180 patients who complete through week 8, which will provide adequate statistical power outlined above for the primary analyses, we plan to recruit 200 patients at baseline.

Randomization and Allocation

We will use a stratified block randomization approach. Participants are randomly assigned to Group A or B, stratified by gender, age, and cancer types. To achieve allocation concealment, the computer-based data management system (REDCap: Research Electronic Data Capture) assigns participants to 1 of 2 groups after the study enrollment procedures. Participants are informed of their group assignment (Group A or B) after the baseline assessment (see Table 1). Participants complete the weekly symptom checklist via Epic MyChart, a patient portal, during the intervention phase (Group A: weeks 1-16 or Group B: weeks 9-16). They are shown how to install the MyChart app on their smartphone and to access it on their personal computer or tablet. If they do not have a MyChart account, study personnel assist them in establishing one. The study team provides a smartphone during the study period if participants do not have one or are not willing to use their own device for the study.

Table 1. Study parameters that are completed at baseline, week 8, and week 16.

Study Implementation

Overview

All participants (Group A and B as shown in Figure 2) experience the intervention phase during the study—Group A during weeks 1-8 and weeks 9-16 and Group B during weeks 9-16 (see Figure 2). Hereafter, intervention phase participants will be referred to as “IP.” After enrollment, study personnel demonstrate how to complete baseline assessments using an iPad. Intervention participant (IP) participants are trained on accessing SyMon-SAYS using the Epic MyChart patient portal. IP participants are provided with a card containing their unique ID code and brief instructions for using the system. The card also contains the study personnel’s name and telephone number for any questions that might arise. IP participants are asked to choose a standard day of the week to access the system and complete their weekly symptom assessment. Parents of IP participants are informed that the study team will send a reminder to them 1 day prior to the chosen day regarding the upcoming assessment. IP participants are given a window of 1 business day before and 2 business days after their preferred day to access the system. IP participants complete the SyMon-SAYS symptom checklist (symptom items are available in Multimedia Appendix 1) every week for 8 weeks through Epic MyChart via mobile app, computer, or tablet. If IP participants do not access the system by midnight of the preferred day, study personnel contact the parent the following day (preferred day +1 business day) and remind them to complete the assessment or prompt their child to do so. If the participant does not access the system by midnight of the day following their preferred day, study personnel again attempt to contact the parent by phone (preferred day +2 business days) to remind them or prompt their child to access the system. Study personnel ascertains any issues that might be related to

XSL•FO
RenderX

noncompliance (eg, hospitalization) during reminder calls. At weeks 8 and 16, all participants complete the measures listed in Table 1.

Symptom Clinical Intervention Triggers (Intervention Phase Only)

Children's symptom scores will be automatically monitored and reported to oncology care providers. When a child's symptom score exceeds the preset severity threshold (ie, scores 3 or higher), the system will generate an email alert through Epic messaging to the study team with the child's study ID. Upon receipt of an alert, the study coordinator will access the report in Epic and notify the child's treating team to determine whether a call is needed. If needed, the nurse will contact the parent within 1 business day to ascertain their child's current status (see Figure 3 for study schema). The nurse will document actions taken in Epic.

Symptom Monitoring Summary Report (Intervention Phase Only)

After children and parents complete the week 8 and week 16 assessments, study personnel print out symptom reports (Group A: week 8 and week 16; Group B: week 16 only) in clinic and deliver them to parents of IP participants and treating provider prior to their appointment (either week 8 or week 16). Parents are also encouraged to review the web-based version of the report by logging into MyChart prior to clinical visits. Clinicians in the child's care team are able to review this report in children's medical records, where it is stored along with other usual clinical data. These reports reflect children's cumulative symptom scores between baseline, week 8, and week 16 (Group A in Figure 2) or between week 8 to week 16 (Group B). Parents are encouraged to discuss the symptom reports with their child's treating clinicians.

Additionally, the study coordinator will inform children or parents during enrollment about the symptom management resources website that is linked directly to the symptom report in MyChart. This resource site was created by clinicians at Lurie Children's Hospital and the study team, which contain guidelines on managing symptoms at home and when to contact clinicians in a timely manner.

Study Outcomes

SyMon-SAYS Weekly Symptom Assessment

This checklist consists of 9 symptoms: tiredness, pain, insomnia, lack of appetite, worry, nausea, sadness, itch, and headache. These symptoms were selected by clinicians at Lurie Children's Hospital and referenced to our survey of 25 neuro-oncologists and nurses from October-December 2014 in which they were asked to name the top 3 symptoms to be listed on the report. Each symptom is measured by using 1 item with a 5-point rating scale. The SyMon-SAYS study team selected candidate items from existing instruments. Clinicians of Hematology, Oncology, Neuro-Oncology and Stem Cell Transplant Division, Lurie Children's Hospital reviewed candidate items and finalized items included in the symptom checklist. Final items were drawn or modified from Pediatric Patient-Reported Outcome Measurement Information System (PROMIS) Fatigue, Depressive Symptoms, Anxiety, and Sleep, PROMIS Pediatric Itch Questionnaire – Child, Pediatric Quality of Life in Neurological Disorders–Pain, Pediatric Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events (Ped-PRO-CTCAE), Pediatric Functional Assessment of Anorexia/Cachexia Treatment, and Pediatric Functional Assessment of Cancer Therapy – Brain. Symptom Checklist items can be found in the Multimedia Appendix 1. Each item was measured by using a 5-point rating scale. An alert will be generated by SyMon-SAYS via Epic messaging when patients endorse a rating of 3 or higher.

Usability, Acceptability, and Engagement of the SyMon-SAYS Program

Feasibility, acceptability, and engagement will be evaluated using mixed methods across child-parent dyads and clinicians.

For the quantitative methodology, we will calculate the percentage of weekly symptom assessments that children complete, the number of weekly symptom scores that exceed a prior threshold to trigger alerts, as well as clinician documentation to symptom alerts in the EHR. In addition, a subset of participants (parent-child dyads) will be interviewed to obtain their feedback on the symptom report discussions with their clinician and their experience participating in the SyMon-SAYS study at the end of the intervention phase. Children and parents will be interviewed independently. Efforts will be made to balance gender (children and parents), ages (children), clinical variables of children as well as English- and Spanish-speaking participants (all children are English-speaking). Participants whose parents speak Spanish will be interviewed in Spanish.

At the completion of the study, clinicians, including attending physicians, fellows, advanced practice nurses and physician assistants, and registered nurses, will also be interviewed by either individual interviews (via telephone) or email survey to obtain their feedback on the symptom report, the study, and suggestions on how to make it more accessible and child friendly.

We plan to interview up to 30 parent-child dyads and up to 20 clinicians. The telephone interviews will be recorded for transcription and subsequent summary of feedback. Members of the study team will use selective qualitative analysis methods and an iterative coding process to identify common themes and develop coding rules to apply to interviewees' comments. The comments will then be compiled and summarized in frequency tables denoting the number of times certain responses emerge. Both frequency and the relative importance placed on the theme will be used to evaluate usability, acceptability, and engagement along with quantitative results.

Adherence to Intervention

The adherence to the SyMon-SAYS Intervention will be evaluated by using the percentage of dyads completing the assessments at all time-points, excluding those who are off-study or deceased.

XSL•FO
RenderX

Measures Used for Primary and Secondary Outcomes

Modified Symptom Management Barriers Questionnaire

The modified Symptom Management Barriers Questionnaire (SMBQ) is a 23-item tool designed to assess the attitude (perceived barriers) of parents with children diagnosed with cancer toward the assessment and management of their child's symptoms. The SMBQ comprises items that encompass various recognized barriers to achieving effective symptom management. The original version of the SMBQ [9] items was devised with input from experts in symptom assessment and management and interviews with patients and their spouses. The study team made adjustments to the items to ensure their suitability for parents of children with cancer, such as replacing the pronoun "I" with "my child."

Pediatric PROMIS

Change in HRQoL over time will be analyzed by examining changes in the pediatric PROMIS measures. We will administer computerized adaptive tests (CATs) of the domains in the PROMIS Pediatric Profile [50]: (1) physical function-mobility, (2) physical function-upper extremity, (3) depressive symptoms, (4) anxiety, (5) anger, and (6) relationship with peers. The pediatric PROMIS offer good reliability across 2-3 standard deviations of the experiences of children 8-17 years old.

Self-Efficacy: NIH Toolbox Self-Efficacy

The National Institutes of Health (NIH) Toolbox initiative was developed to identify, create, and validate measures in the broad domains of cognitive function, emotional health, motor function, and sensory function [51,52]. Measures of self-efficacy, defined as a person's belief in their capacity to manage their functioning and have control over meaningful events, were developed within the emotional health domain. This measure is available for children aged 8-12 years, adolescents aged 13-17 years, and adults aged 18 years or older and is available as CAT. These measures demonstrated good psychometric properties; US general population norms are available. Patients and parents will complete age-appropriate CATs.

Statistical Analysis

Analysis for Aim 1: Evaluate Efficacy of SyMon-SAYS After 8 Weeks and its Maintenance Effects at Week 16

The coprimary outcomes of the study will be perceived symptom management barriers, child's and parent's self-efficacy, and child's anxiety and depression. Data obtained from baseline, week 8, and week 16 will be analyzed. The primary analysis of intervention efficacy will focus on differences in changes between Group A and Group B in perceived barriers to managing symptoms, self-efficacy and depression, and anxiety from baseline to week 8. We will fit mixed effects models for repeated measures. Barriers, child and parent self-efficacy, depression, and anxiety will each be examined separately as dependent variables in these models (ie, each with separate models). We also will explore the associations of demographic variables (eg, gender), individual factors (eg, health literacy), and clinical characteristics (eg, intensity of treatment) on primary outcomes. We will control for multiplicity among coprimary outcomes with the Benjamini-Hochberg [53] procedure.

Secondary outcomes are changes in other domains of HRQoL, including fatigue, mobility, and peer relationships, as well as symptom burden. We will use the same approach to changes in patients' PROMIS Fatigue, PROMIS Mobility, and PROMIS Peer Relationships will take the same approach as that described above for primary outcomes using mixed effects models. Regarding from baseline to week 8 (Group A) or from week 9 to week 16 (Group B) estimated by calculating the area under the curve (AUC) of each symptom score plotted over time for each participant. The AUC will be then divided by the total time to rescale back to the original units. We will calculate a *P* value for differences in AUC curves between arms with a Wilcoxon rank test.

We hypothesize that group A participants will report fewer perceived barriers, less symptom burden, better self-efficacy, and better HRQoL over phase 1 (weeks 1-8) and then either stay the same or continue to improve over phase 2 (weeks 9-16; exploratory end points), when they continue to receive the SyMon-SAYS intervention. Group B participants, on the other hand, are not expected to report significantly different scores from baseline to the end of phase 1 (ie, week 8) but are expected to report significantly improved outcomes at week 16 than the scores at the baseline.

Analysis for Aim 2: Evaluate Factors Associated With Aim 1 Efficacy Outcomes

For each of the Aim 1 outcomes, we will code individual patients as having improved or not improved by a clinically important threshold. Then, we will examine whether patient and parent contextual factors (eg, patient demographic variables, parent health literacy, and disease severity) are associated with improvement in each outcome (each modeled separately) using multivariable logistic regression models.

Analysis for Aim 3: Evaluate Predictors of Adherence to the SyMon-SAYS Intervention and Preference of SyMon-SAYS Versus Usual Care

We will estimate participants' adherence to SyMon-SAYS during the intervention phase (weeks 1-8 for Group A and weeks 9-16 for Group B), defined as percentage of dyads completing the assessments at all time-points. Preference for SyMon-SAYS versus usual care will be assessed using relevant items in the patient and parent EXIT evaluation survey. These item responses will be descriptively summarized with frequency distributions. Clinicians' perceptions of the acceptability and usefulness of SyMon-SAYS (Evaluation Form) will be similarly assessed by summarizing responses to survey items.

We will identify predictors of intervention adherence and preference using ordinal regression models using data from both groups' intervention phases (weeks 1-8 for group A, weeks 9-16 for group B). Based on number of weekly system assessments completed, patients will be classified as high adherence (completed 7 or 8 weekly assessments), intermediate adherence (completed 3-6 weekly assessments), or low adherence (completed 1 or 2 or fewer weekly assessments). Parent and patient contextual factors to be examined as predictors such as

XSL•FO
RenderX

gender, age, race, parent education, and parent health literacy as well as clinical characteristics such as treatment types. Additionally, we will repeat the same analysis using data from week 9- week 16 from group A to explore whether the group membership (ie, high, intermediate, or low adherence) changed between phase 1 (baseline to week 8) and phase 2 (week 9-week 16) as well as predictors associated with the group membership.

Data Quality and Management

In order to ensure adequate numbers of patients with data for the primary end point analysis, we increased the sample size to account for 20% dropout. Prior to performing analyses, we will evaluate the amount, reasons, and patterns of missing data. We will compare the baseline characteristics of patients with and without complete data. If necessary, multiple imputations of weekly symptom data for secondary end points by chained equations will be used to impute missing data.

To be in compliance with NCI's established publications and data-sharing policy for projects that are funded as part of the Beau Biden Cancer Moonshot Initiative, we will create a data codebook that explains each variable in our databases. We will create deidentified databases in easily-readable formats (eg, tab-delimited) for the express purpose of data-sharing. Underlying primary data for the publications will be made broadly available through our Dataverse site [54]. We will make our publications immediately open access. Publication author eligibility guidelines will be followed. Electronic copies of publications will be deposited in PubMed Central with proper tagging of metadata to ensure web-based discoverability and accessibility within 4 weeks of acceptance by a journal.

Study Timeline

We plan to complete this study in 60 months, including startup (2 months), report development (3 months), assembling symptom management information from web-based resources (8 months), programming SyMon-SAYS (6 months), pilot testing the system, training study personnel, modifying the system based on pilot feedback (6 months), study implementation (36 months, including 16 weeks follow-up), data analysis and manuscript preparation (6 months). Recruitment began in April 2021 and is expected to be completed in Spring or Summer, 2024.

Results

This study has received approval from the institutional review boards of Northwestern University (STU00210598) and Ann & Robert Lurie Children's Hospital of Chicago (IRB 2019-3018). Recruitment began in April 2021 and is anticipated to be completed by Spring or Summer 2024. Following the completion of data collection and analysis, the results will be submitted for publication in a manuscript describing the updated trial results.

Discussion

SyMon-SAYS has several unique features that will significantly advance self-management through incorporating patient-reported symptom monitoring with IT. SyMon-SAYS is incorporated into the EHR to minimize clinic workflow disruption to clinicians and facilitate accessibility by parents and patients, thereby promoting adherence in children, parents and clinicians. Integrating PROs into the EHR has shown improved outcomes in adult patients with cancer [55]. Similar efforts in patients with pediatric cancer are still in their infancy with either focused on patients with pediatric cancer who were hospitalized [37] or were not incorporated into electronic medical records [56]. While SyMon-SAYS captures symptoms occurring between clinical visits. SyMon-SAYS produces user-friendly graphic symptom reports of scores displaying change over time that are presented to parents and clinicians. Parents (and clinicians) will be able to track patients' symptom levels over time, which can enhance their awareness of symptom variability, contribute to increased symptom and illness or disease knowledge, seek medical help in a timely manner, and promote their ability to prepare for communicating with the clinical team [57].

The study has some potential caveats that will need to be considered in interpreting the findings and should be addressed in future research. We considered several randomization strategies, including cluster randomization by physician versus individual-level randomization by patient-parent dyad. Due to the limited number of eligible physicians within a single institution, we deemed it best to randomize by patient despite the known limitations, the greatest of which is contamination. Although exposure to the intervention may influence physicians' discussion or management of their patients in the waitlist control (group B, weeks 1-8), they will not have access to symptom reports for their patients who have not yet crossed over from control to intervention. Given the potential for interinstitutional variability in functionalities to support routine symptom surveillance, we elected to conduct a single institution randomized phase 2 trial to detect an efficacy signal prior to moving to a pivotal phase 3 trial across multiple institutions if our findings demonstrate that the intervention is efficacious. This future trial would randomize by the clinic. We chose a waitlist control design primarily because it exposes Group B participants to both usual care and the SyMon-SAYS intervention, allowing them to state their preferred approach for symptom management. Instead of a cross-over design, we chose to have group A participants continue intervention during weeks 9-16 as it is not reasonable to discourage them from accessing reports and resources available in the Epic EHR that they are exposed to in weeks 1-8. Additionally, this approach allows us to evaluate the durability of the SyMon-SAYS intervention. This study will provide a better understanding of factors impacting patients' and parents' preferences, which can inform the development of individualized interventions to manage symptoms more effectively. We will review the frequency with which participants access web-based information resources. Group differences in frequencies of accessing information resources will not be evaluated during weeks 9-16, as there may be a sustained benefit from weeks 1-8. Thus, the primary comparisons will occur using data collected during the first 8 weeks.

XSL•FO
RenderX

Conclusions

In conclusion, we believe that this randomized waitlist controlled trial of the SyMon-SAYS system will provide preliminary efficacy estimates, gauge feasibility and acceptability, identify predictors of engagement, and suggest strategies to strengthen adherence and adoption in subsequent trials of digital symptom monitoring and management tools in children with cancer across the disease continuum, from active therapy to long-term follow-up.

Acknowledgments

This trial is funded by a cooperative agreement with the National Cancer Institute (5U01 CA246612; principal Investigator: JSL). The contents of this manuscript are solely the responsibility of the authors and do not necessarily represent the official views of the United States Government.

Data Availability

Once the primary results are published, the underlying primary data for the publications will be made widely accessible through the Dataverse [58].

Abstract

Background: Youth in the child welfare system (child welfare–involved [CWI] youth) have high documented rates of mental health symptoms and experience significant disparities in mental health care services access and engagement. Adolescence is a developmental stage that confers increased likelihood of experiencing mental health symptoms and the emergence of disorders that can persist into adulthood. Despite a high documented need for evidence-based mental health services for CWI youth, coordination between child welfare and mental health service systems to increase access to care remains inadequate, and engagement in mental health services is low. Navigator models developed in the health care field to address challenges of service access, fragmentation, and continuity that affect the quality of care provide a promising approach to increase linkage to, and engagement in, mental health services for CWI youth. However, at present, there is no empirically supported mental health navigator model to address the unique and complex mental health needs of CWI youth and their families.

Objective: Using a randomized controlled trial, this study aims to develop and test a foster care family navigator (FCFN) model to improve mental health service outcomes for CWI adolescents (aged 12-17 years).

Methods: The navigator model leverages an in-person navigator and use of adjunctive digital health technology to engage with, and improve, care coordination, tracking, and monitoring of mental health service needs for CWI youth and families. In total, 80 caregiver-youth dyads will be randomized to receive either the FCFN intervention or standard of care (clinical case management services): 40 (50%) to FCFN and 40 (50%) to control. Qualitative exit interviews will inform the feasibility and acceptability of the services received during the 6-month period. The primary trial outcomes are mental health treatment initiation and engagement. Other pre- and postservice outcomes, such as proportion screened and time to screening, will also be evaluated. We hypothesize that youth receiving the FCFN intervention will have higher rates of mental health treatment initiation and engagement than youth receiving standard of care.

Results: We propose enrollment of 80 dyads by March 2024, final data collection by September 2024, and the publication of main findings in March 2025. After final data analysis and writing of the results, the resulting manuscripts will be submitted to journals for dissemination.

Conclusions: This study will be the first to produce empirically driven conclusions and recommendations for implementing a family mental health navigation model for CWI youth with long-standing and unaddressed disparities in behavioral health services

Introduction

Background

After a decade-long decline in the number of youth in placement outside of the home (ie, foster care) in the United States, the foster care caseload in most states rose between 2014 and 2019. The current foster care caseload exceeds 400,000 in the United States [1], with another approximately 165,000 youth receiving court-mandated services within their own homes [2]. Youth in out-of-home or foster care placement and those remaining in the home but are child welfare system and court involved are collectively referred to as *child welfare–involved (CWI)* and are considered some of the most underserved with respect to behavioral health care access in the United States. The COVID-19 pandemic has further increased the number of youth entering the child welfare system owing to having lost parents or caregivers from COVID-19–related death [3].

Rates of mental health symptoms and diagnoses in CWI youth are high, particularly among adolescents. The vast majority are referred to child welfare agencies because of child abuse or neglect [4], and, as a result of trauma experienced in their home of origin, the majority display mental health or behavioral health challenges [5]. According to the National Survey of Child and Adolescent Well-Being, much more than half of a national sample of youth in out-of-home care display behavioral or social competency problems [6], and studies that include smaller samples or regional samples suggest similar results [7,8]. Among 815 CWI youths aged 12 to 17 years, 43% reported at least 1 mental health concern, including attention-deficit/hyperactivity disorder (ADHD; 19%), suicidality (14%), anxiety (14%), depression (9%), and co-occurring substance use (23%) [9]. Youth in out-of-home care report higher rates of mental health problems than peers of a similar age [10,11]. Depending on the study, between 35% and 85% of all youth in out-of-home care experience a mental health condition [12], and youth in out-of-home care are 3 times more likely to be prescribed psychotropic medications for their mental health conditions [13].

Adolescence is a critical developmental period for the assessment, diagnosis, and treatment of mental health symptoms. Vulnerability to mental health disorders increases significantly in adolescence, and the emergence of disorders during this period (eg, early psychosis) increases the likelihood of persistence into adulthood [14]. Rates of depression escalate in adolescence, particularly among girls with extensive trauma histories (such as CWI youth) who are at substantially higher risk for poor mental health, substance use, and legal outcomes. Adolescence also encompasses unique factors associated with the transition to young adulthood (eg, for those aged 16-17 years), making it a highly vulnerable developmental stage for CWI youth [9]. Adolescents who are placed in out-of-home care face unique risks because chronic placement instability is the norm rather than the exception, particularly for older adolescents [15-17]. Studies demonstrate that youth with mental health difficulties are more likely to be moved from one placement to another, and these moves create or exacerbate mental health concerns [18,19]. These concerns are exacerbated for racial and ethnic minoritized youth [20] and reify ongoing and long-standing behavioral health disparities among CWI youth. Identifying adolescent mental health needs, matching these needs to appropriate services, and providing supports for mental health care access and linkage have great potential to resolve or offset challenges manifesting in adulthood.

Despite high need for evidence-based mental health services for CWI youth, ample evidence suggests that coordination between child welfare and mental health service systems is inadequate. Access to care for CWI youth is hampered by multiple system-level barriers, such as frequent change of placement as well as underreporting of mental health problems by foster parents, social workers, and physicians [13]. National survey data (n=3803) highlight a substantial gap between the identified need for and use of mental health services in child welfare populations, particularly among older youth: 66% of those aged 11 to 14 years have clinically significant mental health needs, yet only 26% use mental health services [21]. Data local to the site of the proposed project demonstrate critical gaps in mental health screening and full assessment, with only 28% of all youth assessed within 2 months of case opening, 45% by 3 months, and 69% by 6 months. Furthermore, by 12 months, 11% of youth had their case closed before ever receiving a mental health assessment [22].

The public health impact of gaps in mental health services delivery among CWI youth is significant. Untreated mental health concerns among CWI youth persist when they leave the out-of-home care system and transition to independence [23]. CWI youth are also likely to have dual (or *crossover*) involvement with the juvenile legal system [24], which can further exacerbate unmet services needs and disparities within this population. Persistent mental health concerns in this population can also contribute to placement instability [25] and re-entry into the child welfare and juvenile legal systems [26], which both compound mental health difficulties and strain public health systems and economies. Unaddressed mental health

XSL•FO
RenderX

services needs also perpetuate racial and ethnic disparities in services access, engagement, and quality in this population, as well as perpetuate the root causes of these disparities (eg, systemic racism and discrimination), which have notable public health consequences. Data local to the site of the proposed project mirror national statistics, documenting the alarming overrepresentation of African American and Latinx youth in the child welfare system [21]: 36% of CWI youth aged 12 to 17 years are African American compared with 6.1% of the entire county population.

Navigator models (ie, the use of a navigator to support access to, and transition through, complex health care systems) provide a promising approach to increasing linkage to, and engagement in, mental health services for CWI youth with high rates of unaddressed mental health concerns. Navigator models have been successfully developed and deployed in other contexts (eg, cancer and HIV), with demonstrated improvements in service tailoring, linkage, and treatment retention [27]. A small number have also been developed for general adolescent populations with behavioral health needs (eg, the Family Navigation Project) [28]. However, existing mental health navigator models have not been empirically developed or tailored for system-involved (ie, child welfare or juvenile legal system) youth and families who have unique, complex multisystemic factors associated with mental health care needs and access.

Mobile health (mHealth) technology is gaining empirical support for improving adolescent mental health and behavioral health (eg, substance use) outcomes. Data suggest that SMS text messaging is a useful tool to improve youth attendance in outpatient mental health treatment [29] and can prevent adolescent substance use relapse [30]. A recent meta-analysis (n=14 studies) concluded that SMS text messaging technology is a promising substance use prevention strategy for adolescents and young adults [31], the majority of whom have access to, and regularly use, their mobile phones despite unique adolescent barriers to constant access and use (eg, service payment, continuous service, and no access while at school during the day). Our own work with community-supervised court-involved adolescents and their caregivers suggests that families and involved juvenile legal personnel and providers all heavily rely on digital and mHealth technology for communication and care coordination (eg, SMS text messaging, emailing, and social media instant messaging) [32].

Despite the promise and prevalence of mHealth technology, there is no systematic, empirically supported strategy leveraging mHealth to enhance family-based approaches to improving CWI youth mental health service use and outcomes. Studies show that only some caregivers are ready for electronic messaging support for health care [33] and that depending on caregiver race or ethnicity (eg, Latinx ethnicity), socioeconomic status (eg, low status) and age (eg, younger age), SMS text messaging may be more or less appealing as a tool for adolescent health care engagement [33,34]. Parent outreach via bidirectional SMS text messaging to enhance the uptake of adolescent vaccine and well care services improved these adolescent health outcomes [35], suggesting that a caregiver-level mHealth intervention may be effective in improving other adolescent health outcomes (eg, mental health). Caregivers of CWI youth have the additional context of juvenile legal system and child welfare system surveillance and involvement (eg, mandated youth treatment, sanctions-based approach to noncompliance, and information-sharing concerns) that might differentially affect their response to mental health navigator interventions, particularly those that incorporate mHealth for service tracking or monitoring. Given the high numbers of staff, providers, and systems that often operate separately and with minimal coordination to support CWI youth, mHealth has unique potential to improve communication between families and systems to support linkage to, and engagement in, mental health services.

Given the significant need for an empirically driven, timely, coordinated, and collaborative interagency response to addressing the mental health needs of CWI youth, the proposed project aims to develop and test an empirically derived navigator intervention that relies on interagency codevelopment and incorporates state-of-the-art mHealth technology to improve linkage to, and engagement in, mental health services among CWI youth. A randomized clinical trial (N=80 caregiver-youth dyads) comparing the navigator intervention with standard of care (clinical case management services) for CWI youth has the potential to have large-scale trial applicability and to be feasible and acceptable for eventual system implementation and adoption.

Study Objectives

This study will be the first to develop and test a foster care family navigator (FCFN) intervention for CWI youth that has the potential to significantly improve adolescent mental health disparities, particularly for racial and ethnic minoritized youth. The primary goal of the study is to assess the feasibility, acceptability, and preliminary impact of the FCFN intervention on the mental health services cascade of care (eg, screening, assessment, and treatment initiation) outcomes. Using a randomized controlled trial (RCT) design, we will randomize 80 families to receive either the FCFN intervention or standard of care (clinical case management services): 40 (50%) to FCFN and 40 (50%) to control. Qualitative exit interviews will inform the feasibility and acceptability of the services received during the 6-month period. Primary trial outcomes are mental health treatment initiation and engagement. Other pre- and postservice outcomes, such as proportion screened and time to screening, will also be evaluated.

Juvenile Justice Behavioral Health Services Cascade

The juvenile justice behavioral health services cascade, hereinafter referred to as the *cascade*, was recently developed (adapted from the HIV cascade of care models) [36] as part of the Juvenile Justice Translational Research on Interventions for Adolescents in the Legal System (JJ-TRIALS) study, a National Institute on Drug Abuse–funded, large-scale, multisite research and implementation science collaborative. JJ-TRIALS developed the *cascade* as a unifying framework for juvenile legal system and behavioral health partners to collectively (1) identify system-level substance use service strengths and needs along the continuum of care and (2) codevelop and test interventions to improve adolescent substance use service linkage and

XSL•FO
RenderX

outcomes along the *cascade*. The *cascade* framework can also inform multiple interrelated research goals and be easily adapted for empirical application and testing with other youth populations (eg, foster care youth), systems (eg, child welfare system) and health (eg, mental health) outcomes [37] as in the proposed study. Figure 1 presents a hypothetical adapted *cascade* framework for CWI adolescent populations using the same cascade of care steps but modifying the involved systems (eg, from juvenile legal system to child welfare system). Table 1 presents step definitions (developed by the JJ-TRIALS group) adapted to CWI youth and system processes.

Figure 1. Example of juvenile justice behavioral health services cascade adapted for child welfare–involved (CWI) youth.

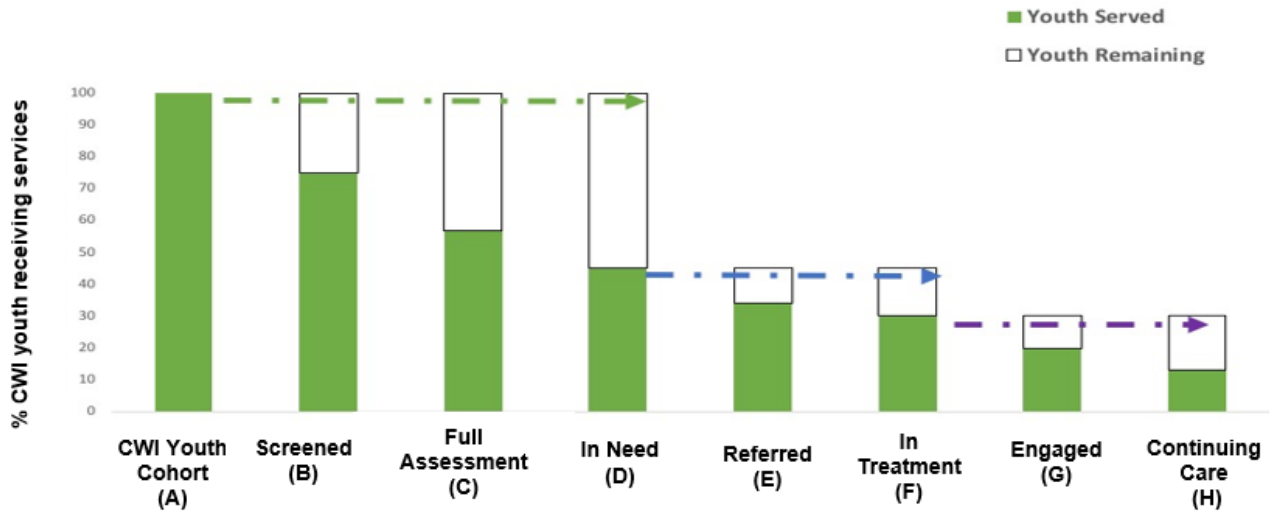

Table 1. Behavioral health services cascade definitions adapted for child welfare–involved youth and the foster care mental health (FCMH) system.

Step	Operational definition	Calculated proportion (based on step)
A. Child welfare referrals	Total number of referrals to FCMH over a designated period of time, less any youth already in treatment at that time	N/A[a]
B. Screened	Subset of FCMH referrals (A) with a screening date	B/A
C. Full clinical assessment	Subset of FCMH referrals (A) with a full clinical assessment (includes if follow-up to screening or other clinical assessment)	C/A
D. In need	Subset of FCMH referrals (A) with a need for mental health treatment based on screener, clinical assessment, or other sources of information	D/A
E. Referrals to treatment	Subset of those in need (D), referred by the child welfare or FCMH systems to mental health treatment	E/D
F. In treatment	Subset of those referred to treatment (E) who have a treatment start date	F/E
G. Engaged in care	Subset of those in treatment (F) who stay in treatment for at least 6 weeks (based on treatment discharge minus treatment start date)	G/F
H. Continuing care	Subset of those engaged in treatment (G) who are still receiving treatment after 90 days	H/G

[a]N/A: not applicable.

Digital Health Application (Chorus) and Approach

The FCFN intervention incorporates digital health technology grounded in participatory informatics (using the secure web-based Chorus platform [Chorus Innovations, Inc], which involved end users and navigators in app codevelopment as an inherent and critical component of successful navigation [38]). Chorus is an established digital health platform that provides the basis for a web application named Fostering Connections, which is accessible to a broad range of people (similar to visually creating slides in Microsoft PowerPoint) and includes interactive messaging and mobile web app capabilities [38]. Fostering Connections was adapted based on feedback from CWI families and stakeholders and is designed to support the navigation process across multiple dimensions by (1) supporting bidirectional SMS text messaging (and shared dashboards) to enhance communication between navigators and families, (2) including reminders for upcoming session and behavioral health services appointments, (3) storing navigation documents and resources, and (4) including surveys for completion by navigators. Thus, it is a proven and reliable system that will allow navigators to effectively opt in as well as communicate with, and engage, participants and other providers; in addition, it can be developed and tailored according to research study needs.

XSL•FO
RenderX

Hypotheses

We hypothesize that youth receiving the FCFN intervention will have increased rates of mental health treatment initiation and engagement compared with youth receiving standard of care. We will also explore hypothesized mechanisms of intervention impact (eg, navigator satisfaction, youth treatment motivation, and perceived barriers to care) as well as potential moderators (eg, sex, race, ethnicity, and out-of-home placement status).

Methods

Study Design

Up to 5 FCFNs and 80 families (caregiver-youth dyads) will participate in the RCT to assess the preliminary impact of the FCFN intervention on mental health services use. CWI youth (in in-home or out-of-home placement) aged between 12 and 17 years as well as their caregivers will be referred for study participation at the point of referral from the child welfare system to a partnering mental health clinic (hereinafter referred to as the foster care mental health [FCMH] clinic) that specializes in serving foster care youth by linking them to specialty mental health services. Enrolled families will be randomized to either the FCFN intervention or standard of care.

Enrolled CWI youth and their caregivers will complete a computerized set of questionnaires (on a tablet device, mobile phone, PC, or laptop computer) at baseline, midintervention (1-month after baseline), and at 3 and 6 months after randomization.

The trial has been registered with ClinicalTrials.gov (NCT04506437).

Intervention Condition (FCFN)

Families (n=40) who are randomized to the FCFN intervention will complete six 60-minute intervention sessions in the first 2 to 3 months of the 6-month period. Sessions can be scheduled on a weekly or biweekly basis. The 6 sessions, described in Figure 2, are as follows: *Introduction to the navigator and navigation services*, *Specialty mental health services orientation*, *Clinical care team mapping*, *Barriers to care and stress management*, *Therapy expectations and stigma*, and *Values and motivation to engage in treatment*. The 6-month intervention period also includes brief check-ins with youth and caregivers, typically conducted through the Fostering Connections web application, by telephone and videoconferencing, depending on the preference and availability of families. The 6 intervention sessions will be audio recorded to separately assess for FCFN intervention fidelity by trained study staff (raters).

Figure 2. Session-by-session content.

Standard of Care (Clinical Case Management Services) Condition

Families (n=40) who are randomized to standard of care (comparison condition) will receive clinical case management services *as usual*, delivered by FCMH clinic case managers. The role of FCMH clinic case managers is to identify mental health treatment referral resources in the community that match current youth mental health service needs. FCMH clinic case managers facilitate direct referral to a community provider and then provide this information for the family to link to community-based care. FCMH clinic case managers do not typically meet with youth and their families directly but rather follow the existing FCMH clinic protocol of facilitating referrals and linkage via telephone and other communication with youth and their families and their FCMH clinic screening clinician.

Participants

FCMH Clinic Study Sample

Recruitment for the study commenced in August 2020 and will conclude by March 2024. Historically, the FCMH clinic has served an annual average of 100 unduplicated youth aged 12 to 17 years with mental health screening and other related services for those with medical necessity. The average length of time in the court dependency process is 6 months, but can be as long as 12 months in cases of family reunification, and up to 18 months in cases of permanency planning or transition-age youth.

XSL•FO
RenderX

Youth who reach the age of 18 years while receiving FCMH services are eligible for, and continue to receive, services without disruption.

Racial, Ethnic, and Sex Considerations

FCMH clinic data from the 2017-2018 period suggest that the ethnic representation of youth will be approximately 29% Hispanic or Latinx and that the racial representation will be 29% African American, 3% American Indian or Alaska Native, 18% Asian or Pacific Islander, 14% European-American or White, 3% multiethnic, and 4% other. Of the FCMH clinic adolescent caseload, male adolescents represent approximately 41%, and female adolescents represent approximately 59%. African American and Latinx youth are disproportionately represented, given that, of the total population in the clinic's surrounding area, African Americans comprise only 6.1% and Latinx only 15.1%.

Behavioral Health Considerations

On the basis of FCMH clinic data from the 2017-2018 period, medical records identified the primary disorder diagnosis as 43% adjustment, 24% mood, 22% anxiety (including posttraumatic stress disorder [PTSD]), 7% behavioral (eg, oppositional), 1% psychosis, and 3% deferred.

Inclusion and Exclusion Criteria

Eligible participants will be youth aged between 12 and 17 years who have an active dependency petition with the local unified family court (newly filed or existing when the RCT commences), are referred to the FCMH clinic for services, have an involved caregiver or legal guardian who can consent and participate in the intervention, and whose family has mobile phone access. The exclusion criteria include youth and caregivers who are monolingual in languages other than English or Spanish, caregiver impairment that would preclude providing informed consent, and the lack of an available guardian for consent.

Recruitment and Consent

Study staff will be embedded in the FCMH clinic setting to introduce the study and procedures to eligible families at the time that families meet with FCMH clinic staff (eg, to complete the mental health screening). FCMH clinic staff will refer eligible families to meet with study staff. Interested youth and families will be separately assented or consented in a private place (FCMH clinic staff will not be involved). We will obtain a waiver of parental consent for referred youth.

Randomization

Participants will be randomized (using a computer-generated randomization tool) to either the FCFN intervention group (40/80, 50%) or the standard of care group (40/80, 50%) directly after consent and completion of the baseline assessment.

Ethics Approval

This study was approved by the institutional review board at the University of California San Francisco (268565) and was conducted in accordance with the ethical standards of the Helsinki Declaration.

Assessment Data Collection

Multiple sources of data will be collected, including electronic medical records (EMRs); mobile phone or web entry in the Fostering Connections web application; and self-reports from the FCFNs, youth, and caregivers (Textbox 1). Cascade mental health services–level data will be extracted from EMRs at baseline and at 1, 3, and 6 months for participants in both conditions. Assessments will be conducted via mobile phone or tablet device, depending on participant preference.

XSL•FO
RenderX

Textbox 1. Study measures.

Identification (percentage of court cohort aged 12-17 years; electronic medical record [EMR])

- Percentage screened (Child and Adolescent Needs and Strengths [CANS; short form]), percentage assessed (CANS), and percentage in need
- Time to screening, full assessment, and determination of need (number of days)

Transition (percentage of those identified as in need; EMR)

- Percentage referred for treatment and percentage who initiated treatment
- Time to referral and initiation (number of days)

Retention (percentage of those referred for treatment; EMR)

- Engaged in care (≥6 weeks of attendance)
- Continuing care (number of total sessions completed)

Navigator background (foster care family navigator [FCFN])

- Age, race and ethnicity, education, training, and years in child welfare field

Number and types of contacts with navigator (Chorus platform, FCFN, youth, and caregivers)

- Video, SMS text messaging, in person, and telephone

FCFN intervention fidelity (FCFN)

- Developed as part of prior study procedures

Therapeutic Working Alliance (youth)

- Twelve-item Working Alliance Inventory [39], used in the Cannabis Youth Treatment Study [40], that assesses youth's perception of therapeutic alliance over time

Navigation Satisfaction Tool, Part I [41] (youth and caregivers)

- Twelve items that address client satisfaction with navigation services (eg, How satisfied are you with the navigator's ability to listen and understand your concerns? How satisfied are you with the frequency of contact with the navigator?)

Evidence-Based Practice Attitude Scale-50 (FCFN)

- A 50-item scale [42], developed and validated with mental health service providers, that assesses global attitudes toward the adoption of evidence-based practices

Barriers to Care Questionnaire (youth and caregivers)

- A 39-item scale (subscales of skills, marginalization, stigma, expectations, knowledge and beliefs, and pragmatics) [43] that assesses perceived barriers to child health care access; items are rated on the extent of the problem (ranging from 100 for "no problem" to 0 for "very big problem"), with higher scores indicating fewer barriers (items are at 5.7 grade reading level)

Motivation for Youth's Treatment Scale (youth and caregivers)

- A psychometrically valid 8-item scale [44] that youth and caregivers complete to measure intrinsic treatment motivation with the subscales of problem recognition and treatment readiness

Mobile health (mHealth) feasibility or satisfaction (Chorus platform, youth, and caregivers)

- Mobile phone type, mobile phone service interruptions, number of mobile phone numbers, most preferred types of SMS text messages, number of messages opened or read, and responses

Usability of mHealth intervention components or "system": System Usability Scale (SUS; FCFN, youth, and caregivers)

- A 10-item measure [45] widely used to evaluate web applications that has proven superior to other measures; the SUS yields a single number representing a composite measure of the overall usability of the system being studied, and scores will be compared with established norms for levels of usability; our goal is a score of 80 (top 10% of scores), which reflects excellent usability and is associated with recommending the product to a friend

Sociodemographics (EMR, youth, and caregivers)

- Race, ethnicity, sex, education, income, legal history, and placement type

XSL•FO
RenderX

Pediatric Symptom Checklist (EMR, youth, and caregivers)

- A 35-item measure of child emotional and behavioral problems that has been identified as a feasible method for the early detection of mental health difficulties [46] and intervention outcomes measurement [47]; items are rated as "never present" (0), "sometimes present" (1), or "often present" (2), with the total (summed) score ranging from 0 to 70; for children and youth aged 6 to 18 years, the cutoff score is 28 (≥28=impaired)

University of California Los Angeles Posttraumatic Stress Disorder Reaction Index for Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5; youth)

- An instrument that screens for exposure to traumatic events and the frequency of posttraumatic stress disorder symptom occurrence during the past month (ranging from 0=none of the time to 4=most of the time) [48]; items map directly onto DSM-5 intrusion, avoidance, and arousal criteria, whereas 2 additional items assess associated features (fear of recurrence and trauma-related guilt); scoring algorithms permit tabulation of the total score as well as B, C, and D subscale scores

Brief Symptom Inventory (caregivers)

- A 51-item measure of past week mental health symptoms [49]

Parent-Adolescent General Communication Scale (youth and caregivers)

- A scale that assesses positive and negative aspects of communication via 2 subscales (open family communication and problems in family communication) [50], with 5 items assessing the frequency of communication topics

Parental Monitoring Questionnaire (youth and caregivers)

- A 24-item measure of parental monitoring across 4 areas or subscales (parental knowledge, child disclosure, parental solicitation, and parental control), with higher scores indicating higher levels of monitoring domains [51]

Measures

Overview

Youth and caregivers in both conditions will each complete the electronic study assessment at baseline and at 1, 3, and 6 months (4 times in total). Unless it is specifically noted, all of the following measures will be collected from youth and caregivers across both conditions. FCFN navigator measures are also included.

Primary Outcome Measures

Cascade of Care Services

We will collect EMR data that will include (1) percentage screened (for mental health needs), percentage assessed (received full mental health assessment), and percentage in need (determined to meet medical necessity criteria for mental health services); (2) time to screening, full assessment, and determination of need (number of days); (3) percentage referred for mental health treatment as well as percentage who initiated treatment; (4) time to referral and initiation (number of days); (5) whether the youth engaged in treatment (whether they had ≥6 weeks of treatment attendance); (6) number of total mental health treatment sessions completed; (7) sociodemographics (to provide collateral EMR data on race and ethnicity, sex, education, income, legal history, and placement type); (8) Child and Adolescent Needs and Strengths (CANS) screener and full assessment (the number and descriptions of needs and strengths and based on the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition [DSM-5], diagnosis per the CANS rating and resources manual with regard to children and youth aged 5-18 years); and (9) Pediatric Symptom Checklist score (collected by the specialty mental health provider and entered into the EMR as part of standard clinical and billing practice).

Therapeutic Working Alliance

The 12-item Working Alliance Inventory (WAI) [39], which was used in the Cannabis Youth Treatment Study [40], assesses youth perception of therapeutic alliance over time.

Navigation Satisfaction Tool, Part I

The 12-item Navigation Satisfaction Tool (NAVSAT), Part I [41], addresses participant satisfaction with navigation services (eg, How satisfied are you with the navigator's ability to listen or understand your concerns? How satisfied are you with the frequency of contact with the navigator?)

Barriers to Care Questionnaire

This 39-item scale (subscales of skills, marginalization, stigma, expectations, knowledge and beliefs, and pragmatics) assesses perceived barriers to youth health care access [43]. Items are rated on the extent of the problem (ranging from 100 for "no problem" to 0 for "very big problem"). Higher scores indicate fewer barriers. The items are at 5.7 grade reading level, and thus youth can complete this questionnaire.

Motivation for Youth's Treatment Scale

This is a psychometrically valid 8-item scale that youth and caregivers complete to measure intrinsic treatment motivation with the subscales of problem recognition and treatment readiness [44].

System Usability Scale

The System Usability Scale (SUS) [52] is a 10-item measure that is widely used to evaluate web applications and has proven superior to other measures. The SUS yields a single number representing a composite measure of the overall usability of the system being studied [45]. The SUS scores will be compared with established norms for levels of usability. Our goal is to reach a score of 80, which is in the top 10% of scores, reflects excellent usability, and is associated with recommending the

XSL•FO
RenderX

product to a friend (youth and caregivers; intervention group only).

Pediatric Symptom Checklist

This 35-item measure of child emotional and behavioral problems [46] is widely used in diverse pediatric primary care settings and has been identified as a feasible method for the early detection of mental health difficulties and intervention outcomes measurement [47]. Items are rated as "never present," "sometimes present," or "often present" and scored 0, 1, and 2, respectively. The total (summed) score ranges from 0 to 70; for children and youth aged 6 to 18 years, the cutoff score is 28 (≥28=impaired). We will collect this separately and in addition to available EMR Pediatric Symptom Checklist data to measure changes in symptoms over time (ie, for repeated measures).

Brief Symptom Inventory

This 51-item measure will be used to rate the extent to which parents have been bothered in the past week by their own mental health symptoms [49].

Texas Christian University Drug Screen 5

This 17-item measure assesses past 12-month quantity and frequency of alcohol and drug use and the perceived level of functioning and impairment associated with substance use (youth only) [53].

Parent-Adolescent General Communication Scale

This scale will assess the positive and negative aspects of general communication via 2 subscales (open family communication and problems in family communication) [50]. Five items assess the frequency of communication topics.

Parental Monitoring Questionnaire

This 24-item measure is designed to assess parental monitoring across 4 areas or subscales (parental knowledge, child disclosure, parental solicitation, and parental control) [51]. Higher scores indicate higher levels of monitoring domains.

Child and Adolescent Services Assessment

This assessment consists of a semistructured interview that obtains information about service use for mental health problems across multiple sectors (eg, juvenile legal system and schools) [54]. Information about the type of facility, the professional discipline of provider or providers, outpatient services, and out-of-home placements is obtained, and the measure has adequate reliability (intraclass correlation coefficient=0.74-0.76). We will categorize the length and nature of treatment received to increase the generalizability of our study results. We will also add items related to participants' arrest history.

University of California Los Angeles PTSD Reaction Index for DSM-5

This instrument is used to screen for exposure to traumatic events and assess the frequency of occurrence of PTSD symptoms in the past month [48]. We will use a modified version of this measure that will only ask about the total number of exposures to traumatic events and not the specific type of event or any details related to the event.

Sociodemographics

We will collect data on race, ethnicity, sex, education, income, legal history, and placement type.

Number and Types of Contacts

Data regarding the number and types of contacts between the FCFNs and youth and caregivers will be collected from the Fostering Connections web application (eg, total number of messages sent and received, number of messages read, content of the messages, and number of contacts with the FCFNs).

FCFN Feasibility, Acceptability, and Satisfaction: Evidence-Based Practice Attitude Scale-50

This 50-item scale was developed and validated with mental health service providers and assesses global attitudes toward the adoption of evidence-based practices [42].

FCFN Feasibility, Acceptability, and Satisfaction: FCFN Fidelity Forms

As part of intervention delivery, the FCFNs will rate the adherence to sessions (eg, activities completed and number of contacts) of youth and caregivers. The FCFNs will also complete their own feedback session forms after each of the six 60-minute sessions to document the occurrence of planned activities and content and the occurrence of additional activities (that might not have been part of the FCFN manualized intervention), as well as any aberrant events.

Exit Interviews With Youth and Caregivers

A subsample of 12 families or 24 participants (6 youths and 6 caregivers or 12 participants from each condition) will be invited to participate in an exit interview at the end of the 6-month intervention period to inform feasibility, acceptability, and satisfaction with the FCFN and standard of care (clinical case management services) conditions. Each participant will be offered a US $40 gift card (applicable to those who are allowed to receive it).

Exit Interviews With Foster Care Family Navigators

Up to 5 FCFNs will be invited to participate in an exit interview at the end of the pilot RCT study phase to provide more detailed feedback on their experiences of delivering the FCFN intervention and to inform future trials. Each participant will be offered a US $40 gift card (applicable to those who are allowed to receive it).

Statistical Analysis

Quantitative Analysis

Overview

Analyses will be conducted using SAS 9.4 (SAS Institute Inc) [55]. Preliminary analyses will include an examination of descriptive statistics and distributions. Scaled psychometric measures (eg, the Barriers to Care Questionnaire) will be scored according to established algorithms and internal consistency reliability examined. Item-level missing data will be minimized through the programming of surveys; multiple imputation (PROC MI) will be used for item-level missing data if missingness is random. A unified statistical framework—generalized linear mixed models (GLMMs; PROC

XSL•FO
RenderX

GLIMMIX)—will be used for most analyses. These models account for the clustering of participants and for unit-level missing data.

Cascade Outcomes

GLMM analyses of dichotomous outcomes (screening, treatment initiation, etc) will include intervention (FCFN group vs control group) as a fixed between-participants effect. Cox regression analysis (PROC PHREG) will be used to compare the interventions on time-to-event outcomes (eg, time to assessment) using a shared frailty model that accounts for clustering within pods. The potential mediators and mechanisms of change, measured longitudinally (at baseline and at 1, 3, and 6 months) only for FCFN intervention participants, will be initially examined for intervention impact using GLMMs that include a repeated within-participants time effect. The majority of the mediators are scaled variables, anticipated to have normal distributions, but final models and link functions will be chosen based on observed distributions. It will not be possible to test mediation without data from the control group. Therefore, we will identify potential mediators to be studied in the future trial by first determining which potential mediators change between baseline and month 1 or month 3 and then examining whether month 1 or month 3 values and changes between baseline and month 1 or month 3 are associated with cascade outcomes.

Moderators

We will examine potential moderators (eg, sex, gender, race and ethnicity, and mental health symptoms) of intervention impact by adding the potential moderators one at a time, given the modest sample size, to the models used to examine cascade outcomes and mediators. Analyses of cascade outcomes will include moderator × intervention interactions, and analyses of mediators will include moderator × time interactions.

Qualitative Analysis

All individual interviews will be digitally recorded and transcribed verbatim. Interview facilitators will review the recording and write notes within 48 hours of each interview completion to construct an executive summary of the main discussion points and topics. Executive summaries have been used successfully in the work conducted by the principal investigator (MTS) to provide data quickly and provide evidence of whether discussion theme saturation is achieved. Key data from executive memos will be immediately entered into ATLAS.ti software (version 7; ATLAS.ti Scientific Software Development GmbH), and the results will be presented to the investigator team. After the completion of the executive summaries and development of the FCFN intervention content, interview data will be analyzed according to inductive thematic analysis methods. An initial codebook will be developed based on the interview guides and corresponding transcripts. To improve reliability and to ensure adequate intercoder agreement, one of the authors (ED) and a clinical research coordinator will compare coding patterns and refine the codebook until consensus is reached and then generate memos to highlight connections between codes and subcodes. Quotations from participants will be compiled and concepts and relationships pertinent to core themes developed. We will seek out and compare unique themes relevant to the analytic subgroups (eg, those based on age, sex, gender, race, and ethnicity) to capture important thematic group differences. Final codes and memos will be compared and combined into overarching themes and subthemes. Themes will be discussed, refined, and named for the final analysis. The principal investigator will provide guidance on coding and analysis at regular study meetings. ATLAS.ti software (version 7) will be used to facilitate the analyses.

Results

The study was funded by the National Institute of Mental Health on April 20, 2020. The trial is open and recruiting. We propose the enrollment of 80 dyads by March 2024 and final data collection by September 2024. After final data analysis and the writing of the results, the manuscripts will be submitted to appropriate journals for dissemination, with main findings published by March 2025.

Discussion

Summary

This study is a protocol for an RCT testing an empirically derived FCFN intervention with adjunctive digital health technology (the Fostering Connections web application) to support linkage to, and engagement in, mental health services among CWI youth. The FCFN intervention encompasses six 60-minute family-based intervention sessions designed to address barriers to, and build motivation for, engagement in outpatient community-based mental health services for CWI youth (aged 12-17 years). On the basis of prior literature on health navigator models delivered in community-based settings, we hypothesize that youth receiving the FCFN intervention will have higher rates of mental health treatment initiation and engagement than youth receiving FCMH clinic standard of care (clinical case management services).

The strengths of this study include the use of a randomized study design to maximize internal validity and scientific rigor as well as the use of empirically supported intervention models (ie, health navigation, family-based support, and motivational interviewing) that have been successfully implemented in community-based settings with diverse populations. The study also builds off prior community-engaged mixed methods work involving interagency collaboration, EMR data collection, and qualitative research (eg, system stakeholder interviews, youth and family interviews, focus groups, and direct observation) to develop and iteratively refine the FCFN intervention and study procedures to enhance scientific rigor and relevance. The study is also designed to maximize real-world implementation potential through the delivery of the FCFN intervention by existing staff at a community-based mental health clinic for CWI youth.

Potential limitations and design considerations include a partnering clinic that does not serve a sufficiently large sample size of CWI youth to be the sole site for the next phase of the large-scale trial. However, our investigators have existing research partnerships with other nearby large northern California counties that would allow us to expand and conduct large-scale FCFN intervention testing with other mental health clinics

XSL•FO
RenderX

serving CWI youth using the same design approach as the pilot trial. Furthermore, sample size limitations may limit the current potential to analyze outcomes by those receiving the FCFN intervention as part of in-home services versus out-of-home placement and other demographic variables (eg, ethnoracial identity, gender, and socioeconomic status). Placement type and stability are important to consider in terms of intervention impact; thus, we will descriptively explore how outcomes may differ according to these variables to inform the future larger trial.

Conclusions

This study intends to move the field forward in several ways. First, it will extend a recently developed services continuum of care framework for legally involved youth with substance use (the juvenile justice behavioral health services cascade framework; JJ-TRIALS) and address the mental health service strengths, gaps, and needs of CWI youth, families, and systems. Second, the pilot trial design will provide an opportunity to engage community stakeholders and leverage existing staff resources for *real-world* intervention testing while also allowing for the measurement and observation of design feasibility and acceptability for a future large-scale hybrid 1 (efficacy or effectiveness) trial. Third and last, the incorporation of digital health tools will aid the navigation process (eg, tracking, care coordination, and communication) to ensure that CWI youth are receiving optimal care that navigators, outside providers, and other relevant CWI systems can measure. The inclusion of an established digital health platform (Chorus for the Fostering Connections web application) supports the navigation process by supporting bidirectional SMS text messaging, appointment reminders, and critical navigation document sharing to enhance communication across FCFNs and families. Taken together, such innovations will allow the study team to provide first-time empirically driven conclusions and recommendations related to the processes, strategies, and preliminary impact of a family mental health navigation model for CWI youth.

Acknowledgments

This study is supported by the National Institute of Mental Health of the National Institutes of Health (NIH; R34MH119433; principal investigator: MTS). Abstract

Background: Māori are the Indigenous people of Aotearoa (New Zealand). Despite global acceptance that cervical cancer is almost entirely preventable through vaccination and screening, *wāhine* Māori (Māori women) are more likely to have cervical cancer and 2.5 times more likely to die from it than non-Māori women. Rural Māori residents diagnosed with cervical cancer have worse outcomes than urban residents. Living in rural Aotearoa means experiencing barriers to appropriate and timely health care, resulting from distance, the lack of community resourcing, and low prioritization of rural needs by the health system and government. These barriers are compounded by the current screening processes and referral pathways that create delays at each step. Screening for high-risk human papillomavirus (hrHPV) and point-of-care (POC) testing are scientific advances used globally to prevent cervical cancer.

Objective: This study aims to compare acceptability, feasibility, timeliness, referral to, and attendance for colposcopy following hrHPV detection between a community-controlled pathway and standard care.

Methods: This is a cluster randomized crossover trial, with 2 primary care practices (study sites) as clusters. Each site was randomized to implement either pathway 1 or 2, with crossover occurring at 15 months. Pathway 1 (community-controlled pathway) comprises HPV self-testing, 1-hour POC results, face-to-face information, support, and immediate referral to colposcopy for women with a positive test result. Pathway 2 (standard care) comprises HPV self-testing, laboratory analysis, usual results

XSL•FO
RenderX

giving, information, support, and standard referral pathways for women with a positive test result. The primary outcome is the proportion of women with hrHPV-positive results having a colposcopy within 20 working days of the HPV test (national performance indicator). Qualitative research will analyze successes and challenges of both pathways from the perspectives of governance groups, clinical staff, women, and their family. This information will directly inform the new National Cervical Screening Program.

Results: In the first 15-month period, 743 eligible HPV self-tests were performed: 370 in pathway 1 with POC testing and 373 in pathway 2 with laboratory testing. The positivity rate for hrHPV was 7.3% (54/743). Data collection for the second period, qualitative interviews, and analyses are ongoing.

Conclusions: This Māori-centered study combines quantitative and qualitative research to compare 2 clinical pathways from detection of hrHPV to colposcopy. This protocol draws on rural community practices strengths, successfully engaging Māori from a *whānau ora* (family wellness) approach including *kanohi ki te kanohi* (face-to-face), *kaiāwhina* (nonclinical community health workers), and multiple venues for interventions. It will inform the theory and practice of rural models of the use of innovative technology, addressing Māori cervical cancer inequities and facilitating Māori wellness. The findings are anticipated to be applicable to other Indigenous and rural people in high-income countries.

Introduction

Background

Māori are the Indigenous people of Aotearoa (New Zealand). *He Tapu Te Whare Tangata* reflects the veneration of *wāhine* Māori (Māori women) and people with cervices as sacred *whare tangata* (houses of humanity) from a Māori worldview [1]. The overall name of this project "He Tapu Te Whare Tangata—a model for empowering rural solutions" affirms the importance of women's right to best health.

Whānau (families) living in rural Aotearoa face barriers to appropriate and timely health care. This is a complex issue involving distance from main centers, the lack of community resourcing, and low prioritization of rural needs by the national health care system and government. Residents of rural areas have poorer health outcomes than those living in urban areas, and for Māori, who experience inequities in access to care, social determinants of health, and quality of care, this is accentuated [2-4]. To address these barriers, effective solutions for rural Aotearoa should involve both innovative technologies and community empowerment. Using the cervical cancer screening pathway, this partnership project pairs innovative technology with community control of the care pathway to reduce barriers to timely care.

Cervical cancer is one of the few cancers preventable through both vaccination and screening. Screening can detect precancer of the cervix that can be treated, halting the development of a potentially fatal outcome. *Wāhine* Māori are twice as likely to have cervical cancer and 2.5 times more likely to die from it than non-Māori women [5]. Māori living in rural areas diagnosed with cervical cancer have worse outcomes compared with urban residents [6]. These cancers disproportionately affect young *wāhine* Māori and are the second leading cause of cancer death for *wāhine* Māori aged 25-44 years [7,8]. These inequities are unacceptable and are caused by barriers to screening, diagnosis, and treatment [9].

Most cervical cancers occur in women who have not undergone screening or are screened less frequently [10]. The National Cervical Screening Program (NCSP) shows that the target level of 80% of *wāhine* Māori screened within the previous 3 years is not achieved in any region; once screened, there is a failure to achieve a timely diagnosis and treatment of abnormalities for *wāhine* Māori [9]. Fewer *wāhine* Māori have a colposcopy within an appropriate time frame following a high-grade abnormality when compared with non-Māori women. Furthermore, the proportion of women who had no record of any subsequent follow-up at 90 days is 4.4% for European women but 8.6% for *wāhine* Māori [11].

The current national screening approach for cervical cytology involves an invasive procedure using a speculum, which requires attending a clinic with associated transport and other costs. Cervical screening in rural Aotearoa is performed by the primary care nurse or physician, and the tests are sent to a centralized laboratory for analysis. The results are returned to the primary care clinician, who then notifies the patient. If the result is abnormal, the clinician writes a referral letter to a gynecologist requesting an appointment for a colposcopy. Hospital departments then control all further investigations and treatments. Delays can occur at each point, which in turn create barriers to access, timely diagnosis, and treatment [12].

Human papillomavirus (HPV) is the causative agent of cervical cancer. Infection with certain oncogenic (cancer forming) high-risk types of HPV cause changes in the cells of the cervix that can lead to cancer. Compared with cytology, HPV-based screening is a better test; it provides 60% to 70% greater protection against developing invasive cervical cancers [13,14].

XSL•FO
RenderX

The World Health Organization recommends that all countries transition to HPV testing as the primary method for cervical screening [15-17]. It is also internationally recognized that a self-taken swab that uses molecular amplification testing platforms such as polymerase chain reaction is as effective in detecting high-risk HPV (hrHPV) as a clinician-taken sample [18,19].

The present cytology-based NCSP is changing to HPV primary testing this year [20]. HPV self-testing is an equitable tool for cervical screening. Increasing coverage with HPV self-testing will potentially contribute to a more equitable NCSP [20]. A recent randomized controlled trial found that offering an HPV self-test was almost 3 times more likely to result in a cervical screen for underscreened *wāhine* Māori compared with offer of conventional cervical cytology [21]. Qualitative research has shown that HPV self-testing is highly acceptable to *wāhine* Māori, although many who had a positive result felt that more information and support were needed to guide them through the colposcopy process [1,22].

Point-of-care (POC) technology enables on-site HPV testing of self-collected vaginal swabs. The Xpert HPV test by Cepheid has been clinically validated to detect infections with 14 hrHPV types (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, and 68) that are likely to be associated with cervical disease (eg, cervical intraepithelial neoplasia 2+). The Xpert HPV test differentiates between HPV16 and HPV18/45, which are linked to approximately 70% of cervical cancers. The 14 hrHPV types assessed by the Xpert HPV test are associated with >90% of cervical cancers, as demonstrated in a recent Australian study [23]. The sensitivity and specificity of the Xpert HPV test are comparable with those of other well-established HPV central laboratory-based assays and fulfill the World Health Organization's criteria for use [19,24].

The research center Te Tātai Hauora O Hine (The National Centre for Women's Health Research Aotearoa, Victoria University of Wellington) was invited to partner with the Iwi (tribal) group Ngāti Pāhauwera Development Trust (NPDT) and Māori health provider Ngāti Porou Oranga (NPO, previously Ngāti Porou Hauora) to try a new clinical pathway for colposcopy using HPV self-taken vaginal swabs, POC testing, and direct referral to secondary services. In the early stages, Tipu Whaipua, a Wairoa-based community steering group formed through a prior research project with NPDT, helped inform the development of the design [25], which was guided by the principles of Ngāti Pāhauwera—*Pakatō i te ata, Pakatō i te ahiahi, Maure mahi Māuri ora* (planning for the future health and well-being of the people) and *Mahia nga māhi o Kahukura* (imagining and creating a better future).

NPO is a Māori primary health organization; it is the sole provider for a challenging geographic area, with a flourishing research and innovation program. The vision of the late Dr Paratene Ngata was "for Ngāti Porou Hauora to lead our own research, as a tikanga (traditional, customary way) and research-based centre of excellence for Hauora Māori" [26]. These principles provided the foundation for this research partnership and the resulting study, "He Tapu Te Whare Tangata—a model for empowering rural solutions."

This study combines a cluster crossover intervention trial with qualitative work to address inequities in the clinical care pathway to colposcopy for *wāhine* Māori in rural Aotearoa. This study pairs HPV self-testing with POC technology in a novel community-controlled cervical cancer prevention pathway. This easy-to-use technology with a 1-hour turnaround provides quick results for women *kanohi ki te kanohi* (face-to-face) and the ability to provide immediate woman-centered care, including information, *manaakitanga* (support), *whānau* (family) involvement, and shared decision-making. This, in turn, allows for immediate referral to colposcopy appointments for follow-up of positive tests.

Objectives

The objectives of this study are as follows: (1) to compare 2 pathways of care on the timeliness, referral to, and attendance for colposcopy following hrHPV detection (quantitative) and (2) to assess the acceptability and feasibility of the 2 cervical cancer prevention pathways (qualitative).

Methods

Overview

This is a cluster randomized crossover trial, with 2 primary care health practices (study sites) as clusters. Each site was randomized to implement either pathway 1 or pathway 2 in the first study period (15 months) and then crossing over to implement the other pathway in the second study period (15 months). The trial design is summarized in Figure 1.

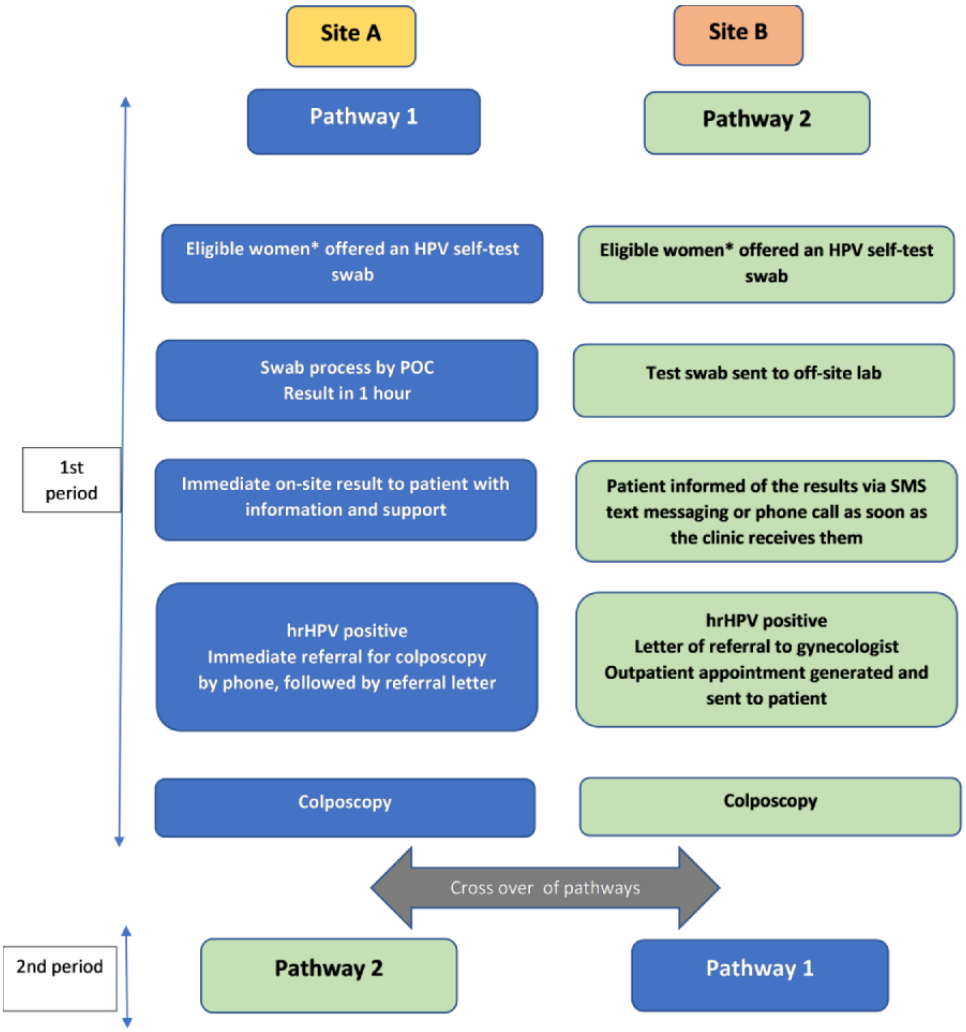
Pathway 1 is HPV self-testing and POC results within 1 hour, with face-to-face information, support, and immediate referral to colposcopy for women with a positive test result for hrHPV—the community-controlled pathway.

Pathway 2 is HPV self-testing and laboratory analysis, followed by usual results giving, information and support, and standard referral pathways for women with a positive test result for hrHPV—the current standard pathway.

We hypothesize that pathway 1 will improve timely access to colposcopy compared with pathway 2.

We hypothesize that community control of the care pathways is acceptable and feasible for rural Māori communities.

This study is informed by the Kaupapa Māori inquiry paradigm. This paradigm sees being Māori as normal and challenges how Māori have been, and continue to be, constructed within a colonized worldview. It promotes a structural analysis of inequities for Māori, seeking to more fully understand people's lives and the systemic determinants of their health and wellness [27,28]. In this paradigm, Māori worldviews, ways of knowing, and *mātauranga* Māori (Māori knowledge) are seen as valid and legitimate.



Non-Māori colleagues working collaboratively in a strengths-based approach are included in the team, which is Māori led [29]. With this Māori-centered approach led by *Kaumātua* (Māori elders and knowledge holders), we seek to combine multiple ways of knowing and seeing the world. Māori are involved at all levels, including protocol development,

XSL•FO
RenderX

instigation, follow-up, and trialing of this innovative clinical care pathway [25]. Research practices reflect *tikanga* Māori (Māori customs), including the importance of place, relationships, and Māori self-determination [26,27].

The 2 rural North Island community primary health care practices are in Hawke's Bay and Tairāwhiti on the East Coast of the North Island of Aotearoa at sites A and B, respectively. These 2 primary health care providers serve a predominantly rural and Māori population. The Hawke's Bay practice is based in 1 health center in a rural town covering an area of approximately 4000 km^2. The Tairāwhiti practice includes 5 clinics situated in small rural communities, covering a coastline of >200 km.

Figure 1. He Tapu Te Whare Tangata—a model for empowering rural solutions: study design. HPV: human papillomavirus; hrHPV: high-risk human papillomavirus; POC: point-of-care. *Eligible women: women aged 24.5 to 69.9 years due or overdue for cervical cytology.

Outcomes

The primary outcome is the proportion of women having a colposcopy within 20 working days from the test, for those women with a positive test result for hrHPV.

Secondary outcomes are of those with a positive hrHPV test result:

- Proportion of women having a colposcopy within 40 working days of the test
- Proportion of women having a colposcopy within 20 working days of referral
- Proportion of women having a colposcopy within 40 working days of referral
- Time from test to colposcopy
- Time from referral to colposcopy
- Number of high-grade lesions (cervical intraepithelial neoplasia and carcinoma)
- Planned treatment for women with high-grade histology at colposcopy.

Secondary outcomes include of all women taking the HPV test:

- The proportion of women who test positive for hrHPV
- The proportion of women who test negative for hrHPV
- The proportion of women who have invalid results
- The proportions due for screening, underscreened, or never screened.

Qualitative outcomes are as follows:

- To explore and understand the successes and challenges of both pathways from the perspectives of the governance groups, clinical staff (nurses, doctors, *kaiāwhina* [nonclinical community health workers], and specialists),

XSL•FO
RenderX

and women (including *whanau* or family supporters) at both sites
- To understand this new screening pathway to advise and inform a more culturally responsive NCSP.

On the basis of the percentage reported for *wāhine* Māori throughout Aotearoa, we estimated that 56.4% of women in the control arm will have a colposcopy within 20 working days following referral for a positive HPV test [30]. We aim to detect a 50% increase (relative risk 1.5) from 56.4% to 84% in the primary outcome for the intervention arm. A sample size of 80 women (n=40, 50% in each arm) in a 2-period, 2-cluster randomized crossover trial will provide 80% power at 2-sided α of .05 to detect a 50% increase in the intervention arm. With only 2 practices serving as the clusters, the sample size does not account for the cluster effect, which will be considered as a fixed effect in the final analysis.

The order of treatment for each practice has been randomly allocated by the study statistician using computer-generated random numbers. Using the eligible population list for each practice, the research team randomly allocated half of the under- or never-screened women to priority recruitment in the first study period and half to the second study period. This was done to reduce the potential bias from unequal recruitment of under- or never-screened women between the 2 study periods. The lists for priority recruitment were provided to the practices.

As this is a 2-period, 2-cluster randomized crossover trial, each practice acts as a comparator for the other practice during the trial period.

Blinding of participants and clinicians is not possible. The 2 trial statisticians will be unblinded and compile the data set and conduct the statistical analysis.

The inclusion criteria were women aged 24.5-69.9 years eligible for cervical screening in these 2 rural areas. In line with the current NCSP protocol, women can present for the first screen up to 6 months before their 25th birthday and be included. Women can present for screening up to 6 months before their due date and be included [31]. Women who are due for screening or who are underscreened (underscreened is defined as never screened or ≥4 years since last screening) are eligible.

Women with heavy bleeding at the time or those using a vaginal cream that might interfere with the test are asked to return at a later date. Women who opt for cervical cytology or whose general practitioner advises a speculum examination and cervical cytology can also participate in the study by taking an HPV self-taken (or clinician taken) swab first. Women who have symptoms such as abnormal bleeding can still be offered an HPV test, but they will also be seen and assessed by a general practitioner and may require assessment by secondary gynecology services despite a negative hrHPV test.

Primary care clinicians (physicians and nurses) and *kaiāwhina* at both sites received training from the research team on how to obtain informed consent from women. Training was conducted in person or via a video link. Trained clinicians or *kaiāwhina* obtain informed consent from women in both pathways for a copy of their HPV results (and if colposcopy is required, copies of histology results) to be sent to the researchers and the ordering health practitioner.

Women are also asked if they can be contacted later by a qualitative researcher for an interview on their experiences of the pathways (pathway 1 or 2, the HPV self-test, and overall process) and any subsequent follow-up. Other key stakeholders from general practice (management and staff) and the wider community have been identified and invited to participate in an interview.

Physicians, nurses, and *kaiāwhina* at both sites received an HPV update and information sharing session with the research team before recruitment started. These updates included the role of HPV in cervical cancer, the HPV self-test, the role of POC testing, how to obtain informed consent, how to instruct women on taking a self-taken swab, how to follow-up results, the role of the research team, and how the study will run. Training is augmented by regular ongoing contact between the research team, clinic staff, and managers.

All eligible women in both pathways are offered an HPV self-test. The participants receive verbal, written, and pictorial instructions from a physician, nurse, or *kaiāwhina* on how to self-collect a vaginal sample using a nylon-flocked swab (Copán FLOQswabs). Most sample collection takes place at the primary care practice, but some women self-collect the sample in their homes during a *kaiāwhina* visit or take one home from the clinic. Women in pathway 1 are provided information about POC testing. Women in both pathways who have positive HPV results are offered usual support to attend colposcopy. This includes petrol vouchers, transportation, and a support person to accompany them.

Intervention Description

Overview

The site randomized to pathway 1 for the first period nominated ≥2 primary care clinicians and *kaiāwhina* to be trained by qualified members of the research team in the operation and daily quality audit of the Cepheid GeneXpert IV instrument. POC training was overseen by the research team's molecular scientist in the week before recruitment began. This consisted of orientation and familiarization runs using contrived samples and official training directly from Cepheid via a video link. The technology is robust, but user training and support are vital. Only those holding a training certificate issued by Cepheid are authorized to run patient samples. Regular in-person, on-site POC updates run throughout the trial. User and instrument proficiency testing is built into the implementation process and conforms to the New Zealand Best Practice Guidelines for Point-of-Care Testing [32]. In addition, the research team and site clinicians involved in POC testing are participants in the Royal College of Pathologists of Australasia Quality Assurance Program [33]. The Cepheid GeneXpert IV instruments used in this study are loaned from the Australian Centre for the Prevention of Cervical Cancer.

A 2- to 4-week washout took place between the 2 study periods. The second site received the same training schedule on how to use the Cepheid GeneXpert IV instrument, and the instruments were transported, set up, and tested at the second study site.

XSL•FO
RenderX

Pathway 1

Following self-collection, the vaginal sample is processed onsite by the Cepheid GeneXpert IV instrument, taking approximately 1 hour, and the result is documented in the patient management system (PMS). The intention is for women to receive the HPV test result in person onsite, as soon as the test result is available.

Women with hrHPV-positive results receive immediate on-site information about the result, its significance, the next steps, and support. An appointment for colposcopy is made straight away by a phone call to the appointment clerk at the hospital. This phone call is followed up with a referral letter from the referring primary care clinician.

Women with hrHPV-negative results are informed of the result and its significance and advised that they will not need screening for 5 years.

If a woman is unable to stay for an hour to receive her test result, her contact details are taken, and she is contacted as soon as the result is available.

Pathway 2

Following vaginal sample self-collection, the woman is asked how she would prefer to receive the result (by SMS text messaging, phone, or in person). The sample is then transported at room temperature to the diagnostic laboratory as part of the practice's routine laboratory collection. hrHPV genotyping is performed using the Roche Cobas 4800 system. This system detects 14 hrHPV types (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, and 68) and provides a result which distinguishes types 16 and 18 from "other" high-risk types [34]. The use of dry vaginal swabs has been validated in international published studies, and the laboratory is undertaking this testing "off-label" [35,36]. The samples are disposed of in line with the standard pathology laboratory procedures. Test results are sent electronically (encrypted as other routine results) to the ordering primary care clinician and entered into the PMS, as cytology results would be.

Women with hrHPV-positive results are informed of the result and its significance by phone or in person. Information regarding the next steps and support are provided. The primary care clinician sends a referral letter to the colposcopy service at the hospital. The woman is triaged for a colposcopy appointment, and the appointment time is sent to the woman by mail, with or without phone follow-up.

Women with hrHPV-negative results are informed of the result and its significance and advised that they will not need screening for 5 years.

Data Collection and Analysis

Regular 3 monthly visits to the research sites are made by the members of the research team. These visits include updating the clinic staff on any amendments and audits of the PMS to ensure that the results are documented accurately and coded, given to women, and followed up appropriately. The research team's molecular scientist visits regularly to audit the POC instruments and sample testing process compliance. The practices have ownership of their data and all the results. Researchers are readily available via phone and email to support practices.

The ordering clinician and practices have the primary responsibility for follow-up. For clinical safety, the unblinded study statistician checks for colposcopy referrals and attendance. This is checked no sooner than 3 months from the hrHPV test date, so the primary outcome is not influenced but ensures that practices can contact any woman who has not yet attended a colposcopy appointment.

Follow-up colposcopy and treatment performed within the public health service are free for Aotearoa citizens and permanent residents. The new NCSP will start in September 2023, and the women in this trial will be registered with the new program appropriately.

Data collection and management are conducted as follows: copies of consent forms, POC test results, and laboratory results are provided to the research team by the study sites and used to track recruitment and monitor safety. Every 6 months, the colposcopy services provide data to the study statisticians: colposcopy attendance and date, colposcopy assessment and outcome, cytology result (if any) at colposcopy, histology, treatment plan, and any treatment provided. No other research team members have access to colposcopy data.

Each person using a health or disability support service in Aotearoa has a unique National Health Index (NHI) number [37]. The research team provides the NHI numbers of the participating women to the National Screening Unit to obtain cervical screening and clinical history at the start of the study period from the NCSP. The NHI number is also used to obtain ethnicity, the deprivation index (socioeconomic status), and age from the NHI data set.

The NHI number is replaced with a unique study code in all research data sets for analysis. No individuals will be identifiable in the reporting of study findings.

Study-specific source documents are maintained in locked file cabinets in locked rooms of Te Tātai Hauora o Hine, Victoria University, Wellington. Electronic data are stored on the secure Victoria University of Wellington server in restricted access folders and password-protected files. The data will be retained for 10 years and then destroyed securely.

Qualitative data collection is conducted as follows: up to 40 women who screen and test positive for HPV 16/18/"Other" (across both study sites and both pathways) and who indicate on their consent form that they are happy to be contacted for an interview will be approached by a *wāhine* Māori researcher. They are invited to take part in an interview at a time and location that suits them and are encouraged to bring any *whānau* (family) or other support. During the interview, they are provided a *koha* (gift) as a small token of appreciation for sharing their experiences and perspectives. Key informants from primary care (eg, clinical staff, nonclinical staff, and management), colposcopy services (eg, clinical and nonclinical staff, and management), and the wider community are invited to be interviewed, either individually or in small groups. Most interviews are conducted in person, but some may be conducted by telephone or Zoom (Zoom Video Communications)

XSL•FO
RenderX

depending on COVID-19 precautions and participant preferences [37]. Informed consent is obtained before the interview commences. The researcher takes time to follow culturally appropriate rituals of encounter that help to create a comfortable and safe environment for the interview [38]. Interviews are semistructured around 4 discussion points that aim to elicit rich, nuanced qualitative data. Participants are asked about the acceptability of the screening pathway, perceived level of empowerment and decision-making in the pathway, preferences for screening services, and recommendations for future screening programs. Participants are encouraged to add or ask anything else at the end of the interview. The interviews are audio recorded and transcribed verbatim.

All statistical analyses will be performed using SAS (version 9.4; SAS Institute) and R (version 3.4.2; R Foundation for Statistical Computing). Analyses will be intention to treat and conducted at the individual participant level. All tests of significance are 2-tailed and at a 5% significance level throughout the analyses. Continuous variables will be compared with *t* tests or Mann-Whitney *U* tests, and categorical data will be compared using chi-square tests, as appropriate.

A generalized linear regression model with a binomial distribution will be used to analyze binary outcomes, a linear regression model will be used to analyze continuous outcomes, and the cluster design will be taken into account in the analyses. For the primary outcome, both unadjusted and adjusted analyses for potential covariates measured at baseline will be conducted (eg, deprivation index and age). Unadjusted and adjusted odds ratios will be reported with corresponding 95% CIs and associated *P* values. Relative risks will also be estimated using Poisson regression models with robust error estimates. For the primary outcome, participants with missing data will be assumed as not having a colposcopy within 20 working days. Sensitivity analyses will be conducted for the primary outcome to assess the robustness of the results, which will include per-protocol analyses (where participants with any protocol deviations will be excluded). Additional sensitivity analyses may be considered, such as the potential impact of COVID-19 restrictions or extreme weather events. Subgroup analyses will be conducted for ethnicity, screening history, HPV type, and symptoms (if the numbers are sufficient). Time to notification and time to colposcopy will be analyzed using Kaplan-Meier curves, log-rank tests, and Cox proportional hazard models.

Qualitative data will be analyzed thematically. This will involve reading and rereading the transcripts, coding sections of data inductively, and combining and rearranging the codes to create themes and subthemes [39]. NVivo12 (QSR International) qualitative data analysis software will be used to assist in the coding and theming of data. In reporting the themes, feedback from participants will be written about in a way that groups their talk about common issues and how these issues are interrelated.

Importantly, the governance of this project rests with NPDT and NPO, giving community control of leading-edge POC technology. The study coordinating center is National Centre for Women's Health Research Aotearoa and includes the roles of the principal investigator, project manager, investigators, research assistants, and Kaumātua. The study coordinating center is responsible for the day-to-day conduct of the trial and supports the practices to participate. This study is a multi-institutional, multidisciplinary, and international research collaboration. There are regular meetings once a week with the research team and once a month with the participating clinics. An external, independent data monitoring committee appointed by the Health Research Council of New Zealand was set up at the request of the research team and meets every 6 months to monitor safety and review recruitment progress and data completion. The National Centre for Women's Health Research Aotearoa regularly meets the Ministry of Health National Screening Unit to update on the study progress and inform the new NCSP.

Harm to the participants in this trial is very unlikely. In that event, women are eligible to apply for compensation from the national Accident Compensation Corporation, just as if they were injured in an accident, at work, or at home. This study uses the national Health and Disability Ethics Committee's (HDEC) definitions for serious adverse events, protocol deviations, and protocol violations. Events meeting these definitions are reported to the data monitoring committee and HDEC, along with the actions taken in response to any event.

Ethical Considerations

Ethics approval was granted on December 2, 2020, by the HDEC (Ref 20/NTB/311). All major protocol amendments are submitted to the HDEC for approval. Locality assessment authorization was granted by the Tairāwhiti District Health Board and Hawke's Bay District Health Board. Written informed consent is obtained from all participants.

Results

The first 7 months of the project was spent preparing for the trial (Table 1). Recruitment began in February 2021, and period 1 was completed on April 29, 2022. After a 3-week washout period, period 2 recruitment began on May 23, 2022. This protocol is version 3, dated February 2022. In the first period of 15 months, a total of 743 eligible HPV self-tests were conducted: 370 in pathway 1 with POC testing and 373 in pathway 2 with laboratory testing. The positivity rate for hrHPV was 7.3% (54/743) overall. This is within the globally recognized range of 6% to 15% [40]. The data collection for the second period is ongoing. Once data collection is completed, analysis will report the results for the primary and secondary outcomes. Qualitative data collection and interviews are near completion, and the analysis of themes is ongoing. We expect that final results and analysis will be published in late 2023.

Discussion

Principal Findings

This study combines a cluster crossover intervention trial with qualitative work to address inequities in the clinical care pathway to colposcopy for *wāhine* Māori in rural Aotearoa. This study pairs HPV self-testing with POC technology in a novel community-controlled cervical cancer prevention pathway. The 2 objectives are to compare the 2 pathways of care on the timeliness, referral to, and attendance for colposcopy following hrHPV detection and assess the acceptability and feasibility of the 2 cervical cancer prevention pathways. This protocol draws on the strengths of rural community practices that are successfully engaging Māori from a *whānau ora* (family wellness) approach.

It is known that POC technology is as good as other polymerase chain reaction platforms for testing hrHPV and that self-taken vaginal specimens are as good as clinically taken cervical specimens using these platforms [18,19,24]. There are studies examining POC HPV testing and clinical pathways in low-income countries, but to our knowledge, there is no literature on POC testing and the pathway to colposcopy for disadvantaged populations in high-income countries [41].

Strength and Limitations

The strengths of this study include that it is informed by a Kaupapa Māori inquiry paradigm. This study was a collaboration between community, Iwi (tribes), rural primary health care clinicians; secondary care gynecology services; and the research team. Health care workers were trained to use POC technology and supported with regular quality assurance. This will lead to the possibility of testing for and treating other common infections in remote or environmentally isolated regions.

The limitations of this study include the recruitment for this study during COVID-19 disruptions and lockdowns and severe flooding and damage to infrastructure due to Cyclone Gabrielle, which affected both research sites. There was a difference in the research sites, as one site had 1 large rural clinic and the other site had 5 small rural clinics; however, there will still be the ability for the analysis to compare each site with itself on each pathway.

Conclusions

The findings of this study will inform the theory and practice about rural models of the use of innovative technology, addressing Māori cervical cancer inequities and facilitating Māori wellness. Our goal is to enhance outcomes, which necessitates continuous consultation among our partnership (including researchers, community members, Iwi, and primary care providers) with various groups. Our priority for the dissemination of results will be firstly the community, Māori health organizations, and strategic organizations that have been part of the research process. Maintaining the link between academia and Māori communities is part of our commitment to ongoing consultation and dissemination. We have ongoing regular consultation with the National Screening Unit, with the goal that this community intervention, if successful, will directly inform future changes to the NCSP to prioritize Māori and lead to a program that meets the needs of Māori. It is expected that these impacts and solutions may be appropriate for other Indigenous and rural people in high-income countries.

Acknowledgments

The authors would like to thank the primary care clinicians and staff at research sites and colposcopy teams at 2 district hospitals for their ongoing contribution to the study. The authors would also like to thank Frances King, the previous manager of Ngāti Porou Oranga, for her help and coordination of site visits, and Emma Tapp and Rebecca Lucas-Roxburgh at Medlab Central Limited for their advice and expertise. The study sponsor and Health Research Council of New Zealand (HRC) have no role in the study design; collection, management, analysis, and interpretation of data; writing of the report; or the decision to submit the report for publication. Neither the study sponsor nor the funder has ultimate authority over any of the abovementioned activities. This project received funding from HRC and the Health Delivery Research Project (grant 20/550).

Data Availability

All named investigators will have access to the final trial data set. This research aligns with the Te Mana Raraunga Principles of Data Sovereignty, which strictly govern Māori data use and sharing. Data requests with evidence that the proposed use addresses and upholds these principles may be sent to *He Tapu Te Whare Tangata*, rural empowering data manager [42], for consideration by the project data management and principal investigator.

Authors' Contributions

BL is the principal investigator and contributed to the conceptualization, study design, funding acquisition, methodology, project administration, resources, supervision, visualization, preparation of the original draft, and writing—review and editing. EJM contributed to the conceptualization, study design, data curation, funding acquisition, methodology, project administration, supervision, preparation of the original draft, and writing—review and editing. FS contributed to the conceptualization, data curation, funding acquisition, methodology, project administration, software, supervision, and writing—review and editing. JAS contributed to the conceptualization, project supervision of molecular science technology and training, methodology, resources, and writing—review and editing. AA contributed to the study design with expertise in qualitative methodology, investigation, data curation, funding acquisition, methodology, project administration for qualitative sections, formal analysis, and writing—review and editing. MG contributed to the data curation and management, statistical planning, funding acquisition, methodology, project administration, software, formal analysis, supervision, and writing—review and editing. VP is the study statistician and contributed to the data management, statistical planning, formal data analysis methodology, and writing. NKS contributed his expertise in qualitative methodology, investigation, data curation, formal analysis, and writing. BK contributed to the study design, community and rural primary care expertise, methodology, and writing. MT contributed to the study design, community and rural primary care expertise and consultation, methodology, writing, and review. HW provided community and rural primary care expertise and consultation, provided rural research expertise, and contributed to writing and review. MB and CSL provided Iwi community expertise and consultation and contributed to the study design, community and Iwi leadership and mentoring, methodology, writing, and review.

Conflicts of Interest

MS is an investigator on the Compass trial for which her organization, The Australian Centre for the Prevention of Cervical Cancer (ACPCC), has received kits and partial funding from Roche for the Compass trial. VCS Pathology has received funding from Copan for independent assessment of Copan products. VCS Pathology has also received Equipment or supplies from Abbott, AusDiagnostics, BD, Cepheid, Copan, Hologic, Microbiologics, MicroBix, NRL, Qiagen, Rovers, Roche, and Seegene for research purposes.

Abstract

Background: Attention-deficit/hyperactivity disorder (ADHD) is one of the most common neurodevelopmental disorders among children. Children with ADHD have challenges in understanding social cues and behavioral problems when entering a social setting. Virtual reality (VR) has been applied to improve cognitive behaviors in children with ADHD. Previous studies have not adopted VR to improve social interaction competence and appropriateness in children with ADHD. VR offers a more effective alternative to therapeutic strategies for children with ADHD.

Objective: This study aims to examine the feasibility and effectiveness of social VR training in enhancing social interaction skills compared to traditional social skills training in children with ADHD. We hypothesize that participants in the social VR training group are likely to perform better on social interaction skills than those in the traditional social skills training group.

Methods: In this nonblinded, 3-arm randomized controlled trial (RCT), 90 participants with ADHD recruited from the community will be randomized 1:1:1 to the social VR intervention group, traditional social skills training group, or waitlist control group. The child psychiatrist will conduct assessments for each participant at baseline and after the intervention. The Social Skills Rating Scale–Parent will be used to assess the social interaction skills of the participants before and after the intervention. Participants in the social VR intervention group and traditional social skills training group will receive twelve 20-minute training sessions for 3 weeks. The participants in the waitlist control group will receive no training. The primary outcome measure is training acceptability and compliance. The secondary outcome measures are the child psychiatrist's assessment and the Social Skills Rating Scale–Parent before and after the intervention. Another outcome measure is the Behavior Rating Inventory of Executive Function and Attention. Differences in the scale scores will be examined using a *t* test and an *F* test.

Results: This study is set to commence in the fourth quarter of 2023. It is anticipated that participants in the social VR intervention group will exhibit superior social interaction skills than those in the traditional social skills training group.

Conclusions: To our knowledge, this RCT is the first study examining the feasibility and effectiveness of a social VR-based intervention for enhancing the social interaction skills of children with ADHD in Hong Kong. The VR-based social skills training is expected to provide a safer and more effective environment for children with ADHD to learn than the traditional approach. This study can lead to a full-scale RCT.

Introduction

Background

Attention-deficit/hyperactivity disorder (ADHD) is one of the most common neurodevelopmental disorders frequently diagnosed in school-aged children. It is characterized by pervasive symptoms of inattention, hyperactivity, and impulsivity. There are 3 main types of ADHD: inattentive type, hyperactive-impulsive type, and combination type. ADHD impacts the children's emotions, behaviors, and ability to learn [1]. The hyperactivity and inattention levels of children with ADHD are noticeably higher than expected, causing distress or problems at home, at school, and with peers. The global prevalence rate of ADHD is about 5% to 7% [2]. According to the data from the Family Council in Hong Kong [3], there are 14,580 students with ADHD in Hong Kong, which is the second-highest number among the 9 types of special education needs.

Executive functions refer to a set of cognitive processes that enable an individual to plan, organize, manage, and execute a task, which includes working memory, cognitive flexibility, and inhibitory control [4]. Children with ADHD's executive functions can be delayed by up to 32% compared with typically developing peers [5]. Such delay can have tremendous impacts on the daily lives of individuals with ADHD [6]. For instance, inattention symptoms cause these children to have difficulty concentrating and listening to others, become distracted by the environment, and become overwhelmed [6]; hyperactivity symptoms cause high levels of distraction, sharing scattered thoughts, and excessive talking; impulsivity symptoms cause inappropriate initiation of conversations and becoming aggressive [4]. These children have relatively poor self-control, inhibitory control, emotion regulation, attention, and working memory [5]. Hence, children with ADHD have challenges in understanding social cues and behavioral problems when entering a social setting. They have difficulty comprehending some nonverbal expressions (body language, eye contact, and facial expressions) and spoken communication (pitch, speed, tone, and volume), making it difficult to listen to others and share their thoughts appropriately when interacting with them [7]. The social skill deficit causes it to become difficult to build friendships or even peer rejection [7]. To further avoid peer rejection, some of these children may avoid social interaction. Thus, it is critical to assist these children in developing appropriate social interaction skills.

ADHD has been associated with a wide range of detrimental impacts on those affected and imposes a severe financial burden on families and society [8,9]. The social problems faced by children with ADHD are associated with strained family relationships and social isolation from peers, which, in turn, can adversely affect emotional well-being, as some of them may experience both anxiety and depression [10]. Several studies reported that the economic burden of raising a child with ADHD was 5 to 6 times that on their counterparts, and the parents of children with ADHD tended to be fired and have low work efficiency [8,9,11]. Therefore, adequate and appropriate treatments should be provided to alleviate their behavioral issues and high health care costs. The commonly used social skills training tools among children with ADHD are traditional instructions, modeling, role-play activities, and behavior rehearsal [12]; however, these methods are limited to time and space and are short of real-life scenarios [13].

Virtual reality (VR) has emerged in plenty of domains as a promising tool for therapy and rehabilitation. Numerous studies adopted VR in improving cognitive behaviors in children with ADHD; however, the focuses of these studies were cognitive functioning in the context of daily living, attentional performance, and impulsivity [14-16]. None of these studies used VR to improve social interaction competence and appropriateness in children with ADHD. Furthermore, VR provides controllable immersive environments to engage children, sustain their attention, and allow them to effectively gain skills in a safer environment [17]. VR systems generally consist of a head-mounted display and screen so that the therapy can be conducted in a relatively low spatial limitation. Although no study has used VR to investigate social interaction skills in children with ADHD, previous studies have advocated the use of VR-based social skills training for children with autism spectrum disorder (ASD) [18-20]. Most of the studies about children with ASD also included some real-life scenarios—for example, classrooms, transportation, and supermarkets—in their social skills training program. This implies that children can develop social skills in a safe and controlled setting that can be designed in accordance with their needs [21]. VR can create different real environments for children to practice in repeatedly [21]. VR can provide instant feedback, which can help children recognize the appropriateness of their social interaction in practice [22]. The differences in social skills between children with ADHD and those with ASD are that the former are easily distracted, avoid or dislike concentrating on one thing, and are more likely to interrupt others when they are speaking, while the latter are less aware of others around them, overly attached to one object that they like, and find it difficult to give meaning to their speech [23]. Due to these discrepancies, the design of a social VR intervention in this study will be integrated with more instantaneous events, objects, and avatars in each scenario to improve the problem of distraction among children with ADHD. In addition, social VR, which allows more than 1 user to appear as avatars in a lifelike environment and connect with other users in real time, will be adopted in this study instead of VR to enhance engagement and interaction among children with ADHD.

Considering the prevalence and advantages of social VR, we plan to develop a social VR training program that contains 3 real-life scenarios and compare the effects of social VR training

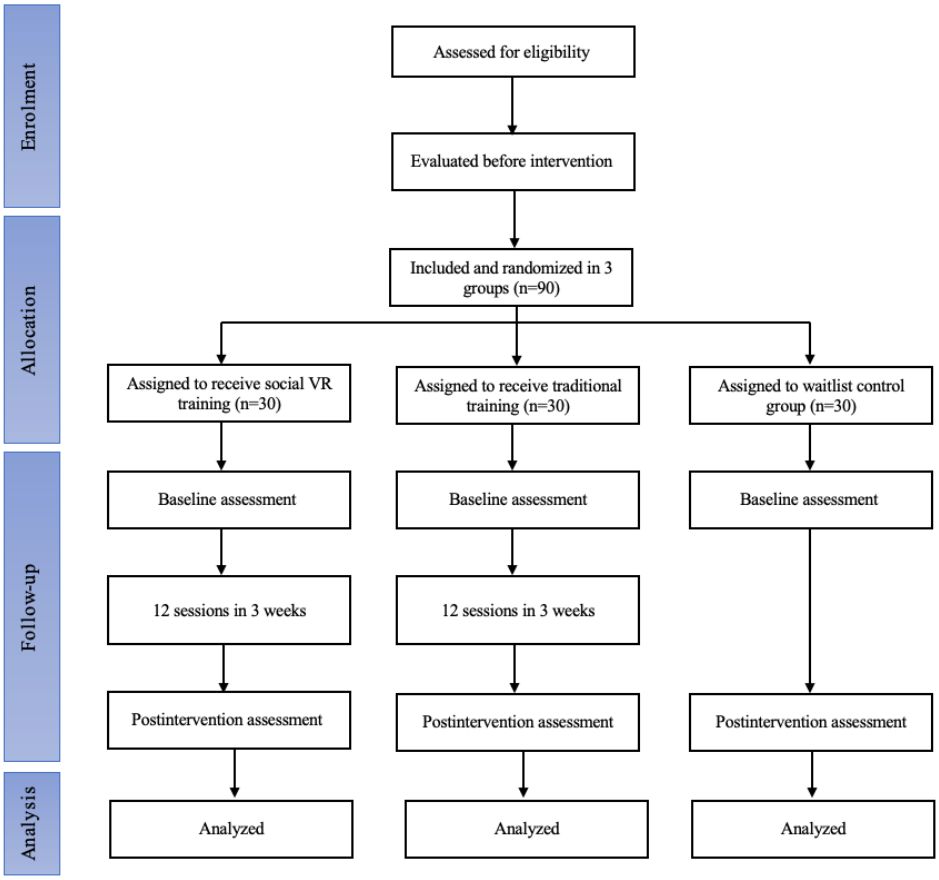
XSL•FO
RenderX

and traditional social skills training on social interaction skills, inhibitions, emotional control, behavioral and emotional difficulties, and conduct disorders for children with ADHD in Hong Kong receiving no training as a control.

Cultivating sufficient and appropriate social interaction skills for children with ADHD is a vital step to assist them in integrating into the community. VR technologies offer a more effective alternative to therapeutic strategies for children with ADHD. However, no previous study has adopted social VR to assess the competence and appropriateness of social interaction in children with ADHD, and no randomized controlled trial (RCT) has compared the effectiveness of social VR training and traditional social skills training on enhancing social interaction skills in children with ADHD. Traditional social skills training for children with ADHD lacks the provision of real-life scenarios and is limited by time and space. Social VR allowing real-time connection and interaction between patients and the virtual instructor has been absent in previous studies.

To fill these research gaps, we proposed conducting a 3-arm RCT to answer the research question of whether social VR training has higher effectiveness than traditional social skills training in enhancing the social interaction skills of children with ADHD in Hong Kong. The findings of this study are expected to unveil the clinical impacts and compliance and acceptability of social VR training for enhancing social interaction skills among children with ADHD.

Aims and Hypotheses



The study targets children diagnosed with ADHD and aims to (1) develop a social VR intervention, (2) investigate its effectiveness in improving the social skills of the children compared to traditional social skills training, and (3) evaluate the acceptability of and compliance with social VR training for enhancing social interaction skills. We hypothesize that participants in the social VR training group may perform better on social interaction skills than those in the traditional social skills training group. Participants in the waitlist control group are expected to show no change in social interaction skills compared with the 2 intervention groups.

Methods

Overview

This study will be a 3-arm RCT comparing the effects of a social VR intervention with those of traditional social skills training on social skills and executive functioning of children with ADHD. Participants in the social VR intervention group and those in the traditional social skills training group will receive 12 training sessions for 3 weeks (4 sessions per week), and those in the waitlist control group will be asked to retain their usual lifestyles for 3 weeks. The overall design of the study is illustrated in Figure 1.

Figure 1. Flowchart of the study.

XSL•FO
RenderX

Participant Selection Criteria

Individuals who meet the inclusion criteria will be recruited. The criteria are as follows: (1) age between 6 and 12 years; (2) being ethnic Chinese; (3) residing in Hong Kong; (4) having received a diagnosis of ADHD by a Child Assessment Service in Hong Kong or via private practice; (5) being stable on pharmacological or psychological treatment (or both) for ADHD 8 weeks before baseline; (6) no initiation or change in pharmacological treatment for ADHD during the intervention period; (7) ability of the child and at least one of the child's parents or legal guardian to read Chinese and speak and listen to Cantonese; and (8) willingness to provide informed consent by both participants and one of their parents or legal guardian.

Exclusion criteria are as follows: (1) comorbid autism; (2) an estimated IQ lower than 85 (determined using the Wechsler Intelligence Scale for Children–Fourth Edition; Hong Kong); (3) ASD (previously diagnosed by health care professionals); (4) comorbid acute psychiatric disorder (previously diagnosed by health care professionals); (5) a comorbid severe physical disability (eg, blindness or deafness); and (6) having a learning disability in understanding and using spoken Chinese, calculating, and motor coordination.

Sample Size

Teare et al [24] and Whitehead et al [25] indicated that studies with a sample size of 20 participants per arm have at least 80% power and 90% confidence. A pilot study by van der Oord et al [26] involved 40 participants (20 in the control group and 20 in the intervention group) to examine the efficacy of computerized executive functioning remediation training with game elements in children with ADHD. The sample size of this pilot RCT is more than the recommended sample sizes and that of the published pilot studies; hence, a proposed sample size of 90 (30 per arm) could provide more reliable results. To obtain a statistical power of 90% at a significance level of .05 and assume that the maximum dropout rate is 50%, we aim to recruit 30 participants in the social VR group, 30 in the traditional social skills training group, and 30 in the waitlist control group (ie, a total of 90 participants).

Ethical Considerations

Ethical approval for the study has been obtained by the Human Subjects Ethics Application Review Committee of The Hong Kong Polytechnic University (HSEARS20221221003). Informed consent will be sought from the participants and their parents or legal guardians.

Procedure

Recruitment

Participants will be recruited from nonprofit organizations and community centers. The inclusion and exclusion criteria will be listed on the recruitment poster. Interested participants or parents who provide written informed consent will be further evaluated for inclusion and exclusion criteria by a clinical psychologist or a student with a master's degree in clinical psychology. Participants who meet the inclusion criteria will be invited to perform an IQ test at the university at baseline.

Randomization

Eligible participants will be randomized to the social VR group, traditional social skills training group, or waitlist control group. A computer-generated randomizer will be used to generate the random allocation list. Randomization will be undertaken by another research assistant not directly involved in the study. A number generated by the computer will be assigned to each eligible individual who will be randomly allocated to the 3 different groups based on the number. Parents or legal guardians will receive an email and a telephone call with a notification regarding allocation to groups 1-3.

Social VR Intervention

This social VR intervention is being developed to enhance the social interaction skills of children. The participants will wear a head-mounted display for the social VR intervention. Each session of the social VR intervention lasts for a maximum of 20 minutes to ensure that the participants focus on the intervention and to prevent causing any physical effect [27]. The duration will be adjusted depending on the emotions of the participants during the intervention. The social VR intervention will mainly help the participants enhance their social interaction skills and executive function. The intervention contains three real-life virtual scenarios, including (1) a classroom and playground, (2) mass transit railway, and (3) a supermarket and restaurant. One scenario will be adopted in each session. The sequences of the scenarios used in each session will be the same for all participants. During the social VR intervention, an research assistant will also appear as one avatar in the scenario to guide the participants to complete a series of tasks. Each intervention session will be conducted in a classroom independently for each participant.

Traditional Social Skills Training

An instructor with a background in education, psychology, or social work will teach the participants social interaction skills through traditional instructions and role-play activities. Four modules will be covered in the 3-week training: (1) how to introduce yourself and basic social skills, (2) how to listen to others, (3) how to share with others, and (4) learn to understand how people feel and how to empathize. These modules have been applied in many studies [12,28]. The content of this training will be as similar as possible to the social VR training. The training lasts 20 minutes, which depends on the participants' emotions. Each training session will be conducted in a classroom independently for each participant.

Waitlist Control Group

As in Beck et al's [29] study, the participants in this group will receive no training and they can participate in the social VR training after the intervention period. To ensure consistency in the experiment, the participants are not allowed to initiate or change their pharmacological treatment during the 3-week intervention period.

Outcomes Measures

Questionnaires

The parents or legal guardians of the participants will complete a structured questionnaire at baseline and immediately after the

XSL•FO
RenderX

last session. Demographic information, including age, gender, medication, ADHD symptoms, and game experience will be recorded at baseline. The questionnaires include questions about social skills and executive functioning. The satisfaction of the participants and their parents or legal guardians with the training program will be assessed at week 3. VR sickness of the participants in the social VR group will be evaluated after each session. The clinical psychologist who evaluated the performance of the participants will be blinded to the treatment condition. The questionnaires will include the scales described in the following paragraphs.

Primary Outcome Measure: Assessment of Training Acceptability and Compliance

The attendance of the participants during the training will be recorded. To verify the validity of the findings, training-nonadherent participants will be excluded, which will be stated in the consent form. Absence in 3 or more training sessions will be considered nonadherence. The participants will be asked about their willingness to partake in this kind of training with a 7-point Likert scale question, which is used to reflect the acceptability of the intervention. The retention rate should be at least 85% according to a prior feasibility RCT [30].

Compliance with the training program will be evaluated by the communication log, in which the parents record their children's daily activity and emotions in the 3-week intervention period. The participants' parents will be reminded to attend the training by telephone in the first 4 training sessions and by WhatsApp, Signal, or WeChat in the fifth and eighth training sessions. No follow-up reminder will be provided in the remaining 4 sessions. These data will be used to evaluate their compliance.

Secondary Outcome Measures

Social Skills Rating Scale–Parent

The social skills of the children will be assessed using the Chinese-translated Social Skills Rating Scale–Parent (SSRS-P), which will be scored by the participants' parents before the first session and after the last session. This scale consists of 3 subscales, including self-control, assertiveness, and initiative and cooperation, with a total of 31 items. A 3-point Likert scale (never, sometimes, or often) is used to score. The SSRS-P is a validated instrument that has been commonly adopted in clinical trials of psychiatric and neurological disorders.

Child Psychiatrist's Assessment

One child psychiatrist will score the basic social skills of the participants in 15-minute tasks before the first session and after the last session to obtain an objective evaluation. The basic social skills assessment is adapted from the scale of Riggio [31]. Broken blinding is unavoidable in the child psychiatrist's assessment. To minimize unblinding bias during the assessment, each participant will be identified by a case number.

Behavior Rating Inventory of Executive Function

The Chinese-translated Behavior Rating Inventory of Executive Function (BRIEF), used to assess executive functioning in children, will be scored by the participants' parents before the first session and after the last session. The subscales of inhibitions (16 items) and emotional control (10 items) will be adopted in this study. A 3-point Likert scale (never, sometimes, or often) is used to score.

Satisfaction

Satisfaction is measured by a question rated with a 7-point Likert scale: "What grade would you give to this training program?" Both participants and parents or guardians have to answer the question.

Process Evaluation

Process evaluation of the training will be assessed by investigating (1) the recruitment rate, (2) participant completion, (3) side effects of training measured by participants' sickness or physical discomfort in the VR environment, and (4) safety assessment including adverse events and reasons for withdrawal.

- Recruitment rate: the recruitment rate is at least 48.5% of all referrals according to a prior feasibility study [32].
- Participant completion: participants attending at least 9 of the 12 (75%) sessions are considered to have completed the program [33].
- Simulator Sickness Questionnaire: the Simulator Sickness Questionnaire measures the motion sickness or physical discomfort of participants in a VR environment. Nine items will be measured, including discomfort, fatigue, headache, eyestrain, sweating, nausea, difficulty concentrating, blurred vision, and dizziness, with yes-or-no questions for each item.
- Assessment of safety: (1) adverse events: participants' parents or guardians will be asked, using open-ended questions, whether the participants experienced any adverse events during training. The severity and relationship of the adverse event to the intervention will be documented and investigated. (2) Reasons for withdrawal: when a participant withdraws before completing the study, the reasons for withdrawal will be recorded.

Statistical Analysis

All statistical analyses will be performed using SPSS software (version 26.0; IBM Corp) and are 2-sided with a level of significance of <.05. Demographic information of the participants will be summarized with frequency and percentage values for categorical variables. The continuous variables will be summarized with mean and SD values. The change from baseline to week 3 within each arm will be tested using *t* tests. To examine the between-group difference in measure outcomes from baseline to week 3, repeated analyses of covariance with adjustment of baseline characteristics will be conducted. To evaluate improvements during the intervention period among the 3 groups, *F* tests will be performed with primary and secondary outcome measures at the beginning of the first session and at the end of the last session. An intention-to-treat analysis will be performed. This analysis is considered the most appropriate approach to analyze RCT data by the highest-quality studies that have used the CONSORT (Consolidated Standards of Reporting Trials) standard [34].

XSL•FO
RenderX

Results

Significant changes are expected to be noted in the mean values of the secondary outcomes, namely basic social skills as assessed by child psychologists, and social skills and executive functioning as assessed by parents, using the intention-to-treat principle. Conducting this pilot RCT will determine the feasibility and potential of social VR interventions in improving social interaction skills in children with ADHD.

Discussion

Anticipated Findings

To the best of our knowledge, this RCT is the first study examining the effectiveness of a social VR intervention for enhancing the social interaction skills of children with ADHD in Hong Kong. The study will contribute to evidence-based practice by testing the effectiveness of social VR training versus traditional social interaction skills training for children with ADHD. It may determine a causal relationship between social VR training and traditional social skills training on social interaction skills and executive functioning. The results of this study will provide clinical psychologists with an effective means to improve the social interaction skills of children with ADHD in Hong Kong. Social VR used in this study strengthens the attractiveness of the training and the interaction and communication between patients and guiders and the real-life situations. Considering their high availability and accessibility, the cost and time of developing the social VR programs would be worthwhile if they could be promoted among more children with ADHD to enhance their social interaction skills with limited human resources. In addition, these findings will facilitate the development of a social VR training program that is customized for children with ADHD in Hong Kong, resulting in the improvement of these children's social skills and psychological well-being; this will be beneficial in integrating them into society. There is potential for the government to set up an accreditation scheme to enhance the social VR training to cater to the children with special education needs in various settings, including special schools, integrated schools, community centers, and social support groups.

Conclusions

This pilot RCT has the potential to enhance the understanding of the feasibility and effectiveness of using social VR to improve social skills in children with ADHD. This will help determine whether the use of social VR is acceptable for children with ADHD and understand which approach (ie, social VR or traditional social skills training) is most likely to achieve better outcomes. It will also determine the feasibility of a larger trial.

Acknowledgments

This project is supported by a grant from the Project of The Hong Kong Polytechnic University (1-BDSC).

Authors' Contributions

KPW and JQ conceptualized the intervention. Both authors read and made comments on the previous drafts of the manuscript and have approved the final manuscript for publication.

Conflicts of Interest

None declared.

Abstract

Background: Women with overweight and obesity are at higher risk of developing complications in pregnancy such as gestational diabetes and longer-term chronic conditions. Research concerning health behavior change interventions during pregnancy and postpartum shows promising effects, but implementation into routine services is sparsely investigated. Most interventions focus on the antenatal or postpartum life stages, failing to meet the needs of women. IMPACT DIABETES Bump2Baby is a multicenter project across 4 high-income countries developed to test the implementation of an antenatal and postpartum evidence-based mobile health (mHealth) coaching intervention called Bump2Baby and Me (B2B&Me) designed to sit alongside usual care in the perinatal period.

Objective: We aim to explore the feasibility and implementation of the B2B&Me intervention and investigate the effectiveness of this intervention in women at risk of gestational diabetes.

Methods: IMPACT DIABETES Bump2Baby is a hybrid type 2 effectiveness-implementation study, which integrates an evidence-based mHealth coaching app that includes personalized health behavior change coaching provided by health care professionals alongside antenatal care from the first antenatal visit to 12 months postpartum. The mHealth app offers the possibility of synchronous calls, asynchronous contact (including coach-participant text and video messaging exchanges tailored to the participant's needs), and ongoing access to an extensive library of bespoke intervention materials. Participants will interact

XSL•FO
RenderX

asynchronously with their health coach throughout the intervention via the app. This randomized controlled trial across 4 clinical sites within Ireland, the United Kingdom, Spain, and Australia will recruit 800 women in early pregnancy to evaluate the effectiveness on postpartum weight. The Exploration, Preparation, Implementation, and Sustainment implementation framework is the theoretical underpinning of the study. The implementation evaluation will be assessed at the individual, hospital staff, and broader community levels using the Reach, Effectiveness, Adoption, Implementation, Maintenance (RE-AIM) framework. Data sources for the RE-AIM evaluation will include app and platform analytics, screening and training records, participant medical records, key informant interviews, participant and partner exit interviews, cost data, study questionnaires, staff surveys, and blood sample analyses.

Results: The study was approved and registered with the Australian New Zealand Clinical Trials Registry on November 19, 2020. Recruitment commenced on February 9, 2021, and data collection is ongoing. Publication of the results is expected in 2024.

Conclusions: This is the first hybrid effectiveness-implementation study of an 18-month mHealth coaching intervention in at-risk women that we are aware of. As research aims to move toward real-world implementable solutions, it is critical that hybrid studies are conducted. The data from this large multicenter study will be useful in planning the potential implementation and scale-up of evidence-based perinatal health behavior change interventions.

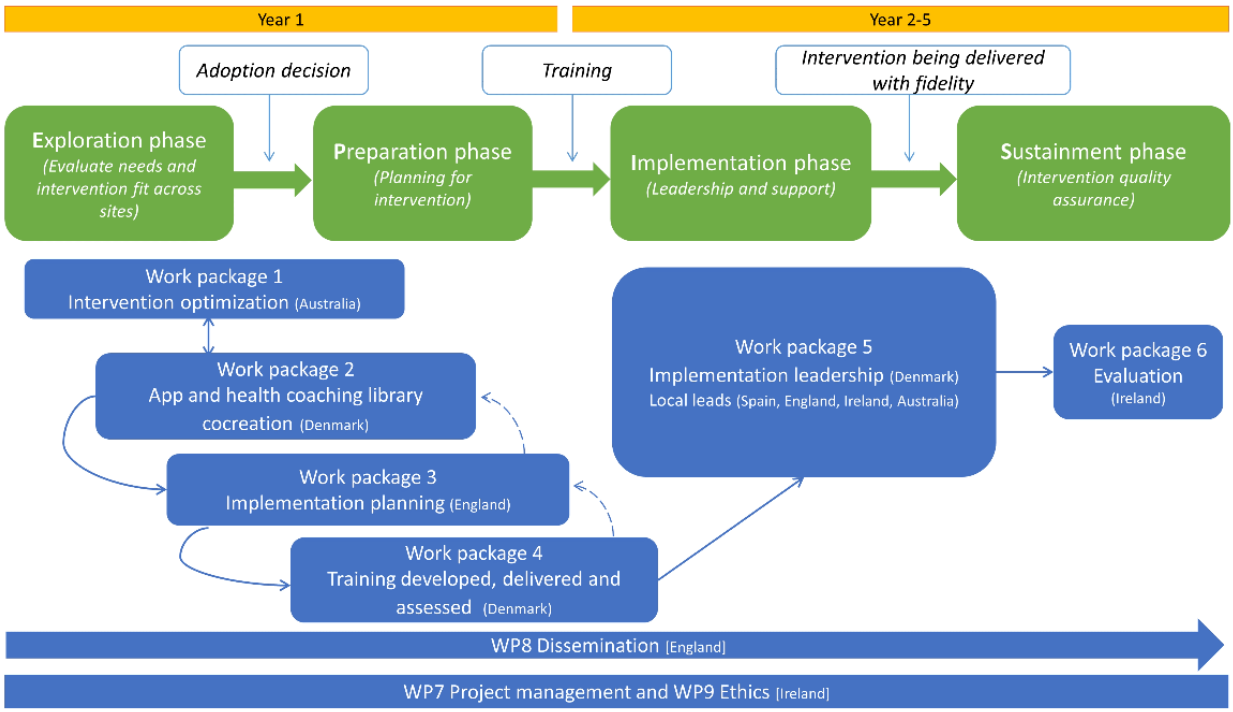
Introduction

Overweight and obesity are growing worldwide health concerns. For women in their reproductive years, this brings an increased risk of serious pregnancy complications such as preeclampsia, gestational diabetes mellitus (GDM), cesarean delivery, and stillbirth [1,2]. Obesity in pregnancy impacts offspring health with higher rates of congenital anomaly, large for gestational age, childhood obesity [3-5], gut microbiota dysbiosis, behavioral problems, or altered brain functioning, among others [6]. GDM is one of the most common pregnancy complications impacting approximately 1 in 7 pregnancies worldwide [7], with immediate and long-term health impacts for both mother and baby [8-10]. Excessive gestational weight gain (GWG) increases the risk of developing GDM and independently increases child obesity risk [2,11] and a woman's risk of obesity, heart disease, and type 2 diabetes (T2DM). GWG is frequently retained after birth and compounded by interpregnancy weight gain with a cycle of increasing weight through the reproductive years [12,13].

Pregnancy is a key time point to intervene and yield a benefit for both mother and child [12]. Meta-analyses show that behavioral interventions during pregnancy provide cost-effective support for optimizing GWG, GDM prevention and treatment, T2DM conversion prevention, and postnatal weight retention [14-16]. Meta-analyses have also identified that antenatal behavioral interventions are associated with reduced GDM and emergency cesarean delivery, and as a result the US Preventative Task Force now recommends implementing them [17]. Interventions to reduce postpartum weight retention are challenging to deliver but offer health benefits [18] with individual participant meta-analysis data showing that decreasing prepregnancy or early pregnancy maternal BMI reduces childhood obesity [11]. Current evidence, therefore, supports the efficacy of antenatal, postpartum, and interpregnancy health behavior change interventions in diet and physical activity during pregnancy and postpartum for improving maternal and child outcomes. Key evidence gaps include that studies typically focus on intervening during either the antenatal or postpartum period but not both and that studies tend to be short in duration (6 months is the average duration), which is known to be less effective at supporting sustained health behavior change [19-21]. Importantly, a large research translation gap exists around achieving adequate population penetration, participation, and implementation at scale with efficacious prevention interventions [19,20,22,23]. Limited studies have explored intervention implementation aspects beyond highly controlled clinical trials [19,23].

While the implementation of health behavior change interventions is recommended at a population level, identifying women at higher risk of adverse outcomes for targeted intervention is likely to yield improved health and economic benefits. This includes identifying women at risk of developing GDM through risk factor screening [24,25] and recognizing higher risks in different BMI groups with variable GWG guidelines [26]. However, few studies have focused on implementing these approaches with large variations in guidelines [27] and limited uptake in practice [8], which fails to identify pregnant women who would benefit from intervention. Postpartum and interpregnancy reach, penetration, and participation are all key barriers to both efficacy and implementation, and evidence is not yet strong enough to recommend population-level scale-up. Few studies have engaged women in pregnancy to optimize reach and participation in the face of competing family demands and less contact with the

XSL•FO
RenderX



health system [28]. Again, implementation research in the real world that addresses these barriers is vital to inform population-level strategies and future roll-out and scale-up.

Methods

Context

IMPACT DIABETES Bump2Baby (IDB2B) is a 5-year European Union and Australian research innovation project looking to demonstrate the implementation of an evidence-based system of care for the prevention of T2DM, overweight, and obesity in women at risk of GDM (Figure 1). It is designed to be delivered in the antenatal setting of 3 European countries (Ireland, England, and Spain) and Australia. Within IDB2B, the Bump2Baby and Me (B2B&Me) health behavior change intervention was designed during formative work and will be subject to a randomized controlled trial (RCT) to test the integration of screening for at-risk women, the mobile health (mHealth) app, and personalized health coaching in pregnancy through to 12-month postpartum. The detailed B2B&Me RCT protocol is published elsewhere [29], with the focus here being on the implementation protocol. The formative work included the selection of the GDM risk screening tool. The Monash tool [30] was selected as it incorporated overweight and obesity, it was shown to have reasonable accuracy, it was based on the best available evidence, and it was validated internationally [31]. The B2B&Me intervention design was also closely informed by robust evidence from pregnancy including systematic synthesis of the evidence on health behavior change interventions in pregnancy [15,19] and postpartum [18,20,32] to identify key intervention and implementation components required in our intervention study design. The B2B&Me intervention design was also closely informed by robust evidence from pregnancy [33,34] or postpartum [35,36] low-intensity, theoretically underpinned, and low-cost interventions led by the international authorship team. These health behavior change interventions [33-36] were systematically deconstructed and reconfigured considering the systematic synthesis and the Behaviour Change Wheel Framework [37] to develop the B2B&Me intervention. The intervention was designed to be delivered using mHealth, which enables remote delivery via an app and personalized remote health coaching during pregnancy and postpartum, and to run in parallel to standard health service provision. The design of the health coaching via a health care professional and optimized health behavior change content in the app was focused on supporting a meaningful coaching relationship with the woman at the center of B2B&Me.

Figure 1. The Exploration, Preparation, Implementation, and Sustainment framework applied to the IMPACT DIABETES Bump2Baby project (2020-2024).

Aims

The overarching aim of IDB2B is to contribute to the prevention of maternal and child overweight, obesity, T2DM, and other noncommunicable diseases. It seeks to achieve this through a hybrid type 2 effectiveness-implementation study that combines evidence-based antenatal and postpartum health behavior change interventions into a single seamless support program (B2B&Me) that optimizes health outcomes for the mother and baby and contributes to the prevention of T2DM and adverse long-term programming effects in the offspring. The primary efficacy outcome of the B2B&Me trial will be reduced postpartum weight gain and secondary health outcomes include the health of the mother and child. The secondary implementation aims are to explore the fidelity of health coaching training, delivery, and receipt; the feasibility of the B2B&Me implementation strategy through a process evaluation; and the intervention's

XSL•FO
RenderX

reach, cost-effectiveness, adoption, implementation, and maintenance.

Study Design

This is a type 2 hybrid effectiveness-implementation study. Type 2 hybrid designs have a "dual focus on the clinical intervention and implementation-related factors" with a clear implementation strategy that is deemed plausible in the real world [38]. Here, implementation factors may be secondary outcomes or coprimary ones [39]. We plan to study the effectiveness of the intervention using the B2B&Me RCT data as the primary outcome. We will evaluate the implementation process using the Reach, Effectiveness, Adoption, Implementation, Maintenance (RE-AIM) framework [40] to examine the reach, efficacy, adoption, implementation, and maintenance as secondary outcomes.

Health System Context

The health care systems in Ireland, England, Spain, and Australia are similar. They use a government-supported system where universal free care is provided to all eligible citizens and residents. The private health system is funded by individuals and subsidizes the costs of private care and provides greater choice in where health care is provided (public, private, or semiprivate). IDB2B was located within public care systems, and Figure 1 describes the work packages that formed the project.

Framework

The Exploration, Preparation, Implementation, and Sustainment (EPIS) framework was used to scaffold IDB2B [41,42]. The framework was developed out of the public sector and allied health services systems in America and has 4 main implementation process phases (exploration, preparation, implementation, and sustainment) with outer and inner organizational contexts and factors identified [41]. EPIS also includes innovation factors that relate to newly implemented intervention characteristics and bridging factors that explore the interplay between inner and outer contexts [41]. The exploration phase for IDB2B will involve evaluating current needs to ensure the intervention fits across system levels, organization levels, and staff and recipient levels through key informant interviews, site-level surveys, and systematic reviews. The preparation phase involved planning for the B2B&Me intervention through staff training, usual care service mapping, and awareness raising. The implementation and sustainment phases will be assessed using the RE-AIM framework [40], which measures results along the dimensions of reach, effectiveness, adoption, implementation fidelity, and maintenance.

Study Sites and Eligibility Criteria

IDB2B delivered the B2B&Me RCT in a single maternity health service site within Ireland, Spain, England, and Australia, and the usual care provided in each one is described in Table 1. The Monash GDM screening tool will be used to screen women at all sites attending antenatal care in their first trimester [30]. Women scoring ≥3 are eligible to enroll. The IDB2B study population will include women of reproductive age 18 years or older and attending their service for maternity care in the study sites that meet the B2B&Me eligibility criteria [29]. Key informant interviews will be conducted with senior staff involved in the delivery of antenatal services at each site. The interviews will also be conducted with the research teams and health coaches involved in delivering B2B&Me at each site. General hospital staff will be approached to participate in site-level surveys. All staff within the sites will be eligible to participate in the site-level surveys and the key informant interviews.

Intervention

While the intervention is described elsewhere [29], briefly, it consists of a hybrid model that consisted of a smartphone app (Liva Healthcare provider) and linked health care professional health coaching (Figure 2). The health behavior change techniques within the intervention combine 3 frameworks that share a core person-centered philosophy to guide the structure of the program delivery and integration of behavior change techniques and relational techniques, these being social cognitive theory [51], the reciprocal triad of causation [51], self-determination theory [52], and the transtheoretical model of behavior change [53]. The health coaches will be allied health care professionals with an interest or training in midwifery and maternal and child health. They will receive 5 days of training prior to engaging with participants. The health coaching training will be a mixture of pedagogical approaches, including direct instruction, modeling, skills practice, and problem-solving, all supported by self-directed learning and self-reflection, outside of the formal 5-day program. Liva Healthcare has an existing internal quality development and assurance program where team leaders conduct regular supervision meetings with coaches. These sessions are frequent for new coaches until they demonstrate the expected coaching competencies based on systematic observation of coaching data. Hereafter, the frequency decreases over time to quarterly supervision sessions. Women will commence the intervention in their early pregnancy and will be offered a personalized baseline session where they meet their health coach during a synchronous web-based video call lasting 45-60 minutes. During this session, coaches establish a relationship with each woman, support them to set some initial health goals, and instruct them on the use of the smartphone app. The app offers the possibility of synchronous calls, asynchronous contact (which includes text and video messaging exchanges between the coach and participant tailored to the woman's needs), and ongoing access to an extensive library of materials developed specifically for the intervention (Figure 3). The women will interact asynchronously with their health coach throughout the intervention via the smartphone app. The health coach will have access to a dashboard that allows them to provide asynchronous, continuous coaching across a large volume of women. During pregnancy, the asynchronous interactions occur once a week for the first 4 weeks and then biweekly until birth, resulting in a total of 14 contacts. If the woman is diagnosed with GDM (typically 24-26 weeks of gestation), an additional 15-minute synchronous video call will be included as well as additional educational material on GDM. The health coaching content during pregnancy centers on diet and physical activity for a healthy pregnancy, it also includes emotional aspects, breastfeeding preparation, expectations for delivery, and so forth. For the postpartum period, a synchronous call is scheduled for 6-8 weeks after delivery to re-engage participants in the coaching program, to have a delivery debrief with the coach, and to set new goals tailored to the postpartum period. This is followed by 1 weekly and 22 biweekly asynchronous contacts. The postpartum health coaching content centered on diet and physical activity for the woman and child including infant feeding and active play. Participants can spread out the timing of any contacts to suit their needs. The smartphone app collects detailed analytics on the woman's time spent in the app, number of resources accessed, type and amount of goals set, goal progress, communications with health coaches (number of coach messages accessed and responded to), communications with peers within the app, and self-monitoring data (steps, activity, and diet).

Data Collection

Overview

Table 2 demonstrates the RE-AIM evaluation framework for the IDB2B project. Each evaluation item is described in greater detail.

XSL•FO
RenderX

Table 2. Evaluation framework for IMPACT DIABETES Bump2Baby project (2020-2024) that incorporates the Bump2Baby and Me randomized controlled trial across 4 countries in women at risk of developing gestational diabetes.

RE-AIM[a] dimension and definition	Indicator	Data sources
Reach		
Penetration and participation in B2B&Me[b]	• % women screened and randomized out of hospital population (penetration) • % women eligible agreeing to participate in the trial (trial participation)	Screening records in IDB2B[c] database
	• % women completing minimum health coaching sessions (health coaching participation) • App and platform analytics for intervention women (mHealth[d] engagement)	Liva Healthcare app and platform analytics
	• Characteristics of participants by each site compared with the hospital population (representativeness)	Screening records in IDB2B database and hospital annual reports
Effectiveness		
B2B&Me impact on outcomes	• Change in BMI at 12 months postpartum • % women with any complications recorded • Change in BMI at delivery • % women diagnosed with GDM[e] • % women delivered via each mode of birth • Placenta weight recorded (g) • Infant birth weight (g), length (cm), and head circumference (cm) • Duration of breastfeeding • Change in physical activity/diet/sleep/quality of life/depression/blood glucose and lipid levels at 12 months postpartum • Infant growth pattern and neurodevelopment during the first year of life	B2B&Me questionnaires and blood sample analysis
	• % women scoring ≥3 on Monash Gestational Diabetes Risk Scoring Tool out of a total number of women screened (gestational diabetes "at-risk" prevalence)	Screening records in the IDB2B database
Adoption		
Site and individual level willingness to initiate B2B&Me	Site adoption: • Number of site training sessions delivered • Attitudes and engagement assessment of key informants and general staff	• IDB2B database • Key informant interviews and general staff questionnaires
	Health coach adoption: • Number of health coach training sessions delivered • % retention of health coaches	Liva Healthcare platform data and IDB2B database
Implementation		
Fidelity of B2B&Me to protocol and uptake of the intervention	Health coaching fidelity: • Health coaching fidelity index scores for each health coach • % women who receive a minimum number of health coaching sessions • Health coach training testing scoring • % women who record goals as part of health coaching • Maintenance of health behavior change goals achieved	Liva Healthcare app and platform analytics
	Program fidelity: • % scheduled visits completed • Number of protocol adaptations and rationale for changes	IDB2B database, exit interviews with participants and partners (where available to participate)

XSL•FO
RenderX

RE-AIM[a] dimension and definition	Indicator	Data sources
	Implementation challenges: • Exploratory findings developed through key informant interviews, focus groups, and RCT[f] working group minutes	IDB2B database, exit interviews with participants and partners (where available to participate)
	Health economic evaluation: • Total intervention cost • Integrated cost-effectiveness	Cost of intervention components Intervention effectiveness for primary outcome
Maintenance		
Extent to which B2B&Me has the potential for long-term effects	• Potential for future implementation across key informants and women	Semistructured interviews

[d]mHealth: mobile health.

[e]GDM: gestational diabetes mellitus.

[f]RCT: randomized controlled trial.

Reach

Reach includes data on penetration, which is how many in the service were eligible and how many of those engaged and were recruited. Participation relates to adherence and dropout. The reach measures will be collected from the absolute screening numbers for each site and recording reasons for declining or ineligibility, participation records, app analytics, and health coaching completion data. This will yield data on the proportion and representativeness of individuals who are willing to participate in the intervention. We will apply a novel trial recruitment process, whereby individuals initially express interest in participation before randomization. Once randomized, participants will be provided with an arm-specific information sheet and consent form. Thus, participants know what intervention they are signing up to and this provides some estimate of intervention reach, which is not available from a standard consenting process.

Effectiveness

A detailed description of the data collection for the effectiveness evaluation is available in the RCT protocol publication [29]. The maternal and child data will be collected in the IDB2B database, which is purpose built and allows for secure web-based data entry for both participants and research staff with the ability to audit record entries and changes over time. All biological samples collected will be processed on site and frozen to −80 °C before shipping to Dublin for analysis. Screening data including Monash GDM risk tool scores and medical records for GDM diagnosis will be further explored to understand how effective the GDM screening tool was in predicting GDM diagnosis.

Adoption

The adoption data will explore the proportion and representativeness of the setting and intervention agents willing to initiate the intervention. All quantitative data collected during the intervention will be at the site level and entered into the IDB2B database by research staff when transcription has occurred. The adoption measures will be collected using a short anonymous digital and paper attitudinal survey of hospital staff at clinical sites. All hospital staff will be invited to participate from senior management to administrative staff. The validated survey [54] asks for the staff's opinions on screening women to provide a diet and physical activity intervention and weight management to women at high risk of developing GDM. The survey will be circulated to staff at the start and end of the project. The responses will be analyzed comparing baseline views to those collected at the end of the project to provide insight into the readiness of the inner context to uptake the intervention and whether it was normalized in the longer term. This aligns with the EPIS framework preparation and sustainment phases measurement. Additional qualitative data will be collected by conducting stakeholder interviews with maternity services staff in leadership positions to explore adoption as well as other RE-AIM aspects. Longitudinal interviews of key stakeholders such as clinical nurse managers at each clinical site will be carried out during the project, aiming for quarterly. These semistructured interviews will assess the local context and environment to measure what is happening within the hospital clinics and services that might impact the intervention and how well it fits with the current routine care.

Implementation

Data collected on implementation fidelity measures will come from health coach training sessions, health coaching analytics collected within the app, attendance records for meetings, and participant visits and logs for all documentation changes and reasons. The health coaching training will include training on the smartphone app and coach dashboard; an introduction specific to the trial, insights into the participant journey; both synchronous and asynchronous consultation frameworks; qualitative coaching aspects; and the management of critical time points like disengagement, relapse, and medical escalation.

XSL•FO
RenderX

The training will address housekeeping and content review procedures, followed by an activity checklist and 2 initial consultation role-play exercises with feedback sessions as well as dedicated time for questions and answers. After the health coach training, each coach will complete a checklist of tasks within the app and platform and complete a practice baseline synchronous call with another experienced health coach. The health coach qualitative supervision framework assists the Liva supervisor in assessing 9 key competencies across the coaching journey. The supervisor evaluates each competency, which is scored individually, to ensure that all relevant competencies are covered in a repeatable fashion. When evaluating competency, the supervisor reviews a minimum of 3 participants using the app and 5-8 if the health coach is new to the role. Of these, the supervisor reviews 4-5 videos or interventions. While carrying out an evaluation of competency, the supervisor can allocate a 0, 1, and −1 or an N/A to each competency in the supervision framework. A score of −1 is assigned when a coach is not achieving the requirements of the competency, or when the supervisor assesses that there are significant improvements to be made. A score of 0 is assigned when a coach infrequently achieves the requirements of the competency or when the supervisor assesses that there are improvements to be made. A score of 1 is assigned when a coach fulfills the requirements of the competency or when the supervisor assesses that there are minimal insignificant improvements to be done. An "N/A" score is assigned when the area in question is not relevant or not possible to assess on this occasion. In completing the framework, a total score is calculated automatically. This score is a quantitative measure to assist the supervisor. After a supervision has taken place, the supervisor delivers feedback to the coach. This score will be evaluated alongside the fidelity index that was developed for the initial synchronous coaching sessions with independent specialist input. This fidelity index identified 18 health coaching techniques that need to be delivered in the initial health coaching session. The index assesses the use of relational techniques used to build a constructive empathic working alliance between the coaches and the study participants, and specific behavior change techniques used to facilitate individuals achieving their health goals.

The health coaching analytics include data relating to the number of participants coached, coach capacity, percentage contacts delivered on schedule, retention rate, demographics, goals set by participants, and coach rating by Liva supervisor. Women and their partners will have exit interviews at the end of the project with research staff. Health coaches will participate in focus groups following the active intervention completion in all sites. The exit interviews and focus groups will be semistructured and follow topic guides with prompts to provide a deeper understanding of implementation measures. The focus group and interview topic guides were informed by the EPIS framework, predominantly the implementation and sustainment aspects. The interviews and focus groups will be conducted by an experienced qualitative researcher independent of the maternity service. The recording of interviews and focus groups will be conducted using a digital audio recorder. The transcription will be conducted by trained staff, and all transcripts will be independently checked for accuracy before anonymization.

Maintenance

Participant-level maintenance of behavior change will be measured by goals achieved within the smartphone app. The adherence, retention, and loss to follow-up of participants in the mHealth coaching and the trial will inform future delivery. The cost information on the intervention delivery will be collected by participant questionnaires at 3 monthly intervals postpartum and from medical records for pregnancy data. The measures that will be collected from medical records include birth outcomes, length of hospital stay, admission to neonatal intensive care unit, and medications. The postpartum questionnaire will collect data on childcare use to support health behavior change and costs associated with health care professional visits. The health service's interest in delivering the screening tool in usual care will be explored using key informant interviews at the trial completion.

Data Analysis

Reach

The representativeness of the participants will be assessed within each site and barriers and enablers to participation will be explored using participant exit interviews.

Effectiveness

We will assess the RCT impact on the intervention's prespecified primary and secondary outcomes [29]. The reach evaluation penetration data will support the prevalence analysis of women at higher risk of developing GDM.

Adoption

We will use process data to assess site and health coach adoption. Additional surveys and key informant interviews will be conducted over the course of the intervention to inform other aspects of the adoption. The interview transcripts will be analyzed inductively using reflexive thematic analysis [55] and deductively using normalization process theory [56] to explore this aspect.

Implementation

We will assess the fidelity of the health coaching delivery and the program. The fidelity of delivery will be assessed separately for synchronous coaching and asynchronous interactions. For the synchronous coaching, these will be digitally recorded. These recordings will then be reviewed, and each health coaching technique identified and timed. This will then be compared with the specified techniques to be used from the Health Coaching Manual and used to generate an index of congruency. For the asynchronous coaching, we will code the Health Coaching techniques used in each coaching message. This will then be used to generate a technique profile aggregated for each individual from all interactions and aggregated for each coach. We will also do an exploratory analysis of the key informant interviews and focus groups using thematic analysis to identify implementation challenges. The key informant interviews and focus groups will take a variety of key stakeholder perspectives including hospital staff, health coaches, and the participants. They are informed by the EPIS framework. These data will be complemented by the RCT working group meeting minutes, which ran monthly for the duration of the

XSL•FO
RenderX

project and detailed implementation challenges from the perspective of the trial.

Cost-effectiveness analysis (CEA) is a well-founded and widely used method within health economics, where the costs and outcomes of a specific intervention are compared to an alternative (normally usual care). The CEA produces an incremental cost-effectiveness ratio (ICER). This ratio is compared to established willingness to pay thresholds and to similar interventions to evaluate the cost-effectiveness and comparative effectiveness of the studied intervention. The CEA explained in this analysis plan will be used to evaluate the costs and health outcomes of the IDB2B intervention compared to usual care. The results from the analysis will serve as a foundation for health care policy makers in the decision-making surrounding the implementation of the intervention.

The 2 main health outcomes for the economic evaluation are health-related quality of life measured using the quality-adjusted life year (QALY) approach and BMI 12-month postpartum. QALYs are a summary health outcome measure routinely used for economic evaluation integrating quantity or time and quality of life into a single index. QALYs will be calculated based on responses from the EuroQol 5 dimensions long (EQ-5D-L) questionnaire, and country-specific value sets will be applied. Effects (QALYs and BMI) for the economic evaluation will be measured at the individual level over an observation period corresponding to the trial follow-up time of individual patients. The cost-effectiveness analyses will be performed from both a health sector perspective and a societal perspective. Cost categories for the economic evaluation from a health sector perspective include the value of all health care consumption, pharmaceuticals, and the cost of the intervention itself. The CEA from a societal perspective entails incorporating indirect costs, that is, productivity losses due to short-term and long-term sickness (sick leave). Information on the usage of health services will be collected at the individual level for all patients enrolled in the trial. These services will be captured from the electronic case report forms maintained by IDB2B clinical sites. If a patient visits health providers that are not one of the trial centers, the number of diagnostic and treatment procedures will be obtained based on self-reporting by patients. Valuation of the resources identified and measured will be done using country-specific diagnosis-related group tariffs. Comparing treatment effects and costs between 2 alternatives results in an ICER, which is calculated as follows:

where C^{IDB2B} and C^{UC} are the mean costs among patients in the IDB2B and usual care arms, while E^{DB2B} and E^{UC} are the mean effects (QALYs or BMI).

Depending on the effect measure chosen, the ICER expresses the additional costs per unit decrease in BMI or per QALY gained if IDB2B is used by pregnant women at risk of GDM. Concluding whether the intervention or the comparator is the cost-effective alternative depends on the societal willingness to pay (for a specific country), that is, if the ICER is below the willingness-to-pay threshold the intervention will be regarded as cost-effective. The evaluation will follow the Consolidated Health Economic Evaluation Reporting Standards (CHEERS). The analysis will pool data from all countries as well as conduct country-specific estimates with a comparative analysis of the health system and contextual factors affecting cost-effectiveness across countries. To estimate the long-term cost-effectiveness of the IDB2B intervention, a Markov cohort model will be used.

Maintenance

The future potential implementation of the B2B&Me program will be explored through semistructured interviews with key informants and participants from each participating site. The interview transcripts will be analyzed inductively using reflexive thematic analysis [55] and deductively using normalization process theory [56] to explore this aspect. The impact of the lengthy health coaching duration will also be explored as the 18 months of coaching is novel within this field.

Ethics Approval

The National Maternity Hospital Human Research and Ethics Committee was the primary approval site (EC18.2020) with approvals from University College Dublin HREC-Sciences (LS-E-20-150-OReilly), Junta de Andalucía Comités de Ética de la Investigación con Medicamentos/Comité Ético de Investigación Provincial de Granada (2087-M1-22), Monash Health Human Research Ethics Committee (RES-20-0000-892A), and NHS Health Research Authority and Health and Care Research Wales (21/WA/0022).

Results

Recruitment commenced on February 9, 2021, and data collection is currently ongoing. Publication of the results is expected during 2024.

Discussion

At the end of this 5-year project, we aim to assess the effectiveness and implementation of a complex intervention aligned with maternity services for women at high risk of developing GDM. It is clear that structured diet and physical activity interventions in antenatal care are associated with improved maternal outcomes, such as less GWG [19] and T2DM prevention, and that the capacity to implement such interventions in antenatal care settings is limited. There is a great need to conduct more pragmatic implementation research to generate learnings that could benefit the broader antenatal and postnatal care settings [18,19] and develop interventions that transcend pregnancy into the longer postpartum period in at-risk groups. The communication gap between maternity service and primary care is a well-known challenge for GDM management [22] but also wider continuity of care.

While the evaluation of the B2B&Me's mHealth coaching intervention effectiveness will be valuable, the implementation process assessment will make an important contribution as well. The duration of the health coaching particularly through the mHealth platform is novel, with the average duration being 6 months [57]. The type 2 hybrid effectiveness-implementation study design was selected because both aspects are

XSL•FO
RenderX

complementary for evaluating this complex implementation project. The effectiveness evaluation takes a best-practice approach using an RCT. An important future implementation consideration of the design was the decision to ensure the data required to screen for eligibility were collected within routine care at the first antenatal visit for all 4 countries. This will facilitate the screening being potentially embedded within usual care as opposed to other risk factor screening tools that use biochemical or nonroutine tests [58,59]. The RE-AIM framework evaluation will yield valuable data that are important for the adoption of the intervention, if proven to be efficacious, and support wider implementation learnings.

IDB2B is not without limitations. The use of an RCT design brings with it the known issues with recruitment of those with potentially different demographics to the wider maternity population and the process of seeking consent will inherently curtain reach. We will measure the penetration of the study population as a means of looking further into this potential limitation, but we will likely not be able to control it. In the analysis of the implementation, it is likely that variation across countries will be a factor that will affect our data. We are planning to measure and potentially account for socioeconomic and ethnic variability among the women participating, but we cannot account for these factors among other stakeholders. This study cannot account for changes in the standard of care provided in primary care for reasons such as the COVID-19 pandemic. Any changes that occurred within the 4 maternity services' usual care should be accounted for within the longitudinal stakeholder interviews.

The project has the potential to provide a high-quality implementation assessment of a complex mHealth coaching intervention across multiple maternity services and the postpartum period. The IDB2B project has the potential for more general usage as an mHealth coaching platform beyond the B2B&Me RCT in the control and prevention of GDM and the long-term consequences for the mother and the offspring, if found to be effective. We expect that the results of this evaluation will yield important findings that will potentially support the improved health of women and children over the first 1000 days and beyond.

Acknowledgments

This project is funded by the European Union Commission Horizon 2020 grant entitled "Implementation Action to Prevent Diabetes from Bump 2 Baby (IMPACT DIABETES B2B)" under grant agreement 847984, with collaborative National Health and Medical Research Council, Australia co-funding under grant number APP1194234. Protocol

Evaluating the Feasibility and Acceptability of a Digital Pre-Exposure Prophylaxis Navigation and Activation Intervention for Racially and Ethnically Diverse Sexual and Gender Minority Youth (PrEPresent): Protocol for a Pilot Randomized Controlled Trial

Abstract

Background: To end the HIV epidemic by 2030, we must double down on efforts to tailor prevention interventions to both young men who have sex with men and transgender and nonbinary youth. There is an urgent need for interventions that specifically focus on pre-exposure prophylaxis (PrEP) uptake in sexual and gender minority youth (SGMY) populations. There are several factors that impact the ability of SGMY to successfully engage in the HIV prevention continuum, including uptake of PrEP. Patient activation, having the knowledge, skills, and self-efficacy to manage one's health, is an important indicator of willingness and ability to manage one's own health and care autonomously. Patient navigation also plays an important role in helping SGMY access PrEP and PrEP care, as navigators help guide patients through the health care system, set up medical appointments, and get financial, legal, and social support.

Objective: This study aims to evaluate the feasibility and acceptability of a digital PrEP navigation and activation intervention among a racially and ethnically diverse sample of SGMY living in the Los Angeles area.

Methods: In phase 1, we will conduct formative research to inform the development of PrEPresent using qualitative data from key informant interviews involving PrEP care providers and navigators and working groups with SGMY. In phase 2, we will complete 2 rounds of usability testing of PrEPresent with 8-10 SGMY assessing both the intervention content and mobile health delivery platform to ensure features are usable and content is understood. In phase 3, we will conduct a pilot randomized controlled trial to evaluate the feasibility and acceptability of PrEPresent. We will randomize, 1:1, a racially and ethnically diverse sample of 150 SGMY aged 16-26 years living in the Los Angeles area and follow participants for 6 months.

Results: Phase 1 (formative work) was completed in April 2021. Usability testing was completed in December 2021. As of June 2023, 148 participants have been enrolled into the PrEPresent pilot randomized controlled trial (phase 3). Enrollment is expected to be completed in July 2023, with final results anticipated in December 2023.

Conclusions: The PrEPresent intervention aims to bridge the gaps in PrEP eligibility and PrEP uptake among racially and ethnically diverse SGMY. By facilitating the delivery of PrEP navigation and focusing on improving patient activation, the PrEPresent intervention has the potential to positively impact the PrEP uptake cascade in the HIV care continuum as well as serve as a model for the tailoring of PrEP interventions based on behavior-based qualifications for PrEP instead of generalized gender-based eligibility.

Introduction

Background

Because young men who have sex with men (YMSM) account for the vast majority of new HIV infections each year, HIV-prevention research has prioritized this population [1,2]. Among Black men who have sex with men newly diagnosed with HIV in 2017, 34% were between the ages of 13 and 24 years and 41% were between the ages of 25 and 35 years [3]. Rates of new infections among Latino YMSM are similarly alarming—while overall rates of HIV infection among this population declined from 2005 to 2014, new infections among 13-24 year old Latino YMSM increased by 87% [4]. Less is known about the engagement of transgender, nonbinary, and other gender nonconforming youth within the HIV care continuum.

Transgender and nonbinary identities are growing, especially among youth, at a fast rate. In a 2022 US Centers for Disease Control and Prevention (CDC) summary, it was estimated that over 1.6 million members of the US population identify as transgender people (0.5% of the population), and about 300,000 youth (1.4%) identify as transgender people [5]. Of these estimates, 38.5% are transgender women, 35.9% are transgender men, and 25.6% are gender nonconforming. In a 2021 lesbian, gay, bisexual, transgender, and queer (LGBTQ) sampling study of the United States, it was estimated that about 11% of LGBTQ adults identify as nonbinary. This percentage was approximated to just over 1 million nonbinary people (aged 18-60 years) living in the United States at the time of the report [6].

Emerging studies are examining the HIV incidence among transgender and nonbinary people. In a 2019 cohort study of 1608 transgender women, 42% of participants tested positive for HIV. In total, 82% of participants reported they had been tested in the last 12 months, and 96% reported being tested in their lifetime [7]. According to a 2018 analysis of care among transgender men living with HIV from 2009 to 2014, 69% of respondents had undetectable viral loads but only 40% reported HIV or sexually transmitted infection (STI) prevention counseling by a health care professional [8]. In a recent report of new HIV infections among transgender people, sexual contact exposure accounted for 90% of infections in transgender women, 73% of transgender men, and 82% of infections within an "additional gender identity" category [9], highlighting the importance of extending HIV-related interventions to all individuals based on their risk factors for HIV transmission as opposed to gender identity.

If we are to end the HIV epidemic by 2030, we must double down on efforts to tailor prevention interventions to both YMSM and transgender and nonbinary youth, hereafter referred to as sexual and gender minority youth (SGMY), especially youth of color. Pre-exposure prophylaxis (PrEP) uptake has remained exceedingly low among SGMY [10-12]. While there is now substantial evidence demonstrating that YMSM have high levels of PrEP awareness [13,14], very few have ever used PrEP. Strauss et al [14] found that 68% of YMSM recruited from 3 cities (Atlanta, Chicago, and New York City) reported awareness of PrEP; however, only 9% reported having ever used PrEP. The Healthy Young Men's Cohort Study of Black and Latino YMSM has shown that while 90% of YMSM are aware of PrEP and 86% are eligible for PrEP (using CDC criteria), only 23% have ever been prescribed PrEP and just 8% report currently using PrEP [15]. In a 2017 national digital study of transmasculine individuals, 24.2% of participants met criteria for PrEP eligibility based on behavior in the last 6 months. Of those eligible, only 64.9% had received a HIV test in the last year, 33.9% reviewed PrEP information from their provider, and only 10.9% were currently taking PrEP [16]. Within the Transgender Youth of Color Cohort Study, 67% of nonbinary youth assigned female at birth and 65% of transgender men reported condomless sexual interactions in the last 6 months. Despite these rates of condomless sex within the cohort, only 8% had taken PrEP in their lifetime and 3% of participants reported actively taking PrEP [17]. This underscores the urgent need for interventions that specifically focus on PrEP uptake within SGMY populations.

There are several factors that impact one's ability to successfully engage in the HIV prevention continuum, including uptake of PrEP. For example, individual factors such as illicit drug use and depression have been found to create disparities to accessing HIV prevention services [18-20]. In addition, sociocultural and structural determinants, such as inadequate access to health care, mistrust of health care providers, food insecurity, and residential instability, have also been found to serve as barriers to both HIV prevention and PrEP uptake [13,21,22].

In one study of young sexual minority men (n=492), only 14% reported having ever used PrEP; barriers to PrEP uptake included concerns about paying for PrEP and talking to one's provider about sexual behaviors [23]. PrEP-related stigma has also been found to be a significant barrier to PrEP use among YMSM, including negative stereotypes about PrEP users [24-26]. Concerns about needing to use PrEP daily and possible side effects have also been found to serve as barriers to PrEP uptake. Additional factors inhibit transgender and nonbinary people from accessing PrEP [27]. In focus groups conducted with transgender men in San Francisco, barriers around lack of PrEP knowledge, financial concerns, finding a transcompetent doctor, and discussing sexual matters with providers emerged as key themes, mirroring barriers faced by young sexual minority cisgender men [28].

XSL•FO
RenderX

Patient activation, having the knowledge, skills, and self-efficacy to manage one's health, is considered to be an important indicator of the willingness and ability to manage one's own health and care autonomously [29,30]. Recent studies have found patient activation can significantly increase adherence and improve health-related outcomes [31-35]. Numerous studies have demonstrated that patients who are more activated in their care are also more likely to enact preventive behaviors, such as having regular checkups, screenings, and immunizations. Furthermore, research demonstrates that training individuals on how to ask questions and giving them the support to do so increases their participation in their own care and increases their activation levels [36]. A patient activation intervention may be ideally suited for use with SGMY, particularly if the goal is to activate them to become more engaged in their health, their use of health care and HIV prevention services, and PrEP uptake.

Patient navigation could also play an important role in helping SGMY access PrEP and PrEP care. Navigators help guide patients through the health care system and help patients set up medical appointments and get financial, legal, and social support. They may also help patients communicate with their health care providers. Often, patient navigators provide emotional support and help individuals access services to address their basic needs (eg, residential stability, food security, transportation, and language interpretation services) [37,38]. Innovative approaches to PrEP navigation, such as digital delivery using a mobile health (mHealth) app or digital platform, could help youth access care. Although numerous mHealth platforms now exist or are being developed, few are customized for inclusive use by SGMY or have been designed specifically for PrEP uptake. The PrEPresent app adapts an existing mHealth platform, developed by and for SGMY, and uses it to facilitate the delivery of PrEP navigation, increase knowledge about HIV and PrEP, increase intention to use PrEP, reduce PrEP stigma, and increase patient activation.

Theoretical Framework for Intervention

PrEPresent is a PrEP navigation, activation, and support intervention that builds upon the patient activation theory, which is rooted in concepts of self-efficacy and locus of control [39-41], and in the transtheoretical model of change [42]. This model refers to "the individual's knowledge, skills, and confidence in managing [their] own health and care" [43]. Patient activation theory describes an incremental process that patients undergo when becoming protagonists of their care management [44]. Building on this theory, we developed an intervention that is specifically targeted to increase PrEP uptake. Through both the mHealth platform itself and through interactions with PrEP navigators, participants are provided with developmentally appropriate information to (1) increase their self-awareness of their risk for HIV, (2) increase their awareness and knowledge about PrEP, and (3) address PrEP misperceptions and stigma. PrEP navigators also activate participants by increasing their PrEP self-efficacy and helping them develop strategies to address structural barriers related to PrEP uptake, such as obtaining insurance, finding an LGBTQ- and youth-friendly PrEP provider, obtaining transportation, finding a convenient pharmacy, obtaining and refilling PrEP prescriptions, paying for PrEP, developing a routine and reminders for taking a daily pill, and scheduling follow-up clinic visits.

Aims and Objectives

This study aims to (1) conduct formative research to inform the development of PrEPresent using qualitative data from key informant interviews involving PrEP care providers and navigators and working groups with SGMY, (2) complete 2 rounds of usability testing of PrEPresent with 8-10 SGMY assessing both the intervention content and mHealth delivery platform to ensure features are usable and content is understood, and (3) evaluate the feasibility and acceptability of PrEPresent within a racially and ethnically diverse sample of 150 SGMY aged 16-26 years living in the Los Angeles area.

Methods

Ethics Approval

The research and ethics described in this study have been reviewed and approved by the institutional review board of Children's Hospital Los Angeles (CHLA-20-00596). A certificate of confidentiality was obtained from the National Institutes of Health, and a waiver of parental consent has been obtained for participants aged 18 years or younger. This study is registered at ClinicalTrials.gov (NCT05281393).

Phase 1: Formative Research

To inform the development of PrEPresent, we will conduct 2 sets of formative research activities (phase 1A and phase 1B). During phase 1A, we will conduct qualitative interviews lasting 60-minutes with 15 PrEP providers and PrEP navigators serving SGMY. Participants will receive US $35 to complete an interview and will be employed at health care or community-based organizations located in Los Angeles County, at least 18 years old, and of all genders. During phase 1B, we will form 2 working groups, each with 6-10 racially and ethnically diverse SGMY. Participants will meet via chat or videoconference on a weekly basis for a total of 4 weeks and each session will last 2 hours. Participants will be compensated US $50 for each session they attend and will receive an additional US $50 for active participation across the groups. Active participation includes attendance, contributing to session discussions, and participating in session activities. Participants will be (1) aged between 16 and 26 years; (2) cisgender male, transgender people, gender nonconforming, or identify differently from the gender picked for them at birth; (3) gay, bisexual, or some other same-sex identity, or report having had sex with anyone with a penis during the previous 12 months; (4) White or Caucasian, Black or African American, Latinx, Asian-Pacific Islander, Indigenous, Native American or multiracial; (5) living in the Los Angeles metro area; (6) have daily access to an iOS or Android smartphone or tablet with internet access; and (7) know their HIV status and be HIV-negative at time of enrollment.

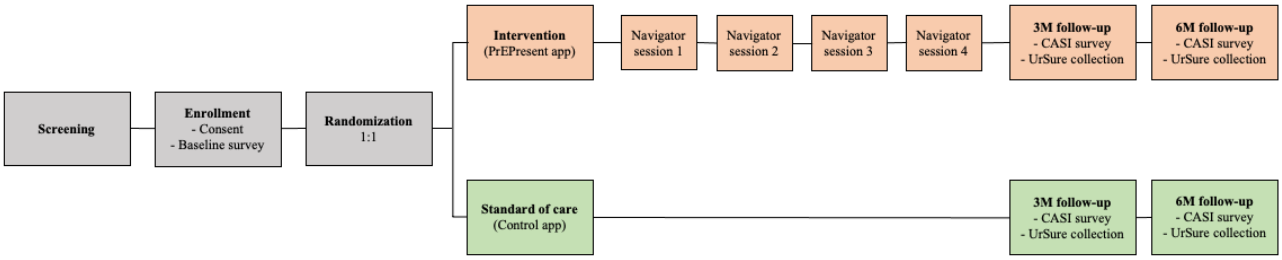
We will engage participants in guided discussions on a variety of topics, including (1) general discussion around health and where participants access health information; (2) experiences discussing sexual health, sexual identity, sexuality, and gender with health care providers; (3) knowledge, attitudes, and beliefs

XSL•FO
RenderX

about PrEP; (4) a PrEP journey activity (ie, use of a digital board game activity to facilitate discussion about the steps young LGBTQ people need to get and stay on PrEP and to develop possible app features and resources that will facilitate this); (5) how participants use mobile phone apps in their daily lives; (6) an app tracking activity (ie, each participant downloads an activity tracking app and reports back on what they like and dislike about the app, and how it could be improved); and (7) specific app features, such as avatars, badges, and discussion forums.

Phase 2: Usability Testing

Following initial development of the PrEPresent digital platform, we will conduct usability testing with 8-10 racially and ethnically diverse SGMY. Study participants will participate in 1 digital focus group to download and review the app, 1 digital (chat or videoconference) session with our live PrEP Navigator (the "PrEPresentative"), and a one-on-one exit interview to provide feedback on the app. Participants will also be asked to complete pre- and posttest surveys to assess app experience and general usability. Participants will be compensated US $40 for each digital session they attend.



During the digital focus group, which will last 60-90 minutes, we will prompt participants for feedback in the following categories: understanding of features, overall impressions of the relevance of the intervention, and additional content or features that might be added to increase their likelihood of use. Then, participants will be instructed to use the app over a 2-week period and to schedule a 30-minute meeting with the PrEPresentative. PrEPresentative sessions will occur via chat or videoconference and will use the app's scheduling and meeting features. These sessions will assess the feasibility of the newly developed features and provide an opportunity to gather feedback about the PrEPresentative role. The one-on-one exit interview will occur approximately 3 weeks after the digital focus group. This will allow participants time to use the app, generate feedback, and meet with the PrEPresentative. The interview, which will last 30-45 minutes, will include questions regarding overall intervention satisfaction, technical functionality and performance, and specific questions about each feature available in the app (medication tracker, resources, goal setting, forums, PrEPresentative, activities, badges, and avatars). Pre- and posttest surveys will be administered before downloading the app and after the 2-week testing period (but before the exit interviews to reduce response bias). Participants will meet the same eligibility criteria as outlined for phase 1B of the study (see above).

Phase 3: Pilot Randomized Controlled Trial

Design

The pilot randomized controlled trial (RCT) to evaluate intervention feasibility and acceptability will enroll up to 150 SGMY living in Los Angeles County, California, who will be randomized 1:1 to either the intervention (PrEPresent app) or control (information-only app) arms. The active intervention period is from 0 to 3 months and participants will complete study visits at baseline, 3, and 6 months (see Figure 1).

Figure 1. PrEPresent pilot randomized controlled trial study schema. 3M: 3 months; 6M: 6 months; CASI: computer-assisted self-interview.

Participants

Participants will be (1) aged 16-26 years; (2) cisgender male, transgender people, gender nonconforming, or identify differently from their gender picked for them at birth; (3) gay, bisexual, or some other same-sex identity, or report having had sex with anyone with a penis during the previous 12 months; (4) White or Caucasian, Black or African American, Hispanic or Latino or Latinx, or multiracial with one of these identities; (5) living in the Los Angeles metro area; (6) have daily access to an iOS or Android smartphone or tablet with internet access; (7) report having insertive or receptive sex in the previous 6 months or report a positive STI result in the previous 6 months; (8) not currently on PrEP and have no plan to start or restart PrEP in the following 7 days; and (9) not currently enrolled in another HIV prevention study.

Prospective participants will be considered ineligible if they are non-English speaking, living with HIV, or if they participated in phase 1 or phase 2 study activities.

Recruitment

Individuals will be recruited from multiple in-person and digital sources. First, study staff will contact potentially eligible youth from 2 existing longitudinal cohorts (Healthy Young Men's Cohort and the Transgender Youth of Color Cohort Study) who consented to being contacted about future research opportunities to assess their interest in and eligibility for PrEPresent. Staff will also use venue-based methods (eg, tabling events, referral from health or social service agencies) via flyers. Digital recruitment will include targeted advertisements on popular social media sites (eg, Facebook and Instagram). Potential participants recruited in any of the aforementioned ways will be directed to the study screening survey hosted on Qualtrics (Qualtrics Inc), a Health Insurance Portability and Accountability Act (HIPAA)–compliant digital software program. After reviewing a brief description of the study and providing consent to be screened, potential participants will complete the brief screening survey and provide contact information for follow-up use. Eligible SGMY will be invited

XSL•FO
RenderX

to an initial in-person or digital visit in which staff will describe the study, confirm eligibility, obtain informed consent, sign a HIPAA release, and complete a baseline assessment. Youth who self-report living with HIV while reviewing eligibility criteria will be linked to care.

Randomization

Participants who meet eligibility criteria, consent to participation in the study, and complete the baseline survey will be randomized in a 1:1 ratio to the control or intervention arm using a prespecified randomization sequence that is reviewed by the study statistician. Randomization will not be stratified.

Intervention Arm

Participants assigned to the intervention will be asked to download the PrEPresent app and will be given a guided tour of the app and its main features (Table 1). Participants will be encouraged to schedule their first navigation session with the PrEPresentative and to use the app's other features on a regular basis.

The PrEPresent platform will include live chat topics for the PrEP navigator, a repository of motivational text messages covering a range of identified barriers and facilitators to PrEP uptake, a curriculum for the PrEP navigator's videoconferencing sessions, and a library of media and informational content to address identified gaps in PrEP knowledge, strategies, and skills. The app also includes an anonymous forum to facilitate peer-to-peer exchange, interactive activities, and a direct portal to engage in one-on-one interactions with the PrEPresentative either through text or video.

Participants randomized to the intervention arm will receive up to 4 sessions with the PrEPresentative over the 3-month intervention period (Table 2). Sessions will occur approximately 1 month apart, with session 1 beginning from the date of enrollment. Sessions will be scheduled via the PrEPresent app and can be scheduled, based on participant choice, via one of three ways: (1) text via app, (2) phone call, and (3) HIPAA-compliant videoconferencing (WebEx). During these sessions, the PrEPresentative will begin developing a tailored plan to link participants to PrEP care screening, HIV or STI testing, or prescriptions for PrEP. The PrEPresentative will also work with participants to increase patient activation (self-advocacy, self-efficacy, and motivation), help them identify a pharmacy to fill prescriptions, if necessary, help them pay for prescriptions (eg, insurance enrollment), and help develop practical, individualized behavioral strategies to support adherence. The PrEPresentative will check in via chat or videoconference at least weekly with participants to (1) ensure their needs continue to be met, and (2) provide reminders and prompts to ensure adherence to PrEP. The PrEPresentative will also use the mHealth platform to deliver motivational text messages, monitor PrEP follow-up visits, and monitor prescription refills. Participants can respond to these messages or engage in text messaging via the intervention app using the secure 2-way communication portal.

Table 1. Overview of PrEPresent app intervention features.

App feature	Description
Health tracker	Medication and habit tracking allows users to visualize patterns in their adherence, self-monitor, and receive feedback for improvement.
Forum	Users can participate in forum discussions and polls to foster community support and peer-to-peer sharing within the app.
Resources	Provides educational content across a range of health topics.
Activities	Supports app engagement and behavior change through information and skill-building.
Goals	Pushes tailored content through a curriculum that keeps users on target with health and wellness goals. Provides milestones, tasks, tips, connections, and journal opportunities related to participant's goals.
Appointments	Connects users to a PrEP navigator to support them along their PrEP journey. Users can request times from available time slots, as well as a preferred method of contact (phone, text, or video).
Ask the expert	Subject matter experts answer anonymously submitted health and wellness questions from users. Questions and answers are visible to all participants to promote shared knowledge and connection to resources.
Avatar customization	Supports ongoing engagement by unlocking new accessories the more users engage with the app.
Care locator	Directory of local services specific to their need. Covers physical health, mental health, legal support, housing resources, and more.
Badges	Users can earn badges for actions taken within the app. Rewards engagement and participation in the study.

XSL•FO

Table 2. Overview of PrEPresentative sessions.

Session	Time point	Delivery window	Topics
1	BL[a]	Days 0-14	Building rapport, introduction to intervention, overview of PrEPresentative role, PrEP[b] motivation, and needs assessment.
2	1 month	Days 15-44	Developing tailored linkage to PrEP plans, adherence strategies (as needed), and supporting ongoing patient activation.
3	2 months	Days 45-74	Reviewing progress, follow-up and adjustments to tailored linkage to PrEP plans, adherence strategies (as needed), and supporting ongoing patient activation.
4	3 months	Days 75-104	Reviewing progress, intervention off-boarding (transition), reinforcement of adherence strategies (as needed), and maintenance of patient activation.
Check-ins	Weekly	Day determined at initial visit	Ensure needs continue to be met, provide reminders and prompts for linkage to PrEP care, medication refills, and adherence.

[a]BL: baseline.

[b]PrEP: pre-exposure prophylaxis.

Standard of Care Arm

Participants randomized to the standard of care arm will be given access to an information-only version of the PrEPresent app that only includes the library of media and informational resources regarding PrEP. These participants will not have access to the PrEPresentative sessions or other enhanced features of the app. Standard of care participants will be encouraged to use the control app on a regular basis.

Follow-Up Visits and Retention

At 3 and 6 months after enrollment, participants will be asked to complete a survey assessment and UrSure (UrSure Inc) at-home test kit to measure PrEP uptake. Study staff will contact participants prior to their target date using the participant's preferred contact method indicated at baseline. Additional reminders will be provided via email, text, and phone call on and after the target date as needed to ensure completion of study visit procedures. Staff may leave messages (voicemails) for participants who consented to this at baseline.

Incentives

Participants will be compensated for completion of surveys at baseline and 3 and 6 months (US $50 each) and urine specimens at 3 and 6 months (US $20 each). If participants successfully complete all survey assessments and specimen collections, they will receive an additional US $50 bonus. Control arm participants can receive up to US $240, while intervention participants could receive up to US $280, as they will be asked to complete a brief satisfaction survey after each of their 4 PrEPresentative sessions (US $10 each).

Data Collection

At the time of enrollment, baseline surveys will be administered, while follow-up surveys will be administered 3- and 6-months postenrollment. Urine specimen results will be collected at 3- and 6-months postenrollment.

Primary Outcome Measures

We will assess the feasibility and acceptability of the patient navigation and mHealth platform aspects of the PrEPresent intervention. We will define patient navigation feasibility as at least half of intervention participants attending on average at least 2 sessions over the 3-month intervention period and mHealth platform feasibility as at least half of intervention participants using the platform on average at least 2 times per week over the 3-month intervention period. Patient navigation acceptability will be defined as a mean postnavigation satisfaction survey score of 4 or higher and mHealth platform acceptability as a score of greater than 70 using the 10-item System Usability Scale [45,46].

Secondary Outcome Measures

Preliminary efficacy of the PrEPresent intervention will include PrEP uptake measured using self-report PrEP use scales at the 3- and 6-month timepoints. Additionally, biological specimens using the UrSure point-of-care rapid urine test of tenofovir will be used. Potential mediators and moderators of the PrEPresent intervention, including PrEP self-efficacy, PrEP stigma, barriers to PrEP use, and patient activation will be assessed via 3- and 6-month surveys.

Statistical Analysis

Univariate statistics (eg, SD, range, and value) will be used to describe the study sample as well as values of the trial measures detailed above. Bivariate analyses will examine relationships among variables of interest. We will also produce summary scores and scales for constructs of interest (eg, System Usability Scale). Scale scores will be created as means or sums of unweighted composite scores depending on original item types.

To assess intervention feasibility and acceptability, we will summarize related data as means and proportions, with the 95% CI, by assessment period. Pre- to postintervention changes will be evaluated with generalized linear mixed models; a subject-level random intercept will be specified. Estimates of changes at each postintervention assessment will be calculated, along with the 95% CI.

We will follow steps for mediation analysis using nonparametric bootstrapping to assess indirect (mediated) effects and determine the CI [47,48]. Both the direct (unmediated) and indirect (mediated) effects of the intervention on each outcome of interest will be estimated and tested. Moderators (eg, racial and ethnic group) will be evaluated in these models, estimating and

XSL•FO
RenderX

testing for differences in intervention effects across groups or other specified subgroups.

Results

Phase 1 (formative work) began January 2021 and was completed April 2021. Usability testing began November 2021 and was completed December 2021. Institutional review board approval for the phase 3 (the pilot RCT) was granted in May 2022 and data collection began the same month. As of June 2023, 148 participants have been enrolled into the PrEPresent pilot RCT. Enrollment is expected to be completed in July 2023, with final results anticipated in December 2023.

Discussion

Overview

PrEPresent is a mHealth intervention that will address evidence-based barriers to engagement in PrEP care for SGMY in Los Angeles, California. The intervention is innovative in that its eligibility criteria are not strictly based on gender but prioritize populations engaging in sexual behaviors that qualify individuals for PrEP usage per CDC guidelines. PrEPresent leads with a patient activation strategy to encourage self-advocacy, self-efficacy, and motivation in accessing care within the HIV care continuum, particularly within sexual and gender minority populations who face medical stigma and structural disadvantages to engagement in affirming health care. The PrEPresentative, or patient navigator, will also use motivational interviewing techniques to address additional barriers such as HIV stigma, sexual wellness education, insurance and provider navigation, transportation, and housing difficulties.

Limitations

During the creation of the PrEPresent intervention, care was taken to conduct formative research with PrEP providers and navigators in the Los Angeles areas to understand barriers and activators to uptake within a local landscape. This research is limited in its generalizability due to its centralization within a major metropolitan city and due to the location-specific resources available surrounding HIV-related care. Both California as a state and Los Angeles as a county offer universal health care coverage and have prioritized PrEP uptake and access within their HIV prevention efforts.

Participant eligibility criteria for the project included meeting the CDC qualifications for PrEP prescription. It is possible that fluctuations in participant sexual activity due to different factors may impact their willingness to uptake PrEP. A limitation of the current protocol is that PrEP uptake is only measured over a period of 6 months. Additional education and guidance throughout the intervention period may have longer-reaching impacts on PrEP willingness and use beyond this timeline.

Additionally, while efforts were made to include youth in formative research with expansive genders, ethnic identities, and experiences to inform tailored, affirming, and engaging app content, there may be population-specific areas that were not addressed among the resources available within the app.

Conclusions

The PrEPresent intervention aims bridge the gaps in PrEP eligibility and PrEP uptake among racially and ethnically diverse SGMY. By facilitating the delivery of PrEP navigation and focusing on improving patient activation, the PrEPresent intervention has the potential to positively impact the PrEP uptake cascade within the HIV care continuum as well as serve as a model for the tailoring of PrEP interventions based on behavior-based qualifications for PrEP instead of generalized gender-based eligibility.

Acknowledgments

The authors would like to acknowledge the contributions of the staff members who contributed to collection, management, analysis, and review of this data: Alicia Bolton, Michael Smith, Lucas Rojas, Gerald Branden Mabe, and Laura Rachel. Abstract

Background: The lack of health care coverage, low education, low motivation, and inconvenience remain barriers to participating in fall prevention programs, especially among low-income older adults. Low-income status also contributes to negative aging self-perceptions and is associated with a high perceived barrier to care. Existing fall prevention intervention technologies do not enable participants and practitioners to interact and collaborate, even with technologies that bring viable strategies to maintain independence, prevent disability, and increase access to quality care. Research is also limited on the use of technology to enhance motivation and help individuals align their perception with physiological fall risk. We developed a novel, 8-week Physio-Feedback Exercise Program (PEER), which includes (1) technology-based physio-feedback using a real-time portable innovative technology—the BTrackS Balance Tracking System, which is reliable and affordable, allows for home testing, and provides feedback and tracks balance progression; (2) cognitive reframing using the fall risk appraisal matrix; and (3) peer-led exercises focusing on balance, strength training, and incorporating exercises into daily activities.

Objective: This study consists of 3 aims. Aim 1 is to examine the effects of the technology-based PEER intervention on fall risk, dynamic balance, and accelerometer-based physical activity (PA). Aim 2 is to examine the effects of the PEER intervention on fall risk appraisal shifting and negative self-perceptions of aging. Aim 3 is to explore participants' experiences with the PEER intervention and potential barriers to accessing and adopting the technology-based PEER intervention to inform future research.

Methods: This is an intention-to-treat, single-blinded, parallel, 2-arm clustered randomized controlled trial study. We will collect data from 340 low-income older adults at baseline (T1) and measure outcomes after program completion (T2) and follow-up at 3 months (T3) and 6 months (T4). Participants will be enrolled if they meet all the following inclusion criteria: aged ≥60 years, cognitively intact, and able to stand without assistance. Exclusion criteria were as follows: a medical condition precluding exercise or PA, currently receiving treatment from a rehabilitation facility, plan to move within 1 year, hospitalized >3 times in the past 12 months, and does not speak English or Spanish.

Results: As of August 2023, the enrollment of participants is ongoing.

Conclusions: This study addresses the public health problem by optimizing a customized, technology-driven approach that can operate in low-resource environments with unlimited users to prevent falls and reduce health disparities in low-income older adults. The PEER is a novel intervention that combines concepts of physio-feedback, cognitive reframing, and peer-led exercise by motivating a shift in self-estimation of fall risk to align with physiological fall risk to improve balance, PA, and negative aging self-perception.

Introduction

Background

In 2020, there were 37.2 million people living in poverty in the United States, approximately 3.3 million more than in 2019 [1]. Every 19 minutes, an American individual dies from a fall, and every 11 seconds, an older individual is treated in an emergency department for a fall [2]. Falls and fear of falling (FOF) are significantly higher in racially diverse low-income older adults than in the general older population [3-5]. There is an association between poverty, fall injury, and mortality, resulting in health disparities [6,7]. Falls cause 95% of hip fractures, 40% of admissions to facility-based care, and 40% of fall victims to lose mobility and independence [8]. In 2018, the direct costs of fatal falls were >US $754 million, and nonfatal falls were US $50 billion, but only US $9 billion was paid by Medicaid [9]. As the number of low-income older adults increases sharply and inequalities continue to grow, this is now a widely recognized problem that requires urgent and significant action [10]. The lack of health care coverage, low education, low motivation, and inconvenience remain barriers to participating in fall prevention programs [11,12]. Low-income status contributes to negative aging self-perceptions [13] and is associated with a high perceived barrier to care [14]. A higher level of concern over falling and FOF were more prevalent in low-income older adults and functional independence in daily activities [12]. Low-income status is independently associated with FOF, which induces activity restriction [15] and functional decline [16]. People who live in low-income communities are less likely to engage in physical activity (PA) [17-19]. The lack of PA is related to falls and poor quality of life [20,21].

Addressing maladaptive fall risk appraisal (FRA) can be challenging owing to self-report bias and cognitive deficit. We developed an *FRA matrix*, a graphical grid categorizing perception (levels of FOF) and body function (level of balance) into four groups: (1) rational FRA (low FOF and normal balance), (2) incongruent FRA (low FOF despite poor balance), (3) irrational FRA (high FOF despite normal balance), and (4) congruent FRA (high FOF and poor balance) [22,23]. On the basis of our previous works [24-26] and other studies [27], approximately 64% to 79% of older adults had maladaptive FRA. Older adults in maladaptive FRA groups were 2 to 3 times more likely to fall than those in adaptive FRA [24,25]. Those with irrational FRA serve as a barrier, creating a high FOF that inhibits low-income older adults from staying physically active. High FOF restricts mobility and daily activities and increases fall risk [28], with chronic FOF predicting an increased risk of functional decline [16]. Individuals with FOF overestimated their gait performance and showed deficits in motor imagery of gait [29]. They may not exhibit increased FOF and subsequently fall if they accurately appraise their physical abilities [27]. Evidence, including our data, indicates that an intervention program must help older adults reframe FRA and maintain PA [27,30]. We found that the FRA matrix is associated with moderate to vigorous PA (MVPA), Centers for Disease Control and Prevention (CDC) fall risk score, self-reported strength and flexibility, difficulty walking several city blocks, and left-hand average handgrip strength [31].

Older adults with FOF overestimated their gait performance and showed deficits in motor imagery of gait [29]. Older adults may exhibit less FOF and subsequently fall if they accurately appraise their physical abilities [27]. In addition, maladaptive FRA can result in activity withdrawal, decline in physical and cognitive abilities, and increased social isolation [23]. Therefore, adaptive FRA is a key component of activity participation and maintenance of self-reliance [32]. Several types of interventions focus on reducing FOF [33-41]; however, some degree of FOF can increase conscious awareness and reduce fall risk by encouraging individuals to avoid exposure to unnecessary risks [42]. Low-income older adults with better-perceived physical health may experience less FOF [43].

In addition, existing fall prevention intervention technologies do not enable participants and practitioners to interact and collaborate [44] even with technologies that bring viable strategies to maintain independence, prevent disability, and increase access to quality care. Acceptability, privacy issues, technology costs, implementation costs, and barriers have rarely been addressed [44]. Research is also limited on the use of technology to enhance motivation and help individuals align their perception with physiological fall risk [45]. Offering additional advantages, technology-based exercise interventions have good adherence and may provide a sustainable method of promoting PA and preventing falls [45,46].

We developed a novel, 8-week Physio-Feedback Exercise Program (PEER) [32], which includes (1) technology-based physio-feedback using a real-time portable innovative technology—the BTrackS Balance Tracking System (BBS), which is reliable [47,48] and affordable, allows for home testing, provides feedback, and tracks balance progression; (2) cognitive reframing [49] using the FRA matrix; and (3) peer-led exercises [50] focusing on balance, strength training, and incorporating exercises into daily activities. Our pilot study supports the feasibility and acceptability of using BBS technology in low-income communities to screen individuals with maladaptive FRA. It also supports using the results to tailor interventions to improve PA and reduce falls [31,51,52]. The findings highlight reducing sedentary time to help shift from irrational to rational groups and increasing MVPA time to help shift from congruent and irrational to rational FRA groups. We found a significant

XSL•FO
RenderX

difference in sedentary time between the rational and irrational groups (P=.04). This indicates that if a person exhibits high FOF despite their normal balance (irrational), they tend to be more sedentary compared with people with low FOF and normal balance (rational). Importantly, we showed that the FRA matrix and 4-group quadrant design (irrational, incongruent, congruent, and rational) allows stratified analysis, which provides a more efficient overall fall risk assessment, which has rarely been reported in the literature.

Aims and Hypotheses

Aim 1 is to examine the effects of the technology-based PEER intervention on fall risk, dynamic balance, and accelerometer-based PA.

The hypotheses are as follows:

- *H 1.1:* The PEER group will reduce the fall risk compared with the control group.
- *H 1.2:* The PEER group will improve the dynamic balance compared with the control group.
- *H 1.3:* The PEER group will improve accelerometer-based PA compared with the control group.

Aim 2 is to examine the effects of the PEER intervention on FRA shifting and negative self-perceptions of aging.

The hypotheses are as follows:

- *H 2.1:* The PEER group will have a more adaptive shifting compared with the control group.
- *H 2.2:* The PEER group will have a more positive shift in their perceptions of aging compared with the control group.

Aim 3 is to explore participants' experiences with the PEER intervention and potential barriers to access and adoption of the technology-based PEER intervention to inform future research. A purposive sample of 30 participants from the PEER group will participate in semistructured one-on-one interviews to explore their perceptions of barriers to access and adoption of technology and intervention.

Methods

Study Design

This is an intention-to-treat, single-blind, parallel, 2-arm clustered randomized controlled trial study. We will collect data at baseline (T1) and measure outcomes after program completion (T2) and follow-up at 3 months (T3) and 6 months (T4) to test our hypotheses. We include a retention period of 6 months to determine whether fall risk, dynamic balance, PA, altered maladaptive FRA (FRA shifting), and negative self-perceptions of aging are maintained without ongoing intervention. This study is registered on ClinicalTrials.gov (NCT05778604).

Settings

The intervention will be offered in low-income, independent living communities, units, and apartments in Orlando, Florida. Florida has a large aging population with drastically different income levels and degrees of socioeconomic status [53]. The diversity of potential participants is also high, as Florida's population is approximately 17% African American, 3% Asian, 26% Hispanic or Latinx, and 54% non-Hispanic White [54].

Study Participants

A sample of 340 participants will be enrolled if they meet all the following inclusion criteria:(1) aged ≥60 years, (2) cognitively intact based on Mini-Mental State Examination score ≥24 [55], and (3) able to stand without assistance. Exclusion criteria were as follows: (1) a medical condition precluding exercise and PA, such as feeling pressure when performing PA; (2) currently receiving treatment from a rehabilitation facility; (3) plan to move within 1 year; (4) hospitalized >3 times in the past 12 months; and (5) does not speak English or Spanish.

Power Analysis and Sample Size

The sample size estimate was based on the primary outcomes of fall risk (CDC fall risk score) and PA (normalized MVPA) for aim 1 and the secondary outcome of FRA shifting (BBS score) for aim 2. The difference in the normalized mean MVPA between the PEER group (mean 3.67, SD 2.54) and the control group (mean 5.38, SD 2.68) and the difference in the fall risk score between the PEER group (mean 2.72, SD=3.23) and the control group (mean 2.21, SD=2.06) are considered markers of PA and fall risk, respectively. Considering a clinically relevant normalized difference in MVPA of 1.7 (SD 2.60) and a fall risk score difference of 0.50 (SD 2.56), the medium effect size Cohen d=0.25, intraclass correlation (ICC) of 0.8, and a significance level of are used for the calculation of the sample size. A sample size of 120 participants per arm is needed to reach 80% statistical power to detect the difference between the PEER and control groups on repeated measures of normalized MVPA. A sample size of 120 participants per arm is needed to reach 80% statistical power to detect the difference between the PEER and control groups on repeated measures of normalized MVPA.

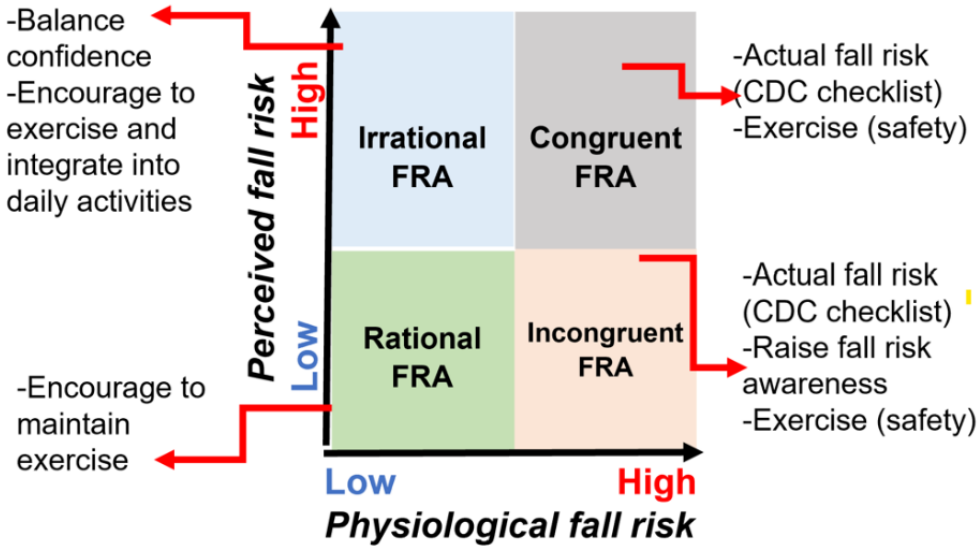
In addition, the sample size was also based on the following: (1) at least 3 sites per arm; (2) an initial hypothesis that at least 10% (34/340) of the irrational, incongruent, and congruent FRA would shift to rational FRA after PEER completion; (3) an approximate study adherence rate of 80% [56], and (4) an estimated study dropout rate of approximately 40% (136/340) over time. Therefore, the sample size was increased from 120 to 170 per arm, resulting in a total of 340 participants. On the basis of our pilot study [26], we estimate that approximately 60% (204/340) of the low-income older adults will meet all inclusion and exclusion criteria and will be interested in participating in this study. We estimate that a minimum of 567 low-income older adults will be screened to identify 340 low-income older adults for enrollment, and approximately 240 low-income older adults (120 per arm) are needed to complete the study. Given the sample size of 120 per arm, a significance level of P=.05, and 80% power, considering a clinically relevant BBS mean score difference of 8 (SD 12), the effect size Cohen d=0.36 can be achieved to compare the intervention effect based on secondary outcomes.

Recruitment, Randomization, and Procedures

Research sites will be recruited through a partnership with local communities, personal contacts, referrals, and phone calls. The

XSL•FO
RenderX

unit of randomization is an independent living senior community, which is defined as a company-owned facility with a design for low-income independent adults aged ≥55 years and without health care services provided on campus. Research sites will be selected based on the prespecified criteria, including the number of residents, geographic proximity (urban vs suburban), and ability to implement the intervention. We plan to recruit 6 sites (3 intervention sites and 3 control sites). Collectively, approximately 10 sites and 800 low-income individuals are available for screening, and we can add sites, as they are abundant in the area. The participating sites will be randomized to either the intervention or control group in a 1:1 ratio. RX (coinvestigator and statistician) will use a computerized pseudorandom number generator to determine the randomization order in advance. The project director (PD) will reveal the randomization of the sites before the study [57]. Following randomization, we will recruit participants using standard strategies, including placing flyers on information boards and participating in open-house sessions or health fairs for face-to-face recruitment. Participants will also be recruited from their units by email. We will screen participants by a phone call to determine their initial eligibility, and those eligible will be invited for the baseline assessment. The research staff will explain the study and complete the consent process. The PEER intervention sites will be required to select 6 to 7 volunteers called *peer coaches* (PCs) to lead the exercise group, and the PCs will be eligible if they report having a regular PA routine or having an educational background in health care; are aged >55 years; can read, write, and understand English and Spanish; and are committed to delivering the protocol for 8 weeks. JS (coinvestigator) and the principal investigator (PI) will provide two, 3-hour sessions to train the PCs in balance and strength training, safety in the exercise, and participant motivation in collaboration with a successful PC from our pilot study. Each PC will be matched to 8 to 10 low-income older adults in the PEER group according to the place of residence and will supervise low-income older adults in groups while they are engaged in group exercises. This procedure was successful in our pilot study.



Intervention

The PEER consists of 3 components with 3 steps.

Step 1: Technology-Based Physio-Feedback

The research assistant (RA) presents the BTrackS software (Balance Tracking Systems, Inc) to display the participant's BBS scores with interpretations and then categorizes the participants into 4 groups (irrational, incongruent, congruent, and rational) according to the FRA matrix and plots the position in 1 of the 4 quadrants on the FRA matrix chart (Figure 1). The RA will provide physio-feedback to the participants at baseline (T1) and after program completion (T2).

Figure 1. Technology-based physio-feedback. CDC: Centers for Disease Control and Prevention; FRA: fall risk appraisal.

Step 2: Cognitive Reframing

Cognitive reframing will be based on the FRA matrix. We will present the FRA matrix, and activities will be tailored based on the quadrant that the participant fits (Figure 1):

- *Quadrant 1* (irrational): focus on increasing balance confidence and maintaining exercise.
- *Quadrant 2* (incongruent): focus on individual fall risk factors from the CDC fall risk checklist, enhance fall risk awareness, and participate in the exercise.
- *Quadrant 3* (congruent): focus on individual fall risk factors from the CDC fall checklist and participate in the exercise.
- *Quadrant 4* (rational): encourage to maintain exercise.

Step 3: Peer-Led Exercises

Peer-led exercises focus on balance, strength training, and incorporating exercises into daily activities. A trained PC will lead the group-based exercises for 60 minutes (8-10 per group). Exercise training includes 4 sets of warm-ups, strength for the upper and lower body, balance (standing and moving), and stretching of the upper and lower body. Our training sessions follow the guidelines established by the American College of Sports Medicine, which take into account the frequency, intensity, time, and type of exercise recommended for each individual level of progression. These levels are classified as beginner, intermediate, and advanced [58,59]. On the basis of these guidelines, a duration of 91 to 120 minutes of exercise

XSL•FO
RenderX

per week is the most effective in improving overall balance performance [60]. Therefore, the dose of exercise that will be tested in the PEER group is 120 minutes for 8 weeks (60 min/wk for group exercise led by the peer and at least 30 min twice a wk for individual exercise). We will offer a booklet with exercise instructions in both English and Spanish, featuring illustrations to guide users through each exercise set. The booklet contains a diverse range of exercises that can be easily incorporated into daily routines, such as cooking. The participants will be instructed to keep a weekly log of their exercise activities, noting the type and duration of each activity they performed at home.

Treatment Fidelity and Monitoring

The PI and PD will oversee the treatment fidelity and monitoring plan. We will use a modified Treatment Fidelity Assessment Tool based on National Institutes of Health's Behavioral Change Consortium treatment fidelity research [61]. In total, 5% (17/340) of the intervention sessions will be randomly observed by the PI using the modified Treatment Fidelity Assessment Tool, including treatment design, training, delivery of treatment, receipt of treatment, and enactment of treatment skills [61,62]. It is evaluated on a 3-point scale (1=present, 2=absent but should be present, and 3=not applicable). Problems identified, including deviation from the protocol, will be discussed with the research team, assessors, and interventionists biweekly. Retraining will be provided if adherence is <90%. A continual process evaluation plan will be used in this study. The plan is based on the guidelines of the Medical Research Council framework [63], which includes three components: (1) implementation, (2) mechanisms of impact, and (3) contextual factors. The implementation of the PEER intervention will be evaluated based on fidelity (whether the PEER was delivered as intended), completeness (quantity of the PEER implemented), adaptation (alterations made), and reach (characteristics of the population reached). The mechanisms of impact (how the delivered PEER produced change) and contextual factors (how context affects implementation and outcomes) will be assessed in this study. Adherence to the PEER intervention will be monitored by phone calls by a PC. Adverse events will be monitored throughout the study period. Low-income older adults will be instructed to contact RAs, the PI, or the PD if they have falls, near falls, or a change in status that led to medical attention. Contact will be recorded by the RAs. The low-income older adults will be asked to identify reasons for adherence as well as nonadherence. A project logbook, registration checklists, participant records, and self-reports will be used to collect these data.

End Points

The intervention will be delivered per protocol until 1 of the following end points is met (whichever occurs first): (1) unable to participate in PEER activities (eg, exercise), (2) past 8 weeks of enrollment, and (3) other exclusion criteria are met (eg, severe cognitive problems).

Control Group

The control group or enhanced usual care will receive an information pamphlet about falls (English or Spanish version) developed by the CDC Stopping Elderly Accidents, Deaths, and Injuries–Older Adult Fall Prevention. These pamphlets provide details on fall risk, ways to prevent falls, how to check for safety, postural hypotension, chair rise exercise, what they can do to avoid falls, ensure safety, and manage postural hypotension [2]. The control group will be encouraged to discuss fall prevention with their primary care provider and continue their regular activities for 6 months. They will be offered the PEER intervention when the study concludes. They will receive monthly phone calls from the RA to record a monthly fall incidence log.

Outcome Measures and Data Collection

Primary Outcome Measures

Fall Risk

Fall risk will be assessed using the CDC's Stopping Elderly Accidents, Deaths, and Injuries fall risk checklist. It consists of 12 statements related to physical and psychological fall risk factors, with responses of either yes or no. If a person scores ≥4 points, it suggests that there is a risk of falling [2]. The sensitivity of this checklist for discriminating fallers and predicting future fallers among community-dwelling older adults is 73% to 80% [64].

Dynamic Balance

Dynamic balance will be assessed using the "Timed Up and Go" (TUG) and "Sit to Stand" (STS) tests suggested by the CDC [2] and the American Geriatric Society [65]. It is important to conduct >1 balance test, as some participants may be identified as at risk on one and not another [64]. The TUG test is a commonly used method for evaluating functional mobility and predicting the risk of falling [66,67]. The TUG test has been validated among older adults in the community [68]. The TUG test has been proven to be effective in assessing older adults at risk of falling, with a sensitivity and specificity of 87% [69]. The STS is reliable for various populations [70,71]. For the TUG test, participants will stand up from a standard armchair, walk at a normal pace for 3 m, return, and sit down again [72]. Participants who complete the TUG test in <12 seconds will be classified as having a low fall risk [73]. Then they will complete the STS. To begin, the participant should sit in the center of the chair, crossing their hands at the wrists and placing them on the opposite shoulder. They should keep their feet flat on the floor, their back straight, and their arms against their chest. Then, they should repeat the motion of standing up and sitting back down for 30 seconds. The results will be scored based on their age and sex as suggested by the CDC [2].

PA Measures

PA participants will have their activity levels monitored using ActiGraph GT9X Link wireless activity monitors for 7 consecutive days. These devices, which are triaxial accelerometers, will be worn on the nondominant wrist by all participants. The GT9X Link has a sample rate of 30-100 Hz and a dynamic range of ±8G. It also has a rechargeable battery that lasts up to 14 days and can store up to 4 GB of data for 180 days. Information is collected every minute. A sensor checks if the device is being worn or not. The GT9X Link gives accurate 24-hour measurements of PA, such as steps taken, energy expended, intensity, and the user's position. Measuring

XSL•FO
RenderX

PA through accelerometry is a reliable method (ICC=0.98), especially when assessing free-living individuals [74]. It has been validated through comparison with measurements of direct observation, energy expenditure, and sedentary behavior [75,76].

Secondary Outcome Measures

FRA Shifting

FRA shifting consists of (1) maladaptive shifting, which is moving from the rational quadrant into any other quadrant, and (2) adaptive shifting, which is moving from irrational, incongruent, or congruent into the rational quadrant [77]. We use the FRA matrix, a graphical grid categorizing levels of FOF (mind) and levels of balance (body) into four quadrants [22,23]: (1) *rational:* low FOF (short Falls Efficacy Scale-International [FES-I] ≤10) and normal balance (BBS ≤30), (2) *incongruent:* low FOF (short FES-I≤10) despite poor balance (BBS>30), (3) *irrational:* high FOF (short FES-I>10) despite normal balance (BBS≤30), and (4) *congruent:* high FOF (short FES-I>10) and poor balance (BBS>30).

Levels of FOF

Levels of FOF will be assessed using the short FES-I. It is a 7-item self-report questionnaire (English and Spanish version) that provides information on the level of concern about falls for a range of activities of daily living [78]. On a 4-point Likert scale, low-income older adults will be asked to rate their concerns about the possibility of falling when performing 7 activities such as dressing. The scores range from 7 to 28 [79]. Higher total FES-I scores indicate higher FOF [78]. Scores of 7 to 10 indicate low concern about falling, whereas scores of 11 to 28 indicate high concern about falling [80,81]. The short FES-I has been validated in community-dwelling older adults [80]. Cronbach α=.97 and ICC=0.979 among older adults [82].

Levels of Balance

Levels of balance will be assessed using the BBS. During the BBS, a piece of sturdy furniture or a standard walker will be placed within the participant's reach to reduce the risk that FOF will contaminate performance and enable even frail people to participate. Individuals will stand as still as possible on the BTrackS Balance force plate with their hands on the hips and eyes closed [83]. After the test, there are three results: (1) baseline, postbaseline, and percentage of changes; (2) comparison with sex and age group; and (3) levels of fall risk. In comparison with the age group, the software uses the BBS Normative Database to compare the individual with others in their age group. The BBS score is dependent on age and sex but not body size so that the percentile rankings can be determined across various age groups and for men and women separately [84]. A scale from 0 to 100 represents the percentile ranking of the BBS. A score of 0 to 30 indicates a low fall risk (normal balance) [84].

Negative Self-Perceptions

Negative self-perceptions will be measured using the Brief Aging Perceptions Questionnaire, which consists of 17 items [84]. In the proposed study, we will calculate an overall negative perception score (range 17-85, as in the study by Fawsitt et al [85] and Freeman et al [86]) by summing all negative scales after reverse scoring positive subscales. In our pilot study (N=48), this measure's Cronbach α was .64.

Additional Measures of Interest

Social Determinants of Health

Social determinants of health from the PhenX tool kit include protocols related to demographics or participants' characteristics including age, sex, education, history of falls, the number of comorbidities, access to health services, health literacy, and access to health technology [87].

Depression

Depression will be measured using the Patient Health Questionnaire-9. The Patient Health Questionnaire-9 (English and Spanish) is a valid and reliable tool for screening depression in older adults [88,89]. It has high internal consistency (Cronbach α=.89) [88,89]. Participants will score how often each symptom (eg, feeling tired) was present within the last 2 weeks. The total scores range from 0 to 27, with scores ≥10 indicating moderate depression [88].

Anxiety

Anxiety will be measured using the Geriatric Anxiety Inventory-Short form, which consists of 5 items, investigates 3 dimensions of anxiety (somatic, cognitive, and affective), and is rated on a 4-point Likert scale, ranging from 0 (not at all) to 3 (all the time) [90-92]. It has adequate internal consistency and validity for screening anxiety in older adults [93].

Incidence of Falls

We will measure the number of falls and near falls. A *fall* is defined as an unexpected event in which an individual comes to rest on the ground, floor, or a lower level. An *injurious fall* is defined as hospitalization for or receipt of outpatient care because of a fall [94,95]. A *near fall* is a stumble event or loss of balance that would result in a fall if sufficient recovery mechanisms were not activated. At least 2 compensatory mechanisms (eg, unplanned movement of the arms, legs, and trunk tilt) should be activated [96]. The number of falls and near falls will be assessed using a monthly fall log by low-income older adults and follow-up phone calls by RAs.

Exercise Adherence

A weekly exercise log is designed from our pilot work to record activity including the types and duration of exercise that low-income older adults performs at home. A weekly exercise log will be handed to the PC at the group exercise in the week after.

Data Collection

Demographic data (eg, age, sex, living status, and education level), perceived general health, self-report of vision, medication use, urinary incontinence, and the number of falls in the past 6 months will be assessed at baseline to provide context about low-income older adults. A trained RA will perform all baseline and follow-up assessments and will be blinded to the group assignment. Low-income older adults will be instructed not to inform assessors of their group status. All questionnaires and tests (except the PA test) take approximately 60 to 90 minutes

XSL•FO
RenderX

to complete, and no risks or discomfort were associated with the balance and PA tests in our pilot studies.

Data Management and Integrity

Data files will be built on a password-protected computer using REDCap (Research Electronic Data Capture; Vanderbilt University), which will be housed on a secure university server [97,98]. RX (coinvestigator) and RAs will be responsible for data cleaning and will teach the data entry system to the study team members who will be recording data in REDCap. Following an initial audit, the data will be double entered, and files will be matched to verify the accuracy of the data for the first 5 participants, after which a random 5% (17/340) of the total sample will be double checked periodically throughout the study. The data will be systematically examined for out-of-range values and inconsistencies. We anticipate no more than 5% missing values on any 1 item, as data will be collected in person on site and via phone calls. Missing data will be identified and obtained during follow-up interviews or with follow-up contact with participants. We will create an audit trail to identify and correct issues, protect participants' privacy, ensure confidentiality, and maintain data integrity [99]. If causes of error other than random variation are identified, we will modify or adjust our procedures and train team members as needed.

Data Analysis

We will collect demographic information from the participants for the study. We will compare baseline variables, such as essential participant characteristics, primary, and secondary end points, to summarize the differences between the 2 groups at the start of the study (T1). For the analysis of categorical data and continuous data, the chi-square test and 2-tailed *t* test will be used. We use R (version 4.1.2; R Foundation) for data analyses, with a significance level of P=.05.

Aim 1 is to examine the effects of the technology-based PEER intervention on fall risk, dynamic balance, and accelerometer-based PA.

The hypotheses are as follows:

- *H 1.1*: The PEER group will reduce the fall risk compared with the control group.
- *H 1.2*: The PEER group will improve the dynamic balance compared with the control group.
- *H 1.3*: The PEER group will improve accelerometer-based PA compared with the control group.

Data will be analyzed according to the intention-to-treat principle [100]. We will model the fall risk, dynamic balance, and accelerometer-based PA as longitudinal outcomes consisting of 4 measurements (baseline or T1, after program completion or T2, follow-up at 3 months or T3, and follow-up at 6 months or T4) using the longitudinal linear mixed model (LMM) [101]. The LMM allows all low-income older adults and their available data to be included in the analysis, even for unequal group sample sizes, and the group heterogeneity can be addressed in the variance structure of random effects. It is hypothesized that the PEER group will show improvement in all outcome measures over time. To test hypothesis *1.1*, between-arm differences for fall risk scores, the likelihood ratio test (LRT) [101] associated with LMM will be used from all follow-up assessment visits. Similarly, the LRTs will be used to test hypotheses *1.2* and *1.3* for between-arm differences for dynamic balance and PA, respectively. The CDC-recommended scoring scheme will be adopted to process fall risk, TUG, and STS data [102]. For example, the average score of the number of STS repetitions a person can complete is based on different age and sex groups [102].

Raw acceleration data from ActiGraph will be downloaded and converted to ".csv" files using ActiLife 6 Software (version 6.13.4; ActiGraph LLC). PA data will be processed using the R package *GGIR* (version 2.4-0). *GGIR* R package used to process multiday raw accelerometer data for PA research [103] includes (1) auto-calibration of acceleration signals according to local gravity [104], (2) detection of nonwear time, and (3) calculation of the average magnitude of dynamic acceleration corrected for gravity (ie, Euclidean Norm Minus One) over 5-second epochs and expressed in milli-gravitational units (mg) [105]. Nonwear time and sustained abnormally high accelerations will be imputed using the default settings [105]. The Euclidean Norm Minus One cut-off points will be used to estimate the total time spent in sedentary behavior, light intensity PA, and MVPA in participants.

For missing data treatment, the missing values will be imputed using the method of multiple imputations [106]. The maximum number of missing values within a scale will be based on the guidelines provided by the scale developers or based on a limit of 25% missing values. In the first analysis, all low-income older adults will be included according to their original group assignment [100]. Participants in the PEER group who completed at least 5 of the 8 group-based sessions will be included in the per-protocol analysis. Although every attempt will be made to ensure that low-income older adults complete all assessments, there may be some participant attrition over time. The missing data mechanism is assumed to be missing at random. The dropout patterns or missing data rates for the 2 arms will be examined to assess the differences. When possible, the models should be modified to account for relevant factors such as age, sex, general health perception, and the number of falls in the 6 months leading up to the baseline. To determine the impact of the PEER intervention during follow-up evaluations, the group-by-time interaction term will be incorporated into the model. Effect sizes (Cohen *d*) [107,108] will be calculated based on the estimated means and the pooled SD.

Aim 2 is to examine the effects of the intervention on FRA shifting and negative self-perceptions of aging.

The hypotheses are as follows:

- *H 2.1*: The PEER group will have a more adaptive shifting compared with the control group.
- *H 2.2*: The PEER group will have a more positive shift in their perceptions of aging compared with the control group.

To test hypothesis *2.1* (FRA shifting), the 4 FRA quadrants will be determined by grid coordinates based on 2 continuous level measures (BBS and short FES-I scores). We will classify shifting into 2 types: maladaptive and adaptive shifting.

XSL•FO
RenderX

Adaptive shifting is moving from irrational, incongruent, or congruent to rational. The outcome is a percentage of low-income older adults with baseline (T1) in irrational, incongruent, or congruent quadrants who end up in the rational quadrant after program completion (T2). Maladaptive shifting is a movement from rational to any other quadrant, and the percentage of low-income older adults will be calculated. After program completion (T2), the baseline FRA categories (T1) may remain the same or shift to a different FRA category. We will form a 4×4 contingency table for the 4 FRA categories at each follow-up time point (T3 and T4) to summarize the shifts. The standard 4×4 table analysis will be performed to examine the FRA shifting, either using a chi-square test or exact test, depending on the actual counts observed in the 4×4 table. The BBS and short FES-I scores will be collected in 4 planned visit time points (T1, T2, T3, and T3). We will use the Generalized Linear Mixed Model (GLMM) to analyze these 2 end points for assessing the difference between the PEER intervention and control arms on the shift of FRA categories [109]. Our longitudinal data on the PEER effects of different types of shifting on low-income older adults will contain repeated binary measures of the shifting status over time. The binomial GLMM with the logic link will allow us to assess the difference between the 2 arms in FRA shifting, and the associated LRT [101] will be used to test hypothesis *2.1* if a significant adaptive shifting is detected in the PEER group compared with the control group. The GLMM can address the group heterogeneity by specifying the corresponding covariance structure in random effect terms.

To test hypothesis *2.2*, positive shift in their perceptions of aging, the longitudinal mixed model analysis of variance will be used to test the effects of the intervention by comparing the PEER group with the control group from all follow-up assessment visits. Measurements, such as the negative self-perceptions of aging, can be incorporated into the GLMM model to investigate their potential role as mediators of FRA shifting and examine the effects of the intervention.

Aim 3 is to explore participants' experiences with the intervention and potential barriers to access and adoption of the technology-based PEER intervention to inform future research.

Rationale

A qualitative approach will allow us to explore the complex, multilevel pathways through how the PEER intervention affect at individual and peer-group levels. We may also identify barriers to successful FRA adaptation and barriers to access and adoption of the technology-based intervention that cannot be identified in quantitative data but will be important to consider in the future. Interviews with participants will provide insights into the variability across settings and implementation factors that will be instructive for program and policy planning. Importantly, interviews will amplify the voices of low-income individuals who traditionally hold less power in program planning [110].

Design and Sample

We will use in-depth, one-on-one, semistructured interviews with up to 30 participants from the PEER after the completion of the intervention (T2). Semistructured interviews will help ensure that key concepts are addressed while allowing flexibility to adjust and rearrange questions to maximize interview flow and useful data collected. Theoretical sampling will help us gain the perceptions we need in terms of demographic and experiential variation [111,112]. We will sample until saturation of themes and content has occurred. The interviews (30-40 minutes) will be conducted by a trained interviewer either in person or by phone or web conferencing and will be audio recorded. The COREQ (Consolidated Criteria for Reporting Qualitative Research) [113,114] will be used during all phases of the process to optimize quality.

Interview Guide

The National Institute on Minority Health and Health Disparities research framework [115] will help inform the development of the interview guide and focus on the (1) three domains of influence (biological, behavioral, and sociocultural) and (2) two levels of influence (individual and peer groups) that are most relevant to participant experiences and intervention evaluation. Interview questions will focus on their experience of participating in the PEER intervention, acceptability of PEER, potential barriers to accessing and adopting PEER in the community, and recommendations for future work. Consistent with the standard qualitative methodology, interview guides will be pilot-tested and adjusted based on findings from early interviews [116].

Analysis

Data will be analyzed based on the analytic process of interpretive description, which is used to develop findings for clinical practice [117,118]. VL (coinvestigator) and the PI will generate initial codes focusing on participants' experiences with PEER and will meet to establish consensus on the coding and using the NVivo software (version 12; QSR International) to aid in sorting and organizing the data. Consistent with the interpretive description, we will maintain an open stance toward coding to understand participant experiences [118]. Coding will continue until no new information is forthcoming from the data and the categories appear "saturated" [112]. Field notes will be coded to aid data interpretations and provide context, as they will contain interviewers' impressions and observations during the interviews [111]. We will collate codes into themes, review them for their fit to the data, and categorize and label themes. We will conduct initial analyses on all data as soon as they are collected to allow for theoretical adjustments to the questions and guide sampling strategies for future interviews.

Domains of Quality

We will enhance quality via the following strategies:

- Maximal variation in sampling by ensuring variability on the factors that likely influence participants' experience (age and context). We will enhance the credibility of the data and seek out a range of responses to the PEER, both positive and negative.
- Throughout the study, we will document all the methodological decisions and the reasoning behind them to maintain an accurate audit trail and ensure interpretive rigor [111].

XSL•FO
RenderX

- After identifying general themes and subthemes in the qualitative data analysis process, the entire research team will review and discuss a summary through peer debriefing [119].
- We will encourage team members who are not directly involved in the analysis to provide feedback and ask critical questions about the methods, decisions, and interpretation.
- Inference transferability will provide a description of the participants to allow for transferability of findings to similar settings, contexts, and people [120].

Ethical Considerations

The Institutional Review Board of the University of Central Florida granted ethics approval for this study (protocol STUDY00003206) on October 14, 2022. All participants will receive information before participation.

Results

As of August 2023, the enrollment of participants is ongoing.

Discussion

Principal Findings

Our developed PEER intervention is focused on providing physio-feedback using technology, promoting cognitive reframing, enhancing peer-led exercises, and incorporating exercises into daily activities. We aimed to examine the effectiveness of the technology-based PEER intervention on 3 primary outcomes (fall risk, dynamic balance, and accelerometer-based PA) and 2 secondary outcomes (FRA shifting and negative self-perceptions of aging). We hypothesized that the PEER group will reduce the fall risk, improve the dynamic balance, and improve accelerometer-based PA compared with the control group.

Our pilot study found that the PEER intervention (n=19) had a significant reduction in the CDC fall risk score from preintervention to postintervention (effect size Cohen *d*=0.6; *P*=.02) [32]. We also found that the PEER group had significant improvement in the TUG (*P*=.001; Cohen *d*=1.0) and STS (*P*<.001; Cohen *d*=0.95) tests [32]. In addition, in a pilot study [77], 11% of participants in the PEER group (n=19) had adaptive shifting compared with none in the control group (n=22). Up to 32% of the participants in the control group had maladaptive shifting compared with only 5.3% in the PEER group [77].

Existing fall prevention intervention technologies do not enable participants and practitioners to interact and collaborate [44] even with technologies that bring viable strategies to maintain PA, prevent disability, and increase access to quality care. The physio-feedback using portable technology is a vital component of the PEER intervention for screening fall risk at home or in their communities and initiating a fall risk communication between older adults, their caregivers, and practitioners. The physio-feedback and cognitive reframing strategies improve older adults' competence by aligning their physiological fall risk with FOF or body and mind and increasing their fall risk awareness [116]. Few studies focused on improving PA in socioeconomically disadvantaged groups [121] despite recommendations for action on the social determinants of health for improving PA. Regular PA improved quality of life and reduced fall risk and mortality [122]; however, a lack of motivation to participate in PA is a crucial barrier. The peer-led exercises with peer coaching strategies may help build a connection and increase the motivation to participate in PA for older adults [50].

Future Implications

This study addresses the public health problem by optimizing a technology-driven, tailored approach that can operate in low-resource environments with unlimited users to prevent falls and reduce health disparities in low-income older adults. It also supports using the results to tailor interventions to improve PA and reduce falls [31,51,52]. If effective, this intervention can provide an innovative, scalable, and accessible model for fall prevention in diverse and underserved populations. The use of a noninvasive technology that does not require special training and can operate in low-resource environments may scale up the intervention for low-income communities. The BBS can be used for fall risk assessment, tailored interventions, and tracking the changes in balance performance. Technology-based physio-feedback regarding balance has a positive effect on balance confidence and task selection, which could help reframe unrealistic perceptions and lead to healthy behaviors. This study is conducted by an interdisciplinary team and collaborates with community-based and public health organizations, which will ensure the research is relevant, contextually appropriate, and will ultimately be translated into real-world settings.

Limitations, Potential Challenges, and Alternatives

There are several limitations and potential challenges including (1) recruitment and retention, (2) respondent burden, (3) staffing, and (4) lack of skills to use BBS technology.

Recruitment and Retention

Although the recruitment and retention of low-income older adults in randomized controlled trial studies is often challenging, our tailored strategies will address these issues by ensuring that our bilingual RAs are well trained, providing information in English and Spanish versions, and using a straightforward data collection process.

Respondent Burden

During the intervention, the PCs and RAs will complete a weekly exercise log and monthly fall or near falls logs. After the 8-week intervention, the only data to be collected monthly from participants will be the fall logs. These were used successfully in our pilot study; we found no falls and 2 near falls in the PEER group.

Staffing

Our staffing plan ensures coverage by study personnel for 8 weeks of the intervention and the 3- and 6-month follow-up assessment.

Lack of Skills to Use BBS Technology

This study does not expect low-income older adults to test themselves using the BBS. We will train an RA at each site to run the test.

Conclusions

More than half of all older adults have maladaptive FRA, leading to reduced PA and a corresponding increased risk of falls. This study focuses on fall interventions tailored to low-income older adults who have a mismatch between physiological fall risk (body) and perceived fall risk (mind). The PEER is a novel intervention that combines concepts of physio-feedback, cognitive reframing, and peer-led exercise by motivating a shift in self-estimation of fall risk to align with physiological fall risk to improve balance, PA, and negative aging self-perception that no one has studied before. The major strength of this study is the use of a noninvasive technology that does not require special training and can operate in low-resource environments with unlimited users. The PEER intervention can be implemented on a large scale in community settings. Such an approach may reach older individuals at risk who do not participate in or are not referred to standardized conventional training programs to help them prevent falls and reduce health disparities.

Acknowledgments

This project is supported by the National Institute on Minority Health and Health Disparities of the National Institutes of Health under award R01MD018025. Abstract

Background: Poor oral health is common in nursing home residents, and health care professionals report numerous barriers when it comes to the provision of oral care for care-dependent older adults, such as a lack of oral health knowledge and skills, care-resistant behaviors in residents, lack of adequate oral care routines, insufficient systems for documentation of issues related to oral health, a high workload, and unclear responsibilities. An intervention, SmartJournal, has been developed to assist health personnel in preserving older patients' oral health. SmartJournal is a digital tool with three components: (1) documentation of oral hygiene routines; (2) monthly oral health assessment; and (3) education on geriatric oral care. An updated framework for research on complex interventions has been used to guide the various phases in the development of this intervention. This study focuses on the evaluation phase.

Objective: We aim to assess (1) the effectiveness of SmartJournal use in enhancing nursing home caregivers' capability, opportunity, motivation, and routines related to oral care; and (2) whether SmartJournal use results in improved oral health for nursing home residents.

Methods: We will use a cluster randomized controlled trial to assess impacts of SmartJournal use as specified under study objectives. Nursing homes located in Rogaland, Norway, will be recruited and randomly assigned to an intervention and a control group. The intervention group will be provided with tablets containing SmartJournal and support from research staff, while the control group will continue with existing oral care routines. Both groups will receive oral hygiene packages. The intervention will last for 12 weeks. Measurements will be performed in both groups at baseline, 3 months, and 9 months and include (1) a survey assessing caregivers' capability, opportunity, motivation, and routines related to oral care; and (2) assessment of oral health status in residents using mucosal-plaque score as a primary outcome measure. Analyses will include descriptive statistics and statistical techniques to look for changes and differences in the study variables within and between the intervention and control groups throughout the study period. Associations between study variables will also be investigated.

Results: Recruitment of nursing homes for the intervention and control groups was completed in February 2023. Recruitment of individual participants (ie, nursing home residents and caregivers) is ongoing, and baseline measurements are being performed consecutively. Results are expected to be ready for analyses in fall 2024.

Conclusions: We aim to assess the effects of SmartJournal use on oral care and oral health in nursing homes. Results from this work may inform further development and implementation of SmartJournal and similar digital tools aiming to enhance health care services offered to care-dependent people. Finally, SmartJournal may have potential as a learning tool in educational programs for nurses and other health care professionals.

Introduction

Background

Poor oral health is common in frail and care-dependent older adults and includes tooth loss, poor oral hygiene, a high prevalence of dental caries and periodontal disease, defective dental prostheses, hyposalivation, and various oral lesions caused by misfitting dentures or precancerous or cancerous states [1,2]. Alarmingly, oral health is shown to be the most neglected area in Norwegian nursing homes [3], and oral health care is the first task to be downgraded due to a lack of resources [4]. A study by Willumsen et al [5] indicated that more than 40% of Norwegian nursing home residents have unacceptable oral hygiene. Neglect of oral health, resulting in poor oral hygiene, may cause infections and inflammation both locally and systemically. Oral infections have been associated with systemic conditions such as atherosclerosis [6,7], diabetes [8], and aspiration pneumonia [9,10]. Aspiration pneumonia is a highly mortal disease, and a review by Sjøgren et al [11] estimated that 10% of all deaths from pneumonia in nursing homes could have been prevented with improved oral hygiene. Moreover, chewing difficulties as a result of poor dental status have been associated with altered dietary habits, malnutrition, and cognitive decline [2]. Yet, the oral health of care-dependent older adults does not receive the necessary attention [12]. A few decades ago, most older adults were denture wearers. Today, an increasing number of older adults keep their natural teeth, often in combination with complex fixed or removable prostheses [13]. While dentures are easy to manage, more complex prosthetic devices can pose a challenge with regard to handling and cleaning [14]. Thus, the care-dependent older adults have to rely on caregivers to maintain satisfactory oral health [15]. In Norway, nursing home residents (and other care-dependent people) have a statutory right to good oral hygiene and necessary dental treatment [16]. Health personnel are responsible for preserving these rights through daily oral hygiene routines and referral to dental professionals when needed. Research from Sweden and Denmark has shown that about 80% of nursing home residents need assistance with daily oral hygiene practices [15,17]. Thus, it is disturbing that health care professionals report numerous barriers when it comes to the provision of adequate oral care assistance. The most frequently reported barriers are lack of knowledge and skills [18] and care-resistant behaviors (CRB), in particular among patients with dementia [18,19]. A study by Willumsen et al [5] showed that more than 50% of Norwegian nursing home residents with dementia refuse oral care assistance. In cases of frequent CRB, daily oral care may be postponed repeatedly, resulting in poor oral hygiene and an increased risk of oral and systemic infections. Other reported barriers include a lack of adequate oral care routines, a lack of systems for documentation of issues related to oral health [20,21], a high workload, and unclear responsibilities [19].

Various tools have been developed to assist health personnel in providing oral care to older adults. One example is “oral care cards” with illustrated instructions about how to carry out daily oral hygiene routines with individual patients. Another example is “signature lists” to document daily oral care. These tools may function well but have some shortcomings. While oral care cards do not allow for documentation of oral health issues, signature lists do not contain information on individual needs. Moreover, text-based diagnostic tools such as the Revised Oral Assessment Guide (ROAG) [22] and the Oral Health Assessment Tool [23], have been developed to assist caregivers in recognizing oral conditions. However, research indicates that these tools may not be well suited for nondental professionals [24,25]. Other limitations of the above-mentioned tools are that they lack procedures for documentation of deviance related to oral health and that none of them include strategies for handling CRB.

The SmartJournal Intervention

As a response to the shortcomings of existing tools and to overcome reported barriers to the provision of adequate oral care in nursing homes, an intervention tailored to nursing staff has been developed by researchers at the Oral Health Centre of Expertise Rogaland, Norway, in close collaboration with innovative research and development institutions and dental and health care professionals. An updated framework for research on complex interventions, developed jointly by the United Kingdom’s Medical Research Council and the National Institute for Health Research [26], has been used to guide the various phases of intervention development: an innovation phase (completed), a feasibility study (completed), and an evaluation study (recruitment is ongoing). An overview of the phases is presented in Table 1. This study focuses on the evaluation phase.

XSL•FO

Table 1. SmartJournal study overview describing aims, methods, and participants for each phase of the study.

Phase	Aims	Methods	Participants
Phase 1: innovation (completed)	Develop an intervention (digital tool) to reduce or overcome barriers related to oral care in nursing homes (theoretical basis: the COM-B[a] model [27]).	• Step 1: collaborative innovation based on current literature, meetings, and workshops with stakeholders resulted in the SmartJournal prototype. • Step 2: initial, small-scale functionality tests with the test panel. • Step 3: refinement of the tool based on results from functionality tests.	• Step 1: practitioners and researchers within dentistry, geriatric nursing, health education, eHealth, and the development of digital learning tools. • Step 2: health personnel (n=11) recruited from nursing homes in Rogaland, Norway. • Step 3: researchers and engineers.
Phase 2: feasibility study (completed)	Investigate health personnel's acceptance of and experiences with the SmartJournal prototype in a nursing home setting.	• Real-life testing of the SmartJournal prototype in nursing homes. • Design: mixed methods, cross-sectional study • Qualitative data: thematic analysis of data from semi-structured interviews. • Quantitative data: statistical analysis of data from survey questionnaires.	• Health personnel were recruited from 3 nursing homes in Rogaland, Norway. • Semistructured interviews (n=11). • Survey questionnaire (n=86).
Phase 3: evaluation study (in progress)	Evaluate the effectiveness of SmartJournal use on: (1) caregivers' capability, opportunity, motivation, and routines related to oral care; and (2) residents' oral health (theoretical basis: the COM-B model [27]).	• Step 1: Further refinement of the tool based on results from phase 2. Functionality tests with different test panels. • Step 2: 12-week intervention with measurements at baseline, 3 months, and 9 months. • Design: Cluster-randomized controlled trial with nursing homes randomly assigned to intervention (SmartJournal use and support) and control group (continue with existing oral care routines). • Measures: a survey questionnaire assessing caregivers' capability, opportunity, motivation, and routines related to oral care. Clinical assessment of residents' oral health: MPS[b] [17] and tooth count [28].	• Step 1: refinement of the tool, researchers, and engineers. • Functionality tests: panels of auxiliary nursing students (n=70) and master students in innovation and knowledge development (n=20). • Step 2: a total of 12 nursing homes in Rogaland, Norway: 6 in the intervention and control groups, respectively. Power analyses suggest 360 residents (n=180 in each group). All eligible caregivers are invited to participate.

[a]COM-B: capability, opportunity, motivation model of behavior.

[b]MPS: mucosal-plaque score.

The intervention addresses key behavioral components as postulated by the capability, opportunity, motivation model of behavior (COM-B) [27]. According to the COM-B model, there must be sufficient capability (C), opportunity (O), and motivation (M) present for a given behavior to occur. Hence, this intervention seeks to facilitate oral care in nursing homes by providing strategies to improve caregivers' capability, opportunity, and motivation for this task. The intervention is constructed as an interactive and easy-to-use app for tablet named SmartJournal. SmartJournal consists of 3 modules. Module 1, "registration of oral hygiene routines," offers a system for simple checkbox registration of daily oral hygiene routines (ie, whether they have been performed or not). It also includes an open text field for additional comments if relevant (eg, reasons for not performing oral hygiene routines or strategies used to reduce CRB in the patient). This straightforward registration ensures documentation of oral hygiene routines and deviations related to such routines, keeping health personnel informed about potential oral hygiene issues for individual patients. Module 2, "monthly oral health assessment," offers a system for monitoring the patient's oral health status through monthly check-ups. In this component, the principles of the text-based tool ROAG are transformed into an image-based, interactive learning and assessment tool. As for ROAG, conditions for 6 oral sites (lips, mucous membranes, tongue, gingiva, teeth, and prosthetic devices, including all forms of removable dentures and fixed prosthodontics) are graded as follows: grade 1=healthy or normal condition, no need for measures; grade 2=pathology, need for measures at a "local level" (ie, at the nursing home, delivered by nursing home personnel); and grade 3=advanced pathology, need for measures delivered by dental professionals (in the nursing home if feasible, at a dental clinic if necessary). SmartJournal contains several validated example pictures for each grade for all 6 oral sites. This part of the tool is also checkbox-based to limit health personnel's workload related to documentation. Upon completion of the monthly oral health assessment, health personnel receive a summary report with suggestions for tailored preventive or curative measures to be initiated, thus reducing the risk of deteriorated oral health in the patients. Module 3, "electronic learning (e-learning)," offers an easily accessible knowledge base that includes information on geriatric oral health, standard equipment and procedures for daily oral hygiene routines in patients with natural teeth and various prosthetic devices, and oral care for patients with special care needs (including patients with swallowing difficulties, bedridden patients, and patients on palliative care). It also includes detailed information on scientifically documented strategies that may

XSL•FO
RenderX

be used to approach patients with dementia who refuse oral care assistance. These strategies are adapted from the interventions Managing Oral Hygiene Using Threat Reduction [29,30] and Mouth Care Without a Battle [31]. The content in this part of the tool is illustrated with photos and figures and includes a video with recommendations on how to handle situations where patients refuse oral care assistance. The acceptability of the SmartJournal prototype has been tested in a feasibility study. Preliminary results from this study indicate that SmartJournal is well accepted among its users. According to survey data collected from caregivers employed at 3 nursing homes in Rogaland, Norway (n=86), 72% (62/86) reported that SmartJournal is a useful tool, 94% (81/86) reported that it is easy to use, and 69% (59/86) reported that they would like to use a refined version of the tool in the future. Further results from the feasibility study will be published elsewhere.

Further Improvement of the SmartJournal

Recently, the SmartJournal prototype has been further improved and adapted to the nursing home setting. Since user involvement is a central feature in the development of interventions [32], this improvement was guided by results obtained from the feasibility study (ie, information acquired from meetings, qualitative interviews, and survey questionnaires). The improved version has been subjected to 2 functionality tests in a controlled laboratory environment. These tests were performed by the Norwegian Smart Care Cluster, a national and international collaboration arena for companies, municipalities, hospitals, public organizations, user organizations, academia, research and development institutions, and investors that works to develop sustainable health solutions for the future [33]. Insights gained through the tests have been used for additional, minor adjustments to the tool, which is now ready to be tested in the evaluation study described in the following sections.

Aims and Objectives

Since SmartJournal seems to be well accepted among its potential users, this study aims to evaluate the impacts of its use. More specifically, the objectives of the current research are to assess (1) the effectiveness of SmartJournal use in enhancing nursing home caregivers' capability, opportunity, motivation, and routines related to oral care tasks and (2) whether SmartJournal use may result in improved oral health for nursing home residents.

Methods

Design

A pragmatic cluster randomized controlled trial [34] will be used to assess the effects of SmartJournal use as specified under study objectives. Public nursing homes located in the southern part of Rogaland, Norway, will be recruited and randomly assigned to an intervention group and a control group. Institutions housing long-term residents will be included, while institutions with primarily short-term residents, institutions already following a specific protocol for oral care, or institutions participating in other comprehensive interventions are excluded (Textbox 1). Nursing homes in the intervention group will be provided with smart tablets containing SmartJournal and user support (a help desk) by research staff employed at the Oral Health Centre of Expertise Rogaland, while nursing homes in the control group will continue with existing oral care routines. Both groups will receive oral hygiene packages, including toothbrushes for permanent teeth and prosthetic devices, dental floss, interdental brushes, toothpaste, and inspection mirrors, to make sure that oral hygiene equipment is easily accessible for all participants. Nursing homes and individual participants will not receive information about who is included in the intervention and control groups, respectively. They will only receive information that is relevant to their participation. The chosen study design (a cluster randomized controlled trial) facilitates this masking by reducing the possibility of contamination between the groups. The intervention will last for 12 weeks. Measurements will be performed at baseline, 3 months, and 9 months.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for the SmartJournal evaluation study.

Inclusion criteria

- Nursing homes
  - Located in Rogaland, Norway
  - Long-term facilities
- Residents
  - Long-term residents (ie, residents with the nursing home as their permanent address)
  - Residents with and without dementia who can undergo oral examination
- Caregivers
  - All types of nursing staff (nurses, auxiliary nurses, students)
  - Full-time and part-time staff

Exclusion criteria

- Nursing homes
  - Specialized nursing homes (eg, psychiatry and substance abuse)
  - Short-term facilities (eg, rehabilitation and respite care)
  - Nursing homes already following a specific protocol for oral care or those participating in other comprehensive interventions
- Residents
  - Short-term residents
  - Critically ill and terminal patients receiving palliative care
- Caregivers
  - Staff with purely administrative tasks (eg, heads of institutions)

Participants and Procedures

Strategies used for recruitment of individual participants (caregivers and residents) and procedures for delivery of the intervention will be similar to those used in the feasibility study since they proved to be successful. Resource groups, comprised of heads of wards and selected nursing staff, will be established at each of the included nursing homes. Meetings will be scheduled to adapt the delivery of the project to each individual institution's resources and facilities, and members of the resource groups will be assigned the task of recruiting individual participants. Written informed consent will be requested for both residents and caregivers to be enrolled in the study. Nursing home residents constitute a vulnerable group in which many individuals may have reduced decision-making capacity. For these individuals, deputy consent will be obtained from their next of kin. Residents receiving end-of-life palliative care are excluded (Textbox 1). Both full-time and part-time nursing staff will be included. Health personnel with purely administrative tasks (ie, heads of institutions) are excluded (Textbox 1). Following recruitment of participants and baseline measurements, nursing homes in the intervention group will be provided with SmartJournal toolboxes and packages with oral hygiene equipment, while nursing homes in the control group will receive oral hygiene equipment packages only. The SmartJournal toolboxes include smart tablets with SmartJournal installed, antibacterial touchscreen wipes, flashlights for monthly oral inspections, an instruction video, an instruction book, and SmartJournal information posters. The oral hygiene equipment packages include toothbrushes for permanent teeth and prosthetic devices, dental floss, interdental brushes, toothpaste, and inspection mirrors. Training, follow-up, and technical support for SmartJournal users will be provided by project staff employed at the Oral Health Centre of Expertise Rogaland.

Measurements

The effectiveness of SmartJournal in enhancing nursing home caregivers' capability, opportunity, motivation, and routines related to oral care tasks will be measured by a survey questionnaire capturing components of the COM-B model [27]. Caregivers in both the intervention group and the control group will be asked to fill out the survey questionnaire three times: at baseline, 3 months, and 9 months.

The effects of SmartJournal use on nursing home residents' oral health will be assessed by low-invasive oral inspections using the mucosal-plaque score (MPS) [17] as a primary outcome measure. MPS is comprised of a 4-point plaque score (PS) and a 4-point mucosal score (MS). PS=1: no visible plaque; PS=2: plaque is barely visible; PS=3: moderate amount of plaque; and PS=4: large amount of plaque almost covering the whole surface of teeth. MS=1: normal mucosa; MS=2: mild inflammation;

XSL•FO
RenderX

MS=3: medium inflammation; and MS=4: strong inflammation. For both scores, if in doubt between 1 and 2, dental personnel are instructed to score 1. If in doubt between 3 and 4, they are instructed to score 4. The MPS index is designed to evaluate oral health and oral hygiene in groups of individuals. This makes it a suitable index to be used when conditions are not optimal to assess the patient's oral health. In a nursing home setting, dental personnel have limited equipment and poor lighting compared to an ordinary dental clinic setting. Therefore, using an index designed to be applied outside a dental clinic setting is feasible in this context. Moreover, the number of natural teeth will be counted and used as an additional outcome measure. The number of natural teeth is a frequently used measure of oral health in older adults since it is associated with nutritional status, general health, and quality of life [28]. Residents in both the intervention group and the control group will have MPS assessed and teeth counted three times: at baseline, 3 months, and 9 months. All clinical assessments will be performed by dental professionals employed at the Oral Health Centre of Expertise Rogaland, Norway. Calibration has been undertaken to ensure the reliability of the clinical measurements.

Additionally, patient journal data shown to be associated with oral health (ie, sociodemographics, medical conditions, and prescribed medication) will be retrieved and used to describe the study sample. These data will also be included as covariates in statistical analyses investigating factors associated with oral health among residents included in this study.

Power Calculations and Estimation of Sample Size

Experiences from the feasibility study show that resident participation may pose a challenge due to the high rates of morbidity, mortality, and CRB in this part of the population. The estimation of sample size is largely reproduced from Overgaard et al [35], who also used MPS as a primary outcome variable in their study on oral health in nursing home residents. Overgaard et al [35] based their power calculations on reductions in MPS ≥2 from 60% to 15%, as reported by Hede et al [17]. Like Overgaard et al [35], we assume α=.5, a power of 80%, a 33% dropout rate due to the residents' frailty, and a median resident time of 2 years. A medical statistician has been consulted to further adapt the calculations to this study's setting (taking into account the number of eligible nursing homes and residents in the southern part of Rogaland), recommending the inclusion of 12 nursing homes each with 30 residents who opted for oral health assessments. Thus, a total of 360 residents will be included for oral health assessments, 180 in the intervention and control groups, respectively. All eligible caregivers in the 12 included nursing homes will be invited to take part in the survey capturing components of the COM-B model as described in the Measurements section. Experiences from the feasibility study indicate that this broad inclusion strategy, along with assigning the recruitment task to members of the institutions' resource groups, fosters a sense of community regarding project participation. This may, in turn, motivate institutions and individual participants to remain part of the project throughout the study period.

Data Analyses

The statistical software package SPSS (IBM) will be used for data analyses. These analyses will include descriptive statistics (to describe the samples) and statistical techniques to look for changes and differences in the study variables within and between the intervention group and the control group throughout the project period, for example, 2-tailed *t* tests and ANOVA tests. We hypothesize that SmartJournal use will lead to favorable changes in variable scores in the intervention group as compared to the control group. In caregivers, it will lead to increased scores on the measured COM-B components (survey data), and in residents, it will lead to improved oral health as measured by improved MPS and, possibly, fewer natural teeth lost. Additionally, regression analysis may be used to investigate associations between study variables while adjusting for potential covariates (eg, age, gender, ethnic origin, educational level, medical conditions, and prescribed medication).

Ethics Approval

This study is approved by the Norwegian Regional Committee for Medical and Health Research Ethics (REK 2022/472796). The SmartJournal intervention aims to assist nondental care providers with preserving nursing home residents' statutory right to good oral hygiene and necessary dental treatment. Respect for the individual's intrinsic value, self-determination, and situation pervades the development and anticipated use of the tool. The project is guided by the intentions of the Declaration of Helsinki and ethical guidelines provided by the Norwegian National Research Ethics Committees. Informed consent will be obtained from nursing home caregivers and residents before data collection. Consent forms are designed in accordance with the templates for information material provided by Sikt, the Norwegian Agency for Shared Services in Education and Research, and the Regional Committees for Medical and Health Research Ethics. Nursing home residents constitute a vulnerable group in which many individuals may have reduced decision-making capacity and, thereby, difficulties giving free and informed consent to being participants in research. However, since the overall aim of the SmartJournal intervention is to assist health personnel with preserving oral health in this particular group, it is essential to include them in the research. Therefore, if residents have reduced decision-making capacity, deputy consent will be obtained from their next of kin.

Data registered in SmartJournal (ie, data for residents included in the intervention group) will be transferred to a research database at the University of Stavanger. At the SmartJournal login website, health personnel are asked to enter three codes: one code for the nursing home, one (personal) caregiver code, and one (personal) resident code. The codes for caregivers and residents will be listed in an identification key that is only available to authorized project staff. At the end of the project, data will be deidentified, and it will not be possible for anyone to link any information to individual participants. Data obtained from questionnaires, clinical assessments (MPS, number of teeth), and patient journals are registered with the same individual codes as data registered in SmartJournal, which makes it possible to link data obtained from all sources. Extractions from the University of Stavanger database and data from

XSL•FO
RenderX

questionnaires will be stored in a highly secured data system at the Oral Health Centre of Expertise Rogaland. Only authorized project staff will have access to the data.

Results

Recruitment of nursing homes for the intervention and control groups was completed in February 2023. Recruitment of individual participants (ie, nursing home residents and caregivers) is ongoing, and baseline measurements will be performed consecutively. Results from measurements at all time points (ie, baseline, 3 months, and 9 months) are expected to be ready for analyses in fall 2024.

Discussion

Principal Considerations

Poor oral health in care-dependent older adults is a substantial public health problem, as it is associated with reduced general health and quality of life in this growing part of the population [1,2,6]. Research has revealed that oral health is the most neglected area in Norwegian nursing homes [3], resulting in unacceptable oral hygiene in large proportions of nursing home residents [5]. As described in the Background section, numerous barriers to adequate oral care in nursing homes have been reported, including a lack of knowledge and skills among nursing staff, CRB in patients with dementia, a lack of adequate oral care routines and systems for documentation of oral care issues, a high workload, and unclear responsibilities [18-21]. Thus, there is an urgent need for interventions that can improve oral care and oral health among care-dependent older adults. Previous tools developed to assist health personnel in providing oral care to frail older adults have shortcomings, and some of them are not well suited for nondental professionals [24,25]. The SmartJournal intervention was developed to overcome these challenges, following principles of responsible research and innovation in terms of stakeholder involvement, acceptability, functionality testing, and quality testing, with continuous attention to issues related to ethics and sustainability in this study's context [36].

Strengths and Limitations

Among the strengths of this study is the application of an established framework for research on complex interventions [26], including theory such as the COM-B model [27], to guide intervention development, testing, and analyses. Another strength is that the study includes data from several different sources and modes of data collection, that is, caregivers' responses to survey questionnaires, SmartJournal registrations on oral care routines, patients' oral health status (ie, clinical outcome measures), and selected data from patient journals. Thus, the "common methods problem" is reduced compared to situations where only one data source is available. However, this study also has some limitations that have to be mentioned. The self-report measures used to assess caregivers' capability, opportunity, motivation, and routines related to oral care may be subjected to bias related to recall, introspective ability (ie, participants may not be able to assess themselves accurately), interpretation of questionnaire items, socially desirable responding (ie, the tendency to answer questions in a manner that will be viewed favorably by others), and sampling (ie, people who complete the questionnaire are the sort of people who are inclined to complete a questionnaire) [37]. There is also a risk of getting a low response rate from caregivers due to the general lack of time and high workload among health personnel [38].

Conclusions and Dissemination

This study aims to assess the effects of SmartJournal use on oral care and oral health in nursing homes. Results from this work may be used to inform the continued development and implementation of the SmartJournal intervention in nursing homes and other caring facilities, including in-home care. Similarly, the findings may inform the development and implementation of other digital tools aiming to enhance health care services offered to care-dependent people. Moreover, since oral health knowledge and skills seem to be inadequate for nondental health care professionals, SmartJournal may have potential as a learning tool in educational programs for nurses and other health care professionals. Results from the study will be published in high-impact academic journals and other relevant channels of dissemination, including academic and practitioners' conferences and various public media.

Peer Review

Multimedia Appendix 1 contains the peer review report by the Regional Research Funds Rogaland, Norway.

Time Schedule

The study is scheduled between February 1, 2023, and December 31, 2025 (Table 2).

Table 2. Anticipated time schedule and research activities for the SmartJournal evaluation study.

Activities	Period
Recruitment and baseline measurements (T0)	First quarter of 2023 to second quarter of 2023
Intervention[a]	Second quarter of 2023 to fourth quarter of 2023
Measurements at 3 months (T1)[a]	Fourth quarter of 2023 to first quarter of 2024
Measurements at 9 months (T2)[a]	First quarter of 2024 to third quarter of 2024
Analyses and dissemination	Fourth quarter of 2024 to fourth quarter of 2025

[a]The intervention will last for 12 weeks. Since the start date may vary between the included nursing homes, a 12-month period is scheduled to perform the intervention and measurements at T0, T1, and T2.

Acknowledgments

The authors would like to thank the colleagues at the Oral Health Centre of Expertise Rogaland, in particular Ann Kristin Berge Haugland and Linda Næss, who have made substantial contributions to the development of the SmartJournal tool. We would also like to thank our collaborative partners: the University of Stavanger (UiS), in particular the Department for Development of Digital Learning Resources at UiS; the University of Bergen (UiB); the Centre for Development of Institutional and Home Care Services (USHT) in Rogaland; and the Norwegian Smart Care Cluster. Last but not least, we would like to thank the nursing homes, patients, and caregivers participating in this project.

The initial phases of the SmartJournal project (ie, development of the prototype and the feasibility study) were funded by the Regional Research Funds Vest (project ID 291051/2018) and the Oral Health Centre of Expertise Rogaland, Norway. The evaluation study is funded by the Regional Research Funds Rogaland, Norway (project ID 332666/2022).

Data Availability

The data sets generated and/or analyzed during this study are not publicly available due to the sensitive nature of the information, and because participants' consents for public data sharing were not obtained.

Authors' Contributions

VHB and KSH contributed to development and pretesting of the SmartJournal intervention. KSH gave input to on-site procedures. ELM designed and performed the feasibility study. ELM and VHB designed the evaluation study. ELM drafted the manuscript, which was critically reviewed by VHB and KSH. The final manuscript was approved by all authors.

Conflicts of Interest

None declared.

Abstract

Background: Consumption of alcohol is synonymous with military populations, and studies have shown that serving personnel drink more than age- and sex-matched civilian populations. While ingrained in the military culture, excessive alcohol use is associated with increased rates of disciplinary issues, sickness absence, and loss of productivity, as well as contributing to a burden of acute and chronic health problems. Alcohol brief interventions can reduce alcohol use in civilian populations, but there is a paucity of evidence relating to the effectiveness of similar interventions in military populations. The DrinksRation smartphone app was designed to have a basis in behavior change technique theory and focuses on providing interactive behavioral prompts tailored to a military population. It has previously been shown to be effective in a help-seeking veteran population.

Objective: The primary aim of the Military DrinksRation randomized controlled trial study is to determine whether it is similarly effective in a serving military population.

Methods: We compare the effectiveness of the DrinksRation smartphone app with treatment as usual for personnel identified at risk of alcohol-related harm using the Military DrinksRation study that is a 2-arm, single-blind, 1:1 randomized controlled trial of the UK Armed Forces population. It is hypothesized that the DrinksRation app will be more efficacious at reducing alcohol consumption compared to treatment as usual. Recruitment will be predominantly from routine, periodic dental inspections all service personnel regularly undertake, supplemented by recruitment from military-targeted media messaging. The primary outcome is the change in alcohol units consumed per week between baseline and day 84, measured using the timeline follow-back method. Secondary outcome measures are a change in the Alcohol Use Disorders Identification Test score, a change in the quality of life assessment, and a change in drinking motivations and app usability (intervention arm only) between baseline and day 84. A final data collection at 168 days will assess the persistence of any changes over a longer duration.

Results: The study is expected to open in August 2023 and aims to enroll 728 participants to allow for a study sample size requirement of 218 per arm and a 40% attrition rate. It is expected to take up to 12 months to complete. The results will be published in 2024.

Conclusions: The Military DrinksRation study will assess the efficacy of the smartphone app on changing alcohol use behaviors in service personnel. If a positive effect is shown, the UK Defence Medical Services would have an effective, evidence-based tool to use as part of an alcohol management clinical pathway, thereby providing better support for military personnel at risk of harm from alcohol drinking.

Introduction

Overview

Consumption of alcohol is highly prevalent in the United Kingdom, with 65% of men and 50% of women reporting having consumed an alcohol-containing drink in the past week [1]. Consumption in the general population has steadily risen since the 1950s, with the most significant increase among women [2,3]. Exploration of drinking trends across the United Kingdom suggests that there has been an overall small reduction in intake in recent years. However, this is due to moderate reductions in the prevalence of drinking (from 70% to 60%) and alcohol intake in young men aged 16-24 years [2]. This reduction masks a 3 unit per week increase in alcohol intake and an increase in the prevalence of drinking by women. While there has been a reduction in the number of drinkers and the amount consumed by the 16-24-year-old age group, they are the group most likely to binge drink, a trend that transfers into the military population. A large cross-sectional study demonstrated that UK military personnel consume alcohol at rates higher than age- and sex-matched civilian personnel [4]. Military personnel are additionally more likely to drink excessively [4,5]. This binge pattern is attributed to the populations being "young single individuals [who] are less likely to have children and other domestic responsibilities that make heavy drinking less frequent or possible" [4] and the military culture of communal risk-taking [5].

Alcohol's negative effects are wide-ranging and associated with harm to health, accidents, criminality, social disruption, and poor occupational outcomes [1]. For those aged 15-49 years in England, alcohol misuse is the single largest risk factor for ill health and premature death [3]. UK defense data suggest that 59% of military personnel are at risk of alcohol-related harm, which is higher than the general population (42%) [6]. Alcohol was linked to, or the cause of, almost 5% of aeromedical evacuations between 2018 and 2019, and the number of personnel with an alcohol abuse or misuse read code in their primary care clinical notes increased from 457 to 584 between November 2017 and April 2019 [6]. From a health perspective, alcohol is implicated in much of the mental health burden within defense primary health care (DPHC) and complicates other health-related activity through interactions with medication, treatments, and direct exacerbation of symptoms [6,7].

Alcohol is implicated in military disciplinary issues [8,9] and occupationally, alcohol misuse is associated with a loss of productivity, in a dose-dependent manner, through increased rates of sickness absence and presenteeism [3,5]. The occupational impacts of alcohol on the military are more extensive than in the civilian workforce due to the nature of military employment [4,5]. Recognizing the impact that alcohol has on the effectiveness of military personnel, there are various strategies aimed at reducing their alcohol use. Personnel aged 30 years or younger have mandatory alcohol lectures that highlight the harmful effects of excessive consumption and disciplinary issues complicated by alcohol attracting more significant punishment [10].

National guidance recommends alcohol brief interventions (ABIs) for patients identified as consuming alcohol at hazardous or harmful levels [11]. An ABI is "a simple intervention aimed at individuals who are at risk through drinking above the guidelines but are not typically seeking help for an alcohol problem" [12]. All UK Armed Forces (AF) personnel are screened for risky drinking behaviors using the Alcohol Use Disorders Identification Test for Consumption (AUDIT-C) [13] at periodic dental inspections (PDIs). A "brief intervention" is given to personnel who record a score of 4 or more (men) or 3 or more (women). There is concern, however, that recent apparent reductions in alcohol intake reflect reporting bias rather than an actual reduction in the AUDIT-C score. An intentionally low misrepresentation of actual intake would avoid the individual being given an ABI or offered a referral to the general practitioner [14] and avoid any associated concerns about the career impact of being identified as being at risk of harm from drinking.

Existing evidence for the effectiveness of ABIs appears robust, with an extensive Cochrane review determining they can reduce alcohol consumption by 2 standard drinks per week after a year [15]. However, this defined an ABI as "a conversation comprising 5 or fewer sessions of brief advice or brief lifestyle counseling and a total duration of less than 60 minutes" [15]. This exceeds the time available for opportunistic ABIs within DPHC consultations. The Cochrane review also excluded digital interventions, which are intuitively of huge relevance in a young, digital native population such as the AF. Face-to-face interventions may be effective, but not if they are not accessed by a digital generation [16-18]. A narrative review of 10 studies involving military personnel and veterans found that web-based interventions may be of benefit [19]. There remains a paucity of evidence available for the effectiveness of ABIs on military populations, or indeed, for which aspects of behavior change theory are effective in a population with rigid command structures and regulations.

The primary purpose of the DrinksRation randomized controlled trial (RCT) study is to determine whether similar effectiveness is found in a serving military population.

Military DrinksRation (MDR) Study Aim

DrinksRation is a military-focused smartphone app that has been shown to be effective in reducing alcohol consumption in a veteran, help-seeking population [20]. The primary purpose of this RCT is to determine whether the DrinksRation app has similar effectiveness in a serving, non–help-seeking military population. An effective app could support or integrate into the defense alcohol management pathways and provide support to service personnel while they wait for specialist intervention from defense community mental health services. Additionally,

XSL•FO
RenderX

if the links between drinking behaviors and social and health outcomes are better understood, there is scope for future policy design to target the precipitating factors leading to a more positive and healthy life.

Methods

Ethical Considerations

This study was approved in September 2023 by the Ministry of Defence Research Ethics Committee (MODREC; registration number: 2154/MODREC/22) and registered as a clinical trial with the International Standard Randomised Controlled Trial (ISRCT) number registry (submission number: 42646). Any amendments to the protocol will be registered with ISRCT and approved by MODREC.

Study Design

The MDR study is a 2-arm, single-blind, 1:1 RCT of the UK AF population comparing the effectiveness of the DrinksRation smartphone app with treatment as usual (TAU) for those at risk of alcohol-related harm. It is hypothesized that the DrinksRation app will be more efficacious at reducing alcohol consumption compared to TAU.

Study Sample

A protocol for the veterans' RCT of the DrinksRation app calculated a sample size of 37 participants in each arm to achieve significance and a target of 620 invitations to cover nonparticipation and attrition [17]. Assessing the sample size for a serving (nonveteran), non–help-seeking population, an effect size of 4 units of alcohol per week, and a mean consumption of 30.5 (SD 14.9) units/week were used. Consumption is based on a large systematic review of face-to-face ABIs [21]. The mean change of 4 units is based on a change of 2 units detected in a systematic review for the general population [21]; 7 units detected in a previous DrinksRation study [16]; and 4 units being used in the help-seeking veteran RCT [17]. The sample size was calculated as 218 per arm. The study will aim to recruit 728 participants to allow for a 40% attrition rate. Defense statistics state that 59% of the serving AF population are at risk of alcohol-related harm [6]. This equates to approximately 7250 personnel per month having a PDI and being eligible for the study.

Recruitment

Potential participants for the MDR study will be currently serving UK AF personnel identified through PDIs and self-identification following study publicity. All 148,000 serving military personnel are offered PDI at least annually. Before the PDI, all personnel are asked to complete an AUDIT-C screening tool. Those scoring at increasing risk of alcohol-related harm to health (≥5) are given an alcohol brief intervention by the dental staff, which consists of a single brief discussion around the risks of drinking lasting 2-3 minutes. Those scoring in the higher risk group (8-10) or suggesting possible dependence (11-12) are offered a referral from the dentist to a general practitioner for follow-up.

The trial will be publicized through service-specific communications, social media, and recruitment posters displayed across the UK defense estate. Additionally, potential participants will be identified through service-specific communication, including links and QR codes to the study website promoted through single service information pathways and on the defense intranet. MyNavy and similar apps within the defense gateway will also be used to announce the trial and direct potential participants to the study website. Military-focused social media, such as #MilTwitter and AF-specific Facebook groups, will be asked to promote the study and host links to the study website. Posters with a short link and QR code for the study website will also be displayed in areas of high footfall in large establishments.

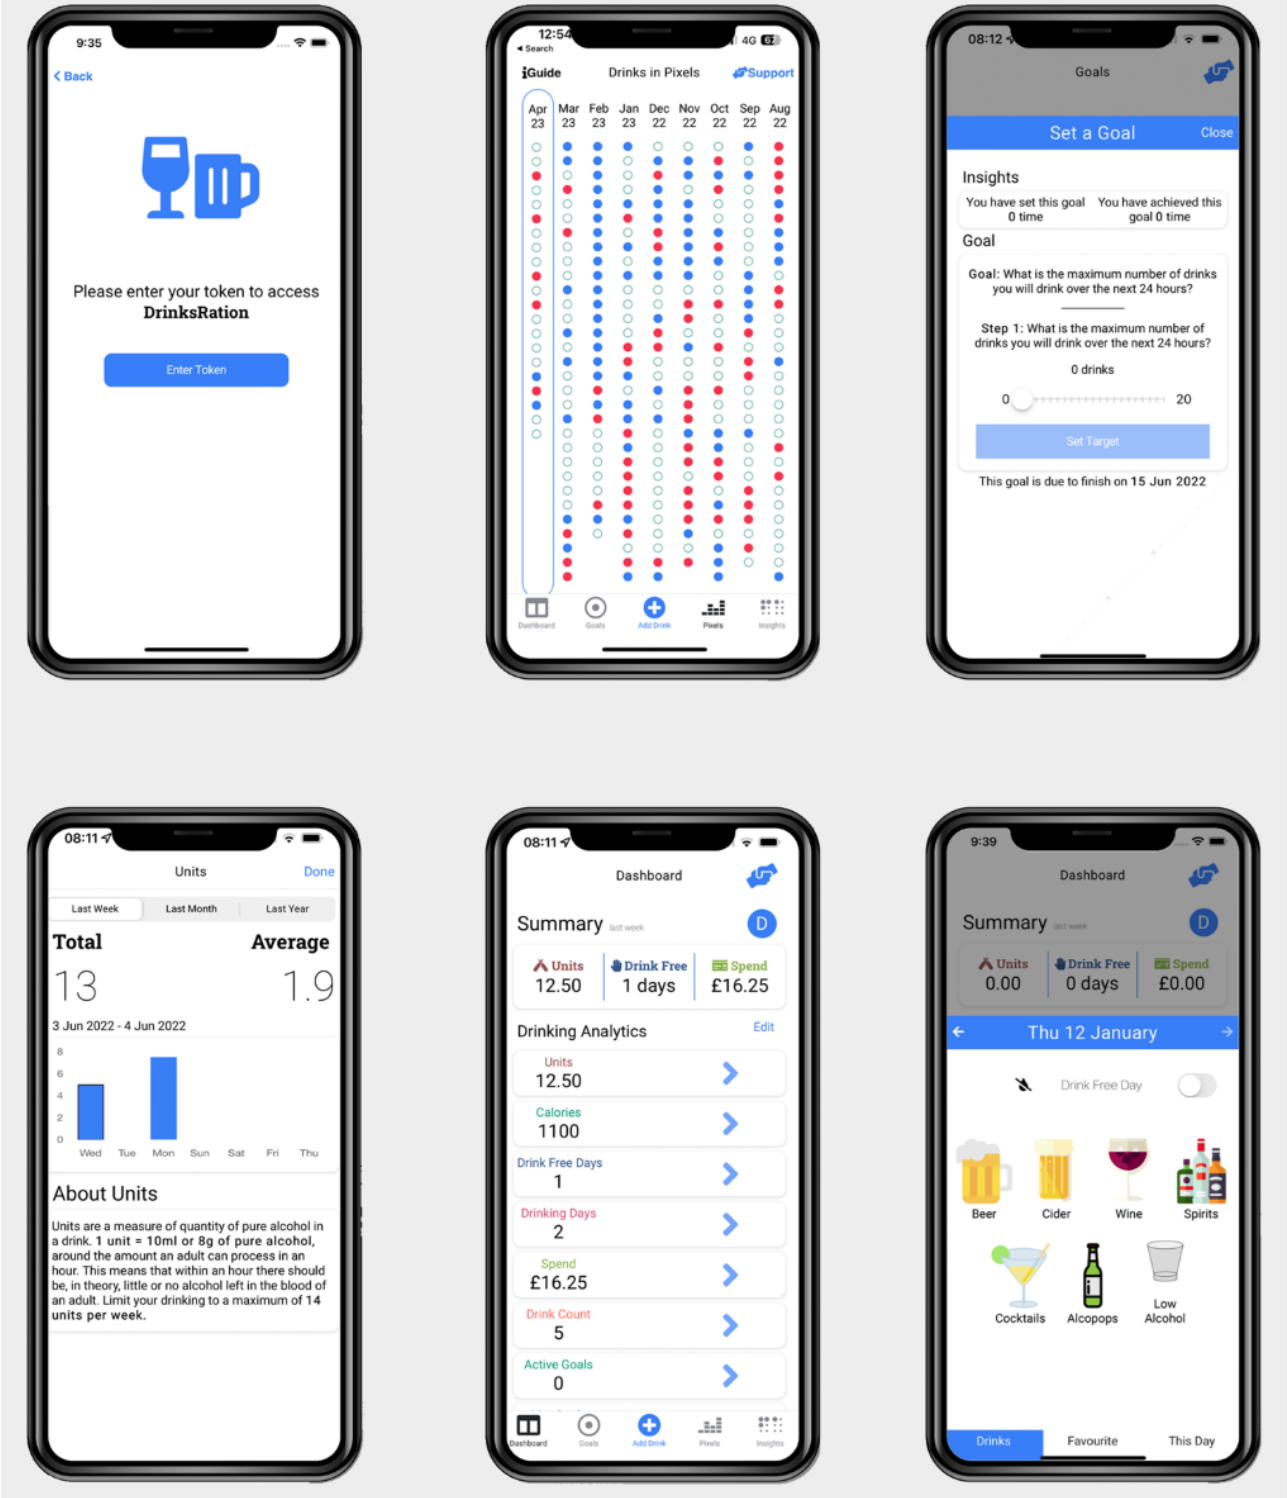
All potential participants will be screened for eligibility using a web-based AUDIT-C tool [13] on Research Electronic Data Capture (REDCap) [22]. Those scoring ≤4 will not be eligible for the DrinksRation RCT. Personnel scoring ≥5 will be given an ABI either in the form of the standard defense guidance on reducing alcohol use or by the dental staff as per usual management. Personnel will then be directed to the participant information sheet (PIS), eligibility criteria, and web-based consent form on REDCap.

Participants will be included in the study if they are currently serving UK AF; have an Android or iOS smartphone and are willing or able to download the DrinksRation app; report an AUDIT-C score of ≥5; and provide a telephone number or email address for participant safety purposes.

Participants will be excluded if they are unwilling or unable to download the DrinksRation app or if they scored ≤4 on AUDIT-C. There will be no exclusion on the grounds of harmful drinking identified by AUDIT-C screening.

There are no age or sex restrictions on participation beyond those of the military population. Specifically, personnel aged 18 years or younger are not excluded from the MDR study, as they form a small proportion of the UK military population. While the purchase of alcohol by those aged 18 years or younger is illegal, consumption by underage personnel does happen, and age does not proffer any immunity against potentially harmful drinking behaviors [23]. Indeed, living with people who are drinking alcohol increases the likelihood of a child drinking (odds ratio 3.6 for children living with 3 or more drinkers) [3].

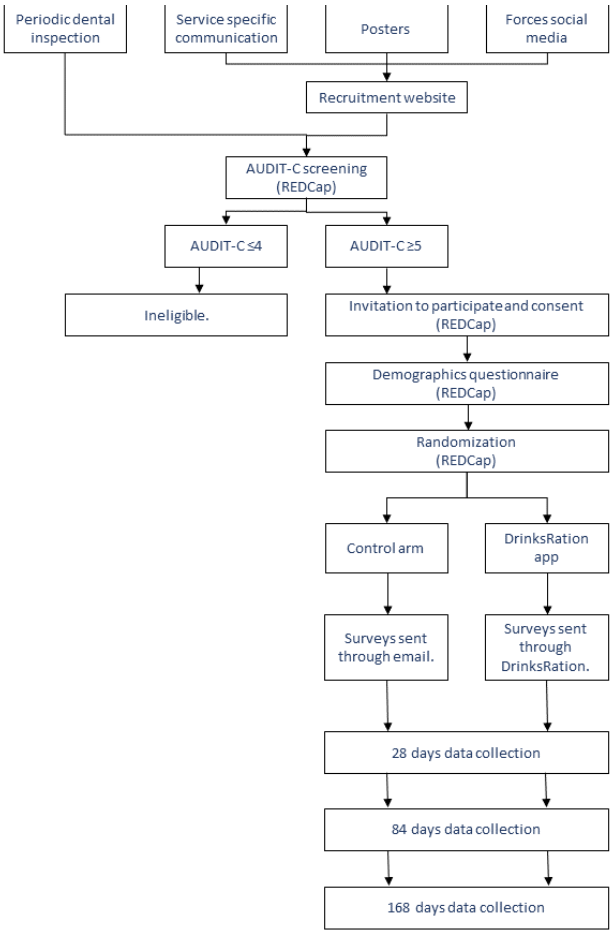
After consenting to inclusion in the study and the collection of baseline demographics, participants will be randomized to the intervention group or TAU group using the embedded REDCap randomization module.



Intervention

Participants randomized to the intervention arm of the RCT will be sent an email link to the DrinksRation app with a unique reference code to enable data linkage between REDCap and DrinksRation. The app's function, theoretical basis, and supporting evidence are fully described elsewhere [16,20,24]. Images of the app and its functionality are shown in Figure 1. After downloading the app, on first use, participants will be prompted to complete baseline assessment surveys. App usage and further surveys were then presented by the app with push notifications to the participant, highlighting the need for completion. Participants will be asked to use the app for a

XSL•FO
RenderX



minimum of 28 days. Participant flow through the study is shown in Figure 2.

Figure 1. Military DrinksRation randomized controlled trial: smartphone app screenshots.

XSL•FO
RenderX

Figure 2. Study flow diagram. Primary and secondary outcomes are assessed at day 84, with outcomes reassessed at day 168 in order to understand the longer-term benefits of the intervention. AUDIT-C: Alcohol Use Disorders Identification Test for Consumption; REDCap: Research Electronic Data Capture.

Control

Participants randomized to the control arm will receive baseline assessment and all further surveys through email with the same periodicity as the intervention group. The control group will be asked to complete the surveys and will be given access to the DrinksRation app at the end of the study period. Noncompletion of surveys will prompt an automated push notification (intervention arm) or email (control arm) reminder after 24 hours. The structural difference between the arms was considered unavoidable due to the difficulty of creating a sham digital psychological intervention [25]. If a pared-down "dumb" version of the app were offered to the control arm, then it would be difficult to determine whether any effect was due to the visibility of the app or interaction with the app. A previous study of the DrinksRation app showed a large attrition rate in the control arm when participants were given a dumb version of the app [20].

Randomization and Blinding

Participants will be randomized using the in-built randomization module of the REDCap program. This module automatically allocates participants to either the DrinksRation app or the TAU group based on a randomization table generated on the internet using the Sealed Envelope website [26]. Two participant blocks in a 1:1 ratio will be used. Randomization will be stratified by sex because it has previously been shown that alcohol use in the UK military is different between the sexes [4]. The randomization module will be programmed by the study independent medical officer (IMO), who is not blinded to the allocations in order to enact the safety protocols if required. The researchers had no visibility of programming, and role-based access to REDCap prevented access to any identifiable information or allocation for the research team. There was no contact between researchers and participants at any stage of the trial.

Participants were blinded to the intervention as they were told that the research involved them completing various surveys about drinking behaviors, health, and well-being. The study IMO will not be blinded to allocation and will have data access rights allowing him to link the participant reference codes to personal identifiers in case of any adverse events.

Measures

The primary outcome measure is a change in alcohol units consumed per week between baseline and day 84, as measured by the timeline follow-back method [27]. Secondary outcomes are a change in the Alcohol Use Disorders Identification Test (AUDIT) score, a change in the quality of life assessment, and a change in drinking motivations and app useability. While the DrinksRation intervention aims to reduce alcohol intake at 84 days, a final data collection at 168 days will assess any persistent benefits.

XSL•FO
RenderX

Data will be collected through a selection of surveys pushed to the participants in line with the periodicity detailed in Table 1.

The study instruments are all validated for the general population and are detailed in Table 1. The alcohol and mental health symptomatology surveys were included in the veteran's trial. The MDR trial additionally includes surveys for drinking motivations (Drinking Motives Questionnaire 9-item tool [DMQ-R]), recent life events (Recent Life Events Questionnaire [RLE-Q]), gambling motives (Gambling Motivations Questionnaire [GMQ-9]), and domestic abuse and sexual assault (National Crime Survey for England and Wales). These behaviors have been associated with both alcohol consumption [3] and a military population [40,41]. A tertiary outcome of the MDR study is to assess the correlation of these issues with alcohol use within the military population. This information does not contribute to the assessment of the app's effectiveness, but it is valuable information for UK defense policy makers.

Statistical and Analysis Plan

The MDR study is based on a recently completed study of veterans, which was sponsored by the Forces in Mind Trust. Analysis will therefore be undertaken in accordance with the published protocol for that study [16,20]. There will be no interim analysis. The threshold for significance will be P=.05. Effect sizes will be reported.

XSL•FO
RenderX

Descriptive statistics (eg, demographics and response rate) and independent sample *t* tests and chi-square tests will be carried out to explore and identify potential differences between the intervention and control arms at follow-up. An intention-to-treat method will be used for primary outcome analysis, such that those who are lost to follow-up will be retained in the primary analysis. Multiple imputations will be performed to estimate missing data, where appropriate. The primary outcome analysis will examine whether there is a statistically significant difference between the intervention and control arms on change in self-reported timeline follow-back UK units consumed. Repeated-measures mixed modeling analyses will be conducted to examine the primary hypothesis that those randomized to receive the DrinksRation app will report a greater reduction in alcohol consumption compared with control participants from baseline to 3-month follow-up (day 84).

For the secondary outcomes, changes in the AUDIT score and World Health Organization Quality of Life- Best Available Technique Reference Document (WHOQOL-BREF) computed quality of adjusted life years will be assessed using repeated-measures mixed modeling. These analyses will be repeated to assess changes between baseline and follow-up and will serve as a secondary outcome to assess the long-term impact of the intervention on participants [17]. Tertiary outcomes will be assessed for correlation with alcohol consumption and will be reported separately to the RCT outcome.

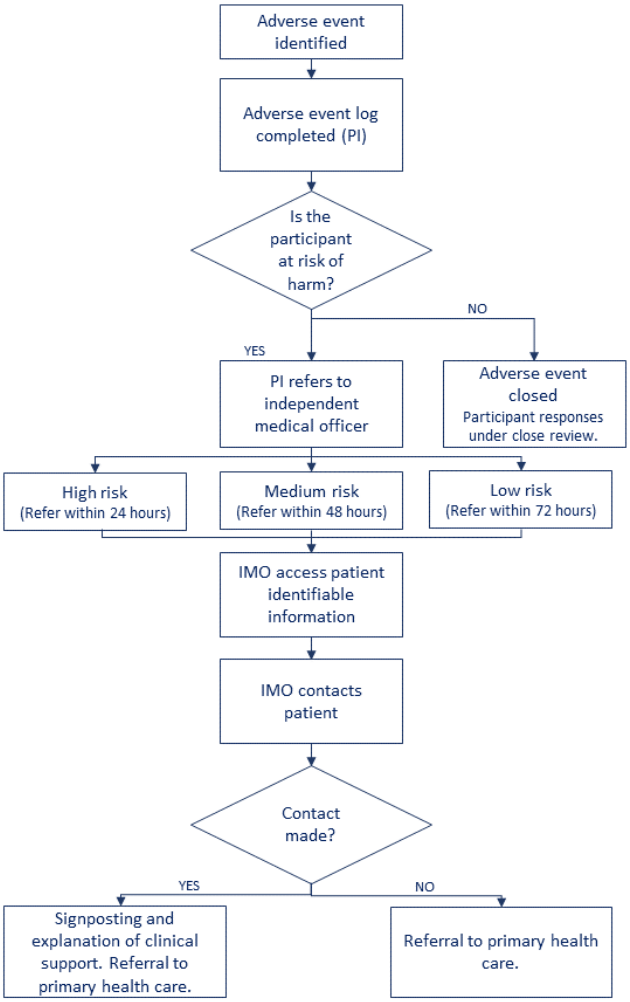
The study will be reported in line with the CONSORT (Consolidated Standards of Reporting Trials) [42] criteria for RCTs and the Template for Intervention Description and Replication guide [43]. The study was designed in accordance with the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) statement [44].

Data Management and Confidentiality

All study data will be captured and held electronically within REDCap or the DrinksRation app, depending on the participant arm. There is no physical paperwork and no requirement for any. Consent forms are held electronically within REDCap. Data will be processed and stored in line with the General Data Protection Regulation (GDPR) Article 6 (1.e) “processing is necessary for the performance of a task carried out in the public interest or in the exercise of official authority vested in the controller” [45]. DrinksRation app data are stored on Google-managed, UK-based servers contracted by the King’s Centre for Military Health Research (KCMHR). All other study data are held within the defense medical services REDCap servers at the University of Birmingham.

Data Monitoring

A data monitoring committee is not necessary because the intervention is well-defined and not considered to be a risk to participants [46]. Prompts to complete surveys will be sent to participants through the app (intervention arm) or by email (control arm). A reminder notification will be sent if surveys are not completed within 24 hours. There is no further follow-up for missing data. Missing data do not impact further survey prompts being sent; all participants will receive notification when the next survey is due in accordance with Table 1. No additional plan to promote participant retention is required because the app evaluation needs to consider natural attrition rates and adherence to app usage.



Adverse Events

The investigators will review the data weekly to identify any potential adverse events. As per the veteran’s DrinksRation study, an adverse event is defined as a participant either consuming more than 25 units of alcohol in a 24-hour period or giving survey responses suggesting a significant mental health problem [17]. Additionally, participants can register an adverse event or problem by contacting the researchers through the study email address or website.

If an adverse event is identified, the principal investigator (PI) will review the available data for the participant, and if there are concerns, the PI will inform the IMO. The IMO will have access to the patient identifiable information and will contact the patient to facilitate referral to primary care if required and assess suitability to continue in the trial. Figure 3 details the adverse event management plan. All adverse events will be recorded in a risk event log held within the REDCap research database.

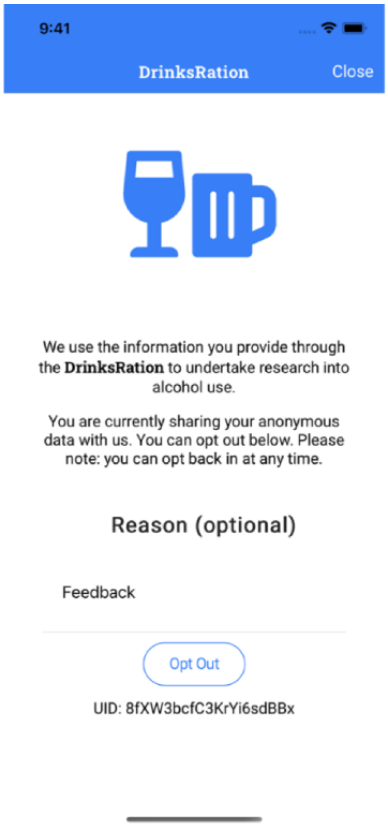
XSL•FO
RenderX

Figure 3. Adverse events management plan showing the unblinded role of the independent medical officer (IMO) in order to address potential harms. PI: principal investigator.

Study Consent and Withdrawal

Consent will be managed on the internet through REDCap; immediately after AUDIT-C screening, potential participants are shown the PIS and study consent form. Consent is captured electronically within the REDCap platform. Participants who want time to think about participation or to ask questions can do so by using the option to "save and return later," therefore allowing participants to consider their participation at their leisure. The study website hosts a "frequently asked questions" document and a contact email address for the PI. Staff in dental centers will be given a standard briefing about the study and asked to direct further questions to the investigators through the study email address. Participants will be informed that their data will be used primarily for the purposes of the MDR study. However, if results indicate that further studies are beneficial for the military community, the data may be further processed to extend the scope of the research in the field of alcohol behavior change. If this is deemed beneficial, then participants will be informed before the compatible processing occurs.

No payment for participation will be made to ensure that payment does not impact app usage rates. Any participant who sustains harm as a direct result of the study can apply for compensation under the Ministry of Defence's No-Fault Compensation Scheme. Details of the scheme will be available to participants with the PIS. The DrinksRation app has been designed and built by KCMHR, is published with open-source coding, and is free to download. It does not provide financial benefit. The PI is employed by the Royal Navy, and academic fees associated with this study are paid for by defense; however, defense has had no influence over the content or design of this trial.



All the data gathered will be written up as part of the thesis submitted for an MD (Research) in Psychological Medicine Research at King's College London. Results will be published with open access in line with best practices [47]. Authorship will be as per this paper. Additionally, an "executive summary" will be written to facilitate access to findings by nonresearchers across defense. Participants wanting to be informed of the study outcomes will be emailed the summary and a link to any published article. Findings will be fed back to key stakeholders within defense.

Participants are able to withdraw from the study at any point up to the point when the data capture is extracted for analysis. At this point, the data will be grouped, and it will no longer be possible to select individual data. Withdrawal from the intervention arm is managed entirely from within the DrinksRation app. Participants visit the "Settings" tab, and the

XSL•FO
RenderX

option to withdraw is visible (see Figure 4 below). To withdraw from the control arm, participants will need to email the PI, either directly or through the study website. Withdrawing participants are given the option to delete the data already collected or allow the research team to use this data.

Figure 4. Participant withdrawal screen, which includes the ability to delete the account or withdraw from the study.

Results

Recruitment will commence in August 2023 and be completed by October 2023. Results are expected by autumn 2023.

Discussion

The existing evidence for brief interventions in alcohol behavior management is robust, with several large systematic reviews published in this area [15,19,21,48,49]. The types of brief interventions used in these reviews are varied and often resource-intensive, with many of the included interventions not aligning with the National Institute of Health and Care Excellence guidelines. These face-to-face interventions have a place in an evidence-based alcohol management strategy but come with a training burden and a requirement for a significant uplift in primary care appointments in order to address the high levels of potentially hazardous drinking in the AF population. This considerably limits their practicality because they exceed the time available within standard primary health care appointments of 10-15 minutes. Digital interventions have been developed to address this issue and have also been shown to have an effect [50]. There are 2 systematic reviews of digital alcohol interventions identified on NHS Evidence [50,51]. They report that digital interventions can reduce alcohol consumption. The larger Cochrane review reports that brief interventions are responsible for alcohol reductions of 22.8 (95% CI 15.4-30.3) g of alcohol per week compared to no intervention [50], approximately 2 standard drinks per week. The smaller review included observational and experimental study types and so quantitative synthesis was not undertaken. A digital solution may be desirable to a digital native population [18] and confers resource advantages over face-to-face interventions. Fundamentally, face-to-face interventions may be effective, but they also may not be accessed by the digital generation, which forms the majority of the current serving AF population [16-18].

The UK AF population also has a relationship with alcohol that differs from that of the general public [5], and there is no existing evidence for the use of brief interventions within the UK AF. A single systematic review including UK AF personnel and veterans was found, but the heterogeneity and risk of bias within the included studies precluded a meta-analysis. The data and narrative synthesis showed that digital interventions may be effective in this mixed population [19]. Interestingly, a statistically significant reduction in binge drinking (mean difference –0.24, 95% CI –0.35 to –0.13 binges/week) [50] was seen with digital interventions, which is not seen in face-to-face interventions (mean difference –0.08, 95% CI –0.28 to 0.12 binges/week) [21]. The finding of effect in terms of binge drinking also makes digital interventions especially beneficial to the AF population [52,53].

The DrinksRation app fulfills the requirement for the intervention to be delivered within available time resources in DPHC and has been shown to be effective in a small-scale study of veterans [16,54]. However, there are some significant

XSL•FO
RenderX

demographic differences between the serving and veteran populations, namely the age profile. A third of veterans are aged 80 years or older; half are aged 65 years or older; and less than 10% are aged 30 years or younger [55]; compared to just under half of the serving AF population being 30 years old or younger [56]. This study will determine whether the DrinksRation app is effective at changing the alcohol use behavior in this younger, serving AF population and, for the first time, provide defense medical services with an evidence-based alcohol intervention designed for military personnel.

Data Availability

The data sets generated during this study are not publicly available in line with Ministry of Defence research policies but are available from the corresponding author on reasonable request.

Conflicts of Interest

DL is a Reservist in the UK Armed Forces. This work has been undertaken as part of his civilian employment. KK is employed by the Royal Navy. This work has not been reviewed or amended by the chain of Command. NF is part funded by a grant from the UK Ministry of Defence and is a trustee (non-paid) of a UK charity supporting the wellbeing of service personnel, veterans and their families.

Abstract

Background: Informal caregivers (ie, individuals who provide assistance to a known person with health or functional needs, often unpaid) experience high levels of stress. Caregiver stress is associated with negative outcomes for both caregivers and care recipients. Mindfulness-based interventions (MBIs) show promise for improving stress, emotional distress, and sleep disturbance in caregivers of persons with Alzheimer disease and related dementias (ADRD). Commercially available mobile mindfulness apps can deliver MBIs to caregivers of persons with ADRD in a feasible and cost-effective manner.

Objective: We are conducting a single-blind feasibility proof-of-concept randomized controlled trial (RCT; National Institutes of Health [NIH] stage 1B) comparing 2 free mobile apps: the active intervention Healthy Minds Program (HMP) with within-app text tailored for addressing stress among caregivers of persons with ADRD, versus Wellness App (WA), a time- and dose-matched educational control also tailored for caregivers of persons with ADRD.

Methods: We aim to recruit 80 geographically diverse and stressed caregivers of persons with ADRD. Interested caregivers use a link or QR code on a recruitment flyer to complete a web-based eligibility screener. Research assistants conduct enrollment phone calls, during which participants provide informed consent digitally. After participants complete baseline surveys, we randomize them to the mindfulness-based intervention (HMP) or educational control podcast app (WA) and instruct them to listen to prescribed content for 10 minutes per day (70 minutes per week) for 12 weeks. Caregivers are blinded to intervention versus control. The study team checks adherence weekly and contacts participants to promote adherence as needed. Participants complete web-based self-report measures at baseline, posttest, and follow-up; weekly process measures are also completed. Primary outcomes are a priori set feasibility benchmarks. Secondary outcomes are stress, emotional distress, sleep disturbance, caregiver burden, mindfulness, awareness, connection, insight, and purpose. We will calculate 1-sided 95% CI to assess feasibility benchmarks. Effect sizes of change in outcomes will be used to examine the proof of concept.

Results: Recruitment started on February 20, 2023. We have enrolled 27 caregivers (HMP: n=14; WA: n=13) as of June 2023. Funding began in August 2022, and we plan to finish enrollment by December 2023. Data analysis is expected to begin in May 2024 when all follow-ups are complete; publication of findings will follow.

XSL•FO
RenderX

Conclusions: Through this trial, we aim to establish feasibility benchmarks for HMP and WA, as well as establish a proof of concept that HMP improves stress (primary quantitative outcome), emotional distress, sleep, and mindfulness more than WA. Results will inform a future efficacy trial (NIH stage II). HMP has the potential to be a cost-effective solution to reduce stress in caregivers of persons with ADRD, benefiting caregiver health and quality of care as well as patient care.

Introduction

Background

More than 1 in 5 Americans (ie, approximately 53 million) are informal caregivers [1]. These individuals provide assistance to known persons with physical, mental, or cognitive illness or disability, often unpaid [2]. Almost half of caregivers who provide help to older adults care for someone with Alzheimer disease or related dementias (ADRD) [3]. Caregivers have been dubbed "the hidden patients" because the negative physical and mental health consequences of caregiving are often underrecognized and undertreated [4]. Nearly 60% of caregivers of persons with ADRD experience high levels of psychological stress, and more than 1 in 3 caregivers of persons with ADRD report that their health has deteriorated due to caregiving responsibilities [5]. Some key sources of caregiver stress include ongoing worry about their loved one's health, concerns about whether they are doing the caregiving job well, challenges navigating regular life in addition to caregiving responsibilities, concerns about the impact of caregiving on their own health, social isolation, and financial strain [6,7]. High caregiver stress is associated with mental health concerns [8], sleep difficulties [9], and an increased risk for morbidity and mortality [10]. In previous studies, 42%-55% of caregivers reported looking for feasible and effective stress management interventions [11]; yet this population often has limited time for outpatient psychotherapy. Given the negative consequences of caregiver stress on the health and well-being of both caregivers and care recipients, decreasing caregiver stress in an accessible delivery format is a public health concern.

Mindfulness-based interventions (MBIs) show promise as an efficacious nonpharmacological treatment to reduce caregiver stress [2]. Mindfulness meditation is defined as paying attention on purpose, in the present moment, nonjudgmentally [12,13]. Practicing mindfulness is thought to help individuals cultivate acceptance and inner peace, regardless of challenging life circumstances [14-16]. Across many populations, the practice of mindfulness meditation is associated with decreased stress [17,18], improved emotional functioning [19,20], and improved sleep [21,22]. Several recent systematic reviews have supported the effectiveness of MBIs for improving stress, emotional functioning, and sleep in caregivers, including caregivers of persons with ADRD [2,14,17,18,21,23-27].

Although research has established the benefits of MBIs for caregivers, the prevailing models of delivery of these interventions fall short for several reasons. First, many of these programs are conducted in person [28], which is sometimes not feasible for caregivers' schedules (eg, needing respite for care recipients) [7]. Second, even when programs have been delivered remotely, these often follow a synchronous format (ie, caregivers must attend remotely at the same time each week), which is challenging given the unpredictability of caregiving responsibilities. Third, traditional programs typically demand substantial amounts of continuous time that caregivers are unable to commit (eg, a traditional mindfulness-based stress reduction program involves 8 weekly 2.5- to 3.5-hour-long sessions as well as 45 minutes of prescribed practice per day) [29]. Fourth, traditional programs require trained providers who are often costly, are not usually covered by insurance, and are not always readily available [30-32]. More feasible, scalable, and cost-effective solutions are needed to deliver MBIs to caregivers.

Mobile mindfulness apps may be uniquely positioned to address the aforementioned barriers by allowing caregivers to practice meditation on their own schedule at little or no cost. The majority of caregivers own a smartphone and regularly use mobile apps [33]. Additionally, adults aged 50 years or older, who represent a sizable portion of caregivers of persons with ADRD, are the fastest-rising users of smartphone technology in the past decade [34]. In qualitative studies, caregivers express interest in using mobile apps for stress management and health information [35] including to learn mindfulness meditation for stress management [36-39]. To the best of our knowledge, there are no consumer-based mobile apps with proven efficacy in decreasing stress, emotional distress, and sleep difficulties among caregivers of persons with ADRD [40]. Although mindfulness-based mobile apps show promise for helping caregivers of persons with ADRD decrease stress, emotional distress, and sleep difficulties, additional research is needed to establish feasibility and efficacy before widespread dissemination.

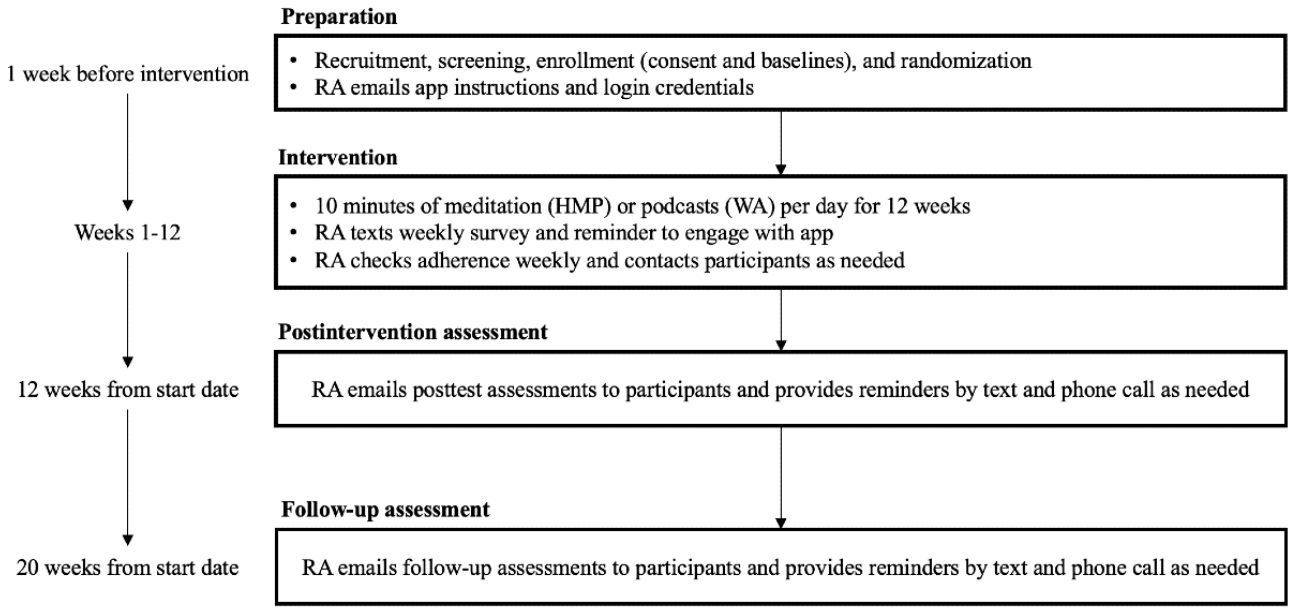
Healthy Minds Program (HMP) is a mindfulness-based mobile app that may be well suited for use with caregivers of persons with ADRD for several reasons. First, HMP is unique because it teaches mindfulness skills grounded in theory [41] with empirical support [42-44]. Having a theoretical underpinning is important because it allows the app to be a vehicle for the delivery of evidence-based mindfulness skills. Second, previous research has shown that HMP reduced emotional distress and burnout in firefighters [44]; improved psychological distress, stress, social connectedness, and mindfulness in adults [43];

XSL•FO
RenderX

and reduced stress and increased mindfulness, self-compassion, and human flourishing in medical students [42]. Third, HMP is free of charge, which increases its reach especially among caregivers who often experience financial burdens because of their role. Fourth, HMP has customizable features (eg, a diverse set of voices to choose from) that have the potential to increase acceptability across race, ethnicity, and gender. Finally, HMP supports content tailoring to include on-screen language and scenarios that are relevant for caregivers of persons with ADRD.

Here, we will be conducting a National Institutes of Health (NIH) stage 1B trial (NCT05732038) comparing HMP with a time- and dose-matched educational control app, Wellness App (WA). Our team tailored the content of both apps to highlight case scenarios specific to caregivers of persons with ADRD. Both interventions (HMP and WA) consist of 12 weeks of guided listening for 10 minutes per day. Participants complete outcome measures at baseline, posttest, and follow-up (2 months after posttest), as well as weekly process measures.

Objectives



The purpose of this paper is to describe the protocol and status of our ongoing single-blind feasibility proof-of-concept randomized controlled trial (RCT) of HMP versus WA in caregivers of persons with ADRD. Our primary hypothesis is that HMP and WA will meet a priori feasibility markers (ie, acceptance and demand benchmarks). Our secondary hypothesis is that participation in HMP will be associated with a greater decrease in caregiver stress (primary quantitative outcome), emotional distress, sleep dysfunction, and caregiver burden, and a greater increase in mindfulness, awareness, connection, insight, and purpose (secondary quantitative outcomes) compared with WA, and improvement will be sustained through the 20-week follow-up. Results will directly inform an NIH stage 2 fully powered RCT of HMP versus WA.

Methods

Study Design and Setting

This NIH stage 1B, single-blind, feasibility, proof-of-concept RCT is testing HMP versus WA (time- and dose-matched control) in caregivers of persons with ADRD. Data collection is underway (started in February 2023; n=27 caregivers as of June 2023). We plan to recruit 80 caregivers of persons with ADRD reporting elevated levels of stress. Our institutional review board approved this study (2022P001601). Figure 1 provides an overview of the study design and timeline.

Figure 1. Study design and timeline. HMP: Healthy Minds Program; RA: research assistant; WA: Wellness App.

Inclusion and Exclusion Criteria

Table 1 presents the study inclusion and exclusion criteria and rationale. These eligibility criteria were informed by previous MBI studies with caregivers, including those of persons with ADRD [2,14,17,18,21,23-27], as well as a previous study with caregivers funded by the NIH (NCT00177489). The criteria are meant to be as inclusive as possible to maximize generalizability by allowing individuals who self-identify as caregivers to participate rather than requiring a certain number of hours spent caregiving, specific responsibilities, or other criteria.

XSL•FO
RenderX

Table 1. Study inclusion and exclusion criteria and rationale.

Criteria	Rationale
Inclusion	
Age 18 years or older	Most caregivers are adults; study procedures are formulated for adults only
English fluency and literacy	Measures, instructions, and app are in English
Meeting criteria for being a caregiver (ie, family or friend of a care recipient who provides care not through an agency) [2]	Population
Perceived Stress Scale (4 items) version ≥6 [45]	Population; ensure that the intervention is needed (not all caregivers experience caregiver stress)
Willing to be randomized	Necessary for scientific rigor
Care recipient must be rated >1 on the Functional Assessment Staging Tool [46]	Population; ensure that caregivers have a threshold of caregiving tasks
Exclusion	
Any planned change in psychotropic pharmacologic treatment for the duration of the study	Treatment confound
Use of any consumer-based mindfulness meditation app for more than 60 minutes per month in the past 6 months	Treatment confound
Current participation in a meditation program (eg, mindfulness-based stress reduction, mindfulness-based cognitive therapy, etc)	Treatment confound
Major illness anticipated to worsen dramatically or require surgery in the next 20 weeks (study duration)	Treatment confound
Active treatment for cancer (chemotherapy or radiation)	Treatment confound
Imminent placement of care recipient in a nursing home or with another caregiver (within 4 months)	Treatment confound
Involvement in another clinical trial for caregivers	Treatment confound
For participants aged 65 years and older: Short Portable Mental Status Questionnaire: ≥4 errors [47]	Validity and feasibility

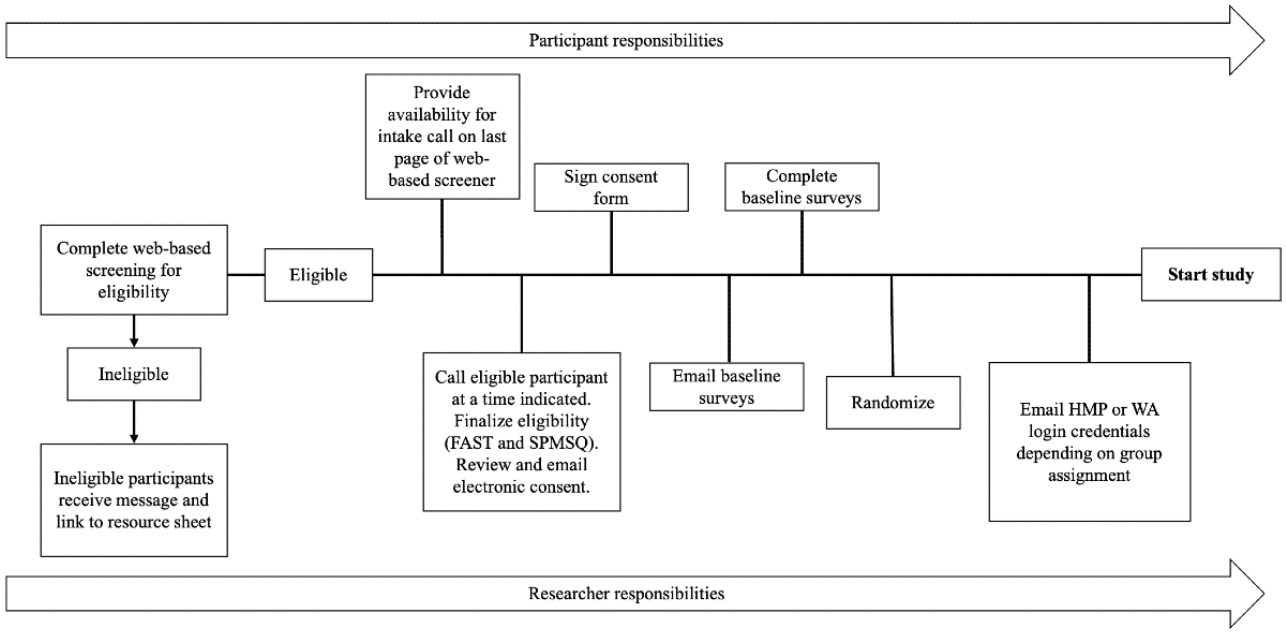
Recruitment and Screening

For this trial, we are focused on recruiting geographically, racially, and ethnically diverse informal caregivers to ensure generalizability. We have established partnerships with a variety of organizations dedicated to supporting caregivers and care recipients (eg, National Alliance of Caregiving and Boston Ministerial Alliance) that share our recruitment materials (eg, flyer) on social media and listservs. Additionally, we directly contact caregivers from our previous nonclinical trial studies that indicated interest in learning about additional research opportunities. Interested caregivers use a link or QR code on flyers, social media ads, and email blasts to fill out a web-based eligibility questionnaire through REDCap (Research Electronic Data Capture; Vanderbilt University) [48]. Caregivers who want more information on the study can contact the research assistant (RA) before completing the screening in REDCap. Ineligible caregivers receive an on-screen message at the end of the screening in REDCap notifying them of their ineligibility along with a link to a resource sheet. For participants who meet initial eligibility criteria, a final survey page appears where they confirm their interest in participating and provide suitable times for a 20- to 30-minute enrollment phone call. During this call, the RA administers the Short Portable Mental Status Questionnaire (SPMSQ; for those over the age of 65 years) [47] and the Functional Assessment Staging Tool (FAST) [46] to finalize eligibility criteria.

Ensuring Validity of Participant Data by Avoiding "Imposter" Participants

Previous research has shown that remote studies have an increased risk of enrolling "imposter" participants (ie, participants who misrepresent themselves to appear eligible for a study) [49,50]. In a web-based study using MTurk (a crowdsourcing service), Hydock [49] found that more than 12% of participants falsified their identities "for the chance of financial gain." To address this concern, our team has identified "red flags" that suggest that a participant is misrepresenting their identity and requires additional attention and screening, including (1) large volumes of back-to-back inquiries following a similar format (eg, all emails are firstnamelastname ####@gmail.com), (2) spelling mistakes and grammatical errors, (3) incorrect or inconsistent survey responses (eg, one participant wrote they heard about this study on Craigslist), (4) providing out-of-service or Google Voice (Google LLC) numbers (the use of Google Voice numbers has been cited as a commonality among many imposter participants [51]), (5) poor sound quality during phone calls, and (6) exaggerated or illogical statements during phone calls (eg, stating, "I take my father with advanced dementia to the gym and we work out together"). These are not exclusion criteria but rather indicate to the research team that

XSL•FO
RenderX



it is possible that the inquiry about the study was made by a potential imposter participant.

Our team has developed a protocol to prevent imposter participants from enrolling. First, when participants inquire about the study on public-facing platforms (eg, "Rally," a web-based platform for advertising research studies across our hospital system), we call them before sending the link to the screening survey. This has been cited in other studies as a strategy to eliminate imposter participants [51]. Second, we have used a "three-strike" system. Once a potential participant has displayed 3 red flags (described above), they are no longer considered eligible for this study. We move these participants to the "suspected imposter" section of our log and do not continue contact attempts; we have noticed that the more we engage with potential imposter participants, the more false inquiries we receive. Third, we do not provide compensation for the completion of baseline assessments; instead, our compensation is divided up between posttest and follow-up, which discourages imposter participants who might enroll for the baseline compensation and then drop out. So far, we have identified 44 suspected imposter participants (approximately 36%) out of the 123 inquiries we have received. We acknowledge that these procedures have the potential to exclude eligible participants (ie, false negatives); however, as a team, we agreed to prioritize the integrity of the data for this small-scale feasibility RCT.

Enrollment

If participants are deemed eligible during the enrollment call, the RA reviews the consent form, answers any questions, and assists the participant with signing the consent form by electronic consent on REDCap. Once the consent form has been signed, the RA emails baseline surveys to the participant through REDCap. Study staff randomize the participants after baseline completion. Our senior biostatistician programmed randomization into REDCap and stratified by gender (given that caregivers tend to be women) [1]. The RA emails the participant instructions to download and login to their assigned app (HMP or WA). To protect participant confidentiality, the study team creates accounts with study-specific login email addresses (eg, mghstridestudy+1@gmail.com and mghstridestudy+2@gmail.com) so there are no personal identifiers (eg, email, name, and date of birth) associated with participants' accounts. The spreadsheet containing login information and the corresponding participant's information is stored in a secure, password-protected database. After receiving instructions and login information, participants have the option of scheduling a phone call or Zoom (Zoom Video Communications) meeting with the RA to assist with setting up their app. Figure 2 summarizes the recruitment and enrollment procedures.

Figure 2. Recruitment and enrollment procedures. FAST: Functional Assessment Staging Tool; HMP: Healthy Minds Program; SPMSQ: Short Portable Mental Status Questionnaire; WA: Wellness App.

Treatment Conditions

Participants in both treatment conditions (HMP or WA) listen to prescribed guided listening on a mobile app for at least ten minutes per day (70 minutes per week) for 12 weeks. Participants download their assigned app through the Google Play (Google LLC) or Apple App (Apple Inc) Store, and participants are blinded to the condition (ie, intervention or control). Participants can complete their daily listening at any time of day. Both apps suggest a specific ordering of the audio clips, but participants can choose to listen to any audio content within the app based on their preferences—the only requirement is that they listen for at least 10 minutes per day. Participants are encouraged to turn on "push notifications" to remind them to do their daily listening, but this is not mandatory. Both apps allow participants to view their daily listening history and mark which content has already been listened to.

XSL•FO
RenderX

Healthy Minds Program

Full details on the HMP app can be found on the web at Healthy Minds Innovations [52]. In summary, HMP is a self-guided meditation app that includes training in mindfulness through the 4 "pillars" of mental training: awareness, insight, connection, and purpose. Guided listening in each pillar trains listeners to be more focused and self-aware in the present moment (awareness), develop skills to strengthen compassionate connection with others (connection), learn about how a person's thoughts affect their emotions (insight), and stay more grounded in one's values and principles (purpose) [41,52]. Each pillar contains guided listening consisting of brief lessons labeled "learn" and meditations labeled "practice." Participants are asked to complete at least 10 minutes of "practice" each day (meditations can be set for 5, 10, 15, 20, or 30 minutes) and are encouraged to listen to the "learn" content in conjunction with their practices. Participants have the choice to make any meditation "sitting" or "active" and can also select the speaker of each meditation, allowing for racial, ethnic, and gender diversity of the speaker. Our multidisciplinary team tailored the HMP app text that introduces and describes the mindfulness exercises to include language, case-based scenarios, and stressors that are common among caregivers of persons with ADRD (eg, gratitude for positive aspects of caregiving).

Wellness App

WA is an investigator-developed time- and dose-matched control that offers daily caregiver-related guided listening consisting of knowledge-based podcasts for the 12-week intervention. If podcasts are longer than 10 minutes, caregivers are instructed to spread the listening out over multiple days to ensure that they are only listening for 10 minutes per day. All podcasts were individually selected by the study team to ensure that their content was relevant for caregivers of persons with ADRD. Examples of topics include "money and the unique needs of the older caregiver" and "how dementia affects sleep cycles." Study staff also listened to ensure that no skills related to mindfulness or meditation were taught in any podcast to remove potential confounds. On the basis of feedback from 13 WA participants, we reviewed participant ratings of podcast quality and updated content to best meet the needs of participants in the control. For example, we replaced "overly negative" or "boring" content with more uplifting stories or engaging podcasts. The app has successfully been used as a control in multiple previous studies testing app-based meditation interventions [53,54].

Strategies for Adherence

Regardless of group, participants are sent a text message each Monday of the intervention reminding them to listen to their daily content for at least ten minutes per day (ie, 70 minutes per week). This text message also includes a brief weekly survey with process measures (Textbox 1). Study staff members download and review participants' listening data each Thursday. If a participant does not listen to at least 75% of their recommended listening in the past week (ie, <52.5 total minutes), a study staff member texts the participant a visual (ie, a "meme") reminder catered toward their treatment condition (Multimedia Appendix 1). If participants do not consent to "meme" reminders, they receive a text message catered to their treatment condition instead (Multimedia Appendix 2). Participants who do not consent to receive text messages receive all reminders and surveys through email. If a participant does not listen to at least 75% of their recommended listening for 2 consecutive weeks, a study staff member calls this participant to troubleshoot potential barriers to adherence. Participants are also offered a monetary incentive for participating in the study (ie, US $20 for completing their posttest assessment and US $30 for completing their follow-up assessment, for a total of US $50).

XSL•FO
RenderX

Textbox 1. Secondary outcomes.

Demographics (pretest)

- Age; gender; biological sex; sexual orientation; race; ethnicity; educational level; employment status; occupation; income; marital status; housing situation; languages spoken; health insurance status; zip code; importance of religion or faith; mental health history; current psychotropic and pain medication intake; overall physical health status; number of individuals to provide informal caregiving to; patient's diagnoses; relationship to patient; duration of caregiving; number of hours of caregiving per week; and whether caregiver is living with patient

Outcome measures (pretest, posttest, and follow-up)

- Perceived Stress Scale-10 [55,56]: assesses perceived stress using a 5-point Likert scale
- Hospital Anxiety and Depression Scale [57]: 14-item measure to assess symptoms of emotional distress (anxiety and depression)
- Patient-Reported Outcomes Measurement Information Systems (PROMIS) Sleep Disturbance Short Form [58]: 8 items assessing sleep
- Applied Mindfulness Process Scale [59]: assesses mindfulness in 3 domains: decentering, positive emotion regulation, and negative emotion regulation
- Caregiver Reaction Scale [60]: assesses caregiver burden. We are administering the following subscales: role entrapment (4 items); role overload (4 items); mastery as a caregiver (4 items); self-mastery (4 items); workplace productivity (5 items)
- Healthy Minds Index [61]: a 17-item measure based on the Healthy Minds Program framework that assesses awareness, connection, insight, and purpose

Process measures (weekly)

- Emotional Distress Thermometer: scale (0-10) to assess how caregivers rate their level of distress each week: "During the past week, how would you rate your emotional distress on a scale from 0 to 10? (0=not at all; 10=extremely emotionally distressed)"
- Sleep Thermometer: scale (0-10) to assess how caregivers rate their quality of sleep: "During the past week, how would you rate your quality of sleep on a scale from 0 to 10? (0=extremely low quality; 10=extremely high quality)"
- Mindfulness Thermometer: scale (0-10) to assess how caregivers rate their level of mindfulness each week: "During the past week, how would you rate your mindfulness on a scale from 0 to 10? (0=not at all; 10=extremely mindful)"
- Stress Thermometer: scale (0-10) to assess how caregivers rate their level of stress each week: "During the past week, how would you rate your stress on a scale from 0 to 10? (0=not at all; 10=extremely stressed)"

Other measures (post)

- Modified Patient Global Impression of Change [62]: a 1-item questionnaire to assess the extent to which caregivers perceive the intervention's improved functioning and symptoms: "Do you think your ability to manage stress associated with caring for your loved one with dementia is now improved, about the same, or worse, as compared to before your participation in this program?"
- Perceptions of daily meditations and podcast: we will assess caregivers' perceptions of their app prescription by asking, "Do you think that the amount of prescribed app content was: too little, just enough, too much?"
- Perceptions of emails and text reminders: we will assess caregivers' perceptions of email and text message reminders by asking, "Do you think that the amount of emails/texts you received was: too little, just enough, too much?"
- Perceptions of the overall study: we will assess caregivers' perceptions of the study by asking, "Do you have any feedback about your experience in this program (content of the program, content of the text message reminders, etc) that you would like to share?"
- Perceptions of prompts and contacts in low adherence situations: We will assess caregivers' perceptions of the number of prompts and contact in situations where they were not adhering to their practice by asking, "Do you think that the amount of prompts you received when you struggled with your practice was: too little, just enough, too much?"

Feasibility Markers

Table 2 outlines the a priori set benchmarks and criteria that are consistent with guidelines for early feasibility studies [63]. We will assess the feasibility (acceptability and demand markers) of both mobile app treatment conditions and participants' perceptions of their involvement in the study.

XSL•FO
RenderX

Table 2. Primary outcomes.

Benchmarks and markers	Description	Criteria
Acceptability benchmarks		
Feasibility of recruitment	We will assess the number of caregivers enrolled from the number of caregivers who were eligible	80 caregivers will be recruited in 6 months; ≥70% of eligible caregivers will enroll
Treatment satisfaction	We will use the Client Satisfaction Questionnaire [64] to assess caregivers' satisfaction with the intervention	At least 70% of caregivers will have scores on the Client Satisfaction Scale over and above the midpoint in both the HMP[a] and WA[b] groups
Credibility and expectancy	We will use the Credibility and Expectancy Questionnaire [65] to assess caregivers' perceptions that the treatment will work after learning about the study.	At least 70% of caregivers will have scores on the Credibility and Expectancy Scale above the midpoint in both the HMP and WA groups.
Demand benchmarks		
Adherence to treatment	We will assess data from the HMP app and the WA to measure adherence to the intervention and the control conditions	≥70% of caregivers will complete ≥75% of weekly prescribed minutes
Dropout	We will assess the number of caregivers who complete the study from the number of caregivers who started the study	>70% of caregivers who start the study will complete posttest assessments; ≤30% attrition
Data collection benchmarks		
Feasibility of weekly REDCap[c] measures	We will assess the feasibility of the weekly REDCap measures sent to patients	≥70% caregivers will answer ≥75% of weekly REDCap measures
Feasibility of quantitative measures	We will assess the feasibility of the quantitative measures sent to caregivers at baseline, postintervention, and follow-up	No questionnaires fully missing in ≥25% caregivers

[a]HMP: Healthy Minds Program.

[b]WA: Wellness App.

[c]REDCap: Research Electronic Data Capture

Quantitative Assessments

The self-report measures and assessment domains were selected consistent with the purpose of the study [66]. Demographics are measured pretest, outcome measures are given during the main assessment points (pretest, posttest, and follow-up), and process measures are administered weekly. Textbox 1 provides a brief description of all self-reported assessments.

Data Analysis

We will assess the acceptability and demand of the intervention in line with Bowen and colleagues' standards for feasibility studies and components of the Behavioral Change Consortium's Treatment Fidelity model [63,67]. Specifically, we will assess the acceptability, credibility, satisfaction, and perceived appropriateness and usefulness of the daily prescribed app content. Benchmarks and measurements for each feasibility construct are listed in Table 2. One-sided 95% CI will be calculated for each proportion to evaluate feasibility benchmarks. Depending on the nature of the estimate or comparison, exact binomial tests, Fisher exact tests, 2-tailed *t* tests, or correlations may be used to summarize the data and test for statistical significance. HMP and WA user data (ie, what content users listened to, when, and for how long) are collected automatically from users.

Consistent with guidelines for early feasibility studies, our analysis will not assess efficacy, as we are not powered to do so [68]. However, we will estimate between-group differences in changes from baseline to posttest (12 weeks) to follow-up (20 weeks) as proof of concept that the intervention shows promise with the intended population [63]. Variance components and effect sizes will be estimated for each outcome. We will use variance estimates from repeated-measures analysis of data on Perceived Stress Scale-10 to guide the design and power calculations for a future trial testing efficacy [69,70]. We will compute the effect sizes of change in these scores to cautiously guide future work. Proof of concept will be demonstrated if the decrease in caregiver stress (Perceived Stress Scale-10, the primary outcome in future trials) in the intervention group from baseline to posttest is greater than in the WA group, with at least small to moderate effect sizes favoring HMP (between-group test of superiority).

Results

The trial is ongoing. As of June 2023, we had enrolled 27 caregivers (14 HMP and 13 WA). We aim to recruit 80 caregivers in total. Table 3 details the select demographics of enrolled participants.

XSL•FO
RenderX

Table 3. Demographics for enrolled participants.

Variable	Participants, n (%)
Gender

Discussion

Scientific Contribution

The intervention at present is catered to caregivers' interest in using mobile apps for stress management and health information [35] including learning mindfulness meditation for stress management [36-39]. This modality addresses barriers to caregiver participation (eg, in-person, synchronous format, time commitment, and cost) for a more feasible, scalable, and cost-effective intervention to reduce stress among this high-need population. The HMP app adapted for caregivers of persons with ADRD seeks to address this clinical gap by testing a no-cost mobile app to reduce stress, emotional distress, and sleep difficulties [40]. This protocol describes an entirely remote, single-blind feasibility, proof-of-concept RCT of HMP versus a time- and dose-matched educational control (WA) in stressed caregivers of persons with ADRD. Our protocol also introduces novel strategies for addressing concerns in mobile app–based RCTs with caregivers, including a protocol for managing "imposter" participants and using "memes" for promoting adherence and engagement.

Limitations

There are important limitations to note. First, our initial recruitment efforts have yielded limited diversity in terms of enrolling caregivers from racial and ethnic minoritized (89% White, 100% non-Hispanic) as well as sexual and gender minoritized backgrounds (96% heterosexual, 100% cisgender). We are now modifying recruitment efforts to attempt to recruit a more representative sample (eg, sharing recruitment flyers with community organizations that serve minoritized older adults and caregivers, and developing Instagram advertisements that target geographically diverse populations). Second, we are delivering this program to English-speaking caregivers only. In the future, we hope to offer HMP in different languages. Third, the fully remote nature of the study increases the likelihood of enrolling imposter participants that are not truly caregivers of persons with ADRD but rather seek to participate for financial benefits; see the Methods section for a detailed plan of how we are addressing this issue. Lastly, it is possible that participants may be unblinded if they carry out web searches about our research.

Conclusions

In summary, we are currently testing the feasibility and proof of concept of HMP versus a time- and dose-matched health education control (WA). Between February and June 2023, we had 27 caregivers enrolled, and we aim to recruit 80 caregivers in total. At the conclusion of this trial, we will examine whether HMP and WA meet feasibility (acceptability and demand) benchmarks, as well as if HMP demonstrates proof of concept in improving stress, emotional distress, sleep, and mindfulness above WA in stressed caregivers of persons with ADRD. Our findings will inform a future, fully powered RCT of HMP versus WA. This work has the potential to pave the way for feasible, scalable, and cost-effective interventions for caregivers of persons with ADRD.

Acknowledgments

This study was funded by grants from the National Institute on Aging (1 R21 AG075187-01A1) and the National Institute Center for Complementary and Integrative Health (1K24AT011760-01) to A-MV.

Data Availability

The data sets generated during this study are not publicly available due to the ongoing nature of the trial but will be available from the corresponding author on reasonable request upon conclusion of the study.

Abstract

Background: Providing Psychotherapy, particularly for youth, is a pressing challenge in the health care system. Traditional methods are resource-intensive, and there is a need for objective benchmarks to guide therapeutic interventions. Automated emotion detection from speech, using artificial intelligence, presents an emerging approach to address these challenges. Speech can carry vital information about emotional states, which can be used to improve mental health care services, especially when the person is suffering.

Objective: This study aims to develop and evaluate automated methods for detecting the intensity of emotions (anger, fear, sadness, and happiness) in audio recordings of patients' speech. We also demonstrate the viability of deploying the models. Our model was validated in a previous publication by Alemu et al with limited voice samples. This follow-up study used significantly more voice samples to validate the previous model.

Methods: We used audio recordings of patients, specifically children with high adverse childhood experience (ACE) scores; the average ACE score was 5 or higher, at the highest risk for chronic disease and social or emotional problems; only 1 in 6 have a score of 4 or above. The patients' structured voice sample was collected by reading a fixed script. In total, 4 highly trained therapists classified audio segments based on a scoring process of 4 emotions and their intensity levels for each of the 4 different emotions. We experimented with various preprocessing methods, including denoising, voice-activity detection, and diarization. Additionally, we explored various model architectures, including convolutional neural networks (CNNs) and transformers. We trained emotion-specific transformer-based models and a generalized CNN-based model to predict emotion intensities.

Results: The emotion-specific transformer-based model achieved a test-set precision and recall of 86% and 79%, respectively, for binary emotional intensity classification (high or low). In contrast, the CNN-based model, generalized to predict the intensity of 4 different emotions, achieved test-set precision and recall of 83% for each.

Conclusions: Automated emotion detection from patients' speech using artificial intelligence models is found to be feasible, leading to a high level of accuracy. The transformer-based model exhibited better performance in emotion-specific detection, while the CNN-based model showed promise in generalized emotion detection. These models can serve as valuable decision-support tools for pediatricians and mental health providers to triage youth to appropriate levels of mental health care services.

Introduction

Background

The mental health care delivery system of care for youth is in crisis. The suicide rate for youths aged 10 to 24 years increased by 62% between 2007 and 2021 [1]. There is a shortage of trained mental health professionals, especially in low- and middle-income countries and communities, having less than one mental health professional per 10,000 people [2]. Training professionals and therapists require comprehensive effort to develop the appropriate levels of clinical skills equal to the trauma-based severe mental health issues in these communities. Conventional training methods, which typically involve long durations of apprenticeship and supervision, are often resource-intensive. The current system struggles to meet the growing demand for mental health services, especially for pediatric patients and youths [3]. Furthermore, evaluating the effectiveness of therapy remains challenging, as mental health conditions are often complex and multifaceted, and current evaluation methods primarily rely on subjective assessments [4].

The use of artificial intelligence (AI) in emotion detection from audio recordings is an emerging approach to address these challenges. Studies have shown that speech carries rich information beyond words, including vital emotional cues and biomarkers associated with mental health conditions [5]. This helps in measuring the effectiveness of therapy and identifying patients in high-risk environments, thus enabling timely interventions. Such quantifying emotions also aids in the optimal allocation of resources by preventing unnecessary treatments [6].

In this paper, we present the development of a deep learning model that classifies emotions using a 15- to 90-second voice sample collected as part of a counseling session. Our study focuses on audio recordings of children with significant psychiatric symptoms partly related to high adverse childhood experience (ACE) scores reading a fixed script. In total, 4 highly trained therapists classified audio segments based on 1 of the 4 emotion intensity levels (none, low, medium, and high) for each of the 4 emotions (anger, fear, happiness, and sadness). The paper reports the development and training of the machine learning (ML) models and discusses the implications of our findings for the broader landscape of mental health care.

As surveyed by Koolagudi and Rao [7], speech emotion recognition (SER) is a prevalent area of research with numerous classification models, feature extractors, and publicly available data sets. However, there are many limitations in the current body of research. Many corpus of speech data are focused on recognizing actor-simulated speech emotion, which contains much higher emotional intensities than what is found in ordinary speech. Additionally, many research results are based on data sets with a limited number of speakers. For example, the IEMOCAP data set [8] is frequently used in literature for SER tasks. However, it comprises actor-simulated emotional utterances from only 10 different speakers. It is also noteworthy that classification of the intensity of emotion found in speech is much more limited. The RAVDESS data set is one of a few publicly available data sets containing actor-simulated audio recordings labeled with emotion intensity (either low or high) [9]. The data sets found in the literature are also very short in duration. The audio clips in IEMOCAP and RAVDESS are both segmented at the utterance level, such that one audio clip only contains a handful of spoken words and is usually only 1-2 seconds in duration.

Numerous model architectures have been used for SER tasks. Zhang et al [10] developed a fully convolutional network (FCN) to classify the emotion type from audio recordings in the IEMOCAP data set [8]. They used an Alexnet-based [11] convolutional neural network (CNN) for feature extraction and a soft-attention–based classifier, resulting in a class-weighted accuracy of around 68%. This approach was appealing to us due to its insensitivity to input length the FCN is able to handle inputs of different sizes without the need to crop or divide inputs into multiple segments.

Participants

Participants were recruited from 3 mental health care centers that focused primarily on children and adolescents from low-income communities. The participants receive mental health services paid for by Medicaid, the Children's Health Institute Program, and the Department of Children and Family Services. The participants are children aged 5-18 years and those referred for behavioral health services through schools, DJJ, and child protective agencies.

Methods

Data Exploration and Processing

The data set used for this project was gathered as part of the National Science Foundation Small Business Innovation Research Phase I and Phase II study. It encompassed 1055 audio recordings obtained during therapy sessions with children who are receiving mental health services and who have been diagnosed with at least 1 DSM (Diagnostic and Statistical Manual of Mental Disorders) condition. The recordings focused on the children reading scripted passages, though the textual content itself was not a central aspect of the project. Each audio recording was meticulously annotated with an emotional

XSL•FO
RenderX

intensity level (none, low, medium, or high) for 4 emotions, namely anger, fear, sadness, and happiness. To ensure robustness, 4 different labelers were involved in this annotation process for each recording, and the attribution of each labeler was recorded.

Throughout the exploratory phase, several noteworthy observations were made regarding the data. One key finding was that meaningful disagreements among the labelers were evident due to multiple labelers providing annotations for most recordings. Additionally, the recordings exhibited a degree of noise, with varying background noise levels, the occasional presence of multiple speakers (such as the therapist themselves), and instances where the speaker sounded distant from the recording device. Moreover, the duration of the recordings varied significantly, ranging from as short as 2 seconds to over 6 minutes. Though the majority fell within the 30-90 seconds range, this presented a notable difference compared to typical data sets found in the existing literature.

A contributing factor to these challenges can be attributed to the data collection process, which took place in the natural environments of the patients, such as their schools or homes. While this approach offers valuable insights, it also introduced certain complexities that needed to be addressed during data processing and analysis.

Data Preprocessing

Label Disagreement

Various methodologies were used to address the discrepancies among labelers in handling emotion intensities. First, we transitioned from a 4-class classification to a binary classification, distinguishing between low and high emotion intensities. To achieve this, we combined the categories “none” and “low” to represent the binary class 0, and similarly, we grouped “medium” and “high” for the binary class. Additionally, we trained 2 distinct types of models: one where the mode predictions across the 4 labelers served as the “ground truth,” and another where we developed individual models for each labeler. This approach allowed us to explore different perspectives and optimize model performance.

Denoising

As stated earlier, some of the voice samples were noisy despite the therapist’s effort to manage the background noise. Although some of the models used have noise resistance capabilities, it was often not sufficient for the models to achieve good results. Therefore, data set denoising had to be carried out. In recent years, neural network denoising has become the state-of-the-art approach to solving speech denoising. Therefore, one of the latest works [3] from Facebook was applied. It uses Demucs architecture, which was originally developed for the task of music source separation [12].

Voice Activity Detection

The data set’s recordings include extended periods of silence and background noise with no speech. When training models, especially those with attention layers, using extensive portions of audio from silent regions leads to less effective results, and the training process takes longer. This issue is partly influenced by participants experiencing severe symptoms of depression or anxiety, requiring substantial support to finish the reading tasks.

To address this, we conducted an experiment where we applied a voice activity detection (VAD) algorithm to identify and remove sections of the audio files where no active speaker was present. For this purpose, we used Silero models to extract these voice fragments [13].

Diarization

Another issue with the data set is the presence of various voices besides those of children, such as therapists asking questions, among others. The inclusion of these additional voices can lead the model to focus on irrelevant parts of the input data, resulting in poorer performance. To address this problem, we conducted experiments involving a diarization algorithm to process the data, retaining only the segments with children’s voices. Diarization models, however, cannot definitively identify child speakers. Nevertheless, in recordings where strangers speak, children’s voices generally dominate in terms of time, making it possible to distinguish and isolate them. It is important to mention that certain recordings experienced high levels of noise, leading to instances where the diarization algorithm detected 3 or more speakers, particularly in shorter audio recordings. Consequently, we decided to filter out such instances from our data set.

Modeling

Fully Convolutional Networks

In recent years, FCNs have emerged as a favored method for speech-emotion recognition due to their modest parameter count and ability to handle variable-length inputs. In this study, we developed FCN models based on the work of [10].

To begin, we computed the Mel spectrogram, which captures both frequency and intensity variations in the audio clip over time, representing it as a single image per recording. The advantage of using FCNs is that they can directly process these variable-length images without the need for resizing or cropping. Longer audio clips produce larger spectrograms, but the FCN efficiently handles them.

Subsequently, the image was fed through a CNN to extract meaningful features from the spectrogram, facilitating emotion intensity classification. Like how individual consonant and vowel sounds can be discerned from inspecting the spectrogram, we posit that comparable features exist for emotion intensity identification.

Finally, the outputs of the CNN are passed through one or more parallel output blocks, each comprising a 1×1 convolution step followed by a global-average pooling layer. This step reduces the dimensionality to the number of emotion intensity classes, independent of the input size. Consequently, classification is achieved without the need for dense layers with fixed dimensions.

We performed fine-tuning on 2 pretrained CNN backbones: Alexnet [11] and Googlenet [14]. Both these architectures are well-known CNNs that were pretrained on ImageNet and have been widely used for various image classification tasks [15,16].

XSL•FO
RenderX

We chose Alexnet for its compact size and previous success in similar speech-emotion recognition tasks in the literature. On the other hand, Googlenet was selected for its use of "inception blocks," which we believed might offer advantages with its convolutional filters of different sizes. To adapt these pretrained networks, we worked with their Pytorch implementations.

Our experimentation explored 2 output layer structures: "single-head" and "multi-head." The models with a single output block enabled the prediction of emotion intensity for one specific emotion, while the multi-head model consisted of 4 separate output blocks, one for each emotion. Although a multi-head model would be more convenient, we aimed to investigate whether there were any performance differences in learning features for classifying a single emotion compared to learning features that could classify all 4 emotions simultaneously.

Speechbrain

All models described earlier require a Mel spectrogram as an input. However, this speech representation has disadvantages, such as loss of information, complexity, etc. It also requires additional model capacity to be trained to extract useful information for each specific task. That is why, in recent times, self-supervised models for speech processing have gained a lot of attention. As can be deduced by its name, these models are trained in a self-supervised fashion like popular Natural Language Processing models such as BERT. The most popular ones are Hubert [17] and Wav2Vec 2.0 [18]. Both models have convolution layers in the beginning and Transformer layers after the convolution layers. The high-level pipeline is similar: the model accepts raw input audio and is trained to predict the cluster number for each audio chunk.

There are, however, some cluster refinement differences between the models. This enables them to extract phoneme-like structures in audio data and helps to extract more useful information, especially for speech-processing tasks. It is important to note that the model has some denoising capabilities by design, as this pipeline resembles the one used to train Automatic speech recognition models. The major difference is that instead of phonemes, we have cluster numbers. These types of models are implemented in a framework called Speech-the brain. In this work, we used architecture Wav2Vec 2.0. To apply this model to our task, its' architecture needed to be slightly modified and fine-tuned. We added a final head as a multilayer perceptron layer after the transformer modules. The model was trained in the usual classification problem manner with MSE loss. The gradient was backpropagated to all Wav2Vec2.0 layers. Each model was trained for 30 epochs. The multilayer perceptron layer has 2 outputs, and the model is trained to differentiate whether an emotion appears in the input or not. The setup with classifying all emotions at once was also attempted but gave poor results compared to a binary classifier.

Ethical Considerations

The study received ethical board approval (protocol #21-TQIN-101) for a multisite pilot involving children and adolescents. We will receive written and informed consent from participants. The activities for patients enrolled in the study include data collected using multiple surveys and a voice sample. The surveys include structured and unstructured voice samples based on a reading selected by the research team. The ethical board approves all the study contents.

Data Collection

ThinkQuality, TQI's Phone App, was used to collect voice samples from youth receiving mental health and family preservation services at the point of care. The data collection process includes concurrently administering a scientifically validated survey. The patient's emotional disorder severity is confirmed based on the scores of the Symptoms and Functioning Severity Scale (SFSS), ACE, and Patient Health Questionnaire-9 (PHQ-9), the patient's diagnosis, and other clinical information from the patient's treatment history. For every voice sample collected, the pilot has a diagnosis or multiple, current procedural terminology code, and the therapist's clinical input. These data serve to categorize voice sample data into distinct categories and train voice-based ML algorithms to distinguish children in need and at high risk. The innovation is focused on families with low socioeconomic status, in which ACEs are common.

Data are collected by therapists (n=35). An Android mobile app collects speech samples, SFSS, PHQ-9, and ACE scale responses. Each therapist receives a 3 to 5-hour in-person training about app installation and access, data (SFSS, voice sample) collection using the app, compliance and parameters, the process of the reward program, communication, and real-time technical support. Data are collected from patients during mental health or other family-based intervention visits weekly or biweekly, based on the intensity of the psychiatric symptoms. Visits occur in a suitable (private) location at home (including foster and group homes) or school as part of a state's commitment to reduce barriers to services and easily access services. Data are collected partially web-based during the service shift secondary to the COVID-19 pandemic.

To elicit speech for recording and analysis, patients are asked to choose from a subset of readings. Patients' reading is recorded for up to 90 seconds—a clock feature in the app signals when the time is up. In general, if the child's reading label is like the grade, the reading could be completed in less than 50 seconds. Voice samples are stored in a separate deidentified database, allowing 3 to 4 psychologists to label the voice sample independently. SFSS, PHQ-9, and ACE responses are collected using the same app. The app scores the surveys immediately and makes the results available to the therapist to share with their patients if it is clinically appropriate; real-time data availability is intended to close the gap in transparency, accountability, and family engagement.

Results

Overview

The primary goal of this research was to investigate diverse data preprocessing and modeling approaches in order to identify fruitful opportunities. As a result, significant dedication was put into testing various combinations within our suggested methodology to discover promising options. To facilitate this process, we extensively used the experiment tracking platform

XSL•FO
RenderX

called Biases. It enabled us to store training results and test metrics, and save potential model candidates for future deployment on the web app. While most models underwent 10 epochs of training with a learning rate of 5e-5, a few were terminated earlier due to the validation loss plateauing without any additional performance gains.

Evaluation Metrics

The evaluation process for the FCN models involved computing metrics using a 15% hold-out test set. Conversely, for the speech brain-based models, metrics were computed using a 10% hold-out test set. Since the task at hand was a binary classification problem, we used precision and recall as our evaluation metrics. The primary objective was to identify a model capable of accurately detecting high intensity of emotion within audio files while keeping false positives to a minimum.

Denoising

First, the denoising effects were evaluated by initially applying a pretrained denoiser model to the unmodified source audio files as a preprocessing step. Subsequently, 3 pairs of models were trained, each corresponding to 1 of 3 emotions (anger, fear, and sadness). Each pair included 1 model trained on the original audio files and another model trained on the audio files with the denoiser applied.

To maintain consistency, only the labels from a single labeler (Labeler 1) were used, given their extensive number of labeled samples. Additionally, a similar pair was trained using the model with all 4 emotion heads. The results of these experiments can be found in Table 1.

The outcomes revealed that denoising alone led to a slight improvement in the Anger emotion, but resulted in a marginal or more significant performance decrease for the FCN model in the other emotions. Moreover, the FCN model equipped with 4 output heads exhibited worse performance when denoising was added.

Table 1. Fully convolutional network model results with and without denoiser for audio samples labeled by Labeler 1.

Emotion and denoise	Precision	Recall
Anger		
No	0.612	0.513

VAD

The impact of VAD on the results was analyzed through a series of experiments. Initially, the unmodified source audio files underwent preprocessing with a pretrained VAD model. In total, 3 sets of emotion-specific models were then trained, both with and without the application of VAD. Additionally, a model with all 4 emotion heads was trained using VAD. The outcomes are presented in Table 2. It was observed that applying VAD led to negligible or marginal enhancements in the single-emotion FCN models' performance while causing a decline in the performance of the 4-emotion FCN model.

XSL•FO

[a]VAD: voice activity detection.

Denoising+VAD

The effects of preprocessing with both the denoiser and VAD were similarly compared. In this case, the unmodified source audio files first had the denoiser applied, followed by VAD. Then, the same 3 pairs of models, one per emotion, were trained, as well as the pair using all 4 emotion heads. The results are shown in Table 3.

The effects of preprocessing with the denoiser and VAD were also compared against a baseline using only VAD (rather than a baseline without any preprocessing). This set of models was trained using the speech brain-based model. The results are shown in Table 4. As we can see, in some cases, denoising boosts the quality, but in some cases, it decreases quality. In cases where quality decreased, the primary cause was extremely noisy data, and the denoiser overcompensated.

Table 3. Fully convolutional network model results with and without both denoiser and VAD[a] combined for audio samples labeled by Labeler 1.

Denoising+VAD+Diarization

Experiments with diarization were also conducted. It can be observed that for a particular labeler, a slight decrease in performance occurred, which indicates overwork. The results are shown in Table S5 in Multimedia Appendix 1.

Alexnet Versus Googlenet

Another comparison we were interested in is how different CNN architectures performed on this data set. Alexnet and Googlenet are both powerful backbones used in similar image recognition tasks. To compare the two, we trained 2 models—1 pair with only a single prediction head (for the fear emotion) while the other pair had 4 prediction heads, 1 for each emotion. These models were trained without any preprocessing steps applied to the audio files. Unfortunately, not many experiments could be run on this combination due to the long training time required for Googlenet (10-15 times slower than Alexnet). Overall, Googlenet performed worse in both cases than Alexnet. Part of this could be attributed to a much trickier training process for Googlenet—it was difficult to dial the learning rate to prevent the model from over-fitting after only 1-2 epochs. The results are shown in Table S6 in Multimedia Appendix 2.

Single- and Multi-Head Models

In our study, we conducted a comparison between models equipped with single and multiple output heads. To achieve this, we trained a model using 4 output heads to predict emotion intensity for 4 emotions. This training used data from a single labeler. Subsequently, we used the same labeled data to train 4 separate models, each with only 1 output head dedicated to predicting a specific emotion. Both Labeler 1 and Labeler 3 data sets were used for this purpose.

Although direct comparison of the results proved challenging, they provided valuable insights. The model with multiple output heads demonstrated reasonable performance and merits further exploration. It is possible that optimizing the model with multiple emotion heads simultaneously may lead to intermediate features that are more generalized, enhancing the prediction of various emotions. For detailed results, please refer to Table S7 in Multimedia Appendix 3.

One Model per Emotion

In the preceding sections, the focus was solely on models trained with data from individual speakers. However, it is more practical to use 1 model per emotion during the inference process. To explore this approach, several experiments were conducted, and the outcomes are presented in Table S8 in Multimedia Appendix 4. For these experiments, all 3 preprocessing techniques (denoising, VAD, and diarization) were applied.

The results obtained from this approach were not as promising as those achieved with separate labelers, mainly due to the lack of consensus among data labelers. This was further confirmed by computing the Krippendorf coefficient for various subsets of labelers, as shown in Table S1 in Multimedia Appendix 5. The majority of combinations yielded results close to zero, indicating a significant lack of agreement among speakers. However, it is worth noting that for the emotion “sadness,” some combinations did achieve a score of 0.45, which is considered acceptable.

FCN Versus Speechbrain

It may also be useful to compare the differences in model architectures. For this experiment, models were trained on a per-labeler, per-emotion basis using both the Alexnet-based FCN model and the Speechbrain model. The preprocessing was consistent in this comparison, with both models using the data set with denoising and VAD applied. Attention-based models like Wav2vec 2.0 can determine temporal relationships, dependencies, and correlations that are not linked with a local aspect like CNN or sequential like an RNN. The wav2vec 2.0 model can capture long-term temporal dependencies from time stamp complexity. Since the audio files contain multiple emotions and are quite long, this explains why wav2vec 2.0 outperforms the FCN-based model. The results are shown in Table 5.

XSL•FO
RenderX

Table 5. Comparing FCN[a] and Speechbrain models using data with denoiser, and voice activity detection applied.

Labeler and emotion	Precision (FCN)	Precision (Speechbrain)	Recall (FCN)	Recall (Speechbrain)

[a]FCN: fully convolutional network.

Discussion

Principal Findings

In this study, we developed a deep learning model to classify emotions from voice samples collected during the psychotherapy session. Audio recordings from a clinical population have been considered a critical step in leveraging AI-driven tools for mental health care. These models can serve as valuable decision-support tools for pediatricians and mental health providers to triage youth to appropriate levels of mental health care services. The ability to accurately quantify emotional states can potentially improve disparities in treatment outcomes, especially for youth from low-income communities and marginalized communities. Our model demonstrated proficiency in predicting therapists' intensity-based labels for different emotions.

There are several implications and potential applications of this proposed model. First, the ability to objectively measure emotional states could complement therapists' subjective assessments, leading to more precise and data-driven clinical decision-making in therapeutic interventions. In addition, quantifying emotions can contribute to streamlining resource allocation in mental health care, ensuring that individuals in critical need receive timely attention; the crisis in youth mental health and projected shortage of qualified mental health providers may require AI-driven solutions to effectively manage resources by focusing on the neediest.

However, the implementation of such models should regard ethical considerations and adoption. Patient privacy and data security must be ensured. Moreover, as AI can significantly augment the capabilities of professionals, it should not be introduced as a replacement for human connection, which is at the root of effective psychotherapeutic endeavors; instead, it should be used as a supporting tool that enhances therapists' abilities to make informed decisions.

Limitations

The study presents several limitations. The quality of speech data, including background noise and speech disorders, continues to affect the accuracy and reliability of the ML model. Second, the sample population may not be representative of the greater US population, limiting the generalizability of findings; participants have at least 1 DSM diagnosis. There are very limited voice samples of happiness. Finally, legal and regulatory considerations, including privacy rules and compliance with regulations, must be reviewed based on the state and jurisdictions and may limit the use of the algorithm. The latter must be considered to protect participants and ensure the lawful use of data [19].

Implication and Future Work

We discovered that many of our models, including our best one, hit some kind of predictive ceiling. We believe data quality may be the limiting factor in this case. Since the data labels apply to long audio segments, information density is relatively low. It is difficult to know whether a specific utterance in a long recording caused a labeler to label the audio anger as high or if the overall tone of the speaker throughout the recording indicated a high anger level. One valuable area for future work would be to break down the audio clips into smaller chunks, perhaps even to the sentence or utterance level. Having more granular labels would enable their data scientists to incorporate commonly used data sets found in literature as additional training samples. We have started breaking down the length of

XSL•FO
RenderX

the audio to 15 seconds and labeling them; accordingly, we plan to publish the result of this process.

Another area of potential future work is to work on model interpretability. Tools like saliency maps are commonly used in vision problems to understand better the features extracted at intermediate model layers. Trying similar techniques to help diagnose the current model limitations would be interesting. Perhaps this could be extended to reconstructing the relevant audio segments from the salient portions of the spectrogram and see if the labelers agree with what the model picks up on.

Conclusions

The children and adolescent system of care remains volatile despite the end of the COVID-19 pandemic that precipitated the current crisis; rural and intercity locations have taken the brunt of symptom severity and lack of access. The integration of digital mental health innovations is crucial in addressing the ongoing mental health crisis; these technologies need to fit into the existing workflow of medical providers and therapists. Speech-based digital biomarkers that can be collected quickly via a user-friendly interface hold promise for identifying emotional distress and functional impairments in this population. This study is one such technology that contributes to the broader digital health transformation and paves the way for proactive and collaborative mental health care services to improve treatment outcomes and reduce disparities for individuals from low-income communities and marginalized groups.

Abstract

Background: Chronic or persistent pain affects one's ability to work or be productive at work, generating high societal and economic burden. However, the provision of work-related advice and support for people with chronic pain is variable or lacking. The Pain-at-Work (PAW) Toolkit was cocreated with people who live with pain, health care professionals, and employers. It aims to increase knowledge about employee rights and how to access support for managing a painful chronic condition in the workplace and provides advice on lifestyle behaviors that facilitate the management of chronic pain.

Objective: We aimed to establish the feasibility of conducting a definitive cluster randomized controlled trial comparing access to the PAW Toolkit and telephone support calls from an occupational therapist (PAW) with treatment as usual (ie, standard support from their employer). Our primary outcomes are establishing parameters of feasibility, acceptability, usability, and safety of this digital workplace health intervention. We will assess the candidate primary and secondary outcomes' feasibility and test research processes for a definitive trial.

Methods: This is an open-label, parallel 2-arm pragmatic feasibility cluster randomized controlled trial with exploratory health economics analysis and a nested qualitative interview study. We aim to recruit 120 participants from at least 8 workplace clusters (any type, >10 employees) in England. The recruitment of workplaces occurs via personal approach, and the recruitment of individual participants is web based. Eligible participants are vocationally active adults aged ≥18 years with internet access and self-reporting chronic pain interfering with their ability to undertake or enjoy productive work. A restricted 1:1 cluster-level randomization is used to allocate employment settings to PAW or treatment as usual; participants are unblinded to group allocation. Following site- and individual-level consent, participants complete a web-based baseline survey (time 0), including measures of work capacity, health and well-being, and health care resource use. Follow-up is performed at 3 months (time 1) and 6 months (time 2). Feasibility outcomes relate to recruitment; intervention fidelity (eg, delivery, reach, uptake, and engagement); retention; and follow-up. Qualitative evaluation (time 2) is mapped to the Capability, Opportunity, Motivation–Behavior model and will

XSL•FO
RenderX

explore intervention acceptability to employees and employers, along with individual and contextual factors influencing the delivery and uptake of the intervention.

Results: Ethics approval was obtained in March 2023. Trial recruitment began in June 2023.

Conclusions: The PAW Toolkit is the first evidence-based digital health intervention aimed at supporting the self-management of chronic or persistent pain at work. This study will inform the design of a definitive trial, including sample size estimation, approaches to cluster site identification, primary and secondary outcomes' selection, and the final health economic model. Findings will inform approaches for the future delivery of this digital health intervention.

Introduction

Background

In the United Kingdom, chronic or persistent pain affects approximately one-third to one-half of the population [1,2]. This figure is predicted to increase largely owing to an aging population [1-3]. Chronic pain poses a high societal and economic burden [4,5]. In England, the direct medical costs of chronic pain amount to approximately £580 million (US $707.6 million), including the total prescription of analgesic medication and pain-related primary care appointments [6]. The broader economic costs to individuals with chronic pain, their employers, and society are substantial because of the costs of health and social care, productivity losses, sickness absenteeism, and early retirement [7,8], estimated to be over £100 billion (US $122 billion) annually [7]. People living with chronic pain report significant impacts on physical and mental health [9] and lower quality of life than the general population and patients with other long-term conditions [10]. The COVID-19 pandemic has increased the overall burden of chronic pain worldwide through the emergence of newly diagnosed conditions and by exacerbating existing conditions or their risk factors [11-13].

The importance of promoting and improving the way in which people self-manage chronic pain conditions is advocated in clinical guidelines [14]. Self-management interventions can be effective in improving pain, mental health, and health-related quality of life outcomes [15]. However, self-management interventions for chronic pain often focus on specific conditions or pain types (eg, *back pain* [16-20], *chronic musculoskeletal conditions* [21,22], *arthritis* [18,23], *chronic orofacial pain* [24], and *cancer pain* [25]). This potentially excludes a broader spectrum of chronic primary or secondary pain conditions (as in Korwisi et al [14]) and individuals who experience pain but lack a medical diagnosis or do not access health care services.

Studies on the management of chronic pain commonly focus only on medical, physical, or psychological strategies for pain management, whereas very few studies have reported on work-related impacts, strategies, or outcomes [26]. However, interventions focused on changes at work for people with chronic conditions (eg, to working conditions, work environment, and work organization) may enhance work participation across a range of chronic diseases [27]. Chronic pain affects people's ability to be productive at work, be fulfilled at work, or remain in the active workforce [9,28-30] and leads to social inequalities (eg, *disability pay gap*). Retaining vocationally active adults in the workforce is important for reducing health and social inequalities because employment is inversely related to pain severity [31] and worklessness is associated with poorer physical and mental health [8,32,33], social exclusion [34], and all-cause mortality [35].

In clinical services, access to work-related advice (eg, occupational therapy) for people with chronic pain is highly variable and influenced by many factors such as referrals, provider availability, and resources [36]. Occupational therapists (OTs) work within health care and occupational health settings, providing interventions for pain management and return to or staying at work, but access to OTs is limited [37].

Researcher-led interventions targeting work-related outcomes are promising (eg, *vocational rehabilitation* [38,39]), but such studies tend to focus on specific conditions (eg, arthritis) and recruit participants from clinical settings (eg, rheumatology clinics), excluding people with other chronic pain conditions and those who are self-managing their condition outside of health care services.

Similar to self-management interventions, workplace-delivered interventions for the management of chronic pain also tend to focus on specific conditions (eg, *back pain* [40-45], *neck pain* [46-48], *shoulder pain* [49,50], and *musculoskeletal conditions* [51-54]); target specific occupational groups or job types (eg, *workers with physically demanding work* [52] or *nurses* [43]); or focus on specific types of intervention (eg, *exercise or physical activity* [41,42,51,55], *physical conditioning* [44], *rehabilitation interventions* [45,56], *ergonomic interventions* [57,58], and *return-to-work or retention interventions* [59-64]). Therefore, many workplace-delivered interventions will not reach the wider population of adults with chronic pain (with or without a formal diagnosis) or the wider spectrum of occupational groups. In addition, the narrow focus of existing interventions means that people with chronic pain need to access information and support from multiple places and may not know where and how to access it.

In practice, employers do not routinely provide support for and advice to employees with chronic pain conditions [65], and the

XSL•FO
RenderX

provision of education and supportive materials for employees with chronic pain is therefore inconsistent or lacking across organizations and sectors. Only 30% to 34% of the UK workforce has access to specialized occupational health care [66]; a more recent estimate of 51% with access [67] was argued to be vastly overestimated [68]. Even when occupational health services are available, some occupational health professionals are not necessarily knowledgeable about chronic pain [69].

Digital approaches to the delivery of self-management are gaining popularity. Immersive technologies such as mobile health (the use of mobile phones and other wireless technology) and eHealth (the use of information and communication technology to support health and health care) have been used to provide pain therapy, education, symptom monitoring, lifestyle advice, health coaching, and cognitive behavioral therapy via virtual reality, mobile apps, or web-delivered programs in adults with diverse pain conditions [70-86]. Such interventions are primarily focused on improving pain, functional disability, or psychological outcomes but do not address barriers to work, facilitators of work ability, or pain self-management in the context of work, and work-related outcomes are often not measured.

In summary, there is a clear need for workplace interventions aimed at building the knowledge, skills, and confidence of vocationally active adults to effectively self-manage their condition at work (eg, through help seeking, adjusting job roles or physical environments, accessing support, and healthy lifestyle behaviors). Intervention is required that delivers comprehensive advice and support across a range of self-management areas, which is suitable for employees with any type of chronic pain working in any type of employment setting. Digital solutions are a potentially low-cost and scalable approach for the delivery of health interventions [87]. They have wide geographic reach and offer flexibility to the end user, which is increasingly valuable in the context of changes in job roles, work patterns, and locations (eg, hybrid or remote working) that have escalated in recent years [88,89].

The Pain-at-Work (PAW) Toolkit is the first accessible digital resource [65,90] designed to support people with chronic or persistent pain in self-managing their condition at work. It is designed to be relevant to any vocationally active adult with chronic pain in any organization type, size, or sector. The PAW Toolkit offers evidence-based advice about chronic or persistent pain, disability rights, work capacity, pain self-management strategies, and signposting to support. The design of the PAW Toolkit considers known enablers and barriers to engagement in digital interventions for people with chronic pain (eg, flexibility for access, inclusivity for people with disabilities, and low technological skill requirement). This intervention has been cocreated, pilot-tested, and evaluated with employees from public, private, and third sector organizations across the United Kingdom, and the comprehensive development processes are described elsewhere [65]. The feasibility and acceptability of the PAW Toolkit across employment sectors and different organization sizes and types, and the feasibility of testing the PAW Toolkit within a trial is yet to be determined.

This study is an important next step toward establishing the effectiveness and cost-effectiveness of the PAW Toolkit as a workplace intervention to support employees with chronic pain. Ultimately, the PAW Toolkit could contribute to reducing social inequalities (ie, *disability pay gap*) and the overall health, societal, and economic burden of chronic pain.

Aims and Objectives

The overall aim of the study is to determine the feasibility of conducting a definitive cluster randomized controlled trial (cRCT) on the effectiveness and cost-effectiveness of the PAW Toolkit with telephone support for vocationally active adults with chronic or persistent pain.

To achieve this, the objectives are as follows:

1. To measure feasibility outcomes to assess whether it would be possible to recruit to a definitive trial (recruitment and retention)
2. To test the feasibility of reaching different employee groups (eg, age, gender, ethnicity, and job role or type), sectors (eg, public, private, and third), and organizational types (eg, small to medium or large enterprises)
3. To explore whether participants and employers find the intervention and trial design acceptable
4. To obtain an estimate of the intracluster correlation coefficient to inform the future sample size calculation for the main trial
5. To collect a range of outcome measures to help identify the most appropriate primary outcome for a definitive trial
6. To assess the feasibility of capturing health economic data in a future trial
7. To design a future trial and implementation plan

Methods

Trial Design

This study is an open-label, 2-arm multicenter pragmatic cluster randomized controlled feasibility trial of the PAW Toolkit compared with a no-intervention control group in working adults with chronic or persistent pain. Both groups will continue to receive treatment as usual (TAU; ie, standard support from their employer). The analysis will be performed on an intention-to-treat basis. The feasibility trial included an exploratory health economics evaluation and a nested qualitative interview study. The study aligns with the Medical Research Council framework for developing and testing complex interventions [91] and will be conducted in accordance with the CONSORT (Consolidated Standards of Reporting Trials) extension to randomized pilot and feasibility trials [92]. The protocol was developed using the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines [93].

Ethical Considerations

The University of Nottingham Faculty of Medicine and Health Sciences Research Ethics Committee granted ethics approval on March 31, 2023 (Faculty of Medicine and Health Sciences 237-0323). The trial was prospectively registered on May 1, 2023 (ClinicalTrials.gov NCT05838677).

XSL•FO
RenderX

Patient and Public Involvement

Our extensive preparatory work to inform the PAW Toolkit development (n=472) was a rigorous collaborative participatory process involving surveys with employees (n=274) and employers (n=107), a stakeholder workshop (n=27), and expert peer review (n=40) [65]. Content was cocreated with "Burning Nights" (a pain charity in the United Kingdom), people living with chronic pain, health care professionals, occupational health and trade union advisers, and employers. Our trial protocol was discussed with 6 members of the patient and public involvement groups at 2 national pain centers. People with lived experience of chronic pain are represented in our trial management group, trial steering group, and trial advisory group. This paper is coauthored by the chair of The Patient Voices Committee of the British Pain Society.

Eligibility Criteria

Settings

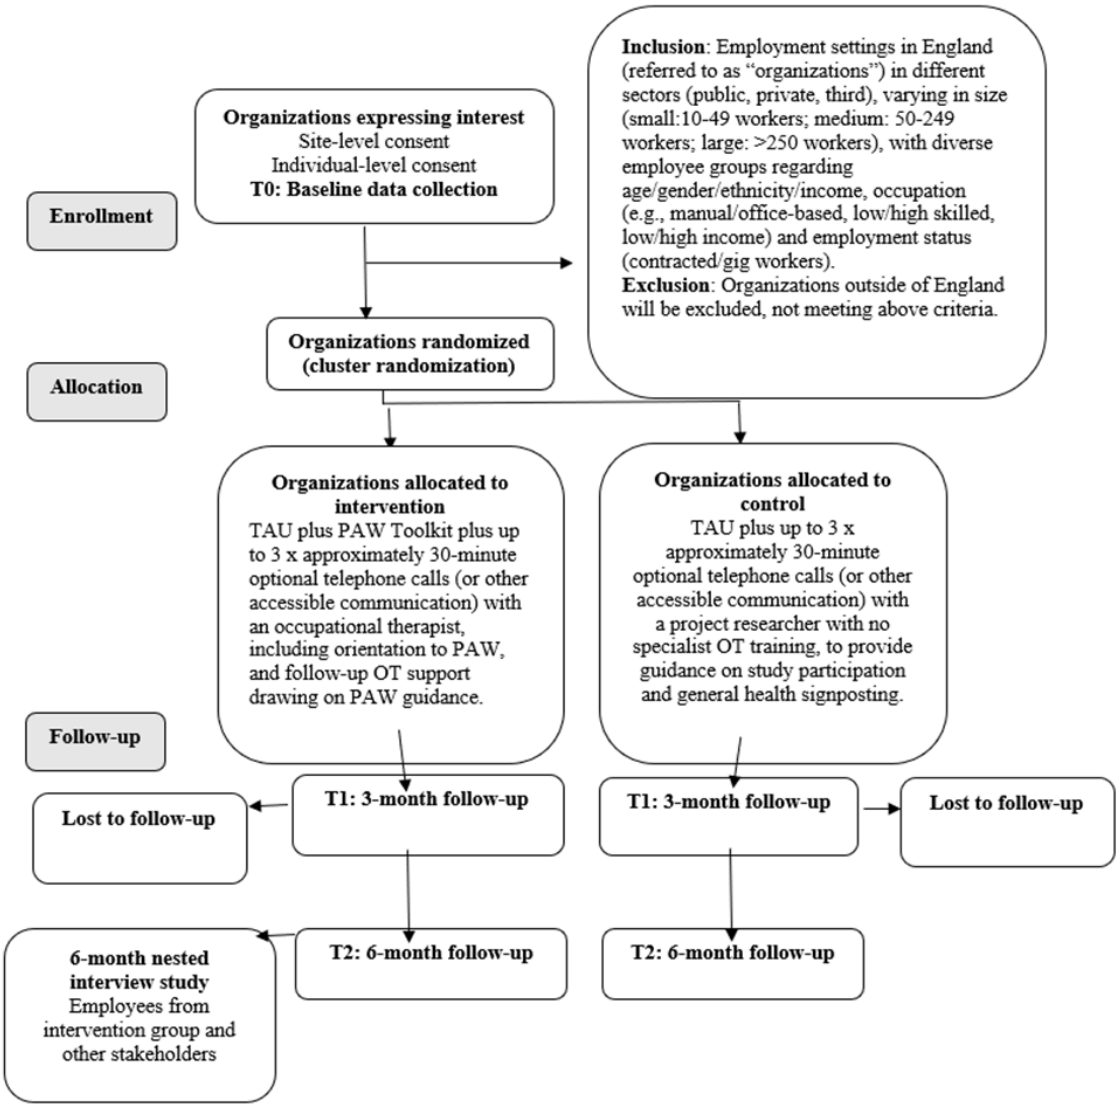
Organizations are eligible if they are located in England, are from any sector (public, private, or third), and have ≥10 employees (small: 10-49 workers; medium: 50-249 workers; or large: >250 workers). At least 8 organizations will be recruited as the unit of randomization.

Participants

Participants are eligible if they are working-age adults (employees), are aged 18 years and older, have self-reported chronic pain interfering with their ability to undertake or enjoy productive work, can comprehend English language, and are able to provide informed consent. We will include employees of any age, gender, nationality, ethnicity, income level, occupation (eg, manual or office based, low or high skilled, and low or high income), or employment status (eg, full or part time, permanent, contracted or subcontracted, volunteer, and gig workers). We use the term "employee" in this protocol to cover any type of worker. Organizations are excluded if they are outside England or are micro-organizations with fewer than 10 employees. Participants are excluded if they do not identify as having chronic pain, are unemployed at the time of recruitment, or are unable to provide informed consent. Employees with an inability to comprehend written English are excluded because it is a requirement to provide informed consent and understand the current PAW Toolkit materials. Although access to the internet is a prerequisite to engage in the study (to be able to use the intervention and complete data collection surveys), we will record the number of participants requiring telephone support for survey completion or challenges with intervention use as a proxy indicator of computer literacy.

Sample Size

A formal sample size calculation is not required for feasibility studies, although based on prior studies with a similar design [94-96], our aim is to recruit 120 employees from at least 8 organizations. Given the variability in organization size, if 120 employees are not recruited from 8 organizations, additional organizations may be recruited. Owing to the variability in the number of employees agreeing to participate in individual organizations, the total number of employees may exceed 120.



Study Procedure

Overview

The recruitment of organizations (cluster sites) and employees (participants) will be undertaken by the study researcher on a rolling basis. Each participant will be involved for approximately a 6-month duration for the feasibility trial, comprising a 6-month intervention period (baseline to final follow-up). In a subsample, qualitative interviews will be conducted at 6 months and within 8 weeks of the study end. The participant's journey through the study is shown in the CONSORT flow diagram in Figure 1. Participants will remain free to withdraw from the trial at any time without giving reasons and without prejudicing their employment or health care and will be provided with a contact point where they may obtain further information about the trial.

XSL•FO
RenderX

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) participant flow diagram. TAU refers to services and provisions provided as routine practice by the participating organization. OT: occupational therapy; PAW: Pain-at-Work; TAU: treatment as usual; T0: time 0 (baseline); T1: time 1 (3 months); T2: time 2 (6 months).

Recruitment of Organizations

Organizations in England will be identified in several ways by promoting information about the study via employer professional networks and platforms (eg, Building People), learned societies and professional organizations (eg, as identified on GOV.UK [97]), and social media (eg, LinkedIn and X [formerly known as Twitter]). Eligible organizations will be sent a formal invitation to participate by email containing a weblink to a study information sheet and consent form, and reminders will be sent to nonresponders. They will have the opportunity to discuss the study (eg, by telephone or videoconferencing) with a member of the project team. Once organizations volunteer to participate, the researcher will review the organization against the eligibility criteria to confirm that the organization meets the entry criteria. Web-based informed consent is obtained from the employer representative ("gatekeeper"). Information about the organization (eg, type, size, sector, and number of employers) will be collected by the researcher via email, telephone, or videoconference call. Gatekeepers will then be asked to provide information about the study to their employees by whichever method is appropriate for their organization. Employers' routes to providing study information to their employees will be recorded. As this is a feasibility study, strategies to incentivize organizations to participate may be added if uptake is low.

Recruitment of Participants

Employees receive information about the study from their employers (eg, email or other employer-selected routes). Employees will self-determine whether they meet the eligibility criteria as the presence of chronic or persistent pain conditions may only be known to individuals. Those who wish to participate in the study will independently access the study information via a weblink that they will receive via email, provide their consent, and complete baseline measures via a web-based data collection form. Employees will receive an email confirmation of their participation and be assigned a unique identifier. Participants will be able to contact the project researcher (by email, telephone, or videoconferencing) with any queries related to their participation in the trial or to access support with completion of the web-based surveys.

XSL•FO
RenderX

Stopping Guidelines

Employees will be made aware that they can withdraw their consent at any time during the trial without it affecting their employment. If a participant chooses to leave the study prematurely, the primary reason for discontinuation will be determined and recorded if possible. Participants who have withdrawn will not be replaced. They will be made aware (via the information sheet and consent form) that should they withdraw, the data collected to date cannot be erased and may still be used in the final analysis. In the unlikely event that an organization withdraws participation after randomization, the organization will not be replaced. The organization will be made aware that the data collected on the organization and employees at that organization to date cannot be erased and may still be used in the final analysis. Participants will be advised that their organization has withdrawn.

Randomization

Organizations are randomized by the study statistician to either (1) active control group or (2) the PAW Toolkit with telephone support. Cluster randomization (rather than individual randomization) is required because of the nature of the intervention and risk of contamination between intervention and control participants working in the same organization. Organizations are randomized into the intervention or control group using an allocation ratio of 1:1. As this is an eHealth intervention, the researcher and participants will not be blinded to group allocation.

Interventions

Active Control Group

Participants will not receive the PAW Toolkit but continue to receive TAU from their employer. The nature of TAU will be recorded as part of the feasibility study. Depending on the employing organization, TAU may consist of but is not limited to any combination of the following: occupational health, counseling, line manager support, and signposting to education about factors that may have positive or negative effects on chronic pain. To help minimize the possibility of outcomes being influenced simply by the additional contact time offered to participants in the intervention group (ie, social support provided by additional telephone calls or contacts), this is an active control group. In this study, active control means that participants can access up to 3 opt-in nonspecialist telephone calls from a researcher for general discussion (eg, their participation in the study), by means of providing a comparable level of social contact that is unrelated to the intervention.

PAW Toolkit

Intervention participants will receive TAU and the web-based PAW Toolkit. The PAW Toolkit is designed to be relevant to any employee with chronic pain in any organization type, size, or sector. PAW offers evidence-based advice on chronic or persistent pain, disability rights, work capacity, pain self-management strategies, and signposting to support. It is based on a theory of change: "Providing employees with access to the PAW Toolkit will increase knowledge about employee rights, how to access support for managing a painful chronic condition in the workplace, and lifestyle behaviours that facilitate the management of chronic or persistent pain. This in turn will lead to improved self-management of pain at work. The ultimate aim is to improve outcomes for individuals (self-efficacy, work ability, job perceptions, health, and wellbeing) and organisations (presenteeism, absenteeism)" [65].

The PAW Toolkit is authored by the lead author (HB) and colleagues (Sarah Greaves, Sarah Somerset, and VA-F) [90]. External peer review was undertaken from January to February 2023 to ensure that the materials were current, and minor updates were completed in April 2023. It is free to access, and participants will not be paid to access it during the trial. The front page includes logos for the institutions that developed the intervention and funded its development, including a university, a pain charity, and a research council. The toolkit is based on direct instruction (information and advice) and experiential learning (advice being acted on by the end user). No training is required to use the PAW Toolkit. Individuals involved in the development processes (eg, stakeholder consultation, peer review, and technical support, as reported in the study by Blake et al [65]) are named in the PAW Toolkit. The pages contain brief text, images, multimedia (ie, video clips), and hyperlinks.

The PAW Toolkit is accessed via a weblink [90]. Each organization participating in the trial will receive a unique link from the study participants recruited from their site. Technical support is available throughout the trial to resolve any arising technical issues. The delivery of the toolkit is asynchronous (ie, not prescheduled and flexible access at a time to suit the end user). Although the PAW Toolkit may be used as a stand-alone intervention, in this feasibility trial, the delivery is supported by up to 3 opt-in OT telephone appointments (approximately 30 min of contact time each) or other accessible communication if requested by a participant, such as SMS text messaging. OT support involves orientation to the PAW Toolkit, individually tailored advice, signposting, and behavioral strategies for managing pain at work, which are aligned with the PAW Toolkit content. Content headings are shown in Figure 2. The sections and contents of the PAW Toolkit are described in Multimedia Appendix 1 [65]. The TIDieR (Template for Intervention Description and Replication) checklist and guide [98] is used to describe the intervention and use parameters (ie, dose, frequency, and duration) in Multimedia Appendix 2.

The intervention draws on the principles of persuasive system design [99] (Figure 3). Detailed mapping of the PAW Toolkit intervention and feasibility trial to the persuasive systems design is described in Multimedia Appendix 3.

Evaluation of the intervention will draw on the Technology Acceptance Model [100] and behavior change theory (Behavior Change Wheel and Capability, Opportunity, Motivation–Behavior [COM-B] model [101]).

RenderX

SMS Text Message Reminders

Participants in both the control and intervention groups will receive SMS text message reminders delivered through an automated system because SMS text messages can improve responses to web-based data collection surveys [102]. For intervention participants only, messages will include reminders to access the PAW Toolkit and OT support, as SMS text message reminders can increase the uptake of health interventions [103]. Message content will be informed by the COM-B model [101], an approach used previously for SMS text messaging aligned with workplace health intervention [104]. The content, frequency, and duration of messages will be determined through patient and public involvement consultation, message peer review, and prior research.

Study Outcomes

Outcomes are separated into (1) those that determine the feasibility and acceptability of a large definitive trial, (2) employer outcomes, and (3) participant-reported outcome measures (PROMs) to inform the choice of the primary outcome for the definitive trial. Outcomes will be measured at baseline (time 0: T0), 3 months (time 1: T1), and 6 months (time 2: T2). Items from the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) [105] will be applied when reporting the findings from our web-based surveys. Multimedia Appendices 4 and 5 provide details of all feasibility and acceptability (Multimedia Appendix 4), employer- and participant-reported (Multimedia Appendix 5) data collection measures, and timeframes.

Employer-Reported Data

At the time of recruitment, details about the employment setting (Multimedia Appendix 5) will be collected from the organization representative ("gatekeeper"). This will document the sector, organization type, and size; number of staff; role of the "gatekeeper" employee representative; views toward workplace culture at the organization; and description of TAU in terms of existing provisions to support staff with long-term health conditions. Sickness absence data will be requested from the organization's records, with consent from the participants at T0, T1, and T2.

PROMs Data

Overview

PROMs (Multimedia Appendix 5) are self-assessed using web-based questionnaires, which include logos for the lead institution (university) and trial funder (charity). Closed, web-based measures will be collected using the Jisc web-based surveys at T0, T1, and T2. To help minimize attrition, participants completing surveys at all 3 time points from both groups will have the opportunity to opt into a prize draw to receive a £250 (US $305) high street shopping voucher. Participants will provide sociodemographic data (ie, age, gender, ethnicity, income, and education); health data (ie, pain conditions, present numeric pain rating scale [0-10], comorbidities, and medications); employment characteristics (eg, employment status, occupation, hours worked, and job features); sector; size and type of employing organization; assessment of their perception of organization culture; and the TAU services or support they have accessed via their employer. TAU may consist of but is not limited to any combination of the following: occupational health, counseling, line manager support, and signposting to education about factors that may have positive or negative effects on chronic pain.

PROMs are collected via a web-based survey at T0, T1, and T2 to measure the changes between time points, as presented in the following sections.

Work-Related PROMs

The Work Limitations Questionnaire-25 [106] is used as a measure of work presenteeism, that is, the "degree to which health problems interfere with specific aspects of job performance and the productivity impact of these work limitations" [107]. The scale demonstrates high reliability and validity in employee populations with chronic conditions [106-108].

The Work Productivity and Activity Impairment Questionnaire: General Health V2.0 [109] is used to measure absenteeism, presenteeism, work productivity loss, and activity impairment during the past 7 days. The validity, reliability, and responsiveness of the scale have been demonstrated in adults with chronic conditions [110-112].

The Work Ability Index Item 1 [113] is used to measure work ability (ie, how well an employee is able to perform their work). Validity and reliability have been demonstrated in employee populations [114].

The Work Self-Efficacy Scale [115] is used to measure employees' perceptions of their capability to manage specific work domains. The scale demonstrates good psychometric properties [116].

Single global items will be used to measure job satisfaction [117] and job stressfulness [118]. These items have established reliability and validity [117,118] and have been used in other employee populations [119]. Turnover intentions will be assessed using a single global item used in a web-based survey with an employee population adapted from [117] and used in [119].

Social support in the workplace will be measured using the Demand Control Support Questionnaire Social Support Subscale [120]. The scale has been shown to be valid and reliable in workplace samples [120].

Psychological and Health-Related Quality of Life PROMs

Depression symptoms will be measured using the Patient Health Questionnaire [121]. The scale has established validity as a screening tool for major depression [122,123].

Anxiety will be assessed using the General Anxiety Disorder Scale [124,125]. The scale has established reliability and validity [124,126,127], including in employee samples [123,128].

Health-related quality of life will be measured using EQ-5D-5L [129]. The scale has been shown to be reliable and valid for use in people with chronic conditions [130,131].

XSL•FO
RenderX

Health Resource Use

Exploratory health economics data capture will be informed by previously published guidance produced by a coauthor (PM) on designing and undertaking a health economics study of digital health interventions [132]. A health care resource use questionnaire will be tested to measure completion rates for items of resource use, such as frequency of use of secondary and primary care, social care, private health care, and medications. Items are adapted from health economics data capture in previous research with pain populations [133,134].

Technology Adoption PROMs

At T1, the intervention group will complete the questions related to technology adoption. Items were developed by the study team and mapped to the Technology Acceptance Model [100] to measure perceived knowledge, perceived ease of use, perceived understandability, attitudes, and behavior related to the intervention. This will provide data to assess whether and how participants engaged with this digital health intervention and provide insights into the likely impacts of this engagement.

Data Analysis

The analysis will primarily be descriptive in line with the aims of a feasibility study. This will include estimates of recruitment and retention rates and descriptive statistics for baseline and follow-up outcome measures. For PROMs, we will undertake a dummy-run analysis presenting total scores (T0 and T1) and change from T0 to T2 (adjusting for baseline). Differences between arms may be presented with 95% CIs, where appropriate. Health economic measures (TAU costs, health care resource use costs comprising medicine use, primary care consultations, hospital stays, and outpatient visits for reasons related to chronic pain, anxiety, or depression) and quality of life measurement using EQ-5D-5L will be presented as unadjusted mean (SD) and median (IQR) values. Regression-based adjusted costs and EQ-5D-5L utility values will also be calculated, with baseline cost, quality of life values, treatment group, PAW Toolkit engagement (time spent), work absence, and respondent demographics as covariates. The percentage of missing data per resource use item and EQ-5D-5L dimension will also be presented. This analysis, along with a framework analysis of patients' views on the relevance of PROMs to self-management of their chronic pain condition (captured as a part of the questionnaires and nested interviews), will guide the choice of relevant PROMs for use in a definitive trial of the PAW Toolkit.

Nested Qualitative Interview Study

At T2, we will conduct semistructured individual interviews with up to 40 stakeholders from intervention sites to explore the views of employees who received the intervention and key stakeholders that employees identify as involved in their support (eg, line managers, company owners, human resources, occupational health, or trade union). Participants will be purposively selected to reflect diverse views from across self-identified employee groups (eg, age, gender, ethnicity, and job type), sectors, organization size, and type. The eligibility criteria for the nested interview study are (1) working for an organization participating in the trial and selected for participation in the nested interview study (employees) and (2) employed in a role providing management or support for employees in a participating organization (stakeholders). The interviews will be held by telephone or videoconferencing (eg, Teams [Microsoft Corporation]) at a mutually convenient time and will be audio recorded with consent. The recordings will be transcribed in full and anonymized. We expect the interviews to last approximately 45 to 60 minutes.

Questions will be developed using a framework for qualitative research in feasibility randomized controlled trials [135,136] and reviewed by people with lived experiences of pain. Interviews will ascertain participants' views about the feasibility and acceptability of the intervention, trial processes and outcome measures, and any perceived changes in individual or organizational outcomes. Employee questions are mapped to the COM-B model [101] to explore influencers of capability, opportunity, and motivation to self-manage their condition at work (including knowledge, attitudes, and confidence).

Employees and other stakeholders will provide informed consent via a web-based consent form. Verbal consent will be audio recorded before the interview. The qualitative researchers undertaking the interviews will provide information to the participants, explain the study, and obtain consent. It will be explained to the potential participant that entry into the study is entirely voluntary and that their employment will not be affected by their decision. Using framework analysis [137], we will explore barriers to or facilitators of engagement with or use of the intervention and recommendations for future implementation.

Results

We received funding from the Nuffield Foundation and Versus Arthritis, and the project started in March 2023. The trial was opened for recruitment in June 2023. The goal is to recruit approximately 8 organizations and 120 eligible participants (approximately 60 in each arm). As of August 11, 2023, three organizations have been recruited and randomized. The trial is currently in the recruitment phase. Data collection is expected to be completed by August 2024. Data analysis will begin once all the data have been obtained, following the established plan.

Discussion

Overview

The aim of this study is to determine the feasibility of conducting a definitive cRCT on the effectiveness and cost-effectiveness of the PAW Toolkit with telephone support for vocationally active adults with chronic or persistent pain. The ultimate aim is to retain vocationally active adults in the workforce, which is important for reducing health and social inequalities. This feasibility trial will ascertain whether it is possible to recruit and retain organizations and eligible participants in a cluster randomized trial and provide insights into the feasibility of reaching different types of organization (of diverse sizes, types, and sectors) and employees (of diverse occupational and demographic groups). The data will determine whether the intervention and trial processes are acceptable to

XSL•FO
RenderX

employers and employees. The knowledge gained from the study will inform the design of a definitive trial, including sample size estimation, approaches to cluster site identification, selection of primary and secondary outcomes, and the final health economic model. This trial will ascertain how the PAW Toolkit can be best optimized in future research and implementation in real-world employment settings.

Our study addresses the limitations of prior studies on (1) self-management of chronic conditions, (2) workplace-delivered interventions for the management of chronic pain, and (3) studies that target work-related outcomes. Through this trial, we provide an intervention that delivers comprehensive advice and support across a range of self-management areas, which is suitable for employees with any type of chronic pain working in any type of employment setting.

Limitations

We are unable to collect data from employees who do not participate in the trial. Workplace research presents challenges in terms of recruitment and high risk of attrition [138]. However, we have also included strategies intended to maximize uptake and retention.

Conclusions

The PAW Toolkit is the first evidence-based digital health intervention aimed at supporting the self-management of chronic or persistent pain at work in vocationally active adults. The PAW feasibility trial will provide novel evidence on the feasibility of a cRCT evaluation of this digital intervention to support vocationally active adults at work, who are living with chronic or persistent pain.

Acknowledgments

The authors would like to thank the coauthors of the Pain-at-Work (PAW) Toolkit, Sarah Greaves and Sarah Somerset; Burning Nights Charity; all stakeholders who contributed to consultations, peer review, and evaluation of the toolkit during the development phase; and Maureen McAllister for input to toolkit updates. They thank the trial steering group, trial advisory group, and peer reviewers of the protocol, particularly Stefan Rennick-Egglestone. Responses to anonymous peer reviews of the protocol undertaken during the funding application process can be found in Multimedia Appendix 6. This project was funded by the Nuffield Foundation's Oliver Bird Fund and Versus Arthritis (ref: OBF/FR-000023820), but the views expressed are those of the authors and not necessarily those of the funders.

Authors' Contributions

HB conceived the study and HB and VA-F developed the intervention. HB, EW, PM, GT, DM, DAW, and KW-B contributed to the study design and secured funding for this research. HB and WJC secured the ethics approval. JH provided therapist advice. AF provided technical support for the intervention amendments. HB drafted the manuscript with input from WJC. All authors have read and approved the final version of the manuscript.

Conflicts of Interest

HB reports grant support from Gilead Sciences, Inc., Midlands Engine (Midlands Health and Productivity Pilot), and The Productivity Institute outside of this study. KW-B and JH report personal fees from the Nuffield Foundation Oliver Bird Fund and Versus Arthritis to support their input to the study. DM reports grant support from Pfizer and Eli Lilly outside this study. DAW reports grant support from Pfizer, Eli Lilly, GlaxoSmithKline, UCB, and Orion Pharma outside of this study. All other authors declare no other conflicts of interest.

Abstract

Background: Fatigue is a strong predictor of negative health outcomes in older adults. Kynurenine, a metabolite of tryptophan, is strongly associated with fatigue. Reductions in fatigue are observed with exercise; however, exercise training does not completely alleviate symptoms. Branched-chain amino acids (BCAAs) have been shown to have advantageous effects on exercise performance and compete with kynurenine for transport into the central nervous system. Thus, the combination of BCAA and exercise may exert synergized effects of mental and physical fatigue. Therefore, we hypothesize that BCAA added to exercise will shift kynurenine metabolism toward enhanced synthesis of kynurenic acid, thereby reducing fatigue.

Objective: This randomized, double-blind, placebo-controlled trial aims to compare the effects of acute (approximately 45 min) and chronic (8 wk) exercise with and without BCAA supplementation on mental and physical fatigue and assess whether the hypothesized outcomes are modulated by changes in kynurenine metabolism in 30 older adults (n=15, 50% per group).

Methods: Older adults (aged 60-80 y) who do not exercise >2 days per week and self-report fatigue (≥3 on a scale of 1-10) will be recruited. Participants will be randomized to either the exercise+BCAA group or exercise+placebo group. Participants will engage in high-volume, moderate-intensity, whole-body exercise training (aerobic and resistance exercise; either in-person or web-based sessions) 3 times per week for 8 weeks. In addition, participants will consume daily either 100 mg/kg body weight of BCAA (2:1:1 leucine:isoleucine:valine) or placebo (maltodextrin) throughout the 8-week intervention. BCAA and placebo powders will be identical in color and dissolved in 400 mL of water and 2.5 g of a calorie-free water flavor enhancer. Muscle biopsies will be collected before and after the intervention after a 12-hour fast to examine changes in the biomarkers of tryptophan metabolism and inflammation. Our primary outcomes include changes in mental and physical fatigue and metabolism after the 8-week exercise training between the 2 groups. Mental and physical fatigue will be measured before and after the intervention. Mental fatigue will be subjectively assessed through the completion of validated questionnaires. Physical fatigue will be measured by isometric handgrip, 1-repetition maximum, chair rise, 400-meter walk, and cardiopulmonary exercise tests.

Results: The study was funded in March 2022, with an anticipated projected data collection period lasting from January 2023 through December 2023.

XSL•FO
RenderX

Conclusions: The discovery that kynurenine concentrations are associated with fatigue and are responsive to BCAA supplementation during exercise training could have important implications for the development of future interventions, both lifestyle and pharmacologic, to treat fatigue in older adults.

KEYWORDS

branched-chain amino acids; kynurenine; fatigue; older adults; exercise

Introduction

Background

The prevalence rate of self-reported mental and physical fatigue among older adults is at least 25% in primary care settings [1]. Mental fatigue refers to a decrease in cognitive resources, whereas physical fatigue refers to the inability of muscles to maintain optimal performance. Studies suggest that mental fatigue may be present before the onset of disability and morbidity [2] and has been reported by older adults to be a main reason for activity restriction and poor compliance with exercise interventions [3]. Although prior studies show that both mental and physical fatigue are associated with low-grade inflammation [4], more research is needed to pinpoint specific biological pathways to connect chronic inflammation to fatigue-associated health declines.

One pathway that may play an integral role in fatigue progression is that of the essential amino acid tryptophan. Normally, 90% to 95% of tryptophan is metabolized along the kynurenine pathway in the liver. Inflammation upregulates kynurenine pathway enzymes outside the liver, causing intracellular and circulating kynurenine or oxidative kynurenine metabolite concentrations to rise. The accumulation of kynurenine and its oxidative metabolites are strongly associated with physical fatigue, including weaker grip strength and slower walking speed [5]. Furthermore, they can readily cross into the central nervous system (CNS) and underlie the behavioral and cognitive impairments caused by inflammation [6].

Evidence in animal models suggests that reductions in physical fatigue often observed with exercise training are mediated by skeletal muscle peroxisome proliferator-activated receptor γ coactivator 1α (PGC-1α), inducing a shift of kynurenine to kynurenic acid [7,8]. This is catalyzed by kynurenine aminotransferase (KAT) enzymes, which prevent the oxidative metabolism of kynurenine as well as its entry into the CNS; this may have an influence on mental fatigue. We have shown that reductions in skeletal muscle inflammation are associated with reductions in mental and physical fatigue after exercise training [9]; however, a recent study in older adults also found that exercise training significantly increased skeletal muscle PGC-1α gene expression and KAT isoforms by nearly 2-fold [10]. These data suggest that the tryptophan metabolism pathway may play an integral role in regulating mental and physical fatigue after exercise.

Exhaustive exercise results in the branched-chain amino acids (BCAAs; leucine, isoleucine, and valine) being taken up by the skeletal muscle, leading to reductions in the plasma concentration. In the past 2 decades, numerous studies have shown the advantageous effects of BCAA supplementation on acute and chronic exercise performance, including improvements in time to exhaustion and strength [11,12]. Furthermore, studies in animal models suggest that BCAAs decrease the transport of tryptophan and its metabolites into the CNS because BCAAs and tryptophan compete for the same carrier system. In addition, it has been shown that the depletion of plasma BCAAs after dialysis is highly associated with mental fatigue [13]. In animal models, BCAAs attenuate changes in skeletal muscle PGC-1α caused by acute exercise by approximately 50% [14]. Although currently unexplored, these data suggest that when combined with exercise, BCAA supplementation may have the ability to modify mental and physical fatigue by modulating the tryptophan pathway.

Objectives

This pilot study will examine the influence of systemic and skeletal muscle tryptophan metabolism on mental and physical fatigue after exercise training with and without BCAA supplementation in fatigued older adults. Our central hypothesis is that 8 weeks of daily BCAA supplementation added to 3-times-per-week exercise training will increase systemic and skeletal muscle expression of KAT, shifting kynurenine metabolism toward the enhanced synthesis of kynurenic acid, thereby reducing mental and physical fatigue.

Methods

Study Design and Overview

We propose a randomized, double-blind, placebo-controlled pilot study. The study protocol follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines [15]. Any deviations from the protocol, breaches of confidentiality, and adverse events will be reported to the institutional review board (IRB) and data safety monitoring board (DSMB) according to local policies. In addition, the DSMB will evaluate study materials and review the collected data to ensure data security, integrity, and quality assurance. The study is registered with ClinicalTrials.gov (NCT05484661). As shown in Textbox 1, the experimental design involves 5 phases, completed over 3 to 4 months. In phase 1, we will recruit, screen, and enroll 30 participants (n=15, 50% per group). In phase 2, all participants will undergo baseline testing (described in the following subsections). In phase 3, participants will be randomly assigned to the exercise+placebo group or exercise+BCAA group, and we will test the acute effects of

XSL•FO
RenderX

BCAA intake on fatigue and changes in the biomarkers of tryptophan metabolism and inflammation through a blood draw that will be performed after a 12-hour fast and 30 minutes after consuming either BCAA or a placebo. Phase 1 to 3 data will be collected at the Sam and Ann Barshop Institute for Longevity and Aging Studies of the University of Texas Health Science Center at San Antonio. Study phase 4 is the intervention and will consist of exercise training 3 times per week over 8 weeks with or without daily BCAA intake. To test the chronic effects of fatigue, participants will repeat all phase-2 tests at the end of the intervention (phase 5). Intervention staff and participants will be blinded to supplement allocation. Participants will receive either the BCAA or a placebo, both in powder form. Only study team members without direct participant interaction will know supplement allocation.

- Questionnaires

Week 0 (phase 3)

- Randomization (1:1)
- Acute fatigue test

Week 1 (phase 4)

- Exercise+branched-chain amino acid group (n=15)
- Exercise+placebo group (n=15)
- 8-wk intervention

Week 9 (phase 5)

- Postintervention assessments (repeat assessments outlined in phase 2)

Phase 1: Participant Recruitment, Screening, and Enrollment

Participants and Inclusion and Exclusion Criteria

The study will recruit a total of 30 community-dwelling older adults from the San Antonio, Texas, area. The inclusion criteria are as follows: (1) fatigue (participants self-reporting ≥3 on a 1-10 scale), (2) aged 60 to 80 years, (3) lack of menses for at least 1 year for women, (4) BMI 20 to 40 kg/m^2, and (5) untrained with regard to structured exercises training (≤2 times/wk). The exclusion criteria are as follows: (1) taking an anticoagulant medication (ie, heparin, apixaban, or rivaroxaban); (2) allergic to lidocaine; (3) neurologic, musculoskeletal, or other condition that limits the participant's ability to complete study physical assessments; (4) active inflammatory, autoimmune, infectious, hepatic renal, gastrointestinal, malignant, or psychiatric disease; (5) cognitive impairment (Montreal Cognitive Assessment [MoCA] score <21); (6) consuming a special diet or protein or CAA supplements; and (7) uncontrolled depression (Center for Epidemiologic Studies Depression Scale [CES-D] score ≥16).

Recruitment

Recruitment methods may include electronic medical record and approved registry queries, posting study flyers at medical offices or senior centers, community engagement activities, and newspaper or web-based advertisements (including social media). Telephone prescreening before the clinic screening visit will be used to ensure that potential participants meet the inclusion and exclusion criteria for enrollment. Those who qualify preliminarily will be scheduled for a full in-clinic evaluation and will be sent an advance copy of the consent form.

XSL•FO
RenderX

Screening

We will conduct an in-clinic evaluation consisting of a medical history; physical examination; resting, seated blood pressure; weight; height; and electrocardiogram. A fasting blood profile for lipids as well as liver, renal, and hematological function will be performed.

Enrollment

Participants will be enrolled if they provide informed consent and pass all required screening assessments.

Phase 2: Baseline Assessment Measures

Participants will complete questionnaires related to their mental fatigue, depression, quality of life, and physical fatigue (they will be asked to perform tests of strength and endurance; Textbox 2). In addition, participants will have blood draws and muscle biopsies to assess markers of inflammation or immune status, quantify amino acid and metabolite levels, and examine changes in muscle gene expression and intracellular signaling pathways (ie, PGC-1α and KAT).

XSL•FO
RenderX

Textbox 2. Baseline and postintervention assessment measures.

Laboratory tests

- Blood draw: plasma, serum, and whole blood will be collected for the assessment of thyroid-stimulating hormone, complete blood count, and a comprehensive metabolic panel with liver function tests and lipid profile. Plasma will be processed for the quantitative assessment of branched-chain amino acids and kynurenine metabolites using liquid chromatography–mass spectrometry, whereas plasma C-reactive protein, interleukin-6, interleukin-1β, and tumor necrosis factor-α will be measured by enzyme-linked immunosorbent assay (ELISA). Immune function (immunoreactivity) will be measured in diluted whole blood stimulated in vitro with 0-1000 ng/mL lipopolysaccharide (LPS) or 0-1000 ng/mL dexamethasone in the presence of 100 ng/mL LPS. Secreted cytokines will be measured by ELISA.
- Skeletal muscle biopsy: vastus lateralis muscle biopsies of the dominant leg will be obtained with a Bergström needle with local anesthesia by a credentialed clinician after a 10- to 12-h fast. Muscle tissue will quantitate local inflammation and tryptophan metabolism markers.

Anthropometric measurements

- BMI: weight (kg) will be measured on a standard physician's scale at baseline and after the intervention without shoes and with light clothing. Standing height (cm) will be measured using a stadiometer at screening. BMI will be calculated as weight (kg)/height (m^2).
- Waist and hip circumference: minimum and maximum waist and hip circumference will be measured with a tape measure. Measurements will be taken by trained personnel and will follow the World Health Organization guidelines.
- Body composition: whole-body dual-energy x-ray absorptiometry will be performed to measure lean and fat body mass and to examine the effect of the intervention on body composition [10,16]. In participants who are overweight where portions of the body fall outside the scan area, a half-body scan of the right side is carried out and a contralateral estimated performed [17].

Quantitative assessments

- Energy intake and expenditure
- Automated Self-Administered 24-Hour Dietary Assessment (ASA24): this validated web-based tool developed by the National Cancer Institute that enables multiple, automatically coded, and self-administered 24-h diet recalls will be used to calculate energy intake. The ASA24 will be used to calculate the Healthy Eating Index (HEI). HEI scores range from 0 to 100, with higher scores indicating better adherence to the Dietary Guidelines for Americans [18,19].
- Activity monitor (ActiGraph): ActiGraph GT9X Link accelerometers will be used to monitor total daily activity energy expenditure (kcal/d). Participants will wear an accelerometer around the right hip continuously for 7 d, except when sleeping, bathing, or swimming. In addition, participants will subjectively log their activity on the days that the accelerometer is worn.
- Short HEI (sHEI): The sHEI will be used to measure diet quality and assess how well dietary patterns align with the key recommendations of the Dietary Guidelines for Americans [20].
- Patient-Reported Outcomes Measurement Information System: this 57-item validated questionnaire will be used to evaluate and monitor 7 health domains (depression, anxiety, physical function, pain, sleep, fatigue, and social health) in adults [21].
- Mental fatigue (self-report measures)
  - Fatigue Assessment Scale: this 10-item validated fatigue measure scale will be used to evaluate the severity of fatigue and its impact on daily living [22].
  - Center for Epidemiologic Studies Depression Scale (CES-D): this 20-item screening test will be used to assess depression and depressive disorder. The CES-D measures symptoms defined by the American Psychiatric Association's Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition for a major depressive episode [23].
  - Minnesota Leisure Time Physical Activity Questionnaire (MLTQ): this validated questionnaire will be used to measure physical activity (duration and frequency) and energy expenditure during leisure time physical activity [24].
  - Insomnia Severity Index: this 7-item questionnaire will be used to assess the nature, severity, and impact of insomnia and monitor treatment response in adults [25].
  - Visual analog scale: this validated psychometric measuring instrument will be used to measure global pain, fatigue, and quality of life, with scores for each measure ranging from 0 to 100 mm and higher scores indicating greater intensity of pain, tiredness, and fatigue as well as better quality of life [26,27].
- Physical fatigue (strength and endurance)
  - Isometric handgrip: handgrip strength of both arms will be assessed using a handheld dynamometer. Measures will be taken in triplicate to take the average of the 3 measures [28].
  - Strength: Knee extension and chest press strength will be measured by a standardized 1-repetition maximum (1-RM) protocol that includes 4 to 6 trials with rest periods. Muscle endurance will be assessed by asking the participant to perform repetitions of the leg extension and chest press exercises at 60% 1-RM to volitional fatigue, with the number of repetitions recorded [29].
  - Chair rise: the chair rise test will be used to assess functional lower extremity strength. Chair stand number will be recorded as the number of chair stands completed as quickly as possible in 30 s with arms folded across the chest [30]. Assessment will be administered following the Stopping Elderly Accidents, Deaths, & Injuries protocol developed by the Centers for Disease Control and Prevention. Furthermore, the amount of time (s) required to sit and stand 5 times in succession will be recorded [31].

XSL•FO
RenderX

- Cardiopulmonary exercise test (CPET): a resting electrocardiogram (ECG) and blood pressure reading will be collected before the test. Open circuit spirometry will be performed during a CPET using a customized protocol to evaluate the cardiopulmonary response (ie, peak oxygen uptake [VO2peak] and ventilatory threshold) to strenuous exertion under clinical supervision and continuous vital sign and ECG monitoring according to the participant's tolerance, perceived exertion, and gait stability. The test will be reviewed and participants cleared to participate by a research clinician [32].
- 400-meter walk: the 400-meter walk test will used to measure walking ability and endurance [33]. The total time (s) taken to complete 400 m, maximal heart rate, and perceived exertion (rated on a scale ranging from 0 to 10, with 10 indicating maximum intensity) will be assessed.

- Frailty: frailty will be classified using the Fried phenotype criteria [34]: (1) self-reported unintentional weight loss of ≥10 lb (≥4.5 kg) in the past year, (2) self-reported exhaustion, (3) low energy expenditure measured using the MLTQ to assess physical activity (duration and frequency), (4) weakness measured via grip strength using a handheld dynamometer in the dominant hand, and (5) slow walking speed measured by 10-foot walk test. A frailty score will be calculated as the number (0-5) of frailty characteristics present. Those with ≥3 of these 5 characteristics are categorized as frail, those with 1 or 2 are categorized as prefrail, and those with none are categorized as nonfrail [35].

Phase 3: Randomization

Participants will be randomized 1:1 to the exercise+placebo group or exercise+BCAA group. At this visit, participants will have resting vital signs assessed and 10- to 12-hour fasting blood draw performed. After the fasting blood draw, participants will consume (blinded) either 100 mg/kg of the BCAA or the maltodextrin (depending upon group allocation) and then will rest for 30 minutes. Immediately after the 30-minute rest, a 400-meter walk will be completed (as outlined in Textbox 2). A second blood draw will be performed within 3 to 5 minutes of completing the 400-meter walk.

Phase 4: Exercise+Placebo or Exercise+BCAA Intervention

Exercise

Participants will attend in-person or web-based exercise sessions 3 times per week for 8 weeks. The exercise training protocol is designed to provide a high-volume, moderate-intensity, whole-body stimulus. The exercise will be prescribed by an exercise physiologist via provided heart rate (HR) monitors. Aerobic exercise training will start conservatively with a goal of 30 minutes total duration at 40% to 50% of maximal HR reserve determined according to the formula developed by Karvonen et al [36]:

$$\text{Training HR} = \%(\text{HRmax} - \text{HRrest}) + \text{HRrest} \quad \textbf{(1)}$$

HRmax is defined as peak HR assessed during a peak cardiopulmonary exercise test (described in Textbox 2). Aerobic exercise will advance weekly, as tolerated, to a goal of 75% to 85% of HR reserve for 30 minutes. In addition, participants will perform resistance exercise using TheraBands. They will perform the chest press, knee extension, leg curl, row, and bicep curl (15 repetitions for 2 sets and to exhaustion on the third set) for 5 major muscle groups. Resistance will be gradually increased to account for strength gains when participants are able to complete 20 repetitions on the third set.

BCAA or Placebo

Overview

This study will use over-the-counter dietary supplement powders. The BCAA supplement is manufactured and distributed by Naked Nutrition. One scoop (5 g) contains 2500 mg of L-leucine, 1250 mg of L-isoleucine, and 1250 mg of L-valine and sunflower lecithin. The placebo (maltodextrin) is manufactured and distributed by Nutricost. One scoop (15 g) contains 14 g of a complex carbohydrate (maltodextrin).

Labeling and Distribution of BCAA and Placebo Supplementation

Following double-blinded procedures, the study team will receive the BCAA or placebo supplements in prepackaged containers for the use of individual participants from the on-site clinical pharmacy. The pharmacy will maintain inventory; ensure appropriate temperature control; label each individual participant container with study and participant ID; and be responsible for storage, inventory, and destruction, following pharmacy protocol.

BCAA and Placebo Consumption

Participants will be randomly assigned to 8 weeks of BCAA or placebo supplementation. Participants will be instructed to consume either 7 to 10 g (100 mg/kg body weight) of BCAA supplement or placebo daily. The powders, identical in color, will be distributed in a double-blind fashion and dissolved in 400 mL of water and 2.5 g of a calorie-free water flavor enhancer (ie, Crystal Light). The supplement to be consumed on nonexercise days will be in prepackaged containers and provided to participants along with water flavor enhancers on a weekly basis. On nonexercise days, participants will be instructed to take the supplement between 9 AM and 10 AM each day and to log each intake on a provided spreadsheet. On exercise days, the supplement will be consumed immediately after finishing exercise training while being monitored by study staff. The distribution and consumption of the supplement will be logged by study staff. In addition, participants will be asked about supplement intake at every exercise session to track compliance. The assessment of side effects will be performed at every exercise session.

Phase 5: Postintervention Measures

After the intervention, participants will repeat all baseline (phase 2) assessment measures and qualitative assessments (Textbox 2).

Outcomes and Analysis

An important goal of statistical analyses is to determine effect sizes to make certain that future studies evolving from the current work are adequately powered. Although data do not exist to provide more precise effect sizes for this experiment, based upon previous studies [37], a mean decrease of 0.64 (SD

XSL•FO
RenderX

0.19) µmol/L in kynurenine concentration was observed after exercise training. The anticipated additive effect of BCAA supplementation is 0.25 µmol/L. Assuming an SD of 0.25 µmol/L, 12 participants per group are necessary to achieve at least 80% power with a significance level of 5%. To allow for a 20% dropout rate, we will recruit a total of 30 participants with the intent of having 24 complete the study.

In light of the small sample size, 2 separate independent samples 2-tailed *t* tests will be used for each outcome measure (ie, mental fatigue and physical fatigue) to compare changes between the BCAA and placebo groups: (1) before and after phase 3 acute exercise (400-meter walk acute fatigue test) and (2) before and after chronic (8-wk changes from phase 2 to phase 5) exercise training. We will use intention-to-treat principles per CONSORT (Consolidated Standards of Reporting Trials) guidelines to avoid the effects of attrition, which may break the random assignment to the treatment groups in a study. All statistical tests will be 2-sided and unadjusted for multiple comparisons.

Participant Safety and Minimizing Potential Risk

Overview

The risks from participating in the research study are mild to moderate and involve some slight temporary discomforts. Procedures that involve a degree of risk include completing the questionnaires, exercise training, functional assessment, BCAA or placebo supplementation (maltodextrin), muscle biopsy, blood draws, and dual-energy x-ray absorptiometry (DXA) scans. Halting the study will be at the discretion of the study clinical staff and DSMB. There is no known risk of stopping the study supplements early or abruptly.

Questionnaires

The questionnaires are time consuming but pose minimal risk.

Exercise Training and Functional Assessments

The physical activity requirement for this study is associated with shortness of breath, muscle soreness, and strains, along with the risk of cardiovascular complications such as chest pain, heart attack, or sudden death. To offset this minimal risk, all participants will undergo prescreening with medical examinations before exercise. In addition, an exercise physiologist or other medical professional will be present for all exercise sessions. There is also a minimal risk of falling during the fatigue assessment walking tests. A standby aide will always be present, and sufficient periods or rest will be provided to minimize risk.

Supplementation

The risks from consuming the BCAA and maltodextrin are expected to be minimal and may include gastrointestinal distress, such as cramps and gas. Participants will be monitored at each exercise session, and any unanticipated or serious side effects will be reported immediately to the study clinical staff, IRB, and DSMB.

Muscle Biopsy

Mild to moderate discomfort is likely but not serious and may include a sensation of pressure or thumping, cramping, pain, soreness, and bleeding. The pain is typically mild to moderate and lasts 5 to 10 seconds. The pain usually stops when the needle is removed but muscle soreness could last for a few days. Ice packs are applied to the biopsy site to minimize discomfort.

Blood Draw

The risks associated with blood sampling include discomfort, bruising, swelling, fainting, and possible infection at the site of sampling. This is minimized by having skilled professionals perform the blood draw.

DXA Scans

Participants will be exposed to a minor dose of ionizing radiation (total 0.6 mrem/scan) during the DXA scans at phase 2 and phase 5 [16], which is well below the dose of a standard chest x-ray (10 mrem; United States Environmental Protection Agency Radiation Sources and Doses [38]).

Data Management

All research records created will be held strictly confidential. A study number rather than the participant's name will be used on study records whenever possible. Electronic data will be password protected and placed on the secure local area network (REDCap [Research Electronic Data Capture; Vanderbilt University]; hosted at the University of Texas Health Science Center San Antonio]). Randomization codes will be created at random and kept electronically by a study team member not directly involved with participants (ie, the statistician). We anticipate that blinding will only be broken before the completion of the study if requested by the DSMB owing to safety concerns. Unblinding before study completion will be reported to the IRB and DSMB.

Ethical Considerations

The study was approved by the local IRB (University of Texas Health Science Center at San Antonio; 20220493H) in accordance with the ethical standards of the responsible committees on human experimentation and the Declaration of Helsinki. Eligible participants will have the study explained and an in-person IRB-approved informed consent will be obtained from each participant. Participants may choose to leave or opt out the study at any time during the study without penalty or loss of benefits they are entitled. All data and biospecimens will be deidentified. Participants will receive US $50.00 compensation after completion of the 2 testing phases (phase 2 and phase 5) for a total of US $100.00 for completion of the entire study.

Dissemination

The results of this study will be made available to health care professionals and the public through the National Library of Medicine PubMed Central website within 1 year after the date of publication. In addition, the findings of this study will be presented at scientific meetings. The study investigators will be responsible for writing all publications and will not use the services of professional writers.

Results

The study was funded in March 2022, with a projected data collection period lasting from January 2023 through December

XSL•FO
RenderX

2023. The screening and enrollment of participants for phase 1 began in December 2022. Data collection began in January 2023 and is projected to be completed at the end of November 2023. As of August 2023, a total of 24 participants have been recruited and enrolled in the study. Data analysis and results are aimed to be published in early 2024.

Discussion

Summary

The purpose of this study is to examine whether the addition of a BCAA to acute and chronic exercise can reduce mental and physical fatigue using a pilot randomized, double-blind, placebo-controlled trial. This study will also address whether clinical outcomes are modulated by changes in circulating and skeletal muscle tryptophan metabolism because this may identify potential targets for future investigation. We anticipate that 8 weeks of a BCAA added to exercise will increase the expression of KAT, shifting kynurenine metabolism toward the enhanced synthesis of kynurenic acid, thereby reducing fatigue.

Fatigue is one of the most common idiopathic complaints in older adults [39], with up to 50% of older adults aged 65 years [40] and 75% of those aged >85 years [41] self-reporting symptoms. Studies show that both mental fatigue and physical fatigue are associated with accelerated decline in physical function and cognition [42], which are strong predictors for the loss of independence in community-dwelling older adults [43]. Although fatigue can significantly affect an individual's quality of life, social well-being, and livelihood [44], its etiology remains unknown, and effective treatment strategies remain elusive.

Tryptophan is the precursor of serotonin and kynurenine, and accumulating evidence suggests that kynurenine metabolic pathways are associated with mental and physical fatigue [45]. A recent study demonstrated that the uptake of peripheral kynurenine into the brain of mice increased kynurenic acid production and induced mental fatigue [45]. This supports previous evidence that has shown that the ingestion of tryptophan by humans can also induce fatigue [45,46]. These data suggest that the tryptophan metabolism pathway may play an integral role in regulating mental and physical fatigue.

Exercise has been associated as a low-cost strategy for improving symptoms linked to fatigue [47]; however, symptoms are not eliminated. A recent randomized controlled trial has shown that exercise training can reduce the incidence of moderate to severe mental and physical fatigue by 30% to 60%; however, 82% of the participants continued to report mild fatigue after the intervention [9]. Animal models suggest that the reduction of fatigue from exercise is mediated by skeletal muscle PGC-1α, which shifts tryptophan metabolism [9] and therefore may influence fatigue. A recent study in older adults found that exercise training significantly increased skeletal muscle PGC-1α gene expression [10]. In addition, it has been shown that sedentary fatigued older adults had decreased concentration and suppression of PGC-1α in muscle tissue compared with nonfatigued older adults [48].

BCAAs play a critical role in the regulation of multiple physiological functions, including nutrient metabolism, energy homeostasis, immunity, intestinal health, protein synthesis, and aging [49]. Evidence suggests that BCAA supplementation can be beneficial during exercise, with studies showing improved ratings of perceived exertions and mental performance [49,50]. The consumption of BCAAs causes a rapid increase in serum concentration and competes with tryptophan for entry into the CNS [51]. In addition, BCAAs have been shown to attenuate changes in skeletal muscle PGC-1α caused by exercise [11,12]. Although currently unexplored, data suggest that, when combined with exercise, BCAA supplementation may have the ability to modify mental and physical fatigue by modulating the tryptophan pathway. Therefore, this study will fill a knowledge gap by determining whether changes in tryptophan metabolism occur after exercise with and without BCAA supplementation and relate to reductions in mental and physical fatigue, because this may identify potential targets for future lifestyle and pharmacologic investigation.

The identification of BCAA plus exercise as being superior to exercise alone could have clinical implications for older adults to improve cardiometabolic and functional risk. By reducing fatigue, older adults may be able to engage in longer periods of physical activity, thereby reducing weight gain common to older adults and improving the mental and physical quality of life.

Limitations

A randomized controlled trial is generally accepted as the gold standard for investigating causal relationships between an intervention and outcomes; however, despite its strength, this study design has potential limitations that should be considered. The small sample size increases the possibility of a type II error, which decreases the power of the comparison. In addition, the potential for heterogeneity between the intervention and control groups could result in false-positive results [52]. The use of self-report measures for some clinical outcomes limits any conclusion from being drawn about cause and effect and limits the generalizability of the results. Furthermore, participants could have low adherence to the study protocol although study has been designed to mitigate risk.

Future Direction

This pilot will provide preliminary evidence for larger grant applications to examine the combined effects of BCAA supplementation and exercise on mental and physical fatigue. In addition, based on the findings from this project, future clinical studies may address how other nutrient-rich foods or supplements or weight loss could further alter the response to BCAA and exercise. Furthermore, there are numerous other important clinical outcomes related to fatigue that could be examined as influenced by BCAA and exercise (ie, muscle quality, fall risk, and cognitive functioning). The discovery that kynurenine concentrations are associated with fatigue and are responsive to BCAA supplementation during exercise training could have important implications for the development of future interventions, both lifestyle and pharmacologic, to treat fatigue in older adults.

XSL•FO
RenderX

Conclusions

Through BCAA supplementation during exercise, the clinical research proposed herein has the potential to provide insight into whether BCAA supplementation can effectively reduce mental and physical fatigue when combined with acute and chronic exercise and whether these improvements are related to alterations in tryptophan metabolism in fatigued older adults. This could have important implications for prescribing exercise in older adults and the development of future interventions, both lifestyle and pharmacologic, to treat fatigue in older adults.

Acknowledgments

The research reported in this publication was supported by the National Institute on Aging (National Institutes of Health) through the Claude D Pepper Older Americans Independence Center at the University of Texas Health Science Center at San Antonio (), the Department of Veterans Affairs (VA) Office of Academic Affiliations, and the San Antonio VA Geriatric Research Education and Clinical Center.

Data Availability

A deidentified final data set underlying all publications resulting from the proposed research will be shared on request pursuant to a data use agreement, appropriately limiting the use of the data set and prohibiting the recipient from identifying or reidentifying (or taking steps to identify or reidentify) any individual whose data are included in the data set.

Authors' Contributions

RNR, JCOC, and MCS wrote the initial draft of the manuscript. All authors have reviewed and edited the manuscript. All authors have approved the manuscript for publication.

Conflicts of Interest

None declared.

Abstract

Background: Young adult cancer survivors (YACS) are at elevated risk for chronic insomnia, even years after completing treatment. In addition to potential health consequences, insomnia can interrupt social, educational, and vocational development just as they are trying to "make up" for time lost to cancer. Cognitive behavioral therapy for insomnia (CBTI) is recommended as first-line treatment for insomnia but remains largely unavailable to YACS due to several barriers (ie, shortage of trained providers, geographic limitations, financial limitations). Traditional CBTI has not been adapted to meet YACS' unique developmental and circadian challenges. To improve availability of effective behavioral insomnia treatment for this population, we developed the Sleep Treatment Education Program for Young Adult Cancer Survivors (STEP-YA), a low-intensity educational intervention delivered virtually online.

Objective: In this phase 2 "proof of concept" trial, primary aims are to test the efficacy of STEP-YA to improve insomnia symptoms and mood in YACS and assess the utility of individualized coaching to improve treatment effects. A secondary aim will explore participant variables associated with clinically significant response to STEP-YA.

Methods: This 2-arm randomized prospective trial will enroll 74 off-treatment YACS aged 20 years to 39 years with clinically significant insomnia. Each participant completes the STEP-YA intervention in a 1-on-1 synchronous online session led by a trained interventionist following a structured outline. The 90-minute intervention presents educational information on the development of insomnia after cancer and offers specific suggestions for improving insomnia symptoms. During the session, participants review the suggestions and develop a personalized sleep action plan for implementing them. After the session, participants are randomized to either the coaching condition, in which they receive 2 telephone coaching sessions, or the no-coaching condition, which offers no subsequent coaching. The Insomnia Severity Index (ISI) and the Profile of Mood States: Short Form (POMS-SF) are assessed at baseline and 4 and 8 weeks postintervention.

Results: Enrollment began in November 2022, with 28 participants currently enrolled. We anticipate recruitment will be completed in 2024. The primary endpoint is a change in ISI score from baseline to 8 weeks postintervention. The secondary endpoint is change in mood symptoms (POMS-SF) from baseline to 8 weeks postintervention. Change scores will be treated as continuous variables. Primary analyses will use ANOVA methods. A within-subjects analysis will examine if the STEP-YA intervention is associated with significant changes in insomnia and mood over time. A 2-way ANOVA will be used to evaluate the utility of coaching sessions to improve treatment effects.

Conclusions: Chronic insomnia has significant negative effects on YACS' medical, educational, and psychological functioning. STEP-YA aims to address their needs; study results will determine if the intervention warrants future effectiveness and dissemination studies and if individualized coaching is necessary for adequate treatment response.

Introduction

Background

Because cancer disrupts their physical, emotional, and social development during a critical period in their life, young adult cancer survivors (YACS) are particularly vulnerable to treatment late effects, including insomnia [1-8]. Insomnia is commonly mistakenly viewed by patients and providers "as a temporary reaction to the cancer diagnosis or treatment" [9], with few long-term consequences. However, insomnia frequently develops into a debilitating chronic condition. As many as 1 in 4 YACS experience significant insomnia many years after cancer treatment has ended [5-7,10]. Chronic insomnia is associated with significant health problems in the general population, including heart disease, obesity, hypertension, diabetes, depression, and anxiety [11-20]. Because of their medical history, YACS are already vulnerable to many of these health conditions, making access to effective insomnia treatment critically important to their overall health [21-23].

Cognitive behavioral therapy for insomnia (CBTI) is a well-established and empirically supported treatment. CBTI is the recommended first-line treatment by the American Academy of Sleep Medicine and American Colleges of Physicians for insomnia disorder in adults [24,25]. Multiple randomized trials have demonstrated CBTI is the most effective long-term insomnia treatment, even compared with pharmacotherapy [26-28]. A review of CBTI for cancer survivors similarly concluded it "provides significant, lasting improvement" [29].

Unfortunately, CBTI is largely unavailable to the growing population of YACS who need it [30,31]. To make CBTI widely available to YACS, several barriers need to be resolved, including the shortage of trained CBTI providers [32,33], the patient burden of standard CBTI regimens [34-36], and the lack of CBTI interventions specifically targeting the needs of YACS. Moreover, as YACS' access to effective insomnia care is limited by geography and other factors [30,31,33,37-39], it is imperative CBTI be made more accessible to them in their communities.

To address these challenges and deliver effective insomnia treatment to YACS, we developed the Sleep Treatment Education Program for Young Adult Cancer Survivors (STEP-YA). STEP-YA is a brief, low-intensity intervention presenting core elements of CBTI in an online educational format. Delivered in a 90-minute, 1-on-1, instructor-led session, STEP-YA educates YACS about causes of insomnia after cancer, including developmental, social, and health factors affecting YACS, and introduces them to CBTI principles and methods. During the synchronous (live) online session, survivors review their current sleep habits and consider alternative strategies consistent with CBTI recommendations. The standard elements of CBTI are presented in STEP-YA but with modifications previously shown to maintain efficacy while reducing treatment demands [40]. Additionally, information particularly salient to the experience of YACS was added, including information about how cancer diagnosis and treatment impact sleep and how to deal with young adult stressors (ie, fear of missing out, disconnecting). Following a self-management approach, the instructor provides guided behavioral planning, encouraging survivors to develop an individualized sleep action plan they will implement after the session.

Objectives

The STEP-YA intervention is designed to address barriers to insomnia treatment for YACS because it is brief, low-cost, low-burden, and targets their specific needs and experiences. Delivered virtually, STEP-YA is available to YACS when and where they need it, without requiring travel to a specialized insomnia treatment site. As a self-management intervention, STEP-YA supports YACS' autonomy by helping them make informed choices to manage their own insomnia [41], without taking the prescriptive stance commonly found in behavioral therapies. The efficacy of STEP-YA is currently being evaluated in a clinical trial described here. The primary aims of the study are to (1) test the hypothesis that STEP-YA improves insomnia symptoms (primary outcome) and mood (secondary outcome) in YACS and (2) determine if improvement in these outcomes is superior in the coaching condition compared with the noncoaching condition. A secondary aim of the study is to explore participant variables associated with clinically significant response to the STEP-YA intervention.

Methods

Study Design

Guided by the Obesity-Related Behavioral Intervention Trials (ORBIT) model for development and early testing of behavioral interventions [42-44], the STEP-YA intervention is being evaluated in an early-stage (phase 2A) randomized clinical trial. Participants are randomized (1:1) to receive the STEP-YA intervention either (1) alone (noncoaching condition) or (2) with the addition of 2 remote coaching sessions (coaching condition). STEP-YA sessions are delivered online via live videoconference. Outcomes are assessed at baseline and again 4 weeks and 8 weeks postbaseline. Participants are off-treatment YACS recruited from treatment centers, advocacy groups, and social media, and will complete all study activities remotely.

Ethics Approval

Prior to study activation and participant enrollment, the study protocol was approved by the Dana-Farber/Harvard Cancer Center Institutional Review Board (Protocol 21-613).

Participants

Participants will be 74 off-treatment YACS aged 20 years to 39 years. To be eligible for enrollment, YACS were diagnosed with cancer (excluding nonmelanoma skin cancer) at least 1

XSL•FO
RenderX

year prior, have received no cancer therapy (excluding chemoprevention) in the prior 4 months, and have no additional cancer therapy planned. Additionally, participants must be able to read and write in English and have significant insomnia as evidenced by an Insomnia Severity Index (ISI) ≥12 [45]. YACS who have specific conditions, medications, or past insomnia treatments that may affect their sleep or response to STEP-YA are excluded; these inclusion and exclusion criteria are detailed in Table 1.

Table 1. Study inclusion and exclusion criteria.

Category	Criteria	Rationale
Inclusion criteria		
General	• Age 20 years to 39 years • Able to read and write in English	Enroll off-treatment YACS[a] able to participate in the intervention currently available only in English
Health issues	• History of a cancer diagnosis (except nonmelanoma skin cancer) ≥1 year prior • No active cancer therapy (excluding chemoprevention) in the past 4 months and no further therapy planned	Enroll off-treatment YACS able to participate in the intervention currently available only in English
Sleep problems	• Significant insomnia, as evidenced by an Insomnia Severity Index (ISI) score ≥12	To test this intervention with individuals with clinically significant insomnia
Exclusion criteria		
General	• Any impairment (hearing, visual, cognitive) that interferes with the ability to complete all study measures independently	Exclude individuals not able to independently complete the study procedures
Health issues	• Diagnosed with bipolar disorder • Report being diagnosed with a seizure disorder or having experienced a seizure in the past 12 months	Exclude individuals for whom behavioral treatment for insomnia may require modification due to medical conditions
Sleep problems	• Intention to adjust (decrease or increase) use of any prescribed or over-the-counter medications taken to decrease insomnia during the study period • Survivors who report being diagnosed with sleep apnea who are not receiving recommended medical treatment for their sleep apnea • Survivors who report suspected sleep apnea who have not completed an evaluation by a sleep specialist • Survivors who report their usual bedtime is not between 5 PM and 5 AM • Employment that involves irregular sleep patterns, such as shift work or frequent long-distance travel across time zones, or employment in a position that could impact public safety	Exclude individuals whose sleep symptoms may require significant modifications in behavioral treatment for their insomnia
Prior insomnia treatment	• Prior participation in a research study that provided an educational or behavioral intervention for insomnia • Prior participation in a behavioral treatment or patient education program for insomnia delivered at the study site • Participation in behavioral or educational interventions for insomnia in the 2 years prior to enrollment (including synchronous and asynchronous online insomnia programs)	Enroll only participants naïve to the insomnia educational programs and behavioral treatments

[a]YACS: young adult cancer survivors.

Recruitment

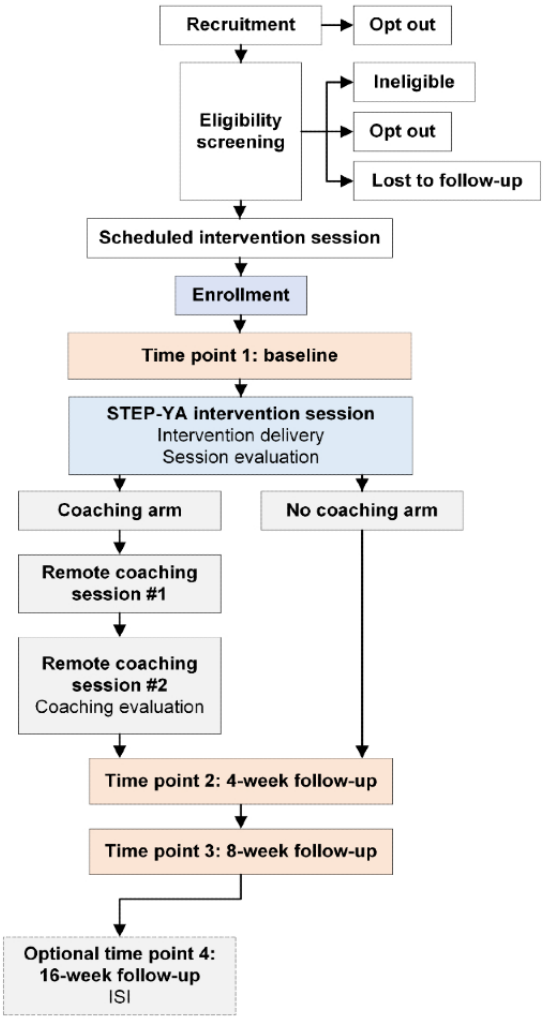
Recruitment materials and procedures are designed to allow YACS to self-refer to the study. These materials include a brief informational video, study information sheet, outreach letters and emails, informational postcards, and brief study descriptions suitable for posting on patient-facing materials distributed by patient support and advocacy groups. All materials provide phone, email, and web contact information for YACS interested in learning more about the study. Examples of these can be seen on the study website [46].

To distribute these materials to potentially eligible YACS, several methods are used. At our cancer center, recruitment postcards are placed in patient waiting areas, and study information appears on hospital screens presenting information and notices to patients. Clinical providers are informed of the study and given recruitment information and materials. In several cases, providers have granted permission to send recruitment letters directly to their eligible patients. Programs that serve supportive care needs at the center are also asked to include study information in their newsletters, emails, or social media posts. Following similar procedures, recruitment information and materials have been shared with providers at several other cancer centers in the United States. Outside of cancer centers, these materials are also posted on research portals, posted on social media sites (ie, Facebook, Instagram,

XSL•FO
RenderX

Reddit), and provided to patient advocacy and support groups (regionally and nationally) for distribution to their members.

Procedures



Screening and Scheduling

YACS who contact the study team are provided with information about the study including the study information sheet, which provides details of the study aims and procedures. Questions about the study are answered through email or telephone contact. Survivors who are interested in participating are offered the opportunity to schedule a screening meeting via videoconference. In this meeting, survivors can ask any additional questions and complete the eligibility screening, which is conducted by a research assistant. Eligible YACS are then invited to schedule an intervention session, while ineligible survivors are provided with resources [47] for finding help for insomnia. Any questions or concerns about eligibility are referred to the study's principal investigator (CJR) for clarification and eligibility determination.

Intervention Session

In the intervention session, eligible participants complete the consent procedure and a baseline survey before receiving the STEP-YA intervention (Figure 1). Following the intervention, participants are randomized to either the coaching or noncoaching condition, and follow-up contacts are scheduled.

Figure 1. Participant study flow chart for the Sleep Treatment Education Program for Young Adult Cancer Survivors (STEP-YA) study. ISI: Insomnia Severity Index.

Consent Process

YACS who are screened for eligibility more than 2 weeks prior are rescreened for eligibility. Potential participants are provided with a study information sheet, which contains all the elements of informed consent. The interventionist reviews this study information and answers any questions the potential participant may have. Individuals who wish to enroll in the study are then asked to provide verbal consent to the interventionist, who documents this in the study record. This study has been approved for a Waiver of Documentation of Informed Consent, as it is a minimal risk study involving no procedures for which signed consent is generally required outside of the research context.

Baseline Survey

After consenting, participants complete a baseline survey. Study staff guide participants in completing the survey using the Qualtrics web-based survey platform [48]. Participants enter data directly into the system, and the study staff do not collect data from participants.

XSL•FO
RenderX

STEP-YA Intervention Delivery

STEP-YA is delivered in a single, 90-minute synchronous videoconference session using HIPAA-compliant Zoom technology [49-51] licensed to our cancer center. Interventionists with graduate-level training in psychology, social work, or a closely aligned discipline are trained and supervised by psychologists with CBTI expertise to deliver the STEP-YA intervention. The interventionist delivers STEP-YA in a 1-on-1 session using a slide deck of 47 slides and following a structured outline. During the session, the participant can see and hear the presenter, view the presentation slides, and ask questions. To support participants in developing and implementing their sleep action plan, take-home materials including a copy of the presentation slides and the sleep action plan template are provided by email. The presentation begins with educational information on the problem of insomnia after cancer and the 3-P model of insomnia by Speilman and colleagues [52], before presenting specific suggestions for improving sleep in YACS. These suggestions are based on the CBTI components of sleep hygiene, stimulus control, and cognitive restructuring [29,35,53-55]. To aid comprehension, this material is presented in 4 sections addressing (1) lifestyle issues (eg, benefits of exercise and limiting alcohol), (2) sleep environment (eg, importance of a dark, quiet bedroom; avoiding bed for nonsleep activities), (3) sleep timing (eg, regular wake time, sleep ritual), and (4) managing expectations and challenges (eg, sleep worry, physical symptoms, social pressures). For each suggestion, the underlying rationale and potential benefits are presented. Both the look and content of the STEP-YA material are targeted to appeal to YACS. For example, text describing the benefits of exercise is accompanied by photos of young adults engaged in traditional and contemporary exercises, (eg, yoga, spin class), and the description of the effects of caffeine includes photos of products YACS commonly consume (eg, energy drinks, green tea, sodas, coffee drinks). In section 4, examples of the social, developmental, and health challenges that YACS may encounter are noted, along with suggestions for managing them. These include living spaces shared with roommates or parents, social pressures, “fear of missing out,” and a tendency toward a delayed sleep phase common in young adults, as well as physical health symptoms (eg, pain or hot flashes). At the conclusion of each section (eg, lifestyle), the participant is asked to review the suggestions in the section and complete their sleep action plan template with the interventionist to record their current sleep practices and behavioral changes they intend to make. Action plans of this kind are central to self-management education [41] and have been shown to increase successful behavior change [56,57]. To close the session, the presenter offers examples of STEP-YA suggestions implemented in a daily routine and asks the participant to review and revise their sleep action plan, including anticipating challenges and planning strategies to manage them.

Randomization and Follow-Up

After receiving the STEP-YA intervention, participants are randomized using Sealed Envelope [58], a commercially available online software application for randomizing patients into clinical trials. Participants are randomized (1:1) to either (1) STEP-YA alone (noncoaching condition) or (2) STEP-YA with the addition of 2 remote coaching sessions (coaching condition). In order to ensure the 2 arms of the study are balanced by age group, randomization, with a block size of 4, is stratified by those aged 20 years to 29 years versus those aged 30 years to 39 years. Participants are informed of whether they have been randomized to receive the coaching sessions, then they are scheduled for their next telephone contact with the study (Figure 1). Coaching condition participants are scheduled for the first coaching session, and noncoaching participants are scheduled for their 4-week follow-up call. Additionally, participants are asked to provide preferences for all future study contact and correspondence (eg, phone, email, text, mail).

Baseline Session Evaluation

At the end of the intervention session, all participants are asked to complete a satisfaction form evaluating their experience with the intervention session. Participants receive a link to a questionnaire on which they report on ease of use and acceptability, satisfaction, and credibility of the session. To promote completion of the questionnaire, participants are encouraged to complete it while still in the intervention session but can choose to complete it later. Participants receive a US $10 gift card upon completion of this evaluation.

Postintervention Follow-Up

Coaching Sessions

Participants randomized to the coaching condition receive 2 individualized remote coaching sessions conducted via phone call: 1 a week following the STEP-YA session and again 2 weeks following their STEP-YA session. Optimal timing for coaching sessions is 7 days and 14 days after the STEP-YA session but may be scheduled between 5 days and 23 days after the STEP-YA session with at least 5 days between coaching sessions. Paraprofessional coaches (ie, research assistants) trained and supervised by psychologists with CBTI expertise follow a structured coaching outline. In the sessions, designed to last approximately 30 minutes, coaches ask participants to review their progress and challenges implementing their personal sleep action plan. Coaches offer support and encouragement and may refer participants to the take-home materials to help answer questions and reinforce program goals and suggestions. Following principles of self-care management and previous coaching interventions successful with cancer survivors [59-63], coaching sessions are not prescriptive but support YACS to use self-management skills, including decision-making, goal setting, self-assessment, and problem-solving, to help them implement their individual sleep action plan. Administrative data on coaching session duration and sessions missed, interrupted, or rescheduled are collected.

Outcome Data Collection

At 4 weeks and 8 weeks postbaseline, study staff recontact participants by telephone at previously scheduled times, ask them to enter follow-up data directly into Qualtrics, and provide technical assistance if needed. Participants who cannot complete the full assessment at that time due to time constraints are asked to complete the 7-item ISI (primary outcome measure) verbally, and their responses are collected; they are then asked to complete the full questionnaire at their earliest convenience.

XSL•FO
RenderX

Participants receive emailed reminders in advance of each phone call. At the 4-week call, participants schedule a phone call for the 8-week assessment. Upon completion of the 4 and 8-week assessments, participants receive a US $25 gift card. At the time of their 8-week follow-up phone call, participants are asked if they would be willing to complete an optional assessment 2 months later. Participants who agree receive a Qualtrics link to the 7-item ISI 16 weeks after the intervention session by email. This takes approximately 1 minute to 2 minutes to complete, and participants do not receive an incentive for this optional assessment. The link is sent again 1 week later for nonresponders, but participants receive no additional reminders.

Intervention Training and Supervision

STEP-YA Intervention

Interventionist trainees familiarize themselves with the STEP-YA protocol and participant-facing STEP-YA materials and discuss these materials with the principal investigator. They are asked to closely review the STEP-YA presentation slides and the structured outline detailing how each slide should be presented to participants before reviewing audiotaped, videotaped, and transcribed STEP-YA sessions. When possible, and with the consent of a participant, trainees attend at least 1 live intervention session to observe STEP-YA administration. Following the session, the interventionist answers any questions the trainee might have and demonstrates postsession procedures. After completing these steps, trainees deliver the STEP-YA intervention in mock interviews with a research assistant (≥2 interviews) and an experienced interventionist (≥1 interview) playing the role of a study participant. Mock sessions are transcribed, scored for fidelity, and reviewed by the principal investigator. Interventionists are approved to conduct STEP-YA sessions with study participants after reliably demonstrating the ability to follow the structured outline for each slide of the STEP-YA presentation in a final mock interview. All interventionists record and transcribe an intervention session (recording only themselves, not the participant) after every 5 to 10 participants. These transcriptions are scored for fidelity and discussed with the principal investigator to ensure adherence to the STEP-YA intervention outline and to reduce deviation between interventionists.

Coaching

Paraprofessionals are trained as STEP-YA coaches using a coaching session outline and semistructured script. Coach trainees listen to a minimum of 3 live coaching sessions conducted by an experienced coach and discuss the flow of the script based on participants' reports of sleep action plan challenges and successes. Trainees then conduct 2 audiotaped mock coaching sessions with an experienced coach or psychologist with CBTI experience acting as a participant and receive feedback on the content of the sessions. Finally, trainees conduct at least 2 live sessions with study participants accompanied in the session by an experienced coach serving as a session co-leader. With approval of the principal investigator (CJR), coaches are then able to conduct their own sessions with study participants.

Measures

Outcomes for the trial are change in insomnia symptoms as measured by the ISI (primary) and change in mood symptoms as measured by the Profile of Mood States Short form (POMS-SF; secondary) [64]. In addition to these scales, measures of demographic and health variables are included, as are measures of participant experience and satisfaction with the intervention. Details of all measures and time points they are given are included in Table 2.

Table 2. Study measures.

Statistical Analysis

Endpoints

This is a randomized 2-arm trial evaluating the STEP-YA intervention when delivered with and without a supplementary remote coaching session. The primary endpoint is the change in ISI score from baseline to 8 weeks postintervention. The secondary endpoint is the change in mood symptoms on the POMS-SF from baseline to 8 weeks postintervention. Change scores will be treated as continuous variables, and primary analyses will use analysis of variance methods. Cohen *d* will be used to quantify within-group effect sizes, and Hedges *g* adjustment will estimate between-group effect sizes. Data collected at the 4-week postintervention assessment will be analyzed using similar methods for descriptive and exploratory purposes.

Missing Data

Participants are randomized after completing a baseline assessment so complete baseline data are assured. Primary analysis will be an intent-to-treat analysis of randomized participants. Based on experience using similar data collection methods, we anticipate minimal missing data (<10%). If needed, we will use multiple imputation to account for missing data. Potential factors in the imputation model include baseline sleep and mood variables. Sensitivity analysis will be used to evaluate the potential impact of imputation on results.

Results

Primary and Secondary Outcomes

Aim 1 of the study will be addressed using a within-subjects analysis including all participants to determine if the STEP-YA intervention is associated with significant changes in outcome measures (insomnia and mood) over time. Aim 2 will be addressed using 2-way analysis of variance with 1 between-subjects factor (coaching vs noncoaching) and 1 within-subjects factor (time) and an interaction term.

To address the secondary exploratory aim, logistic regression analysis will be used to identify participant factors associated with a clinically significant response to the STEP-YA intervention. Analyses will attempt to identify demographic and sleep factors (eg, age, severity of insomnia symptoms) associated with a reduction of ISI scores ≥6 points at 8 weeks. Variables identified in univariate analysis (P<.10) will be entered into a multivariable model estimating STEP-YA response from baseline variables. Analyses will explore these relationships separately in the 2 study arms; pooled analyses including participants across arms will be conducted if univariate analyses indicate the relationships of predictors and outcome are consistent.

Sample Size and Statistical Power for the Primary Outcome

To meet study aims, we require 64 participants with evaluable data but will enroll 74 as a hedge against attrition. Our prior single-session educational interventions have demonstrated large effects on insomnia symptoms of d≥1.00; the study is conservatively powered to detect an effect size of .52 (primary aim). With sample size of 64 (32 per arm), the study will have 80% power to detect an effect of this size within each arm (α=.05). To compare the relative improvement in the primary endpoint between arms, 64 subjects will have 80% power to detect a difference of d=0.62 between arms (α=.05, 1-sided).

Timeline

Enrollment began in November 2022. As of September 2023, 30 participants had been enrolled. We anticipate recruitment will be completed in 2024.

Discussion

Overview

STEP-YA was developed to meet YACS' need for effective behavioral insomnia treatment by addressing the low completion rates and lack of access to care common to standard CBTI treatment [30,37,65] and by targeting developmental, social, and health factors that affect their sleep. As a low-intensity intervention, STEP-YA is not intended to completely replace intensive CBTI treatment, which some YACS likely require. Rather, by meeting the needs of the majority of YACS for whom standard insomnia treatments are not appealing, not needed, or currently not available, STEP-YA aims to reduce treatment barriers and avoid potential overtreatment. Though adapted from 2 previously tested brief behavioral interventions for insomnia with cancer survivors [40,66], STEP-YA is a novel intervention as yet unsupported by clinical testing. As recommended in the ORBIT model for development and testing of novel behavioral interventions [42-44], this trial will provide the first empirical evidence evaluating the efficacy of STEP-YA. Study results will help determine whether evidence of efficacy is sufficient to warrant future trials of the existing STEP-YA intervention and aid in the design of future trials investigating its clinical effectiveness in clinical practice. Additionally, results will help to identify subgroups of YACS most likely to benefit from STEP-YA and help to determine whether individualized coaching or other efforts to further optimize the intervention are warranted. We anticipate that data supporting the efficacy of STEP-YA would lead to Phase 3 efficacy trials of STEP-YA in larger and more diverse populations. In addition, positive trial results would also support implementation research into the potential to deliver STEP-YA in small groups and in collaboration with existing survivor advocacy and support groups, which could increase access to insomnia treatment for YACS.

Limitations and Strengths

Conceptualized within the ORBIT model, this early (stage 2a) trial is designed with a limited scope; it is not intended to conclusively evaluate the efficacy of STEP-YA but to determine if preliminary evidence supporting "proof of concept" for STEP-YA is sufficient to warrant continued efficacy research. As such, the trial design has several notable limitations. Without a control group, study results cannot evaluate how much the observed trial effects are due to natural changes over time or nonspecific effects associated with trial participation. With a modest sample size of English-speaking participants, data on how demographic, cultural, and other participant variables

XSL•FO
RenderX

moderate the effects of the intervention will be limited. Similarly, the study will not be able to shed light on any long-term effects of the intervention for participants beyond the 8 and 16-week time points.

Despite these limitations, the trial is well-positioned to provide new and clinically relevant information regarding insomnia interventions for YACS. STEP-YA represents a significant innovation in behavioral insomnia treatment for YACS by delivering a self-management intervention that is less demanding than standard CBTI and attends to YACS specific concerns. In addition, by using nonclinician interventionists to deliver the intervention synchronously online, it aims to overcome logistical barriers and increase access while avoiding uptake and adherence challenges common to asynchronous insomnia interventions [38,67-70]. Investigating the efficacy of this approach is critical for evaluating the potential utility of the STEP-YA intervention and for the potential of applying these intervention methods to address other behavioral needs in this vulnerable population.

Conclusion

It is well known that behavioral treatment significantly reduces insomnia symptoms but only for those who can access it, which most YACS cannot [30,31]. Our work aims to provide YACS access to empirically supported behavioral insomnia treatment by developing and testing a brief, low-intensity intervention that addresses their needs and interests and can be delivered to them wherever they have internet access. If shown to be effective, this approach has the potential to greatly improve access to the growing population of YACS whose health and quality-of-life are affected by insomnia.

Abstract

Background: Lung transplantation (LTx) is the only treatment option for end-stage lung disease. Despite improvements, primary graft dysfunction (PGD) remains the leading cause of early mortality and precipitates chronic lung allograft dysfunction, the main factor in late mortality after LTx. PGD develops within the first 72 hours and impairs the oxygenation capacity of the lung, measured as partial pressure of oxygen (PaO_2)/fraction of inspired oxygen (FiO_2). Increasing the PaO_2/FiO_2 ratio is thus critical and has an impact on survival. There is a general lack of effective treatments for PGD. When a transplanted lung is not accepted by the immune system in the recipient, a systemic inflammatory response starts where cytokines play a critical role in initiating, amplifying, and maintaining the inflammation leading to PGD. Cytokine filtration can remove these cytokines from the circulation, thus reducing inflammation. In a proof-of-concept preclinical porcine model of LTx, cytokine filtration improved oxygenation and decreased PGD. In a feasibility study, we successfully treated patients undergoing LTx with cytokine filtration (ClinicalTrials.gov; NCT05242289).

Objective: The purpose of this clinical trial is to demonstrate the superiority of cytokine filtration in improving LTx outcome, based on its effects on oxygenation ratio, plasma levels of inflammatory markers, PGD incidence and severity, lung function, kidney function, survival, and quality of life compared with standard treatment with no cytokine filtration.

Methods: This study is a Swedish national interventional randomized controlled trial involving 116 patients. Its primary objective is to investigate the potential benefits of cytokine filtration when used in conjunction with LTx. Specifically, this study aims to determine whether the application of cytokine filtration, administered for a duration of 12 hours within the initial 24 hours following a LTx procedure, can lead to improved patient outcomes. This study seeks to assess various aspects of patient recovery and overall health to ascertain the potential positive impact of this intervention on the posttransplantation course.

Results: The process of patient recruitment for this study is scheduled to commence subsequent to a site initiation visit, which was slated to take place on August 28, 2023. The primary outcome measure that will be assessed in this research endeavor is the oxygenation ratio, a metric denoted as the highest PaO_2/FiO_2 ratio achieved by patients within a 72-hour timeframe following their LTx procedure.

Conclusions: We propose that cytokine filtration could enhance the overall outcomes of LTx. Our hypothesis suggests potential improvements in LTx outcome and patient care.

KEYWORDS

lung transplantation; cytokine filtration; primary graft dysfunction; chronic lung allograft dysfunction; randomized controlled clinical trial

Introduction

Lung transplantation (LTx) remains the standard option for treating patients with irreversible end-stage pulmonary disease [1]. Of all transplanted organs, the mean 5-year survival is the lowest following LTx [2]. The high mortality is highly associated with primary graft dysfunction (PGD), which arises in the first 72 hours after LTx and can lead to chronic lung allograft dysfunction (CLAD) within the first 3-5 years [3]. The cumulative incidence of these 2 conditions is between 40% and 80%. The fear of PGD leads to a low use rate of donated lungs, with only 20% of donated lungs being used [4].

PGD is reflected in the oxygenation capacity of the lung, measured as the ratio of the partial pressure of oxygen (PaO_2) to the fraction of inspired oxygen (FiO_2), which decreases with increasing PGD severity [2]. PGD is diagnosed according to International Society for Heart and Lung Transplantation guidelines [5] if the PaO_2/FiO_2 ratio drops below 300 and radiographic infiltrates are present in the lungs, consistent with pulmonary edema. Consequently, increasing the PaO_2/FiO_2 ratio following LTx is critical and may directly impact survival.

There is a general lack of effective treatments for both PGD and CLAD. When a transplanted lung is not accepted by the immune system in the recipient, a systemic inflammatory response starts where cytokines play a critical role in initiating, amplifying, and maintaining the inflammation leading to PGD [6]. Cytokine filtration can remove these cytokines from the circulation, thus reducing inflammation. Cytokine filtration devices have been shown in vitro and in vivo during orthotopic heart transplantation and kidney transplantation to target and reduce levels of medium– and low–molecular-weight molecules, such as cytokines, pathogen-associated molecular pattern molecules, and damage-associated molecular patterns [7-9]. Other than our feasibility study (ClinicalTrials.gov; NCT05242289) and a case series using extracorporeal cytokine adsorption therapy as rescue after LTx [10], this tool has not been applied to human LTx.

In this study, we want to test whether cytokine filtration improves outcome if administered in conjunction with LTx, for 12 hours in the first 24 hours following the procedure.

Methods

Study Design

The SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist was used when writing this report [11]. This report is based on protocol version GLUSorb-CIP-V1 dated March 4, 2023. All items from the World Health Organization's trial registration data set are found at ClinicalTrials.gov (NCT05526950).

Intervention

The CytoSorb Device (CytoSorb) is a single-use, polymer-based adsorption system for the dialysis of physiological fluids in extracorporeal therapies. It consists of a cartridge, containing a cross-linked divinylbenzene polymer that can be connected to various extracorporeal circuits. Blood is pumped through the CytoSorb cartridge and then returned to the body. The beads bind to a wide range of inflammatory mediators, including cytokines and chemokines. The device has been used in several trials, mostly for cardiac surgery patients [12-17]. The device is Conformité Européene–marked and is to be used within its intended use and indication and according to the manufacturer's instructions.

The CytoSorb device will be connected for 12 consecutive or nonconsecutive hours within the first 24 hours after the end of the surgery. As participants will be in the intensive care unit during this time, adherence to intervention protocol will be the responsibility of the attending physician and perfusionist. The device may be disconnected and reconnected as necessary for the care of the patient, for example during extubation or mobilization. The participant may also be removed from a clinical investigation by the treating physician, and the intervention discontinued if they find that this is in the best interest of the participant. All other concomitant care and interventions will be according to clinical standard procedures for LTx in Sweden.

Purpose of the Clinical Investigation

The purpose of this clinical trial is to demonstrate the superiority of cytokine filtration in improving LTx outcome, based on its effects on oxygenation ratio, plasma levels of inflammatory markers, PGD incidence and severity, lung function, kidney function, survival, and quality of life (QOL) compared with standard treatment with no cytokine filtration.

Study Design and Setting

The investigation is a randomized, parallel group, Swedish national multicenter superiority trial comparing cytokine filtration following LTx to standard treatment with no cytokine filtration. A comparator device will not be used in the control group as there is currently no clinically accepted alternative to achieve cytokine removal from the blood, and thus, the control group will only receive standard LTx treatment. The trial sponsor is Region Skåne and SL is the sponsor representative.

Inclusion Criteria

The participant must meet the following inclusion criterion:

- Eligibility to undergo double LTx at either trial site (Skane University Hospital or Sahlgrenska University Hospital) [18].

Exclusion Criteria

The participant must not meet any of the following exclusion criteria:

XSL•FO
RenderX

- Age <18 years
- Previous organ transplantation
- Presence of any conditions at the time of surgery that require immunosuppressive therapy. Immunosuppressive therapy is defined as:
  - Cyclosporine, tacrolimus, everolimus, or sirolimus—minimum 1 month of treatment prior to transplantation and active treatment at the time of transplantation.
  - Any form of antibody-based treatment that is known for having an immunomodulatory effect taken up to 1 week before transplantation.
- Nonconsent

Patients fulfilling the inclusion criterion and none of the exclusion criteria as shown will be randomized to 1 of the 2 groups. Enrollment will continue until the required sample size is achieved or until the interim analysis.

Any substantial modifications to the protocol after this study begins will be duly communicated to them.

Clinical Investigation Objectives

Primary Objective

The primary objective is to determine whether cytokine reduction by cytokine filtration leads to improved oxygenation in patients undergoing LTx.

Secondary Objective

The secondary objective is to determine whether cytokine reduction by cytokine filtration improves levels of plasma inflammatory markers (including cytokines), lung infiltrates and oedema, arterial blood gas measures, incidence and severity of PGD, need for norepinephrine, mortality, lung diffusion capacity, spirometry measures, acute rejection episodes, chest computed tomography (CT) findings, CLAD, kidney function, and QOL in patients undergoing LTx.

Safety Objective

The safety objective is to determine the number of adverse events and plasma levels of immunosuppressant drugs following cytokine filtration in patients undergoing LTx.

Exploratory Objective

The exploratory objective is the collection of lung tissue, blood, bronchoalveolar lavage fluid samples and, when available, explanted tissue from recipients for future exploratory analyses of cytokines and immune cells in patients undergoing LTx with and without cytokine filtration.

Study Population

This study's population will consist of a representative group (n=116) of patients with de novo double lung transplants in Sweden who fulfill the requirements according to the inclusion and exclusion criteria stated above.

Outcomes

Primary Performance End Point

The primary end point is the oxygenation ratio, defined as the highest PaO_2/FiO_2 ratio within 72 hours after LTx.

Secondary Performance End Points

The secondary end points are (1) plasma levels of inflammatory markers: interleukin (IL)-10, IL-1β, soluble IL-2 receptor, IL-6, IL-8, and tumor necrosis factor α before and immediately after transplantation and at 6, 12, 24, 48, and 72 hours after transplantation and C-reactive protein and white blood cells before and immediately after transplantation and at day 1, 2, and 3 after transplantation; (2) infiltrates and oedema measured by chest x-ray or CT scan of the thorax at day 1, 2, and 3 after transplantation; (3) highest daily arterial blood gas measurements recorded on day 1, 2, and 3 after transplantation, as a measure of lung function; (4) PGD severity as evaluated per standard clinical procedures using a rating scale from 0 to 3 on day 1, 2, and 3 after transplantation, as a measure of lung function; (5) presence of any grade of PGD on day 1, 2, and 3 after transplantation, as a measure of lung function; (6) total dose of norepinephrine administered in the first 72 hours; (7) mortality up to 48 months after transplantation; (8) lung diffusion capacity, measured by carbon monoxide diffusion, at 6, 12, 24, and 48 months after transplantation, as a measure of lung function; (9) forced expiratory volume, forced vital capacity, and total lung capacity measured by spirometry at 1, 3, 6, 12, 24, and 48 months after transplantation, as a measure of lung function; (10) occurrence of any acute rejection episodes (clinically treated and/or biopsy verified) up to 48 months after transplantation, as a measure of lung function; (11) chest CT findings at 1, 3, 6, 12, 24, 36, and 48 months after transplantation; (12) the presence of any CLAD and CLAD subtypes up to 48 months after transplantation, as a measure of lung function; (13) kidney function evaluated by measurement of serum creatinine levels; calculated glomerular filtration rate and need for renal replacement therapy on day 1, 2, and 3 and at 1, 3, 6, 9, 12, 24, and 48 months after transplantation; urea levels on day 1, 2, and 3 after transplantation; and iohexol-clearance at 3, 6, 9, 12, 24, 36, and 48 months after transplantation; and (14) QOL evaluated by the 36-Item Short Form Health Survey at 24 and 48 months after transplantation.

Safety End Points

The safety end points are adverse events, serious adverse events (SAEs), and plasma levels of immunosuppressant drugs (cyclosporine, tacrolimus, everolimus, or sirolimus) in the first 72 hours after transplantation.

Exploratory End Points

The exploratory end points are the collection of a portion of routinely collected transplanted lung tissue by transbronchial biopsy and bronchoalveolar lavage fluid (at least at 1, 3, and 12 mo, with additional time points if clinically indicated), collection of explanted recipient lung tissue, and collection of blood samples (at least before transplantation; immediately after transplantation; 6, 12, 24, 48, and 72 h; 1 and 2 wk; and 1, 3, 6, 9, 12, 24, 36, and 48 mo after transplantation, with additional

XSL•FO
RenderX

time points if clinically indicated) in a biobank for future exploratory analyses. Sample collection protocols will be detailed in a separate standard operating procedure.

Methodology

Medical Chart Review

The following data will be collected from medical charts at specified timepoints: background variables (demographics, comorbidities, therapies, and perioperative data), FiO_2 measurements (baseline and 0-72 h after transplantation, adjusted for ventilation), arterial blood gas measurements (baseline and d 1-3 after transplantation), radiological assessments (infiltrates and edema at d 1-3), PGD severity (d 1-3 using a 0-3 scale), total norepinephrine dosage (first 72 h), lung carbon monoxide diffusion capacity (baseline, 6, 12, 24, and 48 mo), spirometry (forced expiratory volume, forced vital capacity, total lung capacity at 1, 3, 6, 12, 24, and 48 mo), chest CT findings (1, 3, 6, 12, 24, 36, and 48 mo), CLAD assessment (presence and subtype up to 48 mo), renal function (serum creatinine, glomerular filtration rate, need for renal replacement therapy at specified intervals), urea levels (d 1-3), iohexol clearance (3, 6, 9, 12, 24, 36, and 48 mo), mortality data (up to 48 mo), acute rejection episodes (occurrence and type up to 48 mo), immunosuppressant levels (first 72 h), adverse events, and SAEs.

Follow-Up Questionnaires

QOL will be evaluated at 24 and 48 months after transplantation by designated follow-up assessors who are trained in the administration of the questionnaire. QOL scores will be collected using the Short Form Health Survey questionnaire, which assesses QOL and severity of disease for various chronic conditions [19].

Clinical Assessment

Data from assessments and visits will be obtained from the medical records. All data must be supported by the patient's medical records, that is, source documentation, and subsequently stored in an electronic case record form (eCRF).

Safety Assessment

The investigators will report all SAEs and device deficiencies to the sponsor no later than 3 calendar days after they become aware of the event. The sponsor will report to the Swedish Medical Products Agency all of the following reportable events: (1) any SAE that has a causal relationship with the investigational device, the comparator or the investigation procedure, or where such causal relationship is reasonably possible; (2) any device deficiency that might have led to a SAE if appropriate action had not been taken, intervention had not occurred, or circumstances had been less fortunate; and (3) any new findings in relation to any event referred to above. Foreseeable adverse events related to LTx will not be reported [20-26].

Data Safety Monitoring Board

Safety reviews and oversight will be under the direction of a Data Safety Monitoring Board (DSMB). The DSMB will be composed of a statistician and 2 physicians (with knowledge in the therapeutic area) who otherwise are not involved in the clinical investigation and are independent from the sponsor, without any competing interests. The DSMB shall be blinded in their safety assessments but can request to unblind the analysis in case of safety concerns. The DSMB will also carry out the interim analysis of the primary outcome variable described in the statistical analysis section. The clinical investigation can be terminated if the DSMB determines that the number of adverse events in the intervention group is unacceptable.

Blinding

The physicians, perfusionists, and nurses administering the treatment will not be blinded. Thus, unblinding for these parties is not possible. Outcome assessors for long-term follow-up visits after 1 month will be blinded. Statisticians carrying out the analyses after the end of this study will be blinded. In the case of termination of the clinical investigation, the statisticians will only be unblinded after all analyses are complete, regardless of whether this study is terminated on time or prematurely.

Statistical Considerations

Analysis Population

An intention-to-treat (ITT) analysis population will comprise all patients who have been randomized and who have reached the intervention period (the 24 h immediately after the end of LTx surgery), the so-called modified ITT. Patients who were randomized but did not undergo LTx surgery, who died during surgery, or who did not reach the intervention period for any reason will not be included in this population. Analyses based on this population (modified ITT) will group patients according to the treatment they were randomized to receive, regardless of the actual treatment received. We do not expect missing data for the primary outcome variables. Any missing data will be handled as recommended by Jakobsen et al [27].

Descriptive Statistics

Normally distributed continuous data will be presented as the mean (SD) and 95% CIs. Nonnormally distributed continuous data will be presented as the median, IQR, and 95% CIs. Categorical and binary data will be presented as a percentage with CIs, and as absolute numbers. Ordered categorical variables will be presented as the median, IQR, and 95% CIs.

Statistical Design, Method, and Analytical Procedures

All statistical analyses will be performed by an independent statistician. Treatment allocation will remain concealed during the initial analysis, with the 2 groups labelled as "group A" and "group B," ensuring a blinded statistical analysis. All statistical tests will be 2-sided. The distribution of continuous variables will be determined by visual inspection of histograms and quantile-quantile plots. The primary outcome will be based on the mean highest PaO_2/FiO_2 ratio within the first 72 hours (a continuous variable). Differences between treatment groups in the mean highest PaO_2/FiO_2 ratio within the first 72 hours will be compared using a multivariate linear regression model adjusted for, at minimum, the stratification variables (site, age, and gender). Continuous variables, ordered categorical variables, and binary variables measured over time will be compared using

XSL•FO
RenderX

mixed models for repeated measures. The distribution of the data will be checked using quantile-quantile plots, and if the data are skewed, then a generalized linear mixed effects model with the appropriate distribution will be used. A random intercept will be applied at the patient level. We will check model assumptions for each model. Kaplan-Meier survival analysis will be performed for mortality data up to 48 months after transplantation. Median QOL scores from each instrument (ordinal variables) will be compared using the Mann-Whitney *U* test at each time point. Subgroups for analysis shall be described in detail in the statistical analysis plan.

Level of Significance and Power

In the interim analysis (described below), the DSMB will use Pocock stopping boundaries ($P<.03$). Therefore, the 2-sided α value in the final analysis will be $P=.03$. We will use a power of 0.8 (80%).

Sample Size

The power calculation, performed using GPower 3.1 (AdvanSci Research Solutions), is based on superiority analysis assumptions for the primary end point (improved oxygenation ratio, defined as the highest PaO_2/FiO_2 ratio measured within 72 h after LTx). Based on data from a cohort of patients undergoing LTx from Skåne University Hospital in Lund from 2011 to 2020, we estimate that the mean PaO_2/FiO_2 value in the control group will be approximately 300 (SD 100) mm Hg and that values will be normally distributed. We estimate that the average PaO_2/FiO_2 value will be 60 (SD 100) mm Hg higher (effect size) in the treatment group compared with the control group.

The sample size was calculated using a 2-tailed *t* test to compare the PaO_2/FiO_2 values in the treatment versus control groups. We will require 52 participants in each group to achieve the power and α level detailed above. We will add 10% of the required sample size to account for possible dropouts, withdrawal of consent, or mortality in the first 72 hours. Thus, we aim to recruit 58 patients in each group to a total of 116 participants. With this number of participants, we estimate that all secondary outcome variables will have a power of at least 80% at an α level of .05.

Expected Dropout Rates

Based on clinical experience, perioperative and postoperative mortality within the first 72 hours after transplantation is expected to be low. The sample size estimation has been adjusted to account for possible losses due to dropouts. Long-term follow-up visits will coincide with standard visits, and thus we do not expect many dropouts during the long-term follow-up.

Interim Analysis

The DSMB will perform an interim analysis of the primary outcome after at least 30 participants for each group have undergone LTx and reached the intervention period and the 72-hour time point has been passed for the 30th participant in each group. The DSMB will use Pocock stopping boundaries ($P<.03$) as the statistical limit to guide its recommendations regarding early termination of the trial on the basis of rejecting the null hypothesis. If the *P* value for the primary outcome is below .03 at the interim analysis, then a decision will be taken by the trial management team to either stop the trial early or to continue recruitment. This has been accounted for in the sample size calculation above, and no additional adjustments for multiple testing are necessary.

Randomization

An allocation sequence will be created in advance by an independent statistician and linked to a digital randomization module in the eCRF. As each patient is included by the investigator, the next number in the sequence will be revealed and the patient will be assigned to the intervention indicated therein. Randomization is performed using a web-based system (REDCap; Research Electronic Data Capture; Vanderbilt University) and patients are randomized in a 1:1 ratio to 1 of the 2 groups. Randomization will be done using random permuted blocks of varying size, stratified by site, gender, and age.

Replacement

Participants who withdraw or are withdrawn from this study or who are lost to follow-up will not be replaced. If a participant's transplantation surgery is cancelled or rescheduled after they are randomized (they will keep the randomization number if later transplanted), new participants will continue to be randomized until the target number of participants has completed their transplantation surgery.

Site Monitoring

This study will be monitored by an independent monitor before this study begins, during this study's conduct, and after this study has been completed, to ensure study conduct in accordance with the clinical investigation plan, accuracy of entries in the eCRF, adherence to the protocol and Good Clinical Practice (GCP), and progress of enrollment. Monitoring standards will be followed and all checks of the consistency of the source data with the eCRFs will be performed according to the monitoring plan.

Data Management and Data Collection

Forum Söder, a nonprofit organization associated with Lund University and Skåne University Hospital, is contracted for planning and execution of data management activities. Data collected from the patients' medical records, in paper data logs, and from QOL questionnaires will be transferred into an eCRF in the data capture tool REDCap. Automatic validation programs check for data discrepancies in the eCRFs, and by generating appropriate error messages, allow for modification or verification of the entered data by the investigator staff before being saved in the database.

Database Management and Quality Control

The monitor will review the eCRFs entered by investigational staff for completeness and accuracy and instruct the site personnel to make any required corrections or additions. Electronic data capture systems will undergo extensive user acceptance testing before they are implemented to ensure that they are verified and validated. To ensure the system is secured, REDCap is located on Windows server 2012 R2 standard, with

XSL•FO
RenderX

a firewall. Individual log-in with a 2-factor authentication is maintained. The server is backed-up every night. The sponsor, investigators, statisticians, and trial management team will have access to the final data set.

Procedures to Protect Participant Confidentiality

REDCap is compliant with GCP standards and fulfils criteria for handling patient data according to Swedish legislation on management of personal data and the General Data Protection Regulation of the European Union. Patients will be pseudonymized through assignment of a study ID number in the database and the code will be safely stored at each site.

Ethical Considerations

The protocol received approval from Swedish Ethics Committee in September 2022 (registration [daybook] 2022-04567-01) and by the Swedish Medical Products Agency in April 2023 (registration [daybook] 5.1- 2023-23105). Any substantial modifications to the protocol after this study begins will be duly communicated to them. Prior informed consent of the participants regarding participation in the trial and collection of biological specimens will be collected by a trained member of the research team before data collection. All the participants are free to withdraw from this study at any moment without incurring any penalties or consequences with regard to future care or services they might rightfully expect. This study plan has also been reviewed and approved by an independent peer review for funding by the Swedish Research Council (registration [daybook] 2022-00319). Written informed consent will be obtained before any study-related procedures are implemented. This study will be performed in accordance with ethical principles that have their origin in the Declaration of Helsinki and are consistent with ICH-GCP and applicable local regulatory requirements. This study was registered at ClinicalTrial.gov (NCT05526950; September 2, 2022)

Ancillary and Posttrial Care

At the end of this study, participants will continue to receive whatever care is deemed necessary by their physician, regardless of their assigned intervention.

Dissemination Policy

The sponsor shall prepare a publicly available clinical investigation report in accordance with regulation (European Union) 2017/745 within 1 year after the end of this study. Planned dissemination of study findings includes paper publication, conference presentations, and community dissemination (eg, community meetings and social network). Professional medical writers may be contracted for preparation of the clinical trial report and publications. There are no plans to make the full protocol, participant-level data set, or statistical code publicly available.

Results

The recruitment of patients started after a monitor site initiation visit on August 28, 2023. The enrollment is expected to last 3.5 years. The collective rate of LTx at the 2 sites together is expected to be 40-60 patients per year. Since the inclusion criterion is very broad (all patients who are eligible for double LTx in Sweden), we only expect about 1-4 patients per year to be noneligible for this study. Thus, we expect to recruit 30-50 participants per year, making this enrollment time feasible. Long-term follow-up after the end of the investigation is expected to last 4 additional years from the final enrollment. Thus, the investigation and postinvestigation follow-up together are expected to last 7.25 years.

Discussion

Overview

Intolerance to a new lung, which leads to PGD, begins already during transplantation and is driven by intense inflammation caused by circulating cytokines [6]. Cytokine filtration can remove the cytokines that lead to intolerance and subsequent PGD from the circulation, thus reducing inflammation, and could therefore improve outcomes in LTx. However, the effectiveness of the CytoSorb device in LTx has yet to be established. Other than our feasibility study (NCT05242289) and a smaller case series that was rescued with extracorporeal cytokine adsorption therapy following LTx [10], this tool has not been applied to human LTx by any clinic within our network or in any trials that are registered at ClinicalTrials.gov or other registries. Therefore, this clinical investigation is justified and relevant as it will establish the effectiveness of cytokine reduction by cytokine filtration using the CytoSorb device in improving lung function following LTx, an area where there is a high unmet need. The clinical investigation is designed to evaluate whether the investigational device is suitable for the purposes and populations for which it is intended within LTx, namely for removal of cytokines in these patients.

Following LTx, the anticipated clinical benefits of cytokine filtration using the CytoSorb device in LTx are reduced severity and incidence of PGD, improved lung function, improved kidney function, improved hemodynamic stability, and reduced mortality.

In a preclinical study of LTx carried out by Ghaidan et al [28], pigs were randomized 1:1 to undergo LTx with or without cytokine filtration with the CytoSorb device during the first postoperative period and followed for 3 days after transplantation. Cytokine filtration significantly improved lung function, evidenced by increased PaO_2/FiO_2 ratio, and reduced the incidence of histologically confirmed PGD. Treated animals also had lower levels of inflammatory biomarkers in plasma and bronchial alveolar lavage fluid, lower levels of lymphocytes, neutrophils, and total white blood cells; required less inotropic support; and experienced greater lactate clearance postoperatively.

The mechanisms driving PGD are still not fully comprehended, just as the mechanisms of action behind how the CytoSorb device could improve PGD remain not fully understood. Elevated levels of neutrophil extracellular traps (NETs) have been identified in cases of PGD, underscoring the significance of approaches aimed at mitigating their presence [29,30]. While the precise mechanisms underlying PGD are still not fully elucidated, its association with heightened incidences of both

XSL•FO
RenderX

acute and chronic rejection underscores the urgency for the development of proactive interventions [3].

We have recently completed a successful clinical feasibility study of cytokine filtration in conjunction with LTx using a similar protocol as described in this application (ClinicalTrials.gov; NCT05242289). The results from the first 4 randomized patients were published as a brief communication [31]. Treated patients exhibited diminished levels of circulating nucleosomes, as a marker of reduced circulating NETs, and remained free from both PGD and histopathological indications of acute rejection at both 1- and 3-months after transplant. In contrast, patients who did not undergo cytokine adsorption experienced higher levels of circulating nucleosomes, PGD of grades 1 and 3, as well as histopathological signs of acute rejection. Incorporating CytoSorb during transplantation could potentially foster a reduced systemic inflammatory response characterized by lower NET levels, consequently providing support for graft acceptance. We are currently working on finalizing all analyses in the feasibility study. To this point, no adverse events have been reported (unpublished work).

Limitations

Participant-related factors that may compromise the outcome or interpretation of results include baseline characteristics, demographics, lifestyle, and concomitant medications. Participant-related factors will be mitigated by randomization, exclusion criteria, and stratification by gender and age. Multivariate analyses will be used to adjust for the effect of any differences in demographic characteristics and concomitant medication use between the groups.

Site- and procedure-related factors that may compromise the outcome or interpretation of results include minor local differences in clinical procedures. Site-related factors will be mitigated by stratification of randomization by site to ensure equal numbers of patients are randomized to each intervention at each site. Subgroup analyses will be used to examine the effect of any differences between sites.

Conclusions

The investigation is a randomized, parallel-group, Swedish national multicenter superiority trial that compares cytokine filtration following LTx to standard treatment without cytokine filtration. This study aims to investigate the effects of cytokine filtration in conjunction with LTx. This treatment is administered for 12 hours within the first 24 hours following LTx with the goal of improving outcomes. It is hypothesized that cytokine filtration will lead to improvements in lung transplant outcome, enhance lung transplant care, and increase overall survival.

Abstract

Background: East and Southern Africa have the highest HIV incidence and prevalence in the world, with adolescents and young adults being at the greatest risk. Despite effective combination prevention tools, including the recently available pre-exposure prophylaxis (PrEP), HIV incidence among adolescents and young adults in Uganda remains high, and PrEP use remains low. Mental health and substance use (behavioral health) play a role in sexual behavior and decision-making, contributing to an increase in the risk for acquiring HIV. Interventions that target multiple HIV risk factors, including sexual and mental health and problematic substance use, are crucial to ending the HIV epidemic. Yet few interventions addressing HIV related health disparities and comorbidities among adolescents and young adults in East and Southern Africa currently exist.

Objective: This study aims to evaluate the acceptability and feasibility of Kirabo, an SMS text message intervention informed by the information, motivation, and behavior model and to be disseminated through secondary schools. The study will gather preliminary estimates of Kirabo's effectiveness in increasing HIV testing and linking users to mental health counselors.

XSL•FO
RenderX

Methods: We identified Mobile 4 Reproductive Health for adaptation using the assessment, decision, administration, production, topical experts, integration, training, testing (ADAPT-ITT) framework. Mobile 4 Reproductive Health is an evidence-based automated 2-way SMS text messaging and interactive voice response platform that offers sexual and reproductive health information and links users to HIV clinics in East Africa. Through ADAPT-ITT we refined our approach and created Kirabo, an SMS text message–based intervention for linking adolescents and young adults to health services, including HIV testing and mental health counseling. We will conduct a 2-arm randomized controlled trial in Masaka, Uganda. Adolescents (N=200) will be recruited from local schools. Baseline sociodemographic characteristics, HIV test history, and behavioral health symptoms will be assessed. We will evaluate acceptability and feasibility using surveys, interviews, and mobile phone data. The preliminary efficacy of Kirabo in increasing HIV testing and linking users to mental health counselors will be evaluated immediately after the intervention and at the 3-month follow-up. We will also assess the intervention's impact on self-efficacy in testing for HIV, adopting PrEP, and contacting a mental health counselor.

Results: Intervention adaptation began in 2019. A pretest was conducted in 2021. The randomized controlled trial, including usability and feasibility assessments and effectiveness measurements, commenced in August 2023.

Conclusions: Kirabo is a tool that assists in the efforts to end the HIV epidemic by targeting the health disparities and comorbidities among adolescents in Uganda. The intervention includes local HIV clinic information, PrEP information, and behavioral health screening, with referrals as needed. Increasing access to prevention strategies and mitigating factors that make adolescents and young adults susceptible to HIV acquisition can contribute to global efforts to end the HIV epidemic.

Introduction

Background

Globally, adolescents and young adults aged 10 to 24 years represent approximately 30% of people living with HIV. East and Southern Africa (ESA) have the highest HIV incidence in the world, with adolescents and young adults being at the greatest risk [1-3]. AIDS is the leading cause of death for adolescents and young adults in the region and the second leading cause of death for adolescents and young adults worldwide [4,5]. Despite combination prevention efforts, including pre-exposure prophylaxis (PrEP) [6], HIV incidence among adolescents and young adults remains high [1], and PrEP use remains low [7]. Further, in part owing to the lack of access to information and services related to mobility, the uptake of antiretroviral therapy among adolescents and young adults in Uganda living with HIV is considerably lower than that among adults in Uganda living with HIV [8-10].

Mental health and substance use affect decisions regarding sexual and reproductive health (SRH) and can increase the risk for acquiring HIV infection [11-13]. It is estimated that mental illness contributes to an estimated 4- to 10-fold increase in the risk for acquiring HIV [14-17]. In Uganda, alcohol is the primary substance used, and the country has one of the highest per capita alcohol consumption rates in ESA [18,19]. Thus, in the proposed protocol, we primarily focus on alcohol consumption. It is widely recognized that designing interventions for addressing multiple HIV risk factors, including sexual and mental health and problematic substance use, is crucial to ending the HIV epidemic, yet few such interventions currently exist for adolescents and young adults in ESA [20]. Integrating screening for mental health and alcohol use problems with appropriate referral mechanisms into existing SRH interventions may be a feasible first step toward addressing this gap.

In Uganda, household mobile phone ownership has risen dramatically over the last 15 years, from approximately 10% in 2004 to 74% in 2020, yet few people own smartphones [21,22], with a similar pattern in the specific region of study [23,24]. SMS text messages can be sent or received using any mobile phone, and SMS text messaging is the most widespread means of communication in ESA [25,26]. Systematic reviews have indicated that SMS text messaging is a feasible and acceptable method for delivering health interventions [27] focused on substance use [28], mental health [29], and HIV prevention and care [30,31]. Mobile phone–based HIV interventions in ESA are well represented in the literature. However, most mobile phone–based interventions that focus on mental health and substance use have been implemented in Europe and the United States [27-29].

This Study

This study focuses on adolescents aged 15 to 19 years who are in secondary school in the greater Masaka region of Uganda. This is a critical developmental time for intervention, as many adolescents within this age range begin to leave school, search for work, and engage in sex and are thus at an increased risk for HIV infection [32-36]. This is also the age when, if at risk, symptoms of mental disorders typically emerge [37-40]. Consequently, this stage of adolescence is a critical time for preventive interventions, and our preliminary qualitative work shows the importance of mobile phones for finding sexual partners and the as-yet-underused potential for mobile phones

XSL•FO
RenderX

to promote health [23]. As noted earlier, mental health and alcohol abuse are associated with an increased risk for HIV infection. Thus, screening adolescents with mental health or alcohol use problems and linking them to counselors may help address these factors and reduce the risk for HIV infection. We identified the local mental health partner StrongMinds (authors CO, CT, CN, and VM). StrongMinds is an international nongovernmental organization in Uganda that offers free evidence-based, telehealth-based group interpersonal therapy [41-47].

Through our formative work described in the subsequent section, we used the ADAPT-ITT (assessment, decision, administration, production, topical experts, integration, training, testing) [48] framework to adapt and update a mobile phone–based SRH intervention. Our adapted intervention, named Kirabo, is also informed by the information, motivation, and behavior (IMB) model [49] and uses automated SMS text messaging to link adolescents to HIV testing and mental health counselors. Through the proposed research, we will evaluate the feasibility and acceptability of Kirabo and generate the preliminary estimates of Kirabo's efficacy in HIV testing. Adolescents today rely heavily on mobile phones for information and services; therefore, we believe that the proposed intervention could be applied and adapted across ESA and potentially in other underresourced settings [21,50,51].

Methods

Formative Work

We used the ADAPT-ITT [48] framework (Table 1) to adapt an existing evidence-based SRH mobile phone intervention, Mobile 4 Reproductive Health (m4RH), originally designed by FHI 360 [52-55]. Through our formative work, including discussions with our in-country research team (RK, OIN, and PN), we named our adapted intervention *Kirabo*, a Luganda-language gender neutral name that means "gift." In the subsequent section, a detailed description of the adaptation process is provided, including our summary of prior findings and context, a description of the Kirabo pretest, and the proposed design of our randomized controlled trial (RCT) pilot study. Researchers at the HIV Center for Clinical and Behavioral Studies at the New York State Psychiatric Institute (NYSPI) and Columbia University (CU), in collaboration with researchers at the Ugandan office of the International Center for Child Health and Development (ICHAD) at the University of Washington in St Louis, conducted this formative work. Study participants were recruited from secondary schools in southwest Uganda, one of the regions hardest hit by HIV [1]. This region is bordered by Lake Victoria. Most of the population (80%) lives in rural communities and engages in small-scale agriculture. Most of the population (75%) is aged under 30 years [56], and the Ugandan government policy supports HIV testing and PrEP for adolescents, whom they have designated a *priority population* [6]. In the region of study, HIV clinics provide free HIV testing, PrEP, and antiretroviral treatment, although the uptake of these services among adolescents and young adults is persistently low and HIV incidence has remained high [1,6,7,57].

Table 1. ADAPT-ITT[a] phases.

Phase	Methodology
1. Assessment (formative)	• Analyses of quantitative and qualitative secondary data
2. Decision	• Publish formative findings • Submit IRB[b] protocol
3. Administration	• Administer pretest in Uganda (24 adolescents and young adults)
4. Production	• Produce mobile phone–based EBI[c] draft 1
5. Topical experts	• Identify and review "product" with experts
6. Integration	• Integrate expert input to create pilot-ready EBI
7. Training	• Train staff to implement EBI draft 2
8. Testing and evaluation	• Pilot study • Initiate evaluation • Mixed methods: interviews, pre-post surveys, and mobile phone data

[a]ADAPT-ITT: assessment, decision, administration, production, topical experts, integration, training, testing.

[b]IRB: institutional review board.

[c]EBI: evidence-based intervention.

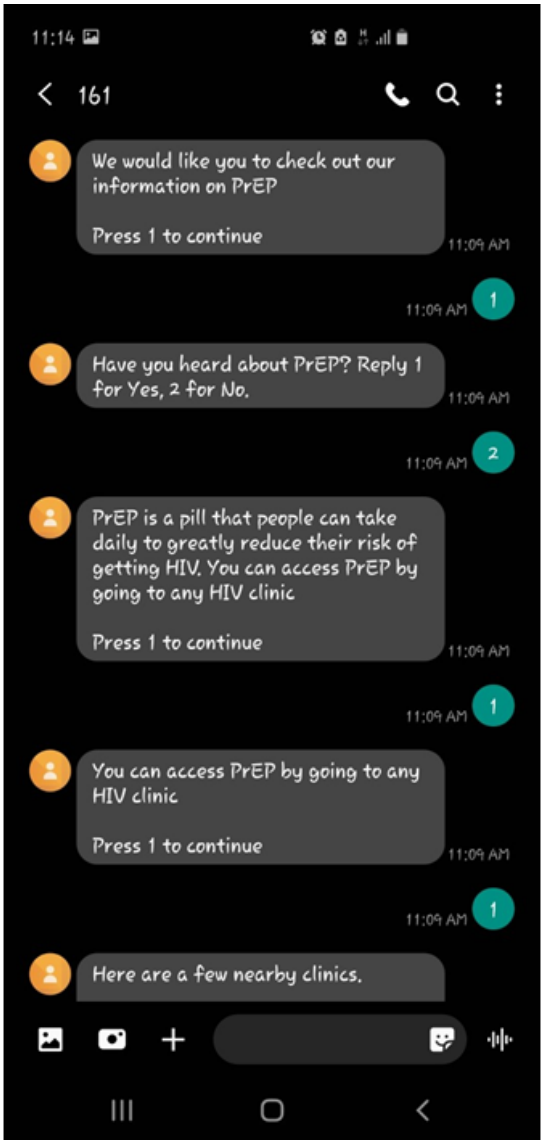
Phases 1 and 2: Assessment and Decision

Overview

We first conducted formative work that involved secondary data analysis of both quantitative and qualitative data to assess how mobile phones may be associated with health risks and may also present opportunities for intervention [23,58,59]. Through our longitudinal analyses among youths in southern Uganda, we found that for adolescents and young adults, mobile phone ownership was associated with social and health behaviors; adolescents and young adults who owned phones were more likely to have multiple and concurrent sexual partners, and adolescent and young adult men who owned phones were more likely to be circumcised [23,24,34,58]. Furthermore, our mixed methods analysis demonstrated how mobile phones were a key tool that adolescents and young adults used to make social and economic connections. In qualitative interviews, adolescents and young adults also expressed an unmet need for mobile phones to provide health information [23]. Adolescents and young adults in southern Uganda are highly mobile, as structural factors, such as the lack of available employment, force adolescents and young adults to move after they leave school and search for work [34]. Mobility makes it difficult to track adolescents and young adults for recommended health care services [8], and mobility is also associated with a greater risk of HIV infection [32-34]. Thus, mobile phones present an opportunity to reach adolescents and young adults with high mobility [25,26,34,50]. We identified m4RH as a candidate for adaptation. m4RH is an evidence-based [52-55] automated 2-way SMS text messaging and interactive voice response (IVR) platform that offers SRH information and links users to HIV clinics in East Africa [52-55]. IVR is an automated technology that allows incoming callers to access information via a voice response system of prerecorded messages. Communicating via the platform is free in Uganda and across East Africa owing to existing agreements between FHI 360, which designed the original m4RH platform, and the regional mobile phone service provider Airtel. However, m4RH was not specifically tailored to adolescents, and it did not include PrEP information, nor did it include any behavioral health elements.

The IMB Model

The IMB model [49] guided our design of new content for the adapted intervention. The IMB model posits that information (in this project, communicated through interactive SMS text messages), motivational factors, and behavioral skills (measured through self-efficacy and intentions) influence the adoption of a new behavior (HIV testing, PrEP uptake, and mental health counseling). Our adapted SMS text messages, beyond communicating basic facts, were organized through narratives, which appealed to emotions, imagination, and value systems [60-63]. Narrative components influence how people think, behave, and develop lasting health-related behaviors and, therefore, influence both information and motivational factors. In the IMB model, *motivational factors* include *positive outcome expectancies*, for example, starting PrEP will enable me to achieve future goals by protecting me from getting HIV; *negative outcome expectancies* are undesirable consequences (eg, HIV infection). Motivational factors that may be enhanced by engaging with the mobile phone platform include *perceived risk*; perceptions of *peer norms*, that is, whether a new behavior is perceived positively or negatively by important referents, such as partners, other women, or family; and *barriers to and facilitators* of adopting preventive behaviors. The IMB model also highlights the importance of increasing *behavioral skills* and a sense of self-efficacy in adopting prevention practices and persisting despite barriers. In short, self-efficacy is a person's confidence in their ability and skills to perform a behavior [64]. We posit that SMS text messaging via the platform will increase adolescents' self-efficacy by providing them with simple and direct information (including information about HIV prevention skills, clinic location and contact numbers, and information about behavioral health counselors), thus promoting their belief that they can perform the target behavior successfully (eg, going to the clinic and taking an HIV test).



Three Main Modifications

In Kirabo, we made the following three main modifications to the existing m4RH approach:

1. In prior work, m4RH was disseminated via radio and magazine advertisements and at family planning clinics [52,53,55,65]. To ensure that we reach the target population of adolescents for Kirabo, we partnered with local schools and will disseminate Kirabo at the schools or via SMS text messages. Our researchers will deliver an IMB-informed oral script, describing Kirabo in person at local schools and further disseminating Kirabo via flyers.
2. When m4RH was designed, PrEP was not available in sub-Saharan Africa. Thus, in Kirabo, we added and updated the existing m4RH HIV prevention menu to include the current information on PrEP and the location of local clinics. To create PrEP messages, we used text from the Centers for Disease Control and Prevention's (CDC) informational materials and published qualitative research studies [66-68]. Figure 1 displays an example of PrEP messages from Kirabo, with the numbers indicating user responses and menu selections. In Figure 1, Kirabo asks the adolescent the following question: "have you heard of PrEP? Reply 1 for Yes, 2 for No." The adolescent then replies "2," indicating that they had not previously heard of PrEP and thus triggering Kirabo to begin to describe PrEP. Furthermore, we added additional details, such as local landmarks, directions, and contact numbers for local HIV clinics. As part of this formative work, we contacted 6 HIV clinics in the southern Ugandan region. Of the 6 clinics, 5 confirmed that they were currently able to prescribe PrEP to adolescents according to the national guidelines and had ample PrEP medication in supply [69]. The clinic location and contact information were included in the adapted intervention.
3. Finally, because we know that mental health is critical to HIV prevention efforts, in Kirabo, we additionally focus on behavioral health. Adolescents will complete screeners, which are then used to tailor the SMS text messages they receive.

XSL•FO
RenderX

Figure 1. Pre-exposure prophylaxis (PrEP) messages.

For mental health, we will measure depression using the 4-item Patient Health Questionnaire (PHQ-4), which includes the first 2 questions of the 9-item Patient Health Questionnaire (PHQ-9) [70] and the first 2 questions of the 7-item Generalized Anxiety Disorder Questionnaire (GAD)-7 for assessing anxiety [71]. For example, question 1 of the PHQ reads, “over the last two weeks, how often have you had little interest or pleasure in doing things?” Possible responses range from “not at all (0)” to “nearly every day (3).” Individuals who score ≥1 on the first 2 questions of the PHQ-9 or GAD-7 will be directed to complete the full measure. If the respondents score 0 on the first 2 questions of these measures, the system will respond with a brief message thanking them for their time. To be cautious and consistent with StrongMinds’ approach, we will use a cutoff point of 8 on the PHQ-9 to determine a referral to a StrongMinds counselor. Additional information regarding these measures is provided in Table 2.

XSL•FO
RenderX

Table 2. Additional information regarding measures and their times of collection.

Construct	Measures	Time
Behavioral, mental health, and alcohol use measures		
Demographics	Items developed for previous Suubi studies [72-74], including age, sex, parents' occupation, household size, orphanhood status, primary caregiver, and community of origin	Baseline
COVID-19 experiences	CASPE[a] (adapted from Suubi+Adherence [74] and the study by Ladouceur [75])	Baseline
HIV testing	Self-report of HIV test (yes/no; past year [at baseline], during the study period [immediately after the intervention], and past 3 months [at follow-up]) confirmed with proof of results from the clinic using measures and procedures adapted from Suubi studies [72-74]	Baseline, immediately after the intervention, and 3-month follow-up
Intention to test for HIV	Questions adapted from a study of secondary school students in Uganda [76]	Baseline, immediately after the intervention, and 3-month follow-up
Self-efficacy	Questions adapted from a study with secondary school students in Uganda [76] and a study with high school students in the United States [77], including questions regarding self-efficacy in testing for HIV, trying PrEP[b], using condoms consistently, contacting a behavioral health counselor	Baseline, immediately after the intervention, and 3-month follow-up
Current HIV prevention strategies	This measure includes items developed for previous Suubi studies [72,73] in Uganda (in addition to a question regarding PrEP; range 5-25; 5 question items; α=.70), for example, "I think it is very important to use condoms every time one has sex," "as a teenager I think AIDS is a threat to my health," and "I think all people my age who have sex should use condoms." Scores range from 4: strongly agree; 3: somewhat agree; 2: somewhat disagree; to 1: strongly disagree.	Baseline, immediately after the intervention, and 3-month follow-up
HIV-related knowledge	This measure includes items from previous Suubi studies [72,73] in Uganda; this measure includes 13 items about HIV infection and prevention mechanisms (range 0-16; 16 question items; α=.83), for example, "HIV can be passed by an infected person even though that person is not feeling sick." Possible scores are 1: true; 2: false; and 3: don't know or 1: not sure; 2: unsafe; and 3: safe.	Baseline, immediately after the intervention, and 3-month follow-up
Sexual risk behaviors	This measure includes items from previous Suubi studies [72,73] in Uganda (range: 5-25; 5 question items; α=.76), for example, "I believe it's OK to have sex without protection with someone you know." Scores range from 1: never; 2: sometimes; 3: about half of the time; 4: most of the time; to 5: always.	Baseline, immediately after the intervention, and 3-month follow-up
PrEP knowledge	Adapted 13-item true-false questionnaire on PrEP knowledge [78,79] including questions such as "PrEP is a pill you can take to prevent HIV" and "PrEP is only for people who are HIV negative"	Baseline, immediately after the intervention, and 3-month follow-up
Depressive symptomatology	PHQ-9[c] [70], a standardized 9-item self-report instrument used to assess depression, is used. Participants rate the frequency of their symptoms over the past 2 weeks. Items are rated on a 4-point scale, ranging from 0 (not at all) to 3 (nearly every day), and scale scores range from 0 to 27. PHQ-9 scores of 5 to 9 represent minimal to mild depression and 10 to 20 represent moderate to severe depression. A score ≥10 has a sensitivity of 88% and a specificity of 88% for major depression.	Baseline and immediately after the intervention

XSL•FO
RenderX

Construct	Measures	Time
Anxiety	GAD-7[d] [71], is a standardized instrument that asks participants to rate their symptoms over the past 2 weeks on a 4-point scale ranging from 0 (not at all) to 3 (nearly every day), is used. Overall scores for the GAD-7 range from 0 to 21. At a cutoff point of 10 (indicative of clinically significant symptoms), the sensitivity and specificity of the scale equal 89% and 82%, respectively. The GAD-7 has a Cronbach α of.92, indicating good internal consistency, and an intraclass correlation of 0.83, indicating good procedural validity.	Baseline and immediately after the intervention
Alcohol use disorder screen	AUDIT-C[e] [80,81], a 3-item screener excerpted from the full standardized 10-item AUDIT tool for assessing hazardous alcohol consumption, is used. Items are scored on a 5-point scale for a possible score of 0 to 12. The higher the score, the higher the risk of hazardous alcohol consumption. AUDIT-C scores of ≥4 in men and ≥3 in women are considered positive for hazardous alcohol consumption.	Baseline and immediately after the intervention
Reported (and confirmed) sessions with mental health counselor	Self-report and local school and clinic records	Baseline and immediately after the intervention
Peer messaging	Self-report of messages shared with peers	Baseline and immediately after the intervention
Technological, feasibility, and acceptability measures		
Survey of acceptability	This measure, adapted from CyberSenga [82] (a mobile health HIV study with youths in Uganda), is a 12-item survey with a Likert scale of 1 to 3 (disagree, somewhat agree, and strongly agree).	Immediately after the intervention
Number of messages viewed	Retrieved via user database consistent with previous m4RH evaluations [54]	Continuous
Type of messages (regarding sexual health, mental health, and alcohol use)	Retrieved via user database consistent with previous m4RH evaluations [54]	Continuous
Mental health and alcohol use screens completed (AUDIT, GAD-7, and PHQ-9)	Retrieved via user database	Continuous
HIV clinic locator (number of times used)	Retrieved via user database	Continuous
Feasibility	Enrollment of recruited adolescents	Immediately after the intervention

[a]CASPE: COVID-19 Adolescent Symptom & Psychological Experience Questionnaire.

[b]PrEP: pre-exposure prophylaxis.

[c]PHQ-9: 9-item Patient Health Questionnaire.

[d]AUDIT-C: Alcohol Use Disorders Identification Test–Consumption.

[e]GAD-7: 7-item Generalized Anxiety Disorder Questionnaire.

Similarly, the GAD-7 [71] will be used to screen and measure the severity of generalized anxiety symptoms among participants. Through Kirabo, we will administer the first 2 questions of the GAD-7. Table 2 provides additional information regarding this measure. To be cautious and consistent with StrongMinds' approach, we will use a cutoff point of 8 to determine a referral to a StrongMinds counselor.

The 3-item Alcohol Use Disorders Identification Test–Consumption (AUDIT-C) [80] will be used to measure hazardous alcohol use (Table 2). Similar brief measures have been used and validated globally, specifically in East Africa and Uganda [18,83-89]. To improve user experience and consistent with the prior work described subsequently, screener length will be determined by an adolescent's response to initial questions. Table 2 provides additional details regarding the AUDIT-C [90].

In our initial version of Kirabo, if an adolescent screened positive for symptoms of depression, anxiety, or hazardous alcohol use, the adolescent was provided with the contact number of our mental health partner StrongMinds.

Phases 3 and 4: Administration of Pretest and Production

The ICHAD has research relationships with 70 secondary schools in the region, and a well-established protocol for recruitment is described subsequently. The field research team (RK, OIN, and PN) worked primarily out of the ICHAD offices in Masaka, Uganda. ICHAD researchers distributed flyers to

XSL•FO
RenderX

students and staff, noting that adolescents aged 15 to 19 years may be eligible to participate. Research team members with no relationship with students conducted the recruitment. Further, students did not receive any class credit or extra credit for participating. Students were compensated for their time at rates consistent with the ICHAD policies and in accordance with Ugandan and US ethics board guidance. Adolescents were compensated 8500 Uganda shillings (US $2.25) for participating in the mobile phone–based portion of the research, and adolescents who joined the focus groups were offered an additional 20,000 Uganda shillings (US $5.30). Teachers were not informed about which students were contacted and consented/assented to participate. We will use similar procedures to recruit for the RCT described subsequently. That said, if the current COVID-19 protocols or other factors result in the school not currently being in session, a head teacher may provide researchers with a list of students who have expressed interest and meet the age eligibility for a final screen by the research team.

To conduct the pretest, we recruited 24 adolescents (aged 15 to 19 years) from 2 secondary schools in southern Uganda. Over a 1-week period, the adolescents were prompted via a daily automated SMS text message, amounting to 5 prompts per week, to interact with Kirabo. We tested the following three different methods of contacting Kirabo: (1) through IVR by dialing 161, (2) through unstructured supplementary service data (USSD) by dialing *161#, or (3) through SMS text messaging by texting "Hi" to 161. IVR allows callers to access prerecorded messages through speech recognition. USSD is similar to SMS text messaging, except that the messages disappear after a texting session. Only adolescents with phone numbers registered in our study could access the messages.

Our daily automated SMS text messages described how the system could be accessed via IVR by dialing 161 or via SMS text messaging by sending "Hi" to 161. On each day of the 5-day pretest, our automated messages encouraged the adolescents to interact with a different component of the platform. Day 1 focused on HIV testing, day 2 focused on PrEP, day 3 focused on mental health, day 4 focused on alcohol use, and day 5 focused on HIV testing again. To select an option, the user should reply with a text using a keyword or code from the provided menu, for example, "press 2 for PrEP information." The platform then automatically responds with a text or an IVR message. Adolescents could choose to interact with Kirabo in English or Luganda, the most commonly spoken local language in the region. Adolescents were advised to use their phones outside school hours, and no adolescents reported conflicts with parents or school staff regarding their use of phones in our pretest. Figure 1 shows an example of how an adolescent could move through the PrEP messages.

During the 5-day pretest, of the 24 adolescents, 22 (92%) accessed Kirabo at least once. In total, adolescents accessed Kirabo 339 times: 145 (42.8%) times through USSD, 83 (24.5%) times through SMS text messaging, and 111 (32.7%) times through IVR. SMS text messaging had the highest rate of message category completion (meaning that an adolescent viewed and responded to all messages; see Figure 1 for a PrEP example), with 83% (69/83) of the access attempts successfully running from beginning to end, compared with 58% (82/145) for USSD and 61% (68/111) for IVR.

Of the 24 adolescents, 22 (92%) completed the behavioral health screeners. The PHQ-9 scores ranged from 0 to 17 (mean 3.99, SD 3.85), and 5 (21%) adolescents scored ≥10 and thus screened positive for clinically significant symptoms of depression. Among the 24 adolescents, 1 (4%) screened positive for suicidal ideation. Our project coordinator followed up with this adolescent and, as dictated by our emergency protocol, used the Columbia Suicide Severity Rating Scale (C-SSRS) [91] to assess suicide risk. The adolescent described that they no longer experienced suicidal ideation. The project director determined that the participant was at moderate risk and then linked the adolescent to an ICHAD mental health counselor for further evaluation and support.

The GAD-7 scores ranged from 0 to 15 (mean 4.39, SD 3.77), and of the 24 participants, 5 (21%) scored ≥10 and thus screened positive for clinically significant symptoms of anxiety. In total, 3 (12%) adolescents screened positive for both symptoms of anxiety and depression. No adolescents screened positive on the AUDIT scale, with scores ranging from 0 to 4 (mean 0.5, SD 1.01).

In focus groups with 19 (79%) of the 24 adolescents, 10 (53%) preferred SMS text messaging and 9 (47%) preferred USSD, noting that SMS text messages arrived more quickly and could be revisited because they were saved on the phone. A female student aged 15 years said, "if the messages are saved, it can help me to seek clarification of what I haven't understood. I can review those messages for me to understand them well." None of the adolescents preferred IVR, which had the most reported issues. The adolescents explained that IVR calls frequently dropped mid-call owing to poor phone service. This would require an adolescent to call back and start at the beginning of the menus. Not surprisingly, the adolescents expressed frustration when describing this process. In addition, although using IVR was free, some adolescents assumed that calling the IVR system would cost them money. Furthermore, adolescents were hesitant to call StrongMinds counselors because they did not want to incur charges. Some adolescents noted that receiving messages after chores in the morning was preferable, whereas the majority preferred to receive messages after school and in the evening.

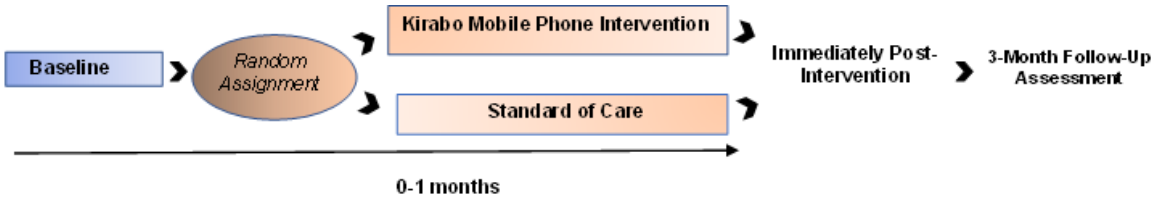
With regard to HIV prevention, most adolescents reflected that Kirabo helped them learn about PrEP and the health centers where they could access HIV services. As one of the adolescents succinctly explained, "it [Kirabo] is good because most of us have not been knowing what PrEP is." Another adolescent added, "the messages I liked most were those regarding PrEP. I got more clarification about PrEP because I only knew about a tablet that you take to prevent yourself from getting infected with HIV, but I didn't know its name." A third adolescent described how Kirabo "directed us to the nearest health facilities where a person can easily access HIV testing and PrEP services." These excerpts and the broader focus group discussions align with prior work showing an unmet need for mobile health HIV prevention interventions for adolescents in the region [23].

XSL•FO
RenderX

Phases 5 to 6: Consultation With Topical Experts and Integration

In addition to weekly meetings where author 1 discussed and designed the intervention and modifications with coauthors 2, 3, and 4, the first iteration of Kirabo was presented to a group of topical experts as part of an HIV Implementation Science and Inter-Centers for AIDS Research (CFAR) Fellowship program (2022-2023; P30AI094189). In the culminating session of this 9-month training program, author 1 presented pretest findings to 30 trainees (graduate students, postdoctoral fellows, and early career faculty) and 5 faculty mentors in person (Drs Sheree Schwartz, Stefan Beral, Patrick Sullivan, and JD Smith). This presentation was given in Baltimore, Maryland, on April 5, 2022. One of the audience members suggested that given the potentially sensitive nature of the messages, we should send a preliminary greeting message with no sexual or mental health content. Another point of discussion was to consider using a shorter follow-up period of 3months as opposed to the initially planned 6 months. Comments on the presentation in combination with our pretest findings led us to make the following three key changes to Kirabo in the proposed RCT:

1. Most adolescents preferred SMS text messaging. Thus, to streamline our delivery, recruitment, and evaluation, we decided to focus on SMS text messaging in this pilot RCT. In addition, to protect privacy, we added an initial message to be sent on each day of the intervention period that asked, “is this a good time to chat?” By contrast, the initial prompt from the pilot test immediately introduced the topic of the day (HIV testing, mood, etc). If adolescents respond with “yes,” then they would be sent the follow-up message that introduces the topic of the week. If adolescents respond with “no,” they would be sent a message that says, “ok thanks, write back with yes when you are free and available.”
2. In the pretest, adolescents who screened positive for symptoms of depression, anxiety, or hazardous alcohol were provided with the contact number of the general StrongMinds counselor. As described earlier, adolescents expressed concern that they would incur charges by calling StrongMinds counselors. Therefore, we revised our methods (including language in our consent forms), and in the RCT, we will provide a daily update to StrongMinds counselors with a list of contact numbers of adolescents who screened positive for symptoms of depression, anxiety, or hazardous alcohol use.
3. On the basis of our initial focus group discussions and our presentation at the HIV Implementation Science Fellowship, we expect that a 3-month follow-up will be sufficient to determine feasibility and accessibility. In addition, a shorter follow-up period will limit the possibility of unforeseen historical or COVID-19–related interruptions.



Phases 7 to 8: Training and RCT Pilot Study

Procedures

We plan to conduct a 2-arm, randomized controlled study via mobile phones among adolescents in the greater Masaka region of Uganda. We will compare Kirabo to an inactive control and evaluate whether adolescents who interacted with Kirabo had higher rates of self-reported HIV testing (yes/no; verified with the HIV clinic when possible) immediately after the intervention and at the 3-month follow-up assessment. Secondary outcomes include differences in condom use, PrEP knowledge, PrEP uptake for eligible patients, HIV-related knowledge and sexual risk behaviors, and antiretroviral treatment uptake for eligible patients. Exploratory aims include the number of participants who screen positive for symptoms of depression, anxiety, and hazardous alcohol use and the proportion of confirmed linkages to mental health counseling.

Adolescents (aged 15-19 years) in the greater Masaka region in southern Uganda who own a mobile phone will be eligible for the trial. Adolescents will be involved in the trial for approximately 5 weeks with a 3-month follow-up assessment (Figure 2). After informed assent and parental permission, the baseline assessment, and confirmation of eligibility, adolescents will be randomly assigned to the Kirabo intervention group or standard of care group. Randomization will be performed in a 1:1 ratio and stratified by gender and school (to minimize contamination) with a block size of 10. We anticipate recruiting students from 20 schools. The treatment assignments will be generated using a pseudorandom number generator. An electronic list of IDs, access codes, and credentials will be provided securely to the sites.

Figure 2. Timeline of participant involvement and measures.

Accessing Kirabo

Twice per week over the 5-week study period, Kirabo will send enrolled adolescents an SMS text message encouraging them to interact with our system. As noted earlier in the pretest, adolescents in the RCT can access Kirabo by sending the SMS text message “Hi” to #161 to initiate an interaction with Kirabo in English or Luganda. In the pretest, adolescents did not report any conflict with parents or school staff regarding their use of a mobile phone to interact with Kirabo.

XSL•FO
RenderX

Measures

Overview

To evaluate the intervention's impact, there will be 3 main assessment time points: baseline, immediately after the intervention, and 3-month follow-up. Table 2 provides a full list of measures. The primary outcome will be self-reported HIV testing, confirmed by HIV clinic records when possible. We will also measure the uptake of HIV prevention strategies (PrEP uptake and condom use) and, although we expect this to be a rare occurrence, the initiation of antiretroviral treatment. For adolescents who screen positive for behavioral health problems, we will confirm self-reports of linking to mental health care with a StrongMinds counselor.

Many of the measures have already been used, pretested, and made culturally appropriate to the Ugandan context in past studies [92,93], including current HIV prevention strategies and HIV-related knowledge. New measures, such as PrEP knowledge, will be adjusted according to the established ICHAD procedures. Specifically, to assess the uptake of HIV prevention strategies, we will compare presurvey and postsurvey scores from the current HIV prevention strategy measures that have been previously used in this region of Uganda with adolescents (Table 2) [72,73]. For questions measuring sensitive behaviors (ie, sexual risks), we will use audio computer-assisted self-interviews so that the participants may take the survey themselves on a minilaptop.

Behavioral Health Screeners via Mobile Phone

As in the pretest, behavioral health screeners will be delivered via adolescents' mobile phones and automatically scored by Kirabo. In addition, we will use the same measures of behavioral health in the baseline and 3-month follow-up battery.

Acceptability and Feasibility Measures

All adolescents in the intervention will complete the 15-item acceptability survey adapted from prior mental, sexual, and reproductive health work among adolescents in Uganda [94]. To further evaluate feasibility, we will use paradata and text count measures previously used by FHI 360 (Table 2) [54].

In addition to the quantitative measures included in Table 2, immediately after the intervention, we will conduct 30 key informant interviews (KIIs) with participants in the intervention group. The KII guide draws from the Consolidated Framework for Implementation Research (CFIR) [95,96], with a focus on the intervention characteristics and the outer setting, and will be adapted from our pretest KII guide. For example, through our pretest and subsequent focus groups, we identified the necessary changes to our intervention based on adolescents' descriptions of outer-setting barriers. Specifically, adolescents reported that they often experienced intermittent mobile phone service. Our earlier version of the mobile phone intervention that included IVR required callers to restart at the initial message each time they called in. Adolescents in our focus groups expressed that restarting the IVR each time a call dropped was cumbersome and frustrating. By contrast, adolescents found that SMS text messaging could be resumed wherever they had left off when their service resumed. Adolescents overwhelmingly selected SMS text messaging as their preferred means of interacting with Kirabo. Acceptability questions will probe adolescents' comfort with content and delivery methods. All adolescents in the intervention will complete the 15-item acceptability survey adapted from prior mental, sexual, and reproductive health work among adolescents in Uganda [94]. To further evaluate feasibility, we will use paradata and text count measures previously used by FHI 360 (Table 2) [54].

Statistical Analysis

Primary and Secondary Outcomes and Analysis

Summary statistics will be used to describe all metrics and compare them between the students receiving Kirabo and those in usual care at baseline, 1-month postintervention assessment, and the final 3-month follow-up assessment. Means and SDs will be used for continuous outcomes, followed by box plots, and frequency tables will be used for binary and categorical metrics. The primary analysis of this RCT will test whether postintervention HIV testing rates among the adolescents who interacted with Kirabo are significantly higher than those who received standard of care. We will use a generalized linear mixed model to determine statistical significance. In the model, the outcome is the binary indicator of whether an adolescent received an HIV test during or immediately after the intervention. We will also examine the differences between the model at the 3-month follow-up. The main predictor is the intervention assignment (Kirabo or usual care). The school will be included in the model as the random effect to adjust for within-school correlations. We will apply similar analyses to investigate the impact of Kirabo on the secondary outcomes.

Depending on the nature of the outcome, we will use different link functions in the generalized linear mixed model. We will use the identity link for continuous outcomes, the logistic link for binary outcomes, and the log function for ordinal outcomes. For incidence/frequency outcomes, a log function with adjustment for exposure time will be used. We will formally test whether the students in the 2 intervention groups have comparable baseline characteristics, including demographic factors, moderators, and variables measuring potential mechanisms of action (Table 2). If any of these variables are significantly different at baseline, they will be included in the model to adjust for their potential confounding effects.

Acceptability Power Analyses

The primary purpose of this pilot RCT is to determine whether Kirabo is acceptable (>70% of adolescents "agree" or "completely agree" with 70% of acceptability measure items) and feasible (enrollment >75%) in this setting. The 100 participants in the Kirabo arm will provide 80% power to detect the proportion of participants who meet the acceptability agreement threshold as significantly greater than 70% if the observed proportion of participants who meet this threshold is at least 83.5%.

Feasibility

The 100 participants in the Kirabo arm will provide 80% power to detect enrollment greater than 75% if the observed enrollment is at least 87.3%. These calculations assume a 1-sided

XSL•FO
RenderX

significance level of 5%. In addition, we will calculate summary statistics of the technological variables to describe feasibility, including paradata (eg, number of adolescents who ever contacted Kirabo out of the total sample and messages and types of messages viewed), and to assess behavioral health, we will divide the number of counselor calls attempted by the number of counselor calls completed. These measures will objectively show whether adolescents were able to use Kirabo.

Effectiveness Power Analysis

There is limited information on the impact of SMS text message–based interventions on increasing HIV testing among adolescents in rural Uganda. We expect that the baseline 12-month HIV testing rate among adolescents aged 15 to 19 years will be 26% [97]. With 200 students (intervention: n=100, 50%; standard of care: n=100, 50%) from 10 schools, we have 80% power to detect an average postintervention HIV test rate of ≥46% at the significance level of.05.

Handling of Missing Data

If more than 10% of the observations are missing, we will use multiple imputation strategy to accommodate missing data, followed by sensitivity analysis. The inclusion of cases with partial data is an important step because the intention-to-treat approach is planned to be the main analytic strategy for the primary aim of generating preliminary estimates of Kirabo's efficacy. If the statistical or clinical significance of treatment effects appears to differ depending on how missing data are addressed in the analyses, such findings will be reported.

Primary End Point Analysis for the Pilot RCT

We will recruit 200 students who own mobile phones and randomize them in a 1:1 ratio into intervention and control groups. The variables of focus are listed in Table 2. The primary end point is the binary indicator of whether there is an increase in HIV testing following the intervention. Chi-square tests will be used to determine whether intervention participants were more likely to take an HIV test in the past month. We will then build a logistic model to estimate intervention efficiency while adjusting for baseline characteristics, including baseline HIV prevention strategies, HIV knowledge, sexual risk behaviors, depression, anxiety, alcohol use, and demographics. The same analysis will be applied to the 6-month postintervention follow-up to determine the long-term effects of the intervention. These estimated parameters allow reliable estimates of sample size, power, and detectable effects for the subsequent study.

Secondary End Point Analysis

We will evaluate the change in behavioral health status and PrEP knowledge before and after the intervention and construct 95% CIs. Generalized linear mixed effect models will be used to reassess the intervention effect on these measurements while adjusting for the baseline characteristics age, gender, and other demographics. Finally, the same analysis will be applied to the 3-month postintervention follow-up measures to determine the long-term effects of the intervention. These estimated parameters allow reliable estimates of sample size, power, and detectable effects for the subsequent study.

Mixed Methods Implementation Analysis

We will use mixed methods, including systematic coding informed by CFIR [95,96], surveys, and paradata, to identify the specific elements of Kirabo that we hypothesize will be predictive of successful implementation [98]. This approach will inform the evaluation of the complex processes that motivate adolescents in underresourced settings to seek care. We will transform qualitative data into quantitative data for adolescent responses pertaining to the variables that IMB and CFIR dictate will be predictive of implementation outcomes. For instance, we will focus on constructs in adolescent KII responses that relate to perceived risks and benefits of care for mental health and alcohol use problems. In addition, for specific constructs, we will incorporate technological data, qualitative data, and referral to care data. We will then link users' actual paradata from their texts (eg, the number of intervention messages viewed) with our adapted m4RH program to their KII responses, survey responses on the perceptions of risk behavior before and after the intervention, and service-seeking rates. This approach will offer a deeper and complex understanding of the ways in which adolescents' beliefs impact their decision to seek care.

Ethical Considerations

The research staff obtained written informed consent from adolescents aged ≥18 years and personal assent and permission from adult parents/guardians for adolescents aged <18 years before study enrollment. The consent processes for adults and children were performed separately to avoid coercion. Both consent and assent forms were translated into Luganda (the most widely spoken local language in the study region) and back-translated into English to ensure consistency. Both the assent and consent processes were conducted verbally in Luganda, given that some caregivers and adolescents were illiterate. The study team received training on Good Clinical Practice (GCP) so that sensitive research activities could be handled appropriately. In addition, all interviewers completed the Collaborative Institutional Training Initiative (CITI) certificate and National Institutes of Health (NIH) certificate for the protection of research participants. All study procedures were approved by the NYSPI Institutional Review Board (IRB), the home institution of the principal investigator (PI), and the in-country local ethics board of the Uganda Virus Research Institute (UVRI; reference number GC/127/835). The ethics protocol was also reviewed and approved by the Uganda National Council for Science and Technology (UNCST; reference number SS969ES). This study was registered at ClinicalTrials.gov (NCT05130151).

Adverse Events and Safety Monitoring

The study will maintain records of adverse events and any referrals for counseling as well as copies of the consent and assent forms. All records will be maintained in a locked filing cabinet at the ICHAD Uganda field office and will be accessible only to the research team. The PI will be responsible for data security and record keeping. The data sets used for analysis will not contain any identifying information, specifically the names and addresses of the participants.

XSL•FO
RenderX

The HIV Center for Clinical and Behavioral Studies has a Performance and Safety Monitoring Board (PSMB) that consists of an independent group of experts. Currently, the members are Stephen Morin (chair), Joseph Hogan, Patricia Marshall, and Timothy Wilkin. The members of the PSMB serve in an individual capacity and provide their expertise and recommendations for studies involving human participants. The primary responsibilities of the PSMB are to (1) periodically review and evaluate the accumulated study data for participant safety; study conduct and progress; and, when appropriate, efficacy and (2) make recommendations concerning the continuation, modification, or termination of studies. The PSMB considers study-specific data as well as relevant background knowledge about the disease, test agent, or patient population under study. The PSMB has defined deliberative processes, including event triggers that would call for an unscheduled review, stopping procedures that are consistent with the protocol, unmasking (unblinding), and voting procedures. The event triggers include serious adverse events. The PSMB is also responsible for maintaining the confidentiality of its internal discussions and activities as well as the contents of reports provided to it. On November 9, 2022, Kirabo was presented to the PSMB. At that time, the PSMB had no concerns regarding the performance, monitoring, or safety of the study and recommended the continuation of the study as planned.

All study personnel based in Uganda will be trained in identifying indicators of conditions that may jeopardize the welfare of participants and the limits of confidentiality. This training, conducted by author FS and research staff, focuses on possible scenarios and key questions used to assess risk. Interview staff are trained to err on the side of caution and told to contact the project coordinator and the Masaka diocese in charge of schools, both of whom are always available, via telephone, in the event of the need to break confidentiality owing to an instance of mandatory reporting. Under the guidance of author FS, author OIN, and the parish priest, research staff are trained either to contact the police to ensure the safety of participants or, if appropriate, to have emergency personnel take the adolescent to the nearest hospital.

Adverse events will be reported according to a project protocol. In addition to the PSMB, described earlier, for this study, the PI (PK), the author FS, the project coordinator (author OIN, based in Uganda), and the parish priest (also based in Uganda) will oversee the safety and monitoring of adverse events. This group is expected to meet in person 3 to 4 times per year and will have weekly conference calls. In case of an adverse event, staff will inform the in-country project coordinator and the parish priest immediately and then the US-based PI within 24 hours (with substantial efforts made to also inform the PI immediately) of the occurrence of a possible unanticipated adverse event. Any occurrence of a possible unanticipated adverse event will be immediately reported and brought to the attention of the NYSPI IRB along with the UVRI Research Ethics Board and Ugandan National Council of Science and Technology IRB. The IRBs and PSMB will determine whether it is appropriate to stop the study protocol temporarily or will provide suggestions and modifications for the study procedures. Possible modifications may include adding new risks to the consent form and reconsenting all study participants.

Kirabo aims at HIV prevention and screening for mental health and alcohol use problems. Preliminary outcome data will be examined monthly by the PI (PK) and authors OIN, FS, JSS, and CAM. If preliminary outcome data indicate a harmful impact of the study on the participants (the adolescents), the NYSPI IRB, as well as the Uganda National Council of Science and Technology, will be notified, and it is possible that the study will be discontinued immediately. However, we do not anticipate any negative effects of participation at this time, as much of the proposed intervention is publicly available through m4RH without adverse events. In addition, findings from earlier studies guiding this application suggest an association with positive outcomes, such as increased knowledge of family planning approaches.

Data Management, Study Oversight, and Monitoring

Human participant protection and data safety are of utmost priority. The primary risk in this study is loss of confidentiality, and there is a possible risk of psychological discomfort or distress arising from the personal and potentially sensitive nature of the information elicited during interviews or intervention sessions. The level and probability of experiencing such risks are minimal, and the monitoring plan described in this paper is commensurate with these risks. All procedures and measures were approved by the UVRI Research Ethics Board and the UNCST as well as the IRBs at the NYSPI and CU and the HIV Center for Clinical and Behavioral Studies PSMB. In addition, the Kirabo intervention was also presented to and approved by the Ugandan Ministry of Health.

Results

Study recruitment commenced in August 2023 (N=200). Data collection and analysis are expected to be concluded by 2025, respectively. At the time of manuscript submission, no data had been analyzed. This trial was registered with ClinicalTrials.gov (NCT05130151), where the results are expected to be published from 2024 to 2025.

Discussion

Principal Findings

Kirabo begins to address the National Institute of Health Office of AIDS Research high priority area of reducing HIV incidence by targeting health disparities and comorbidities, as they challenge the efforts to end the epidemic. The first step in this direction is to promote HIV testing and increase mental health and alcohol use problem screening and linkage to counselors for adolescents and young adults who are symptomatic in regions with a high HIV seroprevalence and limited resources. As described in this protocol, we used the ADAPT-ITT [48] framework to adapt an existing evidence-based mobile phone–delivered sexual health program [54,65,99]. Through this process, including a pretest, we created Kirabo, a pathbreaking approach to link adolescents and young adults to local HIV clinics, PrEP, and mental health and alcohol use problem screening, with referral as needed.

XSL•FO
RenderX

Our pretest results were promising and suggest that it is possible to use school-based recruitment, and the IMB model [49] informed mobile phone SMS text messaging to integrate HIV prevention strategies and mental health care for adolescents and young adults in rural Uganda. The larger population included in our upcoming pilot RCT will provide a clearer understanding of the broad challenges that may impact feasibility and acceptability as well as initial estimates of the intervention effect size.

Mobile phones present an opportunity for contacting, providing information, and motivating adolescents and young adults to seek HIV and mental health care. Although not a panacea, mobile phones have been used for HIV-related sexual health and substance use interventions [100-103] and hold promise for adolescents and young adults who have limited access to the few and frequently overburdened mental health professionals in the region [104,105], specifically in Uganda [18,106,107]. A systematic review of digital innovations for HIV care and prevention noted the need for increased research tailored to context and population to reduce risky behaviors [30]. Furthermore, a review of mobile phone–based interventions in low- and middle-income countries found that they are feasible and improve both HIV and other sexually transmitted infection prevention and care [99]. Notably, a recent systematic review and meta-analysis of digital interventions for common mental disorders in low- and middle-income countries did not include a single study conducted in Africa [108]. The review authors called for future studies “to proactively tackle these challenges and prioritize evaluating digital interventions in low-income countries, especially in Africa, considering its rapidly growing population and potential” [108]. This RCT for evaluating a digital mental health intervention, Kirabo, in Uganda and other recent [109] and ongoing protocols [110] across the continent begin to address this disparity in research.

Limitations

There are some limitations to this protocol. The scope of activity and budget preclude a larger sample size to conduct a full analysis of intervention effectiveness and assess mediators and moderators. Additional studies will be needed to examine whether Kirabo could be implemented on a regional or national level. Further, the technological limitations in the region [23] prevent us from proposing a more interactive digital intervention. Another limitation is that the current protocol will be conducted over a relatively short period (5 weeks of intervention). Additional work could examine whether Kirabo was available for a year or longer and how the linkage to care might fluctuate as adolescents and young adults pass through developmental transitions, which could involve changes in their sexual relationships or potential levels of stress and need for counseling.

Despite these limitations, this protocol will provide preliminary estimates of Kirabo’s efficacy as a tool for promoting linkage to current HIV prevention and behavioral health care for adolescents and young adults who are susceptible to HIV. These preliminary data will serve as the basis for a larger R01 hybrid effectiveness trial [111,112], with the potential to use more advanced technology if it becomes available. This larger-scale trial would include a sufficient sample size to conduct a rigorous analysis of mediators and moderators and a longer-term follow-up to assess the impact of the mobile phone–based intervention on preventing HIV infection by promoting HIV prevention strategies and increasing linkage to care for sexual health, mental health, and alcohol use problems. Digital interventions such as Kirabo may increase access to effective biomedical HIV prevention (PrEP) and begin to address the disparities in access to behavioral health care for adolescents and young adults in Africa. Increasing access to prevention strategies and reducing factors that make adolescents and young adults susceptible to HIV acquisition can contribute to global efforts to end the HIV epidemic.

Acknowledgments

The authors extend their sincere thanks to the staff at the International Center for Child Health and Development (ICHAD) for monitoring and implementing this study. They are also grateful to the schools, participating children, and their caregiving families for agreeing to participate in this study. In addition, they are grateful to Reach the Youth Uganda and the Masaka diocese, their implementing partners. They would also like to express their gratitude for the training provided by the Inter-Centers for AIDS Research and HIV Implementation Science Fellowship (P30AI094189), specifically to mentor Patrick Sullivan for his guidance and encouragement. They thank David Eniola for his review of the manuscript and comments. They thank the Society for Research on Adolescence (SRA) COVID-19 Scholars Seed Grant and mentor Suman Verma for supporting the addition of a measure of COVID-19 experiences. They acknowledge the HIV Center for Clinical and Behavioral Studies at the New York State Psychiatric Institute and Columbia University (P30MH43520; principal investigator Robert Remien), specifically the Statistics, Assessment, and Data Management (StAD) Core and Martina Pavlicova and Cale Basaraba for their comments and assistance with the power calculations. They thank the National Institute of Mental Health for supporting this study (K01MH122319; principal investigator PK). The authors thank Jasmine Chan from the Institute for Implementation Science in Population Health (ISPH), Graduate School of Public Health and Health Policy, City University of New York (CUNY) for her assistance in revising and submitting this manuscript.

Data Availability

The quantitative data sets generated during this study will be made available in the National Institute of Mental Health (NIMH) Data Archive repository [113].

Authors' Contributions

With support and guidance from mentors JSS, CAM, and GW and advisers FS, YW, MY, and LWC, PK conceptualized and received funding for this study and led and supervised all aspects of study implementation. PK drafted the manuscript. PK, RK, OIN, CAM, FS, GW, YW, MY, CO, CT, CN, VM, LWC, and JSS reviewed and edited the manuscript. RK, OIN, PN, and FS supervised study implementation in the field. All authors reviewed the final draft of the manuscript for intellectual property.

Conflicts of Interest

None declared.

Abstract

Background: Alcohol misuse is common in the United Kingdom Armed Forces (UKAF), with prevalence significantly higher than in the general population. To date, digital health initiatives to support alcohol misuse have focused on male individuals, who represent approximately 89% of the UKAF. However, female veterans drink disproportionally more than female members of the public.

Objective: This 2-arm participant-blinded (single-blinded) confirmatory randomized controlled trial (RCT) aims to assess the efficacy of a brief alcohol intervention (DrinksRation) in reducing weekly self-reported alcohol consumption between baseline and a 3-month follow-up (day 84) among women who have served in the UKAF.

Methods: In this 2-arm single-blinded RCT, a smartphone app that includes interactive user-focused features tailored toward the needs of female veterans and designed to enhance participants' motivations to reduce the amount of alcohol they consume is compared with the UK Chief Medical Officer guidance on alcohol consumption. The trial will be conducted among women who have served at least 1 day of paid service in the UKAF. Recruitment, consent, and data collection will be carried out automatically through the DrinksRation app or the BeAlcoholSmart platform. The primary outcome is change in self-reported weekly alcohol consumption between baseline (day 0) and the 3-month follow-up (day 84) measured using the Timeline Follow Back for alcohol consumption. The secondary outcome is the change in the Alcohol Use Disorders Identification Test score measured at baseline and 3-month follow-up between the control and intervention groups. The process evaluation measures include (1) app use and (2) usability ratings as measured by the mHealth App Usability Questionnaire.

Results: RCT recruitment will begin in January 2024 and last for 5 months. We aim to complete all data collection, including interviews, by May 2024.

Conclusions: This study will assess whether a smartphone app tailored to the needs of women who have served in the UKAF is efficacious in reducing self-reported alcohol consumption. If successful, the digital therapeutics platform could be used not only to support women who have served in the UKAF but also for other conditions and disorders.

Introduction

Background

There are 2.5 million military veterans in the United Kingdom (defined by the British government as those who have served in the military for at least 1 paid day), of whom 11% are estimated to identify as female [1]. Female veterans have served in the United Kingdom Armed Forces (UKAF) for >100 years. Although their valuable contribution has been recognized by successive governments and improved military culture. However, with evolving service requirements, they have had a significant impact on the health and well-being of many female veterans [2,3]. Nevertheless, there is a dearth of evidence on the impact of alcohol use on female veterans' health.

The limited existing evidence suggests that female veterans' alcohol use is increasing and that they are significantly more likely to report symptoms of hazardous drinking than female civilians [4]. Increased rates of hazardous drinking were also observed by Palmer et al [5], who found that half of the female veterans (389/779, 49.9%) were misusing alcohol at a hazardous or higher level, which is considered harmful to their health [5]. To place this into context, the UK Chief Medical Officer recommends that people do not regularly drink >14 units per week to keep health risks from drinking alcohol to a low level.

Alcohol misuse often co-occurs with common mental health disorders, including posttraumatic stress disorder (PTSD), anxiety, or depression, and alcohol is frequently used as a coping mechanism [2]. Common mental health disorders are more common in female than male veterans [4]. Research has also shown that female veterans face barriers to accessing mental health support, often owing to misusing alcohol [6,7]. Ultimately, although female veterans drink less than male veterans, their rates of hazardous drinking are higher than those of the general population, putting them at increased risk of poorer health.

The impact of alcohol misuse among female veterans on the wider society (eg, health care use, productivity, and welfare) is unknown. In England, heavy drinking (deemed as drinking >14 units of alcohol/wk) is estimated to cost the National Health Service (NHS) £3.5 billion per year (US $3.9 billion; 3.6% of its annual budget) [8] and is more common in people with mental health difficulties [9]. As female veterans drink more than their civilian counterparts, the relative costs are likely to be even higher. Innovative solutions are urgently required.

In recent years, there has been a growing treatment gap in the United Kingdom, with patients waiting longer for treatment and support for alcohol misuse. To overcome this gap, we developed the DrinksRation platform [10], an automated brief digital intervention designed to support help-seeking veterans in managing and reducing the amount of alcohol they drink [11-14]. DrinksRation is unique in that the app content is tailored using behavior change techniques (BCTs) to promote positive changes in behavior. DrinksRation is the only app targeting alcohol misuse in the UKAF community. It is designed to (1) overcome geographic limitations, (2) use wearable technology (eg, Fitbit and Apple Watch) to inform decision-making and personalization, (3) avoid the stigma associated with receiving help in person, and (4) provide convenience because users can use the app as they prefer (discreetly or openly). The app is freely available on the Apple App Store and Google Play Store. The app has received support and endorsement from Combat Stress and is currently being trialed among serving personnel [15]. DrinksRation is supported by a robust evidence base, including a randomized controlled trial (RCT) that demonstrated that the app is efficacious in reducing alcohol consumption [12].

The DrinksRation app was developed to support veterans who have sought help for a mental health problem and was not designed with potential gender differences in mind. A recent viewpoint highlighted a critical need for feminist intersectionality in digital health to incorporate the unique needs of female individuals [16]. Digital health technologies can bolster gender equality through providing increased access to health care, empowering decision-making about one's health data, overcoming the specific barriers facing female veterans, and reducing the burden on health care systems [17-19].

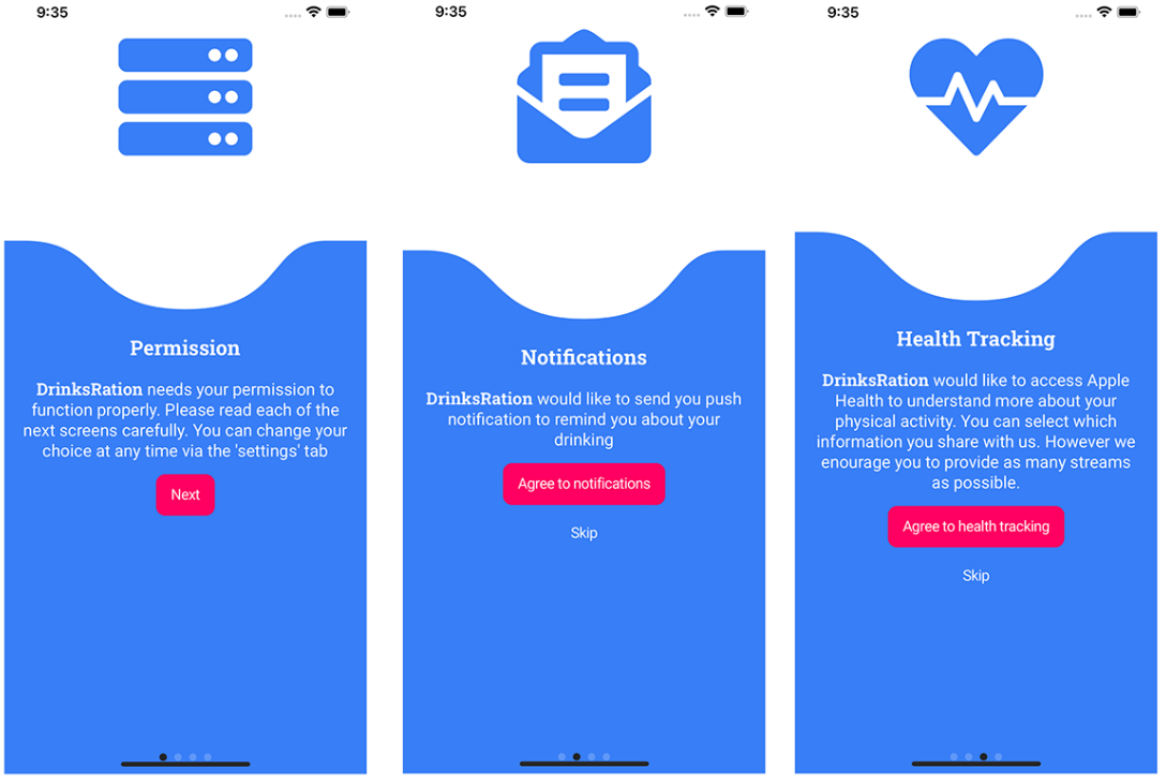
Objectives

This project aims to tailor the DrinksRation app to reflect the specific needs of female veterans and evaluate these changes using a confirmatory RCT. It is hypothesized that a refined version of DrinksRation will be efficacious at reducing self-reported weekly alcohol consumption between baseline and the 3-month follow-up (day 84) among female veterans who drink at a hazardous or harmful level.

Methods

Ethical Considerations

This study was approved by the ethics committee of King's College London (LRS/DP-22/23-36879). The study has been registered prospectively on ClinicalTrials.gov (NCT05970484). After completing outcome questionnaires (day 84) at the primary end point (day 84), participants will receive a US $25 (£20 GBP) Love2Shop voucher. There will be no cash alternative



XSL•FO
RenderX

offered to participants. We will seek informed consent from all participants via the eligibility and consent survey before the collection of any personal data. For participants in the intervention arm, we will additionally ask for specific on-device permissions to enable the full functionality of the DrinksRation app (eg, to receive push notifications or share health tracking data; refer to the example screenshots presented in Figure 1). Participants can change these optional permissions at any time via the settings page of the app.

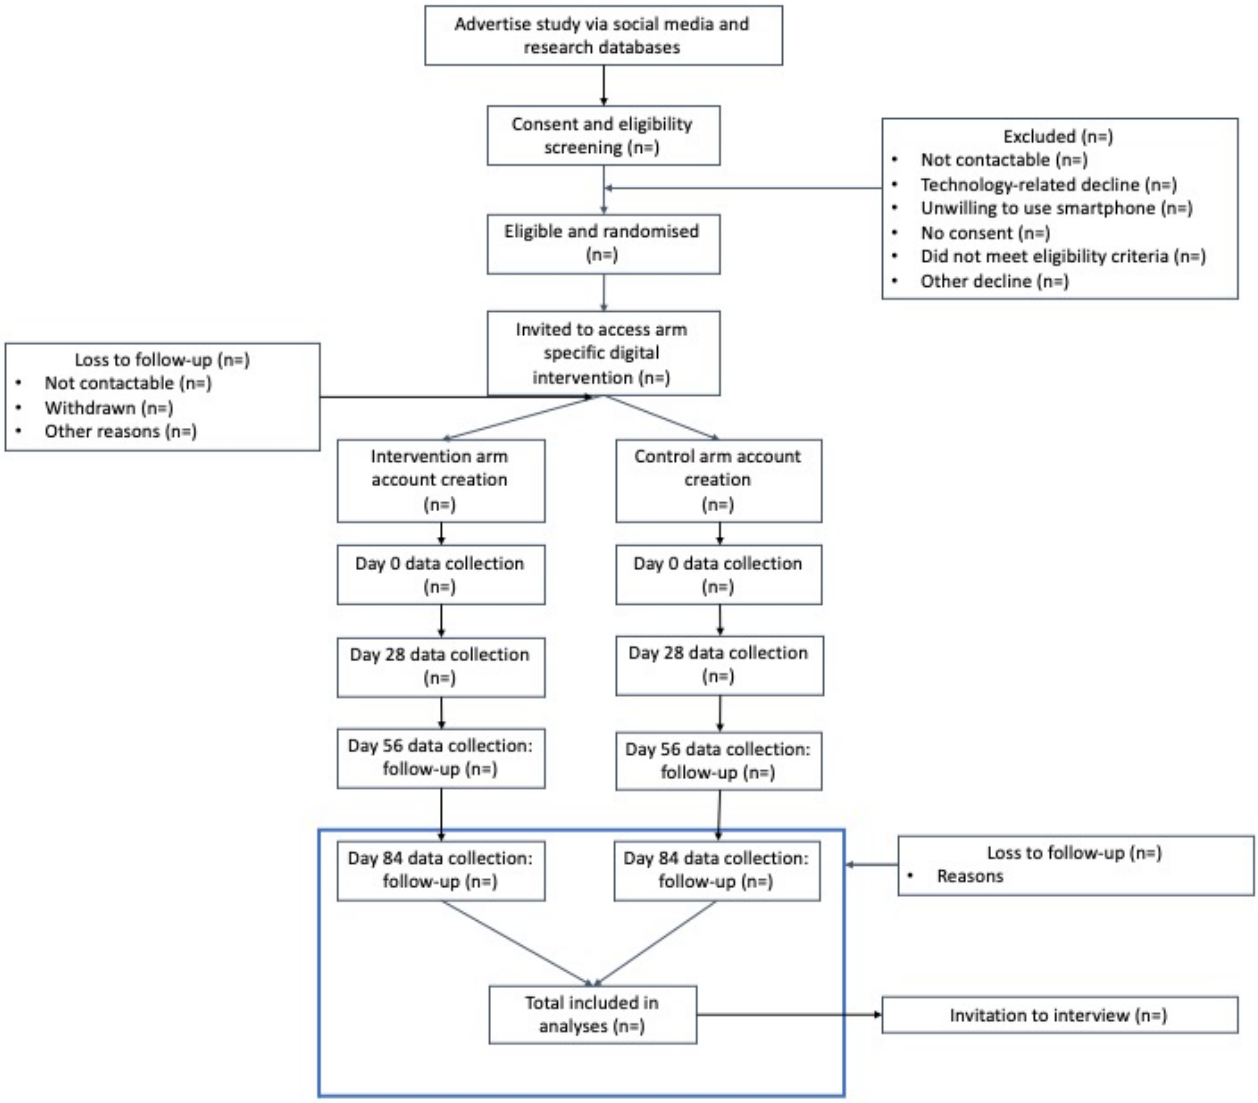
Participants will be informed via the participant information sheet that they can withdraw from the study or withdraw from data collection at any time. For participants who withdraw from the study, we will (1) attempt to collect follow-up information if they agree to continued data collection and (2) retain their existing data if they agree to their use. Alternatively, withdrawn participants can delete their study data by contacting the research team. Participants in the control arm will need to withdraw by contacting the research team, whereas those in the intervention arm can withdraw via the app.

If participants in the intervention arm withdraw, they will be asked to delete the intervention app and denied further access. All data, including those from withdrawn participants, except for those who make a request for their data to be deleted, will be included in the final analysis.

Figure 1. Consent flow screenshot examples presented to all study participants.

Study Design

Overview



This is a 2-arm participant-blinded (single-blinded) confirmatory RCT comparing the DrinksRation smartphone app (intervention arm) with a progressive web application (PWA) presenting NHS-focused drinking advice (named *BeAlcoholSmart*; control arm). The DrinksRation app provides individualized normative advice with features designed to enhance participant motivation, interactive feedback, self-efficacy in modifying their alcohol consumption, and personalized gender-specific messaging. We hypothesize that the intervention arm will be efficacious in reducing alcohol consumption compared with the control arm.

Both the control and intervention arms will be delivered digitally. Participants in the control arm will be given access only to a PWA that comprises a calculator for calculating alcohol units consumed over the previous week, generic public health guidance [20], and weekly reminders to use the calculator (refer to the *Control Arm* subsection for details). Participants in the intervention arm will be given access to the full enhanced DrinksRation app, which includes a range of theoretically driven features and behavioral change messaging (discussed further in the *Intervention Arm* subsection). We have designed this study so that the control arm resembles the intervention arm (eg, an app delivered digitally and usable on a smartphone) but lacks the active ingredients present in the DrinksRation intervention arm (eg, a drinks diary, interactive drinking feedback, and goal setting). This approach was selected to ensure consistency between the arms (both groups receive a digital intervention) and to facilitate participant blinding to treatment assignment.

Participants in both arms will be asked to use the digital interventions for 12 weeks (the intervention period; 84 days). Figure 2 presents the study flow and data collection points.

XSL•FO
RenderX

Figure 2. Study flow diagram. Primary outcome is assessed at day 84.

Intervention Arm

The DrinksRation (formerly called *InDEx* [13,14,21]) app was developed following the Medical Research Council's guidelines for developing and evaluating complex interventions and using a co-design methodology. It was developed by the King's Centre for Military Health Research (King's College London) and Lancaster University with support from experts in smartphone app development, epidemiology, addiction psychiatry, and military mental health. The app is designed to support veterans drinking at a hazardous or harmful level by providing bespoke advice and support.

The app seeks to enhance participants' motivation and self-efficacy in modifying their alcohol consumption using BCTs presented via the in-app content (Multimedia Appendix 1) and through messages sent to participants. The iterative development process, theoretical framework, feasibility trial, pilot, and RCT are reported elsewhere [11-14,21]. Briefly, DrinksRation was developed and tested with 5 core modules (Textbox 1; refer to Figure 3 for example screenshots).

The app is compatible with all modern iOS- and Android-supported devices. Participants in the intervention arm will complete all questionnaires via the app, including additional questionnaires on their mood and general mental health, which are used to personalize the app content and push notifications. Participants will receive push notifications every few hours on the day that each questionnaire is due to prompt the completion of unanswered questions.

XSL•FO
RenderX

Textbox 1. Core modules of the DrinksRation app.

Account management

- Participants can modify personal information (eg, first name and mobile phone number) and app parameters (eg, automatic log out, data-sharing permission, and withdrawing from the study).

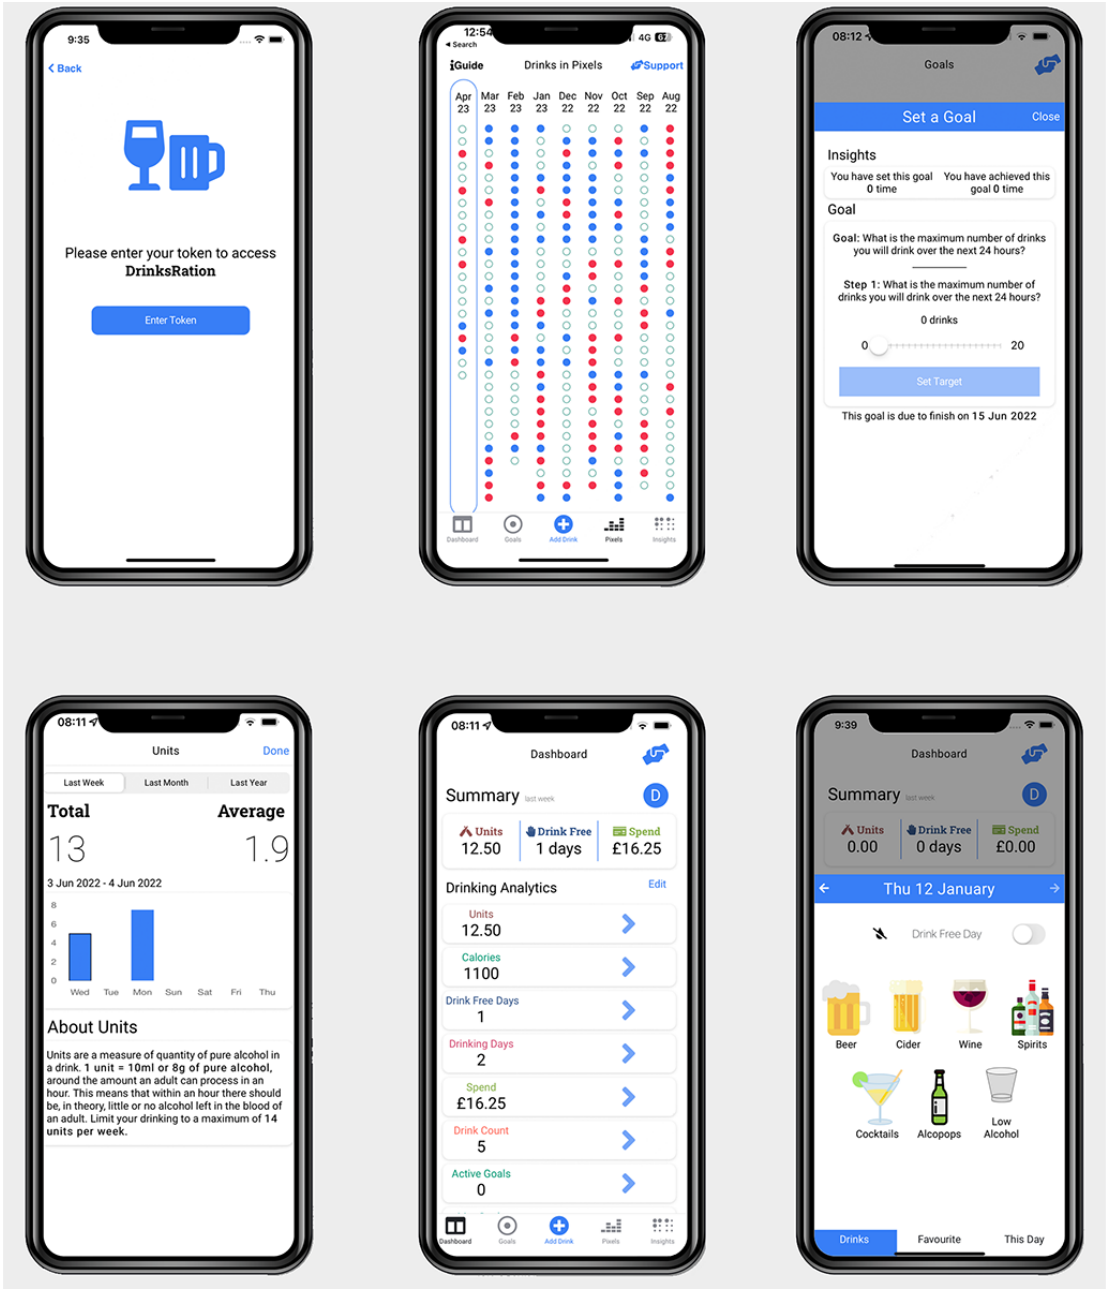
Questionnaire and individualized normative feedback

- This feature captures the participant's responses to a set of questions and aggregates the responses to produce personalized feedback on drinking behaviors.

Self-monitoring and feedback

- This feature records alcohol consumption by participants and provides a range of visual illustrations (eg, charts, figures, and text) to allow for the monitoring of consumption. Furthermore, the participant can select visual metrics relevant to their interest (eg, calories, cost, and exercise required).

Goals (setting and review)



- Participants can set goal or goals based on the implementation intentions (if and then) [22] methodology; visual feedback provides feedback on progress toward achieving the goal or goals set.

Personalized messaging

- Participants are sent tailored messages via push notification, which provide prompts to use the drinks diary, suggest alternative behaviors, and provide feedback on goals.

XSL•FO
RenderX

Figure 3. Example screenshots of the DrinksRation app.

Control Arm

The control arm will receive access to the BeAlcoholSmart PWA. A PWA is a website that looks and behaves like a smartphone app. The PWA can take advantage of smartphone features such as push notifications and haptics without requiring the participant to download it via an app store. The BeAlcoholSmart PWA will be accessible to participants in the control arm via a unique link. The app will contain a 7-day alcohol unit calculator and generic public health guidance on safe drinking [20]. Participants will also receive reminders via email prompting them to consult the guidance provided as part of the BeAlcoholSmart PWA. Control participants will be invited to complete all questionnaires via Qualtrics (Qualtrics International Inc), with an email reminder being sent when they are due.

Participant Co-Design

This study will evaluate an adapted version of the DrinksRation app that caters to the specific needs of female veterans. To ensure that any adaptations and new features are suitable for the target population, we will undertake participatory research—following the guidelines provided in the study by Bell and Pahl [23]—in the form of co-design and cocreation via a patient advisory board (PAB) and a stakeholder advisory board (SAB). The PAB will include those with lived experience of military service, whereas the SAB will include stakeholders and those representing the target population, such as charities treating alcohol misuse. PAB and SAB members will be recruited via our existing networks and communication channels.

We aim to recruit up to 5 members on both the PAB and SAB. Before undertaking any data collection, we will hold 2 roundtable discussions to collect input on the (1) development

XSL•FO
RenderX

of app content, (2) refinement of existing app content, (3) development of new app features, and (4) suitability of tailored messaging.

In addition to PAB and SAB discussions, we will also ask members of the PAB to provide iterative feedback on updates to the DrinksRation app, study protocol, and study findings. Furthermore, we will hold a PAB and SAB meeting every quarter to provide updates on the study progress and to promote research awareness. PAB members will receive a US $13 (£10 GBP) digital Love2Shop voucher for each video session they attend. It is important to note that PAB members will not be allowed to participate in the RCT.

Eligibility Criteria

The eligibility criteria are provided in Textbox 2.

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Aged ≥18 years
- Identify as female (self-reported sex)
- Live in the United Kingdom
- Consume ≥15 UK units (approximately 150 g) of alcohol/wk as measured using Timeline Follow Back for alcohol consumption [24] at baseline (day 0; the choice of a minimum threshold of 15 UK units of alcohol/wk reflects scientific research and UK national guidelines that indicate that regular drinking of >15 units/wk carries increased health risks [25])
- Are veterans of the United Kingdom Armed Forces (UKAF), defined as per UK definitions as having completed at least 1 day of paid employment in the UKAF (verified by self-report at eligibility screening)
- Have downloaded the mobile app onto an iOS or Android smartphone

Exclusion criterion

- Do not own a smartphone

Sample Size Calculation

A power calculation was performed based on previously reported data from the DrinksRation RCT [12]. With 148 participants (n=74, 50% per arm), we will have at least 80% power to detect a difference in alcohol consumption of 3 units (approximately 30 g of alcohol/wk) between the intervention and control arms at the 84-day follow-up assessment. This calculation assumes an SD of 5.6 units, an attrition rate of 40% by day 84, a correlation between successive follow-up assessments of 0.7, and an α of 5%.

We have chosen a minimum difference of 3 units based on treatment effects observed in similar studies [26-28] and in reductions observed in the DrinksRation feasibility trial [11] and the confirmatory RCT among help-seeking veterans [12], which found reductions at 28 days of 22 units between the arms. We have chosen a smaller minimum difference of 3 units, recognizing that treatment effects for brief interventions reduce over time and that the target population for this study is not a help-seeking population.

Recruitment

Participants will be recruited via an existing research cohort [26] and social media [29] following published recruitment strategies [29,30]. The research cohort will comprise participants from the King's Centre for Military Health Research health and well-being longitudinal cohort study [26], and participants will be sent an email inviting them to take part. We will also seek to recruit participants via paid promotional advertisements on social media (eg, Twitter, Facebook, and Instagram) with a link enabling potential participants to complete the eligibility and consent survey.

Potential participants who respond to the email invitation or social media advertisements will be sent an email containing an explanation of the study, a link to the participant information sheet, and an invitation to complete the eligibility and consent survey (Multimedia Appendix 2). Eligible participants will then be randomized (refer to the Randomization and Blinding subsection) and sent instructions on accessing the BeAlcoholSmart or DrinksRation app using a unique QR code. Once they have accessed the platform, they can register an account and complete the baseline questionnaire (day 0).

Randomization and Blinding

Randomization will be conducted automatically when a token code is generated alongside a unique proxy identifier (managed by researcher GW). At this point, participants are automatically randomized to receive the control or intervention arm and are blinded. The randomization procedure is carried out automatically via a randomization algorithm with no human involvement except to provide a proxy identifier. As allocations are generated dynamically, it is not possible to view future allocations. Researchers DL and GW will be unblinded to treatment allocation to enable the management of the BeAlcoholSmart and DrinksRation platforms as well as participant recruitment and retention, whereas researcher EC will be unblinded to treatment allocation to prepare statistical reports. Researchers DL and EC will not be involved in any participant engagement or recruitment. All other members of the study team will be blinded to treatment allocation.

Messaging: Push Notifications and Email Messaging

Participants in the intervention arm (DrinksRation) will receive personalized push notifications to prompt them to use the drinks diary, engage with the app, and complete outcome measures,

XSL•FO
RenderX

as well as to suggest alternative behaviors, provide feedback on goals, and promote a healthy lifestyle. We will use a bank of 180 messages developed previously [13], informed by the Health Action Process Approach framework and targeting specific BCTs.

DrinksRation uses baseline and weekly questionnaires to inform participant messaging and provide an individualized participant-centric approach. Baseline measurements are used to identify suitable messages, and as a participant engages with DrinksRation, regular measurements, including questionnaires (baseline and weekly questionnaires) and the drinks diary, are used to reflect current behavior and attitude. The notifications cover a wide range of topics to target beliefs and motivations with the primary aim of increasing the participant's awareness of their drinking habits and behaviors. The notifications are divided into 3 categories: tailored (personalized to drinking habits as well as baseline and weekly questionnaires), tailored and triggered (tailored to baseline and contiguous measurements and a specific event occurring), and targeted (generic; sent on specific days to highlight inactivity, to remind participants to complete a questionnaire, or to alert participants to a new feature).

The system automatically decides when a message should be sent.

For the control arm (BeAlcoholSmart), participants will only receive notifications (via email) when they join the platform and when outcome measures are due. The welcome email will contain information on how to use the BeAlcoholSmart platform and when future notifications will be sent. The questionnaire emails will include a reminder to consult the BeAlcoholSmart platform and complete a questionnaire. No other notifications will be sent.

Study Instruments

[a]I: intervention arm data collected via app.

[b]C: control arm data collected via Qualtrics (Qualtrics International Inc) through BeAlcoholSmart platform.

[c]PHQ-2: Patient Health Questionnaire-2.

[d]GAD-2: Generalized Anxiety Disorder-2.

[e]ITQ-PTSD: International Trauma Questionnaire for Posttraumatic Stress Disorder.

[f]AUDIT: Alcohol Use Disorders Identification Test.

[g]TLFB: Timeline Follow Back.

[h]A total of 10 participants will be invited to participate in a qualitative interview after day 84.

[i]MAUQ: mHealth App Usability Questionnaire.

[j]Additional participant consent is required.

Baseline Measures

After they have downloaded the respective platforms, participants will be asked to complete a baseline questionnaire to assess physical and mental health, readiness to change, self-efficacy, health status, and sociodemographics (eg, age, gender, ethnicity, employment status, and occupation). The questionnaire set is available in Multimedia Appendix 3, and the schedule is presented in Table 1.

Outcome Measures

The primary outcome in this study is self-reported alcohol consumption measured by the 7-day Timeline Follow Back for alcohol consumption. At baseline (day 0) and 28, 56, and 84 days after randomization, participants will be asked to report the number and types of drinks that they consumed in each of the previous 7 days via DrinksRation or BeAlcoholSmart. Using standard unit measurements (Multimedia Appendix 4), we will calculate weekly alcohol consumption for baseline and each follow-up by summing the number of units assigned to each drink. To maximize the completion of the primary outcome at each follow-up, participants will first be asked to complete the primary outcome measure before completing the rest of the questionnaire. The secondary outcome is the change in the Alcohol Use Disorders Identification Test score, measured at

XSL•FO
RenderX

baseline (day 0) and day 84 follow-up between the control and intervention groups.

Usability

We will examine the usability of the DrinksRation and BeAlcoholSmart platforms using the mHealth App Usability Questionnaire [37] at day 28. Questionnaire responses will be aggregated into (1) overall usability, (2) ease of use, (3) interface and satisfaction, and (4) usefulness. The results will be summarized with means and SDs.

Qualitative Interviews

A random sample of 10 participants from the intervention arm will be invited to participate in a debrief session with the research assistant (RA; researcher GW) at the end of the intervention period. The 60-minute interview will address the participants' experiences of using the DrinksRation app, their views on its acceptability and usability, and what further modifications could be made to improve their experiences of using the app. Interviews will be conducted on the web (via Microsoft Teams or Zoom [Zoom Video Communications, Inc]), and transcripts will be generated and used for analysis. A thematic analysis approach will be used. The findings from the qualitative interviews will be reported separately from the main trial results. Any participant who completes the day 84 outcome measure will receive a US $13 (£10 GBP) Love2Shop voucher as a gesture of goodwill.

Adverse Events

It is not expected that participation in this study will lead to an increase in alcohol consumption or any untoward or unintended consequence. In this study, we have defined 4 categories of risk events (Textbox 3).

Adverse events and serious adverse events will be monitored throughout the intervention period via (1) direct contact between participants to the research team; and (2) a questionnaire presented to participants via the app on days 28, 54, and 84 after randomization. All reported events will be reviewed by a clinician (researcher DM), who, where required, will contact participants to perform a clinical interview and risk assessment. If concerns remain, a signposting booklet to relevant charities will be provided to the participants. The study RA will remove potentially unblinding information before sending it to the study clinician. The study clinician or the RA may register an adverse event based on the definitions outlined in Textbox 3.

Textbox 3. Categories of risk events.

Adverse event

- Any untoward medical occurrence in a trial participant that does not necessarily have a causal relationship with this treatment (eg, consuming >25 units of alcohol in a 24-h period).

Adverse reaction

- Any untoward and unintended medical occurrence in a trial participant that is related to the intervention (eg, reaction to a questionnaire).

Unexpected adverse reaction

- An adverse reaction where the nature and severity of the reaction are inconsistent with the information known about the study.

Serious adverse event, serious adverse reaction, or unexpected serious adverse reaction

- Any adverse event, adverse reaction, or unexpected adverse medical event reaction that (1) results in death, (2) is life threatening or requires immediate safeguarding, (3) requires hospitalization or prolongs existing hospitalization, or (4) results in persistent or significant disability or incapacity.

Project Management Group

Project oversight will be provided by a project management group (PMG). The PMG will be chaired by the principal investigator and attended by all coinvestigators. The PMG will meet every quarter and will be responsible for all aspects of project management, including (1) monitoring the delivery of the scientific results needed to progress the study; (2) monitoring the study against the schedule and act if required; (3) monitoring the study against agreed milestones and the identification of risks to achieving milestones as well as solutions for managing risks and issue resolution; (4) providing access to appropriate resources necessary for project progression, including internal and outsourced resources and the management of these resources; and (5) regular review of a blinded report from the study clinician about adverse and serious adverse events (ie, total numbers pooled across arms).

PMG members will be blinded to treatment allocation.

Executive Steering Committee

An executive steering committee will oversee safety requirements and make recommendations to the PMG. This committee will consist of an independent chair and the study clinician. The committee will receive regular reports from the trial statistician (researcher EC) and the RA on risk and appraise study functions. Concerns and recommendations will be raised with the principal investigator and discussed at PMG meetings.

Protocol Amendments

Protocol amendments will be discussed and approved by the PMG as well as the PAB and minuted. They will be reported in subsequent closed reports (eg, prepared by the unblinded trial statistician). Any approved amendments will be submitted to the King's College London ethics committee for approval and published on the Open Science Framework.

Statistical Analysis

We will describe participant characteristics using appropriate summary statistics (eg, frequency and percentage for categorical items and mean and SD or median and IQR for continuous items).

We will analyze the primary outcome using a linear mixed effect model. The outcome will be the 3 repeated outcome assessments (collected on days 28, 56, and 84). The model will include (1) the baseline measure of the outcome (day 0); (2) a dummy variable indicating treatment allocation (0=control arm and 1=intervention arm); (3) time, measured as weeks since baseline; (4) a treatment × time interaction; and (5) baseline characteristics associated with missingness. The model will additionally include a participant random intercept to account for repeated assessments clustered within individual participants and an unstructured residual covariance matrix. The mixed model will use all available information, retaining participants with at least 1 follow-up assessment, to improve efficiency. Treatment effects (adjusted between-group mean differences in alcohol units) will be estimated from the model for each follow-up separately. Cohen *d* effect sizes at 28, 56, and 84 days will be calculated as the adjusted mean difference divided by the sample SD of the outcome at baseline. The threshold for statistical significance is $P<.05$.

The intention-to-treat analyses will include all participants who complete at least 1 follow-up assessment (day 28, day 56, or day 84).

Analyses will be conducted using Stata (StataCorp LLC) or R statistical software (R Foundation for Statistical Computing).

Process Evaluation

We will examine process evaluation measures as a proxy for app use. These will be reported in three categories: (1) app use based on app analytics data provided by Google Analytics, (2) drinking analytics based on server interactions, and (3) notifications sent by the server. Where appropriate, these will be summarized as either median with IQR or mean with SD.

Access to Study Data

All study data will be made available in an anonymized format alongside any source code via the Open Science Framework. There are no contractual agreements that limit access to, or the sharing of, data.

Data Management

Data collected in this study will be stored on Google Firebase servers located in the United Kingdom, with audited and copied in real time to Google BigQuery data storage to ensure data integrity. Access to these systems is protected using Google authentication and a zero-trust modal. Upon completion of the study, data will be extracted from the Google Firebase servers and Google BigQuery and compared for assurance and data quality.

During active data collection, the research team (DL and GW) will monitor incoming data to ensure that each platform functions correctly. The research team will not contact participants outside of automatic messaging unless they reach out to the research team with queries (managed by GW; eg, with technical issues concerning how to perform a task or if risk alerts are triggered).

Results

RCT recruitment will begin in January 2024 and last for 5 months. We aim to complete all data collection, including interviews, by May 2024. The results of this study will be communicated via publication, lay articles disseminated via stakeholders and collaborators, and a participant newsletter.

The study will be reported following the TIDieR (Template for Intervention Description and Replication) [38] checklist as well as the CONSORT (Consolidated Standards of Reporting Trials) [39] and CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) [40] checklists.

Discussion

Summary

This project aims to tailor the DrinksRation app to reflect the specific needs of female veterans and evaluate these changes using a confirmatory RCT. We hypothesize that a refined version of DrinksRation will be efficacious at reducing self-reported weekly alcohol consumption among female veterans who drink at a hazardous or harmful level. Alcohol misuse is a persistent problem in the UKAF, with estimates forecasting that >50% of those who have left the UKAF meet the criteria for hazardous alcohol use. This is almost double that of the general population [41] and higher in female veterans. Innovative digital interventions can be used to great effect to meet this growing demand for support and treatment for alcohol misuse [42,43].

Currently, there are no smartphone-based alcohol interventions targeting female veterans of the UKAF to reduce alcohol misuse. Therefore, we propose to refine DrinksRation—a theory-driven and user-centered smartphone app—to address this gap for female veterans. Although DrinksRation has been tested in a largely male population, there has been little focus on female veterans. This study protocol describes the design of an RCT to determine the efficacy of DrinksRation among a female veteran population.

The Ministry of Defence Research Ethics Committee and the National Institute for Health and Care Research have identified female veterans as an underserved group regarding support and treatment for alcohol misuse. This is often due to medical services targeting male counterparts, failing to target specific female barriers to care, and a general lack of awareness of female motivations for drinking [17,18,44]. Given the limited evidence to date, there is an urgent need for innovation to support female veterans.

A key strength of this study protocol is the collaboration among the charitable sector, stakeholders, academia, and the UKAF, enabling the development and public release of DrinksRation. A further strength includes remote delivery via a smartphone to overcome issues related to availability or geographic

XSL•FO
RenderX

limitations for participants. Furthermore, DrinksRation is unique in that it uses personalized push notifications to promote positive changes in behavior among participants [45]. This ensures longer-term engagement and adherence. DrinksRation can also be used on any iOS and Android device released in the last 7 years. However, owing to personalization, the app requires an active data connection to function.

This study will not be without challenges, the first of which concerns our ability to recruit and retain a sufficient number of female veterans to power our analysis. This is due to a known issue: many of those who have alcohol-related problems are reluctant to seek help to ameliorate their problems. We planned our recruitment approach following best practice and our prior experiences in recruitment to mitigate this issue. Furthermore, the app has been designed to promote its active use, with frequent reminders, which is expected to promote adherence to the app. Second, we expect that some participants may encounter technical issues related to the app (eg, unable to log drinks or receive notifications) or the mobile device. To mitigate potential technical or mobile device issues, we have undertaken extensive testing across a range of popular mobile devices, and we will allow participants to provide in-app feedback that will be regularly monitored by the research team. Third, participants may reduce engagement or disengage in the control arm because BeAlcoholSmart is a static service. We will mitigate this by promoting its use to participants and ensuring that all information and data are presented appropriately. Finally, we acknowledge that our sample comprises participants who may be undergoing active treatment. To mitigate this risk, we will measure and describe the number of participants in each arm already receiving treatment for alcohol.

Open Access Statement

For the purposes of open access, the author has applied a Creative Commons attribution (CC BY) license to any accepted author manuscript version arising from this submission.

Conclusions

If this study is successful, the DrinksRation platform along with its refined features could be used not only to support women who have served in the UKAF but also for other conditions and disorders.

Acknowledgments

This study has been funded by the Office for Veterans' Affairs (OVA). Combat Stress, a national charity in the United Kingdom that provides clinical mental health services to veterans, has provided sponsorship to the DrinksRation app to cover computing costs. NTF is partly funded by the UK Ministry of Defence. SD and DL have received funding from the OVA Veterans Health Innovation Fund. The views expressed are those of the authors and not necessarily those of the Forces in Mind Trust, the National Health Service, the UK Ministry of Defence, or the OVA.

Data Availability

Data and code syntax arising from the randomized controlled trial will be made available via the Open Science Framework.

Authors' Contributions

DL, EC, NTF, LG, and DM conceptualized the study. GW, DL, EC, NTF, LG, and DM were responsible for the methodology. DL and GW were responsible for the software. DL, EC, NTF, LG, and DM wrote the original draft. DL, EC, NTF, KK, AS, LG, and DM reviewed and edited the draft. DL and EC supervised the study. GW and DL were responsible for project administration. DL, EC, NTF, LG, and DM were responsible for funding acquisition.

Conflicts of Interest

DM is a trustee of the Forces in Mind Trust and is employed by Combat Stress. NTF sits on the independent group advising on the release of patient data at National Health Service Digital and is also a trustee of a military-related charity. KK and AS are full-time member of the UK Armed Forces. DL is a reservist in the UK Armed Forces; this work has been undertaken as part of his civilian employment. SD is a member of the Office for Veterans' Affairs (OVA) Academic Advisory Board and sits on the Forces in Mind Trust Mental Health Steering Group. All other authors declare no other conflicts of interest.

Abstract

Background: Although gaming is a common arena where children socialize, an increasing number of children are exhibiting signs of problem gaming or internet gaming disorder. An important factor to the development of problem gaming is parent-child relationships. A cognitive behavioral therapy–based form of treatment, labeled relapse prevention, has been developed as a treatment for child and adolescent problem gaming or internet gaming disorder. However, no study has evaluated the effect of this treatment among Swedish children and youth nor the role of the parent-child relationships in this treatment.

Objective: This study aims (1) to evaluate a relapse prevention treatment for patients showing signs of problem gaming or internet gaming disorder recruited from child and youth psychiatric clinics and (2) to test whether the quality of parent-child relationships plays a role in the effect of relapse prevention treatment and vice versa—whether the relapse prevention treatment has a spillover effect on the quality of parent-child relationships. Moreover, we explore the carer's attitudes about parent-child relationships and child gaming, as well as experiences of the treatment among the children, their carers, and the clinicians who carried out the treatment.

Methods: This study is a 2-arm, parallel-group, early-stage randomized controlled trial with embedded qualitative components. Children aged 12-18 years who meet the criteria for problem gaming or internet gaming disorder will be randomized in a 1:1 ratio to either intervention (relapse prevention treatment) or control (treatment as usual), with a total of 160 (80 + 80) participants. The primary outcomes are measures of gaming and gambling behavior before and after intervention, and the secondary outcomes include child ratings of parent-child communication and family functioning. The study is supplemented with a qualitative component with semistructured interviews to capture participants' and clinicians' experiences of the relapse prevention, as well as attitudes about parent-child relationships and parenting needs in carers whose children completed the treatment.

Results: The trial started in January 2022 and is expected to end in December 2023. The first results are expected in March 2023.

Conclusions: This study will be the first randomized controlled trial evaluating relapse prevention as a treatment for child and adolescent problem gaming and internet gaming disorder in Sweden. Since problem behaviors in children interact with the family context, investigating parent-child relationships adjacent to the treatment of child problem gaming and internet gaming disorder is an important strength of the study. Further, different parties, ie, children, carers, and clinicians, will be directly or indirectly

XSL•FO
RenderX

involved in the evaluation of the treatment, providing more knowledge of the treatment and its effect. Limitations include comorbidity in children with problem gaming and internet gaming disorder and challenges with the recruitment of participants.

Introduction

Background

In 2013, internet gaming disorder, a syndrome of dysfunctional gaming behaviors that result in distress and affect personal, social, and educational functioning, was included in the appendix of the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) [1] as a disorder that needed further research. Although the prevalence of internet gaming disorder is generally low, an increasing number of children who play digital games exhibit problematic gaming behaviors [2], which often result in dysfunctional social behaviors and mental health problems [3]. Delivering high-quality treatment for children with internet gaming disorder is key. This protocol describes a Swedish research project in which we will implement and evaluate an intervention labeled relapse prevention among children at Swedish child and youth psychiatry clinics.

Gaming, or playing offline or online digital games, has received a lot of attention from researchers and professionals in recent years. In Sweden, 68% of Swedish 13-16–year-old children and 55% of 17-18–year-old adolescents play computer games every day [4]. Gaming has become a common everyday arena where children and young people interact and socialize with others. Although some research suggests that gaming could be associated with more positive psychological outcomes, such as a stronger sense of belonging [5] and higher intelligence [6], other studies indicate that gaming can be linked to poor developmental outcomes such as physical and mental illness in adolescence [3]. Indeed, a small proportion of those who play digital games show a problematic development trajectory, similar to that of substance addiction, which is one of the reasons for including internet gaming disorder as an addiction diagnosis in the DSM-5 [1]. The diagnosis is phrased as "a persistent and recurrent use of the Internet to engage in games, often with other players, leading to clinically significant impairment or distress as indicated by five (or more) of the following criteria in a 12-month period: Preoccupation with gaming, withdrawal symptoms when gaming is taken away or not possible (sadness, anxiety, irritability), giving up other activities or continuing to game despite problems" [1]. Although the prevalence of problem gaming and internet gaming disorder in Swedish children and adolescents is to date unknown, a large European study with 12,938 children of 14-17 years of age reports that 5.1% exhibit problem gaming behaviors by fulfilling up to 4 criteria for internet gaming disorder, whereas 1.6% meet all the criteria for internet gaming disorder [7]. As many digital games are aimed at children, whose cognitive development means they are not always well equipped to deal with the instant gratification of most computer games [8], it is expected that problem gaming among children and adolescents will rise.

A development in the clinical management of the more well-established diagnosis of gambling addiction involving money [9,10] has brought attention to the possible association or co-occurrence of gambling, digital gambling, and problem gaming [11], not least given the development of in-game features such as loot boxes, ie, game-related purchases with a chance-based outcome. Moreover, earlier studies suggest that important correlates to child and adolescent problem gaming are male gender [12], neuropsychiatric disorder [13], difficulties with cognitive regulation [14], and substance use [15]. In addition, as parent-child relationships play an important role in child development [16], relationship features such as parent-child bonds and parent-child communication seem to be critical in terms of the development of problem gaming and internet gaming disorder [17]. Children with close parent-child bonds and open parent-child communication could more easily be offered and accept support from their parents, which subsequently could help them control their gaming behaviors. These factors need to be acknowledged both in routine practice as well as in the development of treatment for children and adolescents with problem gaming or internet gaming disorder.

To date, there is no gold standard treatment for children and adolescents with internet gaming disorder. Cognitive behavioral therapy (CBT) is, however, often identified as a first-line treatment for problem gaming, offering patients help with recognizing triggers and cues for gaming, and for understanding and controlling their gaming behaviors [18]. A CBT-based form of treatment, relapse prevention [19,20], has been developed as a treatment for child and adolescent problem gaming and internet gaming disorder. The relapse prevention program, which includes 3 to 8 sessions, has a motivational and relapse-prevention approach [19] where the therapist explores the target, ie, the problem behavior of the individual. Such program is traditionally used as a tertiary (or indicated) intervention strategy, meaning that such preventive effort is used to alleviate the impact of an ongoing problem and to prevent more complications. Relapse prevention treatment is often provided in outpatient clinics, for reducing the likelihood of relapsing into addiction and substance abuse. It is considered among the most effective preventive efforts for substance addiction [20] and works by teaching the individual to identify both internal and external cues to prevent future relapses in

XSL•FO
RenderX

similar situations. We hypothesize that by targeting these mechanisms, the treatment could also be effective in treating children and adolescents with problem gaming and internet gaming disorder, because of the similarities of these behavioral addictions to substance addiction.

The effect of an intervention such as relapse prevention could, however, be dependent on the general quality of parent-child relationships and interactions between parents and their adolescent children, such that adolescents with strong family bonds and open parent-child communication would be likely to have more promising outcomes than adolescents with poor family bonds and communication. In that sense, the parent-child relationship could be an important moderator for the effectiveness of an intervention. In addition, given that adolescent development happens in interaction with their environment, such as family and more specifically parents [16], it is also possible that an intervention aimed at adolescents would also have a spillover effect on their environments where parent-child relationships are included. In that sense, not only would the individual benefit from such an effort, but the entire family would as well. Although such ideas seem compelling, they have not been tested in a context of gaming or relapse prevention.

Aim and Objectives

The aim of the study is twofold: (1) to evaluate a relapse prevention treatment for patients with problem gaming and internet gaming disorder recruited from child and youth psychiatry clinics across southern Sweden (Region Skåne) and (2) to test whether the quality of parent-child relationships plays a role for the effect of relapse prevention treatment and vice versa—whether the relapse prevention treatment has a spillover effect on the quality of parent-child relationships.

The specific objectives are to:

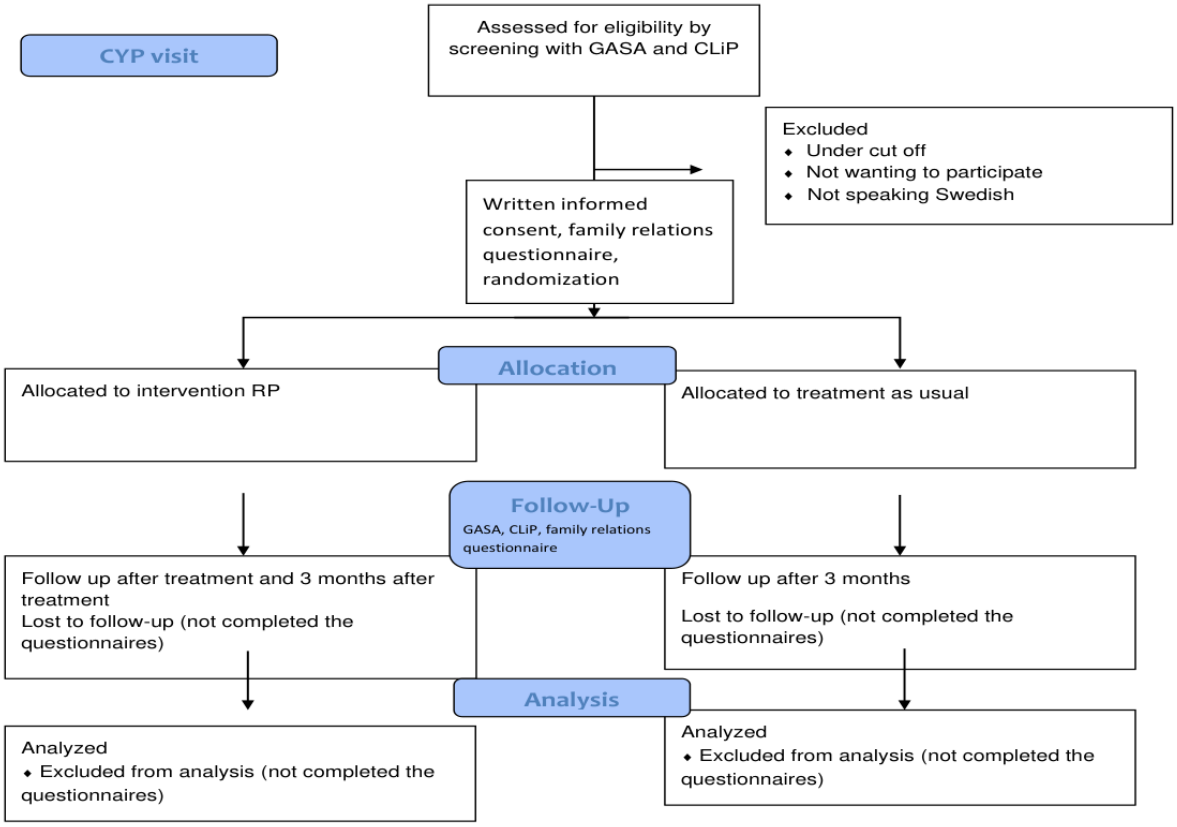
1. Undertake an internal pilot to assess the recruitment and feasibility of delivering the treatment in a child and youth psychiatric clinic.
2. Conduct a randomized control trial (RCT) to determine the effectiveness of relapse prevention on child and adolescent problem gaming and internet gaming disorder.
3. Examine the moderating role of the parent-child relationship, including parent-child bonds and communication on the effect of relapse prevention on child and adolescent problem gaming and internet gaming disorder.
4. Investigate the effect of completed relapse prevention treatment on parent-child relationships
5. Introduce a qualitative component to address:
    - The subjective experiences of relapse prevention treatment among children and adolescents who took part in the program and their view of problematic gaming
    - Perceived attitudes about parent-child relationships and parenting needs in carers whose children accomplished the relapse prevention treatment
    - The feasibility of the treatment among clinicians who delivered the program

Methods

Design

This study is a 2-arm, parallel-group, early-stage RCT with embedded qualitative components. The internal pilot will determine the recruitment and feasibility of the treatment. The recruitment start date is January 1, 2022, and the end date is December 30, 2022.

Recruitment and Eligibility



The trial and the recruitment will be carried out in several outpatient child and youth psychiatric clinics in Region Skåne in southern Sweden. As part of routine practice, all children (ages 12-18 years) coming for their first visit to 4 child and youth psychiatric units in Region Skåne will be screened for gaming or gambling behaviors. Children will be eligible to be included in the trial if they are aged 12-18 years and referred to outpatient child and youth psychiatric clinics in Region Skåne, meet criteria for problem gaming and internet gaming disorder, and have capacity to provide written informed consent. Children below the age of 15 years need to have their caregivers' consent. Children will be excluded if they do not speak Swedish. The clinicians who meet children during their first visit to the child and youth psychiatric unit will inform and invite the eligible children to participate in the study.

Randomization

Participants will be randomized in a 1:1 ratio to either intervention or control. The study will include a total of 160 participants, applying a random allocation sequence using the "chit method" by preparing 160 chits of paper indicating either control or treatment [21]. Each patient will be allocated to a condition (control or treatment), and the chit will not be replaced if the patient drops out of the study. The allocation to treatment and control arms may thus be uneven at certain times during the trial, but the end result of randomization will result in an equal distribution between control and treatment. It will not be possible to blind participants, clinicians, or supervising researchers to randomization allocation. The control group will receive "treatment as usual" at their home clinic. For an overview of recruitment and randomization, see the flow diagram in Figure 1.

Intervention

There is at this time a lack of consensus regarding treatment methods for problem gaming [22], in part due to a lack of clinical research [23]. However, together with 4 experienced psychologists in the field, we developed a manual drawing on previous knowledge in the field of addiction and the field of child and adolescent psychiatric treatment. Relapse prevention for alcohol and substance abuse was used as a theoretical underpinning [20] to develop a manual with 2 aspects in mind: adapting the blurbs and examples for children and adolescents—in part by including a fictionalized adolescent when demonstrating the theme of the particular session; and by structuring the sessions so that they could be easily adapted to fit the participant's primary problem behavior—gaming or gambling. Patients who meet the criteria for disordered gambling or gaming (according to tentative criteria from the DSM-5) will be offered the opportunity to participate in a relapse preventive treatment intervention at their local clinic or where applicable at an adjacent clinic. The treatment will be administered in an individual format and consist of 7 to 9 sessions of 45 minutes over a period of 7 to 9 weeks. The treatment will be offered to participants both in person and via video link to facilitate participation for children and adolescents living further away from the participating clinics.

The treatment consists of three parts: (1) setting goals, (2) understanding and identifying high-risk situations and problem behaviors, and (3) consolidating the new activity schedule and identifying future high-risk behaviors. The first part is focused on examining the patient's undesirable behavior, his/her motivation for change, and establishing goals with the treatment (this part primarily draws on motivational interviewing). This part of the treatment therefore varies between 1 to 3 sessions as participants may have different levels of motivation for changing their primary problem behavior, which is why some participants may require 1 or 2 extra sessions at the start of the treatment. The second part (drawing more from traditional CBT techniques) consists of exploring problematic situations using functional analysis; identifying high-risk situations and events, emotions, and cognitions that induce the problematic gaming behavior or result in a relapse; and managing game time with activity scheduling and practicing problem-solving skills. The final part consists of recognizing early warning signals that may indicate that the primary problem behavior is more likely to occur and consolidating the parts of the treatment that have been the most helpful in maintaining the new activity schedule.

Clinicians (psychiatrists and psychologists) with training in CBT will beforehand be educated in relapse prevention and will throughout the treatment be supervised by a clinician with vast experience of treating adults with gambling and gaming addictions.

Sample Size

Patients who have agreed to participate in the treatment study will be randomized in a 1: 1 ratio between intervention and control group. In our power calculation, we estimated that 40% in the intervention group and 20% in the control group will see improvement through the treatment offered in different groups, and after this treatment fall under the cutoff for problem gaming. With these figures, 160 (80 + 80) patients must be included in

XSL•FO
RenderX

the treatment study for us to be able to demonstrate a significant difference with sufficient power. Given the large number of patients in pediatric and youth psychiatry in the region and the likely high incidence of problem behaviors in the population, we believe it is possible to reach this number of participants in the study.

Ethics Approval

The study was reviewed and approved by the Swedish Ethical Review Authority (Ref 2019-04797, December 13, 2019). Subsequent amendments have been approved (Ref 2021-05592-01, January 3, 2021; Ref 2022-01289-02, March 15, 2022).

Informed Consent

After eligibility is confirmed, written and verbal information about the study will be provided to all participants according to the Swedish Act concerning the Ethical Review of Research Involving Humans (SFS 2003:460). All patients, their carers, and clinicians who verbally agree to take part in the project will be provided with a consent form enabling them to provide written consent. For patients below the age of 15 years, a carer's written consent will be needed for their children to take part in the study. All participants will be informed that their partaking in the study is voluntary; their data would be handled with strict confidentiality; results will be reported on a group level, which means that individual participants will not be identifiable; and they are free to withdraw from the study at any time without reporting a reason for withdrawal. Please see Multimedia Appendix 1 for details. The trial intervention is similar to other clinical practices offered in child and youth psychiatric clinics, which is why we consider the risks with the trial as minimal.

Measures and Data Collection

Background information, including gender, age, housing situation, and diagnosis, as well as primary outcome measures assessing gaming and gambling problems, will be collected via the platform "Blå appen" ("Blue application" in Swedish). Blå appen is a digital platform developed by the child and youth outpatient department in Region Skåne, distributing and summarizing online self-rated questionnaires. It is used throughout Swedish child and youth psychiatry to facilitate the usage of self-rated questionnaires to patients. The secondary outcome measures, including parent-child communication and connectedness and family climate, will be administered in paper format after the child has provided consent to the study. Because the secondary outcomes measures assess general parent-child interactions, specific questions about gaming will also be added. The patients who consent to the RCT will rate their gaming and gambling activity as well as their parent-child relationships before and after the treatment. The "treatment at usual" arm will do the rating of gaming and gambling activity as well as their parent-child relationships at the inclusion and 3 months after the inclusion to the study. The following primary outcome measures will be used:

- The Game Addiction Scale for Adolescents [24] applies to gaming behavior during the previous 6 months based on 7 items. Each question covers one criterion in the DSM-5, answered on a 5-point Likert scale ranging from 1 (never) to 5 (very often) and should according to the developer be counted as endorsed when rated 3 or higher.
- The Diagnostic Screen for Gambling Problems–Control, Lying, and Preoccupation (NODS-CLiP) [25] is the shorter form of the NODS [26], which assesses gambling problems. NODS yield a score ranging from 0 to 10, corresponding to the DSM-4 criteria for gambling, where a score of 5 or more qualifies as pathological, a score of 3-4 corresponds to the subclinical syndrome of problem gambling, and scores of 1-2 corresponds to an "at-risk" status. NODS-CLiP comprises the 3 NODS items that best describe problem gambling, with 3 NODS questions pertaining to loss of Control, Lying, and Preoccupation—the "CLiP."

The following secondary, somewhat adapted, outcome measures will be used:

- Parent-child communication [27] includes six subscales: (1) parent knowledge of child activities (eg, "Do your parents know how much time you spend on gaming?"); (2) parent control (eg, "How often do your parents set rules about your gaming activities?"); (3) parent solicitousness (eg, "How often do your parents ask you about your gaming activities?"); (4) child disclosure (eg, "Do you tell your parents about your gaming activities?"); (5) child secrecy (eg, "Do you hide a lot from your parents in terms of your gaming activities?"); and (6) child feelings of being overly controlled (eg, "Do you think your parents want to know too much about your gaming activities?"). Items are rated on a 5-point Likert scale ranging from 1 (often) to 5 (never).
- Family climate [28] includes 2 subscales, family cohesion and conflict. Although family cohesion assesses the bonds between family members (eg, "In my family, we help and support each other"), family conflict assesses the conflicts between family members (eg, "In my family we often fight with each other"). Items are rated on a 4-point scale, ranging from 1 (not true at all) to 4 (very true).

Data Management

Personal and identifiable data will be collected from patients. Data will be kept confidential and managed in accordance with the Data Protection Act, General Data Protection Regulation policies and Swedish Act concerning the Ethical Review of Research Involving Humans (SFS 2003:460). Data will be held on services located within the Region Skåne databases, stored and secured both physically (in locked cabinets designed for the purpose) and electronically (behind firewalls), and be accessible to the study team only.

Statistical Analysis

Preliminary analyses will be conducted with regression analyses, paired sample *t* tests and ANOVAs. Analyses of pre- to postintervention change will be based on probability modeling using both unadjusted and adjusted models with 95% CIs. Appropriate interaction terms will be included to test subgroup differences in the models [29]. Analyses will be performed in Mplus [30].

XSL•FO
RenderX

Qualitative Component

In addition to the RCT, the study will be supplemented with a qualitative component with semistructured individual interviews in order to capture participants' and clinicians' experiences of the treatment, as well as attitudes about parent-child relationships and parenting needs in carers whose children completed the relapse prevention treatment. Specifically, the interviews with the children will focus on the children's meaning-making of problem gaming, their experiences of the treatment, as well as their reflections on parent-child relationships before and after treatment. The interviews with the clinicians will focus on the clinicians' experiences of carrying out the treatment, as well as their understanding of problem gaming. Finally, the interviews with the carers will focus on carers' attitudes in terms of parent-child relationships before and after treatment of the child, as well as their reflections on potential parenting support needs in terms of their child's gaming.

All interviews will be conducted by staff with knowledge of qualitative interview methodology. Each interview template will be pilot-tested prior to data collection. The respondents will be offered participation through a physical or digital interview. After the collection phase, the generated data will be analyzed with the help of thematic analysis based on the recommendations by Braun and Clarke [31].

Dissemination

Findings from the study will be published in peer-reviewed journals and presented at local, national, and international conferences; workshops with key stakeholders; and interviews, pods, seminars, and lectures with general audiences. Results will also be reported to the funders.

The trial was retrospectively registered on ClinicalTrials.gov (NCT05506384; date of registration: April 13, 2022) due to administrative overload.

Results

The trial started in January 2022 and is expected to end in December 2023. The first results are expected in March 2023.

Discussion

Expected Findings

In this research project, we will evaluate relapse prevention as a treatment for children and youth (aged 12-18 years) showing signs of problem gaming and internet gaming disorder. In addition, we will also test the role of parent-child relationships for the effects of treatment and include a qualitative component involving interviews with children, carers, and clinicians in order to gain a deeper understanding of the treatment and its anticipated effects.

CBT-based forms of treatment, such as relapse prevention [19,20], typically used as a treatment for substance addiction [20], has been adapted to the treatment of child and youth problem gaming and internet gaming disorder. The goal of the treatment is to help the individual to identify both internal and external cues to prevent future relapses in similar situations. More specifically, the relapse prevention treatment is thought to help children to recognize triggers and cues for gaming, as well as to understand and control their gaming behaviors. Therefore, we hypothesize that by targeting these mechanisms, the treatment could be effective in treating children and adolescents with problem gaming and internet gaming disorder. As children are a part of a family system [16], it is likely that aspects of parent-child relationship, such as communication and emotional bonds, would have impact on child gaming behaviors [17]. Acknowledging parent-child relationships as being an important factor for child behavioral development, we hypothesize that the quality of parent-child relationships will play role for the effect of the treatment in a sense that the treatment will be more efficient for children reporting stronger parent-child bonds and communication. In addition, as children and parents interact in a dynamic manner [16], we also expect that the treatment will have spillover effect on parent-child relationships. We also have exploratory components to the projects. As previous research on user acceptability and satisfaction with relapse prevention as a treatment for problem gaming and internet gaming disorder is lacking, we explore how children and their carers, as well as clinicians who carried out the treatment, experience relapse prevention as a treatment for problem gaming and internet gaming disorder among children and youth. In addition, we also explore carers' attitudes in terms of parent-child relationships before and after treatment of the child, as well as their reflections on potential parenting support needs in terms of their child's gaming.

Limitations and Strengths

There are however some limitations to the study. The trial is not blinded, which may have an impact on both the patients' behavior as well as clinicians' practices. On the other hand, blinding does not necessarily ensure internal or external validity of the results [32], which is why we consider this limitation minor. As neuropsychiatric disorder is one of the major risk factors in problem gaming and internet gaming disorder [13], we expect that many of the patients included in the trial with be diagnosed with a neuropsychiatric disorder. This could be a potential limitation of the trial as the effect of the treatment may be affected by comorbidity in children with problem gaming or internet gaming disorder. Another possible limitation is the difficulty with recruiting patients as well as the potential dropout. Many children who game may not be aware of the problems that their gaming is imposing on their everyday lives, which is why they may not be likely to seek help or accept the given support. In addition, they may not be motivated to be engaged in the treatment. Therefore, we offer motivational sessions in the beginning of the treatment. Despite these limitations, there are several strengths to be noted. To our knowledge, this is the first RCT study testing the effect of relapse prevention on child and adolescent problem gaming and internet gaming disorder. As an increasing number of children engage in gaming [4,24], for some children, this activity may include significant problems [6,22] that would need attention from the clinics. Evaluating the efforts made by the clinics may provide more knowledge of the treatment of problem gaming in children. As problem behaviors in children interact with the

XSL•FO
RenderX

family context, investigating parent-child relationships adjacent to the treatment of child problem gaming or internet gaming disorder is another important strength of the study. Further, this study includes a qualitative component involving different parties directly or indirectly involved in the treatment, ie, children, carers, and clinicians. Interviews with children, carers, and clinicians may help gaining knowledge of how the treatment is perceived by the individual who is directly involved in the treatment, the adults who take part in the child's life on a daily basis, as well as the clinicians who are important stakeholders of the treatment.

Conclusion

To conclude, in this project, we will evaluate relapse prevention as a treatment for children and youth (aged 12-18 years) showing signs of problem gaming and internet gaming disorder. The treatment will be evaluated in an RCT. The measures will include gaming frequency and gaming experiences, as well as perceived parent-child relationships and parent-child communication in order to understand the possible of role of parent-child relationship for the effect of the treatment. In addition, the study will also include a qualitative component involving interviews with children, carers, and clinicians in order to gain a deeper understanding of the treatment and its anticipated effects, as well as the parenting support needs the carers express. The results of the project will inform the development of practices in child and youth psychiatric clinics, putting focus on both children and their carers as important stakeholders in the practices.

Acknowledgments

The study was supported by ALF-Swedish government research grant (Ref 89110), Craaford Foundation (Ref 20200862), Fanny Ekdahls Foundation, Svenska spels forskningsråd (Sweden's gaming company research council; Ref 2020-003), Swedish Research Council for Health, and Working Life and Welfare FORTE (Ref 2021-01696).

Data Availability

The data sets generated and/or analyzed during the current study are not publicly available because this study's ethical review does not allow for study data to be in a public repository. Requests to access the datasets should be addressed to ECK or SK.

Authors' Contributions

ECK, SK, SG, FA, and AH designed the trial and, together with IE and MW, contributed to the qualitative component, recruitment, and data collection. SK drafted the protocol. All authors read and approved the final manuscript. All authors have agreed to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Conflicts of Interest

None declared.

Editorial Notice

This randomized study was only retrospectively registered, due to administrative overload. The editor granted an exception from ICMJE rules mandating prospective registration of randomized trials because the risk of bias appears low and the study was considered formative, guiding the development of the application. However, readers are advised to carefully assess the validity of any potential explicit or implicit claims related to primary outcomes or effectiveness, as retrospective registration does not prevent authors from changing their outcome measures retrospectively.

Abstract

Background: Anthracycline-based chemotherapy has been mainstay of adjuvant breast cancer therapy for decades. Although effective, anthracyclines place long-term breast cancer survivors at risk of late effects, such as reduced cardiorespiratory fitness and increased risk of cardiovascular disease. Previous research has shown beneficial effects of exercise training on cardiorespiratory fitness, but the effects of exercise on limiting factors for cardiorespiratory fitness, cardiovascular risk factors, and patient-reported outcomes in long-term survivors are less clear. Whether previous exposure to breast cancer therapy modulates the effects of exercise is also unknown.

Objective: The primary aim of the CAUSE (Cardiovascular Survivors Exercise) trial is to examine the effect of aerobic exercise on cardiorespiratory fitness in anthracycline-treated long-term breast cancer survivors. Secondary aims are to examine effects of exercise training on limiting factors for cardiorespiratory fitness, cardiovascular risk factors, and patient-reported outcomes, and to compare baseline values and effects of exercise training between similar-aged women with and those without prior breast cancer. A third aim is to examine the 24-month postintervention effects of aerobic exercise on primary and secondary outcomes.

XSL•FO
RenderX

Methods: The CAUSE trial is a 2-armed randomized controlled trial, where 140 long-term breast cancer survivors, 8-12 years post diagnosis, are assigned to a 5-month nonlinear aerobic exercise program with 3 weekly sessions or to standard care. Seventy similar-aged women with no history of cancer will undergo the same exercise program. Cardiorespiratory fitness measured as peak oxygen consumption (VO_{2peak}), limiting factors for VO_{2peak} (eg, cardiac function, pulmonary function, hemoglobin mass, blood volume, and skeletal muscle characteristics), cardiovascular risk factors (eg, hypertension, diabetes, dyslipidemia, obesity, physical activity level, and smoking status), and patient-reported outcomes (eg, body image, fatigue, mental health, and health-related quality of life) will be assessed at baseline, post intervention, and 24 months post intervention.

Results: A total of 209 patients were included from October 2020 to August 2022, and postintervention assessments were completed in January 2023. The 24-month follow-up will be completed in February 2025.

Conclusions: The findings from the CAUSE trial will provide novel scientific understanding of the potential benefits of exercise training in long-term breast cancer survivors.

Introduction

Background

Due to advances in diagnostics and treatment, the 5-year survival rate for early breast cancer has surpassed 90% in the Western world, and the number of breast cancer survivors (BCSs) is steadily increasing. Long-term BCS (ie, living beyond 5 years after diagnosis) are at increased risk of several late effects, such as increased risk of cardiovascular disease (CVD) and incidence cardiovascular (CV) risk factors (eg, obesity, hypertension, and dyslipidemia) [1,2].

Cardiotoxicity is a well-recognized adverse effect of anthracycline therapy, which has been a key component of breast cancer therapy for decades. Anthracycline treatment can induce myocardial damage [3,4] and lead to irreversible left ventricular dysfunction and heart failure [5]. Although the incidence of manifested anthracycline-induced cardiotoxicity after breast cancer treatment is approximately 2%-5% [6,7], the incidence of subclinical left ventricular dysfunction may be significantly higher [8].

Previous studies have demonstrated impaired cardiorespiratory fitness (CRF) in BCSs [9,10]. CRF is an integrative measure of global cardiopulmonary and skeletal muscle function assessed as peak oxygen consumption (VO_{2peak}). Reduced CRF is not only an expression of impaired physical functional capacity but is also associated with a greater risk of CVD [11,12]. Cardiac output, pulmonary function, blood oxygen carrying capacity, and peripheral arteriovenous oxygen extraction capacity are physiological determinants of CRF, also termed as limiting factors for CRF. Given the systemic effect of chemotherapy, anthracycline-induced late effects may not be limited to cardiotoxicity, but likely affects the entire cardiopulmonary-muscle axis [13]. In line with this perspective, studies have reported reduced microvessel density, impaired mitochondrial function, and reduced skeletal muscle cell size during anthracycline treatment of breast cancer [14]. To our knowledge, no study has investigated if such adverse effects are present in long-term BCS.

BCS may also face psychosocial late effects, including body image concerns, increased levels of mental distress [15], and chronic fatigue [16,17], potentially negatively affecting their work life and reducing their health-related quality of life (HRQoL) [18,19].

Aerobic exercise has shown to improve CRF in cancer survivors [20], but knowledge on the effects of aerobic exercise on limiting factors for CRF is sparse. To the best of our knowledge, there are no existing data on the effects of exercise training on cardiac morphology and function after anthracycline exposure in long-term cancer survivors.

In nononcological settings, higher levels of physical activity are associated with a dramatic reduction in CVD risk [21]. Studies evaluating such effects among cancer survivors are limited [22]. Adams et al [23] reported improved vascular function and CRF and lower low-density lipoprotein and high-sensitivity C-reactive protein after 12 weeks of supervised high intensity aerobic exercise in survivors of testicular cancer, and similar data on BCS are missing. Finally, exercise training has also been shown to improve mental distress and fatigue [24], and improve HRQoL [25,26] in patients with cancer, but research has mainly been conducted during or shortly after treatment.

Aims and Hypothesis

The primary aim of this study is to examine the effect of aerobic exercise on CRF in anthracycline-treated long-term BCS compared to standard care. Secondary aims are to examine the effects of exercise training on limiting factors for CRF, CV risk factors, and health-related patient-reported outcomes (PROMs) compared to standard care, and to compare baseline values and effects of exercise training between BCS and similar-aged women without prior cancer. Tertiary aims are to investigate long-term effects of the intervention on CRF, CV risk factors, and health-related outcomes 24 months post intervention. We hypothesize that aerobic exercise will improve CRF.

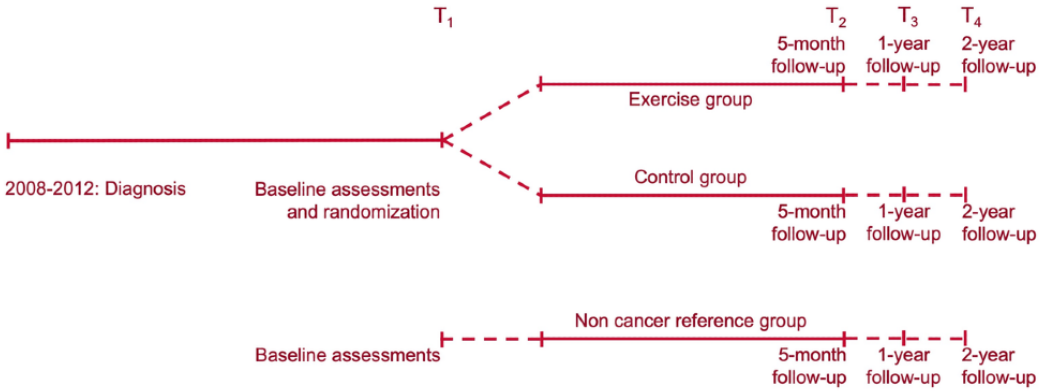
Methods



Ethics Approval

The CAUSE (Cardiovascular Survivors Exercise) trial is conducted according to the Helsinki Declaration, and all study participants will sign informed consent before any study-related procedures. The study is approved by the Regional Committees for Medical and Health Research Ethics (2019/1318) and is preregistered on clinicaltrials.gov (NCT04307407).

Design

The CAUSE trial is a 2-armed, phase II randomized controlled trial that compares aerobic exercise (exercise group) to standard care (control group) in BCS. A third group comprising similar-aged women with no previous cancer diagnosis is also included (noncancer reference group). The exercise group and the noncancer reference group undergoes the same aerobic exercise program. The overall study design is outlined in Figure 1.

Figure 1. Study outline. Participants in the exercise group, control group, and noncancer reference group undergoes assessments at baseline (T1), after 5 months (post intervention) (T2), and 1 and 2 years post intervention (T3 and T4).

Participants

BCS Group

BCS are invited to participate if diagnosed with human epidermal growth factor receptor 2–negative breast cancer stage I-III between 2008 and 2012 (ie, 8-14 years after diagnosis), aged 60 years or younger at the time of diagnosis, and received the anthracycline epirubicin as part of their adjuvant therapy. All eligibility criteria are listed in Textbox 1.

Textbox 1. Eligibility criteria for breast cancer survivors in the CAUSE (Cardiovascular Survivors Exercise) trial.

Inclusion criteria:

- Adjuvant treatment with epirubicin
- Breast cancer diagnosis between 2008 and 2012
- Exercises ≤90 minutes per week
- Physicians' approval of participation

Exclusion criteria:

- Stage IV breast cancer at diagnosis
- Treatment with trastuzumab
- Recurrence of breast cancer
- Presence of other malignancies (except for basal cell carcinomas)
- Former major cardiac surgery
- Presence of a pacemaker
- Chronic atrial fibrillation
- Recent or uncontrolled cardiovascular disease
- Any physical or mental condition restricting adherence to study procedures (by self-evaluation)

XSL•FO
RenderX

Noncancer Reference Group

Participants in the noncancer reference group are women without a history of cancer who otherwise meet the eligibility criteria listed in Textbox 1.

Recruitment

Women who were diagnosed with breast cancer stage I-III between 2008 and 2012, and live within reasonable distance from Oslo, are identified from the Cancer Registry of Norway. An invitation with study information is sent by mail to all candidates. Thereafter, the study personnel contact the candidates by phone to screen for eligibility and provide additional information. Candidates who meet the eligibility criteria and are willing to participate are then invited to baseline assessments.

Participants for the noncancer reference group are recruited in 2 steps. First, BCS randomized to the exercise group are encouraged to invite a similar-aged friend or relative to participate in the noncancer reference group. The remaining participants in the noncancer reference group are recruited through advertisements in news media and through appropriate social media channels. Interested candidates who meet the eligibility criteria are included.

Randomization

BCS are block randomized with a 1:1 allocation ratio to the exercise group or to the control group. Due to the strict eligibility criteria, no additional stratification factors are included. A random sequence of study IDs was made by a random number generator prior to inclusion of the first participant. The allocation sequence is concealed from the study personnel involved in baseline assessment until the baseline assessments are completed.

Assessments

Overview

Study outcomes, assessment methods, and assessment times are summarized in Table 1 and described in detail below. Primary outcome is CRF assessed by VO_{2peak}. Secondary outcomes are limiting factors for VO_{2peak}, CV risk factors, and PROMs. To evaluate long-term effects of the intervention, primary and secondary outcomes are assessed at 24 months (T_4) postintervention. Some PROMs are also assessed at 12 months (T_3) postintervention.

All participants are screened by a cardiologist before the assessments. Presence of possible contraindications to exercise training will be evaluated according to the guidelines from the American College of Sports Medicine. [27].

Primary Outcome

CRF

VO_{2peak} is assessed by an incremental treadmill cardiopulmonary exercise test (CPET) using a modified Balke protocol (RL2700E, Rodby) [41]. The participants are briefly familiarized to treadmill walking prior to the test. The test is continued until voluntary exhaustion despite encouragement by the test leaders. Continuous expired gases are measured breath-by-breath using a gas and volume calibrated metabolic chart (Oxycon Pro, Jaeger GmbH). The highest volume of oxygen consumed across a 30-second period is registered as VO_{2peak}. All exercise tests will be supervised by an exercise physiologist and observed by a cardiologist, following standard clinical guidelines [42].

Secondary Outcomes

Limiting Factors for CRF

The following limiting factors for CRF were will be considered:

- Cardiac function: cardiac morphology and function will be assessed by resting transthoracic echocardiography using Vivid E9 (GE Vingmed). Standard 2D parasternal and apical views are acquired in the end-expiratory phase with participants in the supine left lateral position. Apical 3D recordings will be obtained by stitching together minimum 4 consecutive heart cycles. In addition, left ventricular outflow tract velocity time integral will be obtained immediately after the CPET to estimate maximal stroke volume and cardiac output. Images will be subsequently analyzed offline on EchoPac version 202 (GE Vingmed). Echocardiographic outcomes (listed in Table 1) are measured as recommended by American Society of Echocardiography and European Society of Cardiology [43]. Left ventricular myocardial work will be estimated by a noninvasive method using pressure-strain loop analysis [44].
- Pulmonary function: ventilatory function will be assessed by maximal expiratory flow volume loops (MasterScreen Pneumo Jäger) [45]. The best forced expiratory volume in 1 second and forced vital capacity after 3 acceptable trials will be recorded. Ventilatory capacity, for calculation of breathing reserve during CPET, will be measured by a Maximum Voluntary Ventilation test while breathing as hard and fast as possible for 10 seconds in standing position. Best of 2 maximal attempts will be recorded. The diffusion capacity of the lung for carbon monoxide (DLco) will be measured using the single-breath method, adjusted for serum hemoglobin levels. The average of 2 satisfying

XSL•FO
RenderX

attempts will be evaluated for DLco, DLco/alveolar volume (carbon monoxide transfer coefficient), and total lung capacity. All measurements are in accordance with guidelines from The European Respiratory Society/American Thoracic Society [45,46]. The Global Lung Function Initiative reference equations are used, and the outcomes are expressed as absolute values, percent predicted, and *z* scores [47-49].

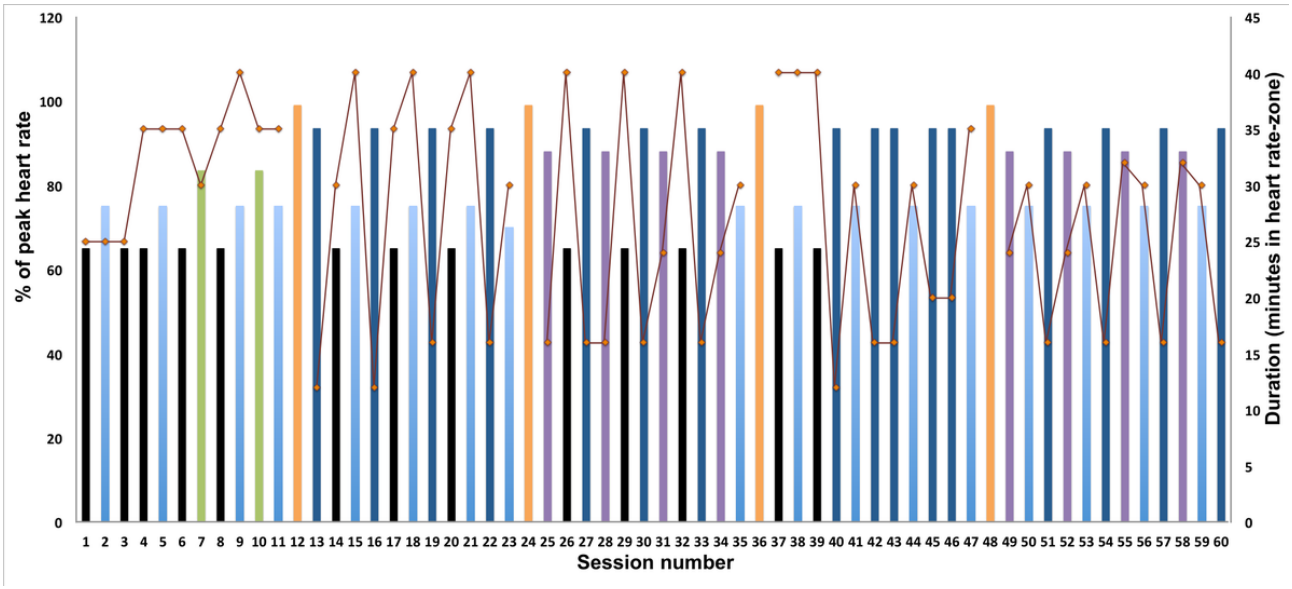
- Blood oxygen transport capacity: hemoglobin mass will be measured using a carbon monoxide (CO) rebreathing method [50]. First, the participant will be seated for 10 minutes, before capillary blood sampling in two 125-µL preheparinized tubes (Clinitubes; Radiometer). Thereafter, the participant will inhale a bolus of 1 mL/kg body weight of chemically pure CO (AGA Norge) administered via a spirometer (Blood tec GmbH). In a closed circuit, the CO will be rebreathed for 2 minutes together with 3 L of pure oxygen (AGA Norge). Two capillary fingertip blood samples will be collected, 6 and 8 minutes following the administration of CO. All blood samples will be immediately analyzed in duplicate for percent carboxyhemoglobin (ABL80 CO-OX FLEX, Radiometer). Hemoglobin mass will be calculated by dilution of CO in blood with correction for loss of CO to myoglobin (0.3% of the administered CO per minute). Blood volume, plasma volume, and red cell volume will be calculated from hemoglobin mass using venous hemoglobin and venous hematocrit.
- Skeletal muscle characteristics: muscle biopsies will be obtained from vastus lateralis muscle by the Bergström Needle-biopsy technique according to standard procedures established in our laboratory [51]. Muscle fiber size and composition and capillary density will be assessed via immunohistochemistry. The content of mitochondrial proteins and proteins involved in β-oxidation is assessed by western blotting [51]. A subgroup of the muscle biopsies will be processed for RNA and DNA extraction. Methylome wide arrays (eg, 850,000 CpG sites, Infinium Methylation EPIC BeadChip arrays, Illumina, or genome-wide bisulfite sequencing) and transcriptome technology (eg, U133 plus 2.0 array or Claricom S HT Human Array or RNA sequencing) will be applied to assess the expression of epigenetically regulated genes.

CV Risk Factors

Resting blood pressure will be measured by an electronic sphygmomanometer (Welch Allyn ProBP 2400) in supine position after echocardiography. Biomarkers listed in Table 1 will be analyzed in accordance with established procedures at Fürst Laboratories from blood samples obtained in a fasted state. Height and weight will be measured by the same scale and stadiometer at all time points (SECA 213). Absolute and relative content of fat mass and lean body mass will be assessed by whole-body dual x-ray absorptiometry (Lunar iDXA, GE Healthcare) in a fasted state. Daily level of physical activity will be measured by accelerometers, using ActiGraph model GT3X+ (ActiGraph LLC). Participants will be instructed to wear accelerometers on the right hip for 7 consecutive days after completion of baseline assessments and during the last week of the intervention period. Smoking status will be recorded.

Patient-Reported Outcomes

An overview of the PROMs is presented in Table 1. Sociodemographic variables including marital status, number of children living at home, and education level will be recorded using the same or modified questions from the HUNT-4 (The Trøndelag Health) study [52]. Lifestyle variables include physical activity and exercise measured by questions from HUNT-4 study and Godin Leisure Time Exercise Questionnaire [28], and information on diet, tobacco, alcohol, and sleep habits will be measured by the same or modified questions from the HUNT-4 study. Work aspects will be measured as in the HUNT-4 study and by the Work Ability Index (Finnish Institute of Occupational Health. Work Ability Index, 2006). Information on comorbidities, HRQoL, and general and breast cancer–specific late effects will be measured using a modified version of that used in the HUNT-4 study, the European Organization for Research and Treatment of Cancer Quality of Life Questionnaires (EORTC QLQ C-30 and EORTC QLQ BR-28), including the breast cancer module [29], and the Satisfaction With Life Scale [30,32]. Neuropathy will be assessed by the scale for chemotherapy-induced long-term neurotoxicity [33], fatigue by the Chalder Fatigue Questionnaire [34], vitality by the Subjective Vitality Scale [31], anxiety by Generalized Anxiety Disorder 7 items [35], and depressive symptoms by a modified version of the Patient Health Questionnaire-9 [36]. Fear of recurrence is measured by Assessment of Survivors Concerns questionnaire [37].



Motivation for exercise will be measured by the Behavioral Regulation in Exercise Questionnaire-2 [38] and sense of exercise mastery by Perceived Competence Scale [39]. In the exercise group only, experience with the instructor and exercise program will be measured by the short version of the Health Care Climate Questionnaire [53] and Basic Need Satisfaction in Exercise Scale [40].

Intervention

The intervention duration is 5 months. Participants in the exercise group perform 3 weekly aerobic exercise sessions aimed at increasing CRF. The exercise plan includes both continuous sessions, with low to moderate exercise intensities, as well as interval sessions performed at higher intensities. The intensity and duration of each individual session and sequencing of the different sessions are outlined in Figure 2. Importantly, the sessions will be scheduled so that the weekly amount of exercise is progressively increased across the intervention period, both in intensity and duration [54]. The preferred exercise modality is inclined treadmill walking or running. The exercise prescription is individually tailored to each participant based on their CPET result.

RenderX

Figure 2. Exercise prescription outline. Bars represents the exercise intensity (% of peak heart rate) at a given exercise session, and the dotted line represents the duration (minutes) at the prescribed exercise intensity in a given session.

In Figure 2, the intensity of each session is depicted by the colored bars as a percentage of the mean peak heart rate (HR_{peak}) for the session. "Black sessions" are performed at 65% of HR_{peak} for 25-40 minutes (n=13), "light blue sessions" are performed at 75% of HR_{peak} for 30 minutes (n=17), and "green sessions" are performed at 83.5% of HR_{peak} for 30 minutes (n=2). "Dark blue sessions" are performed as three to five 4-minute intervals at 93.5% of HR_{peak} with 3 minutes active rest (brisk walking) between intervals (n=16), and "purple sessions" are performed as two to four 8-minute intervals at 88% of HR_{peak} with 4 minutes active rest (brisk walking) between intervals (n=8). Orange bars represent sessions where the CPET exercise protocol is repeated and are conducted every fourth week (n=4). The treadmill speed and grade at voluntary exhaustion at the CPET protocol sessions will be recorded and used to monitor and report training progression throughout the intervention.
