The fourth objective of this study emphasized participants' competencies in emotional management after counseling assistance. This objective will entail both a semistructured interview and a quantitative analysis by using the TMMS, which focuses on participants' attention (perceived attention paid to personal emotional conditions), clarity (perceived understanding of personal emotional conditions), and repair (perceived ability to regulate personal emotional conditions). The TMMS is one of the most commonly used self-administered measurements for perceived emotional competence in older people [29]. It provides the opportunity to bridge current empirical gaps on emotions and to elucidate developmental trajectories throughout a person's life span. Based on the alignment between the ACP contents and items in the TMMS, as well as findings from previous local studies on the impact of counseling [20], we expect older people's competencies in emotional management and decision-making to improve after seeking counseling assistance. Results from this study may assist policymakers in deploying strategies to promote mood repair and emotional management in the Singaporean aging population to improve their receptiveness toward counseling interventions.

Overall, this study takes a holistic look into novel approaches to developing an effective counseling intervention for older people in Singapore. By considering older people's perspectives on pertinent issues regarding dignified care, life and health, end-of-life care, and the impacts of counseling, the challenges and prospects of available counseling services offered at various centers in Singapore can be elucidated. Moreover, patients, health care professionals, and social workers play pivotal roles in decision-making processes and ensuring optimum care during routine hospitalization of older patients' at their end of life. We anticipate that the data gleaned from this study will provide important insights regarding the approaches to developing a feasible and acceptable counseling intervention for older individuals in Singapore, as well as incorporating the intervention into routine care and accentuating potential barriers to seeking counseling assistance among this older population.

Implications

The findings in this study, particularly older people's perspectives on ACP, dignity, life and health, end of life, accessibility and receptiveness toward counseling, and competencies in emotional management and decision-making, should be beneficial to relevant policymakers in Singapore. Counseling is still an emerging field in Singapore, and there is a lack of mandatory counseling service regulations in Singapore. Given the various counseling services provided by professional organizations and private individuals, policymakers may consider the findings in standardizing the service training and counseling content for the increasing older population in Singapore.

This research is also promising in enhancing the target group's health, cognitive, and social functioning aspects. Given the current aim of the Singaporean government to tailor counseling for older people toward their cultural backgrounds [20] and coupled with the fact that older Singaporeans have less access to Western perspectives [59], the findings may assist in incorporating their perspectives into developing effective counseling interventions. Diverse perspectives have been reported to affect older individuals' receptiveness to counseling interventions [55,57].

Another important implication of this study is for the social workers, counselors, and health care professionals who are expected to deliver effective services to older individuals. The findings on older people's perspectives on ACP, dignity, life and health, and end-of-life care could be used to bridge the gap between the various players toward holistic patient-centered care. Moreover, counselors are expected to upgrade their professional knowledge and skills to ensure that older people live with dignity and access essential health and social services for optimal autonomy and independence. Thus, counselors in Singapore may find this study an opportunity to equip themselves with clinical skills to counsel older people.

Strengths and Limitations

Given the paucity of research on counseling as an intervention to enhance older people's dignity within the community, this study has attempted to fill in the research gap between counseling and Singaporean government policy on aging in place, thus adding to the current body of knowledge and literature in the research area both at local and global levels. The variables and specific events investigated in this study, such as receptiveness and accessibility to counseling centers, improved emotional management and decision-making, and quantitative assessment of perceived attention, clarity, and mood repair among older individuals, represent the novelty of this research. To date, only a few studies have considered the lived experiences and interactions of older adults with counselors or social workers. This study represents the first attempt to use mixed research methods to bridge the research gap. This combined approach will facilitate the collection of vital data through in-depth interviews and survey methods to elucidate older individuals' lived experiences and interactions with qualified and Singapore Association of Counseling and Singapore Association of Social Workers–accredited counselors or social workers.

However, the study design enabled the recruitment of participants with similar characteristics, and the inclusion and exclusion criteria used in selecting the study participants might have excluded older individuals with pertinent information on the research topics. Furthermore, the use of semistructured interview sessions also has its limitations, as respondents might be unwilling to provide in-depth information to the questions being asked. Moreover, the ACP instrument used in the qualitative phase has some closed-ended questions in which participants were not free to express their opinions. This might contribute to a degree of response bias. Last, this study has a cross-sectional design, and the findings will only reveal the association between the studied variables, such as accessibility and receptiveness toward counseling, perspectives on dignity and barriers to counseling assistance, and the related impact on emotional management and decision-making. In other words, no causal relationships can be inferred. Longitudinal, prospective, and randomized control study designs are more likely to generate the required data to infer causal effects and relationships between the studied concepts.

Conclusion

Accumulated evidence reflects the paucity of data on the impact of counseling on older people's dignity and emotional management in Singapore. Moreover, their accessibility and receptiveness toward counseling remain underreported. With the rising older population and the need for better care and effective aging, this research will be pertinent in elucidating the role of counseling in addressing the aforementioned issues. Policymakers and relevant bodies can use the findings to implement a model that will enhance older people's receptiveness toward counseling and derive vital benefits from such an intervention.

Acknowledgments

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Abstract

Background: The COVID-19 pandemic has reiterated the need for cohesive, collective, and deliberate societal efforts to address inherent inefficiencies in our health systems and overcome decision-making gaps using real-time data analytics. To achieve this, decision makers need independent and secure digital health platforms that engage citizens ethically to obtain big data, analyze and convert big data into real-time evidence, and finally, visualize this evidence to inform rapid decision-making.

Objective: The objective of this study is to develop replicable and scalable jurisdiction-specific digital health dashboards for rapid decision-making to ethically monitor, mitigate, and manage public health crises via systems integration beyond health care.

Methods: The primary approach in the development of the digital health dashboard was the use of global digital citizen science to tackle pandemics like COVID-19. The first step in the development process was to establish an 8-member Citizen Scientist Advisory Council via Digital Epidemiology and Population Health Laboratory's community partnerships. Based on the consultation with the council, three critical needs of citizens were prioritized: (1) management of household risk of COVID-19, (2) facilitation of food security, and (3) understanding citizen accessibility of public services. Thereafter, a progressive web application (PWA) was developed to provide daily services that address these needs. The big data generated from citizen access to these PWA services are set up to be anonymized, aggregated, and linked to the digital health dashboard for decision-making, that is, the dashboard displays anonymized and aggregated data obtained from citizen devices via the PWA. The digital health dashboard and the PWA are hosted on the Amazon Elastic Compute Cloud server. The digital health dashboard's interactive statistical navigation was designed using the Microsoft Power Business Intelligence tool, which creates a secure connection with the Amazon Relational Database server to regularly update the visualization of jurisdiction-specific, anonymized, and aggregated data.

Results: The development process resulted in a replicable and scalable digital health dashboard for decision-making. The big data relayed to the dashboard in real time reflect usage of the PWA that provides households the ability to manage their risk of COVID-19, request food when in need, and report difficulties and issues in accessing public services. The dashboard also provides (1) delegated community alert system to manage risks in real time, (2) bidirectional engagement system that allows decision makers to respond to citizen queries, and (3) delegated access that provides enhanced dashboard security.

Conclusions: Digital health dashboards for decision-making can transform public health policy by prioritizing the needs of citizens as well as decision makers to enable rapid decision-making. Digital health dashboards provide decision makers the ability to directly communicate with citizens to mitigate and manage existing and emerging public health crises, a paradigm-changing approach, that is, inverting innovation by prioritizing community needs, and advancing digital health for equity.

Introduction

In this digital age, human engagement with and through internet-connected devices generates a substantial amount of big data [1]. The ever-increasing usage of information technology in all spheres of human life has contributed to this phenomenon [2]. The use of these big data, which traditionally exist outside health care systems, has significant implications for the prediction and prevention of population health crises [3]. However, the exponential growth of big data creates challenges to meaningfully extract useful and timely information to inform public health policies [2,4].

Decision-making processes, particularly from the health systems perspective are complex. This complexity is compounded during population health crises, as evidenced by the difficulty that governments and health systems faced during the COVID-19 pandemic [5]. The challenges that the COVID-19 pandemic continues to pose reiterate the need for timely, appropriate, and precise evidence to inform decision-making during the evolving nature of public health crises [6].

The COVID-19 pandemic has revealed the gaps in governmental and health system decision-making while clarifying the need for a transformative change in the way public health crises need to be managed in the future [7]. The challenge in monitoring, managing, and mitigating public health crises, particularly rapidly spreading and evolving communicable disease epidemics and pandemics, is the need to coordinate decision-making processes across local, provincial, national, and international jurisdictions [8].

The COVID-19 pandemic particularly demonstrated the challenges faced by local jurisdictions in implementing federal or state or provincial mandates [9] due to the lack of timely access to jurisdiction-specific evidence [9]. The COVID-19 pandemic has also reiterated the need for cohesive, collective, and deliberate societal efforts to address inherent inefficiencies in our health systems and overcome decision-making gaps using real-time data analytics [10]. Nonetheless, the pandemic has also provided opportunities to decentralize and democratize technology that can support local decision makers with real-time access to big data for timely decision-making [11,12].

However, ethically obtaining, processing, and visualizing big data from citizens is critical to transforming local jurisdictional decision-making processes that impact public health [3,13]. To achieve this, decision makers need independent and secure digital health platforms that engage citizens ethically to obtain big data, analyze and convert big data into real-time evidence, and finally, visualize this evidence to inform rapid decision-making [3,14].

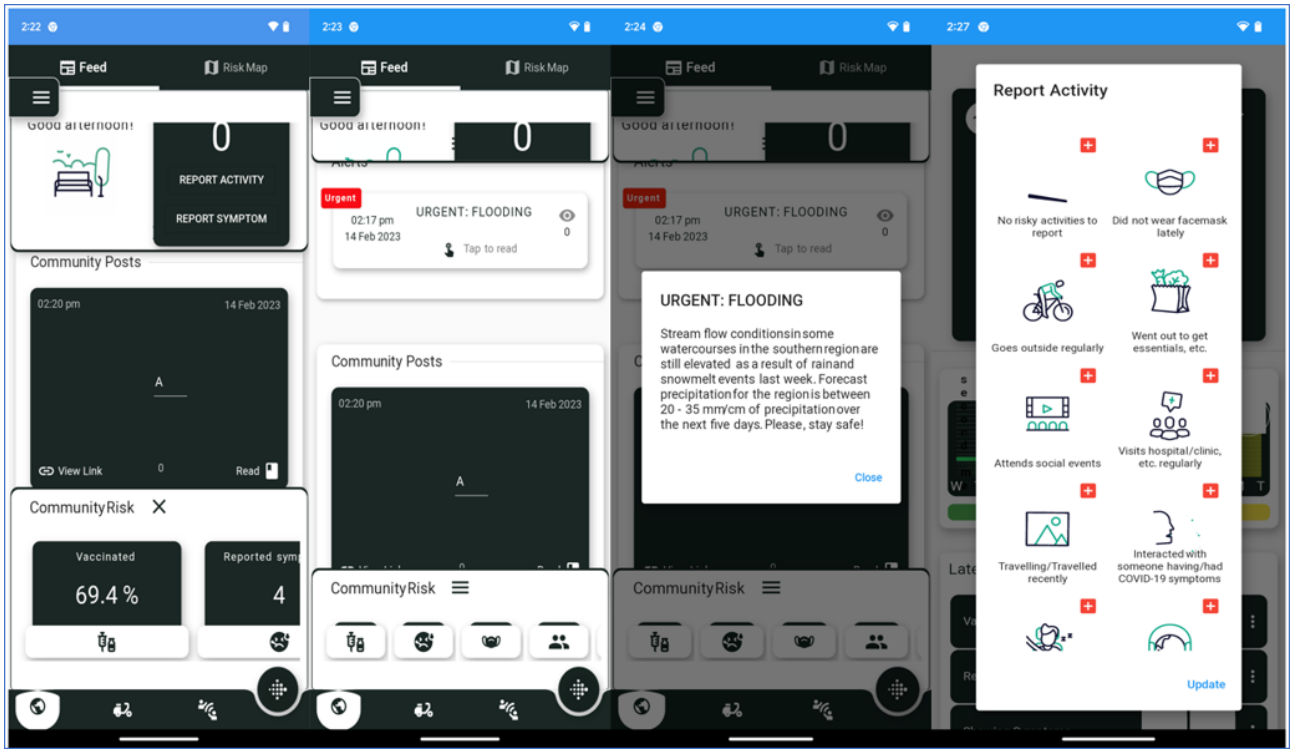
This visualization of data can be realized by the development and implementation of digital health dashboards [15], which are powerful tools to facilitate rapid decision-making [7]. This study enumerates the development of replicable and scalable jurisdiction-specific digital health dashboards for rapid decision-making to ethically monitor, mitigate, and manage public health crises via systems integration, that is, going beyond health systems.

Methods

Dashboard Development Process

The development of the digital health dashboard was in response to transform rapid responses to pandemics such as COVID-19 as well as to decentralize technology that can be sustainable, and scalable across jurisdictions. The primary approach in the development of the dashboard was the use of global digital citizen science to tackle pandemics like COVID-19 [3], which identifies the development of decision-making dashboards as a critical advancement in addressing public health crises via real-time data analytics using citizen-driven big data.

The methodology intersects digital citizen science and mHealth to conceptualize and develop digital health platforms that enable ethical surveillance, integrated knowledge translation, and real-time interventions [12]. Such development requires robust theoretical underpinnings such as the Smart Framework [12], which integrates citizen science, community-based participatory research, and systems science through ubiquitous tools to conduct population health interventions in the digital age. Smart Framework operationalizes the repurposing of citizen-owned ubiquitous communication devices (ie, smartphones), an approach that was incorporated into the development of this digital health dashboard. However, beyond the ability to ethically generate big data for rapid responses, this methodology also operationalizes the capacity of smartphones to enable health equity by empowering disenfranchised citizens to inform jurisdictional policies, that is, digital health for equity.



The first step in the development process was to establish a Citizen Scientist Advisory Council using Digital Epidemiology and Population Health Laboratory's (DEPtH Lab) community partnerships [16]. The diverse and inclusive 8-member council had representation from across varied groups that included gender, ethnicity, and socioeconomic diversity. More importantly, the council consisted of both community members and decision makers, a key component in the development of jurisdictional-specific digital health dashboards for decision-making.

Based on the consultation with the council, three critical needs of citizens were prioritized: (1) management of household risk of COVID-19, (2) facilitation of food security, and (3) understanding citizen accessibility of public services. Thereafter, a progressive web application (PWA) was developed to provide daily services that address these citizen needs (Figure 1). The big data generated from citizen access to these PWA services

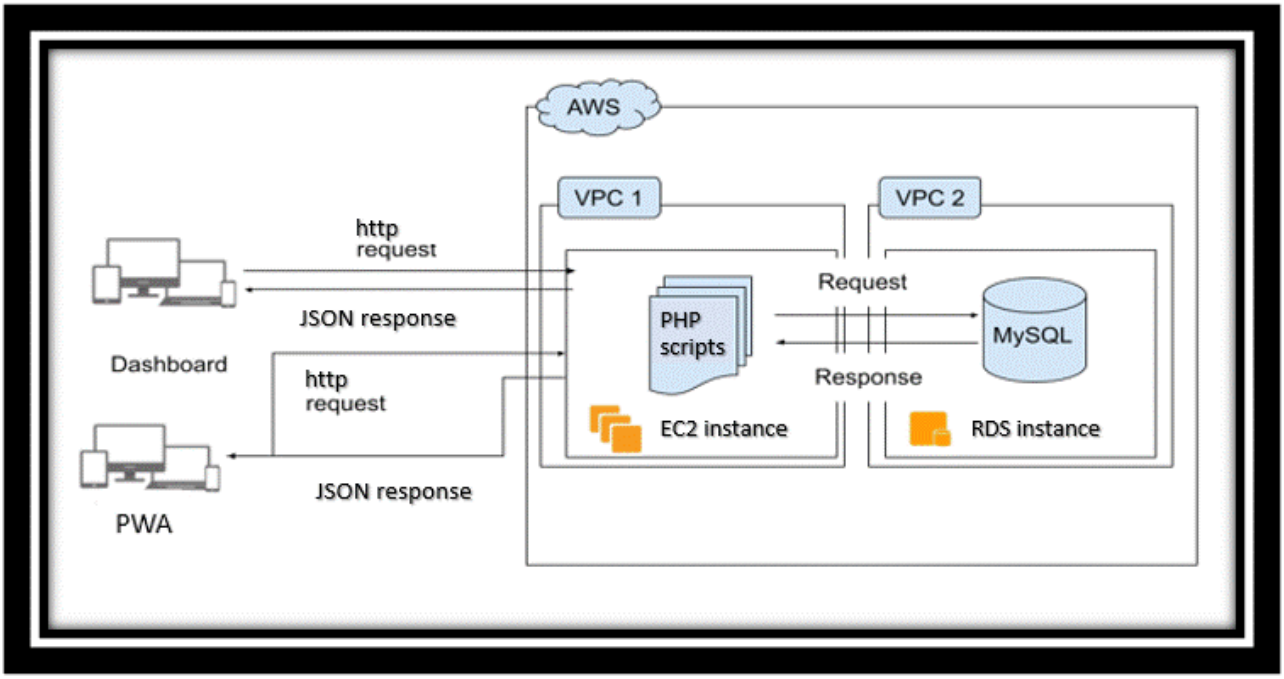
XSL•FO
RenderX

are set up to be anonymized, aggregated, and linked to the digital health dashboard for decision-making, that is, the dashboard displays anonymized and aggregated data obtained from citizen devices via the PWA.

Figure 1. Screenshots of progressive web application.

The dashboard was developed to achieve the following objectives identified by the global digital citizen science policy [3]: (1) implementation of ethical real-time surveillance to assess community health risks, (2) implementation of near real-time integrated knowledge translation based on the data provided by citizen usage of PWA, (3) implementation of evidence-based real-time public health communication, (4) evidence-based decision-making using real-time data analytics to mitigate health risks, and (5) addressing existing and evolving public health crises by developing adaptable, scalable, and replicable digital infrastructure.

The PWA (Figure 1) serves as a public health advising platform for citizens within a jurisdiction, where community members can manage their household risk of COVID-19 based on an evidence-based algorithm that takes into consideration not only the number of members in a household but also individual and collective household behaviors and symptoms. Using the PWA, citizens are also able to interact with jurisdictional decision makers, request food when in need, and report issues with access to public services within their jurisdiction. The PWA also has the capacity to directly receive alerts from decision makers via the digital health dashboard.



The PWA was designed using gamification features derived from Animaker [17], a software developed by RS Raghavan and coded using Flutter Framework. Flutter is an open-source user interface development kit developed and launched by Google Inc (Mountain View, California) and can be used to develop cross-platform applications for Android, iOS, Linux, macOS, Windows, Google Fuschia, and the web using a single codebase [18,19]. Flutter applications are written in Dart programming language [20].

The PWA is linked to the digital health dashboard through the "hypertext transfer protocol" (http) request and "hypertext preprocessor" (PHP) coding, an open-source server-side scripting programming language, which executes programming instructions at runtime [21]. http and custom-written PHP scripts act as a bridge that relays data from one end to another—PWA to database to Digital Health Dashboard [22]. All functionalities of the PWA are directly linked to the connection made with the backend database, via http request and PHP scripts.

Two virtual private cloud environments, which are hosted on Amazon Web Services (AWS), securely store and communicate data between the database, PWA, and the digital health dashboard (Figure 2) [23]. A virtual private cloud is a private cloud computing environment on shared public cloud infrastructure, which allows for secure computing, networking, and storage of information [24]. Within the virtual private cloud environment, both the Amazon Elastic Compute Cloud servers and the Amazon Relational Database servers are located. Amazon Elastic Compute Cloud servers provide secure and reliable server infrastructure with the flexibility to scale-up or -down server needs [25].

XSL•FO
RenderX

Figure 2. Digital health dashboard data flow processes showing linkage between PWA, dashboard, and cloud storage. AWS: Amazon Web Services; EC2: elastic compute cloud; MySQL: structural query language; PHP: hypertext preprocessor; PWA: progressive web application; RDS: relational database service; VPC: virtual private cloud.

Amazon Elastic Compute Cloud servers host the digital health dashboard through a PHP script run from within the server. Amazon Relational Database Server is a database service provided by AWS that stores, organizes, and makes data available through cloud infrastructure [26]. All data that are being generated through the interaction of citizens with PWA are stored and organized in the Amazon Relational Database using MySQL, an open-source relational database management system [26].

The PHP scripts communicate with the Amazon Elastic Compute servers, and MySQL is used to communicate with the Amazon Relational Database servers to organize incoming data in the database. The activities of the Amazon Elastic Compute Cloud servers and the Amazon Relational Database servers are communicated to both the PWA and digital health dashboard via http [27].

The digital health dashboard is coded and developed in PHP, which allows for the creation of dynamic content on websites to interact with databases [28]. Within the digital health dashboard, there is an interactive community statistical navigation system that was designed and developed using the Microsoft Power Business Intelligence tool [29,30]. Microsoft Power Business Intelligence is a tool that connects data from different sources to provide advanced and interactive data analytics via an automatic data feed to the dashboard. This data gateway ensures near real-time visualization of big data on the dashboard, which can be updated from intervals of 5 to 30 minutes. To ensure the availability of a consistent data feed to the digital health dashboard, the MySQL relational database management system is used to query, access, prepare, and integrate the most recent data points [24].

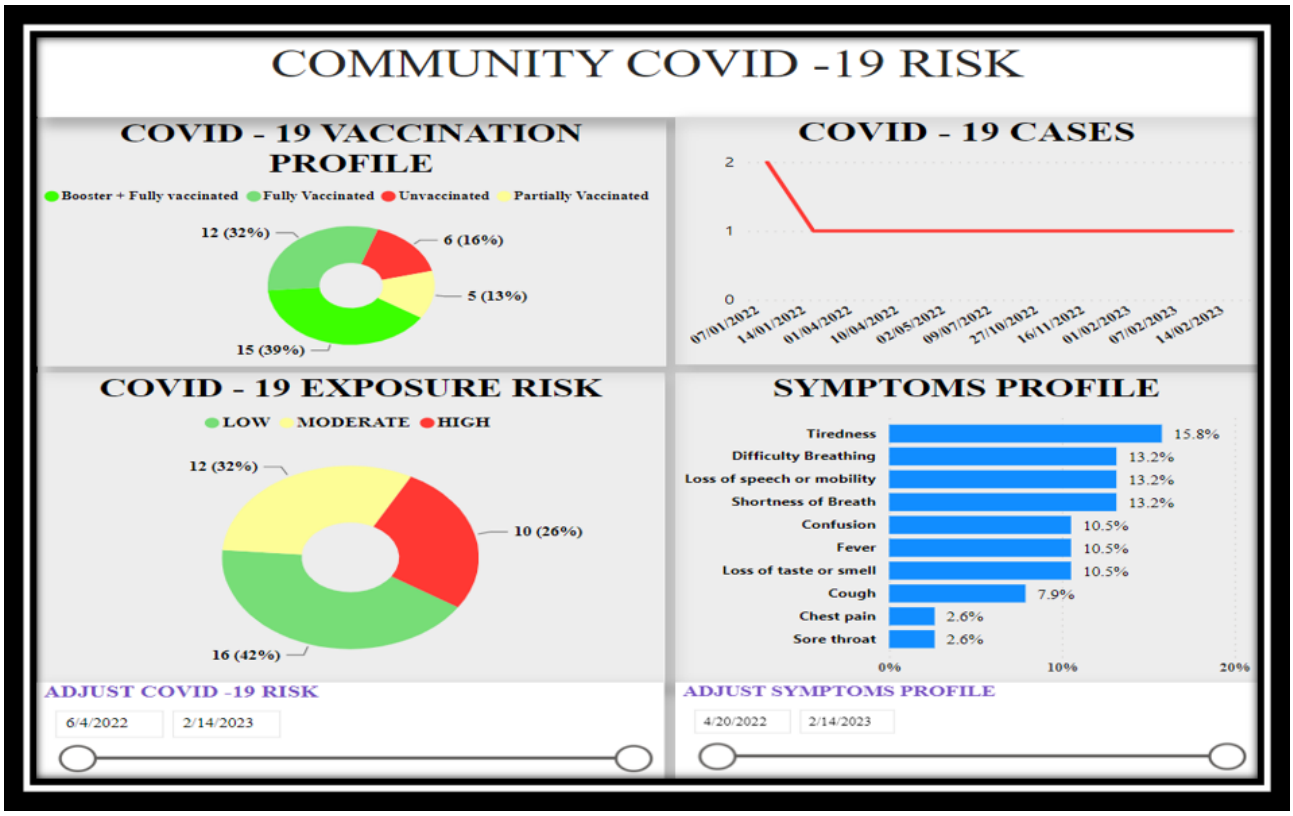
The dashboard system is set up to anonymously assign QR codes to households within a jurisdiction, which allows the PWA to be used only when QR codes are scanned. Figure 2 presents the complete data flow between the PWA, the Amazon Relational Database, the Amazon Elastic Compute Cloud, and the digital health dashboard. Data at rest are encrypted using randomized keys generated by AWS key management service that gives centralized control over the cryptographic keys used to protect data. All users' passwords are hashed and stored using Secure Hashing Algorithms [31], which shorten passwords into smaller forms that cannot be understood using bitwise operation, modular additions, or compression functions.

Data in transit are protected by Cloudflare. All media data are stored in Amazon Simple Storage Service [32], which is an object storage service that offers scalability, security, and performance [32]. Media files are moved through AWS CloudFront, a process that prevents users from directly accessing or manipulating Amazon Simple Storage Service [33,34]. Cloud database access is controlled by AWS Identity and Access Management service [35], which helps to securely control access to AWS resources. Finally, all database access processes are audited through AWS CloudTrail [36], which tracks actions taken on AWS accounts [36], an additional security protocol to monitor and prevent data breaches.

Ethical Considerations

This development process is exempt from ethics review, as study participants were not included in this endeavor. When the digital dashboard will be launched, informed consent will be obtained via the PWA before any data are collected. The information in the informed consent will include the project title, purpose and objectives of the digital health dashboard and PWA, potential benefits and risks, data collection and storage procedures, right to withdraw or drop out and delete the PWA, and contact information for questions, queries, and concerns. Citizens will have to provide informed consent before signing

XSL•FO
RenderX



up to use the PWA. All data from citizens will be anonymized and aggregated before data visualization, analyses, and dissemination.

Results

Overview of the Developed Dashboard

The development process resulted in a replicable and scalable jurisdiction-specific digital dashboard for decision-making that was tested within the DEPtH Lab to confirm not only the real-time linkage between the PWA and the digital health dashboard but also the functionality of all the resultant features. The big data that are relayed to the dashboard in real time reflect usage of the PWA that provides households the ability to manage their risk of COVID-19, request food when in need, and report difficulties and issues in accessing public services. The main components of the dashboard are (1) community COVID-19 risk profile (Figure 3), (2) food security status (Figure 4), and (3) citizen reporter statistics (Figure 5). However, beyond these core components, there are three additional features of the dashboard: (1) delegated community alert system that enables direct communication with community members (Figure 6), (2) direct bidirectional engagement system (Q & A) that allows decision makers to directly respond to citizen queries (Figure 7), and (3) delegated dashboard access (Figure 8) that provides key decision makers to control and specify staff access to individual components of the dashboard, such as the food security status.

Community COVID-19 Risk Profile

It depicts the trend lines of COVID-19 cases in a jurisdiction, the COVID-19 vaccination status of the community, which includes the number and proportion of fully (in this case, 2 doses of Health Canada–approved vaccines) and partially vaccinated community members as well as community members who have obtained booster doses. The vaccination profile also depicts the number and proportion of unvaccinated individuals in the community. In addition to this, based on the algorithm developed by the DEPtH Lab, the daily household COVID-19 risk that PWA users obtain at the frontend is anonymized and aggregated before being reflected on the dashboard within the community COVID-19 risk profile. This feature of the dashboard also shows the evolving picture of community symptoms and behavior profile.

Food Security Status

The food security status feature is a comprehensive decision-making system that enables decision makers to respond to and manage the needs of households in near real time. With a delegated access option, which can be linked with local food banks, the food security status feature provides time-stamped management, displaying the status of the request at various stages: received, processed, dispatched, and delivered. This change of status is reflected in near real time on the PWA, which allows citizens to monitor the progress of their request.

Citizen Reporter Statistics

This feature reflects time-stamped, and detailed statistics of public services access issues reported by citizens within the jurisdiction, including the description of the issue as detailed by the citizens. The dashboard is set up to respond to the citizens' report to ensure that there is clear communication between the decision makers and the citizens. For instance, the citizen reporter statistics are further categorized based on the selected time period to show various aspects of the reports, including the number and proportion of acknowledged reports, and the number and proportion of reports yet to be acknowledged. In addition, there are 2 data visualization layers that display the number of reports awaiting a response and number of reports that received a reply.

Delegated Community Alert System

The decision-making dashboard has a delegated alert system (Figure 6) to send alerts to citizens in the jurisdiction in real time to manage risks, communicate directly, and update citizens of events in the jurisdiction. The delegated level of alerts provides the flexibility to the decision makers to prioritize alerts into urgent and nonurgent alerts. The decision makers have the flexibility to use the alerts from disaster preparation and management to communication of policies.

Direct Bidirectional Engagement System (Q & A)

To enable anonymized engagement with citizens, a bidirectional engagement system (Figure 7) provides decision makers the ability to address citizen queries and inquiries related to jurisdictional policies and procedures. To provide clarity of communication, the citizens are able to visualize the status of their queries and inquiries at various stages, from "received" and "acknowledged" to "processing" and "responded." More

XSL•FO
RenderX

importantly, the decision makers are able to delegate the queries to ensure that the responses are provided in a timely manner.

Delegated Dashboard Access

The dashboard is set up to delegate tasks across decision makers, minimize risk of inappropriate access to data, and manage the needs of jurisdictions efficiently by spreading the load of work across several levels of decision makers (Figure 8). For instance, there is a primary "super administrator" who has access to all aspects of the dashboard and has the capacity to delegate access across 7 different categories, which would delineate access to manage specific systems of the dashboard such as "food security" or "citizen reporter."

Data Visualization

Finally, data that flow from the AWS Relational Database cloud server are processed and converted into meaningful statistics—a key component that enables all dashboard functions. Through data layering, each visual on the interactive and dynamic dashboard can be explored to ascertain specific and more detailed information about the aggregated visualization. The visualization flexibility allows decision makers to understand patterns that are important for rapid decision-making. For instance, a decision maker might be interested in knowing the demographic distribution of fully vaccinated citizens, which can be visualized by selecting the dropdown options within the dashboard.

Discussion

Implications of the Developed Dashboard

During the COVID-19 pandemic, jurisdictions across the world and particularly communities in rural and remote regions faced the need to overcome the decision-making gap that was created due to the lack of timely access to jurisdictional specific information [37]. The pandemic highlighted the inequities between communities, where risk and spread of illness varied due to unequal distribution of adequate health facilities, health care workforce, and health literacy, among other factors [37,38]. The urgency created by the pandemic clarified the need for jurisdiction-specific decision-making technology to address public health crises that prioritizes citizen needs [3]

The pandemic also reiterated the need to decentralize and democratize public health decision-making processes, which would enable rapid responses to public health crises [11,12]. The primary goal of this study was the development of replicable and scalable jurisdiction-specific digital health dashboards for rapid decision-making to ethically monitor, mitigate, and manage public health crises via systems integration, that is, going beyond health systems. The developed dashboard achieves the 5 objectives articulated by the global digital citizen science policy [3].

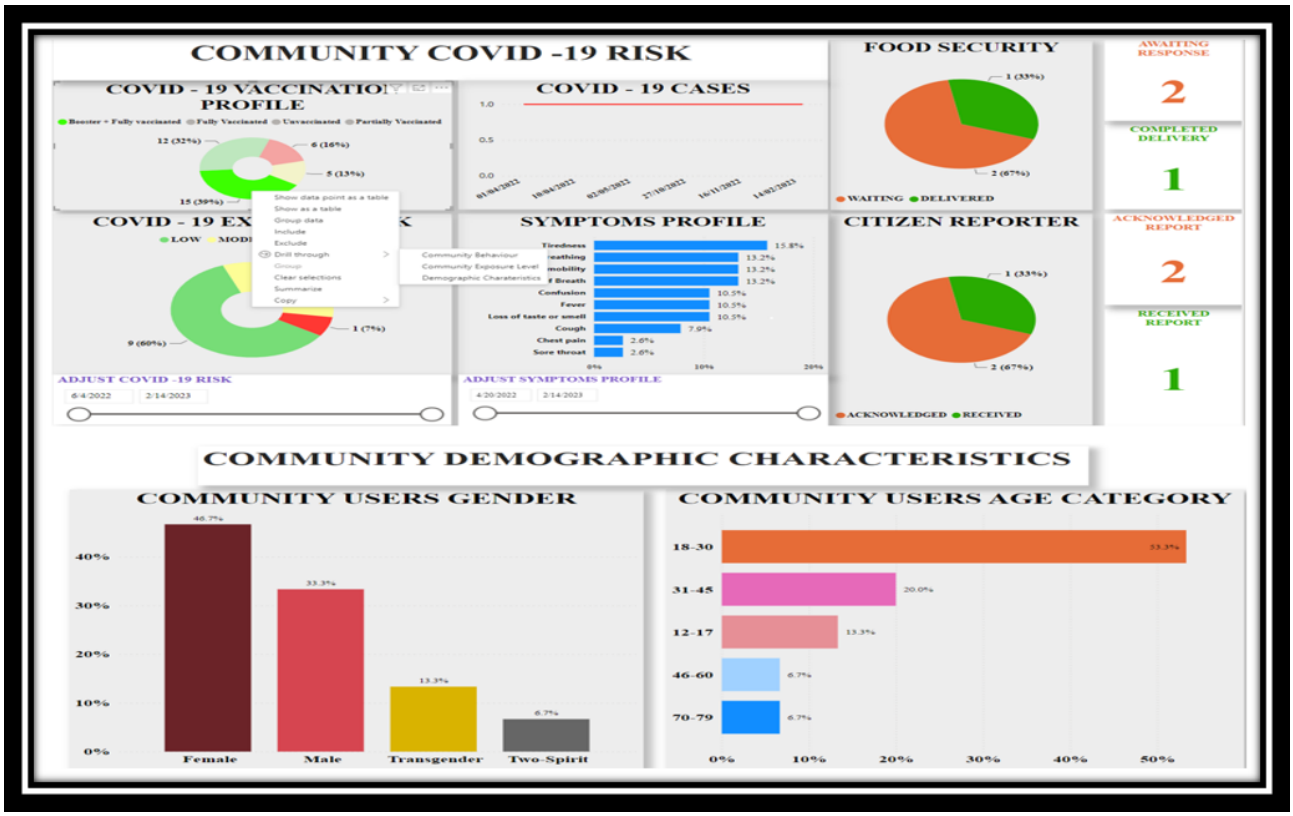
The community COVID-19 risk profile (Figure 3) feature achieves objective 1 of the dashboard development in implementation of ethical real-time surveillance to assess community health risks [39]. The citizen reporter feature (Figure 5) adds another dimension in achieving objective 1 of dashboard development in obtaining personalized and qualitative perception of citizens in understanding access to public services. Food security feature (Figure 4) achieves objective 2 of the dashboard development in implementation of near real-time integrated knowledge translation based on the information provided by citizens. In visualizing the food security status within the dashboard, decision makers not only understand the aggregated needs of households in the community but also respond to the specific needs of each household requesting food [40].

The delegated alert system (Figure 6) addresses objectives 3 and 4 of the dashboard development: implementation of evidence-based real-time public health communication and evidence-based decision-making using real-time data analytics to mitigate health risks. Bidirectional engagement system (Figure 7) adds personalization in achieving objective 3 of the dashboard development: real-time public health communication [41]. The digital health dashboard in general addresses objective 5 of the dashboard development, that is, development of adaptable, scalable, and replicable digital infrastructure to address existing and evolving public health crises. For instance, using the developed digital health infrastructure, changes can be made to the features of the dashboard to suit jurisdictional, citizen, or crisis-specific needs [40].

More importantly, the digital health dashboard that was developed operationalizes four key processes that have important implications in transforming public health policy in the digital age: (1) evidence-based decision-making, (2) digital citizen science for health equity, (3) rapid responses to public health crises, and (4) social innovation: decentralization of technology, and data sovereignty and security.

Evidence-Based Decision-Making

Decision-making from the perspective of managing public health crises goes beyond health systems to include key aspects for survival and societal functioning, such as food security [42,43], maintenance of law and order [44,45], and social support to vulnerable groups [46], that is, systems integration for cohesive decision-making. However, making informed decisions in public health crises can be extremely challenging without accurate data and evidence, particularly in situations like pandemics, where disjointed and disparate information from multiple sources can result in poor decision-making [7,47]. This challenge was particularly pronounced in terms of ineffective information sharing across different levels of governments, with municipal governments having to take decisions at the local level, without concrete evidence [48,49].



To overcome these challenges to timely evidence-based decision-making, citizen-driven big data, which is not only timely but also relevant to specific jurisdictions, can transform local jurisdictional decision-making [3,7,49]. The digital health dashboard for decision-making that we conceptualized and developed, at its core, addresses these challenges by providing municipal decision makers access to ethically obtained big data from their own citizens to enable evidence-based decision-making. The decision-making dashboard can not only provide time-stamped big data about a specific public health crisis (ie, COVID-19) but also enables the management of citizen-reported issues that can range from food insecurity to

XSL•FO
RenderX

access to public services—a functionality that can ethically monitor the status of community health [50].

There is growing evidence that COVID-19–specific dashboards have played a significant role in pandemic management, particularly with regards to vaccine uptake to promote health equity [37]. The decision-making dashboard we developed provides detailed and anonymized aggregation symptoms, behaviors, and vaccine uptake status, which enabled decision makers to develop targeted public health communication in near real time to manage community risks. The data visualization of evolving and time-stamped statistics driven by real-time big data from the citizens of the community (Figure 9) provides a detailed picture of the changing nature of potential public health crises. For instance, it would be possible to understand the variation of prevalence and incidence of symptoms across specific time periods using dashboard functionality. This can be transformative not only for public policy but also for epidemiology in the digital age, where risks can be monitored in real time [51,52].

Figure 9. Data visualization depicting demographic characteristics along with community risks.

In enhancing the operational capacity of digital dashboards, particularly from the perspective of improving jurisdictional capacity, it is important to create delegated access to the dashboard. For instance, our digital dashboard has 7 different categories of access that enable the delegation of day-to-day tasks to ensure evidence-based decision-making across the jurisdictional operations. Moreover, the delegation of decision-making can even be outsourced to different operational sections within a municipal government or even outside the government. For instance, the food security feature could be delegated to a local food bank to ensure timely access to food. Perhaps more importantly, such delegated access enhances data security by providing permission-based restricted access to the dashboard.

In developing digital health dashboards for nonacademic users, particularly decision makers, it is important to prioritize intuitive visualization that does not require basic training in statistics or epidemiology. The data visualization within the dashboard is designed to be dynamic to make complex data sets easy to understand and explore by nonacademic audiences (ie, decision makers and public health practitioners), to extract information quickly, and enhance real-time rapid responses, particularly in the event of a public health crises. To ensure ease of uptake and use of the dashboard, we designed it to be interactive with the layering of data visualization, which allows decision makers to use intuitive tabs or dropdown menus to delve deeper to obtain the information they seek for evidence-based decision-making. For instance, if decision makers seek to obtain more information about community risk of COVID-19, such as distribution of vaccination status across age cohorts, or gender, they are able do this by selecting the available dashboard visualization options. Another key feature of the dashboard is depicting the temporality of data using data slicers, which allow decision makers to streamline evidence by specific time periods. For instance, data for a specific category of information (eg, COVID-19 vaccination) can be displayed over a specific time period, and compared with another category of information (eg, community symptoms) to understand how community behaviors correlate with general health of the community.

In terms of evidence-based decision-making in a world where there are new strains of COVID-19 as well as other evolving epidemics [53], the scalability and adaptability of the dashboard

XSL•FO
RenderX

infrastructure are key to the sustainability of this innovation. Although this digital health dashboard was designed in response to the COVID-19 pandemic, this platform can be easily scaled up and adapted to monitor other epidemics and pandemics by using the developed digital infrastructure. The scalability is not limited to other epidemics or pandemics, but also across different levels of jurisdictions to ensure ethical monitoring, management, and mitigation of existing and emerging public health crises.

Digital Citizen Science for Health Equity

Although citizen science is primarily considered a research approach that is participatory in nature and can range from contribution and collaboration with citizens to cocreation of knowledge [3], it is rarely used in the development of digital health platforms. However, the application of citizen science to public health decision-making processes has gained considerable momentum recently [54-58]. This potential and promise of citizen science informed our methodology for the development of our digital health dashboard. In developing this dashboard, we drew from the principles of the SMART Framework [12] that integrates citizen science, community-based participatory research, and systems science as well as the approaches of the global digital citizen science policy to tackle pandemics [3].

The DEPtH Lab's Citizen Scientist Advisory Council enabled us to shape the dashboard to the needs of both the citizens and the decision makers [59]. The ability to balance both citizen and decision maker needs is critical to the success of digital health dashboards in providing a value perspective to both citizens at the frontend (PWA) and to the decision makers at the backend (digital health dashboard). The value perspective to the citizens is their ability to manage their household risks as well as understand community risks, which is inextricably linked to the functioning of the dashboard, which uses anonymized data derived from the PWA to understand and manage community risks along with the ability to respond to citizen needs in near real time.

Although the application of citizen science to public health is not new [60], this approach of citizen science for the development of digital health dashboards enables new opportunities to address public health crises from a systems perspective. For instance, the development of features to address food security and access to public services was based on the need identified by citizens, an approach that integrates health, food, and social service systems. The development of digital health dashboards using citizen science can potentially improve uptake from citizens as well as enhance scalability and adaptability across jurisdictions, that is, dashboards that are developed to address needs identified by citizens, an approach that will in turn meet decision maker goals in addressing citizen needs [59]. Thus, digital dashboards developed using citizen science can potentially transform public policy in multiple jurisdictions [61]. However, the biggest impact of these dashboards will be in promoting health equity by prioritizing and addressing the needs of citizens in near real time by developing equitable evidence-based policies using big data generated by the citizens themselves [12].

Rapid Responses in Real Time

The real-time notifications feature of the digital health dashboard enables decision makers to engage with their community members effectively and directly to not only inform them about existing and emerging community risks but also to provide evidence-based public health communication. The big data received by the dashboard can be updated at intervals of 5 to 30 minutes to provide decision makers with recent and accurate community health information that can be used for rapid responses. From a public health management perspective, for instance, decision makers can inform community members of evidence of an increase in certain symptoms so that community members are aware of the changing dynamics of the health risks in their community.

However, the digital infrastructure of the dashboard can be repurposed based on the needs of jurisdictions, decision makers, or their citizens. Digital health dashboards can be paradigm changing in the age of climate emergency [62], where disaster management is directly linked with public health. For instance, currently, the digital dashboard is set up to send urgent alerts both with PWA and text alerts to inform citizens of all emergencies. This direct and rapid communication is critical for managing evolving risks that can range from pandemics and floods to forest fires and earthquakes [63,64].

Digital health dashboards can also be used to provide evidence-based public health information as well as policy and program information on a continuous basis. This feature can play an important role in minimizing misinformation and disinformation that is pervasive in this digital age [65]. The misinformation and disinformation related to public health [65], particularly in terms of pandemics, where false narratives about the disease and vaccines can cause considerable public health risks [66], can be minimized using digital health dashboards. The validity of the information can be cited or sourced using trusted external agencies such as the World Health Organization [67]. Nevertheless, it is difficult to address citizen mistrust in institutions, and the digital dashboards that are built using citizen science [3], and that operate using anonymized citizen data to generate evidence, can make incremental changes in citizen perception. Finally, the dashboard also provides a direct, bidirectional, and anonymized engagement with citizens that the citizens can initiate using the "Q & A" feature, which further enhances real-time engagement to build trust.

Social Innovation: Decentralization of Technology and Data Sovereignty and Security

Digital health dashboards for decision-making that are developed for jurisdictions, at their very core, are operationalizing decentralizing of technology and democratization of data using digital citizen science [3,10]. This approach in essence is social innovation that ethically leverages the power of digital technology for decentralization and democratization to enable data sovereignty of individuals and jurisdictions. The decentralization is two-fold: (1) the development of a PWA that takes the platform ecosystem away from the monopolization of big technology launch platforms, that is, Google Play Store and Apple Store, and (2) the dashboard is set up to decentralize access to information, hence enhancing self-determination of

XSL•FO
RenderX

individual jurisdictions. This decentralizing paves the way for the democratization of data, which are owned by citizens at the individual level and, by the jurisdictions, at the aggregated level [68].

This approach facilitates the data sovereignty of both citizens and jurisdictions, which is another important byproduct of the decentralization of technology. The decentralization of technology, democratization of data, and data sovereignty at both individual and jurisdictional levels provide the foundation for robust data security protocols. The design, implementation, and optimal functioning of digital health dashboards are dependent upon data privacy, and security. Apart from the standard measures of user authentication at both frontend (PWA) and backend (digital health dashboard) using multifactor authentication, data security protocols are enabled for both data at rest and data in transit in multiple layers. For data at rest, the first layer of security ensures restricted access to AWS account through identity and access management roles with multifactor authentication.

The second layer ensures that all data at rest are server encrypted using keys generated by AWS Key Management Service. The third layer ensures that all user database passwords are hashed and stored using Secure Hash Algorithm (SHA)-256 and SHA-512. For data in transit, to prevent distributed denial-of-service attacks, we use the Cloudflare-distributed denial-of-service mitigation service to ensure masking of website internet protocol address [69,70]. A distributed denial-of-service attack is a deliberate attempt to stymie a server, service, or network's regular activity by saturating the target or its surrounding infrastructure with a deluge of internet traffic. To further ensure privacy and security of data in transit, Cloudflare server is used for key exchange and establishing the identity of a server by providing forward secrecy, and Advanced Encryption Server 128- Galois counter mode is used to encrypt the Hypertext Transfer Protocol Secure request. All responses are encrypted in the Transport Layered Security connection data and personally identifiable data are stored within user or citizen devices.

Strengths and Limitations

A major strength of jurisdictional-specific digital health dashboards for decision-making is their potential to invert innovation [71]. Inverting innovation is defined as innovation that addresses a critical societal problem by satisfying 3 key criteria: transforming weaknesses into strengths, prioritizing citizen needs over corporate profits, and providing a pathway for rapid scale-up. Our digital health dashboard can respond rapidly to public health crises, by prioritizing both citizen and decision maker needs, and the digital infrastructure can be scaled-up based on evolving needs.

This inverting innovation potential of the digital health dashboard is driven by the digital citizen science approach [3], which is another major strength that ensures that the development process takes into consideration citizen needs. This focus on citizen needs also influenced our decision to prioritize decentralization of technology, democratization of data, and data sovereignty at both individual and jurisdictional levels—all aspects, which are significant strengths of the digital health dashboards. Finally, the primary purpose of development of jurisdictional-specific digital health dashboards is rapid responses using ethically obtained big data to monitor, mitigate, and manage population health crises, which is the most significant strength.

Even though rigorous data protection and security processes are layered into the dashboard development, risks to data security always exist, which need to be assessed on a consistent basis and addressed. Redundancies built into AWS databases allow us to protect the dashboard from ransomware attacks [72], and encryption and anonymization of data secure data privacy. Nevertheless, data privacy protocols need to be addressed on an ongoing basis to ensure that the dashboards comply with laws and regulations that govern jurisdictions [73]. Finally, citizen-driven digital health dashboards are limited by the uptake from citizens within jurisdictions, and the uptake is in turn influenced by internet equity [3] as well as digital divides within and across jurisdictions [74]. Although there is growing evidence of the potential of digital health dashboards to transform health care systems [15], the digital health dashboard that we developed needs to be tested in real-world settings. While the strengths and limitations of this study are specific to the development methodology and approaches, digital health dashboards powered by citizen-driven big data need to be tested in real-world settings to generate empirical evidence that can confirm not only the validity and veracity of citizen-driven big data but also the compliance of citizens and decision makers in using such dashboards for rapid decision-making.

Conclusions

Digital health dashboards for decision-making can transform public health policy by prioritizing the needs of citizens as well as decision makers to enable rapid responses to public health crises. Digital health dashboards also provide decision makers the ability to directly communicate with community members to mitigate and manage emerging population health risks, a paradigm-changing approach to tackle future epidemics and pandemics, that is, inverting innovation by prioritizing community needs with digital technology. Finally, digital health dashboards that are built by using digital citizen science approaches can catalyze systems integration and pave the pathway for rapid scalability to ensure digital health for equity.

Abstract

Background: Strokes pose a particular challenge to the health care system. Although stroke-related mortality has declined in recent decades, the absolute number of new strokes (incidence), stroke deaths, and survivors of stroke has increased. With the increasing need of neurorehabilitation and the decreasing number of professionals, innovations are needed to ensure adequate care. Digital technologies are increasingly used to meet patients' unfilled needs during their patient journey. Patients must adhere to unfamiliar digital technologies to engage in health interventions. Therefore, the acceptance of the benefits and burdens of digital technologies in health interventions is a key factor in implementing these innovations.

Objective: This study aims to describe the development of a discrete choice experiment (DCE) to weigh criteria that impact patient and public acceptance. Secondary study objectives are a benefit-burden assessment (estimation of the maximum acceptable burden of technical features and therapy-related characteristics for the patient or individual, eg, no human contact), overall comparison (assessment of the relative importance of attributes for comparing digital technologies), and adherence (identification of key attributes that influence patient adherence). The exploratory objectives include heterogeneity assessment and subgroup analysis. The methodological aims are to investigate the use of DCE.

Methods: To obtain information on the criteria impacting acceptance, a DCE will be conducted including 7 attributes based on formative qualitative research. Patients with stroke (experimental group) and the general population (control group) are surveyed. The final instrument includes 6 best-best choice tasks in partial design. The experimental design is a fractional-factorial efficient Bayesian design (D-error). A conditional logit regression model and mixed logistic regression models will be used for analysis. To consider the heterogeneity of subgroups, a latent class analysis and an analysis of heteroscedasticity will be performed.

Results: The literature review, qualitative preliminary study, survey development, and pretesting were completed. Data collection and analysis will be completed in the last quarter of 2023.

Conclusions: Our results will inform decision makers about patients' and publics' acceptance of digital technologies used in innovative interventions. The patient preference information will improve decisions regarding the development, adoption, and pricing of innovative interventions. The behavioral changes in the choice of digital intervention alternatives are observable and can therefore be statistically analyzed. They can be translated into preferences, which define the value. This study will investigate the influences on the acceptance of digital interventions and thus support decisions and future research.

Introduction

Background

Strokes pose a particular challenge to the health care system. Although stroke-related mortality has declined in recent decades, the absolute number of new strokes (incidence), stroke deaths, and survivors of stroke has increased [1]. Approximately 40% of patients with stroke present with persistent cognitive, perceptual, and participative disabilities [2,3]. Stroke is the second leading cause of acquired disability [4]. Neurorehabilitation reduces disability and improves functional outcomes [5]. Stroke-related limitations are treated in neurorehabilitation. Most recovery of functions is achieved in the subacute phase (3-6 months after the stroke event) [6]. Neurorehabilitation is a combination of various disciplines [7]. Because of the need for a comprehensive therapy approach, strokes are one of the most cost-intensive diseases in the German health care system, with current treatment costs of approximately €43,000 (US $48,040.40) per patient [8].

Objectives

With the increasing need of neurorehabilitation and the decreasing number of professionals, innovations are needed to ensure adequate care [9]. Digital transformation has opened avenues for improving services, products, and interventions through the increased use of digital technologies [10,11]. In the project *evidence-based robotic assistance in neurorehabilitation* (E-BRAiN), a robot was developed to support daily therapy practice [12]. Researchers investigated the use of the humanoid robot "Pepper" by SoftBank Robotics owing to interaction [13], motivation, software and hardware capabilities, and acceptance. To decide on implementing innovative therapies, decision makers should consider the trade-offs that patients are willing to accept [14]. Discrete choice experiments (DCEs) are a way to identify trade-offs by analyzing preferences [15]. The acceptance of new therapies is a key success factor and is determined by the fulfillment of needs [16-18]. When acceptance information is considered in decision-making, the utility of care decisions can be maximized in the short term [19,20], can strengthen patient orientation and adherence in the intermediate term, and can improve clinical effects in the long term. Financially, the health care system can benefit from faster and more efficient therapeutic outcomes [21,22].

Methods

Ethics Approval

The preference survey instruments, informed consent form, and study design were reviewed and approved by the ethics committee of Hochschule Neubrandenburg (HSNB/177/21). The study considers the Declaration of Helsinki, the Deutsches Bundesdatenschutzgesetz (the German Data Protection Act), the European privacy policy, and Guideline on Good Clinical Practice (CPM/ICH/135/95) regarding the obligation to report serious adverse events.

Informed Consent, Participation, and Dissemination

Participant confidentiality was ensured by pseudonymization of the qualitative interview recordings and will be ensured by anonymizing the data from the quantitative survey (DCE). All participants have provided informed consent in the completed qualitative interviews. Informed consent is also obtained in the quantitative survey. Participants have the right to withdraw from the study at any time and without giving reasons and to request the deletion of the collected data at any time during the survey. All participants will be informed on the opening page of the web-based questionnaire that participation is voluntary. All identifiable details will be removed during future dissemination of findings and in presentations and publications. Researchers' contact information is provided on the last page in case the participants have questions. The participants can contact the researchers directly by phone or via a contact email address. The results of this study will be presented at national and international conferences and published in peer-reviewed journals.

Research Questions and Study Aim

This ongoing study will address the following question: Which criteria of digital technologies impact patient and public acceptance? The aim is to investigate patient and public preferences to generate information on acceptance and analyze the value of digital interventions. Preference evidence is a series of observable human behaviors that can be analyzed by the choices individuals make between alternative health states, health services, or health interventions. Choices define the value of attributes and alternatives in health care.

Acceptance is a requirement for active patient engagement and thus for efficiency (the greatest possible result with the least possible effort) and effectiveness (ability of the intervention to positively improve patients' state of health in a targeted manner). To obtain information on acceptance, it is necessary to understand the trade-offs that patients make by weighing the advantages and disadvantages of therapy options using digital technologies. We also ask whether patients would accept a humanoid robot in neurorehabilitation. Our primary objective is to weight the criteria that impact patient and public acceptance. Secondary objectives include (1) a benefit-burden assessment (estimation of the maximum acceptable burden of technical features and therapy-related characteristics for the patient or individual, eg, no human contact), (2) overall comparison (assessment of the relative importance of attributes for comparing digital technologies), and (3) adherence (identification of key attributes that influence patient adherence). Our exploratory objectives include (1) heterogeneity assessment (how preferences differed based on participant characteristics) and (2) subgroup analysis (to explore and explain heterogeneity based on the correlation between therapy preferences and participants' sociodemographic information, experience-based treatment history, and attitudes). Our methodological aims are to investigate the use of DCE and the impact on data quality, preferences, and choice consistency.

The following assumptions and hypotheses will be examined:

XSL•FO
RenderX

1. Patients engage in a health care process to meet their needs. Health-related needs include therapy outcomes. Therapy outcomes can be measured by goal achievement. Therapy outcomes influence the choice of intervention.
   - H1: The higher the expected success rate, the higher the probability of choosing an alternative.
   - H0: The success rate of an intervention has no influence on the probability of choosing an alternative.
2. Needs involve technical aspects of digital technologies. Undesirable features will have a negative impact on the decisions.
   - H1: The more burdensome or worse a technical aspect is rated, the lower the probability of choosing an alternative.
   - H0: The rating of a technical aspect has no influence on the probability of choosing an alternative.
3. The complete absence of human contact has a negative effect on the decision.
   - H1: The fewer the opportunities for human contact, the lower the probability of choosing an alternative.
   - H0: The opportunity for human contact has no influence on the probability of choosing an alternative.
4. Digital technologies should have certain characteristics according to the goals of a digital transformation (eg, flexibility, adaptability, participation, and empowerment). Characteristics that do not condition flexibility, adaptability, participation, or empowerment negatively impact patients' therapy decisions.
   - H1: The fewer the goals of the digital transformation that can be achieved by the digital technology, the lower the probability of choosing an alternative.
   - H0: Flexibility, adaptability, participation, and empowerment have no influence on the probability of choosing an alternative.
5. Interventions should be individualized for patients in a patient-centered health care system. Patients' preferences differ with respect to their characteristics (sociodemographic characteristics, clinical and digital experiences, attitudes, expectations, norms, behaviors, and abilities).
   - H1: The less patient centered an intervention is, the lower the probability of choosing an alternative.
   - H0: The characteristics of different patients have no influence on the probability of choosing an alternative.

Target Population

We include two study populations: (1) an experimental group (patients with stroke) and (2) a control group (the general population). Only individuals diagnosed with a stroke will be included in the experimental group. For both groups, only individuals aged ≥18 years, who reside in Germany, and who can read and understand German will be included. Limitations in recruitment were expected because of the COVID-19 pandemic at the beginning of the study and during the development of the experiment. Therefore, we decided to include a control group.

Overall Project Design

Both qualitative and quantitative methods are used in this health preference research (HPR) study. A completed qualitative prestudy was used to identify which decision criteria patients consider when choosing innovative therapy options using digital technologies. Furthermore, the impact of these attributes will be determined in a quantitative survey using a DCE. DCE is a stated preference method for economic evaluation [23,24]. This DCE will be used to analyze how patients define the "value" of a digital technology. The analysis is performed using repeated choices between hypothetical therapy alternatives with different attribute levels [25]. The choices can identify which attributes and levels are preferred. Patient benefit derives from preferences, and thus, the benefit can also be defined as value [26]. DCE is a preference elicitation method [27-29]. The use of such choice experiments is also presentive in medicine [30,31]. There are many guidelines and recommendations for the DCE [32,33]. The increasing popularity of DCE reinforces the intention in this study. This paper describes the protocol of the DCE to investigate patient and public acceptance of digital technologies in health care. This paper also describes the methodology used in our ongoing work.

Relevance of the DCE

A targeted literature research on acceptance models was conducted to analyze acceptance dimensions and criteria that impact individual's acceptance. Criteria from different perspectives, such as those of the patients, system, and provider, were analyzed to investigate the concept of acceptance with respect to the value of digital interventions. Acceptance refers to the willingness of individuals to engage in a health intervention or health service [34]. Technology acceptance models provide information on variables that influence acceptance, such as perceived usefulness, perceived ease of use, subjective norms, or user experience [35-37]. Extensions of the models explain the interrelationships between the beneficial influencing factors and the burdensome influencing factors as a balancing process [38]. However, the models are limited in evidence regarding specific attributes that represent a benefit or a cost or burden to individuals or, specifically, patients. No information is provided on how impactful individual aspects of digital information are. HPR studies were conducted to generate evidence regarding the weighting of attributes. Thus, the presented DCE was developed.

The aspects of digital technologies (eg, data processing) have already been examined in various studies. There are studies that focus on digital apps on mobile devices [39,40]. Among these studies, attention is partly focused on data processing only [41,42]. Other studies examine factors of communication (eg, information giving, information transfer, and contact) [41-43]. Most of the studies do not include health-related goal variables [39,44]. Thus, there is a gap in holistic evidence on preference research on digital interventions. This study aims to generate evidence for all possible digital technologies (not only digital apps).

XSL•FO
RenderX

Development of Attributes and Levels

Different digital technologies have been investigated in different studies in the context of therapies and were therefore considered in the prestudy (robots, voice assistants, digital health apps, digital health devices, etc). As digital technologies have an unlimited set of attributes, limitations arise from the fact that decision makers cannot consider all possible attributes in their evaluation [18]. In a DCE, alternatives are described by decision-relevant criteria that are identified from the set of possible attributes [18].

A targeted literature search was conducted to identify the characteristics of health-related interventions in the context of the digital transformation associated with the use of digital technologies. First, digital transformation in health care was considered. Digital transformation became essential due to the rapidly changing and increasing needs and expectations in health care [45-47]. Digital technologies are innovations to achieve certain goals of digital transformation: flexibility of place and time, flexibility of the range of care, expansion of access for patients considering gains and pains, improvement of health literacy, participation and personal responsibility of patients, and improvement of information structures [11,48]. Certain characteristics (attributes) of digital technologies are necessary to achieve these goals. In total, 17 attributes were identified in the literature: communication, emergency communication, contact with professionals, distance to technology, emotions, speech, participation, recognition, feedback, data security, pick-up and drop-off function, entertainment, usefulness, place, location dependency, duration, and frequency.

Formative qualitative research is foundational to the development process of HPR studies [49]. Therefore, we conducted semistructured pilot interviews with patients with stroke (n=14) and experts in neurorehabilitation (n=5) to identify and cluster the decision-relevant criteria from the subset of 17 attributes. Patients were asked to describe their physical and daily living limitations owing to the diagnosis and their experiences with neurorehabilitation. The patients were also asked about their attitude, opinions, and expectations regarding digital technologies. After the humanoid assistance robot "Pepper" was presented, the participants were asked about their attitude toward the robot. Attributes defined from the literature were presented with descriptions on cards. The patients were asked to rank the attributes according to their relevance. Furthermore, the patients described what they thought a future therapy might look like by using a different card of attributes. An interview guide was used for this process. We used semistructured interviews, which allow an open discussion style and an interview to be individualized, allow spontaneous in-depth discussion of interesting statements, and allow a return to relevant key questions [50]. Experts estimated the patients' point of view regarding the questions asked according to their experience. A list of seven decision-relevant criteria was developed: (1) explanation and presentation of exercises, (2) information from digital technologies, (3) contact with professionals, (4) patients' choice in the therapy process, (5) data processing, (6) copayment per month, and (7) therapy success within 6 months. Thus, the list included 5 attributes that are technical aspects (attributes 1-5). In addition, copayment per month and therapy success within 6 months complete the decision context. Therapy success refers to an individual's goal attainment. Goal attainment is determined by the improvement in body function, which in turn leads to a resumption of activities of daily living. The full list was concretized through discussion rounds, such as focus groups and workshops with experts in health care. The final list was transformed into a decision model.

Descriptive Framework

Preference evidence can be identified by observing human behaviors using elicitation tasks. In a preference elicitation task, participants evaluate assigned alternatives or objects according to their preferences. In this study, we determined that the preference elicitation task would lead to the goal of determining a patient's willingness to accept the trade-offs between the characteristics of therapy using digital technologies. The descriptive framework was created to contain all decision-relevant attributes, levels, and descriptions of the decision context that will be used to communicate the content of the elicitation tasks (Table 1).

XSL•FO
RenderX

Table 1. Descriptive framework.

Attributes	Description	Level 1	Level 2	Level 3	Level 4	Level 5
Explanation and presentation of therapy exercises	Patients receive information, instructions, and assistance on how to perform the exercises, with an explanation and presentation of therapy exercises.	Sounds and speech	Descriptive texts	Images	Videos	Spatial movement
Information in therapy	Patients receive information from the digital support system in digital therapies, but there are also digital therapies where patients do not get any information.	No information	Therapy and rehabilitation process	Diagnosed disease	Patient's current health status	Change in health status owing to therapy
Contact with health care professionals	Patients have contact with health care professionals in a digital therapy, but there are also digital therapies in which patients have no contact with professionals.	No contact	Contact is indirect (messages)	Contact is direct (telephone or video)	—[a]	—
Patients' choice in the therapy process	Patients have certain choices in a digital therapy. Therefore, patients have an influence on the design of therapy processes, but there are also therapies where patients have no influence.	No influence	Selection of therapy exercise with a certain degree of severity	Pace of therapy exercise	Time of therapy (frequency, duration, and start)	Place of therapy (eg, home, clinic, or practice)
Data processing	There is data processing in digital therapies. Data about patients are collected and forwarded, but there are also digital therapies where no data are processed.	No data processing	Processing of data about the person	Processing of data about the diagnosis	Processing of data about the progress of the therapy	—
Copayment per month	Patients in digital therapies contribute to the cost of the therapy with a copayment per month. There are also digital therapies where patients have no copayment.	€80 per month	€60 per month	€40 per month	€20 per month	No copayment
Therapy success within 6 months	Patients have success in a digital therapy by achieving their therapy goals. Therapy goals are set at the beginning of a therapy, but not all patients achieve their goals within 6 months.	60 out of 100 patients	70 out of 100 patients	80 out of 100 patients	90 out of 100 patients	100 out of 100 patients

[a]The number of levels of each attribute is not necessarily equal, so the number varies between 3 and 5 levels. Therefore, for the attributes contact with health care professionals, no data are available for levels 4 and 5, and for the attribute data processing, no data are available for level 5. Furthermore, the respondents in the study were recruited in Germany. Accordingly, the data on the copayment per month were given in euros (€) and not in US $ (€0.92=US $1). For visual representations of each level, see Multimedia Appendix 1.

XSL•FO
RenderX

Choice Context

In choice experiments, participants are asked to assume that their therapy decision is made in the context of a specific or their current health condition. Our study sample included both therapy-experienced and therapy-inexperienced participants. Therefore, the participants are asked to assume a health condition that requires rehabilitative therapy.

Elicitation Tasks

The challenge in a DCE is to dissolve the response uncertainty and to trace the preference information back to the individual attributes through repeated choice tasks, with participants "forced" to make a decision between digital therapies. For the professional group, there was no choice available within the choice task. The underlying choice task is a ranking task, which follows a fixed procedure. The choice starts with the selection of the best alternative among 3 choices. The choice is iterated with the remaining 2 so that a complete ranking is achieved. Thus, the DCE uses a best-best choice format [51].

Participants' willingness to choose the digital therapy was determined by the following follow-up question: "Would you really choose the previously selected digital therapy in real life to improve your health?" Recently, the dual response "none" has been established as a variant in choice experiments [52,53]. A dual response of "none" asks for 2 responses for each task: one choice between the available product alternatives and one between the "none" concept and the previous alternatives. Essentially, it is a choice between the most preferred alternative and none. If participants would actually buy or take the alternative, they would not prefer none, but if they would not buy or take the alternative, they would prefer none to the given alternative [54]. The dual response "none" design takes more time to answer and is an increase in analysis effort owing to a complex design. However, more information is generated, which makes the design more efficient and powerful. Estimation errors are reduced, and the underlying model estimate is not significantly changed [52]. This design provides a higher resolution for individual-level preferences. As there is less "missing" information when participants select "none" as their preferred alternative, more information is available for individual-level modeling [54]. The final survey instrument comprised 6 choice tasks. The number of choice tasks was determined by the underlying experimental design, possible number of participants, and information received per task. No names, brands, or companies were named in the presentation of the choice tasks; therefore, the tasks were unlabeled. In addition, unlabeled alternatives were preferred because the study objectives were to estimate the marginal rates of substitution and value equivalents for therapy attributes [18].

Elicitation Format

Participants will be familiarized with the attributes and expressions through descriptions and explanations before the first task. In addition, participants will see a tutorial and exercises to answer the choice tasks. Participants will answer a choice task with a clearly dominant alternative (copayment=none; treatment success=100%) so that an understanding of how to answer the DCE is tested.

Experimental Design

Proper design and implementation of the DCE requires the consideration of the choice context, composition of choice sets, and framing of choice questions and instructions [55]. The results of the preliminary study indicated lower attention and concentration abilities in the experimental group. This finding, along with the evaluation of participants, led to the decision to use a partial design (choice tasks include 4 of the 7 attributes) [18,56]. Experimental design software was used in this study (Sawtooth Software Inc; ChoiceMetrics).

The underlying experimental design is a fractional-factorial efficient Bayesian design (D-error) to maximize the ability to identify participant preferences and variability in preferences across participants [56].

The experimental design was based on the following assumptions: minimal overlap, level balance and orthogonality. *Minimal overlap* means that each level is shown as few times as possible in a task. If the number of levels of an attribute is equal to the number of concepts in a task, each level is shown exactly once. Assumptions also were *level balance* which means that each level of an attribute is shown approximately the same number of times. *Orthogonality* means that levels are chosen independent of other levels so that the benefit of each level can be measured independent of all other effects).

Owing to the complexity of the experimental design in terms of the size of the decision model (7 attributes and 3-5 levels), the experiment was blocked. Combinations of alternatives are drawn from the total selection in 20 blocks in such a way that each level is combined as often and as evenly as possible. The study will analyze both the main and interaction effects. By combining all possible levels with each other (2-way frequency), sufficient information is generated to be able to measure the interaction effects. The allocation of the blockers is randomized. When a survey is stopped and choice tasks are not completed, they are made available to other participants so that all choice tasks are provided.

Survey Instrument Design

Designing an effective survey instrument requires numerous connected decisions that are built on the decision context, attribute selection, and experimental design. The DCE requires a survey instrument that (1) explains to participants the various aspects of digital technologies that may differ across therapy options and (2) asks participants to indicate their preference for therapy options as aspects change. The final instrument is web based and self-completed by the participants.

The information presented to participants was developed by preparing descriptions for each attribute and level. Patients with stroke often experience cognitive impairment. Therefore, special attention must be paid to the layout of the survey. The design of the survey and the potential layout of the choice task should include the appropriate use of text and icons. An appropriate and well-designed layout can minimize the cognitive efforts required to compare alternatives and evaluate trade-offs. Because of the visual perceptual deficits in patients with stroke, icons should have good color contrast, clearly delineated lines, and a monochromatic design. We assessed the clarity and

XSL•FO
RenderX

completeness of the DCE survey instrument and tested different choice formats (selection from 2 or 3 alternatives, best vs best-worst selection, and full vs partial design).

We limited the time required to complete the survey to a maximum of 30 minutes to minimize dropouts and to reduce data quality toward the end of the survey. First, we administered the quantitative survey with the final survey design in the control group. A pilot test was conducted, and the data collection was stopped after 150 completed questionnaires in the control group. Preference data were tested using a conditional logistic regression model to check for appearance validity, assumed signs and coefficients, and estimation problems.

We planned 3 sections for the web-based questionnaire: a study description and introduction to the attributes, the DCE, and the question section on sociodemographic and therapy and technology experience. The content of the survey will be clarified through an introductory description of the DCE survey technique at the beginning of the questionnaire. Here, participants will learn that they will be presented with hypothetical therapy alternatives in various combinations and that each alternative is described by 7 attributes. The questionnaire is expanded with questions on sociodemographic factors (including for inclusion and exclusion), sociocultural background, therapy-related and technology-related experiences, and health and quality-of-life assessment [57]. The questionnaire also includes a questionnaire assessment and questions on digital health literacy [58]. Different questions are designed to analyze the cognitive and perceptual limitations of the experimental group (Textbox 1). Metadata (or paradata) will provide information about the content of the health preference data. These data include the time taken to complete the survey and each question as well as information on dropout rates. The coding software used was Survey Engine GmbH. Textbox 1 presents the structure and content of the survey questionnaire.

XSL•FO
RenderX

Textbox 1. Structure and content of the survey questionnaire.

Introduction to the survey: data protection and technical instructions

- Information on data protection regulations
- Information on responding via tablet and computer or laptop (exclusion: smartphone or iPhone)
- Information sheet for participants (PDF download)
- Declaration of consent for participants (as PDF download)
- Obtaining consent
- Instructions on how to respond to the survey, introduction to question formats, and options for saving an intermediate response status

Testing of cognitive abilities and perception

- A total of 5 picture and text questions (picture recognition, object naming or assignment, temporal or spatial orientation, and memory)
- Identification of cognitive and perceptual limitations with possible influence on the questionnaire response
- Basis: standardized assessments for identification of aphasia, apraxia, visual or perceptual deficits, and cognitive deficits

Introduction to the survey: background of the digital stroke rehabilitation

- Information about the diagnosis of stroke (incidence and shortage of specialists)
- Information about digital technologies (ie, digital support systems) in therapies
- Introduction of terms (digital support systems and digital therapies)
- Information about patient and public preferences, survey content (preference information, experiences, expectations, attitudes, and sociodemographic data), and survey process and structure

Inclusion and representativeness of the study population

- Inclusion: age <17 years, German language skills=intermediate to very good, and, only for experimental group, diagnosis of stroke=is present
- Representativeness in control group based on quota in age, sex, education, and state (for state, not present as quota in sampling)

Diagnosis-related questions

- Objective: to separate the study populations into patients with stroke and the general population
- Diagnosis of stroke; time of diagnosis; consequences of stroke related to physical functions, daily life, and support needs; and current treatment needs

Introduction to the preference survey

- Description of the scenario: rehabilitative therapy using digital technology
- Description and explanation of digital therapies (wording: digital support systems)
- General definition and delimitation of the terms attributes and attribute level
- Description and illustration of all 7 attributes and attribute expressions
- Example or tutorial for answering a choice set

Preference elicitation or discrete choice experiment

- Dominance test: selection from a choice set with an openly dominant alternative (no copayment and 100% treatment success) to test the understanding of choice tasks and quality (validity)
- 6 Choice tasks: choice best, choice second best, and dual response

Additional questions

- Evaluation of therapy goals as activities in daily life via a 5-point Likert scale
- Assessment of digital transformation goals in terms of flexibility of place, time, performance, and adaptability via ranking
- Sociodemographic questions (expanded) on marital status, household or residential situation, and occupational status
- Health status and quality of life
- Rehabilitative therapy experiences
- Experiences with and attitudes toward digital technologies for one's own health

XSL•FO
RenderX

- Questionnaire assessment to evaluate the quality of the survey
- Questions on digital health literacy

Completion of the survey

- Acknowledgment
- Information on how to contact the study team and collaborators

Statistical Analyses

Discrete choice models differ from regular logistic regression because the data are grouped. These models consider the structure of the DCE data, with the same participant providing multiple results for a sequence of different election scenarios [59].

We analyzed the results using conditional logistic and mixed logistic models and performed a latent class analysis to identify heterogeneous preferences [60]. We used the conditional logistic model to calculate the coefficients whose signs indicated a preference direction. Positive coefficients indicated a positive influence of a trait expression, and negative coefficients indicated a negative influence. The larger the coefficient, the greater the influence on the choice decision. The distances between 2 property expressions indicated the magnitude of the influence. The assumption of normal distribution in the conditional logistic model limited the informative value of the calculated coefficients. We used mixed logistic models to analyze preference differences as a function of each individual by calculating SDs and SEs. We tested assumptions to determine whether the preferences of specific groups differed from each other in terms of characteristics, experiences, and cultural background. Latent class analysis was used to generate information on the heterogeneous groups. We used StataCorp LLC to conduct our statistical analyses.

For our analysis, the results from both groups were compared. We did not directly compare the coefficients because of scale effects [61]. The comparison was made by considering the influence of the covariate general population.

Study Sample

We include study participants depending on the target population, sample selection, and the qualitative or quantitative study part of the survey. The quantitative pilot interviews were conducted between March and September 2020. The qualitative pretest interviews were conducted between October and December 2021. The quantitative survey was started by pilot testing (n=150) in January 2022. After pilot testing, participants of the general population will be recruited via a panel provider and patients with stroke will be recruited via a panel provider, E-BRAiN clinical study and Stiftung Deutsche Schlaganfall-Hilfe, and from social networks. The study sample is based on a nonprobability ad hoc sample selection as a self-selection sample depending on availability and on a nonprobability ad hoc sample selection as a quota sample [62,63]. Regarding the full E-BRAiN project, recruitment and in-person participation of patients with stroke were planned within the clinical project. The DCE project was planned in relation to the clinical recruitment and was adjusted according to the pandemic-related constraints and financial resources. Therefore, panel recruitment was expanded to include patients with stroke in the DCE project.

Data Collection

Calculating the sample size for the choice experiments is complex [64]. The question format, complexity of the choice task, desired precision of the results, and need for subgroup analysis are criteria that could modify the sample size [29,65].

For a robust quantitative evaluation of the main effects of a DCE in a simple logistic regression model (eg, mixed logit regression model or conditional logistic model), we calculated the sample size using the following formula: $(n \times t \times a) / c \geq 1000$; $n = (1000 \times c) / t \times a$, where n=number of participants, t=number of choices (choice sets), a=number of choice alternatives per choice set, and c=number of levels (for main effects, c=number of levels of the attribute with the highest number of levels and for interaction effects, c=the largest product of the levels of the 2 attributes with the highest number of levels).

Given 6 choice tasks and 3 alternatives described by attributes with a maximum of 5 levels, a minimum number of 300 participants ($n = [1000 \times 5] / [6 \times 3]$) is needed to represent at least the main effects approximately 1000 times. This resulted in a target sample size of 300. When considering the interaction effects (c=15 in the formula), the resulting n is at least 1000 ($n = [1000 \times 15] / [6 \times 3]$). To adequately account for interaction effects, a sample size of at least 1000 is required to ensure sufficient representation. The final target sample size is approximately 1000 participants.

Data Quality

Our data quality criteria are as follows. First, we require data security. The web-based survey is developed and scripted by the research team. Quality assurances are also conducted. The quality tests follow a predefined test grid. Second, we ensure data integrity by conducting several quality assurance steps, including extensive end-to-end testing, data export and tabulation of test data before the live sample will be launched, validation of the experimental design scripts, and validation of the data analysis scripts. Third, our data require validity and reliability. The following indicators of validity and reliability are collected: completion of the entire web survey in a short period, selection of the predominant alternative in the fixed-choice question, selection of a different alternative in the repeat question, selection of “best” and “second-best” levels always based on a single attribute, straightlining (ie, always the

XSL•FO
RenderX

same answer choice in each choice set), and additional questions to verify DCE data and class determination.

Results

The literature review, qualitative preliminary study, survey development, and pretesting were completed. Recruitment of the experimental group and the control group started in January 2022. Recruitment of the experimental group (patients with stroke) will be conducted in conjunction with the clinical trial of the collaborative project E-BRAiN. All patients in the clinical trial will be surveyed. Data collection and analysis will be completed in the last quarter of 2023.

Discussion

Principal Findings

Acceptance is a multidimensional construct. The requirements for digital technologies include various dimensions [66]. Digital technologies in postacute rehabilitative therapies are increasingly used for patients classified as cognitively, perceptually, and participatively impaired. [67]. These technologies are still largely unknown to users. Successful implementation depends on the acceptance of the patients [18]. In addition to expected clinical success, technical features also affect consumer acceptance.

This paper describes the development of a HPR study. Patient preference information will be provided by analyzing 7 attributes in a DCE. With respect to the mantra of HPR that "choice defines value," the study objective is to weight criteria that impact patient acceptance. Furthermore, a benefit-burden assessment, an overall comparison of different alternative digital interventions, interpretation of adherence, analysis of heterogeneity, and subgroup analysis are aimed at improving decision-making for innovative interventions, such as adopting new digital technologies such as artificial intelligence (AI). This study includes several aspects that further test the hypotheses related to needs, outcomes, technical aspects, human contact, goals of digital transformation, and personal information about patients.

To achieve the objectives, formative preliminary studies were conducted. A list of 17 attributes was tested. The final list of attributes represents the decision context of digital transformation in health care: explanation and presentation of therapy exercises, information in therapy, contact with health professionals, and data processing. To complete the decision context, copayment per month and therapy success within 6 months were added.

To develop the final survey instruments, attributes were described and visualizations for each level were added in a descriptive framework. The developed fractional-factorial efficient Bayesian (D-error) experimental design includes a best-best ranking task in a partial profile. A web-based questionnaire was developed by integrating additional questions on patients' characteristics, experiences, and cultural background. Pretest interviews and pilot testing have led to the holistic adaptation of the survey instrument in terms of descriptions, visualizations, and questions to enhance patient understanding as well as the testing of the experimental design. The analysis, with the help of a conditional logit model, proved the assignment of substantially results and unambiguous β coefficients to the attributes and levels, thereby demonstrating the effectiveness of the experimental design. The further study will use mixed logit models and heterogeneity analysis to evaluate the final study results.

This study demonstrates the importance of investigating patient acceptance and the technical aspects of digital technologies such as AI. Dai and Tayur [68] highlighted in their research that the uniqueness bias is a barrier to patient acceptance, as patients attribute more individuality to a human-guided therapy than to an AI-based solution. To solve this bias, a study of patient perceptions and preferences is recommended [68]. Furthermore, research on rhetoric to improve the adoption of digital technologies such as AI shows the importance of communicative strategies [69]. Another aspect that influences patient acceptance is data privacy and security and the associated risk [70].

To the best of our knowledge, this HPR study conducted a DCE. We attempt to develop a generic model that generates preference information to provide information on patient acceptance of digital technologies.

Limitations

Further investigation must consider the following limitations and challenges:

- Digital transformation in health care is characterized by a large number of attributes to achieve goals (eg, flexibility). The development of the underlying descriptive framework was difficult. Therefore, we consider the goal of digital transformation.
- The characteristics of the experimental group lead to different challenges. Patients with stroke often have limitations related to their cognition, perception, and movement (motor function). This leads, on the one hand, to recruitment challenges owing to lower participation possibilities and lower response rate and, on the other hand, to challenges in the design, layout, and formulation of the questionnaire. Furthermore, pandemic-related inaccessibility was expected.
- Limited financial resources limit the additional number of patients with stroke that can be enrolled via a panel.
- Owing to the recruitment challenges, we decided to include a control group (the general population). Because of the scale effects, the coefficients will not be compared directly. The comparison will be made by considering the influence of the covariate general population.
- Analysis of preference differences between the experimental and control groups will be limited because financial resources do not allow adequate number of patients with stroke to be available via a panel survey.

Another limitation relates to the interpretation of the concept of "value." The term "value" is a broad term used in different contexts. In general, "value" refers to the worth, importance, or usefulness assigned to something based on individual perceptions. However, "value" can be determined by a wide range of terms, such as personal beliefs, societal norms,

XSL•FO
RenderX

economic considerations, and preferences. The economic perspective considers the exchangeable value of goods or services. In contrast, “value” can also compass moral, ethical, or philosophical principles that guide individuals’ behavior. Therefore, it is crucial to emphasize at this point that there is a potential limitation in this paper where the term “value” may be subject to misunderstanding. In this study, the concept of “value” is distinguished from “value judgments”. The term “value judgments” describes the context of ethical, moral, or philosophical aspects [71]. In the context of HPR, “value refers to the subjective assessment of the importance, desirability, or utility individuals assign to specific health-related outcomes or interventions.” It involves understanding and measuring the preferences of individuals when making decisions related to their health and health care. In contrast to judgments, preferences relate to individual choices that are based on subjective likes or dislikes. This is unclear as is. Do you mean “The guiding principle of HPR is encapsulated in the mantra “choice defines value.” This concept highlights the importance of gaining a deeper understanding of patients' preferences, enabling health care providers, regulators, and policy makers to better address the needs of patients? Please revise as applicable [72,73]. As preferences can be influenced by judgments, social determinants, environmental factors, or experiences, we included several questions in the final survey instrument that could be mapped to these influencing factors (eg, cultural background, experiences in therapy, experiences with digital health, and attitudes toward digitization). These questions can be consulted when analyzing the differences between patient groups.

Conclusions

This HPR study provides information on preferences to analyze the criteria that impact acceptance and the value of innovative interventions using digital technologies. Developers, health care providers, and policy makers often make difficult decisions about development, reimbursement, and the choice of the benefit-maximizing intervention for each patient (group). These decisions require information on the value of clinical and nonclinical criteria derived from patient preference information. As patients are the ones who ultimately experience the positive and negative outcomes of treatment, decisions related to health care intervention options should be patient centered and reflect patient values. This is where HPR comes in, providing information about patient values relevant to decision-making [16,17]. This study will inform decision makers about the factors impacting patient and public acceptance. Understanding acceptance will improve decisions and investigations of the development, adoption, and pricing of innovative digital interventions. Furthermore, the aim of reporting the development of this DCE is to represent the standards of DCE development, provide reproducibility to verify the results, ensure transparency and ethical considerations, and improve the efficiency of the research. This protocol offers a transparent, practical, and scientific approach for eliciting patient preferences.

Acknowledgments

The authors are grateful for the support of Prof Dr Thomas Platz and Prof Dr Thomas Kohlmann for numerous and helpful discussions. The authors would like to thank the project leader Prof Dr Thomas Platz and the project managers Stefanie Tobschall and Stephanie Bobe of the research project evidence-based robotic assistance in neurorehabilitation (E-BRAiN). The authors thank the working groups from the University of Rostock under the leadership of Prof Dr Ing Thomas Kirste and Prof Dr Ing Peter Forbrig, from the University Hospital Greifswald under the leadership of Prof Dr Thomas Platz, and from the University of Greifswald under the leadership of Prof Dr Alfons Hamm. The authors also thank Dr Ann Louise Pedersen for the organizational support. The authors are grateful for the technical assistance provided by Rasa Hamilton. This study was part of the research project E-BRAiN, which was funded by the European Social Fund (reference ESF/14-BM-A55-0001/19-A02) and the Ministry of Education, Science and Culture of Mecklenburg-Vorpommern, Germany.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

AF was responsible for data curation. ACM obtained the funding. AF and ACM jointly conducted the research, methodology, and project administration. AF was responsible for software use. ACM was responsible for the supervision of the project. AF completed the visualization and the preparation of an original draft. ACM did the review and editing of the draft. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Demographic changes will raise the need for specialized care of older patients. Oropharyngeal dysphagia has recently been declared a geriatric syndrome reflecting its multifactorial background. Alongside multimorbidity, sarcopenia, frailty, and disability, swallowing disorders increase with advancing age, with prevalence rates reported to be as high as 44% in acute geriatric hospital settings and 80% in long-term care facilities. Hence, systematic screening of older patients to diagnose dysphagia and initiate treatment is of paramount importance to prevent bolus death, aspiration pneumonia, and malnutrition and improve quality of life. Several screening tools have been evaluated in emergency and stroke units. However, no published dysphagia screening tool has been validated in the hospitalized, older adult population using a gold standard in dysphagia diagnostics as a reference test. The validation of the proposed test is a first step.

Objective: The Geriatric Bedside Swallowing Screen (GEBS) study aims to validate a new screening tool developed specifically for older inpatients against an instrumental swallowing evaluation, the flexible endoscopic evaluation of swallowing (FEES), which is considered a gold standard. Primary outcomes to be evaluated are sensitivity and specificity for the GEBS in the detection of dysphagia in a mixed older adult population. The presence of dysphagia will be defined by an instrumental swallowing evaluation (FEES), analyzed by the standardized penetration-aspiration scale.

Methods: To validate the GEBS, a prospective cohort study will be carried out. Two institutions, an acute geriatric department and a long-term care facility, will aim to recruit a total of 100 patients aged ≥75 years. After giving their informed consent, patients will undergo the full screening protocol described in the GEBS as well as an evaluation of swallowing function using the FEES. Investigators will be blinded to the results of the respective other testing. The analysis of pseudonymized data sets will be done by a third investigator. Outcomes to be considered are sensitivity, specificity, diagnostic odds ratio, positive and negative likelihood quotient, and the reliability of the proposed dysphagia screening tool using the κ coefficient.

Results: Recruitment started in October 2022 and will end in April 2024. Data publication is planned for early 2025.

Conclusions: If proven to be a valid screening tool for the early detection of dysphagia, further studies including different older adult populations as well as studies to determine the impact of systematic dysphagia screening on parameters, such as rates of aspiration pneumonia or nutritional status, should be planned. Effective screening of dysphagia will lead to earlier detection of patients with impaired swallowing. Those who fail the screening will be referred to speech language pathology for further diagnosis, thus optimizing care while streamlining personnel resources.

Introduction

Background

Due to demographic changes, by 2100, about a third of the population in the European Union will be aged 65 years and older [1]. Medical professions will need to be specialized in the treatment of older patients. This includes the development of efficient diagnostic pathways to ensure optimal care while not overburdening health care systems. Thus, efficient prevention, early detection, and treatment are becoming more important. One important discipline in the care for older patients is *speech language pathology* (SLP), which contributes to the prevention, diagnosis, and treatment of hearing disorders; voice impairments; difficulties with language production; active communication; and swallowing disorders, also known as *dysphagia*.

Dysphagia has been declared a geriatric syndrome by the European Society for Swallowing Disorders, thus highlighting its importance for medical personnel working with older patients. Common causes for dysphagia are stroke, traumatic brain injury, neurodegenerative diseases, as well as surgeries—most commonly following cancer treatment of the mouth and neck. It is important to note that changes to the swallowing process due to aging, which is known as *presbyphagia*, are not considered pathological. If presbyphagia does not cause nutritional decline or the development of aspiration pneumonia, presbyphagia is considered healthy, older-age swallowing [2,3]. If the aging process, specifically the loss of muscle mass within the swallowing muscles, leads to functional deficits and disordered swallowing with pathological consequences without a known neurological or structural cause, it is defined as *sarcopenic dysphagia* [4]. To distinguish between presbyphagia and dysphagia, regardless of etiology, sound knowledge of a healthy, older-age swallowing process is necessary. The loss of muscle mass associated with normal aging, that is, *sarcopenia*, causes *dynapenia*, which is a loss of function and strength within the skeletal muscles [5]. Continual sarcopenia leading to functional decline contributes to the geriatric syndrome known as *frailty*, which is linked to a higher prevalence and worse prognosis for dysphagia [6]. Dysphagia of all different etiologies affects up to 40% of patients in acute hospital settings as well as up to 80% in long-term care facilities [7-9]. The prevalence of sarcopenic dysphagia in older patients admitted to acute hospitals has been determined to be around 30% [10]. As oropharyngeal dysphagia is closely associated with central nervous system diseases, the prevalence for dysphagia in patients with central nervous system diseases is higher as the diseases progress, with estimates of around 85% in older patients [9].

The diagnosis of dysphagia is typically a 2-step process with a clinical swallowing examination by an SLP, who might refer to an instrumental swallowing examination. There are 2 objective instrumental diagnostic tools. The *flexible endoscopic evaluation of swallowing* (FEES) consists of a protocol to evaluate different consistencies of bolus under visual observation of the pharynx and upper laryngeal structures through a transnasal endoscope [11]. The second possibility is a *videofluoroscopic swallowing study*, where a high-resolution x-ray of the mouth and throat produces a video of the whole swallowing process [12]. Since the FEES system is portable, it can be carried out in a bedside setting and does not require as much compliance as the videofluoroscopic swallowing study. The FEES is considered the gold standard in the dysphagia diagnostics of older patients [13].

Study Goal

As previously described, the identification of patients with impaired swallowing function is of high priority to prevent the occurrence of malnutrition and aspiration pneumonia, as well as bolus death. Considering the demographic changes, routine referral of all newly admitted older patients to an SLP examination will not be feasible. Screening for dysphagia risk has proven to significantly lower pneumonia rates in emergency and stroke units [14-17]. There are several validated screening tools for those populations, for example, the *Gugging Swallowing Screen* [18] or the *Toronto Bedside Swallowing Screening Test* [17], which have excellent sensitivity and specificity for their intended use. Older patients, however, are faced with the challenge of drastically increased time frames for the oral phase of swallowing. This would be a predicator for dysphagia in healthy, younger adults but does not have the same implication in older adults [19].

To search for a screening tool that is validated for an older adult population aged ≥75 years against a gold standard, a systematic review of published screening tools was carried out by the first author, which yielded no results [20]. Of the 40 screening tools that were found (as shown in Table 1), none could be included for further assessment, with the main exclusion criteria being a noninstrumental reference test and a studied population aged <75 years. Some of the studies proposed a new protocol of instrumental swallowing assessments or a clinical bedside swallowing evaluation by an SLP under the term “screening”; those studies were also excluded.

These findings have been replicated by a recent review by Estupiñán Artiles et al [21], as well as the *Arbeitsgemeinschaft der Wissenschaftlichen Medizinischen Fachgesellschaften* (Association of the Scientific Medical Societies in Germany) guidelines for geriatric assessment [22].

XSL•FO

Table 1. Review of published screening tools.

Exclusion criteria	Screening tools (n=40), n (%)
Reference test	1 (2.5)
Population	8 (20)
Reference test + population	26 (65)
Reference test + population + screening tool	2 (5)
Screening tool + population	3 (7.5)

In accordance with diagnostic study guidelines such as STARD (Standards for Reporting Diagnostic Accuracy) and QUADAS (Quality Assessment of Diagnostic Accuracy Studies), new tests should be validated against a robust reference test, usually the gold standard [23,24]. Following these outcomes, this study aims to fill the gap by validating a specific screening tool—the *Geriatric Bedside Swallowing Screen* (GEBS)—to detect dysphagia in a mixed older adult population aged ≥75 years. The aim is to validate the GEBS using the primary outcome measures of sensitivity and specificity concerning the detection of dysphagia when compared to an instrumental swallowing evaluation.

Methods

Test Construction

The starting point for the GEBS was a screening tool already in use at the Department of Geriatric Medicine, Christian Doppler University Hospital, in Salzburg, Austria. It has been demonstrated to be a convenient tool in clinical practice but has never been formally validated. Combined with the results of a thorough review of published evidence on possible reliable predictors for dysphagia, it was developed into a 3-step screening tool. In the first step, 6 risk factors are assessed by observation, patient reports, and chart review (Textbox 1).

Following the assessment of present risk factors and the assurance of patient vigilance, a water swallow test is administered. This consists of swallowing 10 teaspoons of clear water with breaks for voice production and 1 self-administered sip out of a cup. The test is stopped if clinical signs of aspiration such as coughing or wet voice are noted, as well as after the occurrence of one of the following items is noted: breathing difficulties, as a result of the lack of maintaining alertness, head position, or saliva control.

If the water test shows signs of dysphagia and more than one risk factor is present, the third step will be administered, which consists of swallowing a pureed bolus with a consistency of level 4 in the *International Dysphagia Diet Standardisation Initiative* (IDDSI) framework [25]. After making sure that the patient is able to stay awake and upright for 15 minutes; has control over saliva, for example, shows no sign of drooling; and is able to produce voice, several teaspoons of puree are administered with breaks for voice production. The screening must be stopped for decreased vigilance, clinical signs of aspiration, and severe drooling without compensation. Coughing, wet voice, and oral residues are considered indicators for dysphagia.

A point score will be calculated, where a score of 5 points would allow for oral nutrition and medication with pureed food of IDDSI level 4 and thickened liquids of IDDSI level 2 until further examination by an SLP; a score of <5 points would result in the instruction of *nil by mouth* until further examination with a high risk for dysphagia.

This 3-step process of determining risk factors; applying a water-swallow test; and if necessary, administrating a pureed bolus test ensures patient safety while aiming for a high specificity and sensitivity [21,26].

1. Neurological or neuropsychiatric disease
2. Pneumonia within the last 12 months
3. Sarcopenia
4. Unintentional weight loss
5. Symptoms of dysphagia (drooling, wet voice, and coughing)
6. Impaired oral health

Recruitment

Two Austrian institutions will recruit a total of 100 patients with and without known or suspected dysphagia. One study center is an acute geriatric department, whereas the other is a long-term-care facility. Patients' inclusion criteria are an age of 75 years or older and the ability to give informed consent. Exclusion criteria are a history of severe brain stroke with a cut-off of 20 points on the *National Institutes of Health Stroke Scale* [27]; a diagnosis of moderate to advanced stages of cognitive diseases defined by 20 points or lower on the *Mini Mental State Examination* [28]; as well as the presence of a tracheostoma with or without dependence on ventilation [29]. Independently of age, these 3 factors are associated with a high prevalence of dysphagia and would be considered too high for risk of bias for the first validation on a mixed older adult

XSL•FO
RenderX

population. All patients admitted to the acute geriatric department after the start of recruitment fulfilling the inclusion criteria will be considered and asked to participate in the study. In the long-term-care facility, staff will screen patient data and nominate possible participants, who will then be approached for their consent to participate. Recruitment started in October 2022 with a planned time frame of 18 months.

Application of the Index Test GEBS

Patients who have agreed to participate in the study will be screened with the full GEBS even if they do not show a risk of dysphagia after the first 2 steps. If any occurrence during the screening indicates dysphagia and requires the screening to be stopped and the patient to be referred to further assessment, the test result can be included in the study as "fail." To ensure broad validation of the GEBS, the screening can be carried out by nurses, physicians, or SLPs. Investigators will be educated on the correct process and scoring of the GEBS prior to the study. To ensure intrarater reliability, 15 patients will be screened twice with the GEBS by the same investigator with a minimum of 4 hours between both events. To calculate the interrater reliability, another 15 patients will be screened twice by 2 independent investigators blinded to the respective other result of the GEBS.

Application of the Reference Test FEES

Within 7 days of the first assessment using the GEBS, the reference test FEES will be carried out to verify the results. This time frame limits possible changes in the patients' medical status between the 2 investigations of their swallowing function. The FEES is considered the gold standard, objective diagnostic tool for dysphagia in older patients and is considered particularly safe and only mildly uncomfortable for the majority of patients. Reported adverse events are epistaxis, bradycardia or tachycardia, lowering of blood pressure, and changes in heart rate, all of which are rare with a reported occurrence of less than 4%. None of these reported events that were directly caused by undergoing the FEES have ever been reported as leading to permanent damage; all are self-limited and of a very short duration [30,31]. The results of the FEES will be reported using the *penetration-aspiration scale* developed by Rosenbek et al [32] in 1996; it is an internationally established 8-point scale to rate the severity of dysphagia. To limit uncomfortable sensation for the patients while the endoscope is passed through the nasal cavities, a local anesthetic can be used, which does not affect the swallowing function if used correctly [33,34]. The FEES investigators will be blinded to the results of the GEBS.

Statistical Analysis

Outcomes

The 2 main outcomes to be analyzed are sensitivity and specificity to detect dysphagia. These will be calculated using a 2 × 2 matrix. Further, positive and negative likelihood quotient and diagnostic odds ratio will be calculated. To assess intra- and interrater reliability, the κ coefficient will be evaluated. Additional cross-analysis with acquired data such as age; gender; medical diagnosis, including severity if assessed (National Institutes of Health Stroke Scale and Mini Mental State Examination); current diet; and dependency on activities of daily living will be considered as secondary outcomes. Calculations will be carried out using Excel (Microsoft) and SPSS (IBM Corp).

Data Management

Acquired data for the study will be managed and pseudonymized with the keys being stored at the recruiting institution and not available to the study coordinator. Data will be stored using Excel (Microsoft) following the legal requirements of the Austrian government.

Ethics Approval

Ethics approval has been obtained for both study centers. First, the ethics committee of the City of Vienna approved the study (EK 21-212-1021) in March 2022. The ethics committee of the Province of Salzburg gave approval (EK-Nr. 1040/2022) in June 2022. Required changes were the complete exclusion of patients who are not able to give their informed consent due to cognitive diseases as well as minor clarifications in the patients' information document. The study was registered with the ISCRTN registry (11581931) in March 2021.

Results

Recruitment started in October 2022 and will end in April 2024. A planned total of 100 participants will be aimed for. Since there have not been prior studies using the GEBS, no expected effect can be used to calculate a power analysis. Regarding previously published, internationally established screening tools, a case number of 100 patients was decided on. However, if, by the end of the study period, fewer results have been obtained, recruitment will not be extended further. Data publication is planned for early 2025, following the end of the collection period.

Discussion

Expected Findings

The GEBS is, to our best knowledge, the first screening tool for the assessment of dysphagia in older patients to be validated against an instrumental swallowing assessment in accordance with guidelines, such as STARD and QUADAS, while taking into consideration individual predisposing factors. This is highly relevant considering the growing demand for personalized medicine in this age group. Similar to children not being small adults in regard to medication, older patients with frailty are to be considered differently for their changed muscle function, metabolism, and physical activity.

This study aims to provide geriatric facilities in the acute setting as well as in long-term care with a reliable, useful tool to screen patients for dysphagia. If the GEBS shows sufficient results to be recommended for broader use in different geriatric settings, further studies in different geriatric settings are advisable. The impact of systematic dysphagia screening with the GEBS should be evaluated by using end points such as rates of aspiration pneumonia, nutritional status, occurrence of bolus death, as well as the patient's quality of life. Other populations such as patients with moderate to severe cognitive decline or tracheotomy tubes

XSL•FO
RenderX

should also be included in further studies, to determine the validity of the GEBS in different patient groups.

Several studies have shown significant changes in the parameters mentioned above, namely pneumonia rates, nutritional status, bolus death, and quality of life, upon systematic screening for dysphagia in emergency departments or stroke units, so there is reason to expect similar effects in geriatric facilities when using a specialized geriatric dysphagia screening tool [14,16].

The screen will be used as a 2-step process in clinical use after having been validated, so the third part will only be administered if no SLP is available. If patients show a risk for dysphagia during the water swallow test and an SLP is available, the screen will be discontinued, and the patient will be referred to an SLP evaluation straight away. Especially in long-term care facilities in Austria, the presence of an SLP is not always the case. Thus, it is necessary for nursing and medical staff to be able to determine the safest method of oral intake until the swallowing function can be assessed by a specialist.

To spare patients unnecessary diagnostic processes and restrictions in their oral intake, specific diagnostic pathways and case-specific treatment need to be administered. A fast and safe way to ensure oral intake and medication in older patients can assist doctors and nursing staff upon the admission of new patients and streamlines SLP personnel resources.

Limitations

A limiting factor is the exclusion of patients with moderate to severe cognitive diseases. This is a growing population that is highly susceptible to developing dysphagia. This might be a future project after a first successful validation of the GEBS.

Conclusions

With this study, we hope to fill the gap in the health care of the older adult population by minimizing risk factors for patients and workload for caregivers at the same time. Optimized protocols and diagnostic pathways can be developed by implementing systematic, low-level screening protocols. If the results are positive in terms of high sensitivity and specificity, the GEBS will be published internationally, which might have a positive impact on workplaces and the health care of older patients.

Acknowledgments

This study is part of SMJ's dissertation project with BI being the primary supervisor.

Authors' Contributions

RR was involved with planning the study. BI and RR functioned as the primary investigators. SMJ wrote the manuscript, and BI and RR were involved with revision and editing. All authors agreed to the final version.

Abstract

Background: Health care decisions are a critical determinant in the evolution of chronic illness. In shared decision-making (SDM), patients and clinicians work collaboratively to reach evidence-based health decisions that align with individual circumstances, values, and preferences. This personalized approach to clinical care likely has substantial benefits in the oversight of degenerative cervical myelopathy (DCM), a type of nontraumatic spinal cord injury. Its chronicity, heterogeneous clinical presentation, complex management, and variable disease course engenders an imperative for a patient-centric approach that accounts for each patient's unique needs and priorities. Inadequate patient knowledge about the condition and an incomplete understanding of the critical decision points that arise during the course of care currently hinder the fruitful participation of health care providers and patients in SDM. This study protocol presents the rationale for deploying SDM for DCM and delineates the groundwork required to achieve this.

Objective: The study's primary outcome is the development of a comprehensive checklist to be implemented upon diagnosis that provides patients with essential information necessary to support their informed decision-making. This is known as a core information set (CIS). The secondary outcome is the creation of a detailed process map that provides a diagrammatic representation of the global care workflows and cognitive processes involved in DCM care. Characterizing the critical decision points along a patient's journey will allow for an effective exploration of SDM tools for routine clinical practice to enhance patient-centered care and improve clinical outcomes.

Methods: Both CISs and process maps are coproduced iteratively through a collaborative process involving the input and consensus of key stakeholders. This will be facilitated by Myelopathy.org, a global DCM charity, through its Research Objectives and Common Data Elements for Degenerative Cervical Myelopathy community. To develop the CIS, a 3-round, web-based Delphi process will be used, starting with a baseline list of information items derived from a recent scoping review of educational materials in DCM, patient interviews, and a qualitative survey of professionals. A priori criteria for achieving consensus are specified. The process map will be developed iteratively using semistructured interviews with patients and professionals and validated by key stakeholders.

Results: Recruitment for the Delphi consensus study began in April 2023. The pilot-testing of process map interview participants started simultaneously, with the formulation of an initial baseline map underway.

Conclusions: This protocol marks the first attempt to provide a starting point for investigating SDM in DCM. The primary work centers on developing an educational tool for use in diagnosis to enable enhanced onward decision-making. The wider objective is to aid stakeholders in developing SDM tools by identifying critical decision junctures in DCM care. Through these approaches, we aim to provide an exhaustive launchpad for formulating SDM tools in the wider DCM community.

Introduction

Background

Degenerative cervical myelopathy (DCM) [1,2] arises when age-related changes progressively narrow the cervical spinal cord canal, resulting in neurological dysfunction secondary to cord compression [3]. Its exact epidemiology is poorly understood, likely owing to widespread underdiagnosis [4,5]. However, estimates based on imaging studies suggest that DCM could affect as many as 1 in 50 adults [2]. Although surgical decompression can halt disease progression and afford varying levels of recovery in functional status, pain, and quality of life [6-8], most people with DCM [9] will experience lifelong residual disability despite treatment [8,10]. This is often associated with a poor quality of life [11,12], high unemployment rates [8,13], and mental health difficulties [10]. From a socioeconomic point of view, DCM places a substantial financial burden on society [14,15]. In England, United Kingdom, alone, the cumulative costs associated with disability payments, lost productivity, and hospital admission are conservatively estimated at £0.7 billion (US $0.9 billion) per annum [15]. Moreover, DCM affects not only people with DCM but also their families and caregivers, who experience a low quality of life owing to caregiving strain [16]. As the incidence of DCM is expected to increase with aging populations [17], interventions that target the human and economic cost of illness associated with this condition represent an immediate priority for global health care systems and the wider community [18]. Shared decision-making (SDM) represents one such potential cost containment and patient outcome improvement strategy that could be implemented.

A Role for SDM in DCM

Involving patients in collaborative deliberations about their care can foster improved clinical outcomes [19,20] and curtail the needless use of health care resources [21,22]. The epitome of this patient-centric paradigm is SDM, an approach to clinical care wherein clinicians and patients work together to reach evidence-based solutions that prioritize patients' values and preferences [23,24].

Over several decades of scholarship since its emergence in the early 1980s [25], SDM has risen to prominence as a hallmark of quality clinical practice, notably in the realm of unresolved, chronic illnesses [26]. Given the evolving and cyclic nature of many chronic conditions, continual reevaluation and adjustment of initial health management judgments are often required as patients progress through the trajectory of their illness [27-29]. Furthermore, the complexity of chronic illnesses tends to expand over time, presenting patients and health care providers with multiple options, each with its own set of benefits and drawbacks [30]. By engaging patients in the decision-making process and considering the unique circumstances and preferences of each patient along with the potential trade-offs of each option [31], SDM can facilitate the selection of the most appropriate course of action, ultimately leading to improved health outcomes [32]. Indeed, the health management decisions of people with chronic illnesses are optimal when founded on consideration of their preferences, values, and circumstances [33-36].

Therefore, the application of SDM in DCM is likely highly pertinent. People with DCM encounter care decisions that are contingent upon personal, contextual, and technical factors on a fairly recurrent basis [13,37,38]. For example, the clinical manifestation of DCM has a diverse spectrum, with symptomatology that varies from person to person [39]. In the views of people with DCM, seemingly unrelated ailments such as loss of bowel or bladder control can be traced back to the spinal cord [2]. This is important as efficient monitoring of neurological deterioration and understanding when to report novel or developing symptoms is critical [40]. The decision to undergo surgery is a significant consideration, as evidenced by the frequent queries of people with DCM about the suitability of surgery and the best type of surgery for their circumstances [13,37]. For those treated surgically, a range of surgical approaches can address the degenerative changes in the cervical spine [41]. Nonetheless, the decision to offer surgery and its timing is nuanced owing to its risks and the potential for DCM to remain mild [42]. Furthermore, surgery seldom leads to a full recovery; instead, a heterogeneous and lifelong disability is generally expected [8,10-13]. The implications of this can involve multiple distinct complex care pathways, necessitating collaboration across an array of health care disciplines less familiar with DCM [43]. Therefore, it is essential that people with DCM are well prepared to navigate a host of complex decisions. Finally, although treatment decisions are often the focus of SDM tools [44], they represent one of many care decisions that patients encounter [45]. Our experience at Myelopathy.org, a DCM scientific and clinical charity, is that patient health care inquiries encompass a broad spectrum, ranging from "should I modify my day-to-day activities?" to "should I undergo a dynamic MRI?" This variability underscores the diverse range of decisions that people with DCM confront, necessitating decisional support. It is also our experience that these inquiries are often hindered by patients' inadequate knowledge and perhaps misconceptions of DCM [45]. In this regard, people with DCM are poorly supported by a lack of comprehensive, patient-centric, and up-to-date educational resources [45].

The aforementioned considerations, coupled with the inherent recurrent nature of decision-making in DCM, underscore the pressing need for people with DCM to engage in meaningful dialogue with health care professionals (HCPs) and have access to high-quality decisional support. In line with other chronic illness research, we hypothesize that a structured and well-orchestrated communication framework, as formulated within SDM tools, is ideally placed to successfully guide people with DCM through their health journey. Thus, investigating this

XSL•FO
RenderX

area is warranted. In addition, the strategic incorporation of SDM has the potential to aptly support knowledge translation endeavors by identifying critical knowledge gaps and providing a framework for the assimilation of new knowledge into clinical practice [45-47]. This is currently a major challenge in DCM, where awareness of the condition continues to be suboptimal in the medical profession [48]. This is even conspicuous among spinal surgeons, who are considered authorities in the field of DCM [49,50]. To illustrate, a retrospective analysis of surgical decision-making in the United Kingdom found that only the amount of cord compression (as opposed to the guideline recommendations of disease severity) predicted the likelihood of a patient being offered surgery [49,51-53]. As the patient is perhaps the most motivated stakeholder and, importantly, a more recent student of DCM, addressing SDM may also support more consistent and immediate evidence-based care [54-57].

The Rationale for Developing a Core Information Set and Process Mapping Patients' Health Care Journeys

Patients' understanding of their baseline circumstances represents a fundamental starting point for SDM [58]. This is crucial for patients to aptly recognize care options and articulate their preferences [59]. Core information sets (CISs) were pioneered as a means to support informed consent before surgery [60-62] and comprise a distilled list of information items akin to a checklist. Their purpose is to guide an educational conversation between HCPs and their patients by ensuring that critical information about a topic is shared and considered. CISs can help reduce variation in the practice of providing information to patients [63]. Their structured and condensed nature can also circumvent the potential for information overload [64]. Therefore, a DCM CIS centered on delivering information material to the diagnosis stage could assist the efficiency of clinical interactions and quality of onward health decisions by improving patients' knowledge of the condition and their circumstances. As CISs are coproduced using multistakeholder input, their consensus-derived nature would also ensure that the information considered is of agreed importance to both professionals and patients.

Beyond diagnosis, the successful development of SDM tools depends on characterizing the critical decision points along patients' care pathways [65]. A key aspect of quality improvement interventions is identifying whether and when a decision is required [66,67]. Process mapping, the diagrammatic representation of workflows, is frequently used in health settings to understand care processes [68]. By capturing all relevant steps in a sequence of actions, a process map can provide a comprehensive overview of an activity and its potential strengths, vulnerabilities, and limitations. As with CISs, process maps are coproduced via the input of key stakeholders who describe the workflows and cognitive decisions associated with a process [69,70]. Therefore, process mapping the key decisions of people with DCM is instrumental in paving the way for the development of SDM tools, ensuring their foundation in clearly delineated needs.

This research protocol describes the preliminary groundwork required to enable the exploration of SDM tools for DCM. First, we outline the development of a DCM CIS tailored to guide a material discussion between professionals and their patients at diagnosis. Second, we detail the procedure for formulating a global DCM process map that comprehensively captures common critical decisions in the patient journey.

Methods

Overview and Scope

Myelopathy.org and the Research Objectives and Common Data Elements for Degenerative Cervical Myelopathy Community

Myelopathy.org is the first and currently only scientific and clinical charity dedicated to improving the outcomes of people with DCM [71]. The charity has a global professional and lay audience, making it well suited for spearheading the initiative described in this protocol, which forms part of a larger enterprise aimed at promoting SDM in DCM. This will occur through the Research Objectives and Common Data Elements for Degenerative Cervical Myelopathy (RECODE-DCM) platform, an international community of professionals with diverse expertise in spinal care, and people with DCM registered with the charity working together to accelerate knowledge discovery in DCM.

The community was formed in collaboration with AO Spine (a nonprofit organization supporting education and research for spinal surgeons) to develop a research toolkit aimed at accelerating knowledge discovery in DCM [1,4,18,72]. Recognizing the broader opportunities for this community to address knowledge gaps in DCM and support their implementation led to its recognition as a distinct entity [73-75]. The network is now maintained by Myelopathy.org under its advisory board.

The research team formulated 2 objectives for this study, as outlined in the following sections.

Objective 1: To Enhance Knowledge of the Condition Among People With DCM

This will be achieved by developing the first DCM diagnosis CIS using an international multistakeholder (Delphi) consensus process.

Objective 2: To Identify Critical Decision Points in the Medical Care Product Life Cycle That May Benefit From SDM Tools

This will be achieved through a process map exercise involving an international multidisciplinary team of key stakeholders, including patient representatives.

Information on the status of each phase is shown in Table 1.

Table 1. Research study stages, findings summary, and status.

Description	Findings summary	Status
Core information set		
Scoping literature review of educational resources in DCM[a]	>80% of resources geared toward professionals	Completed
Semistructured patient interviews	Varied information needs throughout the patient journey	Completed
Survey of professionals	Survey of professionals to collect their views on the information that people with DCM need	Completed
Delphi consensus survey of professionals and patients	Pending	In preparation
Process mapping		
Preparation, planning, and process identification	Pending	Completed
Data gathering	Pending	In planning
Process map generation	Pending	In planning
Analysis	Pending	In planning
Taking it forward	Pending	In planning

[a]DCM: degenerative cervical myelopathy.

Study Design

Enacting SDM requires insight into decisional dynamics. At its core, this entails discerning the critical timing of decisions and navigating factors related to decisional conflict—a state of uncertainty over a course of action when multiple options are present, each requiring careful evaluation of risks, benefits, and alignment with personal values. Key among the latter is an understanding of the informational demands associated with each decision-making juncture. To meet these requirements, our protocol proposes a mixed methods design that combines the structured, quantitative Delphi consensus procedure with the qualitative, visual approach of process mapping. By leveraging both methods, our study aims to translate evidence-based knowledge and stakeholder experiences into clinically actionable tools for enhancing the health outcomes of people with DCM [76]. The following sections elaborate on our application of the Delphi procedure in constructing the first DCM CIS and process mapping to highlight patients' key decision points.

Objective 1: To Enhance People With DCM's Knowledge of the Condition—Developing the First CIS for Use in DCM at Diagnosis

Delphi Consensus Process Overview

The Delphi technique is a well-established method for achieving consensus among experts on a given topic [77]. It is particularly suited to contexts in which knowledge is ambiguous, empirical evidence is scarce, or priority setting is required [78]. In this procedure, a panel of preselected experts are engaged in a series of structured surveys. Each round incorporates controlled feedback, usually a blend of quantitative and qualitative data, the purpose of which is to foster insights from previous rounds, prompting reflection and the potential revision of viewpoints [79]. Designed to incrementally foster a convergence of opinions, the procedure is usually conducted anonymously, allowing participants to freely articulate their perspectives [80]. The number of rounds, execution of question delivery and response acquisition, and standards of achieving of "consensus" can vary within this general framework. Figure 1 provides a schematic overview of our approach, comprising 2 anonymized web-based surveys followed by a consensus meeting hosted over the internet. Consensus meetings offer a platform for real-time dialogue [81]. This face-to-face component has been observed to play a role in refining and enhancing the group's collective understanding, paving the way for a more sophisticated consensus [82].

The Delphi method has been widely used in health sciences [83] to generate clinical recommendations [84] and standards and guidelines for theoretical or methodological issues [83,85,86] for a range of chronic illnesses such as diabetes [87,88], cancer [89,90], asthma [91], rheumatoid arthritis [92], and spinal cord injury [93,94]. Our objective using a Delphi procedure is to develop a CIS that facilitates optimal communication of information to people with DCM about the condition at the point of diagnosis. Figure 2 shows an overview of the phases involved in developing the CIS.

XSL•FO
RenderX

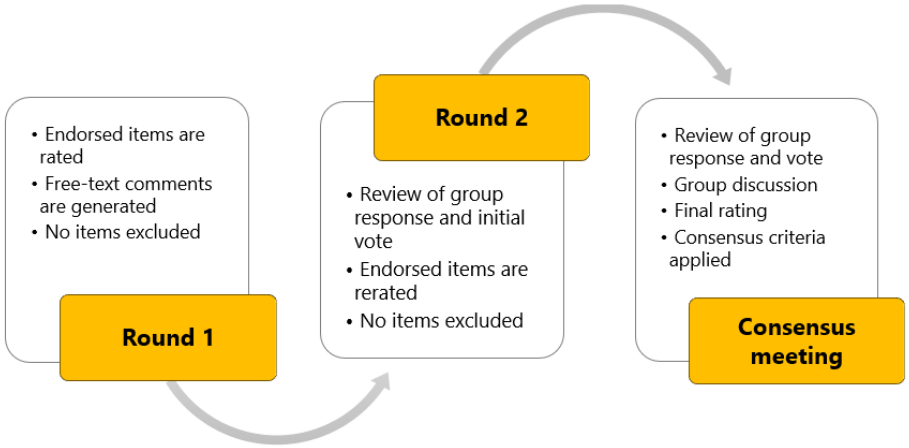

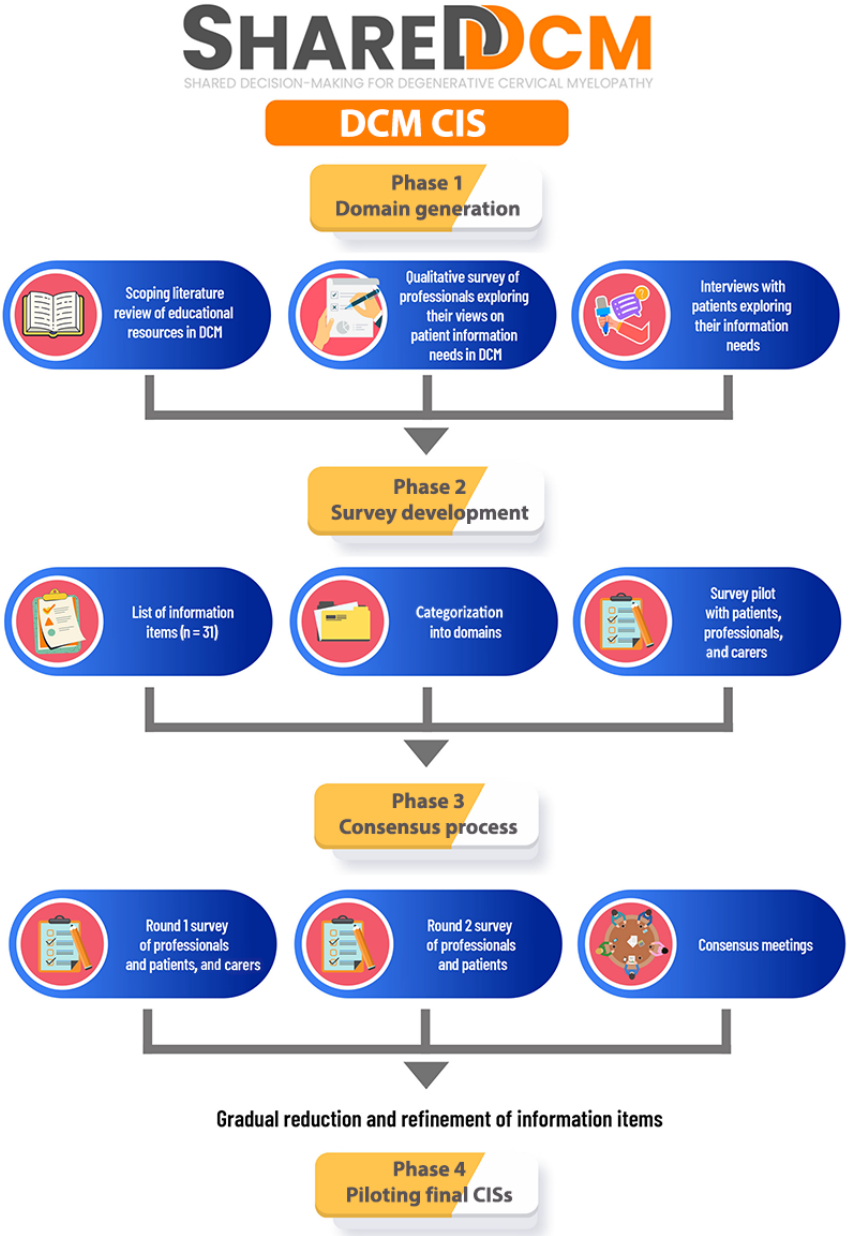

Figure 2. Overview of the phases involved in the development of the degenerative cervical myelopathy (DCM) diagnosis core information set (CIS).

XSL•FO
RenderX

Sample Size

The optimal participant head count for a Delphi study remains a subject of ongoing discussion [82], as exemplified by the historical variance in sample sizes [95]. However, representativeness is not shaped by conventional sampling strategies [96,97] but rather through the expertise of the panel members [98]. Guidelines suggest a minimum of 7 to 15 panelists for optimal reliability [78]. Some believe that exceeding 30 participants adds little value [99-101]. To develop a relevant CIS, our study aims to target the 2 primary DCM stakeholders: people with DCM and HCPs managing DCM. We propose enlisting at least 15 experts from each category, with no upper limit [78,95,102]. We address potential carer involvement in the following section.

Expert Selection

The sample composition significantly determines the validity of the study results [103,104]; therefore, an element of careful judgment is warranted to ensure a "balanced" panel [104-106]. To ensure a judicious selection of experts, this study will use a purposive sampling approach, drawing surgeons, other HCPs, and people with DCM as participants from the specialized RECODE-DCM community. People with DCM will be considered if they (1) have been formally diagnosed with DCM and are at least 6 months after surgical decompressive treatment, the time point at which neurological recovery is considered to halt for most [107], or (2) have undergone at least 6 months of nonoperative management [49]. Professional stakeholders will be invited to participate if they (1) are experienced in managing DCM for at least 5 years; (2) belong to key clinical disciplines, including spinal surgery, neurology, combined physical and psychological rehabilitation medicine, physiotherapy, pain management, and primary care [4,108]; and (3) have no conflict of interest in developing a CIS. All participants will be English-speaking adults (aged ≥18 years).

A diverse and geographically representative panel will be sought, in keeping with the aim of developing an internationally suitable CIS. Adequate patient involvement is vital to this endeavor to help foster evidence-based decision-making [109]. Recognizing the importance of patient perspectives, we propose aiming for a stakeholder target ratio of 1:1:2 (surgeons:other HCPs:people with DCM). The increased representation of people with DCM addresses their typically minor role in such studies and considers recent findings indicating a divergence in clinician- and patient-prioritized outcomes [4] and information needs [45]. This ratio also aligns with the status of people with DCM as the principal beneficiaries of the CIS and enhances its applicability from a patient and public perspective.

For balanced geographical stakeholder representation, a 1:1:1 target ratio is proposed, spanning North America and Australasia; Europe and the United Kingdom; and "elsewhere," comprising Africa and Asia. Including stakeholders from these regions will help ensure that the CIS considers a wide range of health care systems, cultural practices, and resource availability. However, it is worth noting that engaging participants from the "elsewhere" category may prove difficult. These regions, which are often underrepresented in the research community owing to fewer research resources and infrastructure [110], are similarly underrepresented in our specialized RECODE-DCM community. Recognizing this potential recruitment challenge upfront, we will aim to achieve equal regional representation during the final consensus meeting, with no items removed before this stage.

Carers (informal and formal) of people with DCM will also be invited to participate in the Delphi process as they offer significant practical and emotional support to people with DCM [16] and likely hold unique perspectives with regard to their information needs at the time of diagnosis. Consultation with informal carers, often subject to significant caregiving strain [16], may indirectly contribute to their welfare by promoting improved standards of care. However, we acknowledge that the recruitment of carers may be challenging as they are less likely to self-identify, as documented in related research domains [111]. In addition, the number of carers involved in the RECODE-DCM community is currently limited. For these reasons, no stakeholder or geographical target ratios will be specified for this group. Their involvement will be encouraged by existing HCPs and people with DCM in the community.

Participants will be invited to complete round 2 of the Delphi survey only if they have responded to round 1. A dropout rate of approximately 20% is expected from previous Delphi exercises [95,112]. Respondents who complete the Delphi process will be acknowledged in published material. No monetary incentives will be offered.

Generating Information Items

The first step in the Delphi process involves generating a list of information items for the voting consensus process. The procedure comprises 3 steps, described in the following sections.

Scoping Literature Review and Patient Interviews

In structuring the Delphi procedure, we sought to cover the wide spectrum of DCM-related information with the potential to foster patient understanding of the condition, facilitate informed decision-making, and promote efficient self-management. Clinically pertinent items were derived from scientific publications, patient leaflets, health websites, and videos identified in a scoping review of DCM education resources [38]. In total, 150 information resources were reviewed, spanning 115 (76.7%) scientific publications, 28 (18.7%) videos, and 7 (4.7%) health organization resources and health education websites. Items sourced in this manner characterized the disease etiology, pathophysiology, epidemiology, management, and outcome prediction. Additional multidimensionality was added via items sourced from qualitative research involving patient focus groups [10,113] and semistructured interviews [45]. These provided valuable additions focused on the impact of DCM on employment, mental health, and quality of life. The process of deriving the information items was iterative. Each new unique piece of information was noted as an item, and multiple returns to the data were made to ensure the avoidance of duplicates and omissions. This process continued until a preliminary list of information items (n=95) was collated and no new items could be identified.

XSL•FO
RenderX

Professionals' Perspectives

Professionals' views on the information items to be included in the diagnosis CIS were identified using an open-ended qualitative questionnaire (SurveyMonkey; Momentive Inc). Respondents were provided with relevant information via a web hyperlink to the Participant Information Sheet. The sheet included a summary of the research project, its objectives, the inclusion and exclusion criteria, anonymity and confidentiality, and the anticipated time commitment required to complete the survey. To stimulate participant engagement, a short educational video explaining the purpose of the procedure was presented [114]. Biographical information, including training specialty (surgery or other HCP), was collected from consenting participants. Respondents were subsequently directed to a page containing the following open-ended question: "What information do you think people with DCM need to be told at the point of diagnosis about their condition?" It is acknowledged that free-text questions do not generate rich qualitative data [115]. However, our objective was not to elicit robust qualitative insights but rather to generate a list of information items from the professionals' perspectives. To mitigate this limitation, participants were asked to provide a short rationale for each recommended information item. This approach can act as a proxy for qualitative interviews administered to convenience samples [116] and allowed the study team to improve evaluative rigor by understanding the rationale behind the recommendations received. There was no limit on the number of information items that the HCPs could submit.

To facilitate reflective consideration from respondents, participants were presented with a word cloud upon submitting their initial recommendations (Multimedia Appendix 1). Word clouds are a graphic representation of textual data that use frequency counts to display effective summaries of common themes within a given text [117] and have been successfully used previously in DCM consensus work [118,119]. The word cloud generated for this study was produced using qualitative codes derived from the thematic analysis of interviews with people with DCM on the topic of their information needs [45]. This approach was selected to mitigate issues related to language variability that can arise from using direct quotes from the participants, which may be influenced by individual differences in language proficiency, education, and cultural background, and to improve the comprehensibility of the word cloud. Similar adjusted approaches have been used by others [117]. Participants were asked to reconsider their recommendations after viewing the word cloud. As word clouds have been found to promote critical thinking and reflection [120], we hypothesized that this approach would help stimulate professional stakeholders to generate insightful recommendations that are better aligned with patients' needs. The open-ended questionnaire was not issued to people with DCM as their perspectives have already been collected [45].

The Questionnaire

A total of 46 respondents, predominantly spinal surgeons (n=33, 72%), suggested information items (n=312) for inclusion in the Delphi survey. Contributors also included physiotherapists (8/46, 17%) and other HCPs, including neurologists, family physicians, allied health professionals, and researchers (5/46, 11%). The items received were carefully scrutinized for redundancy. On inspection, suggestions paralleled our existing list, demonstrating a broad alignment across all information sources, including the expert clinician group. A multidisciplinary study committee comprising 3 people with DCM, 3 neurosurgeons, a neurologist, 2 consultant physiotherapists, a lay representative, and the study coresearcher condensed the list to 31 information items and classified them into 8 distinct categories deemed to accurately represent their content. For the purposes of developing a CIS, the term "information item" was conceptualized as overarching categories or topics that house more specific, detailed information. For example, the item "lifestyle factors" was an inclusive banner for detailed subjects such as the effects of smoking and occupational trauma on DCM. This approach was chosen to ensure the appraisal of *meaningful* concepts or core educational aspects. The detailed content within each item, although not voted upon, will be accessible for participants' reference throughout the Delphi study. Categorizing information items in Delphi studies is crucial in reducing redundancy and ensuring that all relevant concepts are captured as well as promoting consensus building among expert panelists by clarifying the meaning of each item [79,80]. This also facilitates a systematic and standardized approach to synthesizing diverse perspectives, thereby generating informed recommendations [79,121]. In preparation for pilot-testing, the research team created a draft survey based on the final list and evaluated the software settings, automation, flow, ease of navigation, and completion time. For ease of navigation, only 1 information item was presented per page [122].

Pilot Survey

Pilot-testing was conducted with the study committee. Feedback concerning the language, structure, readability, comprehension of statements, and formatting of the questionnaire was collected through open- and closed-ended questions.

Delphi Survey

An email campaign will be created in Gmail (Google) using a newsletter layout template and sent to HCPs, people with DCM, and carers in the contact directory of the RECODE-DCM network using the multisend function. The multisend option is a built-in mass-email feature that allows emails to be sent in bulk to distinct recipients, thus preserving their anonymity, which is a key feature of the Delphi method [98]. Participants will have the option to opt out of the process at any point through a unique "unsubscribe" link automatically added to each email. Recipients who unsubscribe will be removed from future email campaigns. The email will provide prospective Delphi panelists with a brief overview of the study. Potential panelists will be directed to Delphi round 1 via a SurveyMonkey web link embedded in a participation button at the bottom of the email. The survey will open to a short explanatory video and a web link to the Participant Information Sheet, which will provide a summary of the research project, aims, the inclusion and exclusion criteria, anonymity and confidentiality, and anticipated time commitment. The following biographical data will be collected for people with DCM: age, year of diagnosis, history of surgery or nonoperative management, and employment status. For HCPs, information about their

XSL•FO
RenderX

profession, specialty, job title, and experience in managing DCM will be captured.

Panelists will be asked to independently rate the importance of information items using a 4-point Likert scale ("essential," "very important," "unimportant," and "not at all important"). This range of response categories is more likely to produce stable findings in Delphi studies [95]. Respondents will also be asked to provide a brief rationale for their responses and whether the information items presented could be modified to improve their relevance using a comment box. It is common practice to include in questionnaires that respondents themselves complete an invitation to add issues not covered in the main part of the questionnaire or to expand on terms [123]. The presentation of information items will be randomized using a pseudorandom number generator throughout both rounds [124]. No more than 3 rounds will take place to ensure that the process does not become too repetitive and time-consuming to maintain an adequate response rate [80]. After each round, participants will be asked to read the feedback before responding again to statements.

Data Analysis

Overview

Qualitative and quantitative summaries will be used to understand areas of agreement or disagreement between panelists, generate feedback, and stimulate participants' reflections. All forthcoming data analyses will be carried out by a postgraduate research assistant. Both quantitative and qualitative methods will be used to analyze interround feedback, and the findings will be reported to the panelists and the core research team after each round. The provision of both types of data is essential to enhance rating accuracy [125].

Qualitative Analysis

Free-text comments will be analyzed using inductive content analysis [126], a procedure commonly used with text-based data. Its pragmatic emphasis on theoretical constructs makes this approach particularly suited to practically oriented research where the goal is to describe a phenomenon of interest [127] and generate answers for the application of findings [128]. A summary of the remarks made by other panelists will be displayed anonymously to participants after each round.

Descriptive Statistics

Following each round, panelists will receive aggregate-level summary statistics for each item in the form of frequency percentages, medians, ranges, and IQRs [129]. Participation and attrition rates will be summarized as frequencies and percentages after round 2. Participants will be asked to read the summarized feedback before responding to round 2 statements.

Interrater Stability

Descriptive statistics reflect the level of overall consensus in a given sample but may not account for random change agreement and, therefore, may fail to accurately depict "true" consensus [130]. The κ statistic measures agreement beyond that expected by chance [130]. A weighted κ coefficient will be calculated after round 2 for the between-participant agreement on each information item. This variant is preferred compared with its unweighted equivalent as it is more suited to ordinal data given its ability to account for the magnitude of differences between the agreement levels [131]. The κ statistic will be particularly helpful for guiding the direction of conversations during the consensus meeting, ensuring that discussions are rooted in objective findings. κ calculations will be provided for each information item along with the reference value description of the agreement level in accordance with the study by McHugh [132] (Table 2).

No information items will be removed during these rounds. Data analyses will be conducted using SPSS (version 26; IBM Corp), and graphs will be produced using Microsoft Excel (Microsoft Corp).

Table 2. Level of agreement represented by κ values[a].

κ value	Agreement level
0.0-0.2	None
0.21-0.39	Minimal
0.40-0.59	Weak
0.60-0.79	Moderate
0.80-0.90	Strong
≥0.90	Almost perfect

[a]Adapted from the study by McHugh [132].

Consensus Criteria

Delphi studies lack consensus on the specific threshold for agreement. Significantly, Linstone and Turoff [133] posit that an agreement of >80% is neither the central objective of the Delphi process nor always practically possible. In this study, items rated as "essential" or "very important" by ≥75% will qualify for inclusion, whereas those judged as "unimportant" or "not at all important" by ≥75% will qualify for exclusion. Items not fulfilling these criteria will be defined as not having reached a consensus. This threshold value [134,135] is situated between the 50% consensus supported by some [136,137] and the 100% cutoff point suggested by others [138]. Consensus criteria will be applied after the consensus meeting.

To gain additional insights into the perspectives of the 3 stakeholder groups, comparative statistics will be calculated after each round for review by the core study team. The

XSL•FO
RenderX

parametric 1-way ANOVA will be used to investigate differences in stakeholder responses during each round if the assumptions of normal distribution and homoscedasticity are met [139]. These will be inspected using histograms and the Shapiro-Wilk test and the Levene test for equality of variances, respectively. Statistically significant results will be investigated using post hoc analyses to be chosen in accordance with whether homoscedasticity is met [140]. In the event of violations of the assumptions of normality, the Kruskal-Wallis *H* test, a nonparametric alternative, will be used as it is predicated on rank-based assessment and does not presuppose normality or homogeneity of variance [141]. Moreover, in the event that we are unable to identify sufficient carers to complete the Delphi survey, we will use the independent-sample 2-tailed *t* test to investigate statistically significant differences between HCPs and people with DCM. If the assumptions for the test are not met, we will use its nonparametric equivalent, the Mann-Whitney *U* test. Significance will be assumed at $P<.05$.

Consensus Meeting

The consensus meeting via Google Meet (Google LLC) will be attended by a maximum of 20 randomly selected HCPs, people with DCM, and carers who have completed both rounds of the Delphi survey, preserving the key stakeholder and geographical representation previously described. Participants will be presented with round 2 voting results, as previously described, and asked to anonymously rate the importance of each item for a final time using the polling tool. Frequency percentages will be generated in real time and presented to the voters on-screen to facilitate discussion. The facilitator will guide further discussion regarding any items garnering equal consensus (50%) between the agreement ("essential" and "very important") and disagreement ("unimportant" and "not at all important") before asking participants to vote again. In all other cases, items failing to meet the predetermined ≥75% consensus score will be eliminated.

Reporting the Survey Results

To ensure a thorough description of the Delphi process, survey results will be reported following the Checklist for Reporting Results of Internet E-Surveys [142].

Objective 2: To Identify Critical Decision Points in the Care of People With DCM—Process Mapping the Patient Journey

Overview

Critical decision points in the trajectory of patients will be identified using process mapping, a technique that can aptly describe the workflow and cognitive procedures associated with an activity at the desired level of granularity [143]. We define a critical decision point as a distinct juncture in the care pathway when a professional-patient discussion leads to a care decision. These are essential "go-or-no-go" decisions [59]. Our process map protocol follows the quality criteria framework set out by Antonacci et al [69] to ensure compliance with best practice recommendations. Our approach to each phase is described in the following sections.

Preparation, Planning, and Process Identification

The process map exercise described in this protocol is guided by the need to characterize common critical decision points that adequately represent the global DCM health care pathway. To obtain broad insights, we define the starting point as the time when a person with DCM is diagnosed with DCM and the end point as the time when a person with DCM engages in posttreatment management of the condition. We will define the patient group under investigation as people with moderate or severe DCM treated surgically and people with mild DCM treated nonoperatively [2]. This approach will ensure an all-encompassing investigation of the care route for people with DCM.

Steering Group

It is good practice for process map exercises to be led by a steering group comprising at least one member with lived experience of the condition under investigation and a member with previous process map experience [144]. Following these recommendations, our process map activities will be supervised by the same multidisciplinary study committee overseeing the Delphi consensus process. At a minimum, the committee is envisaged to meet at the beginning and end of project activities, with further meetings as required. Decisions made at meetings will be binding when the meetings are quorate, that is, attended by at least one member of the core research team, one patient representative, and one member with process map experience. Project-relevant communications may also take place via email correspondence as necessary.

Recruitment Strategy and Skills Training

Key informants—English-speaking adults (aged ≥18 years)—will be drawn from the specialized RECODE-DCM community using a convenience sampling approach. Professionals will be approached for participation if they belong to key clinical disciplines, including spinal surgery, neurology, combined physical and psychological rehabilitation medicine, physiotherapy, pain management, and primary care [4,108], and have at least 5 years of experience in managing DCM. People with DCM will be eligible if they have undergone surgical decompressive treatment at least 6 months before, the time point at which neurological recovery is considered to halt [107], and if they have experienced the common care pathway for spinal disorders from primary care to rehabilitative services [145]. This criterion will ensure that participants with DCM are familiar with a wide range of interventions and services along the global spinal care pathway and, therefore, can provide an informed view of its workflow and cognitive decision points. To ensure a global representation of the spinal care workflows and cognitive decisions, both professionals and participants with DCM will be sought at the previously described geographical target ratio. In addition, a 1:1 ratio corresponding to HCPs to people with DCM will be sought in the development of the baseline process map.

An electronic study pack will be provided to those interested in participating, comprising a written study summary, this study protocol, and a Participant Information Sheet containing the study investigators' contact details. To equip respondents with

XSL•FO
RenderX

the necessary process map skills, all consenting participants will be issued a short explanatory document outlining relevant process map symbols alongside an example of a finalized map from a different health care process. Participants will be given the opportunity to contact the study team should they have any questions or require further clarification before commencing study activities.

Data Gathering

To enhance accessibility and foster participant engagement [146], data will be collected using one-to-one semistructured interviews, estimated at approximately 60 minutes and conducted via Google Meet. The interview schedules will be grounded in the literature, aiming to capture information on each step of routine clinical care under investigation [144,145]. To enhance comprehensiveness and incorporate expert input, the topic guide will undergo review and approval by the aforementioned steering group. In total, 2 distinct interview guides will be developed to interview clinicians and people with DCM. For clinicians, we propose a tailored approach in recognition of the specialization inherent in each HCP's role. For example, primary care physicians are instrumental in recognizing the condition and its associated clinical examinations for referral to a spinal surgeon [42]. Specialist surgeons, under the remit of neurosurgery or orthopedics, play a pivotal role in steering the course of management [147]. Specialist practitioners such as physiotherapists play a vital role in assisting in the management of DCM via preoperative physiotherapy and neurorehabilitation programs, primarily used in the context of DCM to manage disability postoperatively [40,148]. Therefore, our interview guide will account for differences in specialists' knowledge of care for DCM by asking HCPs an open question regarding how they manage people with DCM in their role specifically. From there, prompts relevant to each clinician's profession and based on the information they provide will be used to guide the interview. By grounding the topic schedule in the particularities of each professional's role, our approach can help ensure a thorough exploration of clinicians' perspectives, accounting for the nuanced differences across specialties and individual clinical roles within the DCM care pathway. We also recognize that the care pathways of people with DCM differ owing to variations in patients' DCM, flow times between different regions in the world, and guidelines of care [149]. Therefore, patients will be encouraged to share their experiences navigating the care system, focusing particularly on key decision-making points. Prompts will be used to elicit detailed accounts of their journey, the information sources they relied on, their understanding of their condition at each stage, and their level of satisfaction with the decision-making process. Interviews will be conducted until data saturation is reached, that is, until no new information is identified with respect to the research question [150]. At a minimum, it is envisaged that this will involve 20 interviews with HCPs and people with DCM. To allow for the incorporation of new insights generated during the data collection process, the interview guide may be adapted as necessary [151].

A baseline map will be developed by interviewing 3 surgeons and 3 people with DCM from each of the geographical target areas. This approach seeks to ensure that international perspectives are adequately represented from the onset. As surgical intervention is the cornerstone treatment for DCM and surgeons preponderate the research community [50], professional transcripts derived from surgeons specifically (rather than other HCPs) will inform the preliminary map. As women remain underrepresented in clinical surgical practice [152], we will seek to recruit the views of at least one female spinal or orthopedic surgeon in the development of the baseline map. This preliminary map will be developed iteratively through a series of additional interviews with surgeons, other HCPs, and people with DCM while ensuring geographical representation. Interviews will be audio recorded and written informed consent will be sought from all participants. Following their interview, each participant will be provided with a copy of their transcript, a process map created from their interview data, and the evolving baseline map. Participants will be asked to reflect on their interviews and consider whether they wish to supplement the process map. This approach will be used as a means of ensuring data validation and quality and promoting further unbiased contributions to the data [153,154].

Upon reaching data saturation, a selection of interviews will be chosen based on their richness, and the final process maps will be refined by referring to them. Data richness will be defined as "thick" data that best capture the multifaceted complexities of the process under investigation [155]. Participants will be assigned unique study numbers to anonymize their identities in the transcripts.

Map Generation

The baseline map will be developed and schematically represented using Lucidchart (Lucid Software Inc), a web-based diagramming application, and developed iteratively based on information obtained during subsequent interviews. A level of complexity associated with ad hoc variation in the international processes and cognitive decision points is anticipated. To accurately depict this, several process maps may need to be generated. For example, a separate process map may need to be created for preoperative, operative, and postoperative processes. Where possible, relevant clinical pathway documents provided by participants will be used in the development of the process map.

Data Analysis

Interviews will be transcribed verbatim and analyzed using inductive thematic analysis according to Braun and Clarke [156]. This will involve a coding process whereby segments of text are systematically organized according to common concepts and broader themes developed to encapsulate the main topics present in the interview data. The synthesis of these themes will be used to develop a visual representation of the interview data within the process map. The map will be developed iteratively, ensuring the inclusion of emerging themes. The final stage will involve validation to ensure the accuracy and reliability of the process map. This can be achieved through methods such as member checking, peer debriefing, or triangulation, ensuring the credibility and dependability of the findings [157]. The final process maps will be shared with the key participating stakeholders for comments and validation over email. Participant demographic characteristics will be collected during the

XSL•FO
RenderX

interviews and presented in tabular form using frequencies, means, and SDs as appropriate. For HCPs, demographic data will include age, gender, job title, a brief description of their duties, and number of years managing DCM. For people with DCM, this will include age, gender, occupation, year of diagnosis, and treatment (where applicable).

Future Steps

Process maps should be used to guide process improvement initiatives [158]. The process maps generated following this study protocol will inform future efforts by Myelopathy.org to develop SDM tools that will help people with DCM participate in making specific and deliberate choices regarding their health. In particular, at the time of writing this protocol, it is considered that identifying critical decision-making points will allow for the development of widely used evidence-based SDM tools such as patient decision aids [159-162] or patient road maps [28].

Ethics Approval

The University of Cambridge Human Biology Research Ethics Committee has approved the study (approval HBREC.2023.04).

Informed Consent, Data Protection, and Dissemination Strategies

Written informed consent will be sought from participants for both study objectives, that is, in the development of the CIS and process map exercise. All data will be handled under UK data protection regulations. Dissemination strategies for this project will include scientific publication and communication of findings via the Myelopathy.org website and Myelopathy Matters podcast.

Results

Recruitment for the Delphi consensus study began in April 2023. The pilot-testing of process map interview participants started simultaneously, with the formulation of an initial baseline map developed at the end of June 2023.

Discussion

The proposed study protocol outlines a Delphi consensus process that draws on the expertise of clinicians experienced in managing DCM and of people with DCM to formulate a diagnosis-specific CIS. It provides the rationale for undertaking an international process map exercise to characterize the common decision points in the health journey of people with DCM and outlines a strategy for generating outputs that aptly fit the needs of the global DCM community via broad stakeholder consultation.

Significance of the Study

To the best of our knowledge, this is the first initiative that aims to engage people with DCM in the management of their care. Given the high global incidence of DCM [2,163], the outputs of this preliminary study are relevant to a substantial cohort of people with DCM, clinicians, and policy makers worldwide. Most importantly, the CIS aims to address the significant educational deficit identified in DCM [38,45]. Drawing on the tangible impact of structured patient education [164-169], we anticipate that the CIS has the potential to reduce knowledge discrepancies and advance equitable opportunities for quality health management decisions. In particular, as CISs are developed using key stakeholder input, they are ideally placed to facilitate a well-orchestrated communication that mitigates the biases or inadequacies associated with purely professional-led communication [60,63]. Furthermore, educating patients on the condition is one facet of improving their openness to and, arguably, time to surgery [45], potentially driving improvements in health care outcomes [170,171]. This is important as many people with DCM misunderstand the necessity and immediacy of surgery [45]. An appraisal of the CIS will be undertaken following its implementation to assess its efficacy in clinical practice.

In addition, we anticipate that the benefits of the process map in the international DCM care pathways may extend beyond SDM, for example, to addressing timely treatment and improving knowledge exchange [69]. Characterizing the key decision points and matching them to the current evidence base may expose critical knowledge gaps that must be served with targeted research. This means that, as the evidence is updated, so can be the SDM tool, helping accelerate the adoption of evidence into practice. In addition, providing a tangible visual tool to convey the patient experience across different health care settings and among various stakeholders may enhance communication among multidisciplinary teams [69], a recognized objective in DCM [172]. In the long run, the process map can serve as a valuable tool for patient advocacy, spotlighting areas of the care process that are particularly challenging [45], allowing policy makers and care providers to be better informed about the realities of living with DCM. This takes on added significance in low- and middle-income countries [173], where the burden of DCM is high yet access to care remains substandard [149]. Finally, developing a globally shared understanding of DCM care, with its similarities and differences, may facilitate opportunities for local redesign, development, or evaluation [69], leading to improvements in access to treatment [13].

Strengths and Limitations

The proposed study has several methodological strengths and limitations. First, the Delphi method offers an unbiased manner of soliciting consensus when this is lacking [174]. The guarantee of anonymity reduces expert-layperson power asymmetries between clinicians and patients, which are inherent in typical health care interactions [175]. This provision is particularly important to people with DCM, the beneficiaries of the CIS, to assert their viewpoints without reservation. Furthermore, the provision of systematic and controlled feedback fosters transparency, dialogue, learning, and sometimes novel insights that might not have been apparent in isolation [78]. Through its systematic progression, the Delphi method allows for gradual refinement of ideas [176]. Information items put forward for consensus in this manner are likely to become more patient-centric, relevant, and clear, ultimately resulting in the production of a more pertinent CIS. In addition, conducting the survey over the internet broadens the inclusion of people with

XSL•FO
RenderX

DCM, including presurgical DCM, which is poorly represented in the conventional literature [50,177].

This approach also has a number of limitations. Despite comprehensive efforts to source a broad range of expert participants, the conclusions of the study may suffer from limitations associated with the panel's composition. This is the case with any Delphi study [178]. In this regard, our purposive sampling approach may lead to outputs that may not fully reflect all health care contexts and stakeholders' perspectives. Pilot-testing the survey with a smaller representative sample can help ensure its comprehensiveness [179]. Expert judgment may also be influenced by cognitive biases, which is a well-recognized limitation of Delphi studies [79]. To mitigate this, we are curating an expert panel diverse in both roles and geographic locations to promote a more balanced collective judgment [180]. Other efforts to minimize bias throughout the Delphi process include the randomization of survey statements to eliminate primacy effects, requests to participants to include a rationale for their choices, and providing feedback in the form of median rather than mean values [116,124,125]. Compared with evidence-based approaches, expert surveys do not capture cause-effect relationships and are, therefore, definitive [181]. That is, our experts' agreement on the final CIS does not assure the tool's efficacy. To address this concern, the CIS will be evaluated, the specifics of which will be laid out in a separate study protocol.

Finally, inductive thematic analysis provides an adaptable methodology for developing the process map. Its flexibility allows for the generation of unanticipated themes and patterns [156]. Coding and organizing the data around common concepts aids in translating potentially complex data into a digestible visual representation [182]. The iterative nature of this method allows for continuous refinement of the process map, thereby increasing the reliability of the results [183], whereas validation strategies such as member checking and peer debriefing ensure the accuracy, credibility, and dependability of the findings [157].

Conclusions

This is the first study to establish an international-led collaborative framework aimed at enabling SDM in the management of a chronic illness. To the best of our knowledge, this approach has not been used before. The projected benefits of this initiative are poised to improve people with DCM's knowledge about their condition. In the long term, this study is intended to drive the development and deployment of SDM tools in DCM care.

Abstract

Background: Renal transplantation is the treatment of choice for most cases of end-stage renal disease. Recipients need to lead a healthy lifestyle to minimize the potential side effects of immunosuppressive drugs and improve transplant outcomes. There is not much evidence about the best way to increase adherence to healthy lifestyles in kidney transplant recipients, so one of the objectives set by the nursing team is to train people to acquire the necessary skills and tools to be able to take care of themselves. In this sense, the consensual development of appropriate materials may be useful and of interest.

Objective: The aim of this study was to develop an information guide for adults with kidney transplants to be assessed in a subsequent clinical trial as an intervention to increase adherence to healthy habits.

Methods: We used a 3-step, methodological, sequential approach: (1) training from a group of experts and item consensus; (2) review of the medical literature available; and (3) use of the Delphi technique with on-site meetings. A total of 5 nurses from the Community of Madrid Kidney Transplantation Unit in Spain were asked to participate. The patients' lifestyle factors that, according to the medical literature available and experts' opinions, have the greatest impact on the survival of the transplanted organ and the recipients themselves were all described.

Results: After using the modified Delphi method to reach a consensus on the items to be included and the information needed in each, an information guide for adult kidney transplant patients was developed. This guide facilitates the structuring of health care, information, and recommendations necessary for effective self-care for each person. The result is considered to be an easy-to-understand tool, useful for transplant doctors and nurses, in simple language, with information based on the latest scientific-medical evidence published to date, aspects of which will be evaluated in a clinical trial designed for this purpose.

XSL•FO
RenderX

Conclusions: Currently, this guide is the main intervention variable of a clinical trial (registered on ClinicalTrials.gov; NCT05715580) aimed at improving compliance with healthy habits in kidney transplant recipients in the Community of Madrid, Spain. The method used in its development has been useful and agile, and the result is a guide that can be easily updated periodically following the same procedure.

KEYWORDS

compliance; Delphi method; guideline; kidney transplantation; patient adherence; patients

Introduction

Overview

Kidney transplantation is the treatment of choice for most cases of end-stage renal disease because this therapy brings better quality of life and prolonged survival. Also, in the long run, it is less expensive compared to dialysis [1-3].

In Spain, the number of kidney transplants has gone up over the past few years, from 52 transplants per million inhabitants back in 2011 to 62.3 transplants per million inhabitants in 2021 [4].

Importance of Adherence to Healthy Habits and Medication

When someone undergoes a kidney transplantation, they need to change a few habits [5]. This, added to compliance with the drug therapy prescribed, is the key to a successful transplantation procedure [6,7]. Also, to prevent possible side effects associated with immunosuppressant medication and improve the results of transplantation, the patient needs to develop healthy habits [8-14].

According to the kidney transplantation protocol, health care providers should have the necessary tools to provide scientific evidence–based, updated, and quality information to implement measures to help patients with kidney transplantation improve their health-promoting lifestyles after the transplant [15]. This should result in longer survival rates for the organ, fewer complications, and lower health costs.

Promoting healthy habits should be encouraged by health professionals involved in patient care on a routine, daily basis since they can have an impact on the patients' decision-making process in this setting [16,17].

Relevance of Evidence and Consensus in Clinical Practice

The aim of developing this information guide for adult kidney transplant recipients is to increase compliance with healthy habits by harmonizing best practices, which are associated with better outcomes for both the organ and the recipient [18]. This guideline will provide the necessary information regarding self-care. Therefore, patients will be able to manage their own health-disease process and reduce the level of concern as they acquire knowledge on the entire transplantation process.

Also, this information guideline for adults with kidney transplantation will unify criteria regarding the scientific evidence–based information that should be given. Therefore, nurses from the kidney transplantation unit will be able to use this guideline to manage the information that should eventually be given to adult patients with kidney transplants by standardizing practice by espousing structured care and doing so in plain language.

Contribution

The aim of this study was to develop a consensus document providing information for adults with kidney transplants, and this paper aims to present the elaboration process, which we believe has been appropriate and yielded robust results. The secondary objectives were (1) to describe the habits that have an impact on the proper functioning of the transplanted kidney and, therefore, on the survival of the latter, and (2) to identify the most relevant evidence regarding self-care for patients with kidney transplantation. The effect of the developed guideline is being evaluated in a large clinical trial (registered on ClinicalTrials.gov; NCT05715580) titled "Impact of Nursing Intervention on Adherence in Kidney Transplant Recipients."

Methods

Overview

We used a 3-step sequential methodologic approach, as explained in this paper. It is worth mentioning that the development of this guide is part of a much broader research project whose objective is to evaluate the educational process using the information guide as the main tool. This is a clinical trial intended to increase the compliance of the adult population with kidney transplantation with drugs and healthy habits through an informative intervention implemented by the nursing team from the Community of Madrid Kidney Transplantation Unit in Spain. It is expected that by increasing compliance, clinical parameters indicative of poor renal function will improve as well.

First Step: Training From a Group of Experts—Consensus and Item Decision-Making

In the first place, to develop the information provided by the guideline, a group of experts were asked to provide the topics they thought should be included to give adequate and complete information to adults with kidney transplantation.

To select the group of experts, the lead investigator contacted the nurses from 5 different specific kidney transplantation units that are currently operative in the public hospital system of the Community of Madrid, Spain.

XSL•FO
RenderX

During this first contact, nurses were asked to give their consent to receive information on the project, giving them the possibility to participate in such a project.

After obtaining their permission, they were sent an email including an invitation explaining how to participate in the project, information on its objectives, different phases, what their contribution would be, and the informed consent form to participate in it. To select the items that should be included in the guideline, a web-based open first round of questions was sent through email to all participants with all the items they thought should be included in the guideline.

Afterwards, a web-based survey was created that was later developed by the research team from January to April 2022, including two parts: (1) questions on the social and demographic data of the participants; and (2) questions on the content of the guideline; these questions were answered in step 3 of the process, once the bibliographical review that was the basis of the guide had been made.

Second Step: Bibliographic Search

A review of the available medical literature was conducted to define the items that should be included in the information guideline for adults with kidney transplants. Through this review, the most relevant elements that should be taken into consideration regarding proper self-care practices in adults with kidney transplants were identified. Also, the most influential elements affecting the survival of the organ were identified. In addition, the compliance of patients with healthy habits was also assessed, as were the elements that might affect it.

The search was conducted in 3 different electronic databases: Medline/PubMed, Web of Science, and CUIDEN, from January 1, 2012, to December 31, 2022.

Search algorithms were based on the Population, Intervention, Comparator, Outcomes (PICO) strategy (population: adults with kidney transplants; intervention: any intervention aimed at promoting compliance with healthy lifestyles; comparator: no intervention or a different intervention; and outcomes: change in compliance with healthy lifestyles) [19] by selecting keywords using medical subject headings (MeSH) terminology [20]. The key terms used were “kidney transplant* / renal transplant*” and “lifestyle” plus “intervention” and “compliance.” Search strategies were adapted to databases by using different Boolean operators. Search was restricted to reports and manuscripts published over the past 10 years in such a way that all relevant studies that were not obsolete could be retrieved. The eligibility criteria were primary research studies written in any language and describing nonpharmacological interventions to improve compliance in adults with kidney transplants, and the lifestyles proposed by the medical literature. Only clinical trials were considered since only the effects of interventions were sought. No restrictions were put on the study duration or size of the sample. Reference lists of the included publications were also screened to identify additional articles. Reading and data mining were both conducted by 2 independent authors. Dissenting opinions were resolved through consensus.

Afterwards, based on the information provided by the group of experts and the information found in the bibliographic search, the information guideline for adults with kidney transplantation draft version 1 was created. Then, it was emailed to the panel of experts with a web-based survey.

Third Step: Delphi Process With On-Site Phase

In the third step, a consensus group was created using the Delphi technique, followed by an on-site phase. The Delphi technique was based on the following 4 fundamental pillars [21]:

- An iterative process in which experts gave their opinion more than once was created. This gave them the opportunity to reflect on the opinions given based on the proposals made by others.
- Controlled feedback was given after each round, which allowed the free circulation of information inside the group, thus establishing a common language.
- Anonymity was kept during the first round and across the web-based survey, in the sense that none of the group members knew who had given a particular answer. However, and this is why the Delphi modified technique was used [22], this was not possible during the on-site discussion that, nonetheless, brought agility to the consensus process. We consider that this option, the face-to-face discussion, which represents a modification of the Delphi technique, has contributed to fostering the discussion and refining the subtleties of the responses. Textbox 1 depicts the characteristics involved in this modified Delphi technique.
- Finally, a globally calculated answer of the group was given, in which the individual results were included.

Textbox 1. Characteristics of the modified Delphi technique. Modified from Humphrey-Murto et al [22].

1. Email questionnaires
2. Collect decisions anonymously
3. Obtain formal feedback as group ratings
4. Carry out face-to-face interactions
5. Carry out structured interactions

Therefore, to proceed with the modified Delphi technique, the items of the questionnaire—which was web-based—were elaborated to later move on to an on-site discussion.

The following questions were asked across the survey to assess each section of the guideline:

- Do you think that the topics of discussion in this section are appropriate? With a dichotomous response of yes or no,

XSL•FO
RenderX

if the answer is negative, a box opens immediately with the following question: What would you add or suppress?
- Do you think that the message transmitted with the content of this section is appropriate? With a dichotomous response of yes or no, if the answer is negative, a box opens immediately with the following question: What would you change?
- Do you think it is long enough? With three response options: (1) yes; (2) no, it is too short; and (3) no, it is too long. If the answer is negative, a box opens immediately with the following question: What would you add or suppress?
- Do you think that the information provided is appropriate? With three different response options: (1) yes; (2) no, I think some information is missing; and (3) no, I think there is too much information. If the answer is negative, a box opens immediately with the following question: What would you change in the information provided?
- Do you think that the information provided is up-to-date? With a dichotomous response of yes or no, if the answer is negative, a box opens immediately with the following question: What part would you say is outdated? Please, if possible, provide current references.
- Rank from 0 to 4 the relevance of the information provided, with 0 being irrelevant and 4 being positively relevant.

The survey included a total of 105 questions. Given the limited number of participant experts, consensus was only achieved on items on which 4 of 5 respondents (80%) agreed, with mean scores >3.5 out of 4 possible points regarding the relevance of the information provided in each section.

In a third communication with respondents, the information guideline on adults with kidney transplantation draft version 1 was submitted, including a link to a web-based survey.

Finally, after the review that followed the web-based survey, the information guideline draft version 2 was created, followed by an on-site meeting with the group of experts.

On-Site Discussion

Participants were summoned to an on-site meeting that was held at Hospital Clínico San Carlos de Madrid, Madrid, Spain, in October 2022. A total of 5 experts attended the meeting.

A semistructured interview was held at that meeting, where the lead investigator acted as the moderator to discuss topics on which no agreement had been reached. At the end, some time was given to express all comments, suggestions, and doubts deemed necessary by the experts.

After all these steps and their corresponding changes to the information provided, the guideline was edited by inserting images to make it more pleasing and enjoyable for the reader.

The final draft of the guideline was submitted, seeking the approval of the Madrid Health Authority Technical Coordination Commission. A positive report on the guideline was given by this commission.

Ethical Considerations

Study participation was voluntary, and participants were given the option to withdraw their consent and walk away from the study at any time without any repercussions.

The project was conducted in full compliance with the latest iteration of the Declaration of Helsinki and the International Conference on Harmonization Good Clinical Practice Guideline (ICH GCP).

All personal data were tagged with a single code. Only the investigator was authorized to associate data with each participant. The lead investigator is responsible for guarding this information in a confidential way as long as legally required and in full compliance with the Spanish legislation: Organic Law 3/2018, of December 5, Protection of Personal Data and Guarantee of Digital Rights (LOPDGDD), and European legislation regarding data protection: Regulation (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46/EC (General Data Protection Regulation).

This project was submitted to the Hospital Clínico San Carlos Research Ethics Committee as part of the clinical trial project to assess the impact of a nursing intervention on compliance with medication and healthy habits in adult patients with kidney transplantation (22/325-EC_X).

Results

The mean age of the 5 participant nurses was 52.2 (SD 9.7) years, and 80% (4/5) were women with a median of time working as a nurse, at the nephrology unit, and at the kidney transplantation unit of 27 (IQR 19.5-30) years, 21 (IQR 7-24) years, and 3 (IQR 2.5-7.5) years, respectively.

Regarding training, 60% (3/5) were graduates or undergraduates, while 20% (2/5) were holders of a master's degree in nephrology. They all had previously received specific training on kidney transplantation through continuing medical education courses.

In the first round, when an email was sent with an open question to elicit topics of interest that should be included in the information guideline on adults with kidney transplantation, 3 of the 5 nurses involved sent the information they were giving adults with kidney transplantation from their offices, while the remaining 2 responded to the open question with topics of discussion interesting to them and consistent with the information provided by the rest of the group.

After grouping the information provided by the group of experts and the information found in the medical literature available, the information guideline on adults with kidney transplantation draft version 1 was created, including 10 different sections or topics of discussion (Textbox 2).

Through the web-based survey, consensus data shown in Table 1 with all the questions from each section were obtained.

After reviewing the feedback received from the participants through the web-based survey, the contents of the sections on which consensus was reached regarding modifications were eventually updated. The format of the table of contents proposed in draft version 1 was kept and gave way to the information guideline for adults with kidney transplantation draft version 2. Sections on which experts did not agree with the information provided and no consensus was reached on what should be changed were proposed as topics of discussion during the on-site meeting and left for future change (Table 1).

Draft version 2 was discussed in the on-site meeting. After this meeting, the contents were updated once again. Draft version 3 is still pending. However, it will include the index that has not been modified and that coincides with Textbox 1 and all the content approved by consensus from the panel of experts.

After all these steps, it was decided to edit the guideline. Also, to achieve a more visually appealing guideline for the reader, original images created for this purpose were added by the author, who provided them for free.

Discussion

Overview

Health training and education are 2 of the nursing competencies most present in the entire health care process, as are prevention and the promotion of self-care at the base of these processes [23].

The beginning and development of this project took place for 2 main reasons. On the one hand, it was a response to the doubts and questions posed by health care personnel regarding compliance with healthy habits in adult patients with kidney transplants. On the other hand, it was born as a response to a growing demand for information from users who, thanks to patient-centered care and individual empowerment to improve one's own health, have become more self-aware of the entire health-disease process.

As a reflection, this methodology for the creation of an effective guideline—agreed and based on the best evidence available—has been agile, useful, and allowed periodic updates with limited effort.

The usefulness of this guide will be evaluated in the clinical trial (ClinicalTrial.gov; NCT05715580), whose goal is to analyze the impact of an informative nursing intervention on adherence to drug treatment and a healthy lifestyle in patients with kidney transplants and the effect of poor adherence on clinical predictors of poor kidney function.

It seems evident that, beyond the imprint left by each health professional in his or her respective office or unit, having common tools and resources available promotes the development of similar health care strategies within a standardized system of health care provision.

Limitations

One of the limitations in this study was the small group of experts that, although it included all nurses from the kidney transplantation units of the public network of the Community of Madrid, did not take into consideration other professional profiles. Also, given the method used to collect the experts, it was impossible to maintain the anonymity of the group.

On the other hand, a small group was good for obtaining the involvement and cooperation of participants during the entire process—something that was confirmed by the lack of withdrawals—which is typical of this kind of methodology.

Additionally, it is possible that the participants, as experts, only confirmed the relevance of the topics instead of considering all possible issues to address. This could potentially lead to confirmation bias, which could have been mitigated by involving patients or patient associations in the guide development process.

Finally, in the case of the responses requested from the group of experts in the survey, they may be biased by the "framing effect," whereby the formulation, structure, and presentation of the questions could lead to changes in opinion or bias the response. This is a factor that needs to be taken into consideration [24].

Conclusions

Thanks to the methodology used in this research, we managed to describe the habits that, based on the medical literature available and the opinion of experts, have played a key role in the good functioning of transplanted kidneys, thus impacting the survival of both the organ and the recipient.

Therefore, in the information guideline for adults with kidney transplants created as a result of this project, self-care practices identified as necessary and relevant to guarantee the success of transplantation were included.

Although other informative documents already existed for adults with kidney transplantation, the creation of this guideline allowed us to structure the necessary health care, thus generating a single document with all the necessary information and recommendations for patients to implement self-care measures effectively.

Therefore, a useful, easy-to-understand tool for health professionals in the field of kidney transplantation was created using simple language and with the latest scientific evidence available to date.

We hope this new tool will make the work of health professionals involved in kidney transplantations easier. At the same time, we hope it improves the quality of life of adult patients with kidney transplants as well as the quality of care they perceive.

Abstract

Background: Emerging adults living with type 1 diabetes (T1D) face a series of challenges with self-management and decreased health system engagement, leading to an increased risk of acute complications and hospital admissions. Effective and scalable strategies are needed to support this population to transfer seamlessly from pediatric to adult care with sufficient self-management capability. While digital health interventions for T1D self-management are a promising strategy, it remains unclear which elements work, how, and for which groups of individuals.

Objective: This study aims to evaluate the design and implementation of a multicomponent SMS text message–based digital health intervention to support emerging adults living with T1D in real-world settings. The objectives are to identify the intervention components and associated mechanisms that support user engagement and T1D health care transition experiences and determine the individual characteristics that influence the implementation process.

XSL•FO
RenderX

Methods: We used a realist evaluation embedded alongside a randomized controlled trial, which uses a sequential mixed methods design to analyze data from multiple sources, including intervention usage data, patient-reported outcomes, and realist interviews. In step 1, we conducted a document analysis to develop a program theory that outlines the hypothesized relationships among "individual-level contextual factors, intervention components and features, mechanisms, and outcomes," with special attention paid to user engagement. Among them, intervention components and features depict 10 core characteristics such as transition support information, problem-solving information, and real-time interactivity. The proximal outcomes of interest include user engagement, self-efficacy, and negative emotions, whereas the distal outcomes of interest include transition readiness, self-blood glucose monitoring behaviors, and blood glucose. In step 2, we plan to conduct semistructured realist interviews with the randomized controlled trial's intervention-arm participants to test the hypothesized "context-intervention-mechanism-outcome" configurations. In step 3, we plan to triangulate all sources of data using a coincidence analysis to identify the necessary combinations of factors that determine whether and how the desired outcomes are achieved and use these insights to consolidate the program theory.

Results: For step 1 analysis, we have developed the initial program theory and the corresponding data collection plan. For step 2 analysis, participant enrollment for the randomized controlled trial started in January 2023. Participant enrollment for this realist evaluation was anticipated to start in July 2023 and continue until we reached thematic saturation or achieved informational power.

Conclusions: Beyond contributing to knowledge on the multiple pathways that lead to successful engagement with a digital health intervention as well as target outcomes in T1D care transitions, embedding the realist evaluation alongside the trial may inform real-time intervention refinement to improve user engagement and transition experiences. The knowledge gained from this study may inform the design, implementation, and evaluation of future digital health interventions that aim to improve transition experiences.

KEYWORDS

digital health; emerging adults; realist evaluation; self-management; transition to adult care; type 1 diabetes

Introduction

Type 1 diabetes (T1D) is a common chronic condition that affects 9 million people globally [1], including over 650,000 children (aged 0-14 years) and 560,000 teenagers (aged 15-19 years) [2]. T1D management requires knowledge, skills, and motivation to perform daily self-management as well as routine health care management and monitoring throughout the lifespan [3-5]. A total of 42% of individuals with T1D onset during childhood often experience deterioration in glycemic management, which confers an increased risk of chronic complications and acute diabetes complications such as life-threatening ketoacidosis during adolescence and early adulthood [1,6]. Effective health care management and a smooth transition from pediatric to adult care can help mitigate this risk [5,7,8]. Unfortunately, the transition period is fraught with challenges in part because it coincides with emerging adulthood, when individuals are facing a series of changes in their independence and responsibilities for disease management [9]. Current estimates suggest that over 20% of emerging adults experience a gap of over 6 months between pediatric and adult care medical visits during transition [10,11]. Effective transition support must attend to medical, psychological, educational, and vocational needs in order to support sufficient self-management skills [12-14]. Failure to address these needs may lead to adverse health outcomes [14], decreased health system engagement [10], and increased hospital admissions [15].

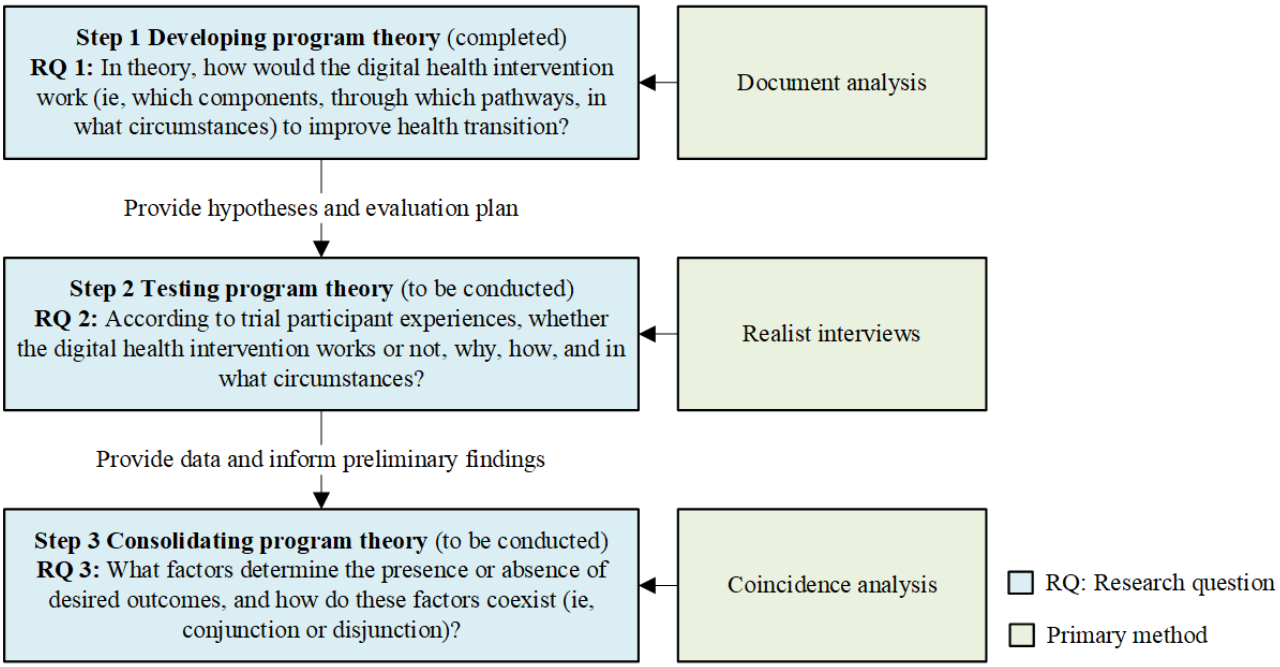
Strategies to improve the transition process have been implemented at the patient, provider, and service levels [16,17], but are often institution-specific or resource-intensive, thereby limiting their accessibility, scalability, and generalizability [18-20]. Digital health interventions are increasingly used to address these limitations while also leveraging the high prevalence of smartphone use among youth [21]. The hypothesized benefits are also compelling, including the flexibility to access and exchange information instantly, irrespective of geographic constraints, at low cost, and the potential to provide more personalized support [22]. Digital health T1D management interventions, through mobile apps [23-25], websites [26], and text messages, emails, or telephone calls [25,27-29], have become increasingly common [23-29] and acceptable [23,26,27] to young adults, with demonstrated impacts on clinic attendance [28] and glycemic control [29]. A recent paper by Cafazzo et al [23] piloting a T1D management mobile app in adolescents found 88% of participants were satisfied with the app. Moreover, they found a significant increase in the frequency of blood glucose measurement among their participant sample. In a pragmatic clinical trial, Butalia et al [28] observed significantly greater outpatient appointment attendance in transitioning youth living with T1D who received a communication technology-based (SMS text message, email, or telephone) transition coordinator intervention as compared to those who received care as usual. Also, through a crossover trial with adolescents, Rami et al [29] found SMS text messaging-based telemedical support feasible and helpful in improving hemoglobin A_{1c} (HbA_{1c}).

However, potential impact can be undermined by the often-reported rapid drop in intervention engagement, which occurs sometime between 2 weeks and 6 months after initial use [30,31]. Among adolescents living with T1D exposed to a

XSL•FO
RenderX

mobile self-management tool, 1 study reported that only 35% of participants were either moderately or highly engaged over the 12-month intervention [24]. Despite this well-known risk, comparatively little is known about how to overcome this common challenge. Relatedly, many multicomponent digital health interventions report aggregate effects [27-29], limiting our ability to understand which elements contribute to achieving the distinct but related goals of ensuring sustained intervention engagement while also effectively addressing the known barriers to desired outcomes.

Realist evaluation, a theory-driven evaluation framework [32], seeks to unpack the black box of interventions by establishing the causal links between intervention resources and associated outcomes while identifying the circumstances needed to facilitate the change in a Context-Mechanism-Outcome (CMO) framework [33-36]. Given the complex and context-specific nature of health interventions [37], they have been increasingly adopted in the health field [34,38-40] to solve the question of what works, for whom, and in what circumstances [41-43].



By acknowledging the potential of realist evaluation in addressing the abovementioned knowledge gaps, we have developed a protocol for a sequential mixed methods realist evaluation embedded alongside a randomized controlled trial (RCT) evaluating the effect of a digital health intervention on the transition experiences of emerging adults living with T1D. Using a realist evaluation framework, the specific objectives of the embedded realist evaluation will be to (1) develop and test the intervention program theory that identifies what elements of the intervention contribute to successful engagement and improve transition experiences, how they do it, and for which groups of individuals; and (2) consolidate the intervention program theory by identifying the crucial combinations of factors that are minimally sufficient for an effective implementation of the digital health intervention and their coexistent causal pathways.

Methods

Study Design

Following Mirzoev et al [40], we plan to conduct this embedded realist evaluation in 3 steps (Figure 1), which include developing (step 1; completed), testing (step 2; to be conducted), and consolidating the program theory (step 3; to be conducted).

Figure 1. Study design and methods.

As a theory-based evaluation and in line with best practices [32,44], this study is guided by a program theory outlining the hypothesized mechanisms through which the digital health intervention is expected to work and the corresponding context, with specific attention paid to user engagement (step 1). We have added an explanatory factor "intervention" (I) to the conventional "context-mechanism-outcome" (CMO) framework [45] following Breton et al [46] and Shams et al [47] to disaggregate the 2 major components of mechanisms (M) in the conventional CMO framework (ie, intervention resources and recipients' reasoning) [36]. This will enable us to specify which elements of this multicomponent intervention contribute to the desired outcomes and how they are influenced by context [44]. Specifically, we have developed the initial program theory in the framework of "context-intervention-mechanism-outcome" (CIMO) to understand for individuals with which contextual characteristics (C), which intervention components and features (I), trigger what mechanisms (M), and therefore yield what target outcomes (O). This initial program theory informs the following data collection and analysis [39].

Since realist evaluation is method neutral [48], this study uses mixed methods and integrates multisource data to test and consolidate the program theory. In step 2, we plan to conduct semistructured realist interviews with participants in the RCT intervention arm in a "teacher-learner cycle" [49]. The interviews will aim to test each of the hypothesized CIMO

XSL•FO
RenderX

configurations by exploring individual perspectives and experiences using "Keeping in Touch" (KiT), including how participants interact with KiT and under what circumstances it facilitates (or fails to facilitate) mechanisms that lead to engagement and improved transition experiences.

Multicomponent interventions often achieve desired outcomes through distinct combinations of factors that interact to produce the outcome, as well as through multiple mechanisms [38]. For instance, the combination of a high level of positive outcome expectancies (ie, belief about the consequence of performing a specific behavior) and a high level of self-efficacy (ie, confidence about the ability to perform a specific behavior) may lead to improved diabetes self-care [50,51], whereas the combination of a high level of outcome expectancies and a low level of self-efficacy may lead to poorer diabetes self-care [51]. This highlights the need to identify difference-making factors as well as the settings in which they make a difference. Coincidence analysis (CNA) is a novel configurational approach underpinned by Boolean algebra to identify the crucial difference-making conditions, which include combinations of factors (including contextual factors and intervention components) necessary to achieve target outcomes and the causal pathways (mechanisms) that lead to positive effects [52]. Therefore, in step 3, we will leverage intervention usage data, patient-reported outcomes, and interview data and perform CNA to gain such an in-depth understanding, according to which we will consolidate the program theory.

Step 1: Developing Program Theory

Document Analysis

We conducted a document analysis to develop the program theory using 2 data sources. First, we reviewed the program documentation, including the intervention design documents, RCT protocol, and data collection materials, to identify its intervention components, extract the corresponding features, understand the assumptions of the designers on how this multicomponent digital health intervention would lead to desired outcomes, and select the corresponding outcome indicators. Second, we reviewed published research articles on behavioral science theories, with special attention paid to digital behavior change interventions (DBCIs) and chronic disease self-management. The objective for reviewing pre-existing theories was twofold: (1) to inform the coding of intervention features, determine the key mechanisms, and identify the individual characteristics that may influence the implementation process; and (2) to select appropriate preexisting conceptual frameworks to inform the development of CIMO configurations, that is, build causal relationships among the constructs [53]. We focused on microlevel theories according to the study objective, that is, to understand the implementation process of a digital health intervention among individuals.

Intervention Components and Features

The KiT intervention [20] was developed using a user-centered design approach that engaged adolescents and emerging adults living with T1D as well as adult and pediatric diabetes providers. Specific intervention content was informed by clinician consultation and an environmental scan of diabetes transition resources mapped to domains of the "readiness of emerging adults with diabetes diagnosed in youth" (READDY) tool with the aim of improving the transition experiences among emerging adults living with T1D (Textbox 1). In addition to providing care coordination support (eg, appointment note-keeping and reminders), KiT is designed to provide personalized T1D informational support (eg, educational content and a question and answer feature) based on an individual's interests and self-reported confidence about their diabetes knowledge and skills using a set of "if-then" rules (Multimedia Appendix 1).

XSL•FO
RenderX

Textbox 1. Brief description of the digital intervention.

Intervention name: Keeping in Touch (KiT)

Delivery method: SMS chatbot

Study population: Emerging adults living with type 1 diabetes (T1D) residing in Ontario or Quebec who are within 4 months of their planned transfer to adult care

Intervention length: 12 months

Intervention development methods: Based on user-centered design approaches (detailed information can be found [54])

Intervention components:

- Informational content (one topic per month):
  - Topics received by all users: 4 topics provided to all participants at months 1, 4, 7, and 10 respectively. Topics include coping with T1D, care navigation, sick day and ketone management, medical insurance and financial support.
  - Topics based on user needs and interests: 8 topics from a pool of 10 candidate topics provided at the rest of 8 months. Topics are determined by the participant's baseline transition readiness status (self-reported confidence about diabetes knowledge and skills measured by the "readiness of emerging adults with diabetes diagnosed in youth" READDY tool) and their interests. Topics include hypoglycemia, pumps and pump programming, insulin adjustments, drugs and alcohol, travel, driving, school and work accommodations, exercise, nutrition and carbohydrates, and sexual health.
- **Question and Answer**: KiT recognizes key words in participants' T1D-related questions and automatically pulls resources from the KiT database to answer their question. Interaction with participants by periodically asking for feedback 5 minutes after providing question and answer responses.
- **Transition care coordination:**
  - Reminder: KiT sends reminders for participants to book appointments and requests them to input their appointment information in the chatbot. KiT then sends appointment and bloodwork or urine test reminders at the participant's preferred times.
  - Note-keeping: KiT allows participants to save a list of items to discuss in their appointments, which is sent back to them 1 hour before their scheduled appointments.
  - Care coordination support: KiT sends prompts to help participants prepare for appointments and reflect on their care experiences.
  - Clinic information: KiT sends information on the adult clinic that the participant will be attending, for clinics included within the chatbot database.

We have identified intervention components and features (Table 1). By performing deductive coding according to existing literature, we extracted several common components and features of DBCIs, including personalization [55,56], problem-solving support [57-59], reminders [55], real-time interactivity [55,60], credible sources [57], user-friendly SMS text message tone [55], and diverse forms of information (enhanced media) [56]. We classified the remaining KiT components (eg, coping with T1D and care navigation) through inductive coding.

Initial Program Theory

We have developed the initial program theory (Figure 2) by integrating 3 empirically validated individual-level behavioral change theories, including "capability, opportunity, motivation, and behavior" (COM-B) [61], "health action process approach" (HAPA) [62], and "technology acceptance model" (TAM) [63].

Figure 2. Initial program theory of the Keeping in Touch (KiT) intervention. COM-B: capability, opportunity, motivation, and behavior; DBCI: digital behavior change interventions; HAPA: health action process approach; T1D: type 1 diabetes; TAM: technology acceptance model.

XSL•FO
RenderX

Informed by COM-B [61], we hypothesize that KiT may improve participants' transition outcomes (ie, transition readiness, self-management behavior, and health outcomes) by triggering changes in individual motivation (ie, self-efficacy, negative emotions, outcome expectancies, behavioral cueing) and capability (ie, knowledge, skills). T1D self-management information and suggestions, transition support information, and problem-solving support may increase participants' T1D and transition-related knowledge and skills [64], and therefore, capability [61]. T1D self-management information and suggestions [65] and problem-solving support [59] may improve one's outcome expectancies and self-efficacy, respectively, which are the key motivational factors of an individual's behavioral change [66]. One's self-efficacy may also be improved by receiving stress management strategies [67]. Meanwhile, stress management strategies may lead to reduced negative emotions [58,67], which have been recognized as one of the most prominent motivational challenges to a successful T1D health care transition [14,68]. Transition reminders may function as behavior cueing to plan for and attend clinic appointments [69]. Well-designed intervention functions, such as personalization, credible sources, and diverse forms of information, may amplify the impact of KiT's intervention content.

The extent to which KiT can trigger changes in health care transition capability and motivation is hypothesized to be dependent on the level of user engagement [38,55,70,71]. Positive intervention outcomes (eg, improved transition readiness) may in turn incentivize increased user engagement [55], suggesting a positive feedback loop. According to TAM [63], user engagement is influenced by 2 core factors, that is, perceived usefulness and perceived ease of use [72], which may be influenced by intervention content and technological functions [73].

Intervention effectiveness depends heavily on the interaction of the intervention with users and their context [55], yet there is a paucity of contextual insights in the DBCI literature, creating a gap in our understanding of which contextual factors influence the efficacy of intervention mechanisms in T1D and how [74]. According to the HAPA framework [62], behavioral determinants, such as self-efficacy [75], outcome expectancies [66,75], risk perception [65,76], and social support [66,77], impact both outcome and the intervention implementation process itself. Contextual factors, such as the complementary or substitute relationships between KiT and other conventional self-management tools (eg, handwritten methods) [38], may also predict user engagement alongside more traditional variables (ie, participant demographics [55,70]).

Step 2: Testing Program Theory

Participants

Eligible participants will include English- or French-speaking emerging adults living with T1D enrolled in the RCT intervention arm who provided informed consent to be contacted for the embedded process evaluation at the time of enrollment in the RCT. We are targeting a conservative sample size of 25-30 participants for the interviews based on previous realist interviews and CNA studies [38,42,78,79].

To increase the representativeness of the interview sample, we will purposively select participants with desired and undesired proximal outcomes of user engagement. This will be achieved by identifying "high-engagers" and "low- to medium-engagers" according to the intervention usage data at month 3 of the RCT. As there is no standard classification or threshold of DBCI engagement, we have used early KiT intervention usage data to identify a feasible definition of engagement. Considering the data availability, we conservatively define "high-engagers" as those with a 100% response rate to question prompts, with all other participants classified as "low- to medium-engagers." All low- to medium-engagers will be invited for an interview. Should resource constraints not allow us to interview all high engagers, we will purposively sample to balance representation by gender and site of recruitment. The iterative sampling will continue until we reach thematic saturation (ie, no new themes are identified in the multisource data analysis), or all interested participants have been interviewed.

Data Collection

To test the initial program theory developed in step 1, we will perform semistructured realist interviews in a "teacher-learner cycle" [49]. The interviews will start with some general questions about the participants' experiences managing T1D and engaging with KiT [80,81]. Based on their level of engagement and responses, the interviewer will act as a teacher to introduce the candidate CIMO configurations to the participant for their comments. After learning about the CIMO configurations, the participant will then act as teacher to confirm, extend, or refute the hypothesized pathways with their own examples of how they reacted to specific intervention components or features, what they saw as influencing their decision-making, and how this was perceived to affect their outcomes [80,82]. For low- to medium-engagers, the interview topics will focus on CIMO configurations regarding user engagement. For high engagers, the interview topics will focus on CIMO configurations regarding user engagement as well as distal outcomes (ie, transition readiness, self-blood glucose monitoring, and blood glucose). The interview guides (Multimedia Appendix 2) will first be piloted to ensure a comprehensive assessment of all relevant CIMO constructs. Interviews will be conducted by PhD-trained research coordinators with qualitative interview training, previous experience conducting semistructured interviews, and in-depth knowledge of the initial program theory. They will also receive study-specific training from the senior study lead, who is an experienced qualitative researcher. Research coordinators will have no previous relationship with study participants or the T1D community. Interviews will be transcribed verbatim by an independent third party.

Data Analysis

Transcripts will be coded using MAXQDA, a software for interview data analysis, and analyzed using the principles of thematic analysis strategies [82,83]. Data will be deductively coded and mapped to the predefined CIMO constructs to reflect triads (eg, context + intervention outcome, intervention mechanism outcome) and tetrads (context + intervention mechanism outcome) that would confirm, extend, or refute the

XSL•FO
RenderX

current CIMO configurations [84]. Open coding will be applied when themes are identified that do not fit within the definitions of predefined CIMO constructs. The findings will be compared against the hypotheses developed in step 1, with a label of "supported," "refined," or "rejected" given to each hypothesized pathway based on the evidence.

Several strategies will ensure the fidelity and credibility of the interview data, such as using multiple sources of data; creating a chain of evidence that documents all elements of the study database; having both broader research team members and interview participants participate in the triangulation analysis and the return of findings (construct and external validity); examining points of convergence and divergence within and among the data set (internal validity through cross-comparative analyses); and having a stepped analysis process with an initial independent review of the data by 2 reviewers who then meet to reach consensus around the common themes.

Step 3: Consolidating Program Theory

Data Integration and Factor Calibration

We plan to triangulate information from realist interviews, intervention usage data, patient-reported outcomes, and a demographic survey as outlined in Table 2. Patient reported outcome and demographic information will be collected through RCT baseline and follow-up surveys. Intervention usage data will be collected by our third-party collaborator, Memotext, which delivers and manages the RCT intervention. Memotext's system logs all incoming and outgoing messages, and they will be sharing them with the research team periodically.

We will create a data set in which each interview participant is treated as a unique case and each CIMO element is included as a variable (as defined in the initial program theory outlined in Figure 2). Where variables are continuous (eg, self-efficacy, negative emotions, transition readiness, and blood glucose), we will include them directly. Where variables are qualitative (eg, knowledge and skills, outcome expectancies, behavioral cueing), we will convert them to data-driven categorical variables that will be defined by the research team and reported in the final manuscript.

Data Analysis

We will conduct CNA using the R package "cna" to consolidate the initial program theory using a bottom-up, data-driven approach [85]. In order to identify the crucial difference-makers of outcomes from a large number of candidate-influencing factors (ie, context, intervention, and mechanism), we will screen the exogenous factors of each outcome before developing CNA models to demonstrate the causal relationships among them.

To achieve factor reduction, we will begin with exploratory data analysis using a routine that operates within the same regularity framework as CNA. Specifically, we will apply the "minimally sufficient condition" (msc) function in the "cna" package to search across the entire data set (ie, all variables and all cases) at once to identify factors with the strongest connections to target outcomes, following the process outlined in Miech et al [86]. We will perform separate analyses in order to identify the minimally sufficient conditions for the presence of desired outcomes (ie, engagement and transition readiness) and those for the absence of desired outcomes, respectively [52,78,79]. For each outcome condition, we will run the "msc" routine 5 times at consistency thresholds of 0.95, 0.90, 0.85, 0.80, and 0.75, examining all 1-, 2-, and 3-condition configurations that meet consistency requirements; have the highest coverage score for their complexity level; and align with theory, background knowledge, case familiarity, and logic [78,87]. Through this process, we will identify a subset of factors to use in the subsequent modeling phase.

In the modeling phase, we will iteratively develop preliminary and final models based on the following criteria: overall model consistency of 0.80 or greater; overall model coverage of 0.80 or greater; and aligns with theory, experience, background knowledge, and logic. Since CNA analyzes data in a bottom-up manner, such analysis will provide empirical findings that can be used to consolidate the initial program theory.

Ethics Approval

Ethics approval for this study was obtained from the Trillium Health Partners Research Ethics Board (ID: 1086). Ethics for the RCT were obtained from Clinical Trials Ontario through the Hospital for Sick Children Research Ethics Board (Project ID: 3986). The registration number for the larger RCT is NCT05434754.

The participants for this realist evaluation will provide their written informed consent at the time of RCT enrollment. The realist evaluation research team will reach out to consenting RCT participants with a web-based survey link and letter of information with the intention of recruiting and scheduling an interview.

This letter informs participants of their privacy and confidentiality protections, specifically that transcripts will be anonymized and that direct quotes used in reports or publications will not contain any information that could be used to identify them. A deidentified file with the study ID and associated participant information (ie, demographic information, transcript number, intervention usage data, and RCT patient reported outcome data) will be used to organize participant information and will only be accessible by the study coordinator. Only deidentified data will be used for subsequent analyses.

Participants will receive a CAD $25 (US $18.50) electronic gift card for completing the interview.

Results

The KiT RCT commenced in January 2023. As of May 17, 2023, a total of 36 participants had been enrolled in the RCT. Of the 15 participants who have been assigned to the intervention arm, 13 consented to realist evaluation. Participant enrollment for this realist evaluation was anticipated to start in July 2023 and continue until we reach thematic saturation, or all interested participants have been interviewed. The study findings are planned to be disseminated through peer-reviewed publications and conference presentations in 2024.

Discussion

Project Findings and Significance

It is widely agreed that digital health technologies have considerable potential to facilitate diabetes self-management and that user engagement is central to whether or not there is an impact [56]. This study will address several gaps in existing literature, including the identification of which specific features of a digital health intervention facilitate sustained engagement, which threshold level of user engagement leads to desired outcomes, and what individual-level contextual factors facilitate or hinder the implementation process [56,88]. This is a novel application of a realist evaluation to explore nuanced relationships in the context of digital health interventions and T1D health care transitions. It may contribute to knowledge from practical and methodological perspectives, respectively.

While implementation strategies are increasingly informed by implementation science, evidence-based selection of combinations of strategies is often lacking [89]. This realist evaluation is conducted in parallel alongside the RCT implementation, which will enable us to inform real-time refinement of KiT by identifying the features that contribute to desired outcomes and demonstrating the mechanisms of action in real-world settings. Further, this contextualized understanding of whether and how KiT leads to change prioritizes the usefulness of information for decision-making by identifying enablers of and constraints on its delivery across a range of settings [37]. The findings may also shed light on the design, implementation, and evaluation of future digital health interventions that aim to improve transition experiences.

This study will synthesize multiple data sources (ie, qualitative interviews, patient-reported outcomes, and intervention usage data) to enable rich complementary insights [90]. Moreover, this study uses CNA, a novel analytical approach underpinned by Boolean algebra. This approach systematically identifies a "minimal theory," that is, the crucial combinations of factors linked to target outcomes [89]. By incorporating CNA, we will be able to evaluate empirically the theory-driven configurational models and refine the initial program theory as needed.

XSL•FO
RenderX

Limitations

First, we are not able to quantify user's engagement relating to informational content (eg, active days of engagement for a specific module [30]) due to intervention constraints, limiting our ability to understand the value of specific educational elements. Moreover, due to the limited number of interactive SMS text messages, we are not able to measure the change in user engagement frequency using indicators such as the daily SMS text message response rate [91]. As an exploratory mitigation, we will use self-report data gathered by semistructured interviews. We will also use the available intervention usage data to create a composite variable (ie, response rate at 3 months) as a proxy to measure the general level of user engagement. Future studies may benefit from collecting user engagement data at the level of each intervention component and increasing the number of web-based texts to facilitate a more accurate measurement of user engagement. Second, we only consider individual-level contextual factors due to the study objective (ie, identifying target populations for the digital health intervention) and data availability. The omission of setting-level factors (eg, access to health care system, social norms) may limit our ability to comprehensively understand the complex conditions that influence emerging adults' sustained engagement and health care transition experiences and therefore limit the transferability of our findings under some circumstances [55]. Third, data collection and analysis will occur in parallel alongside the RCT implementation in order to inform real-time intervention refinement. However, timing the study ahead of RCT end point outcome analysis will limit our ability to understand the impact on end point trial outcomes [90]. This was a conscious decision, as many RCTs show suboptimal results [71,92,93], suggesting a need to focus on upstream outcomes such as engagement as a first step.

Conclusions

Digital health interventions have emerged as a promising resource to support diabetes self-management capacity among emerging adults living with T1D. However, little is known about what components of these interventions are effective, how they are effective, and for whom they are most effective. Taking KiT as an example, our embedded realist evaluation will address this knowledge gap by using a mixed methods design and focusing on an important but often overlooked upstream outcome—user engagement. Besides informing real-time intervention refinements, the knowledge gained from this study may shed light on the design, implementation, and evaluation of future digital health interventions that aim to improve transition experiences.

Acknowledgments

This study is funded by Canadian Institutes of Health Research. The authors wish to thank Dr Edward J Miech for his professional support on the application of CNA in this study.

Data Availability

The data set of this study will be available from the corresponding author on reasonable request.

Authors' Contributions

LD and RS originated the idea for the project. LD and RW were primary drafters and editors of the manuscript. GR, GLB, A-SB, NE-D, MT, JAC, MG, MN, and RS contributed to manuscript revision. All authors have read and approved the final version of this manuscript.

Conflicts of Interest

RS has received speakers and advisory board fees from Dexcom. A-SB has received speaker fees from Dexcom. A-SB is a Fonds de recherche du Québec en Santé (FRQS) research scholar. MN is supported by an FRQS Senior Salary Award. The other authors declare that they have no competing interests.

Abstract

XSL•FO
RenderX

Background: The COVID-19 pandemic disrupted the delivery of diabetes care and worsened mental health among many patients with type 2 diabetes (T2D). This disruption puts patients with T2D at risk for poor diabetes outcomes, especially those who experience social disadvantage due to socioeconomic class, rurality, or ethnicity. The appropriate use of communication technology could reduce these gaps in diabetes care created by the pandemic and also provide support for psychological distress.

Objective: The purpose of this study is to test the feasibility of an innovative co-designed Technology-Enabled Collaborative Care (TECC) model for diabetes management and mental health support among adults with T2D.

Methods: We will recruit 30 adults with T2D residing in Ontario, Canada, to participate in our sequential explanatory mixed methods study. They will participate in 8 weekly web-based health coaching sessions with a registered nurse, who is a certified diabetes educator, who will be supported by a digital care team (ie, a peer mentor, an addictions specialist, a dietitian, a psychiatrist, and a psychotherapist). Assessments will be completed at baseline, 4 weeks, and 8 weeks, with a 12-week follow-up. Our primary outcome is the feasibility and acceptability of the intervention, as evident by the participant recruitment and retention rates. Key secondary outcomes include assessment completion and delivery of the intervention. Exploratory outcomes consist of changes in mental health, substance use, and physical health behaviors. Stakeholder experience and satisfaction will be explored through a qualitative descriptive study using one-on-one interviews.

Results: This paper describes the protocol of the study. The recruitment commenced in June 2021. This study was registered on October 29, 2020, on ClinicalTrials.gov (Registry ID: NCT04607915). As of June 2022, all participants have been recruited. It is anticipated that data analysis will be complete by the end of 2022, with study findings available by the end of 2023.

Conclusions: The development of an innovative, technology-enabled model will provide necessary support for individuals living with T2D and mental health challenges. This TECC program will determine the feasibility of TECC for patients with T2D and mental health issues.

Trial Registration: ClinicalTrials.gov NCT04607915; https://clinicaltrials.gov/ct2/show/NCT04607915

Introduction

In Canada, type 2 diabetes (T2D) affects more than 1 in 10 adults. It is the single most common cause of adult-onset blindness, amputations, and kidney failure and a risk factor for cardiovascular disease, strokes, cancer, mental health disorders, and poor outcomes for all other chronic conditions [1,2]. In addition to the physical challenges, adults living with T2D are at greater risk for mental health issues than the general population. The prevalence of clinically depressive symptoms among people with diabetes is about 30%, which is 2-fold greater than that among individuals without T2D [3]. As such, a comprehensive approach to diabetes management would provide services for both physical and mental health concerns in a personalized and accessible manner [4-7].

Additionally, the negative impacts of COVID-19 on mental health and well-being among adults living with T2D are a growing concern, as this population is at greater risk for diabetes-related distress and depression [8,9]. COVID-19 has accelerated the emergence of web-based care in primary and specialist care in Canada and has resulted in the virtualization of diabetes care and support (physical and mental health) [10,11]. The rapid virtualization of diabetes care has highlighted disparities in the availability and application of digital technologies at the patient and provider level, such as having necessary resources (eg, devices, data sharing, and internet availability) and implementing telehealth effectively [12,13]. The net result is an inconsistent taxonomy and understanding of what constitutes web-based diabetes care and how to provide patient-centered care.

Currently, there is inconsistent or limited access to interprofessional diabetes education, care, and follow-up, and comorbidities such as depression, hypertension, and smoking cessation are often neglected [5,8,14-17]. Few studies have examined a web-based collaborative care model, and none, to our knowledge, have examined web-based care models addressing both mental health symptoms and physical health and diabetes management [18-22]. Overall, these programs consist of technology-mediated communications between patients and various health provider teams. However, not all interventions included a care manager or comprehensive health support (ie, psychosocial, substance use, mental and physical health, and contact with primary care or community providers). Given the greater risk that individuals with T2D will develop physical challenges and mental health issues, it is essential to build on these technological innovations and expand them to provide more comprehensive and collaborative care.

Our innovative solution will leverage a novel approach to web-based care, the Technology-Enabled Collaborative Care (TECC) model [23]. This program will provide a comprehensive approach, including a registered nurse who is a certified diabetes educator (CDE), who will support the management of individuals with T2D and mental health symptoms alongside a multidisciplinary health care team to offer health coaching for behavior change and to provide peer support. The intervention will also support people with their mental health symptoms

XSL•FO
RenderX

(anxiety or depression) that may arise as a result of their diabetes diagnosis, treatment (eg, safe and effective insulin dosing schedules), or worry about access to care during the COVID-19 pandemic through one-on-one health coaching. The goal of this study is to examine the feasibility and acceptability of the TECC model designed to support patients with T2D (or the "TECC-D program") and mental health concerns during the COVID-19 pandemic.

Methods

The research team used the expertise of the investigative team, the CDE, research coordinators, and patient partners to co-design the format of the research study. Guiding principles include the use of existing and available technology for patients, providers, and health systems; structured and measurement-based care; collaboration across institutions and settings; integration of physical and mental health expertise; and client-centered care.

Study Design and Workflow

This is an 8-week feasibility study. Thirty participants who meet the eligibility criteria will participate in the TECC-D program.

Study Setting

Overview

This study is conducted on the internet, using readily available technologies, including REDCap (Research Electronic Data Capture; Vanderbilt University) [24] and Cisco Webex (or "Webex"). REDCap is a secure data-capturing application used to create and manage web-based surveys. Webex, a secure videoconferencing service, is used to communicate directly with participants and to support communication within the study team and the virtual care team (VCT). Participants are also given the option of using a telephone. Email is used to send participants appointment reminders and educational materials. Participants are not required to attend in-person visits, and the existing relationships with their health care providers remain unaffected. Participants are in the study for 8 weeks and followed up at 12 weeks. Participants are not reimbursed for taking part in the study.

Co-design With Providers

The provider-facing side of REDCap is co-designed by our CDE and principal investigators, who specialize in the clinical treatment of individuals with T2D, mental health conditions, or addiction issues. Such co-design efforts include creating a secure documenting section for post–health coaching session calls and a summary page of participant assessment data.

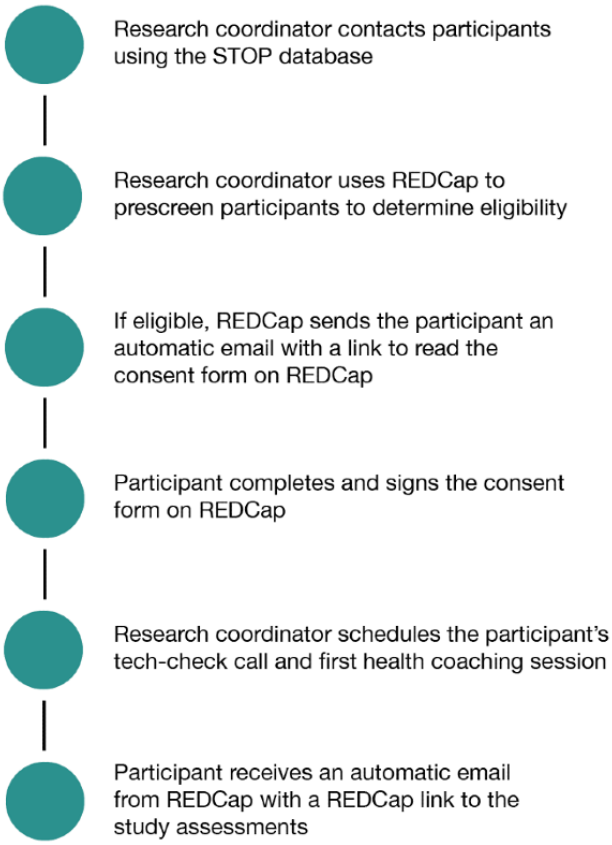
Co-design With Patient Partners

Three patient partners, who are individuals diagnosed with T2D, are involved in the research and VCT aspects of the study. On the research end, the patient partners will review research ethics board submissions, study-specific processes, phone scripts with participants, study assessment types, REDCap presentations of study assessments, and manuscript writing. Specific to the VCT, the patient partners will engage in weekly VCT rounds to discuss participant cases and provide feedback from a patient-partner perspective.

Inclusion and Exclusion Criteria

To enhance generalizability, we use minimum exclusionary criteria. Inclusion criteria were as follows: (1) being an Ontario resident; (2) being 18 years or older; (3) having a clinical diagnosis of T2D for at least 1 year; (4) having access to diabetes education or management in the past; (5) having access to the telephone or internet through computer or mobile; (6) self-reporting experiencing some distress related to COVID-19; (7) being able to provide informed consent; and (8) being able to understand, write, and read English. Exclusion criteria included participants who are pregnant or planning to get pregnant during the course of the study (ie, in the following 12 weeks). Of note, lack of access to digital communication technology is not an exclusion criterion.

Sample Size



This is a single-group feasibility study that aims to gather preliminary data on retention, baseline means, and variances, and examine the degree of and variability in change over time. To meet these goals, we have set the sample size at 30. Given the expected diversity of clinical presentations, patient behaviors, and comorbid mental health conditions, we believe that a moderate number of patients are necessary to allow common challenges in implementation to be identified. This sample size will also enable reasonably good characterizations of variable distributions (eg, for a variable with a mean of 50 and an SD of 10, a 95% CI for n=30 would be 46.3 to 53.7) with descriptive statistics.

Recruitment, Consent, and Enrollment

Individuals will be primarily recruited by a research coordinator via the STOP (Smoking Treatment for Ontario Patients) Program database at the Centre for Addiction and Mental Health (CAMH) in Toronto, Ontario, Canada. The STOP program delivers smoking cessation treatment to people across Ontario through various sectors, including family health teams, community health agencies, aboriginal health access centers, and addiction or mental health agencies. We will contact participants, via e-mail or telephone, who have agreed to be contacted for future research studies and who have a self-reported diagnosis of diabetes, to explore their interest in participating in this study. As most participants will likely come from the STOP Program database, our study population will include individuals who were or are daily smokers. Eligible participants will receive an automatic email to read and complete the electronic consent form via REDCap. An informational video that summarizes the consent form is provided alongside the document. Participants receive a second automatic e-mail with a link to their study assessments and 2 online follow-up appointments: (1) a technology check with a research coordinator to ensure that they are able to access REDCap and download the Webex program and (2) their first session with the CDE. Please see Figure 1 for details.

XSL•FO
RenderX

Figure 1. Recruitment, enrollment, and consent process via REDCap. REDCap: Research Electronic Data Capture; STOP: Smoking Treatment for Ontario Patients.

For participants who do not have access to the internet, the research team will use a verbal consent process, following the organization's research ethics guidelines. First, the study team will send the prospective participant a hard copy of the consent form via mail. Once received, 2 research coordinators will be present during the phone call, where verbal consent will be obtained from the participant. Second, the research coordinators will complete the consent form documentation after obtaining consent and provide a hard copy to the newly enrolled participant via mail. For participants who do not have access to the internet, the study's research coordinator will assist the participants in completing the survey and other study-related steps via telephone.

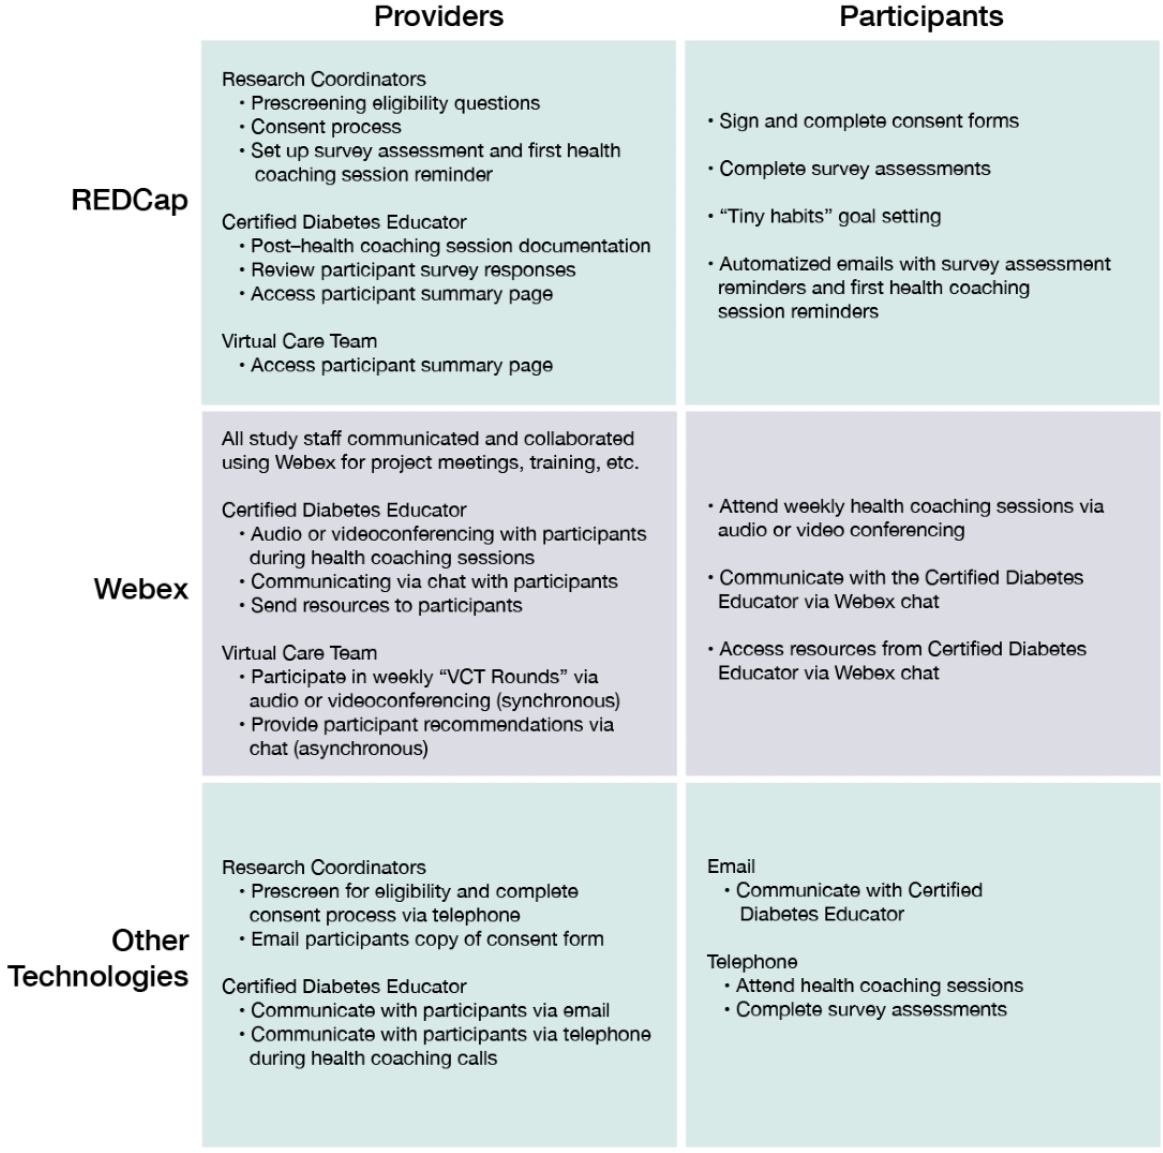
Intervention—TECC-D Program

After providing consent, all participants will participate in the TECC-D program during their participation in the study. In this 8-week web-based collaborative care model, participants are paired with a CDE with expertise in health coaching, cognitive behavioral therapy, and motivational interviewing. Participants are asked to complete their first set of assessments before their first session. The first session (week 1) is approximately 45-60 minutes, and subsequent sessions (weeks 2-8) are 15-20 minutes. Additional 2 weeks are provided (ie, weeks 9 and 10) as an opportunity to make up for missed earlier appointments (ie, weeks 1-8). In each session, the CDE may address diabetes self-management, mental health concerns, or broader health behaviors (including diet, physical activity, smoking, alcohol use, sleep, and stress) using a client-centered approach. The role of the CDE in the participants' care includes weekly web-based check-ins, weekly VCT rounds for individual case reviews, developing individual treatment plans, communicating with the participants' care team (only if consent is received and as needed), and providing community resources. The CDE will help participants create goals, provide educational materials, and explore other health areas. Additionally, the CDE helps facilitate collaborative communication with the participants' existing primary care team and may refer participants to other specialized health services. All sessions are offered via Webex or telephone.

On a weekly basis (or as needed), the CDE connects with the VCT via Webex to review the participants' concerns and goals. The team will comprise a psychiatrist, a psychotherapist, an addictions specialist, a dietitian, and a patient partner. Other specialists (eg, an endocrinologist) will be included as needed. To facilitate asynchronous communication, the CDE uses Webex's chat feature to send the VCT members a REDCap link to the participants' profile and treatment summary. Here, the VCT can provide recommendations in the participants' treatment plan synchronously during a VCT meeting or asynchronously by securely providing their recommendations in the Webex chat. Afterward, the CDE discusses the recommendations from the VCT with the participants to determine how best to implement these recommendations into their treatment plan. Participants are encouraged to communicate these recommendations to their local care providers. The intervention is articulated in Multimedia Appendix 1 [23,25,26], using the Template for Intervention Description and Replication checklist [25].

XSL•FO
RenderX

For participants who do not have access to a computer or smart device (smartphone or tablet), the research team will contact them over the telephone (landline or cell phone). As such, appointments with the CDE will be held via telephone, and if they do not have an email address, then reminder phone calls can be scheduled between the research team and the participant if needed. Any study-related material (consent forms and education materials) is sent via mail using the organization's research ethics guidelines. For participants who have limited knowledge of technological and smart device use, the research team will provide technical support (eg, downloading applications, accessing appointments, and study documents) whenever needed.



Institutional Collaboration

This study includes institutional collaboration between Principal Investigators and research team members from McMaster University and the CAMH, an academic specialty hospital affiliated with the University of Toronto. Essential considerations required for this study, given the institutional collaboration, include the secure transfer of data and information, privacy matters, data and study material access, abiding by the best practices and guidelines from both institutions (eg, research ethics), and finances for study-related costs.

Program Architecture

With the use of REDCap and Webex, the study team is able to build a technology-based collaborative care program to enhance the experience for both participants and the study team. In summary, Figure 2 presents the use of both programs at the participant and provider levels.

Figure 2. Program architecture using REDCap, Webex, and other technologies among providers and participants. REDCap: Research Electronic Data Capture; VCT: virtual care team.

XSL•FO
RenderX

Ethics Approval

Our research is conducted in compliance with the Declaration of Helsinki [27]. This trial was approved by the CAMH in Toronto on January 18, 2021 (REB: 104-2020).

Safety Assessment

Any adverse events will be reported and documented throughout the study period. Research staff are trained to assess for suicide risk and provide crisis interventions to participants who become distressed or endanger themselves or others. To mitigate risk, regular clinical supervision by a registered psychotherapist and a medical doctor and regular meetings with the VCT will be provided in addition to the existing care provided by the participant. Lastly, to monitor the participants' mood, they will complete a depression scale [28] at several points throughout the study, which assesses low mood and suicidality.

Primary Outcomes

As this is a feasibility study, we used a convenience sampling approach to assess the primary outcomes of feasibility (ie, if our intervention can be used successfully in our setting) and acceptability (ie, if our treatment is satisfactory) [29-31]. These include assessing participant recruitment (the recruitment rate [60%] is the number of participants enrolled in the study divided by the total number of eligible participants) and retention rates (the number of participants that completed the program). Key secondary outcomes include the number of participants enrolled, the number of sessions attended, and assessment completion [30-32]. Additionally, this includes how many participants chose to fill out stage 2 ("optional") surveys, to further inform co-design with our participants for future studies. Lastly, the delivery of the intervention will be assessed, including the planned intervention sessions, the duration that the CDE was in each session, the mode of interaction (ie, whether the participant completed their visits via telephone, web-conferencing, or a combination of both), and strategies used by the CDE during health coaching sessions (eg, frequencies and examples of strategies and recommendations posed during visits), using a reporting template used in previous coaching trials [33,34].

Exploratory Outcomes

The exploratory outcomes include clinical health outcomes related to T2D, mental health, substance use, and general health measures using valid and reliable self-reported tools. Please see Multimedia Appendix 1 for details on the rationale, procedures, and methods relating to measuring health outcomes.

Stakeholder Experience and Satisfaction

Stakeholders, including study participants and CDE and VCT members, will have the opportunity to share their experience and satisfaction through interviews in a qualitative descriptive study. Participants will participate after the intervention, following study completion. Brief interviews will be completed one-on-one over the phone or using web conferencing technology. Each interview will be audio recorded, transcribed verbatim, and analyzed using thematic analysis. Research study members, including members of the VCT, will participate when the study is completed.

Data Analysis

In the quantitative analysis, descriptive statistics will characterize the study sample and describe the study assessment data. This will include means, medians, ranges, and distribution.

In the qualitative analysis, a qualitative descriptive design will be used. This includes a close, comprehensive summary of experience and satisfaction using the language of the participants. All interview data will be recorded and transcribed, with close coding used to identify themes through inductive thematic analysis. One study team member will lead the analysis using Atlas.ti (version 22), with other team members contributing to organization and interpretation of identified themes.

Following the analysis of the quantitative and qualitative data, where appropriate, a mixed methods joint display will be created. This joint display will integrate the quantitative and qualitative data and help to explain the study findings more fully.

Assessments

All participants are encouraged to complete the mandatory baseline study survey (stage 1); they have the option to complete an optional set of measures to provide more details about their health (Stage 2). This technique was used to reduce the burden of the survey on participants, as suggested by our patient partners. The first subset of assessments (stage 1) includes demographic and physical health (eg, weight and height, medications, COVID-19–related stress) questionnaires. The Diabetes Self-Management Questionnaire [35] assesses diabetes self-care activities associated with glycemic control. The Diabetes Distress Scale captures 4 critical dimensions of distress: emotional burden, regimen distress, interpersonal distress, and physician-related distress among patients with diabetes [36]. Quality of life is measured using the EuroQol-5 Dimension [37]. Tobacco use is measured using the History of Smoking Index [38]. Psychological and behavioral problems will be measured using the Global Appraisal of Individual Needs Short Screener [39].

The second subset of assessments (Stage 2) includes a visual analog scale (available in Multimedia Appendix 2) to assess the self-perceived benefit and the readiness ruler to assess the motivation and confidence of changing physical activity, nutrition, smoking, alcohol, stress, sleep, and other self-reported behaviors. Alcohol use is measured with the Alcohol Use Disorders Identification Test [40]. The Mediterranean Diet Adherence Screener is used to measure adherence to the Mediterranean diet [41]. Physical activity is measured with the International Physical Activity Questionnaire—Short Form. The Brief Pain Inventory measures pain symptoms [42]. Mental health symptoms will be measured using the Generalized Anxiety Disorder scale for anxiety symptoms [43], the Patient Health Questionnaire for depressive symptoms [28], and the Perceived Stress Scale for stress symptoms [44]. Assessment scales and tools used in this study are consistent with those employed in a previous iteration of the TECC model and supported by the study team.

XSL•FO
RenderX

Results

At the time of submission, recruitment for this feasibility study is complete, and the remaining study participants are finishing the intervention. Data analysis is projected to commence in the fall of 2022, with the results of this study anticipated to be published by September 2023.

Discussion

This is the first study to include a TECC program for adults with T2D (ie, the TECC-D program), including the aforementioned features, where access to digital technology by the patient is not an exclusion criterion.

The primary aim of the study is feasibility and acceptability. All participants receive the TECC-D intervention, which includes weekly health coaching calls with a CDE and personalized recommendations from a VCT. The researchers anticipate that the main finding of the study will be the feasibility of technological and collaborative health program providing diabetes- and mental health–related services to adults with T2D.

As previous studies on technology-based interventions for adults with T2D generally focused on symptom improvement and medication adherence, the goal of this study was to address other characteristics of behavioral change, including physical activity, diet, and smoking.

Additionally, previous studies have seldom engaged the individuals' existing primary and community care teams in their collaborative care treatment.

As such, our TECC-D program puts forward a novel approach to address gaps in both research and health care among individuals with T2D. By using the existing technology in the health care system, implementing co-design of study features with practitioners and patients, and engaging patient partners with T2D, the TECC-D program illustrates a more integrated approach to collaborative care. This program aims to reduce access-related barriers to care to ensure that adults with T2D can receive the personalized, holistic care and the psychoeducation that they require.

Acknowledgments

This work was supported by funding from the Medical Psychiatry Alliance, the Nicotine Dependence Service, the CAMH, and the Inter-Professional Health Research Program at Hamilton Health Sciences. The authors thank Johnathon Tunstead, Gulraiz Khalid, and Elise Tanzini for their contributions and support during the development and implementation processes.

Data Availability

This article reports the protocol of our study. No data are currently available.

Authors' Contributions

This study was conceptualized and designed by DS, RD, FN, SMA, OCM, AC, PG, MH, SK, BM, ES, FT, SR, GL, SS, and PS with study funding acquired by DS, MH, SK, BM, and PS. LV, DS, RD, IA, CW, JM, and PS contributed to project administration with data curated by LV, IA, and LTG, and study resources and software maintained by LV, IA, OCM, and CW. All authors contributed to the writing, review, and editing of this manuscript. CW, LTG, and JM will lead the formal analysis of data supervised by DS, RD, SV, SH, and PS.

Conflicts of Interest

LV, DS, RD, IA, SV, FN, SMA, AC, SH, SK, ES, LT-G, CW, JM, FT, SR, SS, and GL have none declared. OCM reports receiving grant and salary support from the CAMH and AMS Healthcare. PG reports receiving research support from the Canadian Institute of Health Research (CIHR), the Ontario Ministry of Health and Long-Term Care, the Ontario Mental Health Foundation (OMHF), the CAMH, the CAMH Foundation, and an Academic Scholars Award from the Department of Psychiatry, University of Toronto. MH reports receiving consulting fees from Alkermes. BM reports receiving support from the Labatt Family Chair in the Biology of Depression in Late-Life Adults at the University of Toronto. BM currently receives or has received over the past 3 years research support from Brain Canada, the Canadian Institutes of Health Research, the CAMH Foundation, the Patient-Centered Outcomes Research Institute (PCORI), the US National Institute of Health (NIH), Capital Solution Design LLC (software used in a study founded by the CAMH Foundation), and HAPPYneuron (software used in a study founded by Brain Canada). Within the past 3 years, BM has also been an unpaid consultant to Myriad Neuroscience. PS reports receiving grants, salary, and research support from the CAMH, Health Canada, the Ontario Ministry of Health, the Canadian Institutes of Health Research (CIHR), the Canadian Centre on Substance Use and Addiction, the Public Health Agency of Canada (PHAC), the Medical Psychiatry Alliance, the Canadian Cancer Society Research Institute (CCSRI), Cancer Care Ontario, and the National Institutes of Health (NIH). PS also reports receiving funding and honoraria from the following commercial organizations: Pfizer Canada Inc. and Patient-Centered Outcomes Research Institute. Through an open tender process, Johnson & Johnson, Novartis, and Pfizer Inc. are the vendors of record for providing smoking cessation pharmacotherapy, free or discounted, for research studies in which PS is the principal investigator or co-investigator.

Abstract

Background: Studies conducted in the United States such as the National Survey of Family Growth (NSFG) and the Pregnancy Risk Assessment Monitoring System (PRAMS) collect data on pregnancy intentions to aid in improving health education, services, and programs. PRAMS collects data from specific sites, and NSFG is a national household-based survey. Like NSFG, the Surveys of Women was designed to survey participants residing in households using an address-based sample and a multimode data collection approach. The Surveys of Women collects data from eligible participants in 9 states within the United States on contraception use, reproductive health, and pregnancy intentions. In this paper, we focus on the baseline data collection protocol, including sample design, data collection procedures, and data processing. We also include a brief discussion on the follow-up and endline survey methodologies. Our goal is to inform other researchers on methods to consider when fielding a household-level reproductive health survey.

Objective: The Surveys of Women was developed to support state-specific research and evaluation projects, with an overall goal of understanding contraceptive health practices among women aged 18-44 years. The project collects data from respondents in 9 different states (Arizona, Alabama, Delaware, Iowa, Maryland, New Jersey, Ohio, South Carolina, and Wisconsin) over multiple rounds.

Methods: Households were selected at random using address-based sampling methods. This project includes a cross-sectional baseline survey, 2 or 3 follow-up surveys with an opt-in panel of respondents, and a cross-sectional endline survey. Each round of data collection uses a multimode design through the use of a programmed web survey and a formatted hard copy questionnaire. Participants from the randomly selected households access their personalized surveys through a web survey or mail in a hard copy questionnaire. To maximize responses, these surveys follow a rigorous schedule of various prompts bolstering the survey implementation design, and the participants received a modest monetary incentive.

Results: This is an ongoing project with results published separately by the evaluation teams involved with data analysis.

Conclusions: The methods used in the first baseline survey informed modifications to the methods used in subsequent statewide surveys. Data collected from this project will provide insight into women's reproductive health, contraceptive use, and abortion attitudes in the 9 selected states. The long-term goal of the project is to use a data collection methodology that collects data from a representative sample of participants to assess changes in reproductive health behaviors over time.

Introduction

National studies, such as the National Survey of Family Growth (NSFG) and the Pregnancy Risk Assessment Monitoring System (PRAMS), collect data on pregnancy intentions among women of childbearing age to aid in improving health education, services, and programs. Unintended pregnancies, in particular, can have negative health, economic, and psychological impacts on individuals and families. While the rates of unintended pregnancy have declined nationally in the United States since 2008, data indicate that 45% of pregnancies in 2011 were unintended [1,2]. At the state level, the rates of unintended pregnancy among women aged 15-44 years vary from 32 per 1000 women to 62 per 1000 women, with Delaware reporting the highest rate [3].

To support state-specific research and evaluation projects, the Surveys of Women was developed to assess changes in pregnancy intentions and attitudes toward contraception. Initially conceptualized as 2 cross-sectional surveys (a baseline survey followed by an endline survey approximately 5 years later), the project evolved to include follow-up surveys with an opt-in panel to meet the needs of the evaluation team. The Surveys of Women was first launched in the states of Delaware and Maryland with the administration of the baseline survey in 2016.

Data collection for this study used an address-based sampling (ABS) multimode approach. ABS methodological approaches have become the preferred method for respondent selection, compared with random digit dialing designs that rely on telephone interviews. Randomly selecting addresses from a list of known households in an area allows researchers to maximize coverage and improve response rates [4]. Further, the data collection methodology used a series of mailings and nonresponse follow-up activities as recommended by Dillman et al [5,6]. The Dillman method is a well-established method that recommends using distinct contacting strategies to encourage response.

The project increased in scope to support additional research, which included the incorporation of additional evaluation teams as the project expanded into new states and the addition of a follow-up component between the baseline and endline surveys. In addition to Delaware and Maryland, the project has conducted surveys in Arizona, Alabama, Iowa, New Jersey, Ohio, South Carolina, and Wisconsin.

The following report summarizes the study methodology used for the baseline surveys in each state, with a section on the planned differences for the follow-up survey administration.

Methods

Study Overview

The Surveys of Women are multimode, multistate studies with the overarching aim of measuring contraceptive use and understanding reproductive health practices among women aged 18-44 years in 9 states. Data are collected over multiple rounds—a baseline cross-sectional survey, 2 to 3 follow-up surveys, and an endline cross-sectional survey. During the baseline survey, households were selected at random using ABS methods, with any 18- to 44-year-old woman in the household eligible to participate. Women from the baseline could opt-in to participate in additional follow-up surveys. The final stage is a second cross-sectional endline survey. For the purpose of this paper, we will address the methodology for the baseline surveys followed by a brief discussion of the follow-up survey methodology. We also briefly discuss the endline survey, which will follow the same methodology as the baseline administration.

Ethical Considerations

All questionnaires and data collection methods were reviewed and approved by the NORC (National Opinion Research Center at the University of Chicago) institutional review board (IRB). NORC's IRB has obtained a Federal Wide Assurance and is registered with the US Federal Office for Human Research Protections (FWA #00000142). The IRB protocol submitted included sufficient detail on the methodology to ensure that subjects' privacy is protected, and data confidentiality is maintained. Materials reviewed for the Surveys of Women included a description of the study's sample, the methodology used including recruitment methods and incentives, the informed consent language, and the survey questionnaire. All survey administrations (baseline, follow-ups, and endline) included informed consent information for participants on the login page for the web survey and the first page of the formatted hard copy. The consent information included standard provisions related to the voluntary nature of the survey, the right to refuse to answer any question, the confidential nature of responses, the incentives provided, and the contact number for the IRB representative in the event of questions about their rights as a study participant. A specific project toll-free number and email address were provided to respondents as well as for questions and concerns.

Sample Design

Overview

The target number of completed surveys for each baseline was 2000 per state; therefore, the sampling plan for each baseline survey was designed to meet these targets. The sample frame for the cross-sectional baseline surveys was the United States Postal Service computerized delivery sequence (CDS) file enhanced with age-targeted lists [7,8]. The CDS was licensed from an independent vendor and is also referred to as the DSF (delivery sequence file). We geocoded the CDS and, using the geocodes, appended the file with area-level demographic information from the American Community Survey for purposes of stratification. To maintain the coverage of the CDS and allow for oversampling of women with a particular characteristic, the updated CDS frame was deduplicated against a list procured from a vendor—a sample of addresses likely to contain a woman in the target age range of 18-44 years.

Stratification

In all states, the sample was stratified into "high" and "low" density areas for specified variables of interest, such as minority status, rurality, or poverty level. The variables of interest and geographic unit varied depending on the state as shown in Table 1. We adjusted the degree of stratification between the baseline in the original sites (Delaware, Maryland, South Carolina, and

XSL•FO
RenderX

Alabama) and subsequent sites that targeted minorities in order to increase the share of non-White, non-Hispanic respondents. This approach resulted in 4 strata per state: CDS-only low density, CDS-only high density, list low density, and list high density, where list refers to those likely to contain women in the target age range. The CDS-only high-density and list high-density strata were oversampled relative to the respective low strata in each baseline data collection.

Table 1. Baseline sample size and variables of interest.

State	Variables of interest	Unit of stratification	Overall addresses released, n	CDS[a]-only low density, n	CDS-only high density, n	List low density, n	List high density, n
Delaware	Non-White, non-Hispanic population; poverty status	Census tract	14,375	3229	5417	1875	3854
Maryland	Non-White, non-Hispanic population; poverty status	Census tract	13,875	2817	5425	1982	3651
South Carolina	Rural populations (in low-density counties)	County	18,400	6600	4000	4900	2900
Alabama	Rural populations (in low-density counties)	County	18,400	5200	4800	4200	4200
Iowa	Non-White, non-Hispanic population; poverty status	Census tract	14,700	5400	3200	4300	1800
Ohio	Rural Appalachia	County	20,100	9300	2700	6400	1700
Arizona	Non-White, non-Hispanic population; poverty status	Census tract	18,138	7885	1559	6505	2189
New Jersey	Non-White, non-Hispanic population; poverty status	Census tract	24,499	9531	3767	8518	2683
Wisconsin	Non-White, non-Hispanic population; poverty status	Census tract	12,481	4886	1679	4264	1652

[a]CDS: computerized delivery sequence.

Questionnaire

Overview

The goal of each questionnaire was to capture data on respondents' contraceptive use, pregnancy history, health status, and opinions on abortion. Variations among individual state questionnaires existed, including items tailored to their respective state, such as insurance plans or state-specific clinics. All questionnaires were offered in English and Spanish languages.

Questionnaire Development

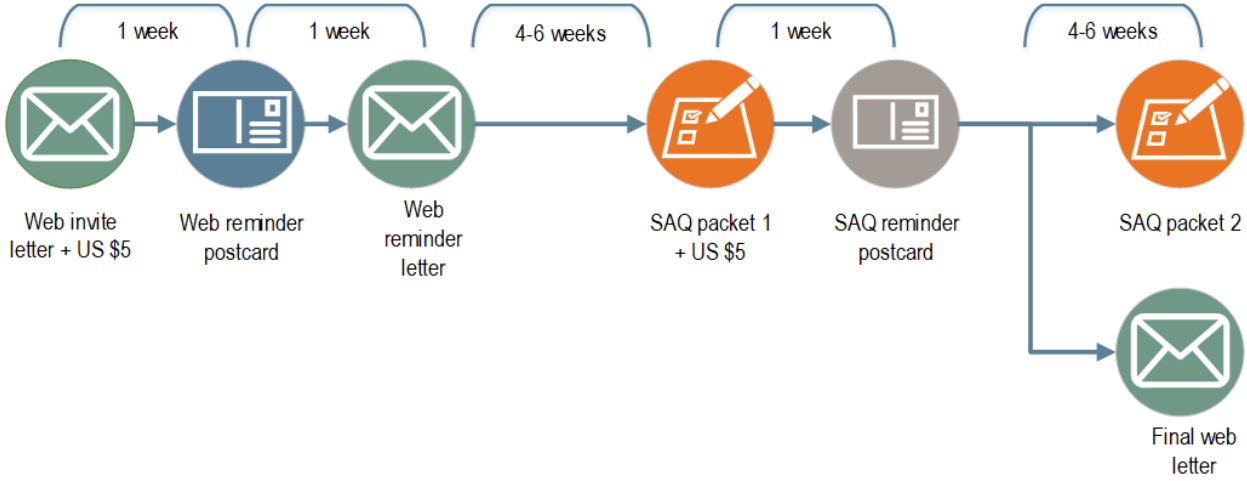
The initial questionnaire (developed for the Delaware and Maryland baseline survey) consisted of items drawn from existing sources, such as the American Community Survey, the Behavioral Risk Factor Surveillance System, the NSFG, the PRAMS, and the Delaware Household Survey. A copy of the questionnaire can be found in Multimedia Appendix 1.

Subsequent baseline state questionnaires were created using the original questionnaire developed for Delaware and Maryland. Prior to the start of each baseline survey, the respective evaluation teams had the option to propose new questions relevant to their goals or propose modifications to existing items.

All questionnaire items were formatted to be self-administered and were formatted with the goal of visual consistency and presentation among self-administered modes (ie, web and paper self-administered questionnaire [SAQ]). For example, questions that were programmed as grids on the web were formatted as such on the paper version. Similarly, items where a follow-up question was embedded into the stem question were indented with arrows directing the respondent to the correct follow-up item on the paper version. A computer-assisted telephone interview (CATI) was programmed and administered during the Delaware, Maryland, South Carolina, and Alabama baseline surveys. Due to low productivity rates with the CATI survey (ie, only 9 completed CATI interviews), the telephone survey was abandoned after the South Carolina and Alabama baseline surveys.

Cognitive Interviews

A total of 11 cognitive interviews (8 with English speakers and 3 with Spanish speakers) were conducted prior to the start of data collection in Delaware and Maryland. Cognitive interviews allow researchers to identify any potential issues within the questionnaire, such as question comprehension, illogical flow, and appropriateness of response options. As a result of cognitive interviews, duplicative questions were identified and removed, double-barreled questions were corrected, response options were modified, and images for birth control methods (eg, intrauterine device, implant, and birth control pills) were added to clarify for respondents what each type of birth control was.



In addition, cognitive interviews were conducted with 10 South Carolina residents and 10 Alabama residents prior to the data collection launch. Cognitive interviews were not conducted prior to the launch of data collection in Iowa, Ohio, Arizona, New Jersey, or Wisconsin as these surveys used established items that did not require additional review.

XSL•FO
RenderX

Survey Design

All Surveys of Women data collections follow a similar methodology, with a series of prompts to encourage response as shown in Figure 1. Respondents were offered the option to complete the web survey first; those who do not complete via the web survey were sent a paper SAQ. A vendor-supplied flag appended to the sample file indicated which addresses may have a Spanish speaker and would benefit from bilingual materials.

Figure 1. Baseline survey case flow. SAQ: self-administered questionnaire.

Data Collection Methods

Respondent Mailings or Prompts

A Surveys of Women study logo was developed and displayed on all printed materials and within the header of the web survey. Four images that represented each state were selected and displayed as an image carousel on the state's web survey login page as well as static images on the front cover of the state's paper questionnaire. All respondent materials contained a project-specific email address and toll-free telephone number should respondents have a question about the study or their participation.

The baseline surveys in each state followed a similar protocol when mailing printed copies of materials. The baseline surveys for Delaware, Maryland, South Carolina, and Alabama offered CATI as a third mode of data collection. A subset of nonrespondents whose addresses could be matched to a telephone number were contacted by trained telephone interviewers to complete the survey over the telephone. Due to low overall response in these 4 states, it was deemed that CATI was not a viable option for attaining completion for this population and was dropped from subsequent survey administrations.

Each mailing was sent to the sampled address and addressed to "[STATE] Resident." The types of respondent contacts are described below.

Web Mailings

First Web Invitation Letter

The first point of contact was an invitation letter, which described the purpose of the study and provided the survey link and the respondents' unique personal identification number. Included with the letter were a noncontingent cash incentive (a US $2 bill for Delaware and Maryland residents and a US $5 bill for all other survey administrations) and a web instructional insert, which showed how to access the survey.

Web Reminder Postcard

Approximately 1 week after the web invitation letter, a reminder postcard was sent to all sampled households reminding them to participate.

Second Web Letter

Sampled addresses that had not responded to the first 2 mailings were sent a second letter requesting participation via the web survey instrument.

Last Chance Letter

A final letter was sent to those who had not yet responded during the final weeks of data collection. The purpose of the letter was to encourage participation before data collection closed.

SAQ Mailings

SAQ Packet 1

Paper questionnaires were sent to sampled addresses who had not responded to the web survey invitation. The packets contained a cover letter, a copy of the questionnaire, an additional noncontingent cash incentive (a US $1 bill for Delaware and Maryland and a US $5 bill for other states), and a postage-paid envelope to return the completed questionnaire.

SAQ Reminder Postcard

Approximately 1 week after sending the initial paper questionnaire packet, a reminder postcard was sent to sampled addresses to remind them to complete and return their paper questionnaire.

SAQ Packet 2

A second and final paper questionnaire was sent to sampled addresses who had not completed the web survey or returned a paper version of the questionnaire. The second packet contained

XSL•FO
RenderX

a cover letter, paper questionnaire, and postage-paid return envelope.

Household Rostering

With almost 10% of households estimated to contain more than 1 eligible respondent, it was important to collect data from additional eligible women in the household, particularly as their reproductive health choices may be different. Therefore, during the baseline surveys, respondents had the option to provide the name and email address of up to 2 additional women, aged 18-44 years, who were living in the household. If additional women were rostered through the web survey, we automatically sent them an invitation letter and unique personal identification number at the email address specified. Women who were rostered via the paper questionnaire were sent an email invitation once the data from the questionnaire had been entered, and the name and email address were made available to project staff.

Incentives

Noncontingent Cash Incentives

All web invitation letters and initial paper questionnaire packets included a noncontingent cash incentive. In the Delaware and Maryland baseline survey, the noncontingent cash incentive was a US $2 bill for the web letter and a US $1 bill for the first paper questionnaire mailing. Due to a lower-than-anticipated response for that baseline study, all future baseline studies increased the preincentive amount to US $5 for both the web invitation letter and the initial paper questionnaire packet mailing.

Postsurvey Completion Incentives

Respondents who completed the baseline survey received a US $10 postincentive in the form of an electronic gift code. Initially, the postincentive offered was in the form of an Amazon gift code. Participants in Arizona, New Jersey, and Wisconsin baseline surveys were offered their choice of an Amazon, Target, or Walmart electronic gift code at the completion of the baseline survey.

Data Processing

Eligibility

At the start of the baseline surveys, two screening questions were asked of household members: (1) “What year were you born?” and (2) “What is your gender?” For those who refused to provide their year of birth, a follow-up question was asked with a list of age categories from which the respondent could select the appropriate age range. To note, Delaware and Maryland used a variation of the age screener item at baseline, originally asking “What is your age (in years)?” These screening questions served to confirm eligibility—a woman aged 18-44 years at the sampled address. Those individuals who did not meet the screening criteria were screened out of the survey, and no further data were collected. Those who were eligible continued into the main questionnaire.

Throughout data collection, cases were reviewed for eligibility. The web was programmed with automated screen-out language, and the paper questionnaire was printed with instructions for the respondent to stop responding and return the questionnaire if either screening question made them ineligible. During postprocessing, ineligible respondents who disregarded these instructions and completed the questionnaire were identified. The main questionnaire data for these respondents were not included in the final data set, and the overall case status was changed to an ineligibility status.

Weighting

Overview

Weights were applied to all data sets and underwent the same set of steps: (1) base sampling weight (W_1); (2) adjustment for unknown eligibility (W_2); (3) adjustment for nonresponse to the questionnaire (W_3); (4) adjustment for household size (W_{4a}); and (5) poststratification (W_4).

Step 1: Base Sampling Weight

All sample lines received a base weight, which reflects the probability of a household being selected and is equal to the inverse of the probability of selection. Each stratum had a different base weight, with the base weight for the list sample being equal to the inverse of the sum of the list probability and the DSF probability.

Examples of the list strata versus DSF strata base weight calculations are:

Stratum 1 (Delaware low-density DSF)

Stratum 2 (Delaware low-density list)

Step 2: Adjustment for Unknown Eligibility

This adjustment to the weights accounted for those who were unable to be contacted and whose eligibility status was unknown. This adjustment used the Census’ Public Use Microdata Sample (PUMS) data to estimate household eligibility for each stratum within a state. Completed cases had no adjustment, while incomplete cases received this calculated rate.

Step 3: Adjustment for Interview Nonresponse

This weight adjustment compensated for differences in response across eligible survey subgroups. Adjustment cells for the interview nonresponse rate are usually defined by state and high or low density.

Step 4: Adjustment for Household Size

The final weight adjustment accounted for within-household eligibility. PUMS data were used to estimate within-household eligibility using race or ethnicity as a comparison point. That is, it was assumed that households with 1 respondent would have the same number of eligible women as average PUMS household data with more than 1 eligible women in the same state and race or ethnic group. The same was true for households with 2 or 3 eligible respondents.

XSL•FO
RenderX

Step 5: Poststratification

This step was a 2-part process—imputation first and then raking. Hot-deck imputation was used to impute missing values for the variables used during the raking process. Across the baseline studies, the missing values imputed for the raking variables ranged from approximately 0.6% to approximately 18%.

Once the values had been imputed, raking was performed across 8 variables—age, nativity, employment, marital status, race or ethnicity, housing tenure, children younger than 18 years in the household, and education crossed with income. The purpose of raking was to reduce bias in survey estimates and achieve representativeness of the target population across those variables of interest. The 8 variables selected represent optimal design based on criteria, such as design effect, weight distribution, and the impact of raking on select outcome variables.

Follow-up Survey Methods

Overview

As mentioned previously, the project includes a set of follow-up surveys that occur in the years between the baseline and the endline surveys. The motivation for the follow-up surveys is to continue to assess contraceptive use and changes in attitudes among participants. The sample for each state's follow-up surveys consists of baseline survey participants who agreed to be recontacted for future studies. Table 2 shows the number of initial respondents who opted into each state's follow-up survey.

Participants can request to be removed from future contact at any point but remain in the panel. In addition, participants are removed from the study panel if the study team learns that the participant was not actually eligible to complete the baseline survey (eg, older than 44 years or younger than 18 years at the time they completed the baseline survey).

Table 2. Panel size by state.

State	Initial panel size, n
Delaware	983
Maryland	957
Alabama	1675
South Carolina	1658
Iowa	1946
Ohio	2066
Arizona	1588
New Jersey	1600
Wisconsin	1577

Methodology

Overview

All follow-up studies follow a similar data collection methodology when mailing printed copies of materials as described earlier for the baseline survey. However, there are a few deviations from the baseline survey protocol, which include (1) locating current contact information, (2) incorporating email and SMS text message prompts, and (3) offering incentive amounts. These differences are described below.

Locating

As the follow-up surveys follow a panel of respondents over a period of up to 3 years, using updated and adequate contact information for the panel is key. Follow-up surveys will be conducted 3 times for participants in South Carolina, Alabama, Iowa, and Ohio, while participants in Delaware, Maryland, Arizona, New Jersey, and Wisconsin will only be contacted for 2 follow-up surveys. Prior to the start of a follow-up survey, the project team sends an email to all panel members who provided an email address with a request to confirm or update their existing contact information.

Throughout data collection, the project team may also conduct individual searches via Accurint, a commercially available locating tool developed by LexisNexis, to locate updated address information for those individuals who have not responded to the mailings or provided the project team with an updated mailing address.

Email Prompts

During each baseline survey, participants were asked to provide their name and contact information (address, telephone number, and email address) to facilitate contacting them for future studies. Email addresses are used to send email prompts and serve as another manner of respondent contact. For participants who had an email but not a name, their initial invitation to participate in the follow-up is sent via email.

The number of prompts and timing of these reminders are at the discretion of the data collector, though all follow-up studies conclude data collection with 1 final email prompt to any sample member who has not yet responded.

SMS Text Message Prompts

Women who participated in the first follow-up surveys for Iowa and Ohio and the baseline surveys for Arizona, New Jersey, and Wisconsin could consent to future contact via SMS text message. Therefore, SMS text message reminders are used for participants in these states. The SMS text messages are sent with an embedded link to the state's web survey log-in page and provide respondents with another way to access the survey.

XSL•FO
RenderX

SMS text messages were only sent to participants who consented to receive these messages and provided a valid telephone number.

Incentives

For those who participate in the follow-up studies, their postincentives are still in the form of electronic gift codes though in increasing amounts. The postincentive for the first follow-up is US $20; it is US $30 for the second follow-up and US $40 for the third follow-up.

Eligibility

Eligible respondents who completed the baseline survey and agreed to future contacts constituted the panel of respondents who would be contacted for the state's follow-up studies. As with all follow-up surveys, it is important that the same respondent participates in each round. As a measure of confirming the individual who responded to a follow-up survey was the same as the original baseline respondent, select demographic variables (age, education, and race) are used as confirmation variables.

During the first follow-up surveys for Delaware, Maryland, South Carolina, and Alabama, these demographic variables were prefilled with the baseline response (if known) into the web survey. The respondents would see the response prefilled and were asked to confirm or update their response.

Regular data reviews, including a review of the demographic variables, are completed during the follow-ups. The study team follows these general steps when reviewing completed cases: (1) Names are compared; if the names match, no further action is taken. (2) If the name does not match, email addresses are reviewed. If email addresses match, no further action is taken. (3) If both the name and email address do not match, responses to age, education, and race are reviewed. If these variables are consistent or there is only 1 variable flagged as a discrepancy, the case is considered a match and no further action is taken. (4) If more than 1 demographic variable is flagged and there is no reasonable explanation for the change (eg, age discrepancy due to change in how the question was asked, increase in education), the case is considered a nonmatch and flagged as the incorrect respondent.

The process to confirm eligibility was refined prior to the start of the first follow-up survey in Iowa and Ohio so that the check on the selected demographic variables was performed systematically. The 5 demographic questions—items about age, gender, ethnicity, race, and education—were moved to the beginning of the survey. Respondents did not see their responses from a prior round; however, the survey was programmed to compare responses to age, education, and race against preloaded values for the case.

With this process, flags are assigned if a response differed from the one previously provided. Respondents continue into the survey if 1 or no flags are triggered. Cases with 2 or more flags indicate discrepant responses; these respondents are taken to a new screen that informs them there is an error with the survey and requests they contact us. Respondents who reach this screen are unable to log back into the survey and are shown this screen until they contact the project team to verify they are the eligible person.

Weighting

The follow-up surveys follow the same weighting methodology as described earlier for the baseline surveys.

Endline Survey Methods

The endline surveys for all states will follow the same sampling approach, data collection methodology, and weighting plan as used for the baseline surveys described earlier. The first endline survey was fielded in 2020-2021 in Delaware and Maryland; at the time of this writing, data processing was underway. Endline survey data collection for the remaining states will continue through August 2023.

Results

This is an ongoing research project and results from data collected from this study will be published independently by separate research and evaluation teams.

Discussion

Conclusions

In summary, the Surveys of Women project follows a standard approach to multimode data collection, which uses a series of prompts to encourage response to the survey. This data collection approach is informed by Dillman et al [5,6] research on multimode surveys and is widely documented in the extant survey methods literature. Additionally, using an address-based sample for the baseline allows the survey to maintain adequate coverage within a state, with the sample stratified into areas in an effort to reach target populations. This project provides an opportunity to use a well-established survey methodology to capture data from a target population on potentially sensitive topics. We will also learn which overall methodology works best for initial participation and subsequent participation in the opt-in panel for follow-up studies, which will be useful for any subsequent, similar projects.

Limitations

As in any household-based web or mailed questionnaire study, there is no accurate or cost-effective way to confirm that all participants met eligibility criteria definitively. Respondent verification was included in the opt-in follow-up surveys to confirm whether the same individual was participating across rounds, but respondent verification is not feasible for the cross-sectional baseline and endline surveys.

Additionally, as noted in "Data Collection Methods" section, we increased our preincentive amounts and modified our follow-up language after baseline participation, and follow-up panel opt-ins were less than expected in Delaware and Maryland. The changes in approach were applied to the subsequent state surveys and allowed for a more robust sample in those states comparatively.

Another limitation to the survey is that it was offered only in English and Spanish languages. Additionally, as a

XSL•FO
RenderX

self-administered survey, it relied on respondent literacy for questionnaire completion and comprehension.

Acknowledgments

The authors received support from an anonymous foundation for the research, authorship, and publication of this paper.

Data Availability

The data sets generated and analyzed during the Surveys of Women study are not publicly available at this time due to the exclusive data usage rights of the funded research and evaluation teams. Data may be made available from the corresponding author upon reasonable request. Data may also become available as restricted use or public use data sets at some point in the future.

Conflicts of Interest

None declared.

Abstract

Background: Germany has a long history of migration. In 2020, more than 1 person in every 4 people had a statistically defined, so-called migration background in Germany, meaning that the person or at least one of their parents was born with a citizenship other than German citizenship. People with a history of migration are not represented proportionately to the population within public health monitoring at the Robert Koch Institute, thus impeding differentiated analyses of migration and health. To develop strategies for improving the inclusion of people with a history of migration in health surveys, we conducted a feasibility study in 2018. The lessons learned were implemented in the health interview survey German Health Update (Gesundheit in Deutschland aktuell [GEDA]) Fokus, which was conducted among people with selected citizenships representing the major migrant groups in Germany.

Objective: GEDA Fokus aimed to collect comprehensive data on the health status and social, migration-related, and structural factors among people with selected citizenships to enable differentiated explanations of the associations between migration-related aspects and their impact on migrant health.

Methods: GEDA Fokus is an interview survey among people with Croatian, Italian, Polish, Syrian, or Turkish citizenship living in Germany aged 18-79 years, with a targeted sample size of 1200 participants per group. The gross sample of 33,436 people was drawn from the residents' registration offices of 99 German municipalities based on citizenship. Sequentially, multiple modes of administration were offered. The questionnaire was available for self-administration (web-based and paper-based); in larger municipalities, personal or phone interviews were possible later on. Study documents and the questionnaire were bilingual—in German and the respective translation language depending on the citizenship. Data were collected from November 2021 to May 2022.

Results: Overall, 6038 respondents participated in the survey, of whom 2983 (49.4%) were female. The median age was 39 years; the median duration of residence in Germany was 10 years, with 19.69% (1189/6038) of the sample being born in Germany. The overall response rate was 18.4% (American Association for Public Opinion Research [AAPOR] response rate 1) and was 6.8% higher in the municipalities where personal interviews were offered (19.3% vs 12.5%). Overall, 78.12% (4717/6038) of the participants self-administered the questionnaire, whereas 21.88% (1321/6038) took part in personal interviews. In total, 41.85% (2527/6038) of the participants answered the questionnaire in the German language only, 16.69% (1008/6038) exclusively used the translation.

XSL•FO
RenderX

Conclusions: Offering different modes of administration, as well as multiple study languages, enabled us to recruit a heterogeneous sample of people with a history of migration. The data collected will allow differentiated analyses of the role and interplay of migration-related and social determinants of health and their impact on the health status of people with selected citizenships.

Introduction

Migration in Germany

Germany is a country of immigration and was the second top destination country worldwide after the United States in 2019 [1]. In 2020, 27% of the population had a so-called migration background, which is defined by the Federal Office for Statistics as the person themselves or at least 1 of their parents were born with a citizenship other than German [2]. In Germany, 17% of the population had their own history of migration [2]. One of the relevant events in the recent history of immigration to Germany was the signing of multiple so-called guest workers recruitment contracts with countries in Southern Europe such as Turkey and Italy and countries in North Africa from the 1950s onward, followed by many returns but also by the immigration of some of the workers' families. Since the 1950s, the immigration of the so-called (late) repatriates from countries of the former Soviet Union began, with most people immigrating during the 1980s and 1990s. During the 1990s, people from the former Yugoslavia fled the wars, and since the 2000s, people from Eastern European countries, for example, Poland, Romania, and Bulgaria, immigrated to Germany or commuted between Germany and their countries of origin in accordance with the European Union Freedom of Movement Act. In particular, during the 2010s, refugees came to Germany from countries such as Iraq, Afghanistan, or Syria. All of these different and heterogeneous groups of migrants and their descendants are subsumed under the statistical category of people with a migration background—except for the so-called (late) repatriates—although their duration of residence, reasons for migration, experiences during the migration process, residence status, and living situations differ. Hence, to identify health resources and health risks in epidemiological research on migration and health, multiple determinants that go beyond the category of migration background need to be considered.

Migration and Health

Previous research showed specific differences in health outcomes between the general population and people with a history of migration in Germany. For example, higher rates of chronic preconditions or diseases, such as vascular and heart disease, obesity, and diabetes, are observed in people with a history of migration [3]; the prevalence of diabetes (mellitus and gestational) is found to be higher in first-generation migrants from Turkey [4]. Furthermore, the prevalence of specific infectious diseases, such as tuberculosis, is higher in migrant groups from endemic areas (eg, several Eastern European and Central Asian countries) [5,6]. Lower outcomes regarding psychological well-being were reported for asylum seekers and refugees than for the general population [7]. In addition, differences were observed in the utilization of health care services, for example, in terms of specialist health care, medication use, or therapist consultation, which are utilized less often by people with a migration background than by those without a migration background [8]. Moreover, the rates of utilization of preventive services, such as cancer screening or health checkups [9], as well as rehabilitative care services [10], are lower among people with a migration background.

The mechanisms underlying these differences in health outcomes cannot be explained by solely focusing on the category of migration background. Social determinants of health—as in the general population as well—need to be considered, for example, living situation; income; the risk of poverty; working conditions [10]; the impact of perceived discrimination [11,12]; or structural barriers in accessing health care services, which are especially prevalent among asylum seekers and refugees [13-15]. To facilitate such analyses, it is essential to include people with a history of migration into national public health monitoring, namely (1) equivalent to their proportion of the population and (2) considering their heterogeneity, for example, by offering different modes of survey administration or questionnaire languages to satisfy different needs.

Participation of People With a History of Migration in Interview Surveys

During recent years, the participation of people with a history of migration was low in the "German Health Update" (Gesundheit in Deutschland aktuell [GEDA]), which is 1 of 3 parts of the national public health monitoring in Germany conducted by the Robert Koch Institute (RKI). For example, in GEDA 2019/2020, overall, 9% of the participants reported a country of birth other than Germany compared with 18.4% of the adult population whose country of birth is not Germany according to population statistics, and 3.9% reported a citizenship other than German compared to the 12.5% of adults living in Germany who have a citizenship other than German [16]. Thus, analyses of differences in health outcomes are difficult, as a selection bias among people with different countries of birth or citizenship might be assumed. Other studies focused on specific migrant groups, for example, those of Turkish origin [4,17,18], so-called (late) repatriates [19,20], or refugees [13,15,21]. Migration-related factors influencing health status can be analyzed within these groups; however, analyses across these groups are mostly not possible, as sampling procedures, methods of data collection, and survey indicators

XSL•FO
RenderX

might differ. Moreover, comparability with the data from population-based public health monitoring is limited.

To overcome these issues, the project "Improving Health Monitoring in Migrant Populations" (IMIRA) was initiated at the RKI in 2016 [22]. One of its aims was to develop strategies for improving the inclusion of people with a history of migration in interview surveys. Therefore, a multilingual mixed-mode feasibility study was conducted among people with Croatian, Polish, Romanian, Syrian, or Turkish citizenship in 2 German federal states, namely Berlin and Brandenburg [23,24]. The findings and lessons learned from this feasibility study were subsequently implemented in the interview survey GEDA Fokus.

Objectives of GEDA Fokus

As described, people with a history of migration are often underrepresented in the RKI health interview surveys (GEDA). Therefore, with GEDA Fokus, we aimed to conduct an interview survey among people with selected citizenships to provide comprehensive data on specific migrant groups to facilitate the analyses of relevant factors impacting their health status. The objectives of GEDA Fokus were as follows:

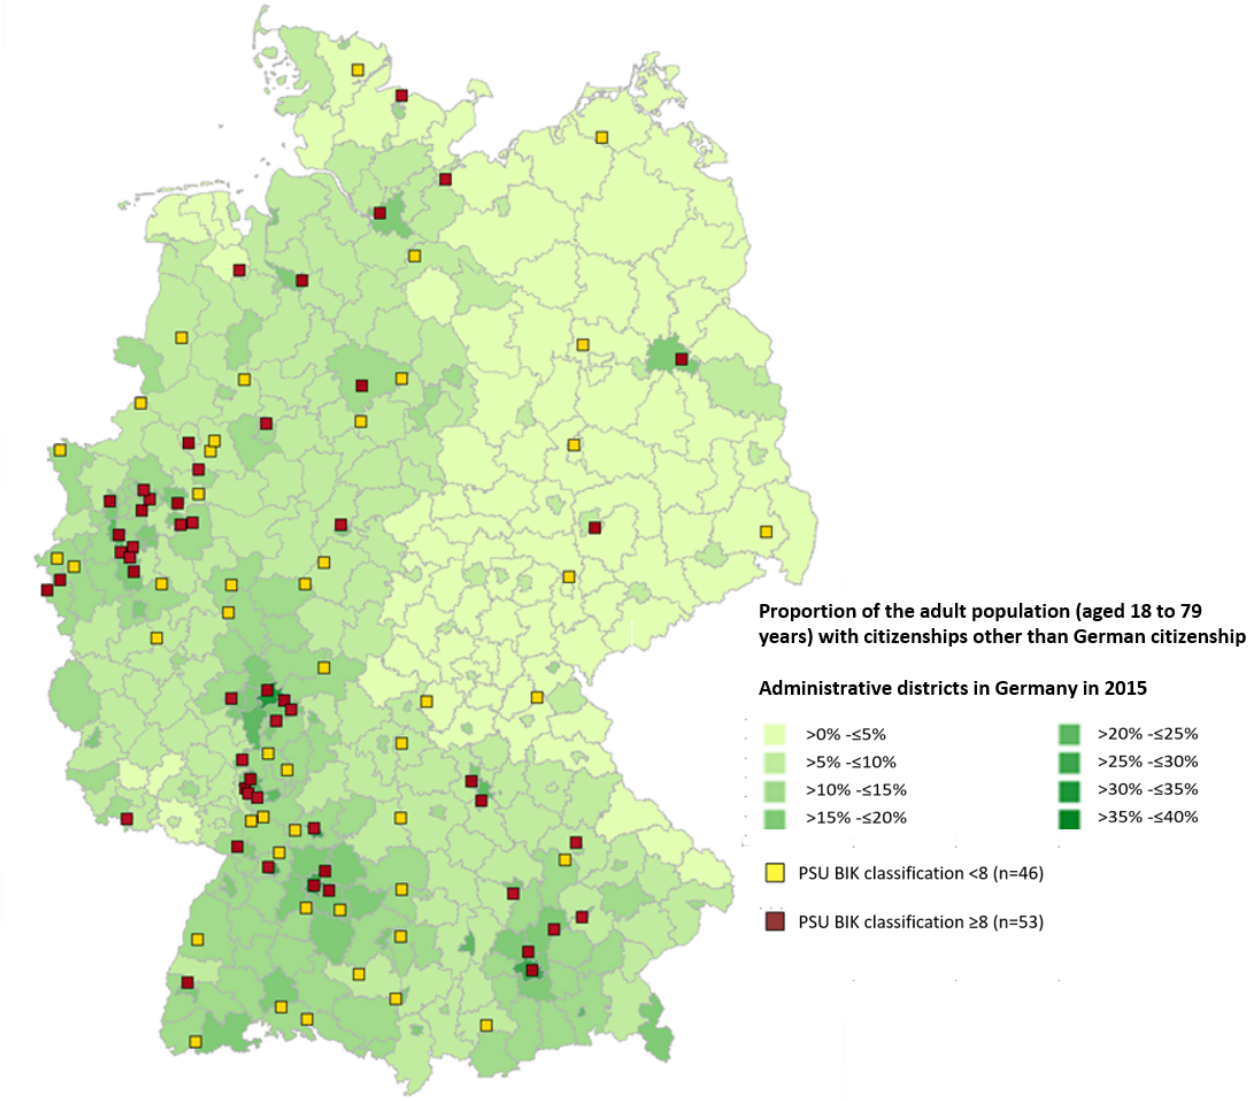
1. Description of the health status of the participants stratified by migration-related factors: the health status of the participants will be described based on a set of core indicators [25], considering migration-related factors with assumed impact on their health, such as duration of residence, residence status, motives of migration, German language proficiency, or perceived discrimination.
2. Methodological analyses to improve the response rate of people with a history of migration in future public health monitoring: the heterogeneity within people with a history of migration in terms of their level of education or income, German language proficiency, or trust in institutions makes differentiated approaches necessary for enabling the accessibility of (interview) surveys for different groups of people. Detailed analyses of recruitment strategies and the use of modes of administration can contribute to a better understanding of how specific subgroups can be reached in future interview surveys.

Methods

Study Design

The interview survey GEDA Fokus was a multilingual survey (Arabic, Croatian, Italian, German, Polish, and Turkish) applying a sequential mixed-mode design, offering a self-administered questionnaire on the web and, in the case of initial nonresponse, on paper. In larger municipalities, personal interviews by (partly) multilingual interviewers to be held either in the study persons' homes or by telephone were also offered. The study persons were randomly selected from residents' registration offices.

Selection of the Study Population



Registries of residents' registration offices were used for sampling, which provides a solid sampling frame for population surveys. Citizenship is the only characteristic captured here that can approximate migration history. By selecting people in this manner, naturalized persons or those of the second migrant generation with only German citizenship cannot be identified. To determine which citizenships to include in the survey (by citizenship), we used data from the Central Register of Foreigners from 2015 to 2017. We conducted model calculations using the Foreigners' Statistic, which is based on the Central Register of Foreigners, considering the current stock, as well as the dynamics (inward and outward migration) of the top 10 citizenships according to the Foreigners' Statistic in 2017. The most common citizenships identified over time in this manner were Italian, Polish, Romanian, Syrian, and Turkish; however, our feasibility study [23,24] showed that sampling from residents' registration offices did not seem effective enough to reach people with Romanian citizenship because of high rates of ineligible addresses. Therefore, it was decided in accordance with the views of the members of the projects' advisory board that Croatian citizenship be included instead of Romanian citizenship, as it was the next most relevant citizenship according to the model calculations. Thus, our study population included people with a registered Croatian, Italian, Polish, Syrian, or Turkish citizenship. Within residents' registration offices, up to 3 citizenships of residents are captured, and all were considered.

Selection of the Primary Sampling Units

Primary sampling units (PSUs) were selected by colleagues at the GESIS Leibniz Institute for the Social Sciences using a Cox algorithm. This selection was based on the following stratification: the classification of federal states into regions (north, south, east, and west), the number of districts and urban municipalities per federal state, and the average proportion of the population without German citizenship within the districts and urban municipalities per federal state. Overall, 120 PSUs were selected (crude number of PSUs=99, as bigger cities such as Berlin were selected more than once): 74 with a Beratung Information Kommunikation (BIK) classification of ≥8 (urban PSUs; crude n=53) and 46 PSUs with a BIK classification of <8 (merely rural areas and smaller cities). The BIK classification systematically structures areas by describing relations between cities and surrounding areas in Germany [26]. A BIK classification of 8 is ascribed to the core areas of cities with 100,000 to 500,000 inhabitants, and classifications of 9 and 10 are ascribed to the core and surrounding areas of cities with ≥500,000 inhabitants [26]. The PSUs selected for GEDA Fokus are displayed in Figure 1.

XSL•FO
RenderX

Figure 1. Primary sampling units (PSUs) of the interview survey German Health Update Fokus (GEDA Fokus). BIK: Beratung Information Kommunikation.

Participants and Inclusion Criteria

People were included in GEDA Fokus if they:

- had a Croatian, Italian, Polish, Syrian, or Turkish citizenship (first, second, or third citizenship according to residents' registration office),
- were aged between 18 and 79 years,
- had their principal residence in one of the selected PSUs, and
- were able to give written informed consent for survey participation.

People were excluded from the survey if:

- their language proficiency in German or one of the offered translation languages was insufficient to answer the questionnaire or interview or
- they were not able to give written informed consent for survey participation.

Sampling Procedures

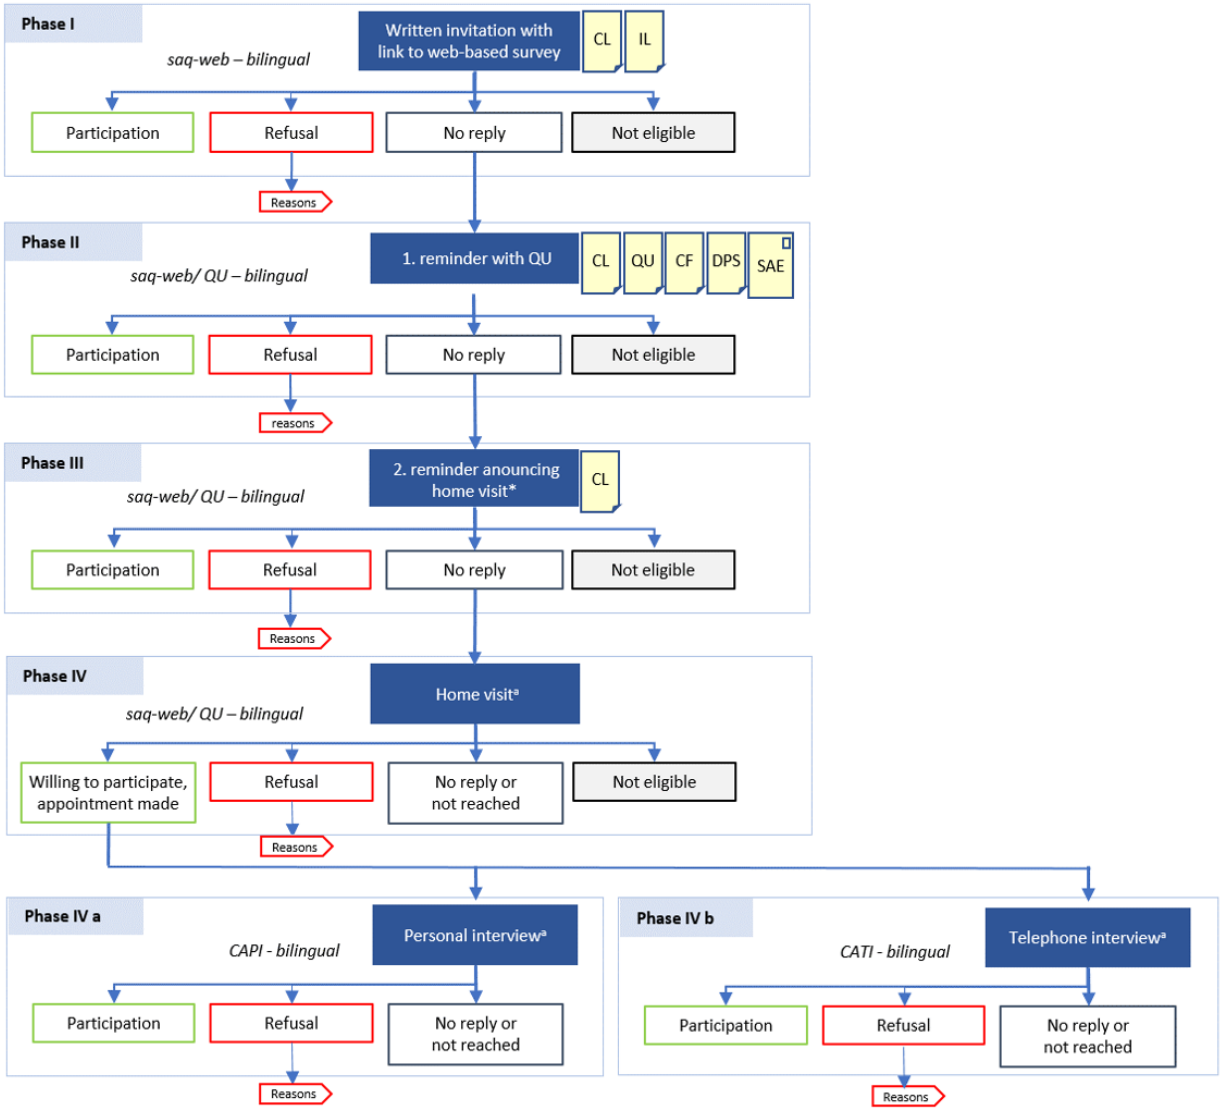
Sampling was carried out at the RKI in 2 tranches; data were cleaned upon reception from the residents' registration offices and forwarded via a secured data link to the external service provider "Kantar GmbH," who conducted the data collection on behalf of the RKI. Kantar GmbH is a market research company that conducts social science and health research surveys. Tranche 1 included 15 PSUs with a BIK classification of <8 and 30 PSUs with a BIK classification of ≥8 (crude n=17). Tranche 2 included 31 PSUs with a BIK classification of <8 and 44 PSUs with a BIK classification of ≥8 (crude n=36). The gross sample comprised 39.53% (13,216/33,436) of study persons in tranche 1 and 60.47% (20,220/33,436) of study persons in tranche 2.

Recruitment of the Participants

In the first study phase, all the selected study persons (N=33,436) received an invitation to participate by postal mail, including a link and log-in information to the web-based questionnaire. The invitation letter and the study information leaflet were bilingual, with a German version on one side and the respective translated version on the other. In the web-based survey, the participants were able to select the German language–only or a bilingual version (eg, German-Italian) of the questionnaire. To ask questions regarding the survey itself

XSL•FO
RenderX

or to refuse participation, the study persons were offered contact options (hotline or email address). In addition, frequently asked questions were posted on a multilingual website.



In the second study phase, all the study persons who neither took part nor refused participation received postal mail with a bilingual reminder including the web link and log-in information for the web-based survey, a study information leaflet, a data privacy statement, and a bilingual paper-based questionnaire. The paper-based questionnaire featured a line-by-line translation (eg, German-Italian). At the end of the paper-based questionnaire, a bilingual consent form was attached that the study persons needed to sign and send back.

The third study phase varied between PSUs with a BIK classification of <8 and those with a BIK classification of ≥8. Study persons in the smaller PSUs only received a second bilingual reminder letter in the form of an enveloped postcard including the web link and log-in information for the web-based questionnaire. In the PSUs with a BIK classification of ≥8, a home visit was announced with the purpose of conducting a personal interview.

In the last study phase, the interviewers (partly bilingual) visited the study persons who had not taken part or refused participation at their homes to either conduct a personal interview or, depending on the preference of the study persons, obtain their telephone number and conduct a telephone interview afterward. The latter option was particularly offered to account for the SARS-CoV-2 pandemic.

If study persons refused participation, the reasons for nonparticipation were collected either on the telephone (hotline) or during personal contact at their home. The study flow is displayed in Figure 2. Data were collected from November 2021 to May 2022.

Sample Size and Anticipated Response Rates

The calculated sample size was 1000 to 1200 participants per citizenship to enable stratified analyses by gender and 3 age groups for an expected prevalence of 5%. The anticipated response rate was 15% on average based on the experience of the feasibility study [23,24], resulting in a gross sample of 33,500 people.

Anticipated response rates were calculated per citizenship based on the response rates observed in the feasibility study (for web-based and personal interviews) and experiences from the GEDA survey 2014/2015 to account for the effect of the paper-based questionnaire on the response rate. The response rate of people with Italian citizenship was estimated as the mean of the response rates of the other citizenships. The response rate of people with Turkish citizenship was comparatively low in the feasibility study and was, therefore, corrected by calculating the mean of the response rate of the group with Turkish citizenship from the feasibility study and the estimated response rate of the group with Italian citizenship for GEDA Fokus. As phase IV in the feasibility study only took place among the groups with Syrian and Turkish citizenship, we estimated the effect of this study phase as the mean of both groups for the groups with Croatian, Italian, or Polish citizenship. We assumed a proportion of quality neutral losses of 10% in the PSUs with a BIK classification of <8 (n=46) and a proportion of 15% for the PSUs with a BIK classification of ≥8 (n=53). Table 1 summarizes the results of these calculations.

Table 1. Anticipated response rates and number of cases of the interview survey German Health Update Fokus (GEDA Fokus), stratified by Beratung Information Kommunikation (BIK) classification and study phases.

Citizenship	Anticipated response rates, %		Gross sample (unadjusted[a]), n		Gross sample (adjusted[b]), n		Participants (net sample), n			
	Phases I-III	Phase IV	BIK<8	BIK≥8	BIK<8	BIK≥8	Phases I-III		Phase IV	Total

Measurements

Key aspects of the survey are the core indicators for describing the health status of people with a migration background that were developed within the IMIRA project [25]. We added several social determinants of health, additional aspects of the utilization of health care, indicators for describing the impact of the COVID-19 pandemic, and the utilization of testing and vaccination. The approximated time for completing the questionnaire was 30 to 45 minutes. Textbox 1 lists the topics covered in the questionnaire.

XSL•FO
RenderX

Textbox 1. Topics covered within the German Health Update Fokus (GEDA Fokus) questionnaire.

Personal information

- Age
- Sex and gender

Overall health status

- General health status
- Impairments in daily life
- Chronic diseases

Diseases

- Myocardial infarction
- Cardiac insufficiency
- Hypertension
- Asthma
- Tuberculosis
- Autoimmune disease
- Chronic kidney disease
- Rheumatoid arthritis
- Lipometabolic disorder
- Depression
- Anxiety disorder
- Coronary heart disease
- Stroke
- Diabetes
- Obesity
- Chronic bronchitis, chronic obstructive pulmonary disease, and emphysema
- Allergies
- Chronic liver disease
- Arthrosis or degenerative joint disease
- Chronic back pain
- Cancer

SARS-CoV-2 or COVID-19

- Laboratory test
- Hospitalization
- Effects of infection control measures
- Diagnosis
- Vaccination

Health care

- Hospitalization
- Utilization of therapy
- Need for health care services
- Vaccinations and utilization of medical services
- Utilization of general and specialist medical care

XSL•FO
RenderX

- Health insurance status
- Incapacity to work due to illness
- Care

Living conditions

- Social support and contacts
- Self-efficacy
- Subjective social status and life satisfaction
- Sense of belonging
- Self-perceived discrimination
- Religion and faith

Health behavior

- Physical activity
- Alcohol consumption
- Body weight and height
- Smoking
- Dietary intake
- Health information

Migration status

- Country of birth
- Reasons for migration
- Residence status
- Year of immigration
- Citizenship or citizenships
- Language proficiency (German and native language if other than German)

Household and housing situation

- Marital status
- Number of household members
- Type of building
- Size of living space

Employment situation

- Formal and vocational education
- Workplace exposure, shift work, and temporary employment
- Employment and occupational status
- Unemployment
- Income

Weighting Procedures

A total of 2 weighting factors were calculated: one of them allows overall analyses across all 5 citizenship groups, and the other considers the marginal distributions within each citizenship group. On the one hand, the weighting factors control for the sampling of the PSUs, and on the other hand, they fit the sample to the marginal distribution of the population. When fitting the sample to the marginal distribution of the population, the weighting factors consider the distribution of region, gender, age, education (International Standard Classification of Education 2011), and the duration of residence of the 5 citizenship groups. Marginal distributions were taken from the Mikrocensus 2018 [27] after restricting the data to the 5 citizenship groups (including dual citizens).

XSL•FO
RenderX

Quality Assurance

The translation of the questionnaire was done by 2 independent translators per language and was followed by a 2-stage editing process. In the first stage, an editor with a medical science background chose the better translations point by point. In the second stage, an editor without a medical scientific background proofread for general comprehensiveness. After typesetting (web-based and paper-based questionnaires), native speakers confirmed the correct translations as well as typesetting.

The data collection process was regularly monitored based on predefined indicators. The interviewers received training on the study aims and study design as well as on data protection and ethical aspects. Regular meetings for process evaluation took place, enabling the exchange of recruitment strategies between the interviewers and addressing the questions they raised.

Ethics Approval

Ethics approval was received on December 22, 2021, from the ethics committee at the Medical University of Charité, Berlin (EA1/250/21). The study was approved by the Commissioner for Data Protection of the RKI without concern as of October 26, 2021. Written informed consent was obtained from all the study participants who completed a paper-based questionnaire or had a face-to-face interview. Oral consent was obtained from the study participants who had a telephone interview. Those who participated on the web consented by clicking on a respective button. The consent form was available in all 6 study languages. The interview data were anonymized and are stored at the RKI. After participation, all the study participants received an incentive in the form of a voucher worth €10 (US $11.4 as of January 3, 2022).

Results

Overall¸ 6038 study participants took part in the survey, of whom 2983 (49.4%) were female. The median age was 39 years, and the median duration of residence in Germany was 10 years, with 19.69% (1189/6038) of the sample being born in Germany (unweighted). The characteristics of the study population stratified by citizenship group are displayed in Table 2. The overall response rate according to the American Association for Public Opinion Research (AAPOR; response rate 1) [28] was 18.4%, ranging from 13.8% in the group with Turkish citizenship to 23.9% in the group with Syrian citizenship. Furthermore, the response rates differed between the smaller municipalities where personal interviews were not offered (12.5%) and bigger cities where personal interviews were offered (19.3%). The self-administered web-based questionnaire (3028/6038, 50.15%) was the most opted mode of administration, followed by the paper-based version (1689/6038, 27.97%). Personal interviews in the study participants' homes were conducted with 17.12% (1034/6038) of the participants, and telephone interviews were conducted with 4.75% (287/6038) of the participants. Of the 6038 participants, 2527 (41.85%) indicated that they had answered the questionnaire in German only, 1008 (16.69%) exclusively used the translation, and 2503 (41.45%) used both languages in the bilingual version of the questionnaire. More detailed results will be published soon.

Discussion

Principal Findings and Outlook

We recruited the first nationwide sample of people with selected citizenships in Germany, representing the major groups with citizenships other than German. The sequential mixed-mode design and provision of multilingual study materials facilitated the participation of different groups of people in the study, for example, participants with lower proficiency in German or less preference for web-based participation. The data from this study will allow us to expand public health reporting on people with a history of migration in Germany, considering the core indicators developed within the scope of the IMIRA project [25]. Furthermore, we will be able to expand the knowledge on the impact of the COVID-19 pandemic on people with a history of migration. In addition, this sample will allow us to analyze factors associated with the health of people with a history of migration in a more differentiated manner, considering different migration-related and social determinants of health such as duration of residence, residence status, or living and working conditions.

Limitations

First, sampling was only possible based on citizenship, as no other migration-related indicator is reliably captured within the residents’ registration offices. Therefore, not all groups of people with a history of migration are included, for example, naturalized people with only German citizenship or people with citizenships other than those that were selected. Therefore, conclusions cannot be drawn for all people with a history of migration living in Germany and can be drawn only for those with the 5 selected citizenships.

Sampling of the PSUs has some limitations, as we do not know the exact number of people with selected citizenships living within the municipalities and cities in Germany; this is especially the case for people with dual or multiple citizenships, as they are not captured within the Foreigners’ Statistics. Therefore, sampling was based on the overall proportion of people without German citizenship within the rural and urban districts. It was not always possible to sample the required number of people per citizenship (gross sample) within the smaller municipalities; this is especially true for people with Italian or Croatian citizenship in the northern and eastern parts of Germany. We filled these gaps by oversampling within the PSUs with a BIK classification of ≥8. Furthermore, the original selection of PSUs was based on the presumption that one-third of the net sample could be recruited in the PSUs with a BIK classification of <8. Once we encountered the problem of drawing enough people for the gross sample within the smaller PSUs, we adjusted this goal to recruit 10% of the net sample within the PSUs with a BIK classification of <8. This might result in cluster effects toward larger cities, which might limit comparisons between the rural and urban areas. Furthermore, this leads to a higher variance of the weighting factors for the participants in the PSUs with a BIK classification of <8. A higher variance of the weighting factors is associated with a lower precision of the estimates.

Furthermore, we offered only 6 languages, whereas other languages might have been required for respondents, for example, Kurdish, which might have been preferable for some people with Turkish or Syrian citizenship. In addition, we originally planned to apply a team translation approach, where 2 independent translators would translate the questionnaire, which would be followed by a moderated process with an editor to find the most accurate translation. Instead, translations underwent a 2-stage editing process; however, it was not possible to manage the moderated adjudication process of the team translation approach under the COVID-19 pandemic circumstances and time constraints.

The COVID-19 pandemic might have impacted the willingness to participate in the survey, as the public opinion on this topic, on the RKI as a national public health institute, and on the measures taken to slow down the spread of the virus were quite controversial during the period of data collection. This might have deterred some study persons from taking part in the survey; others might not have participated because of the fear of

XSL•FO
RenderX

infection during the personal interviews. We attempted to address this issue by offering telephone interviews; however, the pandemic situation might have caused selection bias.

Strengths

Besides these limitations, we want to highlight some strengths of the interview survey GEDA Fokus. First, it resulted in the largest sample of people with their own or a familial history of migration in Germany up to now. Although the indicator "citizenship" has its limitations, as mentioned earlier, we have certain marginal distributions according to Mikrocensus for the people with the selected citizenships, which allow us to weight data to yield generalizable results for this defined group.

The multimodal survey design resulted in accessibility for different groups of people, for example, for older people preferring paper-based questionnaires. In addition, the home visits with personal interviews as the gold standard [29-34] increased participation as personal contact builds trust, and concerns could be addressed directly. Offering multilingual questionnaires facilitated participation for study persons with lower German language proficiency because of, for example, a shorter duration of residence [23,24], as was the case among the participants with Syrian citizenship. Further methodological analyses will contribute to the understanding of how certain hard-to-survey subgroups among people with a history of migration can be reached and will be published soon.

The most newly developed survey instruments underwent cognitive pretesting [35,36] in the 5 translation languages before their application in GEDA Fokus to ensure a common understanding and comprehension of the questions [16,37]. Migration-related concepts, as well as indicators on discrimination, feelings of belonging, and self-efficacy, in connection with other social determinants of health, for example, housing, living, and socioeconomic aspects, will provide important insights into the complex interdependencies between social determinants and migrant health. Reporting the core indicators on the health of people with a migration background [25] will deliver important data to inform public health intervention planning. The indicators used in GEDA Fokus were also used in the European Health Interview Survey (EHIS), which will enable comparisons of the health status with the general population in Germany.

Conclusions

We recruited approximately 6000 participants with Croatian, Italian, Polish, Syrian, or Turkish citizenship (1200 per group) living all over Germany. Multimodal survey administration, including the provision of personal interviews and bilingual study materials, facilitated the participation of different subgroups of people in the survey, resulting in a heterogeneous sample of people with their own or a familial history of migration with selected citizenships. Future data analyses will provide insights into the complex interplay between migration and health, considering different migration-related, social, and structural determinants of health.

Acknowledgments

The authors would like to thank the German Federal Ministry of Health for funding this study (grant ZMVI1-2518FSB411) and all the participants who took their time to take part in the survey. They are grateful for the constant support and valuable feedback of the advisory board members, especially during the process of developing the study design. Special thanks go to the colleagues at the GESIS Leibniz Institute for the Social Sciences for statistical advice and drawing the PSUs. Furthermore, they acknowledge the staff of all the 99 residents' registration offices who made the necessary data available. Finally, they would like to thank their colleagues at Kantar GmbH, who conducted the data collection, for their continuous efforts and close collaboration. Finally, they would like to thank all their colleagues at the Robert Koch Institute who supported this study.

Data Availability

The data sets generated during this study are not publicly available because of data protection reasons but are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Eye tracking provides an objective way to measure attention, which can advance researchers' and policy makers' understanding of tobacco marketing influences. The development of remote webcam-based eye-tracking technology, integrated with web-based crowdsourcing studies, may be a cost-effective and time-efficient alternative to laboratory-based eye-tracking methods. However, research is needed to evaluate the utility of remote eye-tracking methods.

Objective: This study aimed to detail the process of designing a remote webcam-based eye-tracking experiment and provide data on associations between participant characteristics and the outcomes of experiment completion.

Methods: A total of 2023 young adult (aged 18-34 years) cigarette smokers in the United States were recruited to complete a web-based survey that included a 90-second remote eye-tracking experiment that examined attention to e-cigarette marketing materials. Primary outcome measures assessed the completion of the remote eye-tracking experiment—specifically, experiment initiated versus not initiated, experiment completed versus not completed, and usable versus nonusable eye-tracking data generated. Multivariable logistic regressions examined the associations between outcome measures and participants' sociodemographic backgrounds, tobacco use history, and electronic devices (mobile vs desktop) used during the experiment.

Results: Study recruitment began on April 14, 2022, and ended on May 3, 2022. Of the 2023 survey participants, 1887 (93.28%) initiated the experiment, and 777 (38.41%) completed the experiment. Of the 777 participants who completed the experiment, 381 (49%) generated usable data. Results from the full regression models show that non-Hispanic Black participants (adjusted odds ratio [AOR] 0.64, 95% CI 0.45-0.91) were less likely to complete the eye-tracking experiment than non-Hispanic White participants. In addition, female (vs male) participants (AOR 1.46, 95% CI 1.01-2.11), those currently using (vs not using) e-cigarettes (AOR 2.08, 95% CI 1.13-3.82), and those who used mobile (vs desktop) devices (AOR 5.10, 95% CI 3.05-8.52) were more likely to generate usable eye-tracking data.

Conclusions: Young adult participants were willing to try remote eye-tracking technology, and nearly half of those who completed the experiment generated usable eye-tracking data (381/777, 49%). Thus, we believe that the use of remote eye-tracking tools, integrated with crowdsourcing recruitment, can be a useful approach for the tobacco regulatory science research community to collect high-quality, large-scale eye-tracking data in a timely fashion and thereby address research questions related to the ever-evolving tobacco marketing landscape. It would be useful to investigate techniques to enhance completion rates and data usability.

Introduction

Traditional Eye-Tracking Tools and Emergent Challenges

Eye tracking has become an increasingly popular method of assessing visual engagement with marketing and communication materials in tobacco control research and tobacco regulatory science [1,2]. In particular, eye tracking has been used to gain insight into how people pay attention to pro- or antitobacco communication efforts, such as industry marketing tactics [3,4], warning labels [5-10], and other tobacco-related health messages [11-13]. Unlike self-reported surveys or qualitative assessments that could introduce recall and response biases, eye tracking provides objective measures of visual attention to tobacco marketing stimuli that are predictive of information recall and processing [1,14], which can lead to changes in perceptions about tobacco products. Studies using eye tracking can help inform researchers and policy makers about the influence of tobacco marketing exposure among various populations.

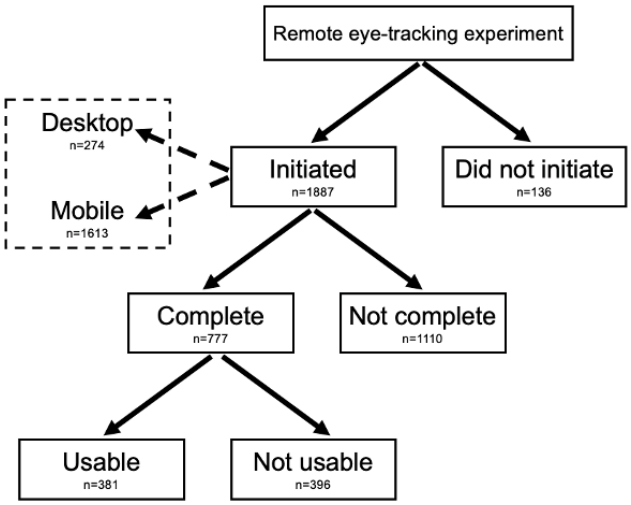
Eye tracking is typically conducted in an in-person research setting, with participants entering a computer laboratory equipped with specialized, infrared eye-tracking equipment, operated by at least 1 research staff member. Challenges associated with traditional eye-tracking studies include the costly and tedious process of study implementation [15], which requires bringing people into a laboratory where they can be tracked individually, as well as geographic restrictions regarding the sample because most study recruitment takes place locally. Such challenges have been exacerbated by the recent COVID-19 pandemic, further highlighting the need for remote, web-based alternatives.

Advantages of Remote Webcam-Based Eye Tracking

Recent developments in web-based remote eye tracking, which accesses users' webcams to capture video images of the face to predict gaze location on the screen, as opposed to the traditional corneal and pupil reflection used in most laboratory eye trackers, make this approach an attractive, available alternative when laboratory studies are not possible. This approach may largely remove the restrictions of conducting traditional eye-tracking studies [16]. There are several benefits of using remote eye-tracking studies. Mainly, these studies can support large-scale, crowdsourced web-based research without geographic restrictions or restrictions pertaining to equipment or staff availability; researchers are also able to immediately and simultaneously obtain eye-tracking data from a large sample of participants. In addition, participants can perform tasks whenever and wherever they choose, as long as they have a computer or smartphone or tablet device equipped with a camera and an internet connection. The ability to conduct an eye-tracking study on participants' own devices in their natural environment makes it ideal for studies that examine participants' attention to commercial marketing materials seen in real life rather than within a controlled laboratory environment.

Remote eye tracking may be especially useful for conducting tobacco marketing research. First, compared with a laboratory setting, performing eye-tracking tasks on personal electronic devices in participants' natural environment may more realistically mimic the context of tobacco marketing exposure, particularly when the marketing stimuli consist of materials publicized on websites and social media platforms. As social media and web-based content become an increasingly common channel of tobacco marketing exposure for young people [17-20], the ability to perform eye-tracking tasks on personal electronic devices becomes especially important. In addition, the capability of remote eye-tracking technology to be compatibly used with large-sample crowdsourced data will facilitate researchers' and regulators' understanding of the influence of tobacco marketing materials at the population level and among subgroups (eg, tobacco users, former users, and never users). Finally, studies examining ever-changing tobacco marketing practices require designs that reflect the most recent marketing tactics and policy changes. Research that integrates remote eye-tracking technology with crowdsourcing data collection can provide rapid responses to surveillance needs and regulatory challenges requiring immediate attention.

Recent research studying the efficacy of remote eye-tracking technology shows that this new technology produces satisfactory accuracy (defined as the capacity to truthfully describe the location of a person's gaze on a screen) compared with the data gathered from a traditional infrared-based eye tracker used in a controlled laboratory setting [16,21-24]; for example, researchers were able to obtain comparable results from a remote versus laboratory-based eye-tracking experiment in 3 tasks commonly used for eye tracking (fixation, pursuit, and free viewing) and found that webcam-based eye tracking is generally suitable for all 3 tasks and holds promise in cognitive science–based research [21]. Together with the potential aforementioned benefits, remote eye tracking may be a potentially viable alternative for researchers that substantially reduces the time and costs associated with conducting a laboratory-based eye-tracking study.



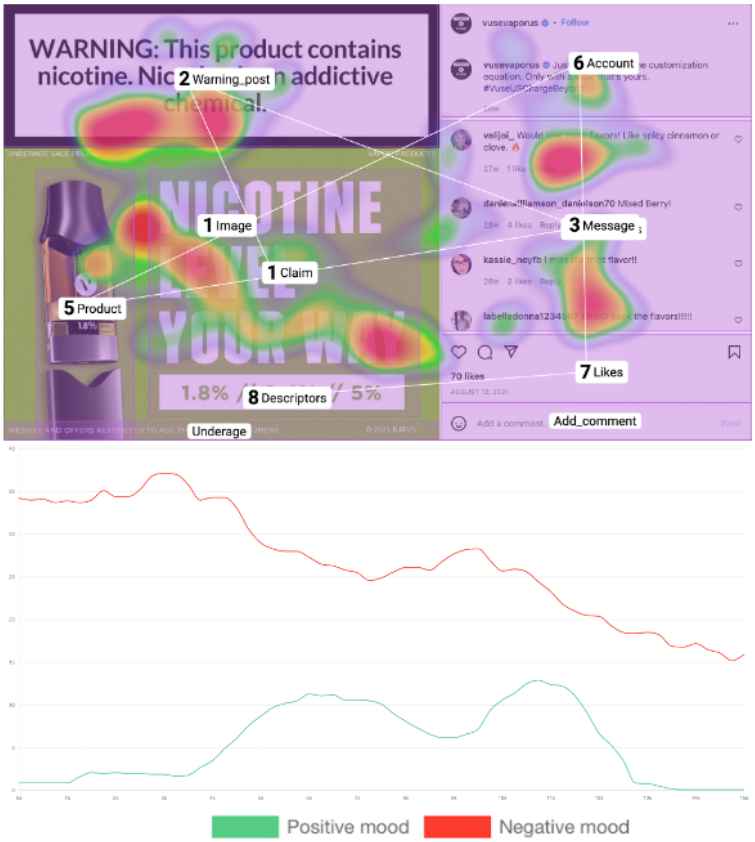
Research Questions and Study Objectives

Because of the novel nature of remote eye-tracking platforms, relatively few publications describe the process of configuring such experiments and integrating them with large-scale crowdsourcing survey platforms. In particular, there are questions of how this innovative method can be used to examine the influence of tobacco marketing materials among a large sample of tobacco users and which subpopulations (characterized by age, biological sex, race and ethnicity, and

XSL•FO
RenderX

other factors) may be more likely to participate in remote eye-tracking studies. Using a large sample of young adult cigarette smokers who participated in a web-based survey through crowdsourcing, this study had two goals: (1) to provide a detailed description of our approach to configuring a remote eye-tracking experiment embedded in Qualtrics (Qualtrics International Inc), a research company used for conducting behavioral science research, including tobacco research and (2) to document associations with demographic, smoking history, and other characteristics of study participants who completed various stages of the remote eye-tracking experiment (Figure 1). Given the potential utility of remote eye-tracking tools for academic researchers, this paper further describes key features of the platform and integrated survey system for remote eye-tracking studies, details potential challenges that may occur before and during data collection, and recommends solutions to streamline the use of the tool and improve data collection quality.

Figure 1. Remote eye-tracking experiment flowchart and distribution of experiment completion. Definition of initiating the experiment: participants who chose to proceed to the eye-tracking experiment using either desktop or mobile devices. Definition of complete: participants who completed the entire experiment (participants who started the experiment but did not meet technical requirements or closed the browser or had timed out before reaching the end were considered "not complete"). Definition of usable: participants whose gaze and emotion were trackable during their session, that is, had proper lighting and did not move.



Methods

Remote Eye-Tracking System

This research used Sticky by Tobii (Tobii AB), a remote webcam-based eye-tracking tool that provides a cloud-based eye-tracking measurement of attention and emotional responses. This tool combines survey questions with remote webcam eye-tracking technology that can be used with cameras for tablet devices and mobile phones as well as webcams for laptop and desktop computers. It can be integrated with a web-based survey tool such as Qualtrics, which can help expand the research team's access to a larger study sample while providing various options for survey formatting. Through designating certain areas of interest (AOIs) on the experimental stimuli, researchers can identify participants' attention and emotional responses to different areas of the stimuli. Data generated from the experiment are automatically streamed to the cloud as they are recorded. On the basis of the analysis of participants' webcam video recordings, the cloud-based eye-tracking software platform generates attention data (measured by gaze patterns via webcam-based eye tracking) and emotion metrics (measured by various emotional expressions via webcam-based facial coding) within hours of data collection (refer to Figure 2 for examples of gaze patterns and emotion metrics). The software also generates heat maps of static gaze visualizations at individual and group levels, which serve as a graphical representation of fixation counts and duration. In addition, researchers can insert questionnaires before or after the stimuli presentation. Data collected from the remote eye-tracking tool and the integrated web-based survey platform can be downloaded from the relevant platform and merged using unique participant IDs.

RenderX

Figure 2. Example of gaze metrics generated by remote eye tracking.

Study Participants and Procedures

Between April 14, 2022, and May 3, 2022, we recruited a web-based convenience sample (N=2023) of young adult cigarette smokers (aged 18-34 years) via Qualtrics. Qualtrics recruits participants through their web-based study panels by sending email invitations to potentially eligible participants. Participants interested in the study first completed a screening survey to confirm their eligibility, for which the criteria were as follows: (1) aged between 18 and 34 years, (2) smoked at least 1 cigarette in the past 30 days, and (3) smoked ≥100 cigarettes over their lifetime. Eligible participants were then shown an informed consent page that described the purpose of the study (to examine the influence of e-cigarette marketing features) and provided details about the survey and the embedded remote eye-tracking experiment. They were instructed that they would need to turn on their cameras to complete the eye-tracking experiment. Participants were also told that their faces would be recorded by video during the remote eye-tracking task; however, they were assured that the researchers would not have access to any recordings of their faces or surroundings. In addition, participants were told that they would receive a complete code for full survey compensation even if they decided to skip the remote eye-tracking section of the study.

Participants who agreed with the informed consent proceeded to the web-based survey, where they answered a series of questions about their sociodemographic background (eg, biological sex, race and ethnicity, and subjective financial status) and tobacco use history (eg, current cigarette smoking and e-cigarette use frequency). Next, participants proceeded to the introduction of the remote eye-tracking experiment, which stated, "Now, we will ask you to look at a few e-cigarette images through a remote eye-tracking experiment. Your participation in this experiment is very important as your response will help us understand the impactful features of e-cigarette advertisements. We greatly appreciate your time and efforts in completing this experiment." Subsequently, participants were asked to indicate the device they were using or opt to skip the eye-tracking section: "If you wish to proceed, please select the type of device you are currently using for completing the survey," with the response options "I do not wish to proceed," "Desktop or laptop screen," "Mobile, tablet," and "Mobile, phone." Those who chose the first option were directed to the end of the survey, where they viewed health education messages about the harms of tobacco use and methods of quitting tobacco before they exited the survey.

As the software requires different experiment setups for mobile (tablet and phone) and desktop (desktop and laptop) devices, participants who wished to initiate the experiment were directed to the corresponding mobile- or desktop-based experiment in accordance with the device they chose. The total time participants engaged with the entire course of the experiment was approximately 5 minutes, which included reading the instructions, processing calibrations, viewing the experimental stimuli, and completing the survey items. Participants who completed the experiment were then directed to view the health education messages on Qualtrics before exiting the survey. In the following sections, we describe the process of configuring the remote eye-tracking experiment and embedding it within the Qualtrics web-based survey platform.

XSL•FO
RenderX

Remote Eye-Tracking Experiment Setup

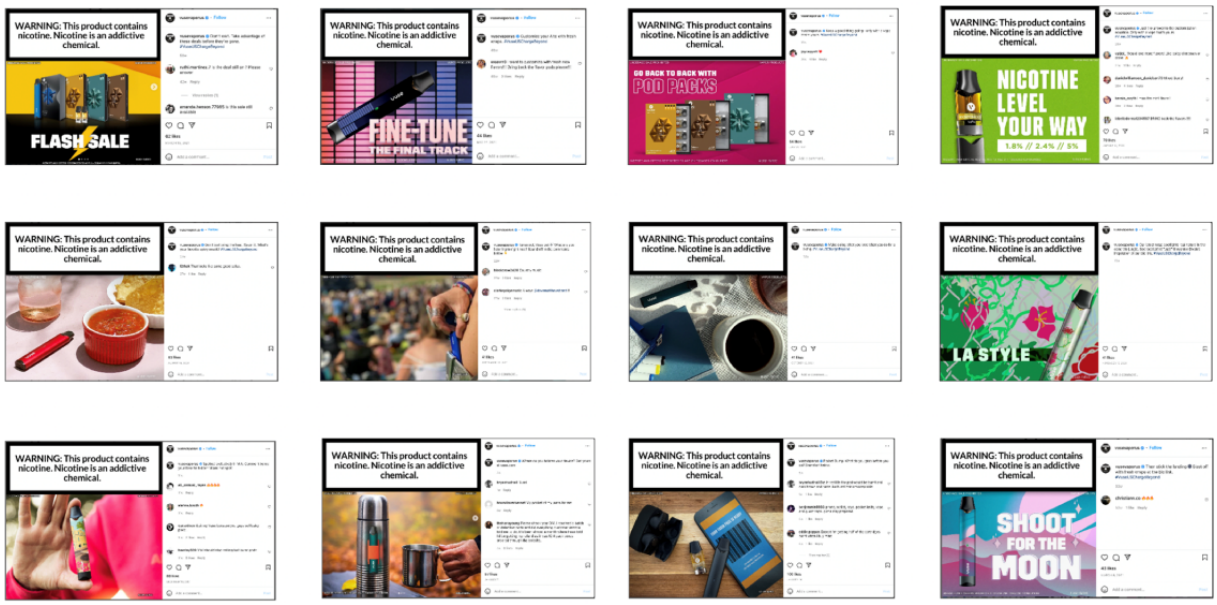
Experiment Setup and Calibration

After choosing to initiate the remote eye-tracking experiment, participants were shown instructions related to the use of the software (Figure 3). After they completed reading through a brief consent message, they were told that their cameras needed to be activated to detect and properly position their gaze before they viewed the experiment's stimuli. After the default setup for calibration had been set up, 2 calibration points were used in our experiment. The first calibration point was set up before participants saw the instructions to properly view the stimuli, and the second calibration point was set up after participants had viewed the stimuli. During calibration, participants were told to attentively follow a moving icon on the screen.

After completing the first calibration, participants were presented with instructions specific to the experiment, which differed slightly for mobile- and desktop-based experiments. For the mobile-based experiment, the instructions read, "Now you will see a social media post about e-cigarettes. Please view the following image by tapping on your screen. When you are finished viewing (scrolling is enabled), tap your screen again to answer the question. Please stay as still as possible during the experiment." The instructions for the desktop-based experiment differed slightly in that scrolling was disabled, and participants could click the mouse or press the spacebar to proceed. We set a duration (ie, 20 seconds) for presenting the instructions, enabling the software to proceed automatically if a participant did not advance manually.

Figure 3. Remote eye-tracking platform use instructions (screenshots).

Designing Stimuli for the Eye-Tracking Experiment



After advancing, participants viewed the experiment's stimuli that consisted of static images of 12 e-cigarette social media posts obtained directly from the official Instagram account of Vuse, a commonly used e-cigarette brand (Figure 4). To fit the stimuli for each experiment on the screen, the posts used in the mobile-based experiment were directly obtained from

XSL•FO
RenderX

Instagram's mobile app, whereas the same posts used in the desktop-based experiment were obtained from Instagram's website. For both experiments, we randomly assigned 1 of the 12 images to be presented to the participants by selecting the option "randomly displaying 1 out of 12 media" within the experiment setup page. We set each stimulus to *fit to screen* for the desktop-based experiment and be *scrollable* for the mobile-based experiment. Participants using desktop devices were allowed to proceed through all stimuli *on mouse click* or *by pressing the spacebar*, and those using mobile devices were allowed to proceed by tapping the screen. We also set a *maximum duration* (ie, 15 seconds) for presenting each stimulus, in the event that a study participant did not advance manually.

While preparing for the experiment, the research team created AOIs within each stimulus. The AOIs were based on systematic coding of the stimuli before designing the remote eye-tracking experiment. Two coders carefully viewed each stimulus and marked visible features (including the image portion and the comment section of the social media posts). To obtain a final set of codes for each stimulus, agreement on the coding was decided after discussion with a third coder. The research team set up the AOIs by creating either rectangular or free-form shapes around the features. We named each AOI according to its content (eg, warning label, package, and marketing claim), which was directly informed by the coding results. Participants were not able to view the boundaries or names of the AOIs.

Figure 4. Vuse social media posts used in the experiment (screenshots).

Setting Up the Survey Question

Immediately after the e-cigarette stimuli presentation, participants were asked about their willingness to use e-cigarettes. After completing this survey question, participants were told that they had successfully completed the remote eye-tracking experiment and were automatically returned to the Qualtrics survey.

Integration of the Remote Eye-Tracking Experiment With the Qualtrics Survey Platform

Setting Up the Audience

The audience portion included selecting the participant source, setting the panel size, and configuring participant settings. In selecting the participant source, we were given the option of sourcing our own participants or having Tobii recruit and field participants based on our eligibility criteria. Our research team chose the former option, and we recruited participants through Qualtrics' web-based study panel.

Embedding the Remote Eye-Tracking Experiment With Qualtrics

As described previously, the Qualtrics survey for this study was configured to redirect users to the remote eye-tracking experiment depending on the device being used by the participant. Consequently, we were required to create 2 remote eye-tracking experiment blocks within our Qualtrics survey: one for desktop users and another for mobile users. We then used display logic on Qualtrics to route people to the relevant eye-tracking experiment. Configuring participant settings gave us the option to create a redirect link and a JavaScript link through which participants could access the eye-tracking experiment. Therefore, we configured participant settings using the Qualtrics survey platform by including the remote eye-tracking experiment *in an external survey platform with JavaScript*. Upon selecting Qualtrics as the survey provider, we were prompted to read a series of instructions on how to properly embed the remote eye-tracking experiment into the Qualtrics survey.

Verification, Review, and Launch

After setting up the audience and embedding eye-tracking experiments within the Qualtrics survey, we proceeded to the

XSL•FO
RenderX

verification page to assess the functionality of our experiments before officially launching them. We ran multiple test sessions for both the mobile- and desktop-based experiments before the official launch. The experiment took <90 seconds to complete. After making a few changes, we launched the experiment, at which point adjustments could no longer be made. The crowdsourcing data collection through Qualtrics' web-based panel took 20 days, and data were obtained from young adult cigarette smokers (N=2023) who completed the survey and passed Qualtrics' data quality checks.

Assessing the Characteristics of the Participants Who Completed the Remote Eye-Tracking Experiment and Generated Usable Data

Survey Measures

A series of survey measures programmed in the Qualtrics survey platform assessed participants' characteristics and tobacco use history. These measures were used to assess which subgroups of young adult cigarette smokers would be more likely to initiate and complete the remote eye-tracking experiment. Specifically, sociodemographic characteristics included biological sex, age, race and ethnicity, sexual orientation, marital status, highest education level, current employment status, current school enrollment, and subjective financial status (Table 1). Tobacco use statuses included cigarette smoking frequency (daily vs nondaily) and current e-cigarette use status (current use vs nonuse). Finally, devices (mobile vs desktop) used for completing the survey and remote eye-tracking experiment were also included in the analysis.

[a]The denominators for the percentages in these column are the n values from the "Full sample" column in the same row.

[b]Participants who responded "Other" or "Prefer not to say" to the biological sex question were excluded because of the small sample size (n=7).

[c]"Non-Hispanic other" includes non-Hispanic Asian, American Indian or Alaska Native, Native Hawaiian or Pacific Islander, multiracial, and other races.

[d]"Other orientations" status includes asexual, bisexual, gay, lesbian, pansexual, queer; questioning or unsure; another identity not listed; and prefer not to disclose.

[e]"Other" marital status includes widowed, separated, divorced, and other not specified in the available categories.

[f]"Other" employment status includes in military service, retired or disabled, and homemaker.

[g]Data for devices used to complete the experiment relate to those who decided to proceed to the Sticky experiment (n=1887).

[h]N/A: not applicable.

Eye-Tracking Data Processing and Completion Metrics

After reaching the recruitment goal, we used the software to generate various eye-tracking metrics (eg, fixations and dwell time), which took approximately 12 hours. Attention data were automatically streamed to the cloud as they were recorded, then processed for completeness while eye-tracking calibration quality was validated. The validation process measures eye-tracking data accuracy by how much the ground truth validation points differ from gaze predictions [25]. The validation results determine the usability of the data for each individual participant: a difference lower than a threshold value of 0.18 is considered usable [25].

Once the eye-tracking data were processed and validated, the software presented several experiment completion metrics that we used as the outcome of our study (Figure 1). Specifically, for data analysis, we generated a variable, *experiment completion*, to capture participants' status of completing the experiment with four mutually exclusive outcomes: (1) did not initiate the experiment (ie, selected "I do not wish to proceed" just before the experimental portion), (2) initiated the experiment but did not complete it, (3) completed the experiment but did not generate usable data, and (4) completed the experiment and generated usable data. Completing the study and generating usable data were determined by the direct output from remote eye-tracking software. Experiment completion data were then merged with the Qualtrics survey data using unique participant IDs.

Statistical Analysis

To understand which subgroups of young adult cigarette smokers were more likely to complete the remote eye-tracking study, we first assessed the sociodemographic backgrounds and tobacco use history of study participants as well as the outcomes from those completing the remote eye-tracking experiment. Next, we used Pearson chi-square tests to examine the bivariate associations between participant characteristics and the experiment completion variable. Post hoc analyses using the Fisher exact test [26] were further conducted to examine the subgroup differences, given the statistically significant chi-square test results. In addition, we ran separate logistic regression models to examine the associations between participant characteristics and experiment completion using models with various outcomes (initiated the experiment vs did not initiate the experiment, completed the experiment vs did not complete the experiment, and generated usable data vs generated nonusable data). After implementing the multivariable regression models to examine the associations between sociodemographic characteristics and experiment completion, we further controlled for participants' tobacco use history, including frequency of cigarette smoking and current e-cigarette use. Finally, we controlled for the device (desktop vs mobile)

XSL•FO
RenderX

used to complete the remote eye-tracking experiment. We analyzed the data using Stata (version 16.0; StataCorp LLC) and set the statistical significance to .05 (2-tailed).

Ethics Approval, Participation, and Informed Consent

This study was approved by the institutional review board at Rutgers University (Pro2022000190). Participants who completed the survey (whether or not they completed the remote eye-tracking experiment) were compensated according to Qualtrics' compensation policy. All participants viewed the informed consent page (including the details of the remote eye-tracking experiment) and agreed to participate in the survey study before they started the survey items.

Results

Table 1 presents the distributions of sociodemographic backgrounds, tobacco use history, and experiment completion of the sample (N=2023). Approximately half of the participants (1018/2023, 50.3%) were female, and more than half (1284/2023, 63.47%) were non-Hispanic White. More than half of the participants (1279/2023, 63.22%) smoked cigarettes on a nondaily basis, and most of the participants (1821/2023, 90.01%) had used e-cigarettes at least once in the past 30 days. Of the 2023 participants, 1887 (93.28%) initiated the experiment, and 777 (38.41%) completed the experiment. Of the 777 participants who completed the experiment, 381 (49%) generated usable data. When considering only mutually exclusive categories, 6.72% (136/2023) of the participants did not initiate the experiment, 54.87% (1110/2023) initiated but did not complete the experiment, 19.57% (396/2023) completed the experiment but did not generate usable data, and 18.83% (381/2023) completed the experiment and generated usable data.

Table 1 shows that biological sex (P=.02), marital status (P=.003), and the electronic device used for completing the experiment (P<.001) were all significantly associated with remote eye-tracking experiment completion. Post hoc analyses show that female participants were more likely than male participants to generate usable data compared with generating nonusable data (P=.01). Among those who completed the experiment, participants who reported having a partner, being single, or having *other* marriage status were more likely to generate usable data (P=.002) compared with those who were married. In addition, participants who used mobile devices were more likely than those who used desktop devices to generate usable data compared with generating nonusable data (P<.001).

Multivariable logistic regressions (Multimedia Appendix 1) show that no participant characteristic was associated with initiating the experiment. In the multivariable regression model that controlled for all covariates, including electronic devices used for the eye-tracking experiment, the results show that non-Hispanic Black participants (adjusted odds ratio [AOR] 0.64, 95% CI 0.45-0.91) were less likely to complete the eye-tracking experiment than those who were non-Hispanic White and that those who lived with a partner (AOR 1.69, 95% CI 1.25-2.28) were more likely to complete the experiment than those who were married. In addition, female participants (AOR 1.46, 95% CI 1.01-2.11), those who currently used e-cigarettes (AOR 2.08, 95% CI 1.13- 3.82), and those who used mobile devices (AOR 5.10, 95% CI 3.05-8.52) were more likely to generate usable data than male participants, those who did not use e-cigarettes, and those who used desktop devices, respectively.

Discussion

Principal Findings

This is one of the first studies to provide a detailed description of the use of remote webcam-based eye-tracking technology to examine attention to tobacco marketing materials, particularly in the context of a web-based sample of participants recruited from a large-scale crowdsourcing effort. This is also one of the first studies to delineate the participant characteristics associated with completing remote eye-tracking experiments and generating usable data. Overall, 49% (381/777) of the young adult smoker participants who completed the remote eye-tracking experiment generated usable data within a 20-day data collection period. This equates to generating usable eye-tracking data from approximately 19 participants per day, potentially signifying a higher efficiency than traditional eye-tracking studies conducted in a laboratory setting. Although the total participation duration for the remote eye-tracking experiment was approximately 5 minutes, approximately 90 seconds of this time was devoted to eye-tracking data collection.

Our results show that several participant characteristics were associated with the completion of the eye-tracking experiment (eg, race and ethnicity) and with the generation of usable (vs nonusable) eye-tracking data (eg, biological sex, current e-cigarette use, and device type). The information gleaned from this study can be used to guide future remote eye-tracking research efforts to investigate attention to tobacco marketing stimuli among various populations.

Remote Eye-Tracking Experiment Completion and Data Usability

Our study shows that of the 2023 participants who provided initial informed consent and started the web-based survey, very few participants (n=136, 6.72%) chose to opt out of the remote eye-tracking experiment even when all participants were informed that they needed to turn on their camera during the experiment and could still receive full compensation if they opted not to initiate the experiment. This finding suggests that, in general, our participants were open to participating in a remote eye-tracking task embedded in the web-based survey. In addition, according to our results, young adult cigarette smokers with various sociodemographic and tobacco use characteristics chose to initiate the experiment in a similar pattern, suggesting that receptivity may be high across various groups.

However, our results also show that more than half of the participants (1110/1887, 58.82%) initiated the remote eye-tracking experiment but did not complete it. There are several reasons why participants might not complete the experiment. Participants might have started the experiment but did not meet the technical requirements—such as having a

XSL•FO
RenderX

camera installed on their electronic device—or they may have been unwilling or unable to turn on the camera at this point once it became mandatory. In the case of those who turned on their camera, they might have had issues related to low internet speed or a webcam with a low sample rate that generated unsatisfying video resolution. In addition, some of these participants may have intentionally closed the browser or timed out before reaching the end of the experiment. This could be due to concerns about personal privacy or because the participants' environment prevented them from engaging in a webcam-based experiment at that time.

Furthermore, our results show that a portion of study participants (396/777, 51%) completed the experiment but did not generate usable eye-tracking data. This might be because of the lighting setup in the participants' environment (background light that was too dark or too strong) or large head or body movements during the experiment. Other possible reasons for generating nonusable data include participants not paying attention to the stimuli during the experiment and not following the calibration dots. It has been shown that eye-tracking data accuracy is directly determined by whether participants can focus on the stimuli with their full attention [27]. In addition, reflections from the participants' glasses may have interfered with the ability to collect eye-tracking gaze data.

Characteristics of Participants by Experiment Completion and Data Usability

Our results further suggest that the majority of our participants (1613/1887, 85.48%) who initiated the eye-tracking experiment used mobile devices rather than desktop devices. This distribution may reflect the overall electronic device preferences of the crowdsourced participants recruited from the web-based study panels. Importantly, our analysis shows that although participants who used mobile devices and those who used desktop devices did not differ in their completion of the experiment, those who used mobile devices were approximately 5 times as likely to generate usable data compared with those who completed the experiment on their computers. We suspect that this may be because of the fewer technical requirements needed to achieve high-quality data collection through mobile devices compared with desktop devices. Alternatively, mobile device users may have different user preferences and backgrounds that contribute to this outcome; for example, mobile device users may be more attentive to the social media marketing stimuli used in our experiment, and therefore they generate more usable data. Future research is needed to explore different contributing factors that lead to generating usable (vs nonusable) eye-tracking data between mobile and desktop users (and the potential implications of this) to inform researchers of best practices for performing such experiments on both devices.

We also found that current e-cigarette users were more likely than nonusers to generate usable data. It is possible that current e-cigarette users were more likely to be interested in e-cigarette–related marketing materials and therefore paid more attention to the stimuli, which resulted in their generating more usable data than non–e-cigarette users. Further analysis based on the eye-tracking data collected from this study will be used to investigate the differences in the eye-tracking metrics (eg, fixations and dwell time) related to viewing the e-cigarette marketing stimuli between e-cigarette users and nonusers. In addition, we observed that female participants were more likely to generate usable data than male participants, even after controlling for all other potential contributing factors. As this is one of the first studies to explore the sociodemographic differences in participants' completion of a remote eye-tracking experiment, little evidence is available to explain this difference among the sexes. In the same vein, little evidence is available to explain the demographic differences (race and ethnicity and marital status) that we observed in completion (vs noncompletion) of the remote eye-tracking experiment; for example, we observed that non-Hispanic Black participants were less likely to complete the experiment than non-Hispanic White participants. We suspect that participants' real-time environment (eg, at work or home, in public or private spaces, with or without others in the background) and engagement in other activities (eg, childcare and performing chores) when completing the experiment may be relevant to study participants' demographic characteristics. These factors may also lead to differential experiment completion outcomes because they may directly affect participants' willingness to turn on their cameras or affect their ability to follow instructions or fully engage with the experiment.

More studies are needed to look into potential explanations of these findings and take into consideration the implications of the differential completion outcomes from participants with various demographic characteristics. If future remote eye-tracking studies continue to show variance in completing the experiment among participants of different sexes and races and ethnicities, it may be necessary for researchers to oversample certain subgroups in remote eye-tracking studies to achieve a balanced data set. This may be particularly true for race and ethnicity and reaching Black and other underrepresented participants, given that one of the potential benefits of remote eye-tracking methodology is the ability to reach and include a more diverse sample, which is important in nicotine and tobacco research for addressing known health disparities.

Recommendations for Improving Experiment Completion and Data Usability

On the basis of our experience in implementing this study, we recommend several strategies to increase data completion and data usability rates for future remote eye-tracking studies. First, researchers can include certain technical requirements for participant eligibility, such as using high-speed internet and using a computer equipped with a high-speed camera. Second, researchers can add certain constraints regarding study completion in the informed consent form—such as participants needing to complete the remote webcam-based eye-tracking experiment, which requires turning on the camera—to receive the full compensation. This may discourage participants who do not wish to turn on their cameras from initiating the experiment and reduce the possibility of participants exiting the experiment before finishing. Third and last, researchers can show participants the instructions before or during the eye-tracking experiment, including reminding them to keep their heads still, avoid sitting near windows, and keep light

XSL•FO
RenderX

sources above or in front of them rather than behind them. Useful instructions for study participants to follow are presented in Textbox 1.

Textbox 1. Tips to be included in remote eye-tracking study instructions to improve data usability.

Before we begin, here are a few tips to help you to better self-calibrate:

- You must sit still and centered for the entire session.
- You must have a strong internet connection.
- Make sure you are in a well-lit room with no light or window behind you.
- Your computer should be placed on a steady table or desk.
- Make sure you are in a comfortable seated position.
- Make sure your sound is turned on.
- Please remove your glasses if you do not need them to see the screen clearly.
- If you need your glasses, ensure that you are in a well-lit room with no light source directly in front that can cause a glare.
- Before you start the session, ensure that you will have at least 5 minutes uninterrupted.

Potential Challenges of Conducting Remote Eye-Tracking Experiments

Given the promising utility of the remote eye-tracking experiment, it is important to note the potential challenges that may arise before and during such an experiment within academic settings. First, although our overall data usability rate was low, almost half (381/777, 49%) of those who completed the experiment generated usable data. Future studies may need to factor in potential data loss when planning participant recruitment and adopt strategies introduced in this paper to improve data usability rates. Future studies may also consider how remote and in-person laboratory studies may be used in tandem; for example, research might incorporate a remote eye-tracking study into a survey with a large participant sample to explore general viewing patterns of stimuli of interest, which may then stimulate research questions and hypotheses that are examined in a more controlled in-person laboratory study. Second, there are limited opportunities for researchers to obtain raw eye-tracking data through using the software. Only some categories of eye-tracking metrics were provided by the software (eg, fixation and dwell time), limiting researchers' ability to gain a more comprehensive understanding of the data generated from the experiments. Third, there may be challenges related to protecting participant privacy because remote eye-tracking data collection requires recording a video of the participant's face. It is recommended that researchers review and evaluate the privacy policies of the eye-tracking software, including limitations on transferring participant data (eg, personal identifiers or video recordings) to researchers or third parties and permanently deleting the data after certain periods of time. It is recommended that researchers include these policies during their submission of the study protocol to an institutional review board. Fourth and last, according to our findings, certain characteristics of study participants who generated usable eye-tracking data may be different from those of study participants who did not generate usable data or did not complete the experiment. Therefore, the results generated from remote eye-tracking experiments may need to be interpreted with caution to avoid population bias.

Study Limitations

The generalizability of our remote eye-tracking study may be limited because of the following reasons. First, the completion rates of the eye-tracking experiment among our participants—young adult cigarette smokers—may be different from those of similar studies among participants with different sociodemographic characteristics or tobacco use history. Specifically, young adults may be more skilled in successfully navigating the technical requirements (eg, turning on the camera) of remote eye-tracking software and less worried about web-based privacy issues than older adults. By contrast, older current cigarette smokers may be less likely to perform attention-intensive tasks such as repeatedly following the movements of dots and carefully viewing the assigned stimuli when they experience nicotine withdrawal symptoms [28]. This may be especially true when the eye-tracking experiment is embedded at the end of a survey after participants have already responded to a series of survey questions and when no additional compensation is provided to encourage the specific completion of the experiment. Second, it is possible that study participants who did not wish to take part in the remote eye-tracking experiment may not have agreed with the study consent to start with. Therefore, we were not able to assess the backgrounds and characteristics of this particular group. Third, the rates of completing the experiment and generating usable data may be different when the remote eye-tracking experiment is designed differently; for example, our experiment involves participants completing 2 calibration points and responding to a survey question at the end, which may be more complicated than other experiments that include 1 or no calibration points or no survey questions. Adding calibration points may improve the accuracy and usability of the data generated by the eye-tracking software but may also potentially extend the length of the experiment and reduce the experiment completion rate. Fourth and last, this study only introduced the process of designing 1 particular remote eye-tracking experiment using 1 particular software platform (ie, Sticky by Tobii). Experiments using other remote eye-tracking tools (eg, Webgazer.js) or with different study designs or experiment setups may involve unique challenges and generate different experiment completion outcomes [29].

Conclusions

Eye-tracking methodology can greatly advance researchers' and policy makers' understanding of individuals' visual engagement with marketing and communication materials in tobacco control research and tobacco regulatory science. Although in-person laboratory methods are considered the gold standard for collecting these types of data, recently developed remote webcam-based eye-tracking technology integrated with large-scale crowdsourcing efforts may be a particularly time-efficient and resource-effective tool for addressing limitations posed by in-person research. This paper describes the process of designing a remote eye-tracking study to explore young adults' attention to e-cigarette social media marketing materials. The experiment completion outcome data from this study are promising because the study generates usable eye-tracking data from approximately 19 participants per day during a 20-day data collection period. The study also provides information on the characteristics of study participants who might be more likely to complete the remote eye-tracking experiment and generate usable eye-tracking data. We believe that remote eye-tracking experiments, integrated with large-scale crowdsourcing efforts, will be a useful tool for the tobacco regulatory science research community to expand the collection of eye-tracking data on a variety of tasks relevant to the impact of tobacco marketing.

Abstract

Background: Management of operating rooms is a critical point in health care organizations because surgical departments represent a significant cost in hospital budgets. Therefore, it is increasingly important that there is effective planning of elective, emergency, and day surgery and optimization of both the human and physical resources available, always maintaining a high level of care and health treatment. This would lead to a reduction in patient waiting lists and better performance not only of surgical departments but also of the entire hospital.

Objective: This study aims to automatically collect data from a real surgical scenario to develop an integrated technological-organizational model that optimizes operating block resources.

Methods: Each patient is tracked and located in real time by wearing a bracelet sensor with a unique identifier. Exploiting the indoor location, the software architecture is able to collect the time spent for every step inside the surgical block. This method does not in any way affect the level of assistance that the patient receives and always protects their privacy; in fact, after expressing informed consent, each patient will be associated with an anonymous identification number.

Results: The preliminary results are promising, making the study feasible and functional. Times automatically recorded are much more precise than those collected by humans and reported in the organization's information system. In addition, machine learning can exploit the historical data collection to predict the surgery time required for each patient according to the patient's specific profile. Simulation can also be applied to reproduce the system's functioning, evaluate current performance, and identify strategies to improve the efficiency of the operating block.

Conclusions: This functional approach improves short- and long-term surgical planning, facilitating interaction between the various professionals involved in the operating block, optimizing the management of available resources, and guaranteeing a high level of patient care in an increasingly efficient health care system.

KEYWORDS

internet of things; artificial intelligence; machine learning; perioperative organization; operating rooms

Introduction

Operating rooms (ORs) are responsible for a large amount of profit and cost [1]. About 60% of all hospitalized patients are treated in the OR [2]. Surgical scheduling is a key process in perioperative organization; it begins by analyzing a list of daily cases and their expected duration. If cases consistently run longer, OR overuse will result in costly overtime pay and staff dissatisfaction. On the other hand, if actual case times are shorter than expected, OR underuse will lead to staff idle time, which is associated with up to 60% higher costs [3-5]. Also, decisions about the number of surgeries to perform during a typical day or week of activity in the OR have a considerable impact on downstream resources and on the efficient flow of patients in the system. Combining higher-level decisions, optimization logic, and management policies with an analysis of the consequences of these decisions that is enabled by simulation tools is an effective approach in health care [6-8]. Also, simulation is useful for testing the expected performance of a process, as well as its performance when it has been revised, modified, or optimized, before implementing it in practice and can also evaluate unexpected scenarios. Case duration prediction is usually demanded by the surgeon who reserves the time slot. With this method, it has been proven that surgeons underestimate case duration up to 42% of the time and overestimate it 32% of the time [9]. Another common approach is to use the electronic health record (EHR) to calculate case duration based on historical data for a given procedure. Decisions based on EHRs have a higher accuracy [10], but available EHRs only generate case durations for the average patient and do not take into account the patient's specific profile (eg, their age, sex, BMI, allergies, or comorbidities). The rise of big data offers novel possibilities for patient-targeted predictions by exploiting machine learning (ML) and deep learning (DL) techniques. In particular, supervised learning techniques are able to identify latent patterns among large quantities of data by training the model to minimize a loss function between the actual output and the desired (ie, supervised) one. The model is afterward able to generalize on unseen cases that belong to the same data distribution. For this reason, ML is also gathering attention in the medical field for both clinical and organizational purposes. Notwithstanding this, we are still in the early phase, and there are several challenges to deal with [11-14] .The main issue to exploit ML is providing accurate and noise-absent samples to the model, which is critical when historical data are collected by human processes. In light of this, the aim of our research project is to develop an integrated technological-organizational model capable of exploiting data derived from ORs to optimize the management and organization of the whole operating block. To achieve such a result, we have first developed an internet of things (IoT) architecture that is able to collect real data to minimize the presence of errors or noise in data and maximize ML performance. Next, we will proceed to develop an optimal scheduler for surgical procedures supported by simulation and able to integrate clinical and anamnestic information with data derived from an analysis of surgical timing and time spent in the recovery room (RR) so as to optimize the system's organization [15].

Methods

Overview

Our research work is a prospective, single-center, interventional study. Patients are included if they are older that the age of majority (18 years in the country where the protocol was drafted); provide signed informed consent; and are undergoing elective abdominal, thoracic, vascular, gynecological, or plastic surgery. If the patient agrees to participate in the study, data will be collected on the expected and actual time from the patient's entry to the operating compartment to their exit. In particular, time spent in the operating room, surgical time, and length of stay in the operating room will be recorded. This information will be integrated with anamnestic data and data relating to hospital stay [16-18]. The goal is to create a technological-organizational programming model able to optimize operating block management. In this work, we identified 50 simple variables for each patient. These features will form a single data set instance. We decided to focus our attention on ML methods instead of traditional methods, as the latter may not be sufficient for this task, often requiring assumptions about data distribution, and may not be able to handle the complexity and volume of the data that we want to use to make predictions. On the other hand, ML methodologies can capture nonlinear relationships between variables, which can be important for predicting times accurately. Moreover, ML algorithms can benefit from large amounts of data to identify patterns, and EHR data contains a large number of variables, including patient anamnestic data, medical records, and surgical details. ML algorithms can extract knowledge from this data and use it for making a much better and more accurate prediction. Finally, ML methods can handle outliers, which can be common in EHR data, and ML methods can generalize well to new data. This is important because we can make predictions for surgery time for patients who are not in the original data set. In this study, we will collect data from 1200 patients. Bearing in mind that this data set will have to provide data to both create the model and validate it, the data set will be divided into 3 parts: a training set (60%), a validation set (20%), and a test set (20%). The project is divided into three phases: (1) using the IoT for data collection and patient enrollment, (2) machine learning for time prediction, and (3) optimization with discrete-events simulation.

In the first phase, which forms the focus of this paper, we developed an IoT architecture to perform indoor localization of patients in ORs and in RRs. Patients who decide to participate in the study are asked to give informed consent. If they agree, they are provided with a personal Bluetooth Low Energy (BLE) beacon tag when entering the operating block or in the ward. The tags are detected by detectors (Raspberry Pi devices; Raspberry Pi Ltd) that are located in the environment of interest. The detectors communicate with a private local area network

XSL•FO
RenderX

(LAN) to manage data flow and to provide additional security levels. Moreover, the LAN does not have any internet access, so the network is not vulnerable to any external attacks. The access to the server, to the sensor configuration module, and to the association interface is password protected and all communication to the server is encrypted. In this section, we describe the components and our solution for monitoring patients' movements inside the surgical block. We realized a client-server architecture that provides communication between the sensor modules and the server in our system. The whole IoT system has several parts, which are listed below.

BLE Beacons

BLE is a wireless communication technology designed for low-power devices that require short-range connectivity and is widely used in IoT environments [19]. BLE technology operates on 2 main channels: advertising and data. For our purposes, we decided to use only the advertising channel in order to detect beacons when they are near to our sensors. For this reason, we adopted the iBeacon protocol (Apple Inc). The iBeacon protocol identifies beacons with a triplet of universally unique identifiers (UUIDs). For this prototype we used the BlueUp (BlueUp Srl) beacon, which has 800 milliseconds of advertisement time. Each patient will be associated with a beacon connected to a numerical, progressive, and anonymous ID to respect patient privacy. The beacon is assigned to each patient and is worn as a bracelet with a wrist band. Being affixed to the patient's wrist is the best compromise between comfort and signal efficiency.

Sensor Modules

As a sensor module, we used a Raspberry Pi 4 device running the 64-bit Raspian OS. The sensor module continually scans for BLE advertisements, checking them against a list of preregistered beacons provided by the central server. Using a list allows us to ignore nonregistered beacons, saving bandwidth and processing resources. The sensors autoconfigure themselves. They can be rebooted or shut down at any time. When the sensors receive a beacon advertisement, they append the package received and its timestamp into a JSON file and forward the information to the central server over a transmission control protocol.

We estimate the patient's presence inside a specific room in the operating block using the residence time within the range of action of the sensor. Every sensor has its own residence time and a tunable threshold of signal sensitivity. This last parameter can increase or decrease the sensor's range of action. If the beacon remains for a certain amount of time in the action range of a sensor, the beacon is marked as entered into the room.

Central Server

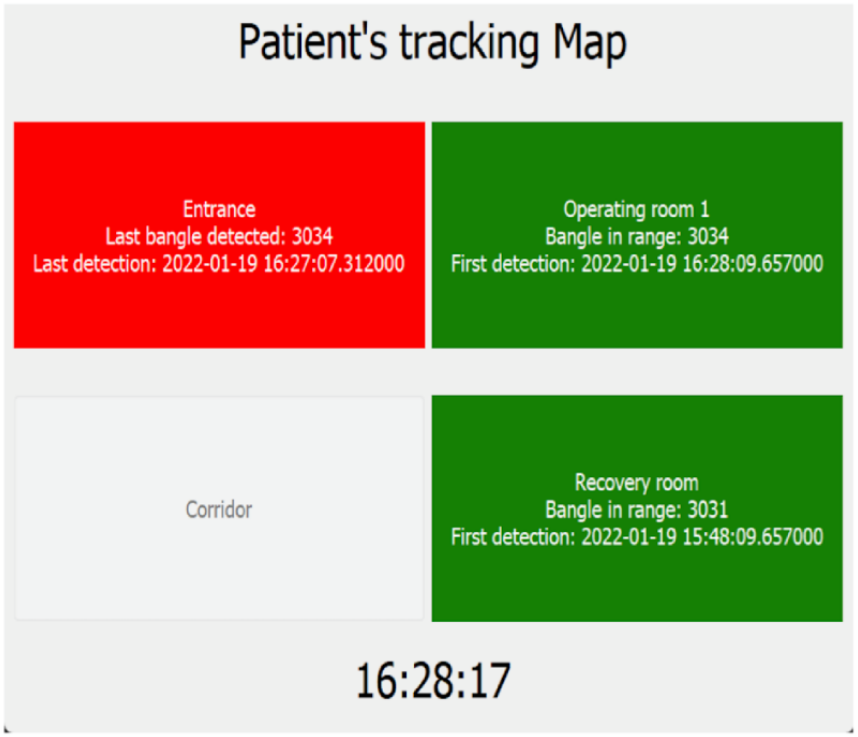
The central server indexes and collects the data coming from the sensor modules. It has the following duties: (1) storing records coming from each detector in a MongoDB database (MongoDB Inc); (2) coordinating distributed solution and message exchange using a publish-subscribe mechanism based on message queue telemetry transport (MQTT), and finally, (3) exposing a web server that is used as a unique interface between the software architecture and the hospital medical staff. The central server hosts the eclipse Mosquitto-based MQTT broker (Eclipse Foundation Inc). When it receives the packets from the sensors, it determines whether the beacon is in the room where the sensor is located. Our implementation of the beacon server used a Python-based service and exploited the MongoDB database to store the various events. The data format is shown in Table 1. The central server also has the duty to send information to the edge modules regarding the list of preregistered beacons, the identity of the sensor itself, and a time-synchronization message.

Table 1. Data stored by the server for each sensor when an entry is recorded in the database.

Fields	Description
uuid	Universally unique identifier for the beacon
minor	Contains the unique beacon ID
macAddress	Beacon MAC address
timestamp	First detection timestamp
last_detection	Last detection timestamp (continuously updated)
flag	Boolean value that if true specifies that the patient is currently in that specific room
Patient ID	Unique number assigned to a specific patient

Client Interface

The client interface, hosted by the central server, offers several functionalities. The first is enrollment. Patient enrollment is done by a member of the medical staff when the patient enters the operating block to undergo surgery. The enrollment is performed using a tablet device that communicates with the web application and by providing the necessary information. The system also provides a graphical interface able to monitor in real time the various movements of patients (Figures 1 and 2).



XSL•FO
RenderX

Figure 1. Screenshot of the home page of the web application responsible for the beacon-patient association. (In the web application, the term “bangle” is used to describe the beacon.).

XSL•FO
RenderX

Figure 2. Screenshot of the graphical interface for monitoring patient movements inside the operating block. Green cells indicate that the patient is near the sensor that is associated with that specific room or place. Red cells indicate that no tracking device has been detected for some time. Finally, gray cells indicate that there is no tracking data for that place.

Ethics Approval

The study was approved by the Comitato Etico Unico per l'Area Vasta Emilia Nord, a local ethics committee (1284/2020/OSS/AOUPR), and was registered on ClinicalTrials.gov on January 11, 2021 (NCT05106621). Written informed consent was obtained for all study participants. The participation of individuals of legal age capable of giving informed consent as subjects in medical research must be voluntary (World Medical Association Helsinki Declaration). The data are collected anonymously and with respect for the privacy of patients.

Results

This research was financially supported by the FIL-Quota Incentivante program of the University of Parma and cosponsored by Fondazione Cariparma with approval in the second half of 2019. As of February 2023, approximately 1000 patients have been enrolled, with an enrollment target of not less than 1200 to 1300.

We schematized a generic path a patient could follow inside the operating block (Figures 3-6).

In addition, if a patient agrees to participate in the study, we collect the following: data about the surgical procedure, personal and anamnestic data, data from the RR, and data on the hospital stay, such as whether the patient was admitted to the intensive care unit.

The prototype of the IoT architecture described and illustrated above was installed successfully in the surgical block and is still functional. We collected data from more than 100 patients. It is possible to see in the final output illustration (Table 2) that combining the data from various sensors allowed us to reconstruct the patient's path.

The second step will involve the application of ML and DL algorithms to study the feasibility of predicting surgical procedure time by providing features of the patient and of the surgery as input. Because of the lack of public data sets or similar approaches in the scientific literature, we are currently performing a feature selection task among more than 50 variables to identify which features can maximize prediction accuracy in terms of the root mean squared error of surgery time. Several ML approaches are possible since the task of intraoperative time prediction can be modeled in different ways. Since the total time in the operating block is the sum of the time spent in the OR and in the RR, this prediction task can be modeled using 2 different ML models or a unique one that tries to directly estimate the total time. Moreover, depending on the data set size, tree-based ensemble models (eg, gradient boosting or extreme gradient boosting; XGBoost) could better suit the task. On the other hand, the complexity of the task and the nonlinear dependency of several features within the target variable of "time required" may require the use of deep neural networks. DL requires larger data collection, but at the same time, it would be possible to exploit its ability to perform representation learning of the input, requiring less feature engineering.

RenderX

Figure 3. Generic patient path illustration within the operating block. The patient accesses the operating block at tracking point 1. Then, the patient's stretcher is swapped at point 2, and a member of medical staff assigns them a beacon and sets up the associated ID. Next, the patient goes to the assigned operating room (point 3). Once the surgical procedure ends, the patient is transferred to the recovery room (point 5), where they are monitored after the procedure. The patient can then either exit the operating block from point 6 or can return to the operating room if there are acute surgical complications. Moreover, during these activities, the patient can remain idle at an unspecified point in the corridor, represented by point 4. Personal data are extracted from the information systems of the Ospedale Maggiore of Parma using pseudoanonymization techniques.

Once ML is trained to predict the surgery time, we will proceed to step 3, which is the use of simulation models of discrete events. In these models, an "event" is an instantaneous occurrence that involves a change in the value of at least one of the system variables; for instance, it could be the entrance of a new patient, the exit of a patient from the system, or the transition of the patient from one room to another. The goal of the simulation model is to reproduce the patients' path within the operating block (including the preoperative, operative, and postoperative phases) to optimize their flow in the system. To this end, some selected key performance indexes will be embodied in the simulation model; examples of these indexes are the number of patients treated daily, use of the OR, and the need for extra time working in the OR. Simulation will be first used to evaluate these indexes in the current scenario ("as is" analysis) then to reproduce new logic for scheduling surgical interventions ("to be" re-engineering) based on multiple prioritization logics or multi-objective optimization. The improvement achieved in the performance indexes will also be evaluated [20].

Discussion

Principal Findings

The use of artificial intelligence (AI), and in particular ML, is expanding in every area, including health care. Many results are now available on the excellent predictive capabilities of these new tools in medicine. Thanks to their use, intelligent tools useful to support health care professionals in daily practice will be increasingly available. Their possible exploitation in the health organization is no exception. Liu et al [21] showed that ML is superior to logistic regression for risk estimation in the context of hospital performance assessment. Furthermore, similar applications can be found in the context of forecasting health care costs, risk of readmission, and hospitalization [21-24].

The study by Luo et al [24] is also very interesting; ML models were applied with the intent of estimating the risk of cancellation of an operating session with the negative impact that this entails both in terms of costs and on waiting lists; therefore, cancellation also translates into delayed access of the patient to surgery. Moreover, a novel approach has been presented by Abbou et al [25]. The authors gathered EHR data from December 2009 to May 2020 for a total of 297,480 interventions at 2 public hospitals in Israel. They predicted the duration of the surgery based on preoperative data, including patient clinical data, the experience of the surgeons, patient nationality, and results of analyses carried out before the operation. They compared the predictions between a naive model and an ML model (XGBoost) with various metrics and found that the use of big data was useful for predicting the duration of interventions in the operating room and that the ML model performed better than their naive model.

However, to apply these models, it is essential to obtain data with quality and precision. Currently, recording times and patient movements within the surgical block is often done manually by the various medical staff involved and subsequently reported in computer systems. However, this detection method is often partial and usually not done in real time. The possibility of enabling direct recording with minimum human interference could increase the quality of the data set and let us obtain more precise results [26-28]. Furthermore, having a system equipped with the ability to independently record the patient's movements, besides reducing the error rate, could allow for lightening the workload of the medical staff themselves and indirectly reducing the changeover time between different patients [24,28-32]. Nevertheless, building a tracking system inside a hospital is not a simple task. Not all hospitals are equipped with the highest technology available. Some hospitals are small and do not have sufficient resources available to install high-technology organizational systems. Others, despite being larger in size, have old structures in which it is not always easy to implement new technologies. Therefore, we decided to look for a solution that suits our needs and is economical, does not require an expensive infrastructure, and is achievable in most situations.

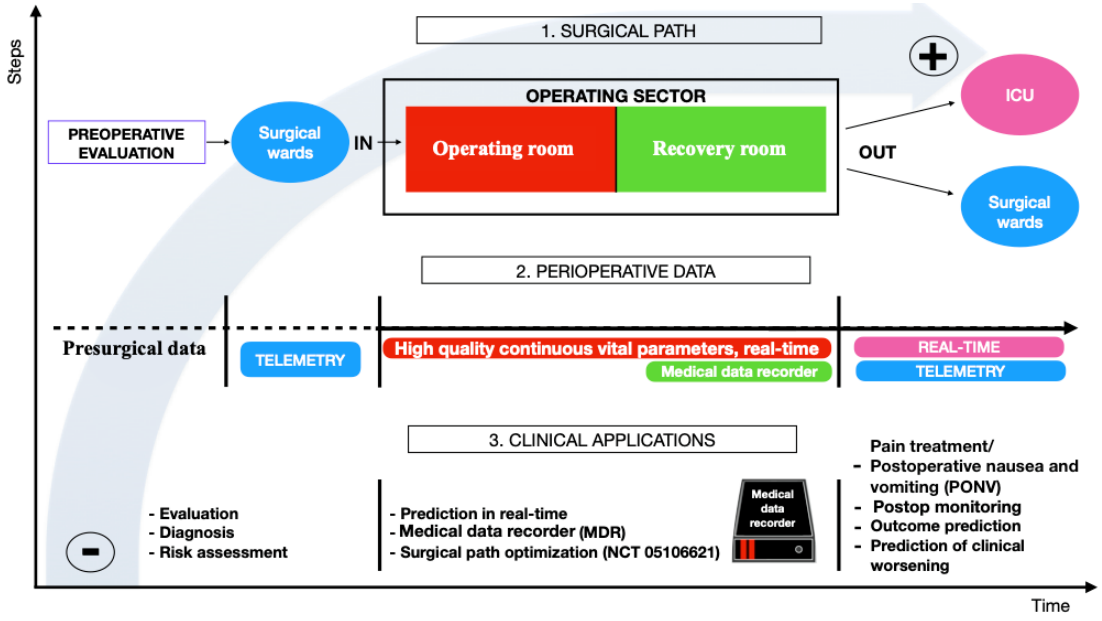
To understand which technologies were the best for our use case, we decided to analyze several options and constraints. The main constraints encountered were ease of installation, the tracking device's battery life, and the tracking device's reuse and cleaning.

Considering these major constraints, we analyzed and considered several technologies. The first was radio frequency identification (RFID); unfortunately, this technology had a cumbersome structure for tracking and the range of action was limited, which could have brought discomfort to the members of the medical staff. Moreover, the RFID device's battery life was not sufficient for our case study. Next, we analyzed ultrawideband (UWB),

XSL•FO
RenderX

which was discarded as well due to the low autonomy of the devices. Finally, we decided to use a BLE tracking device.

BLE fitted our use case because the detectors are small and easy to install, the device's range of action is very wide, and the tracking device's battery life can last several months. Furthermore, our use case does not involve tracking health care personnel, only patients.



Building a tracking system using BLE also has economic advantages; it does not burden the hospital budget and is cost-effective. The system presented above can trace the movements of patients within the OR. The data obtained will form a data set that can be used to perform ML tasks. By combining the tracking data with clinical assessment data, it will be possible to create an algorithm capable of predicting the duration of a specific surgical intervention.

The IoT architecture developed in this study will be useful to collect real data about patient flow in the surgical department. Nonetheless, having solid data and predictions about OR occupancy is still not enough. It is also necessary to create organizational systems capable of using that information. In fact, not being able to transform these results into intelligent tools that can be used in daily practice has been recognized as one of the major limitations that currently hinder the use of these technologies in medicine [33]. To overcome these limits, a simulation model will be developed for reproducing patient flow in the operating block. This model, fed with high quality data, will be used to determine the best scheduling logic in order to optimize the use of resources in the OR. Preliminary testing of the model was performed using randomly generated patient data in an attempt to check its effectiveness in reproducing the system, as well as to embody alternative scheduling logics and return the performance indexes as outcomes. Results, both in terms of the model capability to reproduce the current system and in evaluating its performance, are promising and at the same time highlight the potential for improvement in the efficiency of the surgery department, which is the ultimate aim of the project. In a more advanced phase of the research, the simulation and scheduling logics will be enhanced and further improved by the availability of accurate predictions enabled by an ML model. In general terms, it is expected that an accurate evaluation of patient flow (based on real data) and a reliable prediction of surgery cases (based on the ML model) will make it possible to optimize planning of surgical procedures, consequently decreasing unused OR time and hopefully increasing the number of surgical interventions in a day. This is an innovative aspect of the whole project; indeed, although ML, simulation, and scheduling have been applied in health care environments, their combined use opens new ways for process improvement. This approach, thanks to its consistent predictive performance over various forecast intervals, can positively influence the choices of health care personnel for short-term and long-term strategic planning [34-36].

Conclusions

Surgery has a great impact on the health economy; thus, optimal management of resources destined for the OR becomes crucial. Considering the literature and our preliminary results, it therefore seems possible to assume that the application of AI models in the context of OR organization, associated with an indoor patient traceability system, is not only feasible but could also lead to more targeted organization (Figure 7) [37,38].

Abstract

Background: This nonrandomized exploratory intervention and feasibility study examines how digital assistive technology (DAT), comprising a DFree ultrasound sensor, affects nursing care for continence support and evaluates nurses' willingness to incorporate DAT into the planning and practical implementation of care processes.

Objective: The relief provided by DFree in the clinical care setting and the extent to which it supports nursing care for activities of daily living pertaining to "micturition" is unclear. DAT DFree is expected to reduce nurses' workload in clinical continence-care settings and was designed as a human-technology interaction that ensures a high level of usability for the subjects (ie, the nurses) and increases user acceptance by at least one level (eg, from average to slightly above average) during the study.

Methods: Approximately 45 nurses from neurology, neurosurgery, and geriatric medicine clinics and polyclinics at the University Medicine Halle will be included in the 90-day (3-month) intervention on-site in the respective wards. After the wards are equipped with digital technologies, the participating nurses will be trained to use DFree and will be able to select DFree as a possible patient-care resource if the anamnesis includes bladder dysfunction among only patients who are willing to participate. The willingness of nurse participants to use DFree in planning their care process will be assessed using the Technology Usage Inventory at 3 measurement points. The primary target values include the results of the multidimensional Technology Usage Inventory assessment that will be processed using descriptive statistics. Ten participating nurses will be invited to conduct extensive guided interviews that are intended to provide information about the device's usefulness and feasibility in the specific field of continence care and possible improvements.

Results: It is expected that the intention to use will be confirmed by nurses, and the number of nursing problems, such as bladder dysfunction-induced bedwetting, will be reduced with a high rating of DAT usability.

Conclusions: First, this study aims to produce multilevel innovative impacts, including practical, scientific, and societal effects. The results will provide practical solutions for workload reduction in the field of nursing support for continence care, where digital assistive technologies are becoming increasingly important. The DFree ultrasonic sensor is a new technical tool for the treatment of bladder dysfunction. Generating feedback to improve technical applications can increase the user-friendliness and usefulness of the device.

KEYWORDS

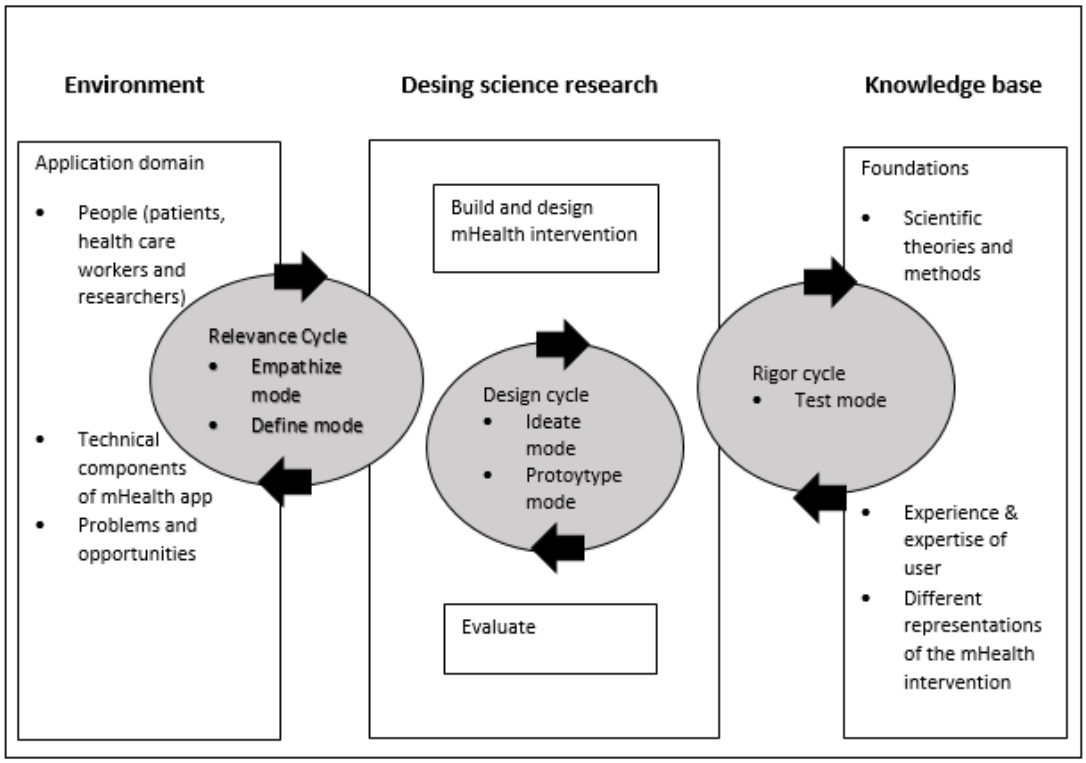
bladder control; bladder dysfunction; continence care; digitization; incontinence; nursing; selfmanagement; ultrasound; urology; user requirements

Introduction

Bladder dysfunction is a health problem that affects approximately 50 million people worldwide [1]. Urinary diseases are diverse and range from simple cystitis to acute postrenal kidney failure [2]. Physical limitations caused by bladder dysfunction can lead to other problems, such as general insecurity, iatrogenic damage, shame, skin damage, irritability and cognition or instability, and the risk of falls [3]. Bladder dysfunction increases the workload of nurses and the costs of care facilities [4-7]. In a rapidly aging society, the number of people with bladder dysfunction will continue to increase [8,9]. "Excretion support," as part of planned, professional nursing care processes pertaining to the activities of daily living [10,11], benefits from digitization when it improves structure, process, and outcome quality in continence care [7]. New digital assistive technologies (DAT) [12,13] possess great potential for meeting both current and future challenges in continence nursing care [14] as DAT promote independence and participative opportunities for individuals with urological conditions [15,16] and support the care of people with bladder dysfunction [17-20]. As the ability to control bladder muscles represents a milestone in achieving independence in early childhood, the loss of bladder control is psychologically stressful. People affected by bladder disorders often isolate themselves and subsequently experience dramatic reductions in their quality of life [4,21-23]. Besides societal problems such as social isolation, exclusion, and loneliness, bladder dysfunction represents a significant risk factor for more frequent hospitalization and nursing home admissions [24]. For example, an increased risk of hip and thigh fractures was associated with urinary incontinence and nocturia [23]. Despite the availability of an increasing number of DAT to support continence care [6,20], the health systems mostly use wearable absorbent products or absorbent pads to report urine leakage and alarms that are evinced with audible, visual, or graphic signals [4-6]. DFree enables incontinence relief by predicting micturition needs and helping people regain control of micturition [25,26]. However, the relief DFree provides and the willingness of nurses to use DFree remain unclear. Despite the high degree of user acceptance demonstrated within a group of patients in preliminary studies [14,19], the questions of workload reduction in continence care for nurses and cost reduction for continence care materials remain unanswered. To bridge this research gap, this study investigates the use of DFree Professional in an inpatient care setting to extend the results of the previous groundwork. This study examines how the DFree Professional facilitates continence care in the inpatient setting and how health and nursing care professionals assess the "usability" of this DAT. Usability refers to the quality of technology use through human-technology interaction, specifically in relation to nursing professionals and their adoption of DAT in their nursing process planning, and this encompasses several aspects, including significance, transparency, and physical access to sociotechnical components, as well as meaningfulness and effectiveness, all of which should be easily accessible to users [27,28]. Usability in this sense depends "on the significance, transparency, and physical access to sociotechnical constellations" [28] as meaningfulness and effectiveness must be particularly accessible to the users [27,28]. Therefore, the following specific research objectives will be evaluated:

1. As a primary objective, it is assessed how DFree supports and facilitates free professional continence care by nurses in inpatient care settings?
2. Identify and describe changes and barriers in the intention to use (ITU) DFree.
3. As a secondary objective, nurses' reception of integrating sensors and the associated software into the operational organization of inpatient care processes, as well as cocreative designing of a process that has a high level of acceptance, get surveyed.

Methods



Design and Conceptual Framework

To ensure that the DFree achieves high usability and acceptance, this study uses a mixed methods design and follows the methodological specifications of a cocreative user-centered design (UCD) that was previously described by Farao et al [29]. UCD is used to determine the context of mobile health apps and the consequences of their implementation from the design stage [29,30]. The implementation of mobile health apps without end-user involvement compromises desired outcomes and leads to unmet health goals and adverse outcomes [29,31]. UCD is an evidence-based approach that involves end users in the development and implementation of technologies and prioritizes their needs [29,32]. The 2 proven UCD approaches comprise the information systems research framework (ISR) and design thinking (DT). The ISR comprises 3 cycles that integrate the everyday realities of end users (relevance cycle) and the scientific and economic knowledge base (precision and rigor cycles) into the development of technical products (design cycle) [31,33-35]. Furthermore, DT uses different modes that occur in iterative processes; the empathize mode determines the end user's initial understanding, which is further analyzed in the defined mode to identify specific needs. Subsequently, the development of a technical product undergoes several rounds of ideation (idea mode, ie, generating multiple ideas), prototyping (prototyping mode, ie, translating ideas into physical representations), and testing (testing mode, ie, refining and improving the prototypes and simulating their use in context). In a further step (implementation mode), a medium- to long-term result evaluation is undertaken that possibly leads to the first step for determining need [36]. Despite these advantages, both approaches have disadvantages. The role of stakeholders in ISR is unclear, particularly in the relevance cycle. This means that scientists are primarily responsible for laboratory and field tests and that stakeholders only participate to a small extent in the planning and implementation stages. In the design cycle, the

XSL•FO
RenderX

technical requirements are disconnected from feasibility, whereas in the precision cycle, economic interests dominate the users' points of actual applicability [37]. In DT, the components that improve usability and effectiveness are unclear, and there is no evidence of the generalizability of the identified key needs to a broader group [36]. UCD combines these 2 user-centric approaches and thereby balances the disadvantages of 1 model with the advantages of the other (Figure 1) by combining empathy and the definition mode of DT and integrating the relevance cycle of ISR [29]. Both approaches show positive effects for improving the identified outcomes, higher usability, and user acceptance of technical products [36,37]. Additionally, the combination pursues the purpose of specifying technology requirements with regard to needs assessment as well as improving cooperation between scientists and end users. Thus, intervening in the precision cycle (ISR) with the test mode (DR) connects the knowledge base of the precision cycle with end-user cooperation for product evaluation, as relying only on the test mode is inadequate to enable further technical product development. Instead, the abovementioned combination makes it possible to include health goal attainment as an evaluation factor of product function and success. In particular, with regard to the design cycle mode, the preliminary work of the research group helped to modify the tasks of this project [14]. The design cycle of the ISR is linked to the idea and prototype modes of the DT. With this combination, end users participate in technical (further) development. An advantage of ISR is that the necessary knowledge for further technical development emerges from empirical results, whereas in DT, the knowledge emerges from end users and developers. Thus, the combination of both approaches was suitable for implementation in this study because of the possibility of comparative analysis to improve DFree by factoring in the interests of users and developers, besides increasing usability. Peters and colleagues [38] showed that usability alone does not enable statements on the actual ITU by potential users, as the satisfaction of basic human needs is a decisive factor in "usability" [28,38-41]. In Basic Psychological Need Theory, the more interaction with a system that satisfies basic psychological needs, the greater the technological engagement of end users [41]. Three basic psychological needs describe more proactive, committed, passive, and demotivated human characteristics: competence (ie, feeling capable), connectedness (ie, feeling connected to others), and autonomy (ie, feeling self-determined) [39-41]. Accordingly, the technological influence on end-user well-being can be better understood and evaluated if the abovementioned 3 basic needs are considered in the developmental process [38], as the needs function as mediating variables between a technical product and the end users' ITU. This means that an increase in autonomy leads to higher engagement. Motivation to use increases with higher competence, whereas increased connectedness increases well-being and ITU. The model assumes that psychological needs consider 5 different levels of analysis: starting with the introduction of technology (adaptation), through interface interaction (interface), dealing with technology-specific tasks (task), technology-supporting behavior (behavior) for the entire life of the end user (life), and the societal level (society). In the METUX model, the basic psychological needs for autonomy, competence, and connectedness positively mediate the design and outcomes of the end-user experience, such as motivation, engagement, and well-being. These variables represent specific, measurable parameters that developers can use to support the fulfillment of basic needs.

RenderX

This monocentric, exploratory, mixed methods study was planned with multiple measurement times that correspond to the "Evaluation" phase in the Medical Research Council framework [43]. Therefore, a concurrent mixed methods design was used to facilitate the concurrent collection of different forms of data, separate analysis of the data, and final merging of the findings [44,45]. By combining qualitative descriptions of nurses' experiences with quantitative ratings of nurses' ITU, we developed more comprehensive knowledge of the influence of DAT DFree in reducing nurse workload in continence care. This study is the first to test and evaluate a DFree ultrasonic sensor in an inpatient care setting with patients and various health care providers (nurses and physicians). In a (cocreative) process for the integration of DFree into the operational organization of the ward's everyday routine, concrete scenarios are outlined to make DFree usable for practical implementation. Finally, we will collect data on user acceptance while testing the DAT under real-world, everyday ward conditions.

Technical Description

The DFree Ultrasound Sensor (Triple W Japan KK) is a DAT that comprises 2 parts: a controller and an ultrasound probe that has the potential to predict the need for voiding (Figure 2).

DFree is a supportive tool for patients with bladder dysfunction. The basic principle of the sensor is based on measuring the degree of bladder expansion during filling by using ultrasound measurements, which then notifies nursing professionals through a signal emitted through an iOS operating system app. For this research project, it was necessary to connect the "Wi-Fi Base Station" to the network of the hospital, which comprises internet access (Figure 3). Owing to the strict security measures of university data centers, this interface issue is a specific challenge in the implementation of projects and introducing data analysis technology into health care provisions in general.

DFree uses ultrasound waves at 10-second intervals to measure the degree of change in the urinary bladder during urine filling. A dedicated notebook app provided information on the expected timing of the next visit to the toilet. The display of bladder filling on the screen can be scaled to 10 levels, triggering an alarm when an individually set threshold is reached. The digitally captured degree of bladder expansion was converted into a numerical value and displayed on a mobile phone or notebook app. Thus, DFree represents a potential supportive therapy option for bladder dysfunction that could help nurses reduce their workload.

Figure 2. DFree ultrasound sensor.

Figure 3. DFree data transfer.

Quantitative Evaluation

Figure 4 shows technology-specific (orange) and psychological (blue) factors of the Technology Usage Inventory (TUI).

As shown in Figure 4, the 8 TUI scales are divided into technology-specific (orange) and psychological (blue) factors and grouped around the ninth scale, ITU. The wording of the individual items, with the exception of the scales "anxiety in technology" (Technologieängstlichkeit = ANG) and "interest" (Interesse = INT), is related to a specific technology. Each scale comprises 3 to 4 items, each of which is to be rated on a 7-point Likert scale. The INT scale uses 3 items on a visual analog scale to record the ITU's specific technology. Overall, the TUI consists of 33 items and encapsulates a modular design whereby individual scales are excluded and item formulations must be adapted to the circumstances (eg, specific naming of technology). The internal consistencies of the scales can be rated as good overall (Cronbach α=.70 to α=.89). Furthermore, the TUI scales (with the exception of ZUG) based on heart rate and heart-rate variability have been positively validated as indicators of stress and were positively validated as indicators of stress and relaxation [46]. Except for the immersion (IMM) scale, all the scales offered by the TUI were used in the DFree study. Immersion refers to the evaluation of the intensity of sensory impressions when using a specific virtual reality app, and this scale is excluded because it was not part of the research question (Table 1).

XSL•FO
RenderX

Figure 4. Technology Usage Inventory assessment (adapted from Kothgassner et al [46], with permission from Oswald Kothgassner).

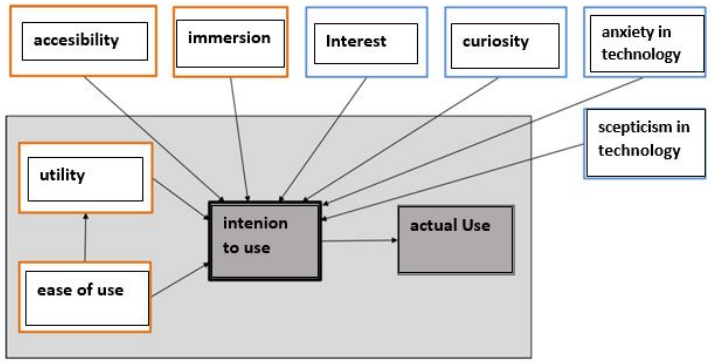

Table 1. Description of the Technology Usage Inventory Scales.

Scale	Description
Curiosity (NEU)	Curiosity and inquisitiveness of a person regarding a specific technology
Fear of using a technology (ANG)	Regardless of specific technology. Overwhelm, fear of using technology
Interest (INT)	Regardless of specific technology. Interest in technology and willingness to obtain information independently
User friendliness (BEN)	Perceived user-friendliness (in the sense TAM[a]) of a specific technology
Usefulness (NÜT)	Perceived usefulness (in the sense of TAM) of a specific technology. Refers to support in everyday life.
Skepticism (SKE)	A person's skepticism and distrust about the use of a specific technology. Assessment of risk, danger, disadvantages
Accessibility (ZUG)	Perceived accessibility (in the sense of availability, buying process) of a specific technology
Immersion (IMM)	Refers to virtual reality apps and is therefore not used here.
Intention to use (ITU)	intention to actually use a specific technology.

[a]TAM: Technology Acceptance Model.

In this study, 3 measurement times (T1, T2, and T3) have been defined (Table 2), and the questionnaire is used at each time point. Before the commencement of the application test (adaptation in the relevance and design cycle), the TUI I Original questionnaire pre-post version—TUI Prä—is used to collect data on a general tendency about technology (fear and curiosity) in the group of nurses before the prototype is introduced. At T2, the prototype is presented for the first time and is thus introduced (design cycle of the interface analysis level). Therefore, the TUI II parallel questionnaire (complete version) will be surveyed in its entirety, and the scales INT, BEN, NÜT, SKE, ZUG, and ITU will be introduced to the nursing staff. At T3 (DT prototyping: testing and implementation mode), measurement will be undertaken, and the group of nursing professionals will test DFree wherein the full version of the TUI II parallel questionnaire (complete version) is represented. The measurement allows statements about changes in the ITU.

For the evaluation, a cumulative value was formed for each scale wherein the ticked answers were added, whereby some items had to be reversed beforehand. The cumulative value starts with 1 as the lowest level of the construct and, depending on the number of items, ranges from 21 (3 items) to 28 (4 items; the highest level). The ITU Scale is an exception because, to evaluate this scale, we measure the distance from the right end point (full rejection) to the answer at the intersection of the line. The distance in millimeters was determined and added to all 3 items (A, B, and C). The maximum scale value achievable is 300. Total scale values are converted into standard values (stanins and percentage rankings) using a standard table (Table 3). Thus, a statement of the relative proportion of participants who achieved the same or lower values is feasible. Therefore, a percentage ranking between 40 and 60 represents the absolute average [46].

The System Usability Scale (SUS) assesses the usability of a system that is subjectively perceived by the user and is demonstrably technology-independent, that is, SUS can be used for a wide range of systems and technologies [47,48]. The 10 items of the SUS are divided into 5 positive and 5 negative statements, each of which is represented on a Likert scale from 0 to 5. The responses are used to derive the SUS item score, which is then converted into the overall SUS score (from 0 to 100). To calculate the overall SUS score, the raw value minus 1 was calculated for all odd items in the first step, whereas the raw value of 5 was subtracted from the even items. For example, if item 1 had a raw score of 4, the score would be 3 (obtained as 4 − 1). For item 2, if the raw score was 2, then the score was 3 (derived as 5 − 2). Next, the newly calculated scores were summed and multiplied by 2.5 to obtain the overall SUS score [49]. Systems are considered fit if they achieve a benchmark of 68 [48,49]. The score is not to be understood as a linear percentage but moves on a percentile and requires a corresponding interpretation [48-50]. In a preliminary study, an adjective scale was developed for a more comprehensive classification of the SUS scores [50] (Table 4).

XSL•FO

Table 2. Measurement times Technology Usage Inventory (TUI).

Measure times	TUI version[a]	Scale
T1: Adoption—before the technology was introduced	TUI original questionnaire (pre-post version)	NEU[b] and ANG[c]
T2: Task—testing the technology	TUI II parallel questionnaire (complete version)	NEU, ANG, INT[d], BEN[e], NÜT[f], SKE[g], ZUG[h], and ITU[i]
T3: Behavior—end of technology testing	TUI II parallel questionnaire (complete version)	NEU, ANG, INT, BEN, NÜT, SKE, ZUG, and ITU

[a]Designation according to the official TUI manual (Kothgassner et al [45]).
[b]NEU: curiosity.
[c]ANG: fear of using a technology.
[d]INT: interest.
[e]BEN: user friendliness.
[f]NÜT: usefulness.
[g]SKE: skepticism.
[h]ZUG: accessibility.
[i]ITU: intention to use.

Table 3. Percentage ranks and stanins.

Percentile rank	Stanine	Percentage (%)
0-4[a]	1	4
>4-11[a]	2	7
>11-23[b]	3	12
>23-40[b]	4	17
>40-60[c]	5	20
>60-77[d]	6	17
>77-89[d]	7	12
>89-96[e]	8	7
>96-100[e]	9	4

[a]Strongly below average.
[b]Slightly below average.
[c]Average.
[d]Slightly above average.
[e]Strongly above average.

The measurement time T1 of the SUS was parallel to the measurement time T3 of the TUI at the end of the trial.

Statistical advice for study planning was obtained from the Institute for Medical Epidemiology, Biometry and Computer Science. As this involved an explorative approach, calculation of the number of cases was unnecessary and was therefore derived from investigations by Faulkner [51], who examined the number of problem identifications in relation to their dependence on the number of subjects. With a sample size of 5 subjects, an average of 85% and at least 55% of 100 problems could be identified, with a very high SD of 9.3. Faulkner [51] indicates that at least 50 subjects are needed to identify an average of 100% of the 100 given problems. As the study duration and the intensity of data acquisition are limited by the human resources available for the project and the project duration, this study used a sample size of up to 45 nurses, which means that 15 nurses are evaluated per ward and per clinical unit.

XSL•FO
RenderX

Table 4. Adjective scale of the System Usability Scale (SUS) score (Bangor et al [50]).

Acceptance range and SUS score	Adjective scale
Acceptable	
90-100	Outstanding: best imaginable
80-89	Excellent
68-79	Good
Marginal	
50-67	So-so
Not acceptable	
35-49	Mad
0-34	Very bad: not imaginable

Qualitative Evaluation

The number of nursing staff members who participate in the expert interviews [52] is limited to 6 to 10 nurses. The selection follows the principles of theoretical sampling, and the aim of the surveys is not to achieve statistical representativeness [53]. Using guided interviews, the survey will be conducted with the clear aim of obtaining specific knowledge that is necessary to answer the precise (and theoretically embedded) research question. The interviews conducted after the completion of the empirical research program on the DFree Professional are useful for obtaining either supply-relevant and "practical" background knowledge or information on the practical implementation of the ultrasonic sensor [52]. The methodological preparation was based on the mechanism-exploring research paradigm of qualitative content analysis that was described by Gläser and Laudel [54], who suggested a 5-step approach commencing with the development of the interview guide and ending by logging the respective surveys [52,54]. Herein, individual steps may be simultaneously taken in parallel to optimize the overall processing time for data collection. The sets of questions fixed in the guidelines were based on preliminary considerations and were developed into a complete guide after the interviews in the first submission (Multimedia Appendix 1).

The methodological recourse to guided interviews for data collection originated from the fact that conducting expert interviews requires good knowledge of the field of investigation [14]. However, challenging hurdles to field access exist within the framework of the DFree study and include the implementation of the DAT and its components in the ecosystem of a clinical ward during normal operational business hours. For example, Adner and Kapoor [55,56] argue that the impact of external challenges through innovation depends not only on their magnitude but also on their position in the respective ecosystem. This implies that the physical functionality of the technology during regular operations in the clinical ward ecosystem is of fundamental importance for assessing the technology itself. Overcoming these hurdles ensures that the surveys of nursing staff on their experiences using DFree Professional within the framework of the nursing process are actually theory-based and methodologically reflected. In the expert interviews, narrative elements relate to the perception of free fitting to problems in continence care from the perspective of nurses are a key focus area [57,58]. The interview guidelines have been developed iteratively using SPSS Statistics 25 [59]. At the end of the 3-month trial period, face-to-face interviews will be conducted using the Phillips Voice Tracer device. All interviews will be transcribed and analyzed based on the content analysis method [54] supported by Microsoft Excel 2016 (Microsoft Corporation) to process data.

All nursing professionals in this study will be recruited through contact with the University Clinic Halle (Saale) and will include those who are employed in clinics for neurology, neurosurgery, and geriatrics. The staff council was informed in advance, and approval of the project was requested.

Ethics Approval

All procedures involving human participants or human tissue will be performed in accordance with the institutional and national research committee ethical standards and tenets of the 1975 Declaration of Helsinki and its later amendments or comparable ethical standards. Informed consent will be obtained from all the participants. This study was approved by the Ethics Committee of the Faculty of Medicine, Martin-Luther-University Halle-Wittenberg (approval no. 2023–031, dated May 9, 2023). The study was registered in the German Register of Clinical Studies (registration no. DRKS00031483), and the protocol has not been published previously.

Results

Data collection would begin in the summer of 2023, and the initial results are expected in the winter of 2023. This study will evaluate the implementation of DFree to support nurses in reducing their workload pertaining to continence care. A change in ITU (TUI Scale) is expected. To investigate the possible causes for the measured change, 7 additional characteristics—curiosity (NEU), anxiety about technology, interest (INT), usability (BEN), usefulness (NÜT), skepticism (SKE), and accessibility (ZUG)—will be evaluated 3 times. Furthermore, this study will generate structured feedback that can support developers in further improving DAT DFree. Consequently, a reduction in the number of unsuccessful toilet visits or uncontrolled micturition events while wearing DFree will be recorded and documented by nurses through numerical counting. This will show whether the use of DFree is a practical

XSL•FO
RenderX

and advantageous measure for mitigating the nurses' workload in the context of continence care. As nurses are often poorly equipped to respond to such DAT implementation, the results should serve as a guideline for further improvement of DFree. The combination of qualitative and quantitative instruments addresses the additional aspects that nursing staff would have in mind but will not be assessed using only a quantitative instrument (TUI). Additionally, a change in the perceived usability of the DFree app among nurses is expected.

Discussion

This pilot study will implement DFree in continence care, give nurses an opportunity to try DFree in real-world practice, and enable the possibility of further cocreative development. The study design enables a novel practical testing of a DAT together with an opportunity for cocreative improvement through direct user feedback. This was the first pilot study to evaluate the use of the DFree ultrasound sensor in an inpatient care setting. This study is the first of its kind and is highly relevant, especially in the context of the barriers to the practical implementation of measures for the digital transformation of health care. The results and experiences from this study facilitate an effect assessment for subsequent studies and serve as a basis for methodological and organizational modifications. Therefore, it is important to evaluate quantitative data in terms of technically meaningful measures. Nonetheless, the study has some limitations, such as the small sample size, diversity of bladder dysfunctions (urinary incontinence and urinary retention), and the impossibility of extrapolating quantitative results to other populations. Additionally, no control group has been included in this study. Nevertheless, this pilot study provides the first assessment of nurses' ITU a DAT, the DFree ultrasound sensor, and provides initial data for further controlled clinical studies. The strengths of this study include the triangulation of quantitative and qualitative data. With regard to the first question on increasing usability, an increase in the SUS score could be considered a technically meaningful measure. Furthermore, changes in the TUI-ITU scale reflect changes in intended use, which is a logical preliminary stage for actual use of the intervention. Finally, at the societal level, the study's results will help explain the influence of DFree on reducing the workload of nurses and encourage nurses to use the DAT in nursing care as an additional resource for better outcomes in bladder dysfunction interventions.

In conclusion, this research protocol has been designed to develop a reflective implementation strategy for DAT with a focus on the provision of support in continence care based on scientific and experiential knowledge. The possible use of the intervention is initiated by a change in the ITU as a logical preliminary stage pertaining to actual use. The possibility of practical testing influences the intended use, which, in the next step, affects the actual use in everyday work. The results of this study will encapsulate practical, scientific, and societal implications and would likely pave the way for further studies and interventions to reduce nurses' workload.

Acknowledgments

We thank all patients for their participation in this study. We also thank the nursing and medical staff of the Departments of Neurology, Neurosurgery, and Medicine of the Faculty of Geriatrics, University Hospital Martin-Luther-University Halle-Wittenberg for their support and the authors of the System Usability Scale and Technology Usage Inventory for their methodological advice. Open-access funding was enabled and organized by the Publikations Foundation of Martin-Luther-University Halle-Wittenberg.

This study was supported by funds from the working group on Health Services Research in nursing at the hospital affiliated with the University of Medicine, Martin-Luther-University Halle-Wittenberg. Triple W Japan loaned the research equipment for this study. We acknowledge the financial support of the Open Access Publication Fund of the Martin-Luther-University Halle-Wittenberg.

Data Availability

The data sets generated and analyzed in this study are available from the corresponding author upon reasonable request.

Abstract

Background: Despite the growing prevalence of depression and anxiety among adolescents, fewer than half access appropriate mental health care. Single-session interventions (SSIs) for depression and anxiety offered in primary care are a promising approach to bridging the treatment gap.

Objective: We aimed to implement a clinical workflow for primary care and behavioral health providers to refer patients aged 13 to 17 years with mild to moderate depression and anxiety symptoms to Project YES (Youth Empowerment and Support), an open-access SSI platform, in a large group medical practice with an integrated behavioral health department.

Methods: Pediatric primary care and integrated behavioral health providers will be educated on the benefits of Project YES for adolescent anxiety and depression and trained in a workflow integrated within the electronic health record system, Epic, to refer patients during well-child visits and pediatric behavioral health visits. Patients with mild to moderate internalizing symptoms based on the 17-item Pediatric Symptom Checklist or youth Pediatric Symptom Checklist will be invited to try an SSI through Project YES. We will examine provider uptake and perceptions of acceptability, feasibility, and appropriateness over time.

Results: The rollout will take place between November 2022 and May 2023, when outcomes will be evaluated. Data analysis and manuscript writing are anticipated to be completed during the summer of 2023.

Conclusions: SSIs such as those available through Project YES have the potential to provide low-cost, evidence-based mental health treatment to adolescents with mild to moderate depression and anxiety. If deemed feasible and acceptable, providing SSIs in primary care settings could significantly improve access to mental health care without taxing pediatric primary care and behavioral health providers.

Introduction

Overview

Among adolescents, the incidence of depression and anxiety has increased significantly over the past decade. In 2019, 37% of adolescents (in the United States) experienced symptoms of sadness or hopelessness, while 21% received a diagnosis of major depressive disorder and 9% were diagnosed with an anxiety disorder [1]. Exacerbating the crisis in youth mental health, the COVID-19 pandemic led to unparalleled disruption in the day-to-day lives of youth and adolescents. School and social events were put on hold, and they observed the consequences of COVID-19 in their families and communities, resulting in a 2-fold increase in depression and anxiety [2].

Despite the rising prevalence of mental health concerns among adolescents, 75% of adolescents with mental health conditions do not receive appropriate care [2] due to a lack of access and acute shortages of qualified pediatric mental health clinicians [2]. Primary care providers are increasingly called upon to identify and intervene with mental health concerns [3], and it is therefore critical for pediatric primary care providers to have effective tools to offer to patients and their families to help manage symptoms. However, such resources are often not available to primary care providers, and patients often wait months before receiving care from licensed mental health professionals following a referral from primary care. Self-guided and web-based single-session interventions (SSIs) are an effective treatment for adolescents with mild to moderate mental health concerns [4] and may provide a stopgap for patients in need of more intensive care who are waiting to receive services. This paper presents the protocol for a novel clinical process for pediatric and integrated behavioral health care providers to refer adolescent patients to use the SSI platform Project YES (Youth Empowerment and Support) at a large group medical practice with an integrated behavioral health department.

Access to Mental Health Care Among Adolescents

In 2021, the surgeon general declared a mental health emergency, prompting responses from multiple sectors to allocate resources to pediatric mental health care [5]. Yet, despite such calls, the population-level mental health of adolescents has worsened throughout the pandemic as growing patient needs are compounded by acute shortages of qualified providers [2,6]. While more than half of all adolescents with mental health concerns do not receive any treatment, even among those who are treated, most do not complete a full course of evidence-based treatment and rarely attend more than 3 to 4 sessions [7]. Beyond the issue of supply and demand, barriers to accessing and completing a clinically appropriate course of treatment for mental health concerns are many. Among adolescents, stigma, shame, and beliefs about who seeks mental health care may inhibit adolescents from accessing necessary interventions [8]. Confidentiality from parents is another important barrier and the Adolescent Health Care Barrier Survey revealed that nearly 40% of adolescents reported forgoing mental health services because they did not want their parents to know [9]. These barriers highlight the need for evidence-based tools which are both acceptable and directly accessible to youth presenting with mood- and anxiety-based symptoms.

SSIs are designed to be intentionally brief, flexible, and potent. Digital SSIs, which can be web-based and self-guided, are a sustainable and low-cost means of disseminating evidence-based treatments at scale [4,10]. SSIs do not rely on patient-provider ratios and can be offered to many patients by just a few providers in under 5 minutes. Their broad accessibility can reduce stigma around mental health concerns and help to normalize the use of appropriate care, whether a patient is going through a challenging time or working through a persistent mental health condition. Furthermore, SSIs can be disseminated in a variety of settings, such as schools and through social media [10,11], and adolescents can use SSIs with confidentiality from their parents. Despite the demonstrated efficacy of SSIs disseminated through social media, they are seldom made available in pediatric health care settings. As digital technologies are increasingly leveraged to close the gap in mental health care, SSIs may provide an additional resource for providers to deploy to adolescent patients.

Evidence for SSIs

Given their demonstrated effectiveness and flexible nature, web-based SSIs allow youth to access mental health support when and where they need it. A growing body of evidence suggests that SSIs hold the potential to reduce a variety of mental health problems. In a meta-analysis of 50 randomized controlled trials targeting youth mental health issues, SSIs were effective (Hedges g=0.32) in improving several clinically relevant outcomes [12]. Notably, SSI effectiveness did not significantly differ between therapist-administered and self-administered interventions. In addition, shorter (<60-minute) interventions were found to be as effective as longer SSIs [12].

In a randomized controlled trial, a virtual, self-administered growth mindset intervention reduced depression symptoms in high-symptom youth 9 months after completion [13]. Other trials of digital SSIs teaching growth mindsets similarly demonstrated their potential to reduce depression symptoms [14-16]. In a diverse group of adolescents recruited from all 50 US states, 2 SSIs improved youth agency immediately postintervention and decreased anxiety, depression, hopelessness, and restrictive eating behaviors 3 months later [17]. Importantly, these SSIs appear to be similarly effective for youth of diverse racial-ethnic identities, gender identities, subjective family social status, and sexual orientations [18].

Web-based SSIs have been evaluated in a more naturalistic setting through an open-access web-based platform called Project YES [19]. Project YES allows adolescents (aged 11 to 17 years) to choose from 3 web-based interventions, each of which spans approximately 30 minutes and includes a core element of evidence-based treatment [10]. Youth may choose from Project Personality (which teaches that personality traits can change), Project CARE (which centers on the benefits of self-compassion), or the Action Brings Change (ABC) project (which encourages youth to engage in activities to improve their mood). Youth can complete as many interventions as they would like, as often as they choose to, and entirely free of charge. In a pilot trial, adolescents who completed an intervention through

XSL•FO
RenderX

the Project YES platform experienced immediate improvements in hopelessness, self-hatred, perceived control, and agency. In addition, youth rated the interventions as acceptable, and 34.32% of youth who started an intervention completed it [10]. This surpassed completion rates for other digital interventions in naturalistic settings (1%-28%) [20].

Project YES has also been culturally adapted and translated into Spanish for youth living in San Antonio, Texas. Through a series of semistructured focus groups, San Antonio youth stakeholders shared their lived mental health experiences and co-designed the adapted interventions [21]. San Antonio youth who completed an intervention in English experienced immediate improvements in hopelessness, self-hatred, and perceived agency. Similarly, youth who completed a culturally adapted and translated intervention experienced immediate improvements in self-hatred [21]. The completion rate was 49.6%, and the interventions were rated as acceptable by youth [21].

Each SSI in Project YES includes shared core elements thought to underlie its effectiveness. Namely, the interventions (1) present youth with brain science to validate the concepts introduced in the activity, (2) empower youth by placing them in an "expert" role, (3) promote retention of the material with "saying is believing" exercises, and (4) include vignettes from peers and valued others [19]. Conceptually, the SSIs operate by shifting proximal beliefs or behaviors (eg, hopelessness, agency, expectancy that change is possible), which are thought to spark behavior change underlying a longer-term reduction of internalized symptoms [17,22]. SSIs are designed with a few key assumptions: (1) something good can come in 1 session, and 1 session may be the last; (2) change can, and is expected to, occur in the moment; (3) and individuals already have the inner capacity to alter their thoughts, emotions, and behaviors to create meaningful change [23]. Altogether, web-based SSIs, such as those in Project YES, are promising options for delivering brief, evidence-based mental health support with the potential to fill need-to-access gaps [24] for youth experiencing mental health problems.

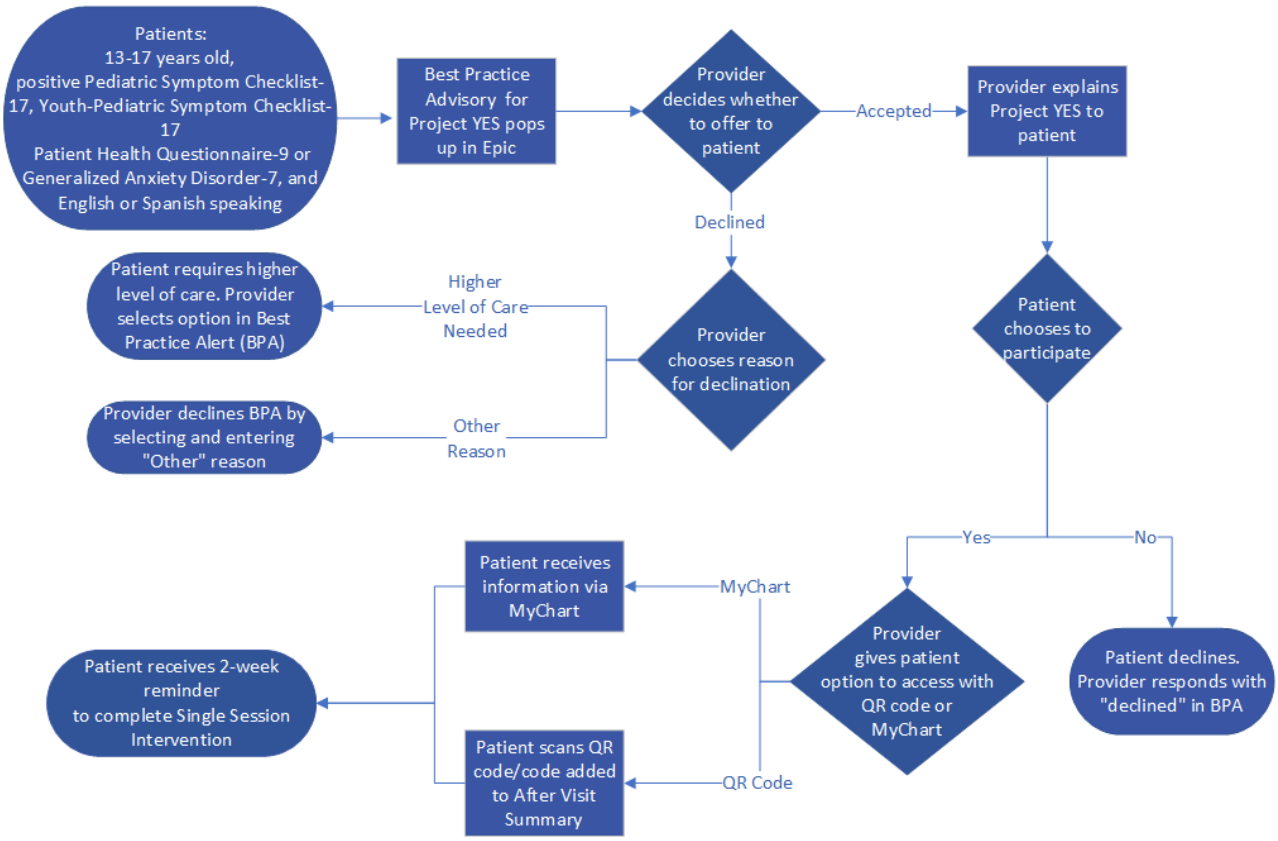
Although SSIs disseminated through social media have been explored in other contexts, less is understood about how to optimize their implementation in primary care settings and integrate them into existing clinical workflows. Identifying best practices for integrating SSIs into current pediatric provider workflows may give providers an additional resource to recommend to their patients experiencing symptoms of anxiety or depression. To this end, the primary objective of this quality improvement pilot is to establish the feasibility and acceptability of delivering a SSI to adolescents with mild to moderate depression and anxiety in pediatric primary care and behavioral health.

Methods

Setting

Reliant Medical Group (RMG) is a multispecialty group medical practice in Massachusetts. With 19 clinics, RMG provides services to 240,000 patients per year, including 64,000 pediatric patients, 29% of whom have been diagnosed with a mental health condition. RMG has an integrated behavioral health department in which patients are triaged by a licensed mental health care provider from primary care to integrated behavioral health services within RMG or in the community. The pediatric behavioral health team has 13 providers, including psychologists, master's level clinicians, nurse practitioners, and psychiatrists who handle prescribing needs. However, the integrated model only serves one-third of the patient population. In 2021, a total of 1910 pediatric patients who were not appropriate matches for the integrated care model were referred outside of RMG to receive services in the greater community. RMG also has a practice research network that includes a team of research scientists and coordination staff to oversee research studies and evaluate quality improvement initiatives. This protocol was developed by a multidisciplinary team including a research scientist, pediatrician, pediatric psychologist, and pediatric psychiatrist in collaboration with the Lab for Scalable Mental Health at Stony Brook University.

Study Design



This paper describes a quality improvement pilot designed to evaluate the feasibility and acceptability of disseminating Project YES in primary and behavioral health care, as well as evaluate short-term changes in mental health outcomes among participants.

Patient Screening

Figure 1 displays the clinical workflow for screening and referring patients to Project YES. First, as part of routine mental health screening during well-child visits, pediatric primary care and behavioral health providers or their medical assistants administer either the 17-item Pediatric Symptom Checklist (PSC-17) [25] or the Youth PSC-17 (Y-PSC-17) [25] to all patients aged between 13 and 17 years. When the total internalizing symptom score is elevated on either of these scales, follow-up screeners such as the Patient Health Questionnaire-9 (PHQ-9) [26] and the General Anxiety Disorder-7 (GAD-7) [27] are administered. Information from these screeners is used to determine whether patients meet criteria for a clinical diagnosis on the spectrum of depression or anxiety and whether routine follow-up is necessary. The PHQ-9 and GAD-7 screeners are also routinely administered as independent screening tools by behavioral health providers as part of the behavioral health visit. Providers will have the opportunity to refer patients to Project YES when the following criteria in Textbox 1 are met:

XSL•FO
RenderX

Figure 1. Clinical workflow for referring patients to Project YES.

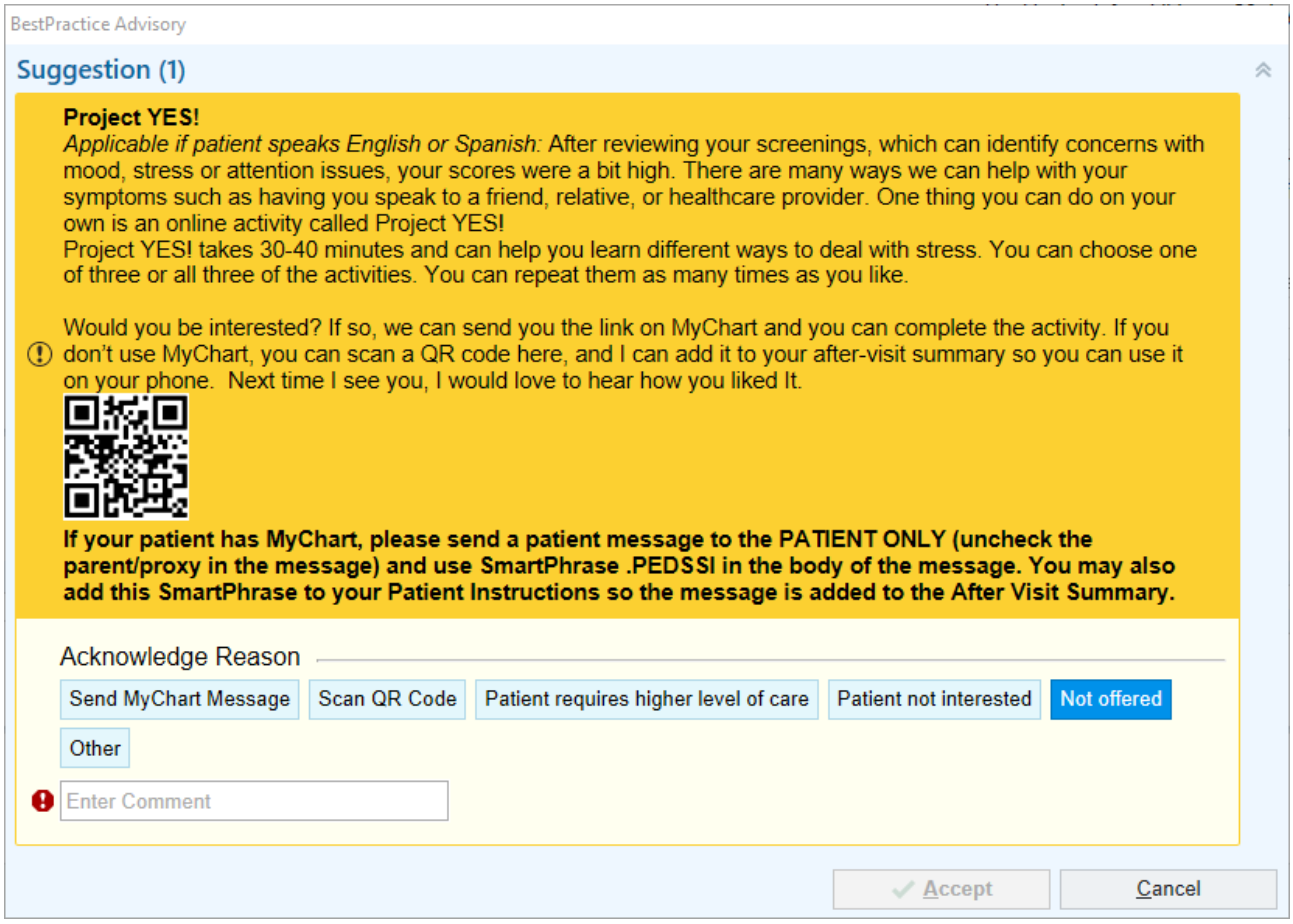
Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Patient is aged between 13 and 17 years.
- Patient meets at least one of the following criteria at the visit or in the preceding 3 months: (1) Patient Health Questionnaire-9 (PHQ-9) score >5; (2) Y-PSC-17 or PSC-17 internalizing score ≥5; (3) total Youth 17-item Pediatric Symptom Checklist (Y-PSC-17) or 17-item Pediatric Symptom Checklist (PSC-17) score ≥15; and (4) General Anxiety Disorder-7 (GAD-7) score ≥5.
- Comfortable speaking and reading in either English or Spanish.

Exclusion criteria

- Active suicidal ideation (score ≥1 on question 9 of the PHQ-9, if completed).



Best Practice Alert

When a patient meets the eligibility criteria, a best practice alert (BPA), displayed in Figure 2, will be triggered in Epic, RMG's electronic health records (EHR) system. The BPA pop-up screen provides instructions for referring a patient to Project YES, including a brief overview of Project YES, its potential benefits, and how to access it. If the patient indicates that they are interested, the provider can offer SSI in 1 of 2 ways:

1. Send the patient a QR code or a link to participate in the SSI through MyChart (the patient front-end of Epic). The MyChart message will include a link to Project YES at the Lab for Scalable Mental Health website and instructions for participating.
2. Provide the patient with a QR code displayed in the BPA that patients may scan using their mobile device, allowing for the retrieval of Project YES for later use. The QR code is also included in the after-visit summary for later use. The QR code will direct patients to Project YES at the Lab for Scalable Mental Health website.

XSL•FO

Figure 2. Best practice alert screen.

Educating Providers on Project YES

First, to ensure representation from participating departments, the implementation team included a pediatrician from the pediatrics department and a pediatric clinical psychologist and pediatric psychiatrist from the behavioral health department. Initial permission and buy-in were sought from the key leadership, including the chief of pediatrics and chief of behavioral health, before designing the workflow. The SSI workflow is targeted toward pediatric and behavioral health providers, including pediatricians, nurse practitioners, clinical psychologists, and master's-level mental health clinicians. All pediatric medical providers and integrated behavioral health providers will be given a brief presentation by members of the implementation team at monthly department meetings, 4 weeks before launching the workflow, and again the week before launch. The introductory presentation covers the gap in care that SSIs can fill, the core elements of Project YES and its 3 interventions, an example of 1 of the SSIs, the evidence base for Project YES, and instructions for referring patients to Project YES during care. Monthly check-ins at department meetings will be held to review processes, answer questions, and gather assessments as well as informal feedback. The monthly check-ins are led by the pediatric behavioral health lead, who is available to answer any questions and address and track comments or concerns. Her contact information is also provided on all materials in the event a provider has questions in real-time.

Each unique clinic also holds individual site meetings where the behavioral health lead will reiterate the core components of Project YES to the staff and providers at each individual clinic. This will also provide the lead an opportunity to introduce new clinical team members to the intervention and referral processes during their orientation. To allow for broader dissemination of information, a monthly behavioral health newsletter sent to all staff in behavioral health and pediatrics will also contain information about the intervention. Lastly, additional materials, such as the PowerPoint slides and other informational materials, will be posted to department shared drives for on-demand review.

Patient Participation

Patients will receive an invitation to participate with a link to the SSI and instructions for participating through MyChart (Multimedia Appendix 1). The patient will click on the link in their MyChart messages that will take them to the Lab for Scalable Mental Health's website. They will be asked to select the module they want to participate in and indicate that they are aged between 13 and 17 years and a patient at RMG in Massachusetts before beginning. The patient will not enter any potentially identifying information. By entering that they are an RMG patient, the Lab for Scalable Mental Health will be able to filter RMG's data for the program evaluation. Before and after completing the module, the patient will be invited to complete a series of anonymous, optional questionnaires within Project YES' Qualtrics interface. In the event a participant in Project YES experiences distress, the Project YES platform

XSL•FO
RenderX

provides a "Need help now?" button on the main website and on each page of the platform that leads to [28]. The linked page provides immediately accessible crisis resources such as the Crisis Text Line, the National Suicide Prevention Lifeline, and a Hotline for LGBTQ+ Youth.

Data Collection

Provider referral records will be collected through RMG's EHR, and anonymous patient engagement and outcomes data will be collected within Project YES' Qualtrics interface by the Lab for Scalable Mental Health and sent to RMG for analysis. Table 1 describes the specific data to be collected and the corresponding methods of analysis.

Table 1. Overview of data collected and analytic methods.

Data	Items	Analytic methods
Behavioral health and primary care providers: EHR[a] data	• Number of eligible patients seen. • Number of referrals made. • Reasons indicated for not providing SSI[b] (patient inappropriate, not interested, or other). • Number of patients selecting QR code versus MyChart message access.	• Descriptive statistics: proportion of providers in each department offering SSI.
Patients: engagement metrics and feedback	• Number of RMG[c] patients who entered the site. • Total number of patients who completed the SSI. • Program Feedback Scale	• Descriptive statistics.
Providers: data collected at monthly behavioral health and pediatric department meetings	• Acceptability of Implementation Measure (AIM). • Feasibility of Implementation Measure (FIM). • Intervention Appropriateness Measure (IAM).	• Descriptive statistics. • Repeated measures ANOVA.

[a]EHR: electronic health record.

[b]SSI: single-session intervention.

[c]RMG: Reliant Medical Group.

Provider Measures

A total of 3 implementation outcome measures will be collected from providers to evaluate the implementation of Project YES. Each outcome measure consists of 4 items rated on a 5-point Likert scale ranging from "completely disagree" to "completely agree." The scales demonstrate high reliability, with Cronbach α reported between .85 and .91, structural validity indicated by factor loadings between 0.75 and 0.89, and test-retest reliability coefficients between 0.73 and 0.88 [29].

Acceptability of Intervention Measure

The Acceptability of Intervention Measure (AIM) measures the appeal of an intervention to target providers (eg, Project YES meets my approval) [29].

Intervention Appropriateness Measure

The Intervention Appropriateness Measure (IAM) measures whether an intervention is fitting and relevant to the target participants within a given setting (eg, Project YES seems applicable) [29].

Feasibility of Implementation Measure

The Feasibility of Intervention Measure (FIM) measures whether implementing a given intervention is achievable within the setting given the time and resources required to carry it out successfully (eg, Project YES seems doable) [29].

Participant Measures

The following measures are the same as those described in previous reports on Project YES; however, in the context of this data collection, we include both the English and Spanish versions. Additionally, this study implemented a single-item question in both English and Spanish surveys, asking whether the participant was a patient with RMG. Only data from participants who select yes to confirm patient status with RMG and report being between the ages of 13 and 17 years will be included in the final analysis.

Demographics

Participants will identify their age range (provided in ranges to maintain anonymity: 10 years or younger, 11-12 years, 13-15 years, 16-17 years, 18 years or older), sex assigned at birth, gender identity, sexual orientation, race or ethnicity, how they learned about Project YES, and whether they are patients at RMG in Massachusetts.

Program Feedback Scale

The Program Feedback Scale (PFS) [30], which is routinely used to evaluate acceptability and user perceptions of SSIs [4,21,23,31] asks participants to rate agreement with 7 statements indicating perceived acceptability and feasibility of their selected SSI (eg, "I enjoyed the program") on a 5-point Likert scale (1="really disagree;" 5="totally agree"). The scale was adapted from existing, validated acceptability assessments of digital interventions; adaptations from existing scales were necessary to exclude items that are inapplicable to web-based SSIs (eg, items referencing frequency of use or interest in continuing to revisit the program). The PFS will also assess participants' open-response feedback. PFS item scores may be evaluated individually or through a mean score across items. Mean responses to each PFS item will be evaluated separately

XSL•FO
RenderX

to gain insight on the acceptability in specific domains (eg, ease of use and understanding, enjoyability).

Ethical Considerations

This quality improvement project was exempted from review by the Optum Office of Human Subjects Research Institutional Review Board (IORG0010356) as it was deemed not human subjects research.

Results

The program was initiated in November 2022 at 1 site to ensure Epic components functioned as intended and then expanded across all sites in December 2022. The program will continue for 6 months before the program evaluation will commence; however, referral, implementation assessment, and patient engagement data will be reviewed iteratively to identify any adaptations that need to be made. Data analysis and manuscript writing are expected in the summer of 2023.

Discussion

Overview

Closing the gap in pediatric mental health care requires rethinking how care is delivered and innovative models to overcome the common barriers of face-to-face therapy while delivering effective, evidence-based treatments. Calls for innovation in mental health care have been made [32,33] and COVID-19 has catalyzed the development of digital technology for mental health [34,35]. Such technology is not often available in primary care settings. Single-session treatments, which provide a single session of face-to-face psychotherapy to patients, have been explored in mental health care settings, reporting medium to large effect sizes [36-38], although they are not as commonly deployed in primary care settings. Importantly, compared to single-session treatments, SSIs may be self-guided and rapidly disseminated among patients by providers without special training. Given that the modal number of psychotherapy sessions patients attend is 1 [7], while a minimum of 12-20 sessions may be required for symptom resolution, SSIs developed with the explicit intention of resolving symptoms in just 1 session are not only more accessible but may also be a more appropriate approach to improving treatment for adolescent mental health conditions. In addition to being a front-line intervention for primary care providers, SSIs may also be leveraged by behavioral health providers and offered as adjunctive or follow-up care for traditional face-to-face therapy.

Strengths and Limitations

Offering patients SSIs in primary care and behavioral health settings is an efficient and cost-effective approach to narrowing the treatment-to-service gap in adolescent mental health care. Approaching this as an implementation project will allow us to understand the feasibility, acceptability, and appropriateness of SSI delivery in a pediatric primary care and integrated behavioral health setting and thus identify potential barriers and facilitators providers may face when offering Project YES to their patients. This information may be used to iteratively adapt the clinical workflow described to streamline the process for providers and patients alike, thus improving uptake. This protocol was developed in close collaboration with a pediatric clinical team and feedback from leadership to ensure that it is relevant, efficient, and can be easily grasped and deployed by providers. Further, making the SSIs accessible to patients with a wide range of symptoms may help reduce stigma around mental health care. Finally, adolescents who may otherwise forgo behavioral health services due to concerns about their confidentiality from their parents can use the SSIs privately without their parents being notified.

Nonetheless, there are several limitations to the study design. Participation is contingent on elevated scores on the screener questionnaires. However, patients who may not meet clinical criteria may also benefit from the SSIs, which can be effective for subclinical internalizing symptoms. To address this, future iterations of this project may explore expanding referrals to all adolescent patients, regardless of meeting screening criteria, or advertising the program on waiting room monitors and in other patient-facing materials. Additionally, this work is only being piloted at a single-group medical practice in Massachusetts and may not be generalizable to other populations. Furthermore, RMG has a predominantly White, English-speaking patient population. Although the intervention is available to Spanish-speaking patients, more work may be needed to understand its feasibility and acceptability in other clinical contexts and among diverse patient populations. Finally, without the use of a placebo-control group to control for potential effects of participating in an SSI in and of itself, the effectiveness data from this study may overestimate potential improvements in symptoms.

Conclusion

While this work explores the dissemination of SSIs in primary care and pediatric behavioral health, SSIs have great potential as a proactive approach to the prevention of mental health concerns. Future work could explore the provision of SSIs to a wider range of adolescents in primary care to examine their potential upstream preventive effects. Furthermore, previous research indicates that parents of adolescents may also benefit from SSIs that are as brief as 15 minutes [4]. While the present workflow was designed to be accessed confidentially by adolescents, SSIs may be effectively disseminated to adolescent parents in primary care settings to raise their expectations for treatment, thus improving patient engagement [4].

SSIs are highly accessible and potent interventions that effectively help to fill the adolescent mental health treatment gap at low costs and require minimal provider time and resources. We anticipate that referring patients to Project YES will be both feasible and acceptable for primary care providers, and its use will be acceptable and effective for patients.

Abstract

Background: Even though various types of suicidality are observed in clinical practice, suicidality is still considered a uniform concept. To distinguish different types of suicidality and consequently improve detection and management of suicidality, we developed a clinical differentiation model for suicidality. We believe that the model allows for a more targeted assessment of suicidal conditions and improves the use of evidence-based treatment strategies. The differentiation model is based on the experience with suicidality that we have encountered in clinical practice. This model distinguishes 4 subtypes of entrapment leading to suicidality. The earliest description of this model and a proposal for usability research has been previously presented in a book chapter.

Objective: In this study, we present the most recent version of the 4-type differentiation model of suicidality and a protocol for a study into the usability of the proposed model.

Methods: The 4-type differentiation model of suicidality distinguishes the following subtypes: (1) perceptual disintegration, (2) primary depressive cognition, (3) psychosocial turmoil, and (4) inadequate coping or communication. We plan to test the usability of the 4 subtypes in a pilot study of 25 cases, and subsequently, we will include 75 cases in a follow-up study. We looked at the case notes of 100 anonymized patients with suicidality who presented to mental health care emergency service in The Hague International Center. The summary and conclusions of the letters sent to the patients' general practitioners after suicide risk assessment will be independently rated by 3 psychiatrists and 3 nurse-scientists for absolute and dimensional scores. The Suicidality Differentiation version 2 (SUICIDI-II) instrument, developed for this study, is used for rating all the cases. Intraclass correlation coefficients for absolute and dimensional scores will be calculated to examine type agreement between raters to examine the usability of the model and the feasibility of the SUICIDI-II instrument.

Results: We consider the model tentatively valid if the intraclass correlation coefficients are ≥0.70. Subsequently, if the model turns out to be valid, we plan to rate 75 other cases in a follow-up study, according to a similar or adjusted procedure. Study results are expected to be published by the end of 2023.

Conclusions: The theoretical roots of the differentiation model stem from classic and contemporary theoretical models of suicidality and from our clinical practice experiences with suicidal behaviors. We believe that this model can be used to adjust

the diagnosis, management, treatment, and research of suicidality, in addition to distinguishing different dynamics between practitioners and patients with suicidality and their families.

Introduction

Thoughts of death or suicide, planning or preparing suicide, attempting suicide, and completing suicide are defined as suicidality [1]. Although suicidal thoughts, plans, and attempts are common, completed suicide is rare. Suicidality is a symptom often found in patients experiencing mental disorder [2]. Except in case of a diagnosis of major depressive disorder or borderline personality disorder [3], suicidality is not a symptom required to meet the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, criteria for any other psychiatric diagnosis.

Suicidality is still defined as a uniform concept [3-5], even though it is complex and multilayered and there are multiple risk and protective factors, including mental disorder, personality traits, biological factors, and psychosocial factors (to name a few) playing a role in the onset and duration of suicidality [6,7]. Scientific knowledge, such as theoretical concepts derived from neuroimaging and research into genetic vulnerability for suicide, will be difficult to apply in clinical practice [8,9], as science has not been able to distinguish different kinds of suicidality or pinpoint drivers or etiology.

It is widely accepted and acknowledged that clinical differentiation of somatic disorders has resulted in improved diagnosis and treatment strategies, for example, for breast cancer [10], diabetes [11], and dementia [12]; yet, no lucid clinical differentiation model for suicidality is available for mental health care [13], and as a consequence, general texts, suicide prevention, treatment guidelines, and scientific research hardly differentiate between various types of suicidal behaviors [14-16].

Mental health professionals confronted with suicidality are not just expected to adequately assess the suicide risk but also to manage the risk and all complexities around those risks [3]. Even when risk and protective factors are identified, the assessment of suicide risks remains complex and completed suicide is unpredictable. Professionals' responsibility and liability are difficult to put into operation when it comes to suicide prevention, and another layer to the complexity of suicide risk assessment is added [17].

The pathway of referral to services partially defines the responsibilities of professionals involved at any point of the pathway. They do not just need to share the responsibilities for prevention of suicide with other professionals and referrers but also share this responsibility in a rational and reasonable manner with the patient or the relatives [18-20]. Everyone involved needs to be aware that not all patients with suicidality can be safeguarded by admission. Admission may protect (temporarily) against suicide but can engender an iatrogenic effect, resulting in maintaining the suicidal state rather than reducing it, which is unwanted [21,22]. This is why the emphasis of the management of patients with suicidality is often focused on safety planning and, if applicable, the treatment of underlying mental health disorders.

The complex dynamics around the risks resulting from suicidality and the focus on safety may lead to formalized and restrictive defensive practice. This is why we believe that it will be helpful to discern different types of suicidality and consider to what extent the patient with suicidality is able to take responsibility for their own safety during recovery from a suicidal condition. Differentiation may also help to determine which treatment conditions could be more tailor-made to diagnosis and treatment in mental health. The differentiation of suicidality may encourage practitioners from various networks to apply clear unambiguous language about suicidality.

The result of the scientific quest for suicidal typologies for clinical practice in mental health care was the development of several theoretical models [23-30]. Those models offered improved insight into the complex processes leading to suicide [29-31]. Classical, contemporary, and empirical typologies of suicide have been established [13] and were important for the development of the model under investigation. For instance, the Integrated Motivational-Volitional Model of Suicidality [31] distinguishes between the onset of suicidal thoughts and the dynamic process of engaging into suicidal acts. However, existing theoretical and empirical typologies of suicidality have limited use [3] in clinical practice for various reasons as follows:

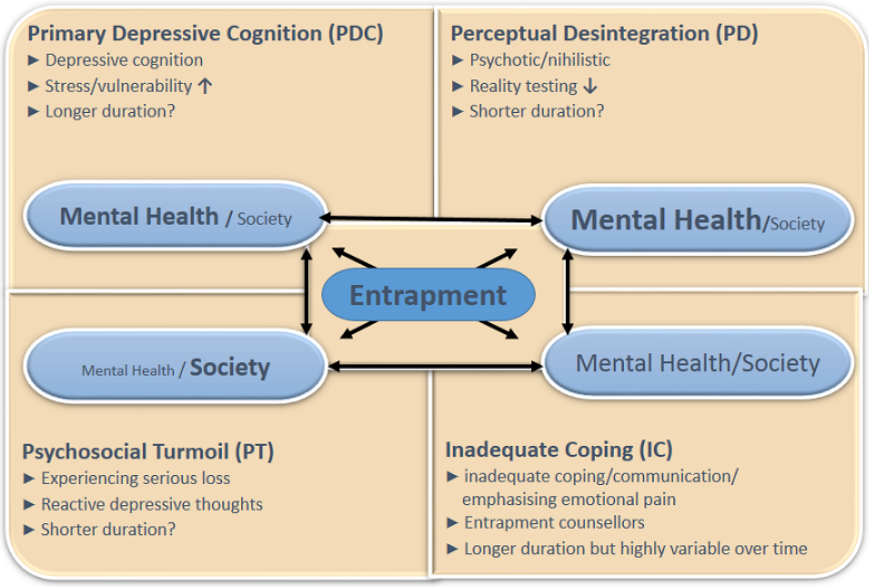
1. The application of suicide typology, which is based on variables not related to entrapment, may result in unreliable suicide risk estimates.
2. The context in which suicidality appears—next to theoretical and empirical typologies—determines whether specific, individual factors increase or mitigate the suicide risk [32]. For example, unemployment, a risk factor for suicide, may result in sudden and quick increase in suicide risk when a breadwinner of the family is laid off, whereas someone with long-term unemployment may experience chronic suicidality due to longstanding exposure to stress, substance abuse, and depression. For people who find it hard to maintain themselves in a work environment,

XSL•FO
RenderX

unemployment can be a blessing in disguise and as such may become a protective factor for suicidality.

The experience of entrapment seems to play a crucial role in the etiology of suicidality as also described in the integrated model of stress vulnerability [33,34] and entrapment [35], which has been developed for the Dutch suicide prevention guideline [16]. The principles of the entrapment theory [23] of suicidality were integrated in the current differentiation model. Entrapment is a mental state in which a person is trapped in the perception that escape is possible by ending their life. We hypothesize that there are 4 ways in which someone might become entrapped. We hypothesize there may be overlap between those paths. We developed a clinical differentiation model for suicidality: the (hypothetic) 4-type model of entrapment of suicidality (h4ME; Figure 1). This model describes 4 subtypes of entrapment of patients with suicidality, with or without mental disorder. Many scientists and practitioners were involved in the development of the h4ME model [3]. The model was revised in 2 Delphi rounds with psychiatrists, psychologists, and mental health nurses who were not involved in the proposed study. The first meeting was in March 2017 with a selection of psychiatrists, people with lived experience with suicidality, peer supporters, nurses, and psychologists employed by Parnassia Mental Health Institute. Feedback from participants of the meetings was provided by email. The second meeting was held during the Dutch Annual Conference of Psychiatrists in 2018 and was attended by psychiatrists only [36]. Feedback from attendees was provided by email.

Another contributor to the development and evolution of the h4ME model was the Dutch Multi-Disciplinary Guideline for the Assessment and Treatment of Suicidality [16] and the Professionals In Training to STOP suicide study [37] examining the effect of an e-learning “train the trainer model on education” and training of mental health care professionals in the application of the guideline principles [38]. Mental health care professionals are trained to assess suicidality in accordance with the Clinical Assessment of Suicidal Episodes [39] to assess to what extent the patient feels trapped (entrapment); the stronger the feeling of being trapped, the higher is the suicide risk [35]. This inspired us to differentiate between etiologies of entrapment (Textbox 1). We hypothesize that all kinds of suicidality encountered in clinical practice (as well as cases of completed suicide) can be assigned to one of the following 4 types [40]:



1. Perceptual disintegration (PD): entrapment originating in the context of disturbed perceptions or (affective) psychotic behaviors
2. Primary depressive cognition (PDC): entrapment in the context of (a) depressive cognition(s)
3. Psychosocial turmoil (PT): entrapment in the context of acute reactivity to a (perceived or actual) loss, offence, adversity, or doom
4. Inadequate coping or communication (IC): entrapment in the context of communicating intense distress or emphasizing emotional pain

It is not known whether this model will encompass the full range of suicidal behaviors occurring in mental health care services though. To optimize the assessment of suicide risks and the care of patients with suicidality, it is necessary to test the usability of this model before it is applied in clinical and research practice (Textbox 2). The objectives of our intended study are as follows:

1. Investigate the usability of the h4ME model—examine whether the h4ME model accurately describes the complete spectrum of suicidality as encountered in specialist mental health care services.
2. Examine whether the Suicidality Differentiation version 2 (SUICIDI-II) instrument allows clinicians to assign cases of suicidality to subtypes as described in the h4ME model.
3. Investigate whether the h4ME model and the SUICIDI-II should be adjusted if it appears that subtypes of entrapment overlap.

Figure 1. The 4 subtypes of entrapment of suicidality and theoretical aspects.

Textbox 1. Descriptions of the 4 subtypes of suicidality (use of narcotics or other substances or somatic symptoms can be viewed as adjustors of which the effect depends on the differentiation of suicidality).

Primary depressive cognition

Suicidality stems primarily from a depressive thought process and there are no psychotic features (yet). The depressive state can be present for a while (eg, weeks or months). Thoughts of suicide, which are part of the cognition and present on a daily basis, are characteristic. There is clear evidence of distress, which can be noticed by the examiner because of the depressive thought process. A classic example would be a depressive disorder, but primary depressive cognition may also be part of an anxiety disorder, autism, etc. The features of a personality disorder may be mixed with the depressive state, or the depressive state may be caused by a personality disorder and become part of a returning thought pattern in which negative cognitions and Beck cognitive triad can be present (negative views about oneself, negative views about the world, and negative views about the future).

Perceptual disintegration (psychotic disturbed perception or behavior)

Suicidality originates from psychosis, which can often be accompanied by affective (depressive) dysregulation or can be affected by it. Usually, the psychotic state has only been present for probably a short time (rather days or weeks than months) and is noticed (or becomes apparent) because of its severity. Suicidality may originate from depressogenic cognition; however, in that case, the severity has developed to such a level that it can be seen as a mood-congruent or mood-incongruent psychotic state. The distress can be understood, but the severity cannot be perceived as comprehensible anymore by the examiner. A classic state is a depression with mood-congruent psychotic features. However, it can also appear among people who, while in a psychotic state, are ordered by their delusions to hurt themselves.

Psychosocial turmoil

Suicidality stems primarily from a severe loss or blow to the ego, leading to a complete upheaval of someone's life. The person experiences enormous guilt, severe shame, or does not dare to look another in the eye anymore or experiences a downfall without being in a psychotic state. There is an unbearable anguish, which leads to a need for release from that pain or the need not to exist anymore, to not be able to feel or escape the awful misery or pending dread. Usually, someone has been in this state for a short time (hours, days, or weeks). Drug use can be extra provoking. The stress is perceivable for the examiner from the perspective of loss or a blow to the ego and there may be slight psychotic features, but one can follow the narrative. Underlying dysregulation of the impulsivity can worsen the state and increase the risk of a lethal outcome.

Inadequate coping or communication

Suicidality stems from a severe feeling of distress and not being able to communicate this properly. There is difficulty with formulating an adequate request for help and one seems to be hoping for a solution by demonstrating suicidality. This behavior usually exists for a longer period (months) and fluctuates severely. This type of a more chronic suicidality is often seen as part of a personality disorder such as a borderline personality disorder. Also, drug use can be an important provoking factor. Suicidality is perceived by others as "externalizing" and fake and can result in aid workers feeling "trapped" in the dynamics. The behavior can coincide with experiences of loss with which the powerlessness is externalized and not internalized. Often, the support system is exhausted and professionals are viewed as failing. The major risk is for professionals to feel manipulated and for the person who is assessed to feel misunderstood and not taken seriously, which leads to an amplification of the behavior, accompanied by an increased risk of suicide. Contrary to how it is perceived by others, the person is genuinely distress. Suicide can be used as the ultimate way to communicate about the distress caused by the perceived unfair or rejection judgment of the person (especially recognizing and exploring the countertransference and offering help to the underlying motivators of suicidality are essential with this type).

XSL•FO
RenderX

Textbox 2. Examples of conclusions and vignettes of entrapment of suicidality typology.

Vignette 1: Perceptual disintegration

This case concerns a mental health act assessment of a 25–29-year-old woman with no history of mental illness, except for a previous one-off assessment. She has 2 (biological) children younger than 4 years of age. She came to the notice of the police when she—in company of the children—started to ring the bells at the houses of total strangers after a 1-sided car accident (total loss) and expressed suicidal and homicidal thoughts, leaving the children behind in a confused state. People involved in the incident were shocked by the bizarre presentation. At the time of the mental health act assessment, we saw a very tense woman who was clearly trying to keep up a facade and could not reason or answer questions adequately. The presentation was suspect of a paranoid state, which possibly already existed for some time. During the police investigation, her statements were bizarre, for example, mentioning that she was murdered. There was some suspicion of substance abuse. The assessment could not confirm direct symptoms of acute suicidality; however, taking into consideration the events, earlier statements, and the ensuing silence, suicide risk was assessed as acutely increased. Because she showed no insight and refused voluntary admission, an involuntary admission was arranged and agreed. The children were placed with foster parents by social services and child and family services.

Vignette 2: Primary depressive cognition

This case concerns a 50–54-year-old man who was referred by the mental health nurse working in the general practitioner practice. He was referred for an emergency assessment within the community team because of low mood and suicidal ideation. He had consistent ideas of different ways to kill himself, though he considered himself a coward. During the assessment, we saw a depressed man with low self-esteem who normally pushes away emotions. After a small incident at work, he completely broke down and has been on sick leave for the last 4 weeks with low mood, anhedonia, ruminations, and sleep problems. Fifteen years ago, he experienced a similar episode and at that time, he did a suicide attempt with medication and alcohol after the death of his father. At the time, he was referred and treated by the community team. Six years ago, he had a myocardial infarction. He was diagnosed with depression. It was possible to agree to a safety plan, and the suicide risk was considered not to be acutely increased. The patient was referred to the community team—with a safety plan in place—for the treatment of depression.

Vignette 3: Psychosocial turmoil

This case concerns a home assessment of the suicide risk of a 20–24-year-old woman with no previous psychiatric history. The general practitioner asked for an assessment after she made suicidal statements following several serious and negative life events over the last few weeks (relationship breakup, termination of pregnancy, debts, death of grandfather, suicide of friend, loss of accommodation). During the assessment, we saw a tense, desperate woman with insufficient coping strategies to manage the situation, becoming overwhelmed as a result. She was unable to pull herself out of the situation and feels so miserable that she does not have any hope of a good outcome. She expressed suicidal ideas and her support system was unable to support her. Her limited coping skills were possibly due to a disturbed personality development and below average intelligence. A respite admission (time out admission) was indicated to stabilize this patient and work toward follow-up treatment in the community. It was not possible to arrange admission or involve intensive home treatment because of limited capacity within those services, though it was possible to set up a safety plan until the next morning and arrange for alternative follow-up care in the community.

Vignette 4: Inadequate coping or communication

This concerned a suicide-risk assessment at “services for acutely disturbed people” of a 45–49-year-old female who wanted to be addressed as male, without a gender reassignment or transformation having taken place yet. They are known with posttraumatic stress disorder, personality problems, autism spectrum disorder, gender dysphoria, and dissociative episodes. In the past, they attempted suicide on several occasions and autoamputated fingers and toes. Patient was discharged from the admission wards 7 days ago or 7 days before the current assessment. Specialized in-patient treatment for this patient with severely disturbed behavior was terminated because adequate treatment was not possible due to splitting, dismissing, and devaluating the treatment plan, projection, and denial demonstrated by the patient. Patient now comes to the attention of community mental health services, referred by the police, after they made serious suicidal statements and threw the phone down when called by the crisis services. The crisis team contacted the police, who found the patient near a canal, in possession of a knife. During the assessment, the patient displayed complex, claiming behavior possibly because she was unable to acquire Dormicum from the assessing team. Prescription of Dormicum was denied because of the inappropriateness of the request. Patient stated they cannot agree to a safety plan a long as they are not provided with Dormicum. Admission was not considered to be suitable because of the recent discharge and the lack of cooperation with the proposed treatment plan in the patient ward. The outcome of the assessment was to send the patient home and contact the responsible professional of the community team. When the outcome was communicated with the patient, they decided to agree with some form of a safety plan.

Methods

Design: Explorative Qualitative Study

Sampling

In a previous study conducted at The Hague Emergency Service, one-third of the assessed patients exhibited suicidality [41,42]. In this study, 100 cases of patients with suicidality were included in the order of entry. For the pilot study, 25 cases will be included. Subsequently, feedback from raters is collected and procedures may be adjusted. Then, 75 other cases (numbered 26-100) will be rated. The identity of the referrer, the patient, the (nurse) practitioner, and the general practitioner cannot be deduced from the results and conclusions.

Raters

Raters (n=6) will be recruited from RFPdW’s professional network (3 psychiatrists and 3 registered nurses); all are employed at psychiatric emergency services. They all have extensive knowledge and experience in assessing suicidality due to clinical or scientific positions outside The Hague Emergency Service. The raters are not involved in any of the cases included in this study. RFPdW will not be a rater. Raters will be asked to independently assign cases to entrapment types by using the SUICIDI-II, an instrument especially developed for this study to investigate to what extent raters agree on the entrapment type that should be assigned to each case (further indicated: type agreement [TA]). Before scoring, raters will be trained in the h4ME model and in using the SUICIDI-II.

XSL•FO
RenderX

The SUICIDI-II: An Instrument for Assigning Cases to Entrapment Types

To determine TA, the SUICIDI-II was designed for this study. The SUICIDI-II should be considered a preliminary systematic description of the 4 entrapment types. From 2018 onward, the SUICIDI-II and previous versions and the h4ME model were presented and discussed during conferences in the context of suicide prevention in the Netherlands and abroad [19,36]. The feedback of the attendees was collected during the meetings. The feedback was processed by RFPdW and MHdG and led to adjustments of subsequent versions of the SUICIDI. The SUICIDI-II describes each entrapment type by 3 propositions. The propositions are hierarchically formulated to indicate whether a type is applicable or not. Scores are rated as 0=type is not applicable, 1=type leaves room for other entrapment types, and 2=matches type and excludes other types. See the following link [43] for the SUICIDI-II questionnaire.

Outcome Measures

TA will be investigated in two ways: (1) by calculating an absolute TA (aTA) score and (2) by two different dimensional agreement scores (d1TA and d2TA). The dimensional scores were introduced because we expect that cases might be assigned to more than 1 subtype. aTA will be examined by asking raters to allocate each case to only 1 entrapment type (type PD, PDC, PT, or IC). This will result in an aTA score. Dimensional TA is scored as follows:

1. d1TA: raters are asked to allocate a total of 4 points to one or more subtypes (minimum 0 to maximum 4 for a subtype); the higher the allocated score, the more a subtype applies.
2. d2TA: raters indicate which proposition (1 or 2) most likely applies to the types they scored for the d1TA as proposed in the SUICIDI-II instrument. Subtypes that were not chosen automatically scored 0 (=not applicable).

Data Analysis

Intraclass correlation coefficients (ICCs) will be calculated to quantify the degree of agreement between the raters on the assigned subtypes: aTA, d1TA, and d2TA. Differences between measurements can be due to real differences (between persons or within persons on repeated measurements) or from noise (differences due to imperfections in the description of the types). This is why we will also calculate an ICC for the extent to which raters agree on which statement (1 or 2) best describes the chosen type (d2TA). In SPSS (version 23.0; IBM Corp), the analyses will be performed with a 2-way mixed-effects model, aTA, according to the guidelines of selecting and reporting ICC [44]. ICCs are numbers between 0.0 and 1.0 with a 95% CI. In a perfect model, when ICC=1, all differences are completely real. In a completely invalid model, all differences are noise and ICC=0. In other words, the higher the ICC, the more the raters agree. An ICC<0.50 is indicated as poor, 0.50-0.75 is indicated as moderate, 0.75-0.90 is good, and >0.90 is excellent [44]. The model is considered valid if the ICC for aTA and the 2D TAs (d1TA and d2TA) are ≥0.70. The model will be adjusted if the ICC or the aTA or d1TA are ≤0.70. The propositions in the SUICIDI-II are considered valid usable if the ICC of d2TA is >0.70 and will be adjusted if the ICC is ≤0.70.

Schedule

The first step is to carry out a pilot study in which we examine the usability of the h4ME model of suicidality. We aim to answer the following questions:

1. Is a selection of mental health care workers capable of dealing with the h4ME model and the SUICIDI-II instrument?
2. Can conclusions from patient records of high-risk patients with suicidality assessed by the outreach psychiatric emergency services be used for rating absolute and dimensional TA?
3. Are the proposed subtypes (PD, PDC, PT, and IC) validly definable when various clinicians independently allocate cases to subtypes? How are subtypes distributed?
4. Are these subtypes dimensionally delineated by using 2 different modes of scoring, and is there consensus when different clinicians independently score them? What is the reliability of the different modes of scoring?
5. Which form of dimensional scoring is preferred?
6. If applicable, how can we improve the SUICIDI-II instrument?
7. What feedback can we provide to raters when there is any indication that raters scored incorrectly?

Step 2 is a follow-up study of 75 cases according to the same (or eventually adjusted) procedure. Further, overlap between subtypes will be investigated.

Ethical Considerations

The Medical Research Ethics Committee Leiden the Hague Delft involving the Human Subjects Act (*Wet medisch-wetenschappelijk onderzoek met mensen*) was consulted prior to the start of this study. The committee decided in 2020 that no approval was needed (G21.021/PV/pv). The medical directorates and privacy officers of the Mental Health Institute Rivierduinen and Parnassia Mental Health Institute approved the study, and both institutes financed the study [3].

Results

Between January 2018 and January 2020, a total of 503 cases of patients with suicidality were examined and assessed by the outreach psychiatric emergency service of The Hague in the Netherlands [42]. Of the 503 cases, 100 were included in this study in the order of entry. RFPdW was medically responsible for the cases. Cases were anonymized, and summarized conclusions were taken from the general practitioners' discharge letters, which were sent after the patients' assessment. Patients gave consent to be included in this study. The letters to the patient's general practitioners are saved in the electronic patient record and were cosigned by RFPdW. The summarized conclusions were copied from the electronic patient record and pasted into a Microsoft Word file. These were distributed among raters. We have elaborated previously on risk management and treatment algorithms (including pharmacological and psychological interventions) across the 4 types (see Table 1), as described before in a book chapter of de Winter et al [3], and revised it.

XSL•FO
RenderX

The results of our study are expected to be published by the end of 2023. Findings of this study will be published in peer-reviewed journals and presented at regional, national, and international professional conferences and meetings.

Table 1. Hypothetical risk management and treatment algorithm

	Perceptual disintegration	Primary depressive cognition	Psychosocial turmoil	Inadequate coping or communication
Severity of the suicide risk	++++[a]	++	+++	+
Duration	Days or weeks	Weeks or months	Days	Days or hours; often exacerbation of chronic suicidality
Influence culture	+	++	++++	+++
Religion	+	++	++++	+++
Spiritual affiliation	+	++	++++	+++
Economic conjuncture	+	++	++++	+++
Social disorder (war, pandemic, etc)	+	++	++++	+++
Live events or loss experiences	++	++	++++	+++
Genetic biochemical factors	Yes	Yes	Maybe	Probably
Influence personality	+	++	+++	++++
Major life events	Yes	Yes	Yes	Yes
True mental disorder	Yes	Yes	Maybe	Mostly
Expected course	Reduction after treatment of psychosis	Reduction after biological and psychological treatment	Reduction when tunnel vision decreases, reduces when peak of mourning has passed	Nonspecific reduction within hours or days or when behavior has been exposed or when underlying problems have come to the surface, risk of acute shift from chronic risk and shift to another type
Recurrence	New psychotic episode, triggering of trauma	Recurrent affective disorder	Recurrent episode of psychosocial stress or continuation of severe stress, received narcissistic affront	Interpersonal stress and perceived powerlessness, lack of external recognition of underlying distress
Reassessment of suicide risk	Several times a day, continuous during treatment, after recovery, with the recurrence of a new episode as precaution during trauma therapy	Several times a day, regularly during treatment, after recovery, new episode when the mood deteriorates	Several times a day, ranging from a few times a day to often, in the aftermath of an acute suicidal episode, during a new episode of severe psychosocial stress or new setback	After the suicidal episode, when continued or renewed lack of recognition of underlying distress, during interpersonal stress and perceived powerlessness
Pharmacotherapy	Antipsychotics (clozapine) or mood stabilizer (lithium), possibly additional benzodiazepines in the event of major anxiety	Antidepressant or mood stabilizer (lithium), restrained use of benzodiazepines when increased risk of impulsivity, short-term benzodiazepines for sleep deprivation	Restrained use of medication, possibly symptom relief for sleep deprivation or great anxiety	Hold back medication when possible (changes in or addition to) pharmacological treatment
Actions during crisis	Admission (if needed), intensive home treatment if risk is acceptable	Emergency care, intensive home treatment	Organize mourning, support from family and relatives, brief admission	(F)ACT, crisis plan, maintain autonomy
Relatives	Involving relatives for discussing acute risk, safety, and treatment	Involving relatives for safety and treatment	Involving relatives for direct support and interaction	Involving relatives more for exploring dynamic interactions

XSL•FO
RenderX

	Perceptual disintegration	Primary depressive cognition	Psychosocial turmoil	Inadequate coping or communication
Follow-up	Outpatient treatment of psychotic symptoms, trauma treatment	Outpatient treatment of depressive symptoms with cognitive behavioral therapy, Collaborative Assessment and Management of Suicidality, Eye movement desensitization and reprocessing	General practitioner	(F)ACT[b], additionally, DBT[c] or Collaborative Assessment and Management of Suicidality or collaborative care; eye movement desensitization and reprocessing; vigilant for change of symptoms
Responsibility of the patient	Increasing when disintegration reduces	Increasing when depressive symptoms reduce	Increasing when "tunnel vision" fades	Retain as much responsibility as possible but be careful by disstress
Responsibility of the caregiver	Decreasing when disintegration reduces	Decreasing when depressive symptoms reduce	Decreasing when "tunnel vision" fades	Holding back of taking over control; offer maximum support; recognize emotional distress

[a]More + symbols indicate greater influence or risk.

[b]ACT: Assertive Community Treatment.

[c]DBT: Dialectical behaviour therapy.

Discussion

Principal Results

The h4ME model, whose usability will be examined in this study, has been designed on the basis of clinical experience with suicidal behavior. Rather than taking the usual route of applying theoretical knowledge to practice, we took the reverse route by proposing a theoretical model based on practical experience [3]. We differentiated appearances of suicidal behavior into types of entrapment—the mental state in the way someone feels trapped in their belief that dying is the only way to escape from distress. In this model, we identified and described 4 different pathways to entrapment. We hypothesize that it depends on the entrapment mode whether the patient is able to take responsibility. We believe that the management of suicidality in accordance with the h4ME model may improve suicide risk assessment; enhance the application of evidence-based treatment strategies; and will be supportive in research of suicide prevention strategies whether it is biological, psychotherapeutic, or social research [2,45-49] or research of effective implementation of suicide prevention tools in clinical practice.

For professionals, the practical management of acute suicide risks is a priority rather than appraising theoretical or scientific concepts about the etiology of suicidal behavior. They may benefit from a theory-based but accessible framework similar to the h4ME model, which is eclectic and based on a fusion of well-known and generally accepted theoretical concepts of suicidality. The main inspiration for the model includes concepts of "dimensions of psychopathology" and the "temperament and character inventory." This model incorporates 2 subtypes of the psychopathology dimension: PD and affective dysregulation (PDC) [50]. The remaining subtypes PT and IC are derived from the "Temperament and Character Inventory" [51], stating that there may be a relationship between personality dimensions, including 2 out of 3 dimensions of character (self-directedness and cooperativeness) and 3 out of 4 dimensions of temperament (harm-avoidance, novelty seeking, reward dependence). Differentiation may provide better insight into etiological relationships between underlying psychological or biological dysregulation processes. We estimate that in the future, the model can be used to determine which available evidence-based treatment strategies are most promising for the various subtypes. For instance, we suggest that the patients with suicidality of subtypes PD and PDC may recover with the treatment of the underlying mental disorders, whereas patients with subtype PT or IC may take advantage of treatment focusing on strengthening coping skills.

We assume that practitioners using the model will find it less complicated to consider suicidality and to put the risks of suicidality in context, and patients with suicidality may feel more comfortable when practitioners better understand patients' motives to contemplate suicide. Additionally, the model can be used to determine the best fitting of a suitable treatment strategy. Finally, application of the model for scientific research may lead to the discovery of novel and more effective treatment strategies and ultimately to more effective suicide prevention. We do not rule out that the 4 proposed types, especially in the context of effective treatment, might be more defined and specified. Additionally, we do not rule out that more subtypes can be identified in clinical and nonclinical populations.

Limitations

The development of the h4ME model is a venture into unknown territory. Little is known of the nature and origin of suicidality, so the model does not provide explanations or answers to the many questions about the onset of suicidality. A limitation of this study is that cases who will be included were willing to seek help. We are convinced that this population does not represent all kinds of people with suicidality, especially those who refuse help or hide suicidal ideation. This may affect the outcomes. In addition, we identified 4 subtypes, automatically excluding possible other types. For instance, people experiencing declining somatic health, loneliness, and existential questions around the end of life are not represented in the model and consequently cannot be rated. This may also affect the outcomes, as raters are forced to indicate a limited spectrum of suicidality,

XSL•FO
RenderX

and this may increase the chance that a high level of TA will be achieved. The anonymized cases and summarized conclusions taken from general practitioners' discharge letters used for this study may be biased because they contain subjective information, written by a clinically experienced nurse and a junior doctor. There may be distortion of the real suicidal symptoms due to a variety of factors such as countertransference, a diversity of professional backgrounds, or the lack of clinical experience.

Suggestions for Further Research

The majority of suicide cases occur outside the reach of mental health care services. Research among these groups is likely difficult because of privacy and ethical issues. Psychological autopsy studies of cases of suicide who are not accessed by mental health care may be useful for further development or fine-tuning of the model. It may reveal a different distribution of types, additional types, and specific information about entrapment pathways, for instance, whether certain types are preceded by other types in the model or whether certain types are the superlative of another type. In future studies also, Likert-scale items reflecting psychopathological symptoms, behaviors, thoughts, emotions, duration, temperament, and character may be used for the eventual differentiation of subtypes. It is important to include other mental health care workers—other than psychiatrists and nurses—in future validity research. It would also be useful to include multidisciplinary teams (including psychiatrists, nurses, nurse practitioners, psychologists, general practitioners, and social workers) as clusters of raters; these teams all may contribute to adjustment and usability of the model and the feasibility of the SUICIDI-II instrument. The usability strategy may be adjusted in future studies. Finally, correlations between subtypes and demographic, context, and (mental) health variables might be investigated.

Conclusions

One of the most poignant results of this model is that the differentiation of professional responsibilities has emerged. Improved clarity about those professional and personal responsibilities allows a more evidence-based discussion, for instance, about working as team, about sharing responsibilities, or supporting others when needed. Ultimately, this is what makes the model truly stand out and gives it added value. The model and the research proposal are in its infancy. So far, the model has been considered useful by clinicians who have rated it or worked with it. It is found to be practical and easy to apply. We welcome feedback, critical considerations, discussions, and suggestions from clinicians, scientists, researchers, and policy makers.

Acknowledgments

We would like to thank the health care workers of the psychiatric outreach emergency service of The Hague and Melissa Hoek-Hus for help in the preparation of the manuscript.

Data Availability

The data sets generated during this study are publicly available as an SPSS file [52]; all parameters (for some that are traceable to an individual) have been coded. The keys for the coded parameters are available from the corresponding author on reasonable request.

Authors' Contributions

All authors made substantial contributions in drafting and critically revising the manuscript. RFPdW, MHdG, DPdB, and MCH contributed to conceptualizing and designing the study and to data acquisition, analysis, and interpretation. DS contributed as an experience expert and peer supporter and to conceptualizing the study. GEvS assisted in outcome interpretation. CMM, ATvdB, JHE, NKG, MvG, and MG contributed as evaluators and raters in the study. All authors approved the final draft and agreed to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: Morbidity rates in pancreatic surgery are high, and frail patients with low aerobic capacity are especially at risk of complications and require prophylactic interventions. Previous studies of small patient cohorts receiving intra-abdominal surgery have shown that an exercise prehabilitation program increases aerobic capacity, leading to better treatment outcomes.

Objective: In this study, we aim to assess the feasibility of a home-based exercise prehabilitation program in unfit patients scheduled for pancreatic surgery on a larger scale.

Methods: In this multicenter study, adult patients scheduled for elective pancreatic surgery with a preoperative oxygen uptake (VO_2) at the ventilatory anaerobic threshold ≤13 mL/kg/min or a VO_2 at peak exercise ≤18 mL/kg/min will be recruited. A total of 30 patients will be included in the 4-week, home-based, partly supervised exercise prehabilitation program. The program comprises 25-minute high-intensity interval training on an advanced cycle ergometer 3 times a week. Training intensity will be based on steep ramp test performance (ie, a short-term maximal exercise test on a cycle ergometer), aiming to improve aerobic capacity. Twice a week, patients will perform functional task exercises to improve muscle function and functional mobility. A steep ramp test will be repeated weekly, and training intensity will be adjusted accordingly. Next to assessing the feasibility (participation rate, reasons for nonparticipation, adherence, dropout rate, reasons for dropout, adverse events, and patient and therapist appreciation) of this program, individual patients' responses to prehabilitation on aerobic capacity, functional mobility, body composition, quality of life, and immune system factors will be evaluated.

Results: Recruitment for this study began in January 2022 and is expected to be completed in the summer of 2023.

Conclusions: Results of this study will provide important clinical and scientific knowledge on the feasibility of a partly supervised home-based exercise prehabilitation program in a vulnerable patient population. This might ease the path to implementing prehabilitation programs in unfit patients undergoing complex abdominal surgery, such as pancreatic surgery.

Introduction

The incidence of pancreatic malignancies is predicted to rise as the aging population grows [1]. The only curative treatment option remains pancreatic surgery, which is highly complex and known for its high postoperative morbidity [2]. Within this already vulnerable patient group, there are unfit patients with low aerobic fitness, translating into a limited reserve to withstand stress during surgery [3,4]. As a consequence, these patients are more prone to postoperative morbidity after pancreatic surgery [5,6]. To effectively identify unfit patients who are in need of preoperative intervention to reduce their perioperative risks, specific preoperative risk assessment is required. In the search for valid preoperative risk assessment diagnostics, preoperative aerobic fitness has been found to have a persistent relationship with postoperative outcomes in major elective intra-abdominal surgeries [5,7,8]. A cardiopulmonary exercise test (CPET), which determines 2 meaningful risk indicators, that is, the oxygen uptake (VO_2) at the ventilatory anaerobic threshold (VAT) and VO_2 at peak exercise (VO_{2peak}), can be used to acquire an objective representation of a patient's aerobic capacity [9].

Physical exercise training before surgery has been reported to effectively increase the aerobic capacity of patients scheduled for major abdominal surgery [10-17]. In the trial of Barberan-Garcia et al [18], high-risk patients scheduled for major abdominal surgery were subjected to a multimodal prehabilitation program consisting of (1) motivational interviewing, (2) a personalized program to promote daily physical activity, and (3) a supervised high-intensity endurance exercise training program. The mean duration of their program was 6 weeks, and it not only improved preoperative aerobic capacity, but also resulted in a 51% reduction in postoperative complications [18]. Regarding prehabilitation programs in pancreatic surgery, Ausania et al [14] subjected patients with a pancreatic or peripancreatic malignancy, regardless of their physical fitness, to a multimodal prehabilitation program consisting of 5 daily sessions of supervised high-intensity endurance training in the outpatient clinic. Furthermore, patients were trained to perform unsupervised home-based functional and breathing exercises, and nutritional support, as well as pancreatic exocrine insufficiency, was addressed [14]. Although the authors reported an improvement in physical fitness as determined by the 10-meter walk test, no differences in postoperative outcomes were observed [14]. However, since high-risk patients are hypothesized to benefit the most from exercise prehabilitation, adequate patient selection seems essential and greatly influences the effect of an exercise prehabilitation program on improving a patient's aerobic capacity [11,12]. Another important factor influencing the feasibility and effect of a prehabilitation exercise program is the setting in which it takes place. Most reported prehabilitation programs have been carried out in an outpatient clinic. However, as pointed out by Ferreira et al [19], patients prefer a home-based prehabilitation program for reasons such as traveling issues or because a hospital- or community-based exercise program is regarded as too time-consuming. These perceived barriers will negatively influence a patient's adherence to a physical exercise training program, likely resulting in a suboptimal training effect [19]. On the other hand, a possible disadvantage of unsupervised home-based exercise training could be a lack of adherence of the patient, lack of appropriate exercise intensity, and therefore lack of benefit [4]. It is therefore important to provide adequate supervision, preferably by an experienced physical therapist.

In exercise prehabilitation programs within a limited preoperative time window of 4 to 6 weeks, the most efficient training modality to increase aerobic capacity seems to be high-intensity interval training (HIIT) [17,20]. In a study by van Wijk et al [17], high-risk patients scheduled for liver or pancreatic surgery participated in a partly supervised home-based bimodal prehabilitation program consisting of HIIT and high-intensity endurance training combined with nutritional support. Their 4-week prehabilitation program was shown to be feasible and improved aerobic capacity by 17% as determined by performing a CPET pre- and postintervention.

Although several studies investigated the effect of exercise prehabilitation in major abdominal surgery, there is a large heterogeneity in patient selection and prehabilitation program setting, which notably influences its effectiveness and adequate interpretation of results. Therefore, the primary aim of this study is to determine the feasibility of a 4-week, home-based, partly supervised exercise prehabilitation program in unfit patients scheduled for pancreatic surgery. Secondary aims of the study are to evaluate the individual responses to the program on aerobic capacity, functional mobility, muscle strength, body composition, level of perceived fatigue, quality of life, and immune system factors.

Methods

Study Design

The described study is a multicenter feasibility study, and the study will have a pretest-posttest design. The latest version of the study protocol (version 7; May 2022) is presented in this manuscript. Protocol amendments will have to be approved by the Medical Research Ethics Committee of the Maastricht University Medical Center+ and Maastricht University (METC azM/UM).

Eligibility Criteria

In order to be eligible to participate in this study, patients must meet all of the following criteria: (1) age 18 years or older, (2) planned for elective pancreatic surgery at Maastricht University Medical Center+ or at the University Medical Center Groningen, and (3) providing informed consent to participate. Patients are considered eligible (4) if they have a VO_2 at the VAT ≤13 mL/kg/min or a VO_{2peak} ≤18 mL/kg/min. A patient who meets

XSL•FO
RenderX

any of the following criteria will be excluded from participation in this study: (1) they require acute surgery, (2) they undergo surgery in another hospital, (3) they are not able to cycle on a cycle ergometer, (4) contraindications are identified for them to physical exercise training (eg, heart rhythm disturbances, ischemia of the heart muscle), (5) they are unable to cooperate during the testing procedures (eg, insufficient understanding of the Dutch language), and (6) no certified physical therapist is available in their living area.

Recruitment

All patients eligible for pancreatic surgery will be identified at the multidisciplinary team meetings and evaluated by the surgeon at the outpatient clinic. During the outpatient clinic visit, patients will be given full details of the study, and after a few days, patients from the Maastricht University Medical Center+ will be contacted by telephone by a designated investigator to provide extensive information about the study. If patients are interested in participating in the study, a CPET will be performed to check whether the patient fulfills the inclusion criteria, after which an appointment will be planned to perform baseline assessments and to retrieve written informed consent. At the University Medical Center Groningen, all patients scheduled for pancreatic surgery perform a CPET as part of usual care. Based on the CPET results, patients will be asked to participate in this study and an appointment will be planned to perform the remaining baseline assessments and receive written informed consent.

Interventions

Preoperative Home-Based Physical Exercise Training Program

Participating patients will engage in a home-based, partly supervised exercise prehabilitation program before elective pancreatic surgery. The physical exercise training program will consist of HIIT on an advanced cycle ergometer that is placed at the patient's home (Lode Corival Home+, Lode BV; see Figure 1), with the goal to improve the patient's preoperative aerobic fitness. A certified community physical therapist in the living area of the patient will be asked to partly supervise the physical exercise training program. The community physical therapist will receive verbal and written instructions on the use of the cycle ergometer and the goals and content of the program. The duration of the exercise program is 4 weeks, and the training frequency will be 3 sessions per week. The supervising community physical therapist will visit the patient 3 times during the first week, and once in the weeks thereafter to monitor training progression and provide additional instructions if needed. Patients are encouraged to find a training buddy (eg, their partner or a close relative) to help and to motivate them for the unsupervised training sessions. Patients may choose the day and time point of their unsupervised training themselves, with the recommendation to leave at least one day between training sessions for recovery. This approach was chosen in order to promote adherence to the program. Each first training session of the week will be preceded by a modified steep ramp test (SRT) [21] executed under the supervision of the community physical therapist. The SRT, a short-time maximal exercise test on a cycle ergometer, has been proven to be a valid tool to estimate aerobic capacity and allows for individual optimization and progress monitoring of the HIIT program [21-23]. The training program on the cycle ergometer will be personalized weekly to each participant based on their performance during the SRT. Based on SRT performance, the consecutive training sessions comprise HIIT, consisting of a 3-minute warm-up at 20 watts, 14 high-intensity intervals of 30 seconds at 60% of the peak work rate (WR) achieved at the SRT interspersed with 14 low-intensity intervals of 60 seconds at 20 watts and a cooldown of at least 1 minute, thereby taking at least 25 minutes to execute (Table 1). Directly after each completed HIIT session of 20 minutes, the patient is asked by the program installed on the cycle ergometer to fill out the 6-20 Borg scale for rating of perceived exertion. Data about the duration, intensity (WR), heart rate, pedaling frequency, and rating of perceived exertion of each SRT and HIIT session at the cycle ergometer will be automatically recorded by the cycle ergometer at the end of each SRT and HIIT session and uploaded to a web-based platform (Figure 2). As such, community physical therapists and local investigators are able to remotely supervise and monitor training progression and adherence. Once a week, during the supervised SRT and HIIT session, the physical therapist will discuss these findings with the patient. In case of unexpected problems, the community physical therapist can consult the local investigator of the study.

Functional Task Exercises

Next to HIIT on the cycle ergometer, patients will be instructed to carry out functional task exercises 2 times a week on training days at which the HIIT session is not preceded by an SRT, thereby practicing activities relevant to the patient (eg, elastic band exercises, stair-climbing, brisk walking) [24]. An overview of the structure of the overall training program can be found in Table 2. The patient will be instructed to perform at least 3 repetitions of about 30 seconds of different functional task exercises with 30 seconds of rest in between. The functional task exercises will be chosen individually, consisting of activities relevant to the patient, and the intensity and complexity of exercises will be individually reviewed weekly by the physical therapist. Patients will be instructed to perform as many repetitions as intensely as possible, but at least three per functional task exercises. Next to an increasing exercise intensity or frequency, functional task exercises can also progress in difficulty in terms of making exercises more complex and by adding variation.

Table 2. Overall training program structure (weeks 1-4).

Training session 1 (Monday or Tuesday)		Training session 2 (Wednesday or Thursday)		Training session 3 (Friday or Saturday)	
Workout	Duration	Workout	Duration	Workout	Duration
SRT[a]	4-7 minutes	HIIT[b]	25 minutes	HIIT	25 minutes
HIIT	25 minutes	Functional task exercises	15 minutes	Functional task exercises	15 minutes

[a]SRT: steep ramp test.

[b]HIIT: high-intensity interval training.

Usual Care

As part of usual care, all patients are screened at baseline for risk factors associated with postoperative complications and are treated accordingly. This includes screening for nutritional deficits, mental resilience, anemia, iron deficiency, hyperglycemia, and substance abuse (eg, smoking, alcohol consumption). In both participating centers, patients are screened by a trained dietitian as part of usual care. Patients at risk of malnutrition will receive additional nutritional support. When patients are in need of additional support in any of the other areas, such as psychological support or intervention for smoking cessation, this will also be implemented as a standard of care in both centers.

Measurements

Before, during, and after the preoperative home-based physical exercise training program, several outcome measurements will be obtained (Table 3).

Program Feasibility

Feasibility will be determined by (1) monitoring the participation rate of this study as well as reasons for nonparticipation. Reasons for nonparticipation will be asked for during a short interview with the coordinating investigator or treating surgeon. Furthermore, feasibility will be determined by (2) evaluating adherence and fidelity of patients to the physical exercise training program as objectively recorded by the cycle ergometer, which provides insight into training session content (eg, frequency, intensity, duration, premature termination of a training session), (3) dropout rate and reasons for dropout, (4) number and severity of adverse events, and (5) patient and therapist appreciation after completing the program by filling out a short questionnaire based on a previous study [25]. If a patient drops out before the end of the training program, the reasons will be investigated through a short interview with the coordinating investigator.

Aerobic Capacity CPET

For all patients, a preintervention CPET will be performed by a clinical exercise physiologist (Maastricht University Medical Center) or sports physician (University Medical Center Groningen) to assess baseline aerobic capacity, which will be used to make a selection of eligible unfit patients and thereupon invite them to participate in the study (VO_2 at the VAT ≤13 mL/kg/min or VO_{2peak} ≤18 mL/kg/min). After completion of the program, a postintervention CPET will be performed. The outcome thereof will be used to assess the effectiveness of the home-based physical exercise training program to improve aerobic capacity.

The CPET will be executed under controlled conditions using a calibrated electronically braked cycle ergometer in an upright position; the Lode Corival CPET (Lode BV) will be used at Maastricht University Medical Center and the Lode Excalibur Sport (Lode BV) will be used at the University Medical Center Groningen. Patients will be fitted with a 12-lead electrocardiogram to rule out strain-related cardiac ischemia, arrhythmias, and other contraindications for intense physical exercise training during the consecutive exercise program. During the test, patients will breathe through a face mask connected to a metabolic cart; the Vyntus CPX (Vyaire Medical) will be used at the Maastricht University Medical Center and the Quark CPET (Cosmed) will be used at the University Medical Center Groningen for measurements of breath-by-breath VO_2, minute ventilation, and carbon dioxide production throughout the CPET. Finally, heart rate and blood pressure will be monitored, and peripheral oxygen saturation will be measured at the index finger. After 2 minutes of rest measurements, the patient is asked to start cycling. The first 2 minutes consist of unloaded cycling. Thereafter, the WR will be linearly incremented with a 5, 10, 15, or 20 W/min ramp protocol (depending on the patient's self-reported physical fitness) to ensure a test duration between 8 and 12 minutes. Patients will be instructed to maintain a pedaling frequency of around 80 revolutions/min. The test effort will be considered maximal when the patient shows objective signs (ie, heart rate at peak exercise >95% of predicted or a respiratory exchange ratio at peak exercise >1.10) or subjective signs (eg, unsteady biking, sweating, clear unwillingness to continue exercising despite strong encouragement) of maximal effort. CPET interpretation will be performed according to international guidelines by an experienced sports physician or medical physiologist [26]. The last 30 seconds before termination of the test will be used to calculate absolute values at peak exercise. Peak heart rate is the highest heart rate achieved throughout the test. The VAT is described as the point at which the partial end-tidal oxygen tension and the ventilatory equivalent for oxygen reached a minimum and thereafter began to rise in a consistent manner, corresponding with an unchanged ventilatory equivalent for partial end-tidal carbon dioxide tension and carbon dioxide [26]. If this method provides unreliable results, the V-slope method will be applied instead [27].

Aerobic Capacity—Modified SRT

During the physical exercise training program at the patient's home, the physical therapist will assess and monitor aerobic fitness by performing a modified SRT [21] on a weekly basis on the advanced cycle ergometer (Lode Corival Home+; Lode BV) in an upright position. Training intensity will be adjusted based on SRT performance, which is expected to maintain a sufficient training stimulus. A heart rate belt will be fitted around the patient's chest (Xand Cycling) during the test. The SRT starts with 2 minutes of unloaded cycling. Next, the WR will be increased in a ramp-like manner by a constant increment of 10 W/10 s (1 W/s). The total test duration is estimated to be 4 to 7 minutes. The patient is instructed to keep the pedaling frequency constant between 60 and 80 revolutions/minute. The main outcome of the SRT is the work rate at peak exercise (WR_{peak}), defined as the point at which there is a sustained drop in pedaling frequency from 60 revolutions/min despite strong verbal encouragement. After attaining their WR_{peak}, patients will be asked their level of perceived exertion by filling out the 6-20 Borg scale for rating of perceived exertion. They will conclude the SRT with a 2-minute cooldown phase consisting of unloaded cycling at a pedaling frequency of about 40 revolutions/min.

Muscle Strength

To assess the effect of the exercise prehabilitation program on muscle strength, handgrip strength (in kilograms) will be measured at baseline and postintervention using the Jamar dynamometer (Sammons Preston; Rolyon) [28]. Muscle strength, as measured by handgrip dynamometry, is considered to be an indicator of frailty and an independent predictor of complications after surgery [29,30]. Patients will be asked to sit in an upright position with the elbows stretched in a straight line downwards. Patients will be asked to squeeze the handle as forcefully as possible for about 2 seconds, starting with the dominant hand. A total of 3 grip measurements per hand will be performed, with a 15- to 20-second pause between each measurement.

Body Composition

The patient's body height (determined to the nearest 0.5 cm) and body mass (determined to the nearest 0.1 kg) will be measured with a metric measuring tape with a wall stop and an electronic scale (Seca 803; Seca), respectively, at baseline and

XSL•FO
RenderX

postintervention. During the prehabilitation program, the community physical therapist will measure the patient's body mass weekly.

Myosteatosis (ie, skeletal muscle fat infiltration) is a biomarker for cancer cachexia (ie, a multifactorial wasting syndrome leading to loss of skeletal muscle mass with or without loss of fat mass, subsequently inducing progressive functional impairment) and sarcopenia (ie, loss of skeletal muscle tissue). Myosteatosis alone, as well as cancer cachexia and sarcopenia, are associated with increased morbidity and mortality [31,32]. Meanwhile, it has been suggested that physical exercise training improves muscle quality [33]. Therefore, we will evaluate skeletal muscle quantity and quality at baseline and after prehabilitation by analyzing a single slice of a computerized tomography (CT) scan at the midlevel of the third lumbar vertebra (L3), which is where both transverse processes are visible. Body composition analysis will be performed using an automated segmentation system (Mosamatic) developed and validated at Maastricht University [34,35]. Visceral adipose tissue, subcutaneous adipose tissue, and skeletal muscle tissue will be normalized for the patient's body height to calculate the L3 index in cm^2/m^2. Radiation attenuation will be determined by calculating the average Hounsfield unit value of the areas. Low skeletal muscle radiation attenuation is associated with increased myosteatosis [36]. For this study, the CT scans that are part of the standardized diagnostic work-up of patients will be analyzed. Since CT imaging prior to oncologic surgery should not be older than 6 weeks, preoperative CT scans are performed on a regular basis in patients.

Functional Mobility

Functional mobility will be assessed using the 2-minute walk test and 30-second chair-stand test at baseline and postintervention at the hospital, as well as weekly at the patient's home. The 30-second chair-stand test evaluates a combination of lower leg muscle strength, balance, and functional mobility by testing the number of repetitions standing up from a sitting position within 30 seconds [37]. The 2-minute walk test is a feasible method to record the distance (in meters) that is walked over a standardized trail in 2 minutes [38].

Immunological Phenotyping

As the immune system is highly responsive to physical exercise, it has been suggested that structural physical exercise training can improve overall health and may prolong survival in patients with cancer [39]. To exploratively quantify the effect of the preoperative physical exercise training program on the immune system response, blood samples will be taken at baseline and postintervention and analyzed for levels of C-reactive protein, tumor necrosis factor-α, as well as interleukin-6, interleukin-8, and interleukin-10 by multiplex analysis. Moreover, a separate blood sample for each patient will be drawn for storage at –80 °C for future analysis. Blood samples will be stored in the biobank of the participating hospital, for a maximum of 10 years. Future analysis has to be in line with the aims of our ongoing research; if not, informed consent must be retrieved.

Questionnaires

Prior to the start of the physical exercise training program, patients are asked to fill out a perceived fatigue, quality of life, and sarcopenia questionnaire. The level of perceived fatigue is assessed using the Multidimensional Fatigue Index [40], quality of life will be evaluated with the European Organization for Research and Treatment of Cancer Quality-of-life Questionnaire Core 30 (EORTC QLQ-C30) [41], and finally, the strength, assistance with walking, rising from a chair, climbing stairs, and falls (SARC-F) questionnaire [42] is used to screen for sarcopenia in patients. To check for potential improvements in perceived fatigue, quality of life, and sarcopenia, these questionnaires will be repeated after completion of the exercise prehabilitation program.

Study Outcomes

Primary Outcome

The primary outcome of this study is to assess the feasibility of a 4-week, home-based, partly supervised exercise prehabilitation program in unfit patients planned for elective pancreatic surgery. Feasibility is assessed via the participation rate, and by recording reasons for nonparticipation, adherence or compliance and fidelity to the program, dropout rate and reasons for dropout, adverse events during the program, and patient and therapist appreciation.

Secondary Outcomes

Secondary outcomes are to evaluate the patients' responses to exercise prehabilitation on aerobic capacity, functional mobility, muscle strength, body composition, perceived fatigue, quality of life, immune system factors, number of overall postoperative complications within 30 days after surgery, and readmissions within 30 days after discharge. Complications will be graded using the Clavien-Dindo classification and divided into surgical and nonsurgical complications [43,44]. The comprehensive complication index, a continuous scale that also takes into account the number of complications per patient, will be used to summarize complications for each patient [45].

Other Study Outcomes

Data on patient characteristics (eg, age, sex, nutritional status, Charlson Comorbidity Index, American Society of Anesthesiologists score, smoking, location, and type of the tumor) neoadjuvant therapy, and surgical procedure will also be collected for explorative purposes.

Safety

During the preoperative physical exercise training program and 30 days after completion of the program, all adverse events observed by the investigator or his staff or reported spontaneously by the participating patients will be recorded.

Data Analysis

Sample Size Calculation

This study will specifically evaluate the feasibility of a home-based, partly supervised prehabilitation program in unfit patients undergoing elective pancreatic surgery. Thus, the study has a clear explorative character and will analyze individual

XSL•FO
RenderX

responses to the program. Based on the number of patients undergoing elective pancreatic surgery annually and the relatively short study period (<1 year), 15 patients who are willing to participate in the study will be included per hospital, resulting in a total of 30 patients. Results of this exploratory study will provide information on how to proceed in subsequent effect studies. Furthermore, results can be used to optimize the home-based prehabilitation program in the future.

Procedures for Data Checking and Entering

All data will be handled confidentially according to the General Data Protection Regulation (GDPR). Signed informed consent forms and other traceable data will be stored on a local server secured with a password. Coded data will be collected in an electronic case report form created in Castor (Castor), a program aimed at clinical trial data recording and monitoring. Only the principal and coordinating investigator of each center will have access to uncoded data. Variables will be checked for the number of missing, improbable, or impossible values prior to statistical analysis. In case of impossible or improbable values, the patient's data file will be reviewed.

Statistical Analysis

The R software package (R Foundation for Statistical Computing) will be used for statistical analysis. Collected data on patient characteristics will be presented in tables. Continuous variables will be displayed as mean (SD), while categorical variables will be presented as number (n) and percentage (%). Descriptive statistics will be used to answer the primary study parameter of feasibility. As previously described, feasibility will be presented in tables and based on participation rate (n, %), reasons for nonparticipation (n, %, text), adherence to the program (%), dropout rates (%), reasons for dropout (n, %, text), adverse events (n, %, text), patient motivation (scale 0-10), and appreciation (text). The secondary aim is to evaluate the patients' responses over time in terms of aerobic capacity, muscle function, functional mobility, body composition, perceived fatigue, quality of life, and immune system function. Individual response profiles will be graphically depicted and presented in tables. A repeated measurements analysis will be used to analyze changes over time in continuous variables. *P* values <.05 will be considered statistically significant.

Dissemination Policy

Research results will be disclosed and submitted to a peer-reviewed scientific journal, in case of positive as well as negative results. The investigators will prepare the manuscript together. Coauthorship is preserved for all participating investigators and those who at the discretion of the principal investigator constructively contributed to the study. Disputes on the interpretation of results will not lead to an unnecessary delay in publication.

Ethics Approval

This study was approved by the ethical committee METC azM/UM in the Netherlands (METC20-090, NL75340.068.20, September 2021) and is registered in the ClinicalTrials.gov register (NCT05496777). Informed consent will be obtained from all participating subjects. All methods are carried out according to relevant guidelines and regulations.

Results

Recruitment started in January 2022 and will run until patient inclusion is complete (expected in the summer of 2023) at the Maastricht University Medical Center+ (Netherlands) and the University Medical Center Groningen (Netherlands). After data analysis, results on all relevant study outcomes will be published.

Discussion

Results of this study will provide important clinical knowledge on implementing a supervised (partly direct supervision, partly remote supervision) home-based exercise prehabilitation program for unfit patients scheduled for pancreatic surgery. Any potential barriers that hamper the effective execution of a physical exercise training program will be identified by thoroughly analyzing feasibility outcomes. The resulting scientific knowledge will fill in gaps in this literature and will provide the ability to improve preoperative optimization of unfit patients. Proof of feasibility might ease the path to implementing exercise prehabilitation programs in patients undergoing complex abdominal surgery, such as pancreatic surgery. Ultimately, this may lead to better treatment outcomes in vulnerable patient populations. Apart from future patients being scheduled for pancreatic surgery, we expect participating patients to benefit directly from the physical exercise training program due to an expected increase in preoperative aerobic capacity and subsequently have better treatment outcomes.

Several studies indicated that a VO_2 at the VAT <11 mL/kg/min or a VO_{2peak} <18 mL/kg/min, as determined during a CPET, are accurate cut-off points to identify patients that have a higher risk for postoperative morbidity and mortality [5,8]. Nevertheless, preoperative physical exercise training might also be beneficial for patients with mediocre aerobic capacity undergoing pancreatic surgery [46]. In the Netherlands, the mean waiting time for surgery is 4 to 6 weeks, meaning there is sufficient time for patients to participate in physical exercise training programs. Therefore, we have chosen to include all patients with a VO_2 at the VAT ≤13 mL/kg/min or a VO_{2peak} ≤18 mL/kg/min in their waiting period. Previous studies have clearly demonstrated the beneficial effect of exercise prehabilitation on aerobic capacity in patients scheduled for intra-abdominal surgery [13-16,18]. In high-risk patients scheduled for major abdominal surgery, Barberan-Garcia et al [18] demonstrated a 35% increase in aerobic endurance time and a 51% reduction of postoperative complications after a 6-week course of preoperative high-intensity endurance training. More recently, Berkel et al [16] demonstrated a 10% increase in aerobic capacity (VO_2 at the VAT and VO_{2peak}) and an almost 50% decrease in the incidence of postoperative complications in high-risk patients scheduled for colorectal surgery undergoing a 3-week community-based and personalized preoperative HIIT program. Despite evidence suggesting that exercise prehabilitation is effective, there is a large heterogeneity in design and setting among reported prehabilitation programs. Although most of the reported prehabilitation programs were carried out under supervision in an outpatient clinic, patients

XSL•FO
RenderX

clearly prefer a home-based prehabilitation program [19]. Nevertheless, home-based prehabilitation programs should be supervised, since a possible disadvantage of unsupervised home-based exercise training could be a lack of adherence of the patient or lack of appropriate exercise intensity and therefore lack of benefit [4]. A supervised and personalized exercise program in a home-based setting might enhance the participation rate, adherence, and motivation of (high-risk) patients, and has been shown to be the preferred method for a prehabilitation program [4,17,47]. This was illustrated by van Wijk et al [17], who recently reported an 83% adherence rate in their partly supervised home-based training program, which led to an increase of respectively 17.8% and 17.2% in VO_2 at the VAT and VO_{2peak} in unfit (VO_2 at the VAT <11 mL/kg/min) patients undergoing liver or pancreatic resection.

Strengths of this study are its clear study design consisting of a supervised home-based prehabilitation program, the ability to thoroughly assess feasibility in a vulnerable patient population, the use of validated measurement instruments, and the personalized training program based on an individual patient's performance at the weekly executed SRT. This study aims to set the standard for home-based exercise prehabilitation programs in pancreatic surgery. Nevertheless, this study will have some limitations. First of all, the physical exercise training program is only partly supervised by a physical therapist. This may lead to a lower patient adherence to the exercise program and subsequently suboptimal training results. However, the advanced cycle ergometer used in this study automatically captures data on training frequency, intensity, and duration. This enables the physical therapist to monitor training progression and compliance in real-time and gives the opportunity to intervene if necessary. Furthermore, as mentioned before, van Wijk et al [17] have reported an acceptable 83% adherence in their partly supervised exercise program. In addition, given that the primary outcome of interest is the feasibility of the training program, noncompletion of training adds valuable information to the data set. Another limitation might be that our study focuses on exercise prehabilitation while most unfit patients might benefit from a multimodal approach, including screening and subsequent treatment of common risk factors associated with postoperative complications. This screening is part of the usual care in both centers. If necessary, nutritional support, treatment of modifiable risk factors (eg, dyslipidemia, smoking, alcohol consumption), and mental support will be implemented within the patient's individual prehabilitation program.

While hospital- and community-based exercise prehabilitation programs encounter significant feasibility issues when enrolling vulnerable unfit patients, this study will offer unfit patients a unique personalized exercise prehabilitation program with adequate supervision in the setting of their own residence. Hence, it is expected that this study will achieve high adherence rates and subsequently high efficacy in improving patients' preoperative aerobic capacity.

Acknowledgments

This research is part of Food4Health, which has received funding from European Institute of Innovation and Technology (EIT) Health and EIT Food. EIT Health and EIT Food are supported by EIT, a body of the European Union that receives support from the European Union's Horizon Europe Research and Innovation Program. The study protocol has not undergone any peer review by this funding body, nor will they play a role in the analysis or interpretation of future results.

Data Availability

Data sharing is not applicable to this article as no data sets have yet been generated or analyzed.

Authors' Contributions

NDH and AGW prepared the manuscript for publication. BCB, SSR, and MdD performed the ethical approval procedure and communicated with external parties. BCB prepared Figures 1 and 2 and Tables 1-3. BCB, SWMOD, and JMK invented and implemented the protocol. All authors read and approved the final manuscript. All authors reviewed the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Social media platforms have emerged as a useful channel for health promotion communication, offering different channels to reach targeted populations. For example, social media has recently been used to disseminate information about COVID-19 vaccination across various demographics. Traditional modes of health communication such as television, health events, and newsletters may not reach all groups within a community. Health communications for younger generations are increasingly disseminated through social media to reflect key information sources. This paper explores a social media gaming platform as an alternative way to reach young people in health promotion research.

Objective: This protocol study aimed to pilot-test the potential of Twitch, a live streaming platform initially designed for video gaming, to conduct health promotion research with young people. We used COVID-19 vaccination as a topical case study that was recommended by Australian health authorities at the time of the research.

Methods: The research team worked with a Twitch Account Manager to design and test a case study within the guidelines and ethics protocols required by Twitch, identify suitable streamers to approach and establish a protocol for conducting research on the platform. This involved conducting a poll to initiate discussion about COVID-19 vaccination, monitoring the chat in 3 live Twitch sessions with 2 streamers to pilot the protocol, and briefly analyze Twitch chat logs to observe the range of response types that may be acquired from this methodology.

Results: The Twitch streams provided logs and videos on demand that were derived from the live session. These included demographics of viewers, chat logs, and polling results. The results of the poll showed a range of engagement in health promotion for the case study topic: the majority of participants had received their vaccination by the time of the poll; however, there was still a proportion that had not received their vaccination yet or had decided to not be vaccinated. Analysis of the Twitch chat logs demonstrated a range of both positive and negative themes regarding health promotion for the case study topic. This included irrelevant comments, misinformation (compared to health authority information at the time of this study), comedic and conspiracy responses, as well as vaccine status, provaccine comments, and vaccine-hesitant comments.

Conclusions: This study developed and tested a protocol for using Twitch data for health promotion research with young people. With live polling, open text discussion between participants and immediate responses to questions, Twitch can be used to collect both quantitative and qualitative research data from demographics that use social media. The platform also presents some challenges when engaging with independent streamers and sensitive health topics. This study provides an initial protocol for future researchers to use and build on.

Introduction

Role of Social Media in Health Promotion

Social media platforms have emerged as influential channels for health communication, facilitating health promotion and information dissemination to social media users. Social media has been effectively used across varied health promotions' areas including health care decision-making and to promote healthy behaviors and interprofessional communication [1-3]. Social media's impact has been the result of several factors including its broad reach, active engagement by users, and support of multimedia content [1,2]. Social media provides an opportunity to support health promotion, with effective data dissemination enabling more cost-effective and wider reaching health campaigns [1]. It also enables the development of live-streamed content and graphics related to health promotion, which may be more engaging for certain populations [2].

For example, Laranjo et al [4] investigated the use of social media in promoting physical activity. The paper illustrated how social media platforms can engage a wide community and facilitate the interactions with users to motivate healthier choices and behavior change. Health interventions on platforms such as Facebook and Twitter were found to have a positive effect on health behavior outcomes. Similarly, Moorhead et al [5] highlights the role of social media in health information dissemination through examining the potential for collaboration between users and health professionals. It provided rapid communication avenues to aid health authorities in a timely and targeted manner, however it requires careful monitoring and guidance to ensure quality, reliability, and privacy [5]. Timely and effective communication is a significant concern during health crises, such as the COVID-19 pandemic. The pandemic illustrated the usefulness of these platforms for rapid dissemination of information, but also the pitfalls of misinformation [6]. Misinformation and antivaccination sentiments have been widespread and infrequently moderated on social media platforms [7], despite the growing rate of people acquiring their news through platforms such as Facebook and Twitter [8,9].

Further, 1 group that may particularly benefit from health promotion via social media are younger people. With an increasing proportion of the younger population accessing and using social media [10,11], modes of health communication need to adapt in order to actively engage with the community. Without social media engagement, health communications may not reach all members of the community.

Potential of Twitch as a Health Promotion Platform

Twitch has been recognized as the most successful and popular web-based streaming platform across the globe [12]. With over 200 million viewers, social media influencers have amassed large audiences for content spanning from gaming to comedy [12]. Although social media has been used by the government in health communications [13,14], Twitch has potential as an effective additional platform to reach young people due to the target demographic of many of the games and activities that are streamed. The 2-way interactions between streamer and viewer on this platform present a new opportunity for research and health promotion.

Woodcock and Johnson [12] conducted a recent analysis of viewers' experiences of parasocial interactions with videogame streamers on Twitch. The research highlights a male-dominated but mixed audience across the platform and how streamers that actively interact with their viewers in a context separate to health are less likely to engage in inflammatory, irrelevant, or disruptive comments [12]. Harpstead et al [15] highlighted the need for understanding the approaches used in social media research and produced a framework for a research toolkit for streaming platforms through a systematic review. This study outlines the primary methods of data acquisition on Twitch such as log data analyses and survey methods and the data types that can be used [15]. They also found a lack of research that studies the relationship between streamers and their audiences [15].

COVID-19 Vaccination as a Topical Case Study

The COVID-19 pandemic has had a huge impact across the world over the last 3 years. While early international border closures and movement restrictions protected Australia at the start of the pandemic before vaccines were available, there were still many deaths after the spread could not be controlled [16]. At a time of low vaccination rates, the 2021 Delta variant started the first large uncontrolled outbreak in Australia, leading to further border closures and lockdowns [17]. Late 2021 and early 2022 saw the COVID-19 response in Australia largely shift toward vaccination as the primary prevention response to the Omicron subvariants [18]. The majority of Australians received their initial vaccination and a second dose [16]. However, booster vaccination dosage rates were much lower [16,17]. Misinformation continued to linger in the web-based community [19,20] and the needs of people with lower health literacy were inadequately met, leaving much to be improved in health communications.[20,21] At the time of this study, this was the most topical case study to use to explore the potential of Twitch for health promotion research.

Aims

Twitch has been under-used for health promotion and research, but presents an opportunity to engage young people and gather unique perspectives on health issues. This protocol study aimed to pilot-test the potential of using Twitch to conduct health communication research with young men, using COVID-19 vaccination as a topical issue at the time of this study.

Methods

Preliminary Discussion and Protocol Development

In preparation to run a session with a streamer, the research team conducted a series of discussions with a Twitch Account Manager to confirm the requirements from the research team and Twitch. Through this iterative process, we established a

XSL•FO
RenderX

preliminary framework for a protocol that could be used for gathering quantitative and qualitative data from Twitch. This included a strategy to identify an appropriate streamer to run a real time live video session about COVID-19 vaccination, a Twitch protocol for the streamers to run the session and coordination of the retrieval of Twitch data logs. This informed the development of a participant information sheet, consent form, and ethics application to proceed with the live sessions.

Ethical Considerations

Ethical approval was provided by the University of Sydney Human Research Ethics Committee (#2021/880), based on identified Twitch Account Managers who received reimbursement for their time (AUD $100 [US $64.23 on September 21, 2023] voucher), and anonymous stream participants. Managers gave written consent after discussion about this study and reading information about this study. Stream participants were informed of this study at the start of the stream and a representative of the research team was available to answer any questions in the chat. Consent was indicated by participation in the poll and chat. The ethics committee raised some concerns about the potential for children to be identified through public Twitch records, but agreed to approve the protocol if no minors were identified in published quotes through usernames (eg, if birth year was included), and a link to reliable COVID-19 vaccination information was required to be posted at the end of the chat. The link was to the official government information about COVID-19 at the time of this study.

Data Analysis

Once the live stream had been conducted and the Twitch Logs had been retrieved, the chat data was examined to describe the range of comment types provided in response to the poll on COVID-19 vaccination. The Twitch chat log data was pulled by the Twitch Account Manager, which is also available publicly, and sent through to the research team for thematic coding. These data were compiled as an excel sheet with timestamped comments from the stream. It should be noted that these descriptive categories were for data illustration purposes only and detailed thematic analysis was not the aim of this protocol paper. It intends to show the different data types that can be drawn from Twitch for health promotion research. As this project was focused on developing a methodological approach rather than a detailed qualitative analysis, an in-depth analysis was beyond the scope of what was required. However deeper conversation-based analysis could be conducted in future studies.

Results

Overview

In total, 1 session was conducted as a pilot protocol to identify what data types were possible to extract from the stream, followed by a 2 sessions run with a separate streamer to further test the refined protocol. The data gathered from the session can be separated into 3 components: results from the in-stream polls, live chat data from the Twitch logs, and viewer numbers and demographics provided to the streamer. Each is derived through a different mechanism and was discussed with the Twitch Account Manager prior to the live session to coordinate its retrieval.

Participants

Table 1 provides an overview of the sessions that were conducted on Twitch and the usage of the platform.

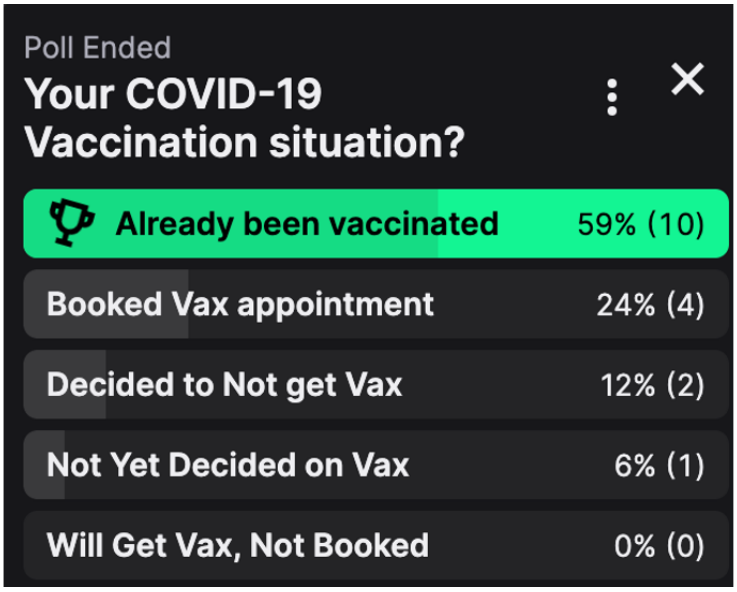
Table 1. Number of views and chat log responses.

Livestream	Number of viewers (average across vaccine section of stream)	Number of poll responses	Number of chat log responses (relevant responses during vaccine section of stream)
Pilot	11	8	N/A[a]
Livestream 1	23	17	45
Livestream 2	15	9	2

[a]N/A: not available.

Pilot Response

The pilot session was conducted to test the feasibility of the protocol for the live sessions and only included the polling component of the project. This was well received by the pilot session's audience with over 70% (n=34) of viewers across the 3 livestreams responding to the poll (total viewers, n=49). As the stream was primarily a small gaming stream, the number of attendees was small with minimal live conversation, however this step was useful in scoping the visual presentation of a live stream and provided a demonstration of what tools were available. This led to a modified protocol for the live sessions, including prompting the poll to the audience, discussing potential chat starters, and access to stream resources such as demographic data and recording.



Poll Data

Each live session commenced with a brief introduction from the streamer followed by a poll that was prepared by the Twitch Account Manager to establish the vaccine hesitancy conversation (see Figure 1). The pilot and first session were conducted in August and September 2021, when booster shots had not been fully introduced, resulting in a set of poll questions focused on current vaccination status and intent to vaccinate. These questions ranged from "decided not to get vax" to "already been vaccinated," as seen in Figures 1 and 2. The wording of the poll was discussed with the Twitch Account Manager, where the use of "vax" was interpreted to be easier to incorporate onto the Twitch platform. This set of questions continued over to the first live session and yielded provaccine sentiments (either vaccinated or have already booked vaccination appointment),

XSL•FO
RenderX

reflecting higher numbers of individuals who had received the vaccination. The new set of poll questions revolved around booster and unvaccinated status to correlate with the shift in COVID-19 context in Australia. Most responders answered with a vaccinated and boosted status.

Figure 1. Example live session poll results.

Chat Log Data

The primary data yielded from both the pilot and live sessions was the Twitch chat log data, which is a recording of each message that is sent to the public livestream (see Textbox 1). This was composed of extracted spreadsheets of responses from Twitch viewers that attended each live session in response to the streamer's questions and comments during a discussion phase. Content of each stream has been limited by setting time parameters on the retrieved spreadsheet. This is a necessary step to filter out content delivered by the streamer that is not relevant to the intervention. Twitch chat logs were not retrieved from the pilot session as the qualitative approach had not yet been developed. However, chat logs from both live sessions were retrieved through the Twitch Account Manager. It was derived from the Twitch Account Manager that this is possible without the support of the Twitch Account Manager; however, this study did not require this. Responses were initiated through the streamer openly discussing their own vaccination status, perspectives, and freely responding to messages delivered in the chat. This created an open-platform discussion and yielded unfiltered perspectives around the vaccine. Overall, Twitch chat logs revealed a range of both positive and negative responses and varying engagement in the health promotion topic. In this case study, response categories included irrelevant comments, false information, comedic and conspiracy responses, vaccine status, provaccine comments, and vaccine hesitant comments. See Table 2 for an example of a chat log extract and the varying categories these quotes fit into.

Textbox 1. Live Twitch session protocol.

- Identify streamer that has interest in participating in this study.
- Participant information sheet to be sent through to the streamer.
- Conduct debrief session with streamer to discuss potential conversations and direction of Twitch live session to cover any issues or concerns from the participant information sheet.
- Researcher to join stream at a coordinated time under Sydney Health Literacy Lab Twitch account. At the start of stream, researcher to send through: "The poll and chat in this stream will be publicly available as per Twitch policy and will be used for research purposes as part of the Sydney Health Literacy Lab COVID-19 project. A summary of the results will be provided here: https://sydneyhealthliteracylab.org.au/projects/."
- Throughout the stream, researcher to monitor the chat but should not intervene so as to influence the direction of the conversation during the livestream.
- At the end of the stream, researcher to send through: "If you have symptoms or questions about COVID-19, call the National Coronavirus Health Information Line on 1800 020 080. If you require translating or interpreting services, call 131 450. You can also find reliable information here: https://www.healthdirect.gov.au/coronavirus."
- Twitch contact to send through an Excel (Microsoft Corp) spreadsheet of Twitch chat log for analysis.

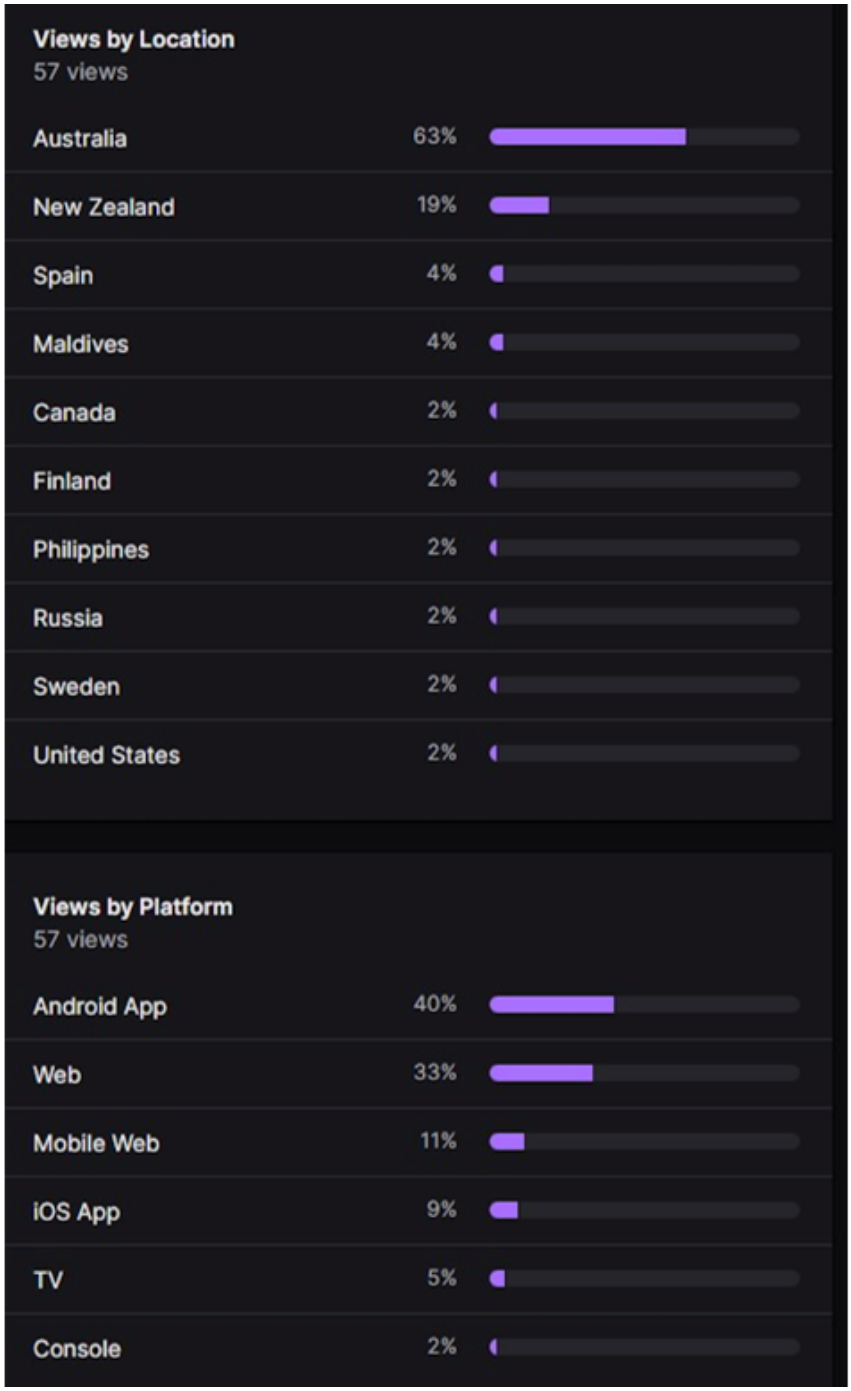
XSL•FO
RenderX

Table 2. Example Twitch chat log and themes from a 1-minute excerpt first live session.

Theme	Chat log quote
Comedic	His 5g is great now
Provaccine	Novavax coming out in november I think
Vaccine status	Me. Im in wa. I know how science and statistics work.
Irrelevant comments	They and I
Comedic	Can confirm no 5G I am sad
Irrelevant comments	Want to know Y
Vaccine status	Me im not allowed ot get vax yet
Irrelevant comments	It looks like a highlighter
Conspiracy	2009 fine by the FDA. They paid 2.3 BILLION us.

Live Twitch Session Protocol

During the live streams, the streamer replied to polling results as they were submitted. However, responses such as "am vaxxed and boosted. No spicy cough yet" were provided without direct questioning from the streamer, illustrating that the polling visual was sufficient to generate a response. It should be noted that there were some viewers who had difficulty in finding where the poll was, evident in "poll is not on [their] screen." However, Twitch viewers can read and respond to other viewers responses and have the capacity to directly refer to another viewer's response. Furthermore, streamers often read the chat and responded promptly to questions posted in the chat. The streamer for the live sessions outlined where the poll could be found shortly after it was asked and facilitated further discussions where possible. This was further supported by other members in the audience, with some answering "@[username] Poll is at the top of chat." This functionality extended throughout the stream, with viewers frequently replying to each other's responses and questions in a conversational tone, which can be seen throughout the Twitch chat logs. This produced a comprehensive collection of responses and perspectives on COVID-19 vaccines that would otherwise be difficult to retrieve. However, audio discussion was not recorded.



The Twitch chat logs demonstrated a range of responses to the health promotion topic even with the small case study sample. Many responses were irrelevant and directed primarily at other components of the stream, such as "sweet dreams are made of you" and "it looks like a highlighter." These comments are either prompted by the streamer or another viewer. False information (ie, not consistent with official health authority information at the time), comedic and conspiracy responses were also prevalent, including responses such as "I'm taking the vaccine out if my 5G doesn't go up" and "[will get the vaccine when] Pfizer isnt the company that paid the single largest criminal fine." Relevant responses were categorized into vaccine status, pro vaccine, and vaccine hesitant comments and were comprehendible. Examples of vaccine status responses include "been vaccinated for over a month now, Biontech for two months now" and "I chose to get vaxxed but [I don't know why]." Vaccine hesitant comments included "I don't want to get the vaccine because I know it hurts" and "I won't get the vaccine unless I get covid." As there is no filter and minimal chat restrictions, open responses from the audience may lead to difficulty in interpreting results as colloquial abbreviations and terms were used on Twitch such as "idk" or "pog." The Twitch Account Manager was aware of such difficulties and alluded to being able to support in interpreting these responses. Further analysis into these responses could be done in conjunction with videos on demand (VODs) as they will provide the contextual background to the prompt or question being asked by the streamer.

Viewer and Streamer Demographics

The Twitch Account Manager also provided the demographics of live session streams (see Figure 2), providing insights into viewer country and platform that the stream was accessed from, however, this did not provide information on other demographic information such as gender or age. This information was not provided by Twitch to the research team even though this information is required to create an account. Further information on viewer demographics could be gathered by consulting the streamer directly. This was not conducted for this study but could be considered in future studies to ascertain further viewer demographics. Figure 2 is a graphical representation of the demographic data that is automatically collected by the Twitch streaming platform after each stream. These data were collected through the Twitch Account Manager or streamer and is not available to the public. An additional facet that can be considered is the selected streamer. The content available on Twitch is separated into several categories. Provided the limited sample size and potential opportunities, a selection criterion for the streamer was not a major consideration for this study; however, an effort was made to expand potential streamers. Through this process, several different demographics were considered, such as female streamers, gaming streamers, comedians, and "in real life" streamers. This will be explored further in the discussion.

XSL•FO
RenderX

Figure 2. Demographics screenshot from Twitch Account Manager.

VODs

Recordings of the sessions are saved to the Twitch platform and can be accessed through the streamer's profile page if this function is enabled. For this project, a recording of the session was provided by the Twitch Account Manager through a link which expired shortly after it was received. Due to difficulties in contacting the Twitch Account Manager once they moved to a different role, this was not followed up on as it was not necessary for the purposes of this project. For future studies, this can be avoided by establishing clearer requirements from both Twitch and the research team.

Discussion

Summary of Findings

This study aimed to develop and test a protocol for using Twitch to engage with young people for health promotion research. The live sessions commenced with a poll to establish the conversation, which focused on COVID-19 vaccination as the most topical health promotion issue at the time of this study. The primary data collected were the Twitch chat log data, which demonstrated a range of responses to and engagement with the health promotion topic. The demographics of live session streams provided insights into viewer country and cross-platform usage of the Twitch viewership, which illustrates the reach of

XSL•FO
RenderX

the session. Recordings of the sessions were saved on the Twitch platform and can be accessed through the streamer's profile page if this function is enabled, however this was not used for the purposes of this study.

Future Potential and Challenges of Using Twitch

Discussions about conducting research on the Twitch platform started with the Twitch Account Manager on Twitter, as there was limited prior research to inform the ethics application and protocol. Several issues needed to be considered, including addressing the fact that children older than 13 years can create an account and view streams. Additionally, there is no age verification procedure on Twitch, making it challenging to ensure minors are not participating. Procedures to minimize engagement with people under 18 through eligibility information can be integrated into this study's design, but they are not foolproof. Ownership of Twitch chat log and VOD data was also an issue that needs to be considered by future researchers. Twitch owns all Twitch data for the first 48 hours after the livestream to promote engagement on the platform. After 48 hours, the data become publicly available and accessible at the streamer's discretion. Access to both the chat logs and VODs could be obtained by communicating with the streamer, but streamers can choose to enable or disable VODs. Therefore, it is important to discuss this with the streamer prior to the session.

Both qualitative and quantitative types of data can be extracted from Twitch live streams. The primary data source explored for this study was open ended discussions and conversations that were recorded in the Twitch chat logs. These data are useful for providing anonymous and unbiased responses from the target population, however more importantly, it provides a platform for health promoters to observe how individuals might interact and respond to others on the internet about a specific topic. This could be used to develop health promotion material using language appropriate to the target group, and can also provide an opportunity for referral to reliable information and health expert input when requested. For research purposes, a link to the research team's website and official government information about the health topic were required for ethical approval. The uptake and impact of such referrals could be explored in future research.

Finally, open-ended responses from communities viewing content on Twitch may lead to inflammatory conversations that could harm the perspectives and emotions of other viewers. The guidelines for managing inflammatory comments on each social media platform varies and can change over time.

Strengths and Limitations

This paper provides a feasible protocol for using a novel method in health promotion research, to inform future research in this area. Several improvements for future researchers were identified during the project. Limitations of the protocol included reliance on the availability of the Twitch Account Manager and streamer, which sometimes led to delays and limits on data access and ownership. When this presents significant barriers to researchers, using publicly available Twitch data from naturally occurring Twitch streams and chats could be considered for analysis. However, this would limit the ability to direct the conversation to a specific health promotion topic.

In future research, the selection of suitable Twitch Account Manager and streamers given this study's aims should be given consideration and prioritized before conducting any live sessions. As this was a case study only, the sample size and diversity of streamers are limited. The Twitch platform provides a variety of contextual and demographic opportunities for future research. For example, responses from a comedy-focused male streamer may differ significantly from those of a gaming-focused female streamer.

Textbox 2 provides a summary of recommendations for future health promotion research using Twitch.

Textbox 2. Recommendations for health promotion research using Twitch.

Recommendations for future research on Twitch

- Minimize communication issues by addressing methodological and ethical concerns (eg, how to deal with inflammatory comments in accordance with the platform policies) prior to engagement with Twitch. Provide resources, forms, and approvals early on to avoid delays.
- Establish communication strategies with the Twitch Account Manager and streamer using appropriate channels such as Discord or Twitter.
- Discuss all requirements, including consent, video on demand recordings, Twitch chat logs, and demographic data before running live sessions. These data should be permanently available and retrieved soon after the livestream.
- Engage a more diverse sample of Twitch Account Managers and streamers to improve the reliability and validity of data gathered.
- Analyze video on demand data in addition to Twitch chat log data to obtain a comprehensive data set including streamer input.

Conclusions

The emergence of new social media platforms has led to the expansion of health promotion strategies beyond traditional methods. This study developed and tested a feasible protocol showing the potential of Twitch as a novel channel for health promotion research with young people. For research, the platform can be used to produce quantitative and qualitative data, but also presents some challenges when engaging with independent streamers and sensitive health topics. This study aims to offer guidance for future research and practice by providing a protocol for researchers to use and build on.

Abstract

Background: Globally, the health care system is experiencing a period of rapid and radical change. In response, innovative service models have been adopted for the delivery of high-quality care that require a health workforce with skills to support transformation and new ways of working.

Objective: The aim of this research protocol is to describe research that will contribute to developing the capability of health service managers in the digital health era and enabling digital transformation within the Australian health care environment. It also explains the process of preparing and finalizing the research design and methodologies by seeking answers to the following three research questions: (1) To what extent can the existing health service management and digital health competency frameworks guide the development of competence for health service managers in understanding and managing in the digital health space? (2) What are the competencies that are necessary for health service managers to acquire in order to effectively work with and manage in the digital health context? (3) What are the key factors that enable and inhibit health service managers to develop and demonstrate digital health competence in the workplace?

Methods: The study has adopted a qualitative approach, guided by the empirically validated management competency identification process, using four steps: (1) health management and digital health competency mapping, (2) scoping review of literature and policy analysis, (3) focus group discussions with health service managers, and (4) semistructured interviews with digital health leaders. The first 2 steps were to confirm the need for updating the current health service management curriculum to address changing competency requirements of health service managers in the digital health context.

Results: Two initial steps have been completed confirming the significance of the study and study design. Step 1, competency mapping, found that nearly half of the digital competencies were only partially or not addressed at all by the health management competency framework. The scoping review articulated the competencies health service managers need to effectively demonstrate digital health competence in the workplace. The findings effectively support the importance of the current research and also the appropriateness of the proposed steps 3 and 4 in answering the research questions and achieving the research aim.

Conclusions: This study will provide insights into the health service management workforce performance and development needs for digital health and inform credentialing and professional development requirements. This will guide health service managers in leading and managing the adoption and implementation of digital health as a contemporary tool for health care delivery. The study will develop an in-depth understanding of Australian health service managers' experiences and views. This research process could be applied in other contexts, noting that the results need contextualization to individual country jurisdictions and environments.

Introduction

Definitions

For the purpose of this protocol paper, the following definitions are being applied: (1) *health services managers* are the "professional managers charged with the responsibility of leading and managing individual health care services, large healthcare organisations and the overall health system" [1]; (2) *digital health* is "an umbrella term referring to a range of technologies that can be used to treat patients and collect and share a person's health information" [2]; and (3) *digital health services* can be seen as the use of digital tools and processes to provide and support the delivery of health care in a digital society [3].

Background

Overview

The health care system is experiencing a period of rapid and radical change. From a global perspective, the aging population, an escalating burden of chronic disease and pandemics, and increasing community expectations are all placing growing demands on health care services [4]. As a response, innovative service models have been adopted for the delivery of high-quality care to meet this burgeoning need and to improve the efficiency, value, and safety of health service provision [5]. Innovation has included the adoption and implementation of digital health solutions, which were not possible a generation ago. Hence, a health workforce with the requisite skills to support such transformation requires new thinking and new ways of working.

Digital Health Transformation Has Been Witnessed

Digital health services have been shown as crucial to developing just-in-time, tailored, and targeted health care that is accessible, affordable, appropriate, and sustainable [6]. Digital health has become "an umbrella term referring to a range of technologies that can be used to treat patients and collect and share a person's health information" [2]. To ensure success in the digital transformation of health services, digital health solutions need to be designed, developed, and delivered in an effective, efficient, ethical, and evidence-based manner under good governance and management [7-10].

The COVID-19 pandemic saw an acceleration in the uptake of digital health solutions globally. This required health care practitioners and providers to adapt to new ways of working, with the ever-present social distancing and travel restriction requirements becoming commonplace. As an example of the accelerated uptake during the pandemic, digital-first strategies, remote monitoring, and digital care approaches were quickly implemented to enable continuity of health care service without physical interactions [11]. Across Europe, digital health systems enabled critical support of public health policies [12,13] improving the monitoring, surveillance, information, and communication regarding COVID-19 requirements and its impact on health care, as well as the recording and monitoring of vaccination bookings [5]. In the United States, "technology innovations and policy prescriptions" [14] and "right-sizing of regulation" [14] were implemented to support the rapid adoption of innovative, digital health technologies. Furthermore, the web-based medical visit requirements under the HIPAA (Health Insurance Portability and Accountability Act) were also recalibrated [14]. Additionally, the Australian federal government's responses to the pandemic included implementing the necessary policy and funding requirements for innovative digital health solutions to be deployed across the country [15].

Demands on a Skilled Workforce

In response to the fast adoption of digital health technologies, a competent health care workforce with capabilities and confidence in implementing and integrating digital health technologies into health service delivery is essential [6,16]. This includes the management and leadership of health care organizations in the digital health context. Some efforts in addressing the required workforce competencies have occurred. For example, the United Kingdom's National Health Service [17] has responded by instantiating the Graduate Management Training Scheme for leadership development that includes a Health Informatics specialization, which leads to a postgraduate diploma in data analytics.

In Australia, the Australian Digital Health Agency [18] has developed the National Digital Health Workforce and Education Roadmap and recently noted that "there has been significant interest in emerging literature that examines the future of work and the impact digital technologies will have on the health workforce, or indeed are having. However, there has not been as much concentration on the planning, programs and strategies required to improve the digital health literacy of the health workforce." Therefore, in the Australian context, it is imperative to focus on the digital health workforce, management competency, and capability development, with contemporary and contextual training that is relevant and responsive to the current health care environment.

Competency, Context, and Performance

How health service managers plan and manage the increasingly complex digital tools in an ever-changing environment, along with the resultant rise in digital health literacy, requires capabilities and contextual competencies to ensure these new technologies are best used to inform both strategic and operational decision-making [19-23]. This is supported by the growing evidence highlighting the importance of the investment required to develop a competent health service management workforce, including through academic credentialing and professional association certifications [24].

XSL•FO
RenderX

Although various management competency frameworks have been established to guide the development of management competence for health service managers [25,26], whether these frameworks have adequately captured the competency requirements for health service managers in managing the necessary, fast-paced change and digital transformation of health care is not evident. This highlights a need to articulate the competencies that are necessary for health service managers to acquire to effectively work with and manage in the digital health context. Therefore, confirming the changing competency requirements for health service managers in managing and leading digital health transformation in health care is warranted. This research is being undertaken in the Australian health care setting to contextualize and inform national frameworks, system enablers, and factors that support Australian health service managers in the digital context.

A review of the literature confirmed that the development of competence is context-sensitive [27,28], with performance improvement resulting from competency development. To improve a health service manager's capability in facilitating and implementing digital health transformation, it is desirable that health service managers develop relevant competencies. Providing an environment that enables managers to fulfill their responsibilities is equally important [29].

Preparatory Phase (Phase 1)

Overview

In exploring the theoretical concepts to inform the research design, the initial focus was on the health informatics competencies required for health service managers to perform effectively in today's health care environment, where the use of health informatics and digital tools is the norm [19-23]. Accordingly, preparatory work was undertaken to first explore competencies and what health informatics competencies already existed within the Australasian College of Health Service Management (ACHSM) Master Health Service Management Competency Framework competencies [1] and in the Australian Health Informatics Competency Framework (AHICF) [30], which apply to health service managers in Australia. It should be noted that in the 2022 revision of the AHICF, an international health informatics frameworks review was included that examined changes in the competency frameworks from the United Kingdom, Canada, Saudi Arabia, and the United States.

Second context, health service managers must be able to deliver these competencies in the context of health services management. Third competency (effective performance), health service managers need to be able to demonstrate competency, so what approach is recommended to measure the attainment of health informatics competencies for health service managers?

Digital competence and the demonstration of these competencies are context-sensitive [27,28]. Understanding the requisite knowledge and skills that are necessary to ensure the development of competency in the digital health environment is crucial, particularly in terms of rapid digital transformation. In addition, structural enabling and inhibiting factors to support a health service manager's demonstration of digital competence must be addressed to ensure the efficacy of this competency. Underpinning this understanding is the importance as to how the development of competence can be supported at the organizational level as well as understanding the challenges health service managers face in demonstrating their competence in the digital context. This understanding must be informed by the system level and organizational factors that can support and enable the development and demonstration of competence in this dynamic, digital environment. Consequently, this preparatory work and the initial findings informed the significance of the research study and the final study design.

Research Focus, Research Questions, and Intended Benefits

The original focus of the research was "improving health informatics competencies for health service managers in Australia." The research project was designed in 2019. Since the COVID-19 pandemic, significant developments in digital health have been witnessed. Following the in-depth literature review, ongoing research work, and prevailing industry activities with the Australasian Institute of Digital Health (AIDH), this highlighted that digital health had now become the umbrella term covering health informatics. Digital health is becoming increasingly relevant in the contemporary environment and is the more commonly used lexicon in the industry. The competency frameworks now being developed internationally are increasingly focusing on digital health rather than health informatics alone [31].

The Australian Digital Health Agency [18] has also identified that "digital health is increasingly recognised as an area for research, capability development and investment" [18]. Therefore, expanding the study from health informatics only, to all aspects of digital health, was more relevant to the current health care context and climate.

The research study will contribute to the development of the capability for health service managers in managing health services in the digital health era and enabling digital transformation in the health context by seeking answers to the following three research questions: (1) To what extent can the existing health service management and digital health competency frameworks guide the development of competence for health service managers in understanding and managing in the digital health space? (2) What are the competencies that are necessary for health service managers to acquire in order to effectively work with and manage in the digital health context? (3) What are the key factors that enable and inhibit health service managers to develop and demonstrate digital health competence in the workplace?

Methods

Phase 1

The following initial 2 steps were completed in order to confirm the significance of the study and study design and to develop a conceptual framework as a research guide to answer the 3 research questions.

XSL•FO
RenderX

Step 1: Competency Mapping

Cognizant of the existing and enduring efforts to support health management competency development in the digital health context, the purpose of this initial step was to comprehend existing structures and factors that can enable competency development and education in digital health management. This guided the primary investigation enumerating the extent to which postgraduate health care management education in Australian universities facilitates the development of informatics competencies. A health care management and informatics competency mapping process was undertaken using industry certification competency frameworks to identify, collect, map, and then distinguish the competencies evidenced in the postgraduate health care management programs. As the leading health informatics competency framework in Australia, the 50 health informatics competency statements from the AHICF were first mapped to the ACHSM Master Health Service Management Competency Framework competencies [1]. These were then mapped to the 21 ACHSM accredited, and the Royal Australasian College of Medical Administrators (RACMA) recognized, postgraduate health care management programs offered domestically in Australia. The ACHSM accredits, and RACMA approves the health care management degrees in Australia. These are voluntary processes that are seen as the recognized industry standard and acknowledgment for higher degrees for health service managers. The mapping process used the "Steps Used to Effectively Map Preexisting Courses to Competency Sets" approach created at the University of Washington School of Public Health's Northwest Center for Public Health Practice, as it has been shown to have a prominent level of assurance in the accuracy of the competency mapping process for university courses [32,33].

Based on the Association of American Medical Colleges' Curriculum Management and Information Tool (CurrMIT) [34], the Competency Mapping Matrix spreadsheet was constructed, which contained the program names, subject or course topic learning objectives, and the 50 AHICF competencies. Each of the 21 postgraduate health care management programs was then reviewed by subject title, learning objectives, and assessments for keywords, competency indicators, and themes that matched with the competency framework. The degree to which the competency was seen as being addressed was then mapped using a four-point criteria scale: (1) not addressed, (2) partially addressed, (3) mostly addressed, and (4) fully addressed. To confirm the reliability and validity of the rating instrument, piloting of the Competency Mapping Matrix spreadsheet was completed with 1 academic and 1 professional services Australian university staff member, both working within health care management postgraduate awards.

An experienced international health informatics academic completed the primary mapping, with a health service management competency specialist and management competency researcher providing oversight. Independent validation was then provided by an expert health informatics competency specialist educator and previous head of a university business school. Interrater reliability of the competency mapping process and tool was used to establish the validity of the mapping itself. Any discrepancies were resolved by a subject matter expert (an Australian professor in health service management) [35].

Step 2: Scoping Review

Overview

The second step was to conduct a scoping review of research literature to confirm the changing competency requirements for health service managers as a result of digital transformation in health care [6]. This published work explored the competencies health service managers need to acquire to effectively manage in the digital health context as well as describing the key factors that enable and inhibit health service managers in demonstrating digital health competence in the workplace. This scoping review of the literature was conducted in 2022 and built on a rapid review undertaken in 2020 [25]. The review was guided by Arksey and O'Malley's five-step framework [36], using the following steps: (1) defining a research question, (2) identifying relevant studies, (3) selecting and confirming empirical studies, (4) data extraction, and (5) collating, summarizing, and reporting results.

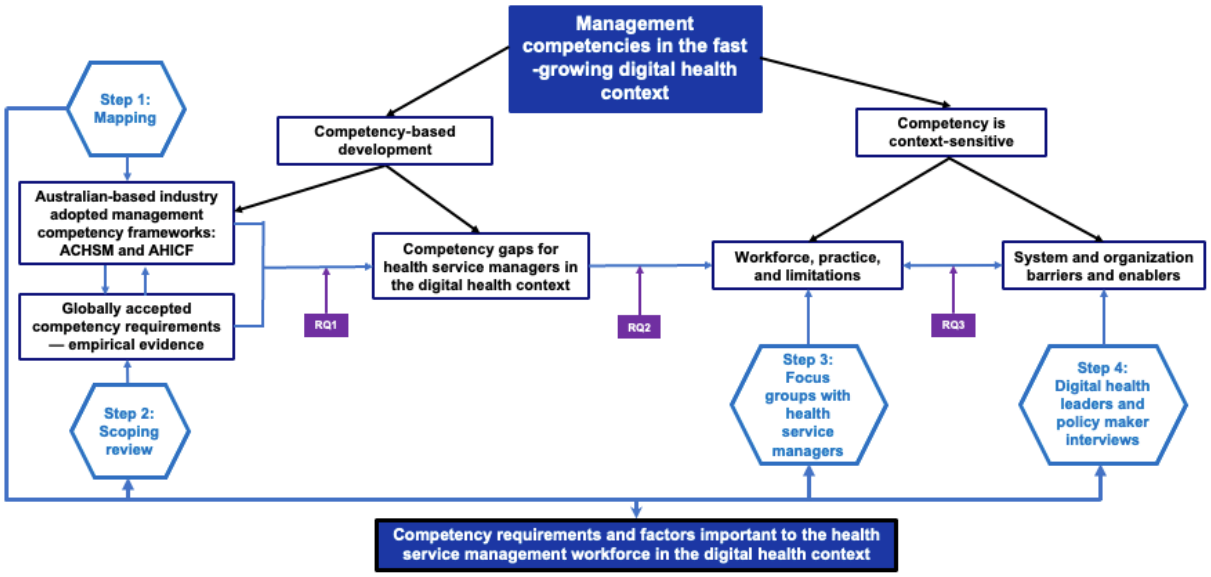
Data Sources and Search Strategies

The following databases were searched: PubMed, Scopus, ProQuest, Web of Science, CINAHL, ACM Digital Library, Google Scholar, and ProQuest Dissertations. The following keywords were used: "digital health," "electronic health," "health informatics," "competencies," "capability," "proficiency," "certification," "qualification," "health manager," "health executive," and "health administrator." A PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) approach [37] was used for eligibility screening. The review searched for publications in the English language since the year 2000 that were peer-reviewed, empirical, and from the gray literature, including government white papers and professional institution position papers.

Data Extraction

Data were extracted from eligible publications and included authors, year of publication, country of origin, the aim of the study, target population, methods for data collection, and key findings related to the scoping review objectives. Content analysis was performed on the extracted data to assist in developing an understanding of the content and identifying the principal themes pertinent to the search focus.

The original search conducted in 2020 generated 1212 publications, and after duplicates were removed, 941 publications were included for title screening. This led to 185 papers being included for abstract screening by 2 reviewers. The revised search conducted in 2022 generated 467 publications, and after the removal of duplicates, 403 publications were included for title screening. This led to 114 papers that were included for abstract screening, which resulted in an additional 4 papers that went through full-text review with the initial 185 papers identified. Full-text review confirmed that 81 publications were particularly relevant to digital health competencies and workforce development in the digital health context. From which, 19 papers pertinent to the focus of the scoping review then underwent qualitative content analysis [6].



XSL•FO
RenderX

Phase 2

Overview

Based on the learnings from the competency mapping, the scoping review, and the knowledge gaps identified in the literature, the conceptual framework presented in Figure 1 has been developed to guide the overall design of the study. The framework follows the research process steps (the blue lines) and addresses the 3 research questions (the purple boxes). The study has adopted a qualitative approach, guided by the empirically validated management competency identification process [27], using the following four steps: (1) health management and digital health competency mapping, (2) scoping review of literature and policy analysis, (3) focus group discussions (FGDs) with health service managers, and (4) semistructured interviews with digital health leaders. This approach is also substantiated by consistent evidence in the international literature supporting the use of these data collection methods in identifying and analyzing informatics and digital competencies in health care [38-41].

Figure 1. Conceptual framework—researching digital health competencies for health service managers. Blue lines show the research process. Purple boxes show the research questions (RQs). RQ1: To what extent can the existing health service management competency framework guide the development of competence for health service managers in understanding and managing in the digital health space? RQ2: What are the competencies that are necessary for health service managers to acquire in order to effectively work with and manage in the digital health context? RQ3: What are the key factors that enable and inhibit health service managers to develop and demonstrate digital health competence in the workplace? ACHSM: Australasian College of Health Service Management; AHICF: Australian Health Informatics Competency Framework.

As mentioned earlier, the first 2 steps have been completed as part of the preparation process, and the overall results from these 2 steps provided the foundation for and informed steps 3 and 4 of this research study. Data collection and analysis, including triangulation of data, will be completed by December 2023. Table 1 details the target populations and the proposed number of participants for steps 3 and 4.

Table 1. Details of the qualitative research study focus group discussions and interviews.

Methods	Focus group discussions via videoconference	Semistructured interviews via videoconference
Focus	To explore the competencies that health service managers need to acquire to effectively work with and manage in the digital health context, along with factors that enable and inhibit the acquisition of these competencies.	To validate findings from the focus group discussions in relation to health service manager competencies, barriers, and enablers for managing in the digital health environment. Also exploring issues that influence digital health policy and practice.
Who are the participants?	Mid-level managers who are responsible for the day-to-day operations of Australian public hospitals. These positions may include department directors, unit managers, and ward managers representing level 3 and 4 management[a] from public hospital settings.	Digital health leaders and chief digital health or clinical information officers from national digital health organizations and public health departments who have executive responsibility for digital health.
Participants, n	48 (8 per group×6 focus groups)	15

[a]Management levels are defined by the organizational reporting hierarchy, with level 1 being the chief executive officer, level 2 reporting to the chief executive officer, level 3 reporting to level 2 management, and level 4 reporting to level 3 management.

Sampling

A purposive sampling technique will be used to identify participants for both the focus groups and interviews, as it enables a deliberate selection of a participant due to their characteristics linked to the study variables. This sampling "involves identification and selection of individuals or groups of individuals that are proficient and well-informed with a

XSL•FO
RenderX

phenomenon of interest" [42]. Furthermore, snowball sampling will be used to assist in locating additional key informants who are information-rich and possess a certain characteristic of research relevance with the target population.

Recruitment

For the FGDs

Potential participants for the FGDs will be invited and recruited from the members of AIDH membership or ACHSM. Invitations of participation will be announced by AIDH and ACHSM in their newsletters and websites. The principal investigator's contact details will be included in the announcement. The announcement will encourage and invite potential participants to contact the principal investigator directly to express their interest to participate. Upon receipt of the expression of interest, the principal investigator will assess the eligibility and contact eligible participants directly via email to provide a formal invitation to participate in the FGD, which will contain a copy of the project information sheet and consent form. The principal investigator will also email those who expressed their interest in participating and who were not eligible and provide them with an explanation as to why they were not selected.

For the Semistructured Interviews

The semistructured interview participants will be invited and recruited from the members of the Digital Health Executive Network AIDH membership or ACHSM membership. Invitations of participation will be announced by AIDH and ACHSM in their newsletters and websites. The principal investigator's contact details will be included in the announcement. The announcement will encourage and invite potential participants to contact the principal investigator directly to express their interest to participate. Upon receipt of the expression of interest, the principal investigator will then assess the eligibility and contact eligible participants directly via email to provide a formal invitation to participate in the semistructured interview, which will contain a copy of the project information sheet and consent form. If there is no response within 5 working days, 1 further email will be sent before the completion of 1 follow-up phone contact. The principal investigator will also email those who expressed their interest in participating and who are not eligible and provide them with an explanation for not being selected.

Ethical Considerations

This research received ethics approval on October 20, 2022, by the James Cook University Human Research Ethics Committee (approval H8877; expiry December 27, 2024). For the focus group and interview participants who respond to the AIDH or ACHSM expression of interest to participate in the general announcement and meet the health service managers' inclusion criteria, an invitation email will be sent to potential participants by the PhD candidate with the participant information sheet and consent form attached to the email. Participants are asked to complete, sign, and return the consent form if they would like to attend the FGD or semistructured interview. The personal information collected will include participant name, position title, name of organization, and email address; however, no names will be retained, participants' identity will not be disclosed, and all information is nonidentifiable. Each participant will be provided with a copy of their FGD or interview transcript, and they can request any specific information in the transcript to be excluded from the analysis. Results of the study will be presented collectively, and no individual information will be used. Participants will volunteer 90 minutes of their time to participate in the FGD or 45 minutes of their time to participate in the semistructured interview; there will be no payment to participate in the research study.

Conducting FGDs and Semistructured Interviews

In total, 6 FGDs will be conducted via videoconference (Microsoft Teams; Microsoft) by the principal investigator and 1 other member of the research team, who will play the role of observer or notetaker. The participants will be 40-50 midlevel managers who are responsible for the day-to-day operations of Australian public hospitals. These positions include department directors, unit managers, program managers, and ward managers, representing level 3 and 4 management from public hospital settings. Management levels are defined by the organizational reporting hierarchy, with level 1 being the chief executive officer, level 2 reporting to the chief executive officer, level 3 reporting to level 2 management, and level 4 reporting to level 3 management. The number of participants is consistent with the qualitative methodology being used to ensure data saturation [43-45]. The FGDs will be conducted for approximately 90 minutes each and digitally captured via the recording functionality of the Microsoft Teams videoconference call. The automatically transcribed text will then be reviewed and proofread for language and readability to provide a full transcript of the discussions.

In total, 15 semistructured interviews will be conducted by the principal investigator via videoconference (Microsoft Teams) with digital health leaders and chief digital health or clinical information officers from national digital health organizations and public health departments, who have executive responsibility for digital health, including authority over all aspects of a significant area of work and accountability for making decisions critical to the organization's success. The number of participants is consistent with the qualitative methodology being used to ensure data saturation [43-45]. Five open-ended questions will guide the interviews. The key informant interviews will be conducted for approximately 45 minutes each and digitally captured via the recording functionality of the Microsoft Teams videoconference call.

For both types of interviews, a person-specific transcription is provided to each participant to amend or delete any of their comments, particularly for validation of accuracy or to clarify a statement, should they wish to do so.

Data Analysis for the FGDs and Semistructured Interviews

All transcripts will be subsequently analyzed using NVivo software (QSR International) or Leximancer software (Leximancer) or other content analysis tools. For the focus group interviews, a thematic analysis will be conducted iteratively with data from the focus groups to develop concepts, categories, and themes. Competencies will then be analyzed and categorized

XSL•FO
RenderX

against existing national and international health service management and digital health competency frameworks. Enabling and inhibiting factors will also be analyzed using Braun et al [46] 6-phase reflexive thematic analysis approach to identify, organize, analyze, and advance insight into themes or categories of the factors emerging.

Importantly, reflexive thematic analysis enables the researcher to highlight meaning as contextual or situated while simultaneously undertaking analysis of the text for meaning [47,48]. Further, the legitimacy and validity of the researcher's subjectivity are not just acknowledged, but it is also an intrinsic asset, as reflexive thematic analysis supports the active role of the researcher in the knowledge generation process [47]. Using the 6-phase reflexive thematic analysis approach as detailed in Textbox 1 augments the acquisition of text patterns and key terms to reveal patterns that were previously unknown and furnish information with meaning [49].

Textbox 1. The reflexive thematic analysis 6-phase approach guiding data analysis [46].

Familiarization

Moving from data generation to analysis, that is, appreciating the data, by becoming immersed in and connecting with the data in different ways.

Generating codes

Moving to a more in-depth and systematic engagement with the data, that is, making sense of the data, by curating a list of terms, filtering out textual noise, and generating clear patterns to extract more valuable insights [49].

Constructing themes

Moving from codes into overarching themes that accurately and coherently represent the data, that is, creating a story about the data, through latent semantic analysis and singular value determination to uncover themes [49].

Revising themes

Moving to candidate themes and reviewing them to see how each theme relates to the others, that is, telling the overall story about the data.

Defining themes

Moving to clear definitions of each theme by elucidating the essence and scope of each theme, that is, what is meaningful about the data.

Producing the report

Moving to a final test of how well the themes work, both individually in relation to the data set and overall, that is, a logical story with sufficient evidence that the themes are relevant to the data.

The semistructured interview transcripts will then be analyzed using reflexive thematic analysis to triangulate the findings with the themes emerging from the FGDs. This will assist in validating the health service manager's competencies required to manage in the digital health context, as well as generating perspectives on both role development and enhancement needs for a health service manager's digital health competency, and aspirational and professional development requirements for health service managers to lead in the digital health space.

Both the FGDs and semistructured interviews will use the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist to "promote explicit and comprehensive reporting of qualitative studies (interviews and focus groups)" [50].

Results

Results from phase 1 of the study, which commenced in October 2019, were published in July 2021 [35] and October 2022 [6] and informed the significance of the research study and the final study design, which are presented here.

Competency Mapping Results

By completing the mapping of the 85 ACHSM Master Health Service Management Competency Framework competencies to the 50 health informatics competency statements from the AHICF, it was found that nearly half of this framework's competencies were only partially or not addressed at all by the ACHSM framework. As the ACHSM framework guides accreditation of postgraduate health care management programs offered domestically in Australia and forms part of the RACMA fellowship program, this indicated that the existing formal graduate-level education may not be adequate in developing health service managers' competency in the digital health era [35]. This published work highlighted an important gap to address—developing skills for the health management workforce relies on industry competency framework requirements that guide the curriculum and training endeavors as well as for the university programs, professional organizations, and individual health care institutions.

Scoping Review Results

The scoping review confirmed the five key activities that influence the development of health management workforce competency and capacity, namely: (1) using competency assessment, (2) guided by competency models, (3) supporting formal professional development, (4) including short-term training activities, and (5) using work-based development. Additionally, the following seven key factors that facilitate development of the health management workforce in the digital health context were also identified and included: (1) acknowledgment and recognition of these new digital responsibilities, (2) the organization's capacity to adopt innovation in a supportive environment to embrace digital health, (3) system-level support and political will, (4) specialized digital technology expertise, (5) an investment in the health service management workforce, (6) being underpinned by

XSL•FO
RenderX

systematic integration in planning, and (7) being used for practice development [6]. How these key activities work in the health care context and how these factors should be addressed require further exploration.

Discussion

Anticipated Findings

Focus Group Discussions

The FGD participants will provide reflections and insights to explore the competencies that health service managers need to acquire to effectively work with and manage in the digital health context along with factors that enable and inhibit acquisition of these competencies. The FGDs will explore the relevance of the additional competencies identified in steps 1 and 2. Findings of the identified list of important competencies from the FGDs will then inform the finalization of the semistructured interview questions.

Semistructured Interviews

The focus of the semistructured interviews is to explore (1) validation of the findings from the FGDs in terms of core health service manager competencies, barriers, and enablers to manage in the digital health environment and (2) in-depth insights affecting digital health influences on digital health policy and practice.

Limitations

It is important to note some limitations associated with a research protocol. The study is qualitative in nature to develop an in-depth understanding of Australian health service manager's experiences and views. The methods described could be applied in other contexts; however, the results may not be generalized to other country contexts. Any recommendations provided in subsequent publications will note these limitations, and suggested findings are contextualized to individual jurisdictions and environments.

Industry Impact

Review of the AHICF competencies was completed by the Certified Health Informatician Australasia Examination Committee in 2022, of which the principal investigator is a member, and version 2.0 of the AHICF [51] now contains 11 leadership and management competencies in domain D, up from the previous 5 management science competencies in domain 4 of version 1.0.

Further, a review of the ACHSM Master Health Service Management Competency Framework was completed by the National Steering Committee in 2022, of which the principal investigator was a member, and version 2.0 [52] now contains 6 digital management competencies in an action domain, whereas no specific digital competencies were articulated in version 1.0.

Conclusions

This study will provide real-time, in-depth insights into the health service management workforce performance and development needs for digital health and will uniquely inform credentialing and professional development requirements for health service management. Further, this will also illuminate the postgraduate programs and continuing professional development requirements for health service management education and training. Developing strategies based on these findings will assist in supporting the health service managers to lead and manage the adoption and implementation of digital health technology and initiatives in the health care sector, including insights into the health care system's digital workforce policy and capacity considerations. This will assist in optimizing the outcomes from adoption of digital health as a contemporary tool for health care delivery and furthering digital transformation outcomes for patients, practitioners, providers, and the public.

Acknowledgments

The authors gratefully acknowledge the Australian Government Research Training Program fee offset scholarship. No generative artificial intelligence was used in any portion of the paper writing.

Data Availability

The data sets generated during and analyzed during this study are not publicly available due to ongoing data collection from participants but may be made available from the corresponding author on reasonable request.

Authors' Contributions

MB, with the supervision of ZL, MM, and MW, conceived and designed the study. MB performed the competency mapping and literature search in collaboration with ZL, MM, and MW. The first draft of the paper was prepared by MB. ZL revised it critically for important intellectual content, upon which all authors then conceptually commented. MB, ZL, MM, and MW provided substantial contributions to the conception of the research protocol. MB and ZL finalized the paper, and all authors approved the final version of the paper.

Conflicts of Interest

None declared.

Abstract

Background: Diabetic foot ulcers (DFUs) cause significant morbidity affecting 19% to 34% of people living with diabetes mellitus. DFUs not only impair quality of life but may also result in limb loss and mortality. Patient education has been advocated to raise awareness of proper foot self-care and the necessity of seeking assistance when a foot wound occurs. Modern technologies, including mobile health (mHealth) interventions such as health apps, bring the potential for more cost-effective and scalable interventions.

Objective: This study aims to examine the feasibility and usability of a newly developed mHealth app called Well Feet, which is a diabetes and foot care education app for individuals at risk of developing DFU.

Methods: Well Feet was developed using an evidence-based and expert panel cocreation approach to deliver educational content available in 3 languages (ie, English, Chinese, and Malay) via animation videos and a range of additional features, including adaptive learning. A nonrandomized, single-arm feasibility study using a mixed methods approach with a series of validated questionnaires and focus group discussions will be conducted. In total, 40 patients and carers will be recruited from a tertiary hospital diabetes clinic to receive a 1-month mHealth intervention. The primary outcomes are the usability of the app and a qualitative perspective on user experience. Secondary outcomes include changes in foot care knowledge, self-management behaviors, and quality of life.

Results: Patient recruitment began in July 2023, and the intervention and data collection will be completed by the end of September 2023. This study has been approved by National Healthcare Group Domain Specific Review Board (2022/00614) on February 10, 2023. The expected results will be published in spring 2024.

Conclusions: Through this feasibility study, the Well Feet DFU education app will undergo a comprehensive quantitative and qualitative evaluation of its usability and acceptance for future improvement in its design. With local contextualization, cultural adaptation, and its multilingual functionality, the app addresses a critical aspect of DFU health education and self-management in a multiethnic population. Findings from this study will refine and enhance the features of the app based on user feedback and shape the procedural framework for a subsequent randomized controlled trial to assess the effectiveness of Well Feet.

Introduction

Background

According to the International Diabetes Federation, 537 million people worldwide (ie, 1 in 10) lived with diabetes in 2021, and this number is expected to rise to 783 million by 2045 [1]. The lifetime incidence of developing a diabetic foot ulcer (DFU) in adults living with diabetes ranges from 19% to 34% [2]. In a 2017 systematic review and meta-analysis, DFU's global prevalence among people with diabetes was estimated to be 6.3%, with Asia having a prevalence of 5.5% [3]. Diabetes-related lower extremity complications affected an estimated 131 million people (1.8% of the total global population) in 2016, with overall age-standardized rates for years lived with disability increasing by 15.9% between 1990 and 2016 [4]. Southern sub-Saharan Africa, South Asia, and Southeast Asia experienced the greatest growth during the period. Despite multiple clinical [5], economic [6,7] and policy [8,9] attempts to address DFU in Singapore, the country is still struggling to combat the rising prevalence of DFU-related complications with a reported 1500 DFU-related lower-limb amputations performed each year [10]. Furthermore, the estimated recurrence rate is 22.1% per person-year [11]. Hence, DFUs impose a significant clinical and economic burden on health care systems around the world as well as significant reductions in the quality of life for those affected [12].

Prevention initiatives, including lifelong patient education and continuous empowerment, are key strategies for successful foot care and management of diabetes, as recommended by evidence-based guidelines [13]. Whether delivered one-to-one or in small groups, diabetes foot health education is resource-intensive and costly—requiring the participation of doctors, nurses, podiatrists, diabetes educators, and allied health professionals. While valuable, foot care and diabetes education sessions lack immediacy, timeliness, access, and flexibility. In Singapore, 36% of patients with diabetes reported receiving no diabetes education [14] and over 51% spend less than a minute checking their feet [15]. Given the unmet need, financial and health workforce constraints, and being in line with modern approaches to education and self-management support, a digitally supported diabetes education mobile health (mHealth) apps using prevention and management of the DFU education program carries the potential to improve health care delivery and increase uptake, equity, and cost-effectiveness of health services related to DFU. Patient-facing technology such as mHealth apps can be blended with face-to-face care to augment the overall delivery of care and health services [16] and impact patients' health outcomes [17].

The other agency that is heavily involved in the management of DFU is the carer. Informal carers are defined broadly as any family member, partner, or friend who provides support to a person having a chronic condition. Carers play a vital role particularly in assisting with wound care, monitoring changes, ensuring foot hygiene, managing medications, offering emotional support, advocating for medical care, and providing education [18]. Carer's involvement improves patient outcomes, prevents complications, and enhances overall DFU care and well-being. For many people with chronic conditions, particularly the elderly, informal carers provide support and take responsibility for many of the care needs. Upskilling informal carers may result in better health outcomes [18]. Training equips them with skills to provide effective wound care, identify issues early, prevent complications, manage medications, offer emotional support [19] and promote timely access to health care. This improves the overall DFU management beyond the hospital walls, which may eventually result in reduction of hospitalizations, lowers costs of health care, and ensures collaborative, sustainable DFU management among patients, carers, and health care professionals.

Related Work

Studies suggest that people living with diabetes show an interest in mHealth apps for preventing and monitoring DFUs [20]. There is a growing body of evidence supporting the potential of mHealth apps to enhance diabetes self-management performance [21]. A few studies have been conducted to assess or validate the potential of an mHealth app for diabetic foot care. Some of them focus on providing wound care trackers [22,23], others on empowering with knowledge on foot-ankle exercises [24], quick tips on foot care and first aid, reminders for medical check-ups, a contacts feature to save health providers' contact information [25], text messaging [26], foot care essentials [27,28], foot care education in 6 animations [29] and tips for self-assessment [30]. Prior to a full trial, feasibility studies are routinely performed to determine whether a future study is feasible [31].

Some of the challenges identified in such interventions include maintaining patient engagement [25], tailoring content to the different stages of complexity of the disease, retaining and applying the knowledge acquired [32]. Thus, there is a need to explore the mechanisms by which evidence-based behavior change techniques and digital features can influence the uptake of digital diabetes and foot care education and ultimately improve diabetes health literacy and self-management behaviors. Even though the validation studies presented promising results, none of the mHealth apps for DFU comprise comprehensive in-depth education on all aspects of foot health, including prevention, inspection, and wound care while concurrently providing support for self-management with tracking features that focus both on feet health and general diabetes care. Additionally, no other tool addresses the need for a multilingual and adaptive solution that fits individual needs, such as the role (patient or caregiver), severity of the condition, and competency levels, concurrently reinforcing learning through notifications and spaced learning. Finally, there is a necessity to understand the user's engagement and app effectiveness in detail using granular click-level data.

RenderX

Aim

This is a "proof-of-concept" feasibility study to evaluate a foot health education app for people living with diabetes, Well Feet, among patients and carers. Prior to a full trial, feasibility studies are routinely performed to determine whether a future study is feasible [31].

Methods

Study Design

This study is a nonrandomized, single-arm feasibility study with baseline, end point, and focus-group discussion design. An explanatory sequential mixed methods approach will be used to assess feasibility and usability of the mHealth app, Well Feet. Our study features a 1-month intervention period carefully designed to strike a balance between meaningful observation and participant convenience. This timeframe enables us to assess the feasibility of the intervention on our selected outcomes. All participants will receive Well Feet, and their feedback will be collected through quantitative and qualitative rating measures. Subsequently, focus group discussions will be conducted to provide valuable insights into their experiences. The reporting of this protocol follows CONSORT (Consolidated Standards of Reporting Trials) 2010 statement extension for feasibility studies [33]. This study has been registered at ClinicalTrials.gov (NCT05564728).

Study Participants

Eligibility Criteria

Both patients and carers will be invited to participate in this study. Inclusion criteria for patients are (1) being diagnosed with type 2 diabetes and attending Tan Tock Seng Hospital Diabetes Clinic, (2) being 21 years or older, (3) being able to speak and read English, (4) owning a smartphone or tablet and can download the app, (5) having internet access, (6) being able to provide informed consent, (7) being Singaporeans or Singapore permanent residents. Inclusion criteria for carers are (1) carers who provided care for a patient with type 2 diabetes for the past 6 months, (2) being aged 21 years or older, (3) being able to speak and read in English, (4) owning a smartphone or tablet and being able to download the app, (5) having internet access, and (6) being able to provide informed consent. Exclusion criteria for patients and carers include being (1) pregnant, (2) an inpatient, or (3) having received formal training in medicine or allied health services.

Recruitment

Patients will be recruited through referrals from attending endocrinologists at Tan Tock Seng Hospital. Recruitment will take place during the patients' routine clinic visits at Diabetes Clinic. The endocrinologists will screen for potential participants' eligibility based on this study's inclusion and exclusion criteria before referring them to the appointed research assistant to complete the recruitment process. At the same time, patients will be asked to nominate their carers to participate in this study. The nomination is optional and subject to patients' and carers' willingness. Notwithstanding, patients without a carer can still participate in this study. Potential patients and carers who choose not to participate in this study will be asked an open-ended question about the reasons. It will be highlighted that answering the question is voluntary. The information will be used to inform about the barriers to recruitment and acceptability of the intervention.

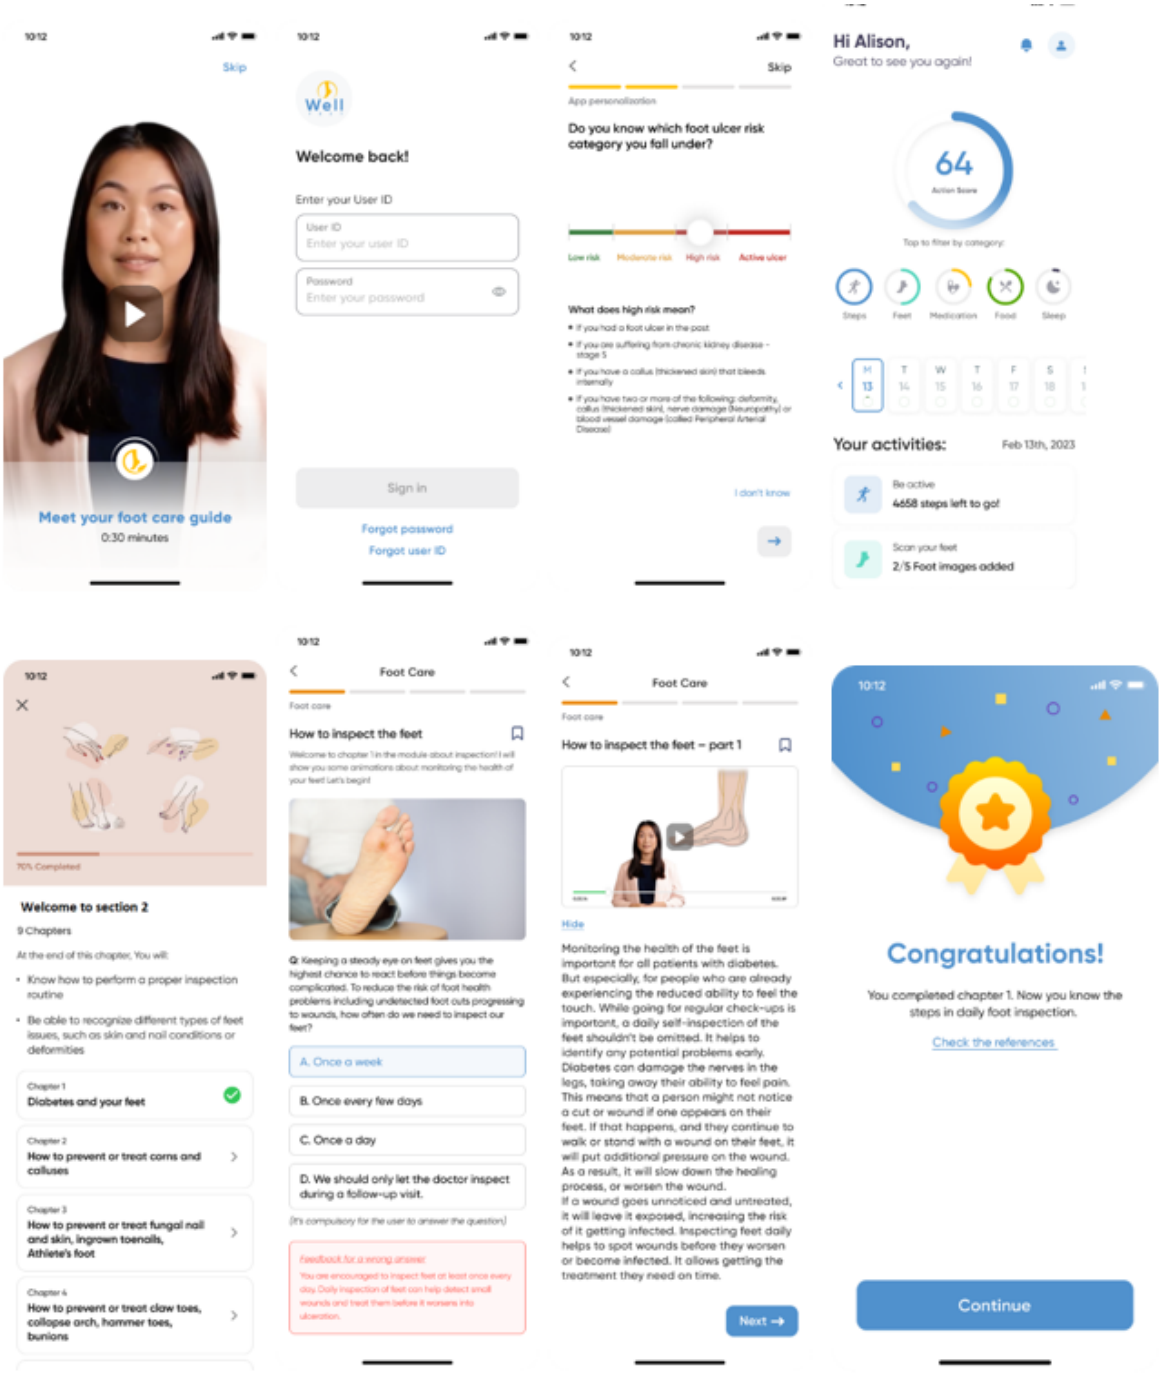
Informed Consent

The research assistant will conduct a briefing for all referred patients and carers in a closed space outside of the clinic room. The briefing involves explaining this study's aim and study's inclusion and exclusion criteria. Additionally, potential participants will be briefed thoroughly about this study's procedures, risk exposure, and all the information included in the informed consent form (Multimedia Appendix 1). The research assistant will provide adequate time for the participants to decide. Participants will be allowed to discuss their decisions with family members before participating in this study. The wishes of the participant will be respected if they choose not to participate in the research. The research assistant or site principal investigator will provide a copy of the informed consent form and obtain written consent from the potential study participants. It will be highlighted to the participants that this study is voluntary, and their participation would not affect their clinical care or any benefits that they are entitled to.

Participants will be advised to retain a copy of the signed informed consent form for documentation, they will also receive a WhatsApp (Meta Platforms, Inc) message confirming their enrollment for this study, contact details, and basic information about study design.

Sample Size and Power Calculation

Since this is a feasibility study, a formal sample size calculation is not required [34]. Our target is to recruit a minimum of 30 participants (with a maximum of 40), evenly divided into groups: persons living with diabetes and carers of persons living diabetes, with 15 participants in each group (with a maximum of 20). This approach is based on a previous study that shows a feasibility study requires 30 or more participants to estimate a parameter [35]. An arbitrary sample size of 30 would provide 0.75 (75%) power to detect a medium effect size of 0.5. Alternatively, a sample size of 40 would provide even greater power at 0.87 (87%).



Intervention

Well Feet mHealth App

Well Feet is a diabetes and foot care education mHealth developed by Nanyang Technological University. The technical building process of the app is outsourced to a university-appointed vendor while the content building process was carried out in-house. The app was made available to download both for iOS and Android. Screenshots of Well Feet's main interface and features are shown in Figure 1.

XSL•FO
RenderX

Figure 1. Selected screenshots from the Well Feet app.

Adaptive Learning Framework

Well Feet is a diabetes and foot care education app and was designed based on an adaptive learning framework to deliver educational modules and action-oriented conversations related to foot care through multilingual (English, Mandarin, and Malay) animations with a deep fake presenter. A total of 21 modules covering 4 themes: introduction, inspection, prevention, and wound care, have been developed by this study's team based on a series of validated and evidenced-based sources including the International Working Group on the Diabetic Foot [36] guidelines as visualized in Textbox 1. The curriculum outline was consulted in 2 rounds in an asynchronous expert panel. Next, the scripts were developed with consideration of readability, cultural relevance, and local context, and were transformed into animations in an iterative design process comprising storyboarding, prototyping, production, and reviews. In total, 54 bite-sized and visually appealing animation videos ranging from 30 seconds to 2 minutes were produced for diabetes foot educational content. The content was prepared in English and translated into Mandarin and Malay. The animations are accompanied by adaptive learning quiz questions that allow us to assess knowledge gaps and trigger spaced learning conversations in case of incorrect answers. The system includes storing an in-depth click-level data which allows a vast analysis of learning and usage analytics.

RenderX

Textbox 1. Overview of the 21 modules included in the Well Feet app.

Introduction

- Categories of risk
- Amputation
- Diabetes and your feet: nerves, blood vessels, skin, joints

Inspection

- Visual inspection
- Foot conditions—skin and nails 1 (corns and calluses)
- Foot conditions—skin and nails 2 (fissures or fungal nail and skin [tinea pedis] or dystrophic nail or ingrown toenails)
- Foot conditions—deformities 1 (claw toes or hammer toes or bunions)
- Foot conditions—deformities 2 (Charcot foot)
- Foot conditions—peripheral neuropathy
- Foot conditions—peripheral vascular disease
- Other foot conditions commonly encountered by patients with diabetes
- Professional foot examination

Prevention

- Hygiene
- Diabetes-friendly footwear
- How to trim nails safely
- Skin care
- Simple exercises for the foot or calf
- Practices to avoid

Wound care

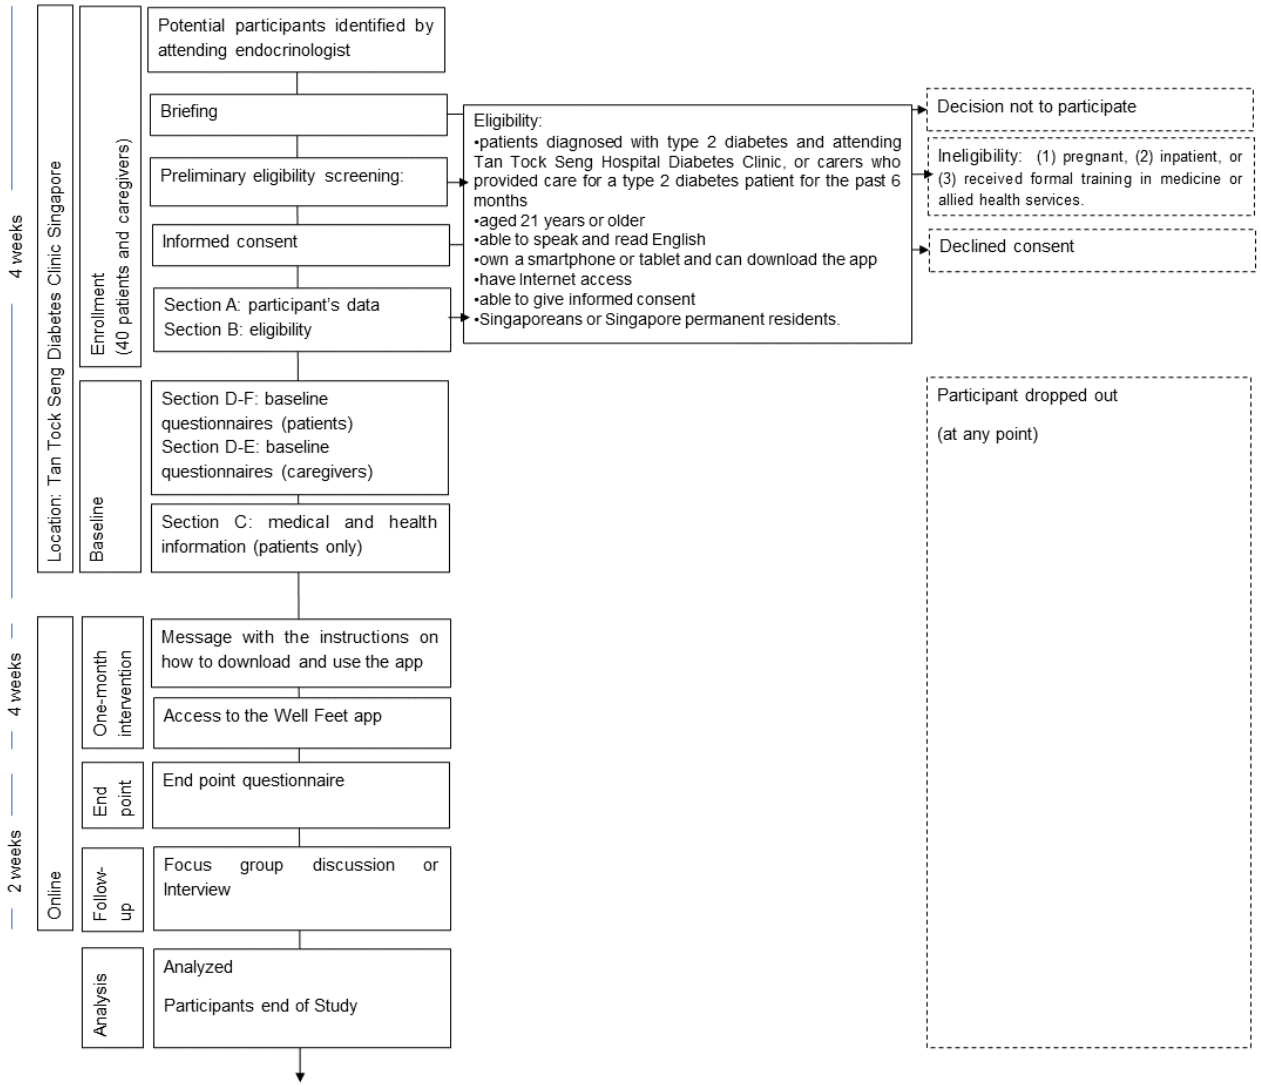
- Wound care—basic
- Diabetic foot ulcer
- Wound care—diabetic foot ulcer

Concurrent with curriculum development, the team was working on identifying relevant app features and conceptualizing app mechanics with instructional experience as a focus to connect user flow between features and align it with desirable behavior changes. In total, 3 levels of learning adaptations have been devised: (1) personalization of the content based on the role served, (2) personalization of the order of the modules based on the user's risk stratification identified in the onboarding process, and (3) personalization of the content based on user's knowledge level through knowledge assessment. This personalization forms the basis of learning framework in Well Feet. Additional features such a Frequently Asked Question chatbot, meal diary, feet diary, medication reminders steps, and sleep tracker are further added to enhance user experience. Finally, the app includes an automated notification system which in case of inactivity prompts the user to use the app.

Setting

Due to the nature of the Well Feet intervention being an mHealth app, participants are anticipated to engage with the intervention at their own discretion. Nevertheless, this study's team will remind the participants at the start of this study to engage with Well Feet app throughout this study's period.

Data Collection



Overview

The participant flow through this study is illustrated in Figure 2. Consenting participants will be assigned with a study ID that will be used as their coded identifier throughout this study. Participants will receive a briefing regarding this study's procedures and will answer a baseline questionnaire using a digital survey platform, REDCap (Research Electronic Data Capture, Vanderbilt University), accessed through a provided tablet. A study ID will be assigned to each participant to keep their answers to the questionnaire anonymous. A research assistant will assist with participants to complete the prescreening and enrollment sections, that is, for the participant's details and eligibility form. The clinical research assistant will access and extract medical records to complete the section with medical and health related information. Participants will complete sociodemographic information and questionnaire sections by themselves. The research assistant may assist the

XSL•FO
RenderX

participants if help is needed. Additionally, the research assistant will access and extract medical records to complete the section with medical and health related information. Carers will go through the same recruitment and briefing flow as the patients. However, no medical record will be extracted for carers. Completion of the questionnaire is on a voluntary basis. If the participant requests to fill out the questionnaire at their own convenience, the research assistant will send them a link to the questionnaire through their preferred communication medium. The research assistant will also follow-up with a gentle reminder to complete the questionnaire in a case the participant did not fill it out.

Figure 2. Participant flow through this study (CONSORT [Consolidated Standards of Reporting Trials]).

The intervention will begin with the participants receiving the link to the app. The participants will be asked to use the app for up to 1 month. At the end of the period, they will be asked to fill out an end point questionnaire and will be invited to participate in focus group discussions or an interview, in case the participant cannot participate in focus group discussions, as a follow-up. To minimize attrition, prompts will be sent via the participants' chosen mode of contact (eg, via email, telephone, SMS text message, or WhatsApp) to indicate it is time to complete the survey or participate in the focus group discussion.

Outcome Measures

This study's outcomes of interest encompass methodological, procedural, and feasibility questions. Various factors are considered. Table 1 displays the primary outcomes including usability of the app and qualitative perspective on user experience. Multimedia Appendix 2 [37-43] displays secondary outcomes, including changes in foot care knowledge, self-management behaviors, and quality of life. Additionally, usage and learning analytics will be collected from the backend of the app.

XSL•FO
RenderX

Table 1. Primary outcomes.

Outcome measure	Measure description	Time frame
Primary outcome		
Usability of a health app among patients and carers at the end of the trial (1 month)	A validated questionnaire, MAUQ[a] [44], will be used to determine the usefulness and applicability of an app with a conversational agent or chatbot among patients and carers. The questionnaire consists of 3 subscales, which are ease of use (5 items), interface and satisfaction (7 items), and usefulness (6 items). Participants rate each of the items using a 7-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree). The usability of the app is determined by the total and average of all statements—the higher the overall average, the better the usability of the app. However, if the average score is lower than 4, it means that the usability of the app is not good. The MAUQ exhibited strong psychometric characteristics, as evidenced by an overall Cronbach α value of .914 [44].	End-of-trial (1 month)
Qualitative perspective on a conversational agent or chatbot app usage experience among patients and carers at the end of the trial (1 month).	A focus group discussion among the app users will be carried out to collect feedback on the user experience at the end of the trial. Qualitative data on app usability, app applicability, app relevance, and user feedback will be retrieved from the focus group discussion.	End-of-trial (1 month)

[a]MAUQ: mHealth (mobile health) App Usability Questionnaire.

Data Management

All data will be handled according to patient Nanyang Technological University data protection and privacy policy [45] as well as National Healthcare Group, Tan Tock Seng Hospital data protection and privacy policy [46] with all participants assigned a study ID to deidentify data and any personal information about participants will be stored separately from deidentified data. Data collected via digital survey platform, REDCap will be stored on secure servers at Center for Population Health Sciences, Lee Kong Chian School of Medicine, Nanyang Technological University. The data gathered through the app will be stored in a university-approved cloud server as a multiencrypted database with authorization granted for principal investigators and study team members to prevent unauthorized persons from accessing the data. All other physical forms will be stored in a locked filing cabinet in the clinical site and will be accessible only to the site-principal investigator and appointed research assistant. User's interaction within the Well Feet app will be monitored to identify participants' signaling their need for more extensive support.

Ethical Considerations

This study was approved by the National Healthcare Group Domain Specific Review Board (2022/00614) and the Nanyang Technological University institutional review board (IRB-2023-157), ensuring that the welfare and rights of all participants is protected in this study. This study will be conducted in accordance to the Helsinki code of ethics ensuring that patients' confidentiality, integrity, and vulnerability are kept throughout their participation. Informed consent will be collected to ensure participants are aware of this study's procedure and their rights to withdraw from this study without the need to give any reason. Participants will be provided with contact information within the informed consent form should they have any concern regarding the conduct of the feasibility study.

Analysis

Quantitative Analyses

The questionnaires answered by the participants will be summarized using descriptive statistics, and the data will be presented as frequencies, percentages for categorical variables and means, SDs, medians, and IQRs for continuous variables depending on the distribution of the variable. Descriptive statistics will also be used to assess measures of app usage. Differences between groups will be analyzed using chi-squared or Fisher exact test for nominal data and changes within the groups over time (pre-post) will be analyzed using the Wilcoxon signed rank test. R (R Core Team) and Stata (StataCorp) will be used for all analyses.

Qualitative Analyses

All focus group discussions will be recorded on a digital teleconferencing platform (ie, Zoom; Zoom Video Communications, Inc), which will then be transcribed verbatim. Any identifiers in the transcriptions will be removed. Thematic analysis will be used to identify participants' experience, overall acceptance, and feedback. The analysis of the responses will start immediately following the first focus group and transcription. Initial codes will be generated, then collated into themes to identify the key patterns and key themes of the focus group discussions using the procedures suggested by Clarke and Braun [47].

Dissemination

This study's findings will be published in an open access journal and via national and international conference presentations.

Results

This study was funded in October 2019 and received ethics approval in February 2023. Recruitment of this study was done in July 2023 with 40 participants enrolled. Well Feet app is expected to be published at Google Play and iOS testflight at the end of August 2023, followed by a month-long intervention period. Analysis of results is expected to be completed by

XSL•FO
RenderX

October 2023, and trial results are expected to be published in spring 2024.

Discussion

Principal Findings

This study is designed with the aim to evaluate the feasibility of Well Feet, a mobile health app designed for people living with diabetes and at risk of DFU. This study will provide insights on Well Feet's added values, potential benefits, and challenges of its use among patients and carers. Through a combination of quantitative evaluation using the validated MAUQ questionnaire and qualitative insight from focus group discussions, this study will provide a perspective on the feasibility of Well Feet particularly on how the app facilitates patients and carers engagement in diabetes foot health management. Additionally, analytics derived from Well Feet usage data will provide a clearer picture on user interaction with features of the app.

Studies ranging from early detection and prevention to self-monitoring apps collectively highlight the potential of mHealth in improving patient outcomes, and addressing challenges in diabetes care [48]. We are expecting that similar to other studies a difference in knowledge pretest and posttest knowledge score will be observed [49,50] and that the app will be perceived as valuable [22,24,25,27,28,51]. However, as the learning curriculum included in Well Feet app is much more comprehensive than in other solutions and encompasses multilevel tailoring mechanisms such as notifications for learning reinforcement and adaptive learning pathway for knowledge gaps identification, we are expecting that the foot care knowledge and behavior results will differ from other studies. The qualitative analysis will additionally help to identify specific behavioral changes among study participants going beyond observing frequency of foot checking [20].

Furthermore, in this study we are aiming at in app exploring usage patterns among the participants, especially those who experienced knowledge or behavior change. Ploderer et al [51] has observed 3 usage patterns when evaluating a wound care tracking app: continuous, temporary, and failing usage. In our study, it is expected that some barriers to usage identified by Ploderer et al [51] will overlap, especially the ones leading to temporary usage such as work commitments and health disruptions. As the sample of participants will vary across different risks of developing DFU and will include low and moderate risk patients, the frustration with lack of healing progress might not arise. The usage and learning analytics of click-level data should allow us to further describe exact app behaviors that constitute each group of users. Usage patterns will be juxtaposed with knowledge and behavior questionnaires' results to further reveal engagement patterns and factors influencing the success of foot care education.

Strengths and Limitations

This study comes with a set of strengths and limitations. A structured approach described in this protocol will be used to assess the practicality and viability of a newly developed adaptive diabetes foot health education, Well Feet, before a full-scale development and deployment. The utilization of both quantitative and qualitative measures enhances the depth and breadth of insights gained from this evaluation. By performing a feasibility study, the research team will be able to identify technical, operational, and logistical challenges early in the process, thus potentially saving time and resources when a larger randomized controlled trial is conducted.

However, there are several limitations worth noting. The small cohort of study participants recruited from a single tertiary hospital limits the generalizability of findings. A follow-up multicenter randomized controlled trial is warranted to predict a proper intervention effect. Second, while only patients who owned mobile devices were recruited, no formal assessment of digital literacy was performed during the recruitment process. As smartphone ownership may not be an accurate indicator of proficiency in using basic phone features [52], patient's engagement with Well Feet app may be impacted by limited digital literacy.

Conclusions

Patient-facing digital health technologies such as mHealth apps promise to support self-management of various health conditions, including diabetes and associated risk factors. Such feasibility research, especially when it encompasses user-centered design and evaluation, contributes to health care services transformation aimed at equitability, patient empowerment, and shared decision-making. Gaining growing attention from researchers [53] and patients [15], mHealth interventions pave the road for future health care where digital solutions, including health education, are seamlessly integrated into routine prevention and care. This feasibility study is a step in embracing technological innovations which aim to optimize advancing a DFU prevention and management and care delivery.

Abstract

Background: Distributed medical education (DME) offers manifold benefits, such as increased training capacity, enhanced clinical learning, and enhanced rural physician recruitment. Engaged faculty are pivotal to DME's success, necessitating efforts from the academic department to promote integration into scholarly and research activities. Environmental scanning has been used to gather, analyze, and apply information for strategic planning purposes. It helps organizations identify current practices, assess needs and barriers, and respond to emerging risks and opportunities. There are process models and conceptual frameworks developed for environmental scanning in the business and educational sectors. However, the literature lacks methodological direction on how to go about designing and implementing this strategy to guide research and practice in DME, especially in the psychiatry field.

Objective: This paper presents a protocol for an environmental scanning that aims to understand current practices and identify needs and barriers that must be addressed to facilitate the integration of psychiatrists from the Dalhousie University Faculty of Medicine's distributed education sites in Nova Scotia and New Brunswick into the Department of Psychiatry, contributing for the expansion of DME in both provinces and informing strategic planning and decision-making within the organization.

Methods: This protocol adopts an innovative approach combining a formal information search and an explanatory design that includes quantitative and qualitative data. About 120 psychiatrists from 8 administrative health zones of both provinces will be invited to complete an anonymous web-based survey with questions about demographics, participants' experience and interest

XSL•FO
RenderX

in undergraduate, postgraduate, and continuing medical education, research and scholarly activities, quality improvement, and knowledge translation. Focus group sessions will be conducted with a purposive sample of psychiatrists to collect qualitative data on their perspectives on the expansion of DME.

Results: Results are expected within 6 months of data collection and will inform policy options for expanding Dalhousie University's psychiatry residency and fellowship programs using the infrastructure and human resources at distributed learning sites, leveraging opportunities regionally, especially in rural areas.

Conclusions: This paper proposes a comprehensive environmental scan procedure adapted from existing approaches. It does this by collecting important characteristics that affect psychiatrists' desire to be involved with research and scholarly activities, which is crucial for the DME expansion. Furthermore, its concordance with the literature facilitates interpretation and comparison. The protocol's new method also fills DME information gaps, allowing one to identify insights and patterns that may shape psychiatric education. This environmental scan's results will answer essential questions about how training programs could involve therapists outside the academic core and make the most of training experiences in semiurban and rural areas. This could help other psychiatry and medical units outside tertiary care establish residency and fellowship programs.

Introduction

Distributed Medical Education

The need to recruit physicians into rural areas and regional centers in Canada is well-recognized. According to a report by Pong et al [1], 9.4% of all Canadian physicians were practicing in rural areas compared with 21.1% of Canadians living in rural and small towns. One approach that has been used to successfully recruit and retain trainees in underserved communities is distributed medical education (DME) [2-6]. DME was first used in postgraduate medical education (PGME) in the 1970s to recruit and retain trainees in targeted rural communities. In the intervening years, it has been widely incorporated into undergraduate medical education (UGME) and PGME [7-9]. Studies have shown that longer rural postgraduate training is strongly associated with rural practice among general practitioners [10-12]. Preliminary studies have also suggested that increased exposure to rural practice in psychiatry residency training programs may increase the number of trainees choosing to practice in these communities after graduating [13,14].

In addition to the potential benefit of recruiting physicians, rural training offers trainees unique clinical experiences and provides first-hand knowledge of the health care systems that exist in rural, small, and underserved communities located outside of the academic centers in regional or "satellite" sites [13,15]. There is also the possibility that exposure to smaller communities and community-based practice may encourage generalism [16]. The Royal College of Physicians and Surgeons of Canada defines generalism as "a commitment to a breadth of practice within one's discipline and responsiveness to patient needs" [17] and suggests that specialty training should include rotations in community-based centers in order to expose trainees to generalism and its importance. Adopting a generalist approach enables physicians to manage uncertainty, approach undifferentiated problems, and incorporate a broad understanding of disease prevalence and psychosocial context into the presenting health care concerns and management of patients [18].

While there is strong evidence regarding the value of distributed education, it is important to recognize that the successful implementation of DME involves more than simply sending trainees to distributed sites. In advance of any expansion of training, it is important to develop a comprehensive understanding of the opportunities it will provide and to identify gaps or barriers that may need to be addressed. The general standards for training programs required by external accrediting bodies must be rigorously maintained to ensure trainees can meet all required learning outcomes. In addition, attention must be paid to the quality of the experience and relationships with the local community, as these greatly influence whether a trainee eventually chooses to settle and practice within that community [8,19].

Because physicians and other professionals at distributed sites are essential to implementing DME, academic departments must be respectful and attentive as they engage and integrate distributed faculty into their teaching and scholarly activities [3,20-22]. Careful consideration of community engagement is key when developing DME programming, given the community preceptors' pivotal role in the development, delivery, and ongoing success of DME programming [20,23-27]. Navigating relationships between partners and establishing sound governance structures are essential components of successful DME [3]. Collaborative efforts must incorporate community values, attitudes, and beliefs [28], and all parties should be sensitive to potential challenges that can arise in communications between physicians practicing within the primary academic center and those practicing outside of it [29].

Organizational Context

Dalhousie University's Faculty of Medicine has 2 campuses. Dalhousie Medical School based in Halifax, Nova Scotia, Canada opened approximately 150 years ago in 1868. A regional

XSL•FO
RenderX

campus Dalhousie Medicine New Brunswick was established in 2010 in Saint John, New Brunswick, Canada. A third distributed campus is planned and will begin accepting students in Cape Breton, Nova Scotia by 2025. Dalhousie University requires anyone completing evaluations of medical trainees to have a faculty appointment, which may be either a continuing appointment or a limited-term appointment.

Clinical training in psychiatry at Dalhousie University comprises both UGME and PGME. In Nova Scotia, there are 2 health authorities where learners may be placed for clinical rotations: IWK Health and Nova Scotia Health. IWK Health provides secondary care to children, youths, and women regionally, tertiary care provincially, and quaternary care for the Maritimes. Nova Scotia Health is divided into 4 geographic zones serving the province: eastern, western, northern, and central. The central zone includes Halifax Regional Municipality, the capital of the province and the largest urban center with a population of 440,000 in 2021 [30]. Dalhousie University's main campus is in Halifax, and this is where the main teaching hospitals are situated. The central zone also contains the majority of the province's psychiatrists. The DME located in New Brunswick provides clinical education through the Horizon Health Network. Preclinical medical education is based in Saint John, and 4 of the province's 7 administrative health zones participate in the clinical education of Dalhousie University's medical students: zones 1 (Moncton), 2 (Saint John), 3 (Fredericton and River Valley area), and 7 (Miramichi).

In both provinces, psychiatrists at distributed sites make valuable contributions to the clinical education of medical students and residents, both psychiatry and nonpsychiatry. Eventually, the department also plans to extend its recently launched international fellowship training program to DME sites in the 2 provinces.

In contrast, psychiatry residency training at Dalhousie University has been more centralized with the majority of time spent in Halifax. While Dalhousie University's psychiatry residents rotate for short periods of time through Saint John, New Brunswick, and Kentville, Nova Scotia, the residency program does not currently meet the rural training requirements as set out by the PGME office, which states 10% of postgraduate training should occur in DME learning sites. To meet this requirement, Dalhousie University's psychiatry residency program has recently expanded its training outside of Halifax to include an inpatient rotation at the Cape Breton Regional Hospital in the eastern zone in their second year of training, a geriatric experience in outpatient clinics in western zone in their third year of training, and a 3-month elective requirement in the Maritimes in their final year of training. Geriatric and child and adolescent psychiatry residency (years 5 and 6) have mandatory DME experiences in rural zones. Nonetheless, the proportion of training outside Halifax is still lower than is desirable.

Greater involvement of distributed sites also offers an opportunity for increasing the training capacity of the residency program. Recently, the Government of Nova Scotia has asked Dalhousie University's Faculty of Medicine to increase the overall number of psychiatry residency training spots in order to address existing vacancies and meet the projected needs of the growing population of Nova Scotia. Similarly, the New Brunswick government is also interested in developing a New Brunswick–based residency program to assist with recruitment and retention of psychiatrists.

These factors (educational needs, institutional requirements, and political priorities) align with the principles underpinning the Dalhousie University Department of Psychiatry's Transformational Plan, which was introduced in 2021. Through this plan, the department seeks to extend its academic mandate to enhance medical education, research, and knowledge translation activities at distributed learning sites in Nova Scotia and New Brunswick.

Environmental Scanning

This paper describes a protocol for an environmental scan of DME sites in Nova Scotia and New Brunswick where the Department of Psychiatry's faculty members are situated. With this environmental scan, we seek to understand the existing resources and determine what is required to fully integrate DME sites into the academic mandate of the Department of Psychiatry.

Environmental scanning has been used as an effective method of gathering information for a variety of purposes. It is defined as "the acquisition and use of information about events, trends, and relationships in an organization's external environment, the knowledge of which would assist management in planning the organization's future course of action" [31]. Gathering, analyzing, and applying information garnered from environmental scans are essential for strategic planning purposes and organizational effectiveness, as it assists with identifying, assessing, and responding to emerging risks and opportunities [32].

There are process models and conceptual frameworks developed for environmental scanning in the business and educational sectors [33-36]; however, the literature lacks methodological direction on how to go about designing and implementing this strategy to guide research and practice in DME. Environmental scanning is crucial in informing strategic planning and decision-making within organizations, and to the best of our knowledge, no framework has been developed to guide this methodological approach in the DME context within psychiatry training. To this end, we have developed a comprehensive environmental scan protocol built upon previous methodologies [31,37].

Methods

Study Design

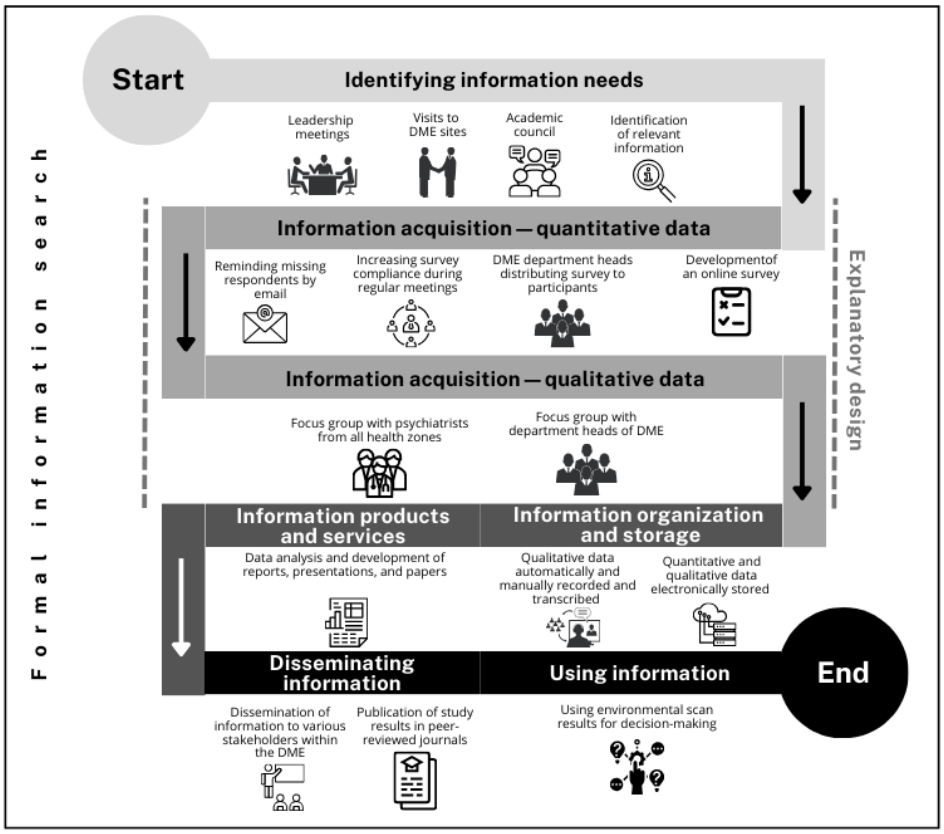
This study is an environmental scan that adopts a formal information search approach [31] and an explanatory design [37], including quantitative and qualitative data. Formal information search (ie, when a deliberate or planned effort is made to obtain specific information) is often used as an environmental scanning mode [31,33]. The information search is structured according to a pre-established methodology and is focused on systematically finding and retrieving detailed information, usually from sources that ensure data quality and accuracy, in order to provide a basis for developing a decision

XSL•FO
RenderX

or course of action [31]. The formal information search approach consists of several interrelated processes that determine the relevance of information, how it will be collected, organized, and stored, what products or services will be developed, and how it will be disseminated and used [38].

Due to the lack of standardized recommendations regarding the methodology to be used in environmental scans using a formal information search approach, the explanatory design was added. The overall purpose of this design is to collect qualitative data to help explain or build upon initial quantitative results [37]. This design starts with the collection and analysis of quantitative data followed by a subsequent collection and analysis of qualitative data.

Study Settings and Participants



This study will include participants from the 8 administrative health zones (4 in Nova Scotia and 4 in New Brunswick) currently involved in medical education. Dalhousie University Faculty of Medicine DME sites comprise mental health and addiction treatment facilities in the eastern, western, and northern zones of Nova Scotia and 4 health zones of New Brunswick. All psychiatrists at DME sites will be targeted for inclusion in the quantitative study. Based on data obtained from limited-term faculty appointments within the Dalhousie University Department of Psychiatry, it is estimated that approximately 120 psychiatrists are working at DME sites throughout Nova Scotia and New Brunswick. The exact number of psychiatrists working in the central zone of Nova Scotia is unknown, and not all psychiatrists at DME sites in Nova Scotia and New Brunswick have Dalhousie University faculty appointments. Thus, it is difficult to estimate the exact sample size for all psychiatrists working at DME sites in the 2 provinces. A representative sample of psychiatrists working at DME sites, from each health zone in Nova Scotia and New Brunswick, will be invited to participate in the focus group discussions. Purposive sampling will be used to identify subjects for key informant interviews. The distributed sites range in size from small rural communities to medium-sized regional centers, and representing the views of faculty in both types of settings will be an important consideration.

Study Procedures and Data Collection

Overview

The procedures of the environmental scan framework will be organized according to 6 interrelated processes or phases, as proposed by Choo [31] and explained as follows. The explanatory design [37] is integrated into these processes (Figure 1).

Figure 1. Overview of the proposed environmental scan framework. DME: distributed medical education.

Identifying Information Needs

In 2022, a series of meetings were held between the leadership of the Department of Psychiatry and the Faculty of Medicine to generate possible options for increasing residency training capacity. Additionally, the head of the department of psychiatry traveled to the distributed learning sites across Nova Scotia and New Brunswick, meeting with the chiefs of the relevant zones. These tours culminated in the establishment of the Nova Scotia and New Brunswick Psychiatry Academic Council, with membership including the zone chiefs for psychiatry at 8 administrative health zones in the 2 provinces, the chief of

XSL•FO
RenderX

psychiatry for the IWK Health authority, the directors of education and research, and the chief operating officer for the Department of Psychiatry. Items discussed during the inaugural meeting of the new Psychiatry Academic Council, which was attended by the dean of the Faculty of Medicine at Dalhousie University and the associate dean for Dalhousie Medicine New Brunswick, included the identification and refining of the categories of information that would be needed for this environmental scan. Following this consensus meeting, the categories of information identified as relevant for this environmental scan were demographics, mental health services and scope of practice, medical education, infrastructure, continuing professional development, and research and knowledge translation. These categories are depicted in the Outcome Measures section.

Information Acquisition

Information acquisition is a critical step in the environmental scan process. It involves obtaining relevant data from the right sources that can provide insights into the various factors that may impact an organization's operations, success, and sustainability. Effective information acquisition is essential for conducting a comprehensive and accurate environmental scan. Without access to reliable and relevant data, the scan may miss important trends and risks that could have significant implications for the organization. By contrast, a thorough and well-executed information acquisition process can help organizations stay ahead of emerging risks, take advantage of new opportunities, and make informed strategic decisions [38].

Following are the steps that will be taken during the information acquisition phase of this environmental scan, in which first quantitative and then qualitative data will be collected.

- Acquisition of quantitative data: Based on the information previously identified, a web-based survey was created, piloted, revised, and adopted. A link to the web-based survey will be sent to the clinical department heads for all the administrative health zones, and they will be asked to distribute the survey link to psychiatrists working within their zones. To maximize the survey response rate, engage community-based faculty, and encourage their participation in further program development, the clinical chiefs will be encouraged to set aside 15 minutes of their monthly zone psychiatrists' meetings for their psychiatrists to complete the survey. In this way, the survey can be completed as a group activity, with each psychiatrist given time to complete the survey confidentially on their personal cell phone or computer. For those not attending the meeting, a second electronic reminder will be sent out to ensure survey recipients complete the survey if they have not done so already. The web-based survey is powered by OPINIO (Object Planet), a web-based survey tool that provides a framework for authoring, distributing, and reporting surveys, which is licensed by Dalhousie University; by completing and submitting the anonymous web-based survey, participants agree to participate in this study. A brief study information leaflet and informed consent will be displayed on the initial page of the survey. The survey comprises 64 multiple-choice questions divided into 5 sections: demographics, mental health services and scope of practice, medical education, continuing professional development, and research and knowledge translation. A final section about study participation includes one question, about the willingness to participate in the focus group. The time expected for survey completion is 15 minutes.
- Acquisition of qualitative data: All the zone clinical department heads in New Brunswick and Nova Scotia will be invited by email to participate in a focus group. A second focus group will be organized for a representative sample of psychiatrists working in the zones who are not clinical department heads. For this group, an email will be sent to all the psychiatrists working at distributed learning sites (excluding the clinical department heads), inviting them to consider participating in a focus group. If interest exceeds demand, block random sampling will be used to select 2 representatives from each administrative health zone. Each of the 2 focus groups will be held over Zoom (Zoom Video Communications), recorded and transcribed verbatim. A transcriptionist will be hired to ensure the transcriptions recorded are accurate. If data saturation (ie, the point in data collection where interviews are no longer generating new information) and sufficiency (ie, that takes into account both individuality and the fact that information is shaped by social factors) [39] are not achieved following the analysis of the qualitative data collected through focus group sessions, psychiatrists who did not participate in the group sessions will be invited to participate in individual interviews until data saturation is achieved. The sample selection method for both focus group sessions and individual interviews (if needed) will involve using a purposive sample, entailing all psychiatrists to participate in the activities. The focus group guide comprises 12 questions, divided into 2 sets of 6 questions. The first set of questions addresses education, covering barriers and facilitators in establishing a distributed learning site, needs or gaps related to the proposed rotation, opportunities that a psychiatry postgraduate education site in your zone would offer learners and the local community, ways to promote and measure faculty engagement, and indicators or outcome measures for ongoing quality assurance and program improvement. The second section focuses on research and scholarship, including barriers and facilitators for establishing research programs, the connection between research and clinical care, personal benefits of research participation, methods to promote and sustain research and scholarly work at your site, and indicators or outcome measures for ongoing research initiatives. The same guide will be used in the individual interviews if those are needed.

Information Organization and Storage

During the environmental scan process, it is important to organize and store information so that it can be easily accessed and analyzed to assist with strategic planning and decision-making. When the information is collected electronically (ie, web-based surveys), the organization and storage of the information are superior because it enables easier and more efficient management of the collected large amounts of data. Electronic data can be easily organized, stored, and

XSL•FO
RenderX

retrieved when necessary, saving time and resources. In addition, electronic data are less susceptible to errors and can be easily shared with team members who may require access. The proposed environmental scan collects quantitative data using the OPINIO platform, an electronic survey platform that enables the collection and management of survey data. OPINIO can generate reports and export data in multiple formats automatically, facilitating data analysis and visualization. Qualitative data from the focus groups and key informant interviews will be generated automatically by the Zoom platform and manually by a transcriptionist. The data will be stored on a secure drive at Dalhousie University, ensuring its safety and confidentiality. Data stored in Dalhousie University's OPINIO server and the university's secure drive are only accessible to authorized users, thereby protecting sensitive data from theft or loss.

Developing Information Products or Services

Developing information products or services entails transforming the data collected during the information acquisition and organization phases into information that can inform strategic planning and decision-making. This step involves analyzing and synthesizing the data collected during the preceding phases into products or services that the organization's decision makers can use. Examples of information products or services that may be developed during this step include reports, presentations, dashboards, and other digital or paper-based visualizations that provide clear and concise information from the environmental scan. This may also involve tailoring the information to the needs of different stakeholders (eg, department heads may require high-level summaries of the key findings, whereas program managers may require more detailed information to support program planning and implementation) [40]. This environmental scan's data analysis strategy will use descriptive and inferential statistics for quantitative data and thematic analysis for qualitative data. The analysis methodology is described in greater detail in the Data Analysis Plan section of this protocol. Following data analysis, PowerPoint (Microsoft Corp) presentations, technical reports, and papers will be prepared by the research team.

Disseminating Information

In the information products and services phase, the aim is to share the developed products or services with the environmental scan participants and other stakeholders to aid strategic planning and decision-making. By spreading information, organizations can raise awareness of critical findings and gain support for necessary actions. Communication channels such as reports, presentations, meetings, newsletters, and intranet sites can be used for internal dissemination. The key findings may also be relevant to external stakeholders, including funders, partners, and regulatory bodies, and sharing them can establish relationships and position the organization as a leader. It is crucial to evaluate the effectiveness of the dissemination procedure to ensure that the key findings have been communicated successfully. Such evaluations can identify areas of improvement for future environmental scans [31-33,38]. Findings from this study will therefore be disseminated to the academic psychiatric and medical community and health and medical education policy makers through technical reports to governments of Nova Scotia and New Brunswick, peer-reviewed publications, and regional, national, and international conference presentations.

Using Information

The use of information is the final step in the environmental scanning process. It entails several analytical and decision-making processes, such as identifying patterns and relationships in data, assessing the implications of different scenarios, prioritizing opportunities and challenges, and developing action plans to address them. To ensure that the environmental scan insights are considered from multiple perspectives, involving a diverse range of stakeholders in using the information is critical. It is also vital to regularly monitor and update the information to ensure the organization is aware of changing trends and emerging risks [41]. Findings from this environmental scan will be used in the second development phase of the expansion of DME that will involve the distributed sites in planning and preparing for potential separate-entry distributed psychiatry residency programs as well as expansion of the Canadian and International Fellowship programs to distributed learning sites in line with the Transformational Plan for the Department of Psychiatry.

Outcome Measures

The environmental scan outcome measures were identified in the initial phase of the environmental scan (ie, identifying information needs). They fall into 6 categories:

- Demographics: Participants will provide their demographic information, including their province and health zone of work, type of medical graduation, type of specialist training, academic appointment within the Department of Psychiatry at Dalhousie University, current academic rank, and gender identity.
- Mental health services and scope of practice: Information about participants' mental health service work, primary and secondary specialization or scope of practice, the practice of psychotherapy, and primary and secondary modes of payment for psychiatric services delivered.
- Medical education: This set of data comprises information about participants' formal medical education training, level of medical education qualification they have received, their knowledge and skills in medical education, areas of medical education they would like to participate in, clinical training and supervision of learners they currently participate in, years of experience providing clinical training or supervision to medical learners, familiarity with the Royal College of Physicians and Surgeons of Canada Competency by Design for residency training, and availability to participate in formal training to facilitate involvement in psychiatry residency training.
- Infrastructure: Opinions on the infrastructure and team set-up for psychiatry resident training, as well as the willingness to participate in clinical training and supervision, offer lectures or skill-based teaching to psychiatry residents and evaluate their skills through skill-based examinations. The barriers that hindered the respondents from contributing to the training and

XSL•FO
RenderX

supervision of psychiatry residents, as well as the potential benefits of having psychiatry residents train on their service, will also be assessed.
- Continuing professional development: The frequency of attendance to the Department of Psychiatry weekly academic grand rounds and the participants' interest in attending and presenting in the grand rounds will be measured. Participants will also be asked about past and future participation in professional development programs organized by the Department of Psychiatry.
- Research and knowledge translation: The survey will assess the respondents' formal research training, level of research qualification received, interest in exploring opportunities for formal research training, and participation in current and preferred mental health or clinical translational research. The survey also assessed the barriers the participants perceived would hinder psychiatrists from participating in research and knowledge translation activities.

Data Analysis Plan

Data analysis will take place immediately after the phase of information organization and before the development of information products and services.

Quantitative data will be analyzed with SPSS (version 28; IBM Corp) using descriptive and inferential statistics. Demographic data and responses to selected questions will be summarized and presented as numbers and percentages. Depending on the outcome of the descriptive analysis, the chi-square test will be used to assess differences in responses between participants based on their province of work or administrative health zones. Binary or multinomial logistic regression analysis may be used to identify key barriers and enablers for expanding UGME and PGME, continuing medical education, research and knowledge translation at distributed learning sites.

Qualitative data will be analyzed thematically using the NVivo software (version 12; QSR International). Thematic analysis, commonly used in qualitative research, draws upon grounded theory [42] and content analysis [43]. Thematic analysis will be used for identifying and reporting on the major ideas expressed. Initially, transcribed data will be independently coded for themes by 2 investigators. These codes will be reviewed and revised jointly by the 2 investigators through a consensus process and then reapplied to the documents. Themes and subthemes will be created for identified barriers and facilitators for the expansion of UGME and PGME, continuing medical education, research and knowledge translation at distributed learning sites. Verbatim quotes from participants for each of the themes will be provided.

Ethical Considerations

This protocol has been submitted to the Dalhousie University Research Ethics Board and received an exemption from Research Ethics Board oversight according to the Tri-Council Policy Statement Ethical Conduct for Research Involving Humans article 2.5 [41]. Prior to completing the web-based surveys, all participants provided explicit consent. The informed consent presented on the initial page of the web-based survey included an explanation of the voluntary and anonymous nature of participants' participation in the study with a particular emphasis on the use of their data for research purposes covering primary and secondary data analysis.

Results

At the time of paper submission, it was anticipated that the findings from this environmental scan would be available within 6 months from the start of data collection. Fortunately, this timeline has been successfully achieved since data collection took place in February and March 2023, and the data have been thoroughly analyzed. One paper, focusing on results related to the psychiatrists' willingness to participate in scholarly activities, was submitted to a peer-reviewed journal in September 2023. Another paper, which delves into the psychiatrists' willingness to engage in academic research activities, is currently under review by the authors and is scheduled for submission to a peer-reviewed journal by the end of this year, with an anticipated publication date in the upcoming year. Study findings will be used to inform the development of policy options and decisions related to the expansion of the psychiatry residency and fellowship training opportunities at DME sites in Nova Scotia and New Brunswick. Options developed and decisions made during the second development phase will be based on information gathered during this initial or information-seeking phase and stakeholder agreements. With this project, we seek to develop an in-depth understanding of existing needs and factors that must be addressed to ensure the success of the proposed expansion of Dalhousie University’s psychiatry residency and fellowship programs using the infrastructure and human resources at distributed learning sites. By identifying challenges and opportunities in advance of the expansion of psychiatry training into a rural area and defining outcome measures to be tracked over time, it will be possible to design and implement processes and structures that will enhance the educational experience of residents and fellows, encourage faculty engagement, and facilitate ongoing program improvement.

Discussion

This paper describes a protocol for conducting an environmental scan at Dalhousie University's DME sites within the Departments of Psychiatry in Nova Scotia and New Brunswick. It seeks to assess existing resources and determine the necessary steps for the expansion and incorporation of DME sites within the academic framework of the Department of Psychiatry. The chosen method was environmental scanning, well-known for its efficiency in gathering information. Nevertheless, none of the existing frameworks have been designed specifically to guide DME research in psychiatry. As a result, this paper presents a comprehensive environmental scan protocol developed by adapting existing methodologies, combining a formal information search strategy with an explanatory design that includes quantitative and qualitative data.

The protocol holds several strengths that considerably enhance its efficacy and potential impact. Its comprehensive approach facilitates the collection of key factors relating to psychiatrists' willingness to engage in research and scholarly activities, which

XSL•FO
RenderX

are essential for the expansion of DME. By incorporating diverse viewpoints and experiences, the protocol comprehensively represents the target population. In addition, its consistency with the existing literature provides a firm foundation for interpreting findings and making meaningful comparisons. In addition, the protocol's innovative approach effectively resolves information gaps in the DME field, providing a unique opportunity to discover insights and trends that may influence the future of psychiatric education.

However, it is essential to acknowledge certain limitations of this protocol. Sample selection methods are dependent on the participation and availability of psychiatrists. While efforts will be made to invite all eligible psychiatrists, logistical obstacles or scheduling conflicts may limit the sample size. Another limitation is the use of self-reporting surveys and focus group sessions for data collection. Participants may provide socially desirable responses or incorrect information. In addition, the collected data are contingent on the participants' perceptions, which may not accurately reflect the situation. Despite the protocol's comprehensive data collection and analysis approach, it does not account for unanticipated variables such as health care policy or socioeconomic conditions that may influence the results.

Insights gained from this project will be used to enhance the quality and delivery of DME in Nova Scotia and New Brunswick. In addition, the information gathered will help answer important and timely questions regarding how training programs can engage psychiatrists outside the academic center and optimize semiurban and rural training experiences. This may be valuable information for other psychiatry and medical departments wishing to expand their residency and fellowship programming beyond tertiary care centers.

Data Availability

The data sets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

LH, RdLD, and VIA wrote the original paper. LH, RdLD, ME, PT, NS, AN, S Satyanarayana, S Siddhartha, PA-B, FR, HM, GG, MB, DP, OC, AR, AM, and VIA developed the methodology. RdLD created Figure 1. LH, RdLD, ME, PT, NS, AN, S Satyanarayana, S Siddhartha, PA-B, FR, HM, GG, MB, DP, OC, AR, AM, and VIA reviewed and edited the paper. All authors have read and agreed to the published version of the paper.

Abstract

Background: The current surgical treatment for patients diagnosed with progressive and severe adolescent idiopathic scoliosis (AIS) consists of the correction of the spinal curvature, followed by posterior spinal fusion (PSF). However, research has uncovered short- and long-term complications of posterior spinal fusion in patients with AIS. Minimally invasive growing rod techniques have successfully been used to treat patients with early-onset scoliosis and neuromuscular scoliosis. It may be questioned if minimally invasive posterior spinal nonfusion (PSnF) surgery with bipolar instrumentation can be used for the treatment of AIS.

Objective: This study will be performed to monitor the efficacy and safety of PSnF surgery by using a commercially available Conformité Européenne-certified spinal implant consisting of bilateral bipolar one-way self-expanding rods (OWSER) for the treatment of patients diagnosed with AIS.

Methods: In 14 selected patients with AIS with Lenke 1-6 curves, minimally invasive PSnF surgery with the OWSER system is performed after the failure of conservative treatment (curve progression of >5° within 1 year). The patients are over 7 years of age, with a major Cobb angle of ≥30°, sufficient flexibility, and a Risser stage of ≤2. Patients will be followed over time, according to the standard medical care. Efficacy will be measured using radiological and patient satisfaction assessments and safety will be determined by the amount of perioperative complications.

Results: Patient inclusion started on November 17, 2021 and we hope to finalize patient inclusion by the beginning of 2025. The first results will be expected by the beginning of 2024.

Conclusions: Minimally invasive PSnF in patients with AIS is presented as a less invasive surgical technique that prevents the progression of the scoliotic curve and that allows minor posture correction of coronal imbalance. This will be the first study to examine whether the PSnF bipolar OWSER instrumentation will be the next generation of surgical instrumentation in AIS.

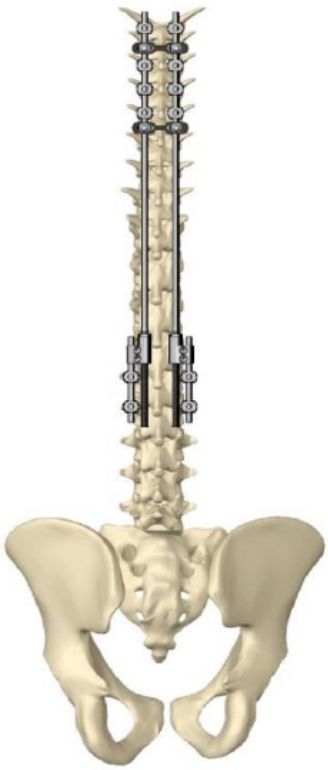
Introduction

Adolescent idiopathic scoliosis (AIS) is a 3D deformity of the spine that is clearly associated with the adolescent growth spurt [1]. Up to 10% of patients diagnosed with AIS require some form of treatment, and almost 0.3% will eventually undergo corrective spinal surgery [2]. When the scoliotic curve exceeds 40° to 45°, surgical correction followed by posterior spinal fusion (PSF) is regarded as the standard surgical treatment for AIS [3,4].

Both short- and long-term complications of PSF have been described in relation to AIS, such as spinal imbalance, implant failure, infection and wound complications, degenerative disk disease (16%), postoperative pain, distal adding-on, and proximal junctional kyphosis [5-10]. These complications all result in additional treatment or possibly a reduced quality of life. Therefore, there is a need for a type of minimally invasive spinal surgery that allows natural growth, enables spontaneous spinal balance correction and prevents full spinal fusion to improve the outcomes of patients with AIS.



Minimally invasive nonfusion spinal surgery in AIS is not new. Anterior vertebral body tethering and a concave distraction technique (ApiFix) have been used as nonfusion techniques in patients with AIS, although with mixed results and high complication rates [11-13]. In spinal deformity surgery, nonfusion techniques with growing rods have been used for patients diagnosed with progressive early-onset scoliosis (EOS) or neuromuscular scoliosis (NMS) [14-16]. The rods function as an “internal brace” of the spine and aim to control or reduce spinal deformity. These minimally invasive nonfusion surgical techniques have been developed to limit the progression of the curve and to improve the thoracic volume while allowing the spine and thorax to grow along with the natural growth of the patient [17].

Proposed Surgical Technique

The surgical treatment described in this protocol is the standard treatment protocol for scoliosis surgery, including perioperative antibiotic prophylaxis, a supine position on the spine table, and intraoperative motor-evoked potential (MEP) and somatosensory-evoked potential (SSEP) monitoring. Traction is applied to the patient’s head using a Mayfield skull clamp, and distal traction (10% to 15% of body weight) is applied with boots on the legs to achieve intraoperative correction. The level of instrumentation is determined according to the principles developed by Lenke [18,19].

A total of 2 short 5-10–cm midline incisions are placed over the high thoracic and thoracolumbar anchor points. In the high thoracic region, 4 pedicle screws are placed. Additionally, 2 transverse process hooks are placed at the upper-level vertebra to prevent proximal junction kyphosis. At the thoracolumbar anchor region, 4 pedicle screws are placed, including a short rod on both sides (Figure 1).

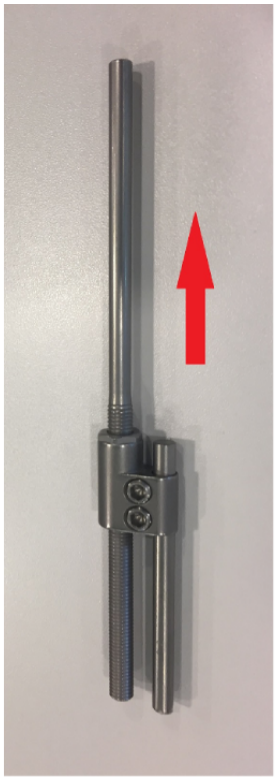


Figure 1. Example of NEMOST growing domino and E-SPINE system construct.

XSL•FO
RenderX

The one-way self-expanding rods (OWSERs) and domino is a CE-marked commercially available form of instrumentation registered as a NEMOST rod (E-SPINE, Euros; corresponding certificate: N°CE639319; Figure 2).

Figure 2. The one-way self-expanding rod (OWSER) and domino registered as NEMOST rod.

The OWSER is inserted into the subfascial plane between the 2 incisions from the caudal to the cranial region, guided by a cranio-caudal introduced chest tube under the superficial fascia. Subsequently, the OWSERs are fixed to the cranial anchors with an additional cross connector between the 2 rods. After the insertion of the rod, a moderate concave distraction is performed before the OWSER is connected to the laterally positioned small smooth thoracolumbar rods.

The initial correction of the scoliotic curve is obtained via intraoperative traction. The sagittal plane correction is obtained as a result of kyphotic rod contouring before rod insertion. The notched ratchet part of the rod, including the temporarily fixed domino connector that is positioned downward, remains straight to allow future elongation. The one-way self-expanding domino connector slides passively and gradually (1-mm step ratchet) along the notched part of the long rod. Rotation of the rod in the domino connector is prevented by a flat part of the notched rod (Figure 2). Postoperatively, patients have unrestricted mobilization during normal daily activities. Patients have follow-up appointments that adhere to the standard protocol of postoperative scoliosis care (Table 1).

The minimally invasive nature of the procedure, combined with the system's ability to allow the patient's natural growth while working as an internal brace, holds promise for improvement in the treatment of progressive AIS. This aligns with earlier

XSL•FO
RenderX

results that have been shown for patients with NMS and EOS [14,20].

To the best of our knowledge, a minimally invasive posterior spinal nonfusion (PSnF) surgery with OWSER has not previously been used in patients with AIS.

This study describes a study protocol for a clinical trial. This study aims to evaluate the efficacy and safety of a nonfusion bipolar self-expanding rod system, here referred to as the "nonfusion OWSER system," in the surgical treatment of patients with progressive AIS. Based on the positive surgical results and relatively low complication rates found when this type of system is used in patients with NMS or EOS [14,16,20], we hypothesize that the minimally invasive surgery using the nonfusion one-way self-expanding rod system (nonfusion OWSER) system is safe and efficient for the surgical correction of progressive AIS.

Methods

Ethical Considerations

The study protocol (version 3, October 29, 2021) describes a single-center cohort study. Ethics approval was granted by the Medical Ethical Committee of the Amsterdam University Medical Center (UMC) in the Netherlands, on May 20, 2020 (METC 2020_023, NL67124.018.19). Due to the COVID-19 pandemic, we were unsure if the study would be able to continue. This has led to a delay in the publication of this study protocol. This study will be conducted according to the principles of the Declaration of Helsinki (2013) and in accordance with the Medical Research Involving Human Subjects Act (WMO). It is registered in the Dutch trial register (NL8659) and the international trial register (NCT04441411). On October 14, 2023, a total of 5 patients have been included in the prospective study.

Participants

All patients will be recruited by 1 single surgeon embedded in a multidisciplinary scoliosis team in the Amsterdam UMC in the Netherlands. Both patients and patients' legal guardians must sign an informed consent form before the patient is included in the study. The inclusion criteria are (1) a diagnosis of AIS, (2) an age of >7 years, (3) a primary Cobb of >30°, (4) failed nonoperative treatment, (5) a Risser grade of ≤2 and a skeletal age of hand and wrist x-rays of ≤14 years, (6) a nonrigid curve, (7) all Lenke types, and (8) no previous spinal surgery.

A patient who meets any of the following criteria will be excluded from participation in this study: (1) nonidiopathic scoliosis: musculoskeletal or neurologic conditions responsible for the cause of the spine curvature (ie, neuromuscular, congenital, or syndromic scoliosis); (2) history of previous spine surgery; (3) Risser grade >2; (3) disease or deformity likely to affect the stability of the device (ie, inadequate anatomy of pedicles, trauma or tumor in fixation region, severe osteoporosis, bone destruction, or poor bone quality); (4) nonreducible scoliosis; (5) known allergy or intolerance to one of the device material; (6) acute or chronic infections, local or systemic; (7) absence or insufficiency of covering tissues; or (8) pathological obesity.

Data Collection and Statistical Analyses

Data will be collected at baseline, directly post surgery, after 2 months, and every 6 months after the operation until 2 years after skeletal maturity (see Table 1).

To describe the included patient group, patient characteristics such as age at surgery, sex, height, weight, medical and surgical history, blood loss during surgery, operative time, length of hospitalization, upper and lower level of fixation, short- and long-term complications (surgical site infections, neurological complications, implant failure, proximal junctional kyphosis, etc), and when applicable, secondary surgery (including the time between the first and second surgery) will be extracted from the patient's medical record. The data will be summarized in tables listing the mean, SD, median, minimum, maximum, and number of subjects for continuous data or in tables listing the quantities and percentages for categorical data, where appropriate.

For the primary goal, to analyze the efficacy of OWSER, the correction of the scoliotic curve will be measured by comparing the preoperative and postoperative Cobb angle with the Cobb angle 2 years after maturity. Radiological parameters will be measured by an orthopedic resident, trained to measure all radiological parameters. Measurements will be randomly verified by a senior experienced spine surgeon. Measured radiological parameters include the main Cobb angle (measured as defined by Cobb [21]), compensatory Cobb angle, correction after surgery, sagittal balance (thoracic kyphosis, lumbar lordosis, and proximal and distal junctional angle), pelvic parameters (pelvic obliquity, sacral slope, pelvic incidence, and pelvic tilt), Risser sign, and vertebral rotation based on full spine standing posterior-anterior and lateral radiographs. Differences between the Cobb angles and growth will be analyzed using repeated ANOVA measures. To correct for possible confounders, a mixed-model regression analysis will be performed including age at surgery, Risser sign, weight, and sex.

Patient satisfaction and function will be assessed using patient appearance (shoulder imbalance and pelvic imbalance) and patient-reported outcome measurements using the Scoliosis Research Society's-22r (SRS-22r) questionnaire. This questionnaire is provided in Dutch and the use of the questionnaire has previously been validated [22]. The safety of the surgical device will be monitored and registered based on (serious) adverse events and complication rates. Radiological and patient-related outcomes will be used to assess the clinical outcomes and with this, the efficiency of the implant. These parameters will be measured at every follow-up moment (Table 1).

In case of missing values at the follow-up, the patient will remain included in the study. Based on the amount of missing values, the patients will be excluded from the calculations from the specific follow-up moment. This will be described in the results section of the specific study. A P value of <.05 will be regarded as statistically significant.

XSL•FO
RenderX

Adverse Events

Adverse events (AEs) and serious adverse events (SAEs) are documented according to the definition of the Dutch Ethics Committee and will be acted on accordingly. AEs are defined as any undesirable experience occurring to a subject during the study, whether or not considered related to the investigational product. These will be actively reported by the subject or observed by the investigator or his staff. All AEs will be recorded throughout the study, and their severity and relation to the investigational device will be determined.

SAEs are documented as any untoward medical occurrences or effects that result in death, are life-threatening (at the time of the event), require hospitalization or the prolongation of existing inpatients' hospitalization, in persistent or significant disability or incapacity, are congenital anomalies or birth defects, or involve any other important medical events that did not result in any of the outcomes listed above due to medical or surgical interventions but that could have been based upon appropriate judgment by the investigator.

The research and treatment team must report any SAEs via telephone or email correspondence within 24 hours after the occurrence of the event to the principal investigator and the delegated medical board of directors. A completed initial SAE report must be sent, as indicated in the study's case report form.

Data Management

All data will be handled confidentially according to the General Data Protection Regulation (GDPR) guidelines. Research subjects will receive a 3-digit ID number upon beginning the study. One patient identification log (Castor electronic data capture will be maintained separately to identify the research subjects and will only be accessible to the principal investigator and the project leader.

Sample Size

To perform a sample size analysis, we compared our study to the study conducted by Miladi et al [23]. The sample size calculation is based on an ANOVA analysis and calculated using the statistical program G*Power (Heinrich-Heine-Universität Düsseldorf) [24,25].

Miladi et al [23] reported the results from the precursor of our OWSER system from the higher thoracic spine to the pelvis in 100 patients with NMS. The mean Cobb angle improved from 89° (range, 25°-149°) to 35° (range, 6°-53°) 3 years after surgery [23]. No SDs were reported. In light of this study, we expect a Cobb angle of 35° at maturity. To use these numbers for the sample size calculation, we assumed a normal distribution of the data; as such, the SDs of the preoperative Cobb angle were 31 and 11.75 for the postoperative Cobb angle [26]. We assumed a correlation of 0.5 and an effect size of 0.4 based on the correction described by Miladi et al [23]. The sample size calculation indicated that 12 patients ought to be included to examine the significant difference between the preoperative Cobb angle and the Cobb angle at the latest follow-up (power: 80%, significance level: 0.05).

Additionally, 20% more patients were included to account for a possible loss of subjects in the follow-up. In conclusion, the highest sample size indicated was 12; therefore, the minimal sample size needed for this study to address the primary goal is 14 patients. After the inclusion is completed, a post hoc power analysis will be performed to conclude if a significant number of patients is included in the study.

Results

Patient inclusion started on November 17, 2021, and we hope to finalize patient inclusion by the beginning of 2025. The first results will be expected by the beginning of 2024. On October 14, 2023, a total of 5 patients have undergone surgical correction with the proposed surgical technique. We aim to publish the 2-year results of these patients in May 2024.

Discussion

Principal Findings

Currently, all patients with AIS and diagnosed with curves exceeding 40° to 45° are recommended surgical correction followed by PSF to fix the patients' spine for the rest of their lives [2,3]. In this study protocol, we describe a protocol to investigate the safety and efficacy of a minimally invasive posterior bipolar nonfusion OWSER for the surgical treatment of patients diagnosed with AIS.

The concept of PSnF for scoliosis surgery is not new. For patients diagnosed with EOS and NMS, multiple successful PSnF options are available and are currently regarded as the standard surgical treatment [16]. However, to the best of our knowledge, this concept has not been used in patients diagnosed with AIS.

The aim of this prospective study is to determine the efficiency and safety of the implant by analyzing radiological parameters (primarily Cobb angle), patient satisfaction scores, and complication rates. The expected primary benefit of this surgical technique is an efficient surgical correction of the Cobb angle without PSF. Because of the minimally invasive character of the surgical procedure, the spinal structures of the apex of the curvature between the thoracic and lumbar anchor points are not altered. Although some cases of auto-fusion have been described when using minimally invasive surgery [14], to the best of our knowledge, no complete full spinal fusion will occur. This might only allow the removal of the nonfusion OWSER at the end of spinal growth in patients in which the curve remains stable for a longer period of time and remains under 30° [27]. In addition, the system allows for a natural correction of the spinal deformity while the correct balance and alignment of the spine are maintained. Because of its self-expanding function, the system allows the patient to follow its final natural growth while functioning as an "internal brace." Finally, due to the minimally invasive nature of the surgical procedure, the overall surgical time and general anesthesia time will be reduced, and the scar length can be limited to two scars that are 5-10 cm in length at the thoracic and lumbar fixation level.

For patients diagnosed with NMS, the positive long-term results of a nonfusion OWSER were described by Gaume et al [20] in 2021. The original nonfusion OWSER provides instrumentation for NMS from T1 to the sacrum. In patients with AIS, however,

XSL•FO
RenderX

instrumentation is only needed for the length of the structural curve. Therefore, we suggest inserting the notched rod at the end of the caudal part of the construct. Hereby, the thoracolumbar approach is performed using a smaller incision. The OWSER instrumentation elongates and corrects the deformity spontaneously alongside the natural growth of the patient, allowing spinal balance correction; it does not touch the apex vertebrae of the spinal curvature and prevents complete PSF. The OWSER instrumentation can be considered an "internal brace."

Although positive long-term results have been published following PSnF surgery in patients with NMS, complications have been recognized. Gaume et al presented their preliminary results of the use of a minimal invasive OWSER for the treatment of patients with NMS. They found an overall complication rate of 38% (n=8), consisting of 14% (n=3) mechanical complications and 24% (n=5) infectious complications [20]. Although these complication rates seem high, compared to the traditional growing techniques, there is an important decrease in complication rates [28].

All of the included patients were fixed from the high thoracic level up to the pelvis. Our patient population will arguably be fixed over a shorter number of vertebrae, lowering the amount of force distributed over the system. In addition, Gaume et al [20] found a postoperative infection rate of 24% (n=5) directly post surgery. In postoperative patients diagnosed with AIS, this would be unacceptable. However, these results cannot be directly translated to our patient population, as it is known that patients with NMS have poor general status [29]. This makes them more prone to infectious complications as compared to the healthy patients with AIS who will be included in this study.

Other possible complications are an inherent part of spinal surgery, such as intraoperative cardiologic complications and neurological complications. The risk of neurological complications will be minimized using intraoperative neuromonitoring via both MEP and SSEP during the surgical procedure. All AE and SAE are monitored based on the guidelines of the Dutch Ethics Committee, and will help determine the safety of the proposed surgical technique.

The absence of a control group could be seen as a potential limitation. In this study, we do not have a control group as we focus on the efficiency and safety of the surgical device. If the device is proven to be efficient and safe, a follow-up will be proposed to compare the postoperative results between the nonfusion OWSER system and the traditional PSF. In addition, this would allow us to discuss the cost-effectiveness of the PSnF surgery compared to the traditional PSF surgery.

Conclusions

In conclusion, this study is designed to evaluate the efficiency and safety of the surgical treatment with a bilateral bipolar OWSER implant in patients with progressive AIS. We hypothesize that the system is safe and efficient in the surgical treatment of AIS, while it serves as an "internal brace," allowing the patients to follow their natural growth and individual balance. To the best of our knowledge, this is the first study to investigate the potential efficacy and benefits of the use of the nonfusion OWSER in patients diagnosed with AIS who failed conservative treatment.

Data Availability

The data sets generated and analyzed during this study are not publicly available due to the fact that the study has not been finalized and data collection has not been completed yet, but are available from the corresponding author on reasonable request.

Abstract

Background: Fibroproliferative or fibrotic diseases (FDs), which represent a significant proportion of age-related pathologies and account for over 40% of mortality in developed nations, are often underrepresented in focused research. Typically, these conditions are studied individually, such as chronic obstructive pulmonary disease or idiopathic pulmonary fibrosis (IPF), rather than as a collective entity, thereby limiting the holistic understanding and development of effective treatments. To address this, we propose creating and publicizing a comprehensive fibroproliferative disease ontology (FDO) to unify the understanding of FDs.

Objective: This paper aims to delineate the study protocol for the creation of the FDO, foster transparency and high quality standards during its development, and subsequently promote its use once it becomes publicly available.

Methods: We aim to establish an ontology encapsulating the broad spectrum of FDs, constructed in the Web Ontology Language format using the Protégé ontology editor, adhering to ontology development life cycle principles. The modeling process will leverage Protégé in accordance with a methodologically defined process, involving targeted scoping reviews of MEDLINE and PubMed information, expert knowledge, and an ontology development process. A hybrid top-down and bottom-up strategy will guide the identification of core concepts and relations, conducted by a team of domain experts based on systematic iterations of scientific literature reviews.

Results: The result will be an exhaustive FDO accommodating a wide variety of crucial biomedical concepts, augmented with synonyms, definitions, and references. The FDO aims to encapsulate diverse perspectives on the FD domain, including those of clinicians, health informaticians, medical researchers, and public health experts.

Conclusions: The FDO is expected to stimulate broader and more in-depth FD research by enabling reasoning, inference, and the identification of relationships between concepts for application in multiple contexts, such as developing specialized software, fostering research communities, and enhancing domain comprehension. A common vocabulary and understanding of relationships among medical professionals could potentially expedite scientific progress and the discovery of innovative solutions. The publicly available FDO will form the foundation for future research, technological advancements, and public health initiatives.

Introduction

Fibroproliferative Diseases

Fibroproliferative wound healing, a process that can disrupt normal organ development and lead to increasing fibrosis and eventual organ failure, can affect nearly all organs and tissues. These fibroproliferative or fibrotic diseases (FDs) [1], including lung fibrosis, liver cirrhosis, atherosclerosis, keloids, progressive renal diseases, and systemic sclerosis, represent one of the most prevalent age-related illnesses, impacting over 800 million individuals worldwide [2]. They contribute to over 40% of mortality in developed nations [3,4], a rate that is anticipated to rise with the aging global population, signifying a growing public health concern.

Despite their significance for public health, FDs have received limited attention in both policymaking and research. While these conditions share fundamental biological processes, they are seldom approached collectively in either in vitro studies or clinical settings, constraining effective investigation of shared mechanisms and hindering the formulation of comprehensive public health policies and adequate clinical care [5].

A PubMed search conducted on November 5, 2022, yielded 140, 1674, and 369,557 records for the terms *fibroproliferative diseases*, *fibrotic diseases*, and *fibrosis*, respectively. However, these numbers are inflated by the inclusion of conditions such as *cystic fibrosis*, which is not an FD.

Significant advances have been made in recent years in understanding the molecular details of fibrosis [6,7], the causes and potential therapeutic approaches of various fibroproliferative disorders [8], and in accumulating genomic data on FDs [9]. Insights into epigenetic changes [10], noncoding RNA's role in fibrosis [11], and the escape of fibroblasts from apoptosis [12] have also been unveiled. Promising therapeutic agents, such as dioscin for liver fibrosis and thalidomide and etanercept for lung fibrosis [13,14], are under investigation. Nevertheless, knowledge gaps remain, particularly in areas such as cardiac fibrosis [15], and efficient antifibrotic therapies are still lacking.

The vast and expanding data on FDs remain largely unsystematized and scattered, limiting our understanding of fibrosis mechanisms and hampering the development of comprehensive therapeutic strategies to target fibroproliferative processes.

Ontology on Fibroproliferative or Fibrotic Diseases

In the realm of information technology, an ontology formally defines entities, classes, and relations, providing a structured representation of a knowledge domain [16,17]. In the context of FDs, this domain extends beyond disease nomenclature to encompass hierarchical structures, relationships between diseases, and a host of associated biomedical concepts, such as wound healing pathologies, epithelial-mesenchymal transitions, collagen deposition, involved pathways, genes, proteins, and external factors [18]. Consequently, the FD domain represents a multidimensional and multilevel ecosystem of data, information, and knowledge.

While ontologies have been developed for FD subgroups, such as the classification of fibrotic interstitial lung diseases by Ryerson et al [18] and cross-disease analyses of genetic underpinnings and implicated pathways [19-21], a comprehensive ontology encapsulating the full spectrum of fibroproliferative disorders remains lacking. This contrasts with efforts in other medical fields, such as the National Cancer Institute Thesaurus [22,23].

Clinical ontologies, like the Systematized Nomenclature of Medicine–Clinical Terms (SNOMED CT) [24-26], serve crucial roles in automating decision support tools, standardizing clinical research databases, and ensuring semantic interoperability. In the emerging field of biomedical informatics, domain ontologies enable the structured representation of concepts and entities and their relationships, forming a conceptual scaffold for domain-specific terminologies. These ontologies can be harnessed for tasks such as reasoning, inference, process identification, software enhancement, and community engagement [27-29].

Despite its potential for accelerating scientific progress and enabling novel solutions, no public FDO currently exists. Our review of the MEDLINE, PubMed, and BioPortal databases and the European Molecular Biology Laboratory-European Bioinformatics Institute (EMBL-EBI) Ontology Lookup Service confirmed this lack of a dedicated ontology for FDs [30,31].

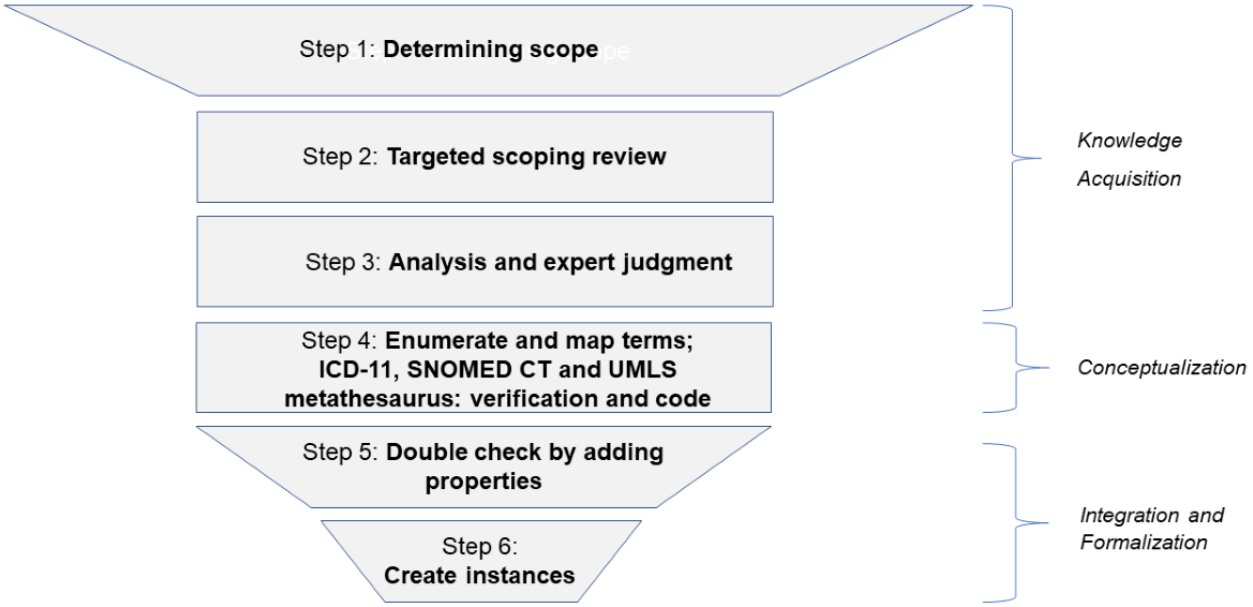
Thus, we aim to create and disseminate an FDO as a public resource, fostering collaboration and enabling future development and refinement. This FDO targets several key objectives: sparking interest among stakeholders, facilitating public health initiatives, and supporting knowledge representation, information retrieval, data integration, health information systems, and biomedical research. We believe that a comprehensive FDO will equip researchers and clinicians to navigate the FD domain efficiently and contribute to the evolution of research and therapeutic strategies.

Methods

In the following, we detail the methodology for the development of a comprehensive domain-specific ontology of FDs.

Development of the Fibroproliferative Disease Ontology

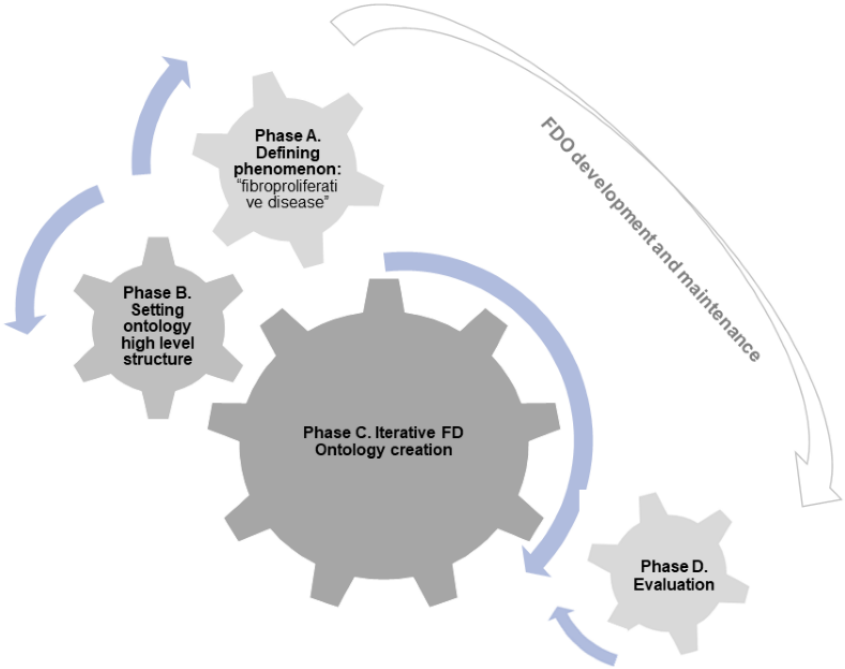
The development of the fibroproliferative disease ontology (FDO) will use a top-down approach, starting with the most abstract concepts within the FD domain and then progressively refining toward specific subconcepts. This process integrates (1) findings from our comprehensive literature survey, which includes the results of scoping reviews (detailed subsequently); (2) a review of key classification systems, including the International Classification of Diseases 11th Revision (ICD-11) of the World Health Organization (WHO) SNOMED CT, and Unified Medical Language System (UMLS) Metathesaurus [32], where pertinent; and (3) the significant expertise of experienced clinicians and researchers in the fields of medicine, biomedical informatics, and public health, notably those previously involved in the large-scale Seventh Framework Program of the European Union (FP7-EU) project Resolve



XSL•FO
RenderX

Chronic Inflammation and Achieve Healthy Aging by Understanding Non-regenerative Repair (RESOLVE) [1]. The ontology will be constructed using the Protégé ontology editor [33] in the Web Ontology Language (OWL) format [34].

The iterative steps for the FDO creation, illustrated in Figure 1, consist of 4 core building blocks (Figure 2) to be systematically applied:



- Building block A will see the expert team delineate the concept of FD, informed by scoping review results and their own professional insight. Here, characteristics specific to FD, including data properties like extracellular matrix (ECM) and collagen deposition and the epithelial-mesenchymal transition (EMT) phenomenon, will be specified. To capture the breadth of the FD phenomenon, the scope will span a range of major biomedical concepts, enriched with synonyms, definitions, and references as driven by scoping review findings and expert judgment. Adherence to SNOMED CT terms and granularity will be sought where feasible, with exceptions made where evidence necessitates exceeding this frame. These defining concepts will be integrated into the FDO as data and object properties unless decided otherwise.
- Building block B focuses on determining the FDO's overall scope, envisioned to encapsulate key categories of FD. Hence, the high-level structure will pivot around body systems and organs, for example, FD of the respiratory system, cardiovascular system, skin, or eye.
- Building block C, contingent on the completion of blocks A and B, will oversee the iterative FDO development. The backbone of this block will involve aligning clinical phenomena with the ICD-11. Additional concepts will be incorporated as data and object properties as the FDO develops, with further refinement driven by future use cases and maintenance needs.
- Building block D will conduct an evaluation module to ensure the ontology's quality and consistency.

Figure 1. Diagram presenting steps to be applied in each phase of creating fibroproliferative or fibrotic disease ontology. Step 1, determining scope of the step based on the expert judgment analysis; step 2, targeted scoping review based on scope search defined in step 2 by experts; step 3, analysis of the scoping review results combined with experts' domain knowledge; step 4, enumerating and mapping identified and included terms, combined with International Classification of Diseases 11th Revision verification, if relevant; step 5, double check, adding properties if relevant; step 6, translating the results into the ontology in a Protégé file by creating instances. ICD-11: International Classification of Diseases 11th Revision; SNOMED CT: Systematized Nomenclature of Medicine–Clinical Terms; UMLS: Unified Medical Language System.

Figure 2. Building blocks and phases proposed for a methodological grid enabling creation of domain ontologies for complex and interdisciplinary clinical and biomedical phenomena, as exemplified by fibroproliferative or FD ontology creation. Phase A, defining a phenomenon concept, defining "fibroproliferative disease;" phase B, setting the ontology structure—determining high-level scope by expert judgment; and phase C, iterative FD ontology creation. Each of the abovementioned phases is to be implemented in a rigorous iterative row of steps. The final phase D involves an evaluation of the ontology followed by a necessary revision, if needed. Steps 1-3 represent knowledge acquisition; steps 4-5 represent conceptualization; and steps 5-6 represent integration and formalization. The chain-wheel or sprocket-wheel shape of the diagram indicates an iterative and combined approach to FD ontology building. FD: fibroproliferative or fibrotic disease.

Collective Domain Expertise of Experienced Clinicians and Researchers Applied to Determining Scope and Analyses of Targeted Scoping Reviews

A multidisciplinary team of experienced clinicians and researchers will collaborate to determine the scope of this study and analyze the results of our targeted scoping reviews. Drawing on the expertise cultivated during the RESOLVE FP7-EU project [1], among other experiences, this team will convene biweekly throughout the study (see Table 1 for study timelines). The meetings will facilitate iterative refinement of conceptual categories and relationships within the ontology, with each stage involving a critical review of current evidence, method refinement, and a discussion of concept applicability.

Table 1. Overview of study timelines.

To achieve consensus, we will use a modified real time Delphi method [35] when necessary. If the team cannot reach a consensus on a particular issue, we will use a 2-round voting system with straightforward digital tools. The first round entails voting on all proposed opinions, while the second round, if needed, narrows the vote to the 2 highest-ranked options from the initial round.

The scoping review will guide the identification of specific concepts within subdomains, allowing us to map FD concepts across various organs (eg, lung, liver, and kidney) and systems (eg, cardiovascular diseases). These findings will be systematically reviewed by the experts for integration into the FDO development process. We will maintain a cycle of

XSL•FO
RenderX

information collection, analytical processing, and subsequent integration into the FDO framework.

Scoping Review of Prevalent Concepts and Domain Literature

We will use a scoping review methodology to extract concepts related to the domain of FDs from the PubMed database's peer-reviewed literature [36]. Given the breadth of our research questions and the inclusion of various study types, a scoping review provides an appropriate approach to fulfilling our objectives. The review stages will adhere to the methodological framework by Arksey and O'Malley [37], as revised by Levac et al [38]: (1) population, intervention, comparison, outcomes, and study (PICOS)-based research question formulation [39]; (2) relevant study identification through a MEDLINE and PubMed database search; (3) study screening based on inclusion and exclusion criteria; (4) data charting, including relevant paper review; and (5) collation and summary of findings. Our report will align with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis–Scoping Review (PRISMA-ScR) framework [40].

Search Strategy

For the first phase (phase A), we will systematically search the MEDLINE and PubMed databases using the search strings *fibroproliferative disease* OR *fibrotic disease*. To map FD concepts across different organs and systems, we will pair these terms with the relevant organ and system subdomain (eg, *fibrosis* AND *lung*). Additional terms and Boolean operators may be introduced based on expert judgment and domain knowledge. Domain experts, clinicians, and researchers involved in the FDO's development will decide on the detailed settings for these searches.

We will refine our search string through test searches, identifying appropriate synonyms, medical subject headings (MeSH) phrases, and keywords. We will also manually search the references of pertinent studies.

Inclusion and Exclusion Criteria

Inclusion and exclusion criteria will be established through the PICOS framework, guiding the screening process. We will include any peer-reviewed study conducted on FDs without study design-based exclusions. We will focus on full-text, peer-reviewed research published since 2019 to reflect the field's recent developments and ensure sufficient evidence gathering. Exclusions include non-English papers, editorials, letters to the editor, commentaries, and press articles (see Multimedia Appendices 1 and 2 for eligibility screening form details).

Selection of Studies

The review team, comprising medical, biomedical informatics, and public health experts, will work in pairs to review papers. Each paper will be independently evaluated by 2 reviewers, with disagreements resolved through discussion (see Multimedia Appendices 1 and 2 for screening details).

Charting the Data

Data extraction will occur through a shared Microsoft Office (Microsoft Corp) Excel form (Multimedia Appendix 3), featuring a combination of close-ended and open-ended questions. Open-ended queries will help identify the article's primary aim and crucial results. We will extract key details, including authorship, publication year, domain, objectives, key results, and significant FD-related concepts, facilitating the development of a domain-specific glossary and ongoing model and ontology construction.

ICD-11: Screening Process Ensuring Globally Accepted Naming Standards and Proper Level of Granularity Across the Fibroproliferative Disease Ontology

The ICD-11 is a universally accepted tool, providing over 1.6 million terms for standardized health care information exchange [41]. It is publicly accessible, endorsed by the WHO, and used globally [42].

To ensure the interoperability of our FDO with this internationally recognized nomenclature and to maintain appropriate granularity, we will align all relevant concepts in our FDO with corresponding ICD-11 terms. This process will encompass all FDs and clinical conditions proposed for inclusion in the FDO. Therefore, we will compare the identified names of FDs with those listed in the ICD-11 classification. Each disease included in our FDO will follow ICD-11 naming conventions and be assigned a corresponding ICD-11 code.

Formalization of Ontology Using Web Ontology Language in Protégé

The FDO will be constructed using the Semantic Web standard OWL through Protégé (Stanford University), a leading open-source ontology editor [43]. Drawing from the scoping review findings and the team's expertise, we will incorporate and model various class entities and properties using pertinent OWL axioms, encompassing classes, object properties, data properties, and annotations. Conforming to best practices [44], relevant terms from the ICD-11 will be externally cross-referenced. The ontologies will not be imported given their distinct developmental contexts; specifically, the ICD-11 serves as an exhaustive disease reference terminology, whereas the FDO concentrates on the FD knowledge domain. Upon completion, the FDO will be uploaded to BioPortal [45], the world's most extensive open-source repository of biomedical ontologies, to facilitate annotation and dissemination.

Evaluation

The FDO will undergo evaluation to ensure validation and verification. The assessment will concentrate on the ontology's consistency, clarity, and comprehensive coverage of the FD domain [46]. Consistency checks will occur both during and after the ontology's development, with the open-source semantic reasoner Pellet (Clark and Parsia LLC) used for this purpose [47].

We will involve domain experts for qualitative evaluations. They will devise proficiency questions to examine the ontology's validity and will provide feedback on all FDO concepts and relationships through semistructured interviews, ensuring alignment with current domain knowledge [48]. To ensure the ontology accurately mirrors intended concept meanings and to maintain its coherence, we will eliminate

XSL•FO
RenderX

irrelevant or incorrect entities, supplement missing terms, and uphold consistency [49].

Fibroproliferative Diseases Ontology Maintenance and Further Development Plan

Like any ontology, the FDO is expected to evolve continually. Realizing a comprehensive ontology for the FD domain is an iterative process, and as such, the FDO must consistently incorporate new concepts and data. It must also stay abreast of knowledge progression or alterations within the domain, ensuring accurate FDO representations. Additionally, regular maintenance by FDO biocurators is essential to rectify any irregularities or errors encountered during FDO use and development [50]. We plan to conduct FDO curation in association with the International Society of Biocuration [51].

The FDO maintenance and development strategy will incorporate 2 major cyclical steps: (1) application of FDO in FD research (use cases) and (2) annual, routine maintenance.

In step 1, subsequent to the initial FDO development, we anticipate its immediate use across multiple use cases. This includes applying FDO to analyze existing FD therapeutic strategies, causative factors, and the role of antimicrobial peptides in FD. Aside from their intrinsic value, these practical FDO applications will contribute to its maintenance and curation by highlighting inconsistencies, irregularities, and nonconformance with current knowledge.

In step 2, FDO biocurators will conduct annual updates, with web-based meetings scheduled each summer.

FDO is designed to accommodate new concepts and properties. Both its maintenance and development will involve ontology population, that is, adding new instances, and ontology enrichment, that is, adding properties to instances [52]. As the primary FDO framework is established and tested in initial use cases, we plan to gradually automate certain tasks related to steps 1 and 2. The progressive integration and reuse of concepts from existing ontologies are also planned as the FDO develops.

Results

The FDO, developed through the methodological framework outlined above, will be made open source, thus becoming a publicly available resource for stakeholders, researchers, and clinicians. The objective of this publication is to ensure transparency and integrity during ontology creation, stimulate domain expert interest, foster acceptance, and encourage continued use once the ontology is released in the public domain. The FDO will be registered and made accessible on BioPortal. Moreover, we plan to showcase the FDO at pertinent scientific conferences through abstracts and presentations. Additionally, the finalized FDO will be disseminated as a peer-reviewed publication.

Discussion

Overview

The protocol we have outlined for the development of the FDO aims to provide a crucial tool for representing and structuring knowledge within the FD domain. The key benefits of representing the FD knowledge domain as an ontology lie in its structured nature, which eases the sharing and dissemination of knowledge and encourages reuse across different research teams, projects, or subspecialties [53]. For example, discoveries in oncology or hematology could spur research in pulmonary medicine. Furthermore, the FDO can facilitate uncovering new relationships or parallels between distinct research findings or identifying knowledge and research gaps [54]. The standardized, interoperable usage of terms will streamline data exchange and integration, potentially accelerating in-depth analysis of general fibroproliferative processes and disease characteristics. Such a structured approach with standardized terminology should also enhance research quality [55]. By leveraging ICD-11 and SNOMED CT terms, we ensure both standardization and consistent granularity across the ontology [56]. This approach is designed to yield a comprehensive ontology of FDs, thereby avoiding the pitfall of incomplete coverage.

However, we anticipate certain limitations with the FDO developed through this protocol, some of which are inherent to biomedical ontologies expressed in OWL description logic [56]. OWL ontologies express relationships between objects, classes, concepts, and their properties, but they do not describe processes or changes occurring over time [57]. This is a significant consideration given that FDs typically involve chronic processes such as pathologies of tissue repair, aging, and senescence. As a workaround, we may consider creating multiple instances to describe a particular FD in the ontology instead of the “one disease, one instance” setting. Despite this, such a workaround introduces other limitations like potential bias, inconsistencies, and increased complexity, which may pose challenges for efficient use and interpretation of the ontology [56].

In conclusion, while the FDO is a promising tool for the representation of the FD knowledge domain, its success hinges on regular updates to keep pace with the evolving understanding of FDs. Therefore, we have planned follow-up activities to ensure that the ontology remains current and relevant.

Conclusions

We will create an FDO as a shared knowledge resource and conceptual framework accessible in the public domain for open usage, including by semantic reasoners and other tools. This facilitates collaboration and promotes ongoing updates and enhancements. The development of the FDO is described as an iterative process involving domain experts, scoping reviews, and the incorporation of existing standardized terminology. Once publicly available, the FDO is anticipated to stimulate research in the FD domain, driving clinical advancements, informing medical research, and influencing public health initiatives. Consequently, it will provide novel insights into the substantial current knowledge gaps in this field of study.

Abstract

Background: Glioblastoma multiforme (GBM) is an aggressive brain tumor with limited treatment options due to the blood-brain barrier's (BBB's) impedance and inherent resistance to chemotherapy. Gold nanoparticles (AuNPs) functionalized with transferrin-like peptides show promise in overcoming these challenges, enhancing drug delivery to the brain, and reducing chemotherapy resistance.

Objective: The primary goal of this study is to establish a detailed protocol for synthesizing and stabilizing AuNPs, functionalizing them with de novo–engineered transferrin-like peptides, and conjugating them with the chemotherapeutic agent temozolomide. This strategy aims to improve drug delivery across the BBB and circumvent chemotherapy resistance. The secondary objective includes an assessment of the safety and potential for in vivo use of the synthesized nanoparticle complex.

Methods: The proposal involves multiple steps with rigorous quality control of AuNP synthesis, stabilization with surfactants, and polyethylene glycol coating. The engineered transferrin-like peptides will be synthesized and attached to the AuNPs' surface, followed by the attachment of temozolomide and O6-methylguanine-DNA methyltransferase inhibitors. The resulting complex will undergo in vitro testing to assess BBB penetration, efficacy against GBM cells, and potential toxicity.

Results: Initial preliminary experiments and simulations suggest successful synthesis and stabilization of AuNPs and effective attachment of transferrin-like peptides. We propose peptide attachment verification using Fourier transform infrared spectroscopy and surface plasmon resonance. Additionally, we will conduct pH stability tests to ensure our functionalized AuNPs retain their properties in acidic brain tumor microenvironments.

Conclusions: The proposed functionalization of AuNPs with de novo–engineered transferrin-like peptides represents a novel approach to GBM treatment. Our strategy opens new avenues for drug delivery across the BBB and chemotherapy resistance reduction. While we primarily focus on in vitro studies and computational modeling at this stage, successful completion will lead to further development, including in vivo studies and nanoparticle design optimization. This proposal anticipates inspiring future research and funding in neuro-oncology, presenting a potentially innovative and effective treatment option for GBM.

Introduction

Our previous work demonstrated that pH buffer solutions in biological systems, such as blood and intravascular fluid, are typically maintained at a pH of approximately 7.4 by a carbonic-bicarbonate ion buffering system (accounting for 64% of buffering capacity). However, human blood pH varies between 7.35 and 7.45, indicating that a shift of 0.10 is significant. The hemoglobin-oxyhemoglobin buffering system accounts for approximately 28% of total buffering capacity, making it a critical process in respiration. For medical purposes, it is possible to determine the percentages of dissolved oxygen, nitrogen, carbon dioxide, and carbon monoxide through gas-liquid chromatography or an elemental analyzer. This analyzer includes a flash combustion furnace, a Porapak chromatographic column, and a thermal conductivity detector.

Moreover, the blood pH buffer comprises systems of acidic and basic proteins (about 7% of the total buffering system) and monoacid phosphates or diacid phosphates (roughly 1%). Enzymes, the central chemical agents of life, catalyze essential reactions with high selectivity. However, they are usually sensitive to pH and can function optimally only within a rather narrow pH range. The acidity of aqueous solutions determines which metal ions are soluble, which ones may become hydrolyzed, or which ones may potentially precipitate. As such, the availability of metal ions in the blood is pH dependent [1-3].

Furthermore, the inherent acidity of the brain tumor microenvironment poses a significant challenge for nanoparticle (NP)-based therapies. Thus, pH stability testing is critical to ensure that our NPs maintain their structural integrity and functional capacity in the acidic conditions of the brain tumor microenvironment.

The global burden of glioblastoma multiforme (GBM), a highly aggressive brain tumor, continues to grow due to its resistance to conventional treatment options and difficulty in drug delivery across the blood-brain barrier (BBB) [4,5]. Significant research has been devoted to developing innovative strategies for GBM treatment. One such promising area is the application of gold nanoparticles (AuNPs) [6,7].

AuNPs are increasingly recognized for their unique properties, including their high surface area-to-volume ratio, modifiable surface, and biocompatibility, rendering them potential vehicles for drug delivery [6,8]. Moreover, the functionalized ability to cross biological barriers such as the BBB makes NPs particularly valuable for brain tumor treatment [9-11].

Simultaneously, transferrin, a naturally occurring iron transport protein, has been shown to assist in drug delivery across the BBB due to the high expression of the transferrin receptor on the BBB and cancer cells, including GBM cells [11]. Transferrin-like peptides, engineered from studies on natural transferrin, could potentially enhance the delivery of therapeutic agents to the brain when conjugated to AuNPs [12-14].

Temozolomide, a commonly used chemotherapeutic agent for GBM, struggles with drug resistance and inadequate delivery to the tumor site. Coating AuNPs with temozolomide, coupled with O6-methylguanine-DNA methyltransferase (MGMT) inhibitors to overcome resistance, might provide a more effective strategy for GBM treatment [4,9,15].

Given the potential synergy among AuNPs, transferrin-like peptides, temozolomide, and MGMT inhibitors, we propose the synthesis, stabilization, and functionalization of AuNPs with de novo–engineered transferrin-like peptides and the aforementioned chemotherapeutic agents [7,13,14]. This exploratory proposal aims to outline a novel protocol for a potentially more effective GBM treatment strategy, offering insights and considerations for future researchers in this field.

Methods

Synthesis and Characterization of AuNPs

AuNPs with a diameter between 160 Å and 200 Å and a neutral or slightly negative charge are synthesized and stabilized with surfactants. We characterize the NPs using electron microscopy and spectroscopy techniques to confirm their size, shape, and surface properties [16-18].

Reagents

The following reagents are used: gold (III) chloride hydrate ($HAuCl_4$; Sigma-Aldrich, lot MKBN2548V; 99.999% purity), sodium citrate dihydrate ($Na_3C_6H_5O_7.2H_2O$; Sigma-Aldrich, batch #SLBG6645V; >99.0% purity), Milli-Q Nanopure water (doubly deionized water with a conductance of 5.6×10^{-8} $\Omega^{-1}\cdot cm^{-1}$ and pH 6.0-7.0 from a type D-4744 Nanopure deionization system or Purelab UHQ system to prepare standard and reagent solutions), all other reagents were of the best available analytical grade, and all vessels in contact with samples or reagents were cleaned by soaking in 5.8 M nitric acid (overnight) and repeatedly rinsed with deionized water before use.

Equipment and Materials

The equipment and materials included are a scale (model AY220; Shimadzu), reaction flasks with a 100-mL mouth, oil bath (silicone+glassware), magnetic bar, a laminar flow hood (TROX-100), Heating and stirring plate (model C-MAG HS4; IKA), 50-mL volumetric flasks, 10-mL volumetric flask, 5-mL weighing beakers, spatulas (nonmetallic), a 0.45-µm filter (Chromafil Xtra CA-45/25; Macherey-Nagel), nitrile gloves, 1-mL micropipette, safety glasses, Pasteur pipettes, plastic syringes, Nalgene 10-mL, and 50-mL Teflon tubes.

General Conditions

Beware of Glassware

The glassware must be previously cleaned with a 40% nitric acid solution and Milli-Q Nanopure water (see below Nota bene, Lab-203 rules for washing glassware) and then dried in the TROX-100 hood. Before the beginning of the experiments, the glassware is placed under the germicidal lamp of the TROX-100 hood for 1 hour. Regarding storage, glassware (class A) must be protected from environmental dust in duly clean, closed, and identified containers.

XSL•FO
RenderX

Nota Bene Glassware cleaning

The method used to clean the glassware is known as drag washing and consists of first washing the glassware with a strong stream of water and letting the tap water overflow when filling the containers. This procedure is repeated at least 5 times. Then, the glassware is immersed in 40% nitric acid for 24 hours and, thereafter, rinsed again with distilled and deionized water until all the acid is removed (at least 4 times, allowing the water to overflow).

Synthesis and Preparation of Solutions

The experiments were carried out at the Catalysis and Interfaces Science Laboratory (LACFI-203) with a controlled temperature of 23±1 °C. The preparation of solutions and the synthesis of NPs should be carried out in the TROX-100 hood (flow 41 and 34.5 m/second). Synthesis should be carried out in a silicone bath. Before starting the experimental procedure, the hood should be sanitized with alcohol, along with all the material that will be placed inside the chapel, for example, supports, micropipettes, and reagent jars.

Experimental Procedure

Heating System

Silicone oil should be previously heated on a heating plate (selector position at 300). In approximately 1 hour, an ideal oil temperature between 110 °C and 120 °C for the experiment is achieved.

Preparation of 10 mL of a 1% (by Weight) Sodium Citrate Solution

Sodium citrate (0.1 g) should be weighed in a 5-mL beaker, completely dissolved in 2-3 mL of water, and transferred to a 10-mL volumetric flask with its volume completely adjusted with distilled water. Thereafter, the 1% sodium citrate solution should be filtered by weight in the 0.45-µm filter (Chromafil Xtra CA-45/25) using a sterile plastic syringe. The solution should be conditioned at room temperature.

Preparation of 50 mL of a 0.01% Gold Solution by Weight

$HAuCl_4$ (0.0050 g) should be weighed in a 5-mL beaker, dissolved completely in 2-3 mL of distilled water, and transferred to a 50-mL volumetric flask. The beaker should be washed with distilled water, and this washing water is transferred to the volumetric flask to remove all $HAuCl_4$ from the walls of the beaker. The volume of the volumetric flask is then completely adjusted with deionized water. The control of Au concentrations follows the methodology described by Fiedler et al [19].

Synthesis of AuNPs

AuNPs with a diameter between 160 Å and 715 Å are prepared as described by Frens [20].

Fifty milliliters of 0.01% gold solution (by mass) should be transferred to the synthesis flask together with a magnetic bar and then placed in a previously heated oil bath. A watch glass should be placed on the mouth of the synthesis flask. In approximately 20 minutes, the gold solution boils, and then the sodium citrate solution should be added as described in Table 1, with stirring (with the stirrer in position 3). Stirring should be carried out for 30 minutes. Thereafter, the heating and stirring should be turned off, and the solution should be allowed to cool to room temperature and transferred to a Teflon tube.

Table 1. Experimental data for the preparation of gold nanoparticles (AuNPs).

Nanoparticle	Sodium citrate (mL)	Diameter (Å)
AuNP size A	1.00	160
AuNP size B	0.75	245
AuNP size C	0.50	410
AuNP size D	0.30	715

Packaging

The solution must be conditioned in a Teflon tube previously washed (as shown in the *Preparation of 10 mL of a 1% [by Weight] Sodium Citrate Solution* section), duly identified at the room temperature of the LACFI-203, and protected from light.

Important Notes (0.01% [By Weight] Gold Solution)

Because it is highly hygroscopic, care should be taken when weighing $HAuCl_4$. The weighted masses are shown in Table 2. The $HAuCl_4$ reagent bottle must be stored in a desiccator [21].

Table 2. Weighted masses for the preparation of solutions.

Nanoparticle	Gold (III) chloride hydrate (g)
AuNP[a] size A	0.0055
AuNP size B	0.0053
AuNP size C	0.0053
AuNP size D	0.0050

[a]AuNP: gold nanoparticle.

XSL•FO
RenderX

Preparation of 10 mL of a 1% (by Weight) Sodium Citrate Solution

The weight of sodium citrate should be 0.1004 g.

Synthesis of AuNPs

To measure the volume of sodium citrate, the micropipette aligned with the laboratory's quality control was used. An error rate of 4% was tolerated, and the volume was 502.21 µL.

Functionalization of AuNPs

We propose coating AuNPs with polyethylene glycol to enhance their stability and biocompatibility [15,22]. Temozolomide, a chemotherapeutic agent, would be either attached to the surface of the AuNPs or could be encapsulated within them [4,12]. Additionally, the NPs' design has to offer co-delivery of MGMT inhibitors to overcome resistance in GBM cells [7].

More data are needed to reveal the overall integrity of AuNPs post synthesis and post modification to validate successful incorporation of peptides onto AuNPs. Thus, verifying peptide attachment and assessing pH stability are fundamental steps prior to initiating in vitro experimental procedures.

Peptide Attachment Verification

After the synthesis and functionalization of the AuNPs, it is crucial to confirm the successful attachment of peptides onto the NPs. We propose a combination of Fourier transform infrared spectroscopy (FTIR) and surface plasmon resonance (SPR) for this verification.

FTIR can confirm peptide attachment by identifying the characteristic absorption peaks of the peptide-NP bond. After the peptide functionalized AuNPs, samples must be freeze-dried and mixed with potassium bromide. FTIR spectra must be collected in the range of 4000 cm^{-1} to 400 cm^{-1}. The appearance of characteristic absorption bands in the FTIR spectrum, not present in the AuNPs without peptides, would confirm the successful attachment of peptides onto the NPs.

For SPR, we plan to coat a gold chip with a layer of the NPs and flow the peptide solution across the chip. The SPR sensor will monitor the real-time interaction between the NPs and the peptides, as reflected by changes in the resonance angle. A shift in the resonance angle upon the introduction of the peptide solution would confirm the binding of peptides to the AuNPs.

Both these methods can provide complementary information—FTIR would confirm the formation of a covalent bond between the AuNPs and peptides, while SPR will provide real-time information about the binding process and the stability of the peptide-AuNP complex.

pH Stability Test

Given the acidic nature of the tumor microenvironment, it is crucial to ensure that our NPs are stable and retain their functionality under such conditions. We propose conducting pH stability tests to tackle this problem. After verifying peptide attachment, NPs are incubated in solutions of varying pH (ranging from pH 4 to 8 to simulate physiological and tumor microenvironment conditions). We then evaluate the size, shape, and surface charge of the NPs through dynamic light scattering and zeta potential measurements, and the functionality of attached peptides is assessed using FTIR or SPR. This provides a comprehensive view of NP stability and functional integrity in a range of pH conditions.

In Vitro Evaluation

The functionalized AuNPs can be tested in vitro using GBM cell lines to evaluate their cellular uptake, cytotoxicity, and ability to overcome drug resistance [6]. As our current proposal is at an early stage, it focuses on in vitro studies and computational modeling. Upon successful completion of these initial stages, we plan to include in vivo animal studies in future protocols.

Optimization of NP Design

Based on the preliminary results, constant optimization of NP design is needed to enhance their mobility within the brain's extracellular space, their penetration from the cerebrospinal fluid into the brain parenchyma, and their targeting efficiency [8]. Future developments in NP design optimization can involve adjusting NP size and shape to improve mobility and penetration, modifying surface properties for enhanced drug delivery and stability, and potentially incorporating targeting ligands that can increase affinity for GBM cells or specific receptors on the BBB. Each step represents a critical aspect of the research process and will contribute to the development of a more effective treatment for GBM. It is important to note that this complex and challenging project requires a multidisciplinary team of researchers with expertise in NP synthesis, drug delivery, cell biology, neuroscience, and oncology.

Ethical Considerations

Since our proposal is centered on laboratory experiments and computational models, no human subjects or data from human subjects are involved in this research protocol. Therefore, human subjects research ethics review, informed consent, privacy and confidentiality protection, and compensation type and amounts for human subjects research are not applicable to our research proposal. However, should the study progress to the stage of clinical trials, all appropriate ethical considerations will be rigorously applied, including but not limited to obtaining ethical approval from the relevant institutional review board, obtaining informed consent from all participants, ensuring privacy and confidentiality, and providing fair compensation.

Results

This proposal is currently theoretical and does not have reportable results other than structured simulations as listed above, where we found that the protocoled AuNPs have a structure capable of attaching transferrin-like peptides and carrying chemotherapeutics, such as temozolomide and MGMT inhibitors to overcome resistance. The authors do not anticipate proactively obtaining funding in the future due to insufficient resources.

Discussion

Limitations

While AuNPs are generally considered biocompatible, there could still be potential toxicity or adverse reactions, especially at the high doses for effective treatment [6]. The long-term effects of AuNPs' accumulation in the body are not fully understood. Moreover, GBM tumors exhibit considerable heterogeneity, wherein various regions within a single tumor may display distinct characteristics [4]. This heterogeneity presents a significant challenge, potentially impeding the effectiveness of a singular therapeutic approach to treat the entire tumor.

As an early-stage proposal, our current focus is to establish the feasibility of our approach through computational models and in vitro studies. Moreover, we plan to generate data on AuNPs' stability and delivery accuracy in subsequent studies.

Comparison With Prior Work

In evaluating our proposal relative to recent literature [8], in particular, the study using radiolabeled AuNPs studded with substance P peptides for GBM treatment, it is clear that our approach offers several distinct advantages and complements existing strategies.

First, our work expands on the drug delivery capabilities of AuNPs. While the previous study used AuNPs for delivering radiation therapy, our nanocarrier approach delivers temozolomide and MGMT inhibitors, which are 2 crucial agents in chemotherapy for GBM [7]. The quality of a nanocarrier broadens the therapeutic range of AuNPs and illustrates their potential to transport various types of drugs.

Second, our study also emphasizes the importance of targeted delivery. Our nanocomplex approach (ie, AuNPs with transferrin-like peptides attached), seeks to exploit the upregulated transferrin receptor on GBM cells, thereby improving the specificity of drug delivery and minimizing off-target effects [12].

Another significant advancement in our study is the AuNPs' ability to cross the BBB [4]. This passage is a crucial immune checkpoint and a key factor in neuro-oncologic therapies, which was not addressed in the previous study [8]. A successful BBB traversal by the functionalized AuNPs would suggest a promising strategy for delivering therapeutic agents to the central nervous system [7].

Furthermore, our study's quality control and safety evaluation offers a comprehensive view of the potential impacts of the proposed treatment [6]. By investigating the toxicity of our compound, we could provide valuable insights into its suitability for further development and potential clinical application.

Conclusions

The functionalization of AuNPs with de novo–engineered transferrin-like peptides presents a novel therapeutic approach for GBM. Our work proposes a detailed protocol explaining the synthesis, functionalization, and stability evaluation of AuNPs. Given the acidic nature of the brain tumor microenvironment, maintaining the structural integrity and functional capacity of AuNPs under these conditions is critical; hence, pH stability tests must be conducted accordingly. We demonstrate a potential modification to the surface of AuNPs to overcome current obstacles in GBM treatment. By introducing ligands or peptides—such as the proposed transferrin-like peptides—that target specific transporters or receptors on the BBB and show high affinity for GBM cells, we anticipate an enhanced ability to cross this barrier. Furthermore, we aim to enable accurate payload delivery by leveraging AuNPs as nanocarriers for temozolomide and MGMT inhibitors directly to the tumor site, potentially reducing chemotherapy resistance and systemic side effects. We hope that our rigorous quality control protocol for the synthesis of AuNPs will permit and inspire further research and potential funding in this field, offering an innovative and effective treatment option for GBM.

Acknowledgments

HDF and AMF would like to convey to Professor Faruk Nome, in memoriam: thanks for all. HDF (retired) would like to thank INCT-Catalysis (National Institute of Science and Technology for Catalysis, Department of Chemistry, Federal University of Santa Catarina, Florianópolis, Brazil), and the Brazilian Foundations CNPq (Brazilian National Council for Scientific and Technological Development), CAPES (Brazilian Federal Agency for Support and Evaluation of Graduate Education), and FAPESC (Foundation for the Support of Research and Innovation of the State of Santa Catarina).

Abstract

Background: According to the first law of thermodynamics, energy cannot be created or destroyed in an isolated system. Water has a characteristically high heat capacity, indicating that the temperature of ingested fluids and meals could contribute to energy homeostasis. Citing the underlying molecular mechanisms, we present a novel hypothesis that states that the temperature of one's food and drink contributes to energy balance and plays a role in the development of obesity. We provide strong associations with certain molecular mechanisms that are activated by heat and correlate them with obesity and a hypothetical trial that could test this hypothesis. We conclude that if meal or drink temperature proves to contribute to energy homeostasis, then depending on its contribution and scale, future clinical trials should attempt to adjust this effect when analyzing data. In addition, previous research and established relationships of disease states with dietary patterns, energy intake, and food component intakes should be revisited. We understand the common assumption that thermal energy in food is absorbed by the body during digestion and dissipated as heat into the environment, not contributing to the energy balance. We challenge this assumption herein, including a proposed study design that would test our hypothesis.

Objective: This paper hypothesizes that the temperature of ingested foods or fluids influences energy homeostasis through the expression of heat shock proteins (HSPs), especially HSP-70 and HSP-90, which are expressed to a greater extent in obesity and are known to cause deficits in glucose metabolism.

Methods: We provide preliminary evidence supporting our hypothesis that greater dietary temperatures disproportionally induce activation of both intracellular and extracellular HSPs and that these HSPs influence energy balance and contribute to obesity.

Results: This trial protocol has not been initiated and funding has not been sought at the time of this publication.

Conclusions: To date, no clinical trials are available regarding the potential effects of meal and fluid temperature on weight status or its confounding effects in data analysis. A potential mechanism is proposed as a basis by which higher temperatures of foods and beverages might influence energy balance via HSP expression. On the basis of the evidence supporting our hypothesis, we propose a clinical trial that will further elucidate these mechanisms.

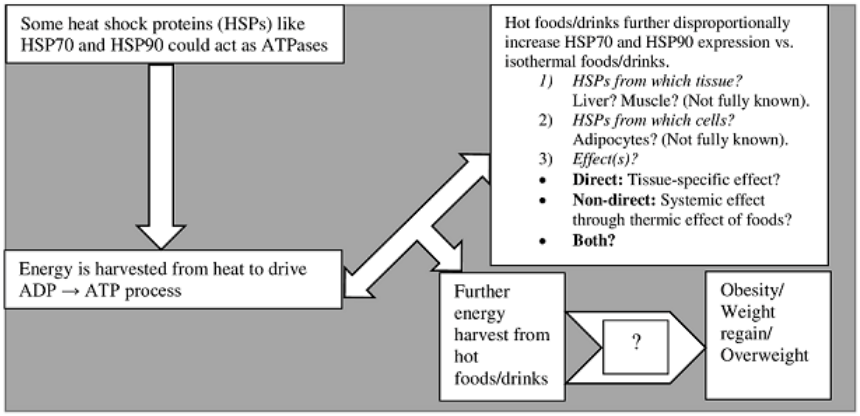
Introduction

Background



The first law of thermodynamics, also known as the law of conservation of energy, states that energy can neither be created nor destroyed in an isolated system [1]. The human body has its own mechanisms to adapt to changing temperatures; however, it is possible that higher or lower temperatures of food and beverages (referred to as dietary temperature) impose some implications on the energy demands of the body. On the basis of diet composition, chewing habits, and the amount of fluid (and its corresponding temperature) ingested, the human body is exposed to a wide range of temperatures [2,3]. This exposure affects the entire gastrointestinal tract, being greatest at the mouth, followed by the esophagus and stomach, with the latter exposed for a greater time [4-7]. Indeed, there have been several studies relating dietary temperature to gastric function [6], frequency of gastric myoelectrical activity [7], gastric emptying time, gastrin release, gastric acid secretion [8], esophageal cancer [9,10], and intraluminal upper gastrointestinal temperature and motility [5]. Although when it comes to energy metabolism, it has been assumed that higher dietary temperatures are dissipated during digestion and do not contribute to energy balance.

One of the most immediate responses of body cells to higher temperatures is the induction and increased synthesis of heat shock proteins (HSPs), especially HSP-70 [11,12] and HSP-90 [13,14]. HSP-70 [15] and HSP-90 [16] possess N-terminal adenosine triphosphatase fragments at their ends and tightly regulate adenosine triphosphate (ATP) activity and ATP hydrolysis [13,17-19], providing the heat energy to drive the adenosine diphosphate to ATP conversion. Indeed, cells exposed to higher temperatures increase HSP activity [11-14], and the time profile of peripheral blood mononuclear leukocytes HSP-70 response to in vitro heat shock is temperature dependent [11,20]. For instance, under in vitro hyperthermic conditions (40-41 °C), the time course was characterized by a sharp rise in HSP-70 concentration immediately after heat shock treatment ($P<.05$ for 40 °C at 0 hours), followed by a steady and progressive decline over time [11].

We have already shown that HSPs can extract energy from the environment (here, dietary temperatures), thereby contributing to the energy balance. The mathematical calculations are beyond the scope of this paper, and interested readers may read our previous paper [21]. The summary is graphically illustrated in Figure 1.

Importantly, obesity has been linked to HSP expression, specifically for HSP antibodies (HSP-27 [22], HSP-72 [23], HSP-60, HSP-65, and HSP-70 [24,25]). The table in the Multimedia Appendix 1 [22,24-26] lists the studies investigating the relationship between anti-HSP antibodies and indexes of body mass and body composition. Specifically, serum HSP-27, HSP-60, HSP-65, HSP-70, and HSP-72 antibody levels are significantly increased in people with obesity compared to people with a normal weight [22-26]. Furthermore, in the diet-induced obese mouse model of insulin resistance, HSP-90 inhibitors activate the heat shock factor 1 stress response pathway and improve glucose regulation [27]. A similar experiment on diet-induced obese mice supports this hypothesis in which HSP-90β knockdown reverses insulin resistance and improves glucose tolerance [28].

Figure 1. Hypothetic mechanism by which hot meals or drinks may contribute to energy balance. ADP: adenosine diphosphate; ATP: adenosine triphosphate; ATPase: adenosine triphosphatase.

Evidence Supporting Our Hypothesis

Intracellular Versus Extracellular HSPs

HSPs help to maintain cellular homeostasis through a mechanism called thermotolerance. Cells exposed to mild stress induce HSPs, which later protect them against subsequent stress. In cells exposed to severe stress, HSPs promote apoptosis. HSPs meanwhile exist in extracellular fluids and contribute to immunomodulation [29]. It is noteworthy that the intracellular HSP function may be different from that of extracellular HSPs, as the latter appears to manifest a function different from the well-known chaperone role [29]. For instance, intracellular HSP-70 exerts a profound anti-inflammatory effect, whereas extracellular HSP-70 activates proinflammatory pathways [30]. In the case of obesity, both intracellular [31] and extracellular [32] HSP-70 levels are significantly greater in participants with obesity than in lean controls. It has been proposed that the ratio of extracellular medium HSP-70 to intracellular HSP-70 contents may be a determining factor to trigger a chronic proinflammatory status, which leads to insulin resistance and the development of type 2 diabetes mellitus (T2DM) [30].

Weight Regain and HSPs

In the only published randomized controlled trial (RCT) linking weight regain to HSPs, Roumans et al [33] explored the expression of stress proteins during weight loss and weight maintenance concerning weight regain. They compared the in vivo findings with the results from in vitro cultured human Simpson-Golabi-Behmel syndrome (SGBS) adipocytes. In total, 18 healthy participants participated in an 8-week dietary program with a 10-month follow-up period. They categorized the participants as weight maintainers or weight regainers based on their weight changes during the intervention. Abdominal subcutaneous adipose tissue biopsies were conducted before and after the diet and after the follow-up. In vitro–differentiated SGBS adipocytes were starved for 96 hours with low (0.55 mmol/L) glucose. Weight regainers showed increased expressions of calnexin, β-actin, HSP-27, HSP-60, and HSP-70. Changes in HSP-27 and HSP-70 and β-actin levels were linked to HSP-60, a novel key factor in weight regain after weight loss. SGBS adipocytes manifested increased concentrations of β-actin and HSP-60 after 96 hours of glucose restriction [33]. In another RCT, 20 young overweight men without metabolic syndrome participated in a 3-week residential program on a low-fat diet and moderate aerobic exercise. After 3 weeks of the diet program, significant reductions in BMI, serum lipids and lipid ratios, and oxidative markers were recorded (P<.05), along with the reduced expression of HSP-90 and HSP-27 [34].

There is ample literature on the effects of heat stress on fat deposition [35], insulin sensitivity [36], and the facilitating role of HSPs in adiposity [37-39]. The most direct evidence supporting our hypothesis comes from studies conducted on pigs. Exposure to low or high ambient temperatures directly impacts heat production and energy balance in pigs [40]. Heat stress causes enhanced adiposity [41] and growth performance through reduced energy and nitrogen use [42]. However, it is noteworthy that novel observations challenge this long-held traditional dogma, linking reduced productive output during heat stress to decreased nutrient intake. It is now clear that the heat stress response profoundly changes postabsorptive carbohydrate, lipid, and protein metabolism independently of decreased feed intake through harmonized alterations in fuel supply and use by various tissues [43]. One might argue whether heat stress in pigs is relevant to the effects of food temperature on energy metabolism in humans, especially when there is no direct evidence to show that ingesting hot food raises body temperature to such an extent. In addition, it may be argued that the association of HSPs with obesity does not automatically infer causation, and it is well known that these systems respond to metabolic stress. Therefore, to test this hypothesis, we prepared a short proposal to conduct a clinical trial, as described in the *Methods* section.

Altogether, these trials might provide preliminary evidence that HSPs contribute to obesity and weight regain. There is evidence that other HSPs, that is, HSP-A12A, regulate adipocyte differentiation and diet-induced obesity through positive feedback regulation with PPARγ (peroxisome proliferator-activated receptor gamma) [44].

To explore the mechanism of the effects of heat stress on porcine adipocytes, Qu et al [35] used an in vitro adipocyte differentiation model to determine the cellular responses that occur during adipocyte differentiation in pigs. Stromovascular cells (preadipocytes) were differentiated for 9 days at a normal (37 °C) or heat stress (41.5 °C) temperature under 5% CO_2. They measured the expression of a long list of heat stress genes, such as HSP-27, HSP-60, HSP-70, and HSP-90, as well as cellular triglyceride and ATP concentration. Expectedly, heat stress significantly enhanced the expression of HSP genes but surprisingly had no effect on the level of PPARγ, although C/EBPα was significantly induced. Heat stress leads to the enhanced expression of genes involved in fatty acid uptake and cellular triglyceride synthesis. With the progression of differentiation, the total cellular ATP significantly decreased. However, cells under heat stress had significantly greater cellular ATP than those under control temperature. They concluded that heat stress promoted increased adipocyte triglyceride storage, possibly through the upregulation of genes involved in fatty acid uptake and triglyceride synthesis [35]. It was later determined that the induction of phosphoenolpyruvate carboxykinase expression in adipose tissue by heat stress indicates that increased glyceroneogenesis might also be involved in increased fat storage in pigs under heat stress [38].

Although exposure to a higher dietary temperature is a different form of exposure to higher environmental heat in animals, these animal studies [35,40-42] have invaluable lessons that can be translated into a clinical trial. The temperature range of heat stress applied usually lies between 37 °C and 41.5 °C for in vitro studies [35], which can theoretically simulate physiological responses during eating and drinking of hot meals and drinks, and ranges between 12 °C and 29 °C for exposure to ambient temperature studies [40], which is an acceptable temperature difference range (Δ) to study higher or lower dietary temperatures in humans.

Participants with obesity showed increased expression of HSP-60, HSP-72, HSP-90, and GRP-94 levels, specifically influencing BMI and percent body fat [45], whereas insulin resistance resulted in a decrease in intracellular HSP-70 levels. It also appears that weight loss can reduce HSP activation, as demonstrated in a recent trial where acupuncture in combination with dietary restriction was effective in reducing all immunologic factors (anti-HSP antibodies including anti–HSP-27, anti–HSP-60, anti–HSP-65, and anti–HSP-70) and weight loss [46]. Altogether, these findings indirectly support the hypothesis that a network composed of different HSPs (mainly HSP-70 and HSP-90, but including other HSPs, possibly via modulation of insulin sensitivity or resistance) may alter energy balance and contribute to weight gain and loss, which may have important implications in obesity treatment and prevention.

Thermic Response

Although the higher temperature of ingested meals and fluids may have some overlap with specific dynamic action (SDA), it should be emphasized that these are 2 different concepts; meal or fluid temperature is a subset of SDA, whereas SDA, or thermic response, is a physiological phenomenon, which

XSL•FO
RenderX

comprises the energy expended on all activities of the body after the ingestion of a meal and leads to a rapid postprandial increase in the metabolic rate. SDA is influenced by the size, type, composition, and temperature of the meal as well as body size, body composition, and multiple environmental factors (such as gas concentration and ambient temperature). In humans, a commonly used estimate of the thermic effect is approximately 10% of the caloric intake; however, the average maximum increase in metabolic rate originating from digestion could reach 25% [47].

However, there is indirect evidence that states that meal temperature might influence energy balance, which is not accounted for by SDA. Meal temperature is one of the determining factors of gastric emptying and absorption of food compositions such as carbohydrates in the duodenum [48], which consequently affects heart rate [8] and thereby metabolic needs. In endotherms, including humans, if meals and fluids are ingested at a temperature lower than the core body temperature, extra heat should be generated to elevate the meal temperature to the body temperature. Thus, the cost of food warming is indicated by the SDA response [47]. The contribution of food warming to SDA should vary as a function of meal temperature and mass. In other words, more energy is expended to warm a large, cold meal compared with a smaller, warmer meal [49]. It might be conjectured that the reverse may hold true for warmer meals and fluids and thereby contribute to energy expenditure and thus energy balance.

The results of direct or indirect calorimetry studies can be criticized; these studies are usually short term and do not account for the influence of between-individual differences in dietary temperatures, neither on the day of calorimetry measurements nor the day before. It might be a good practice to advocate the measurement or control of meal temperature during the day of measurement and at least 1 week before indirect calorimetry. A careful appraisal of the methodology of most laboratory studies shows that, at best, participants are asked to refrain from caffeine and alcohol intake and any vigorous physical activity 1 day before the calorimetry study or a standard diet is prescribed [50-54]. It can also be argued that heat acclimation may partially promote thermoregulatory adaptations in people who consume hot foods and fluids. This might be true; however, this has not been experimentally tested. In addition, there might be an interaction between dietary temperature and some ingredients of food composition (for instance, capsinoids) or some dietary behaviors (such as the frequency of consuming ingredients like capsinoids) that might circumvent thermoregulatory pathways.

In a recent meta-analysis, increases in HSP-70 protein expression after heat acclimation were shown to be moderated by the number of heat acclimation days [12]. In other words, there is a strong possibility that between-individual differences in eating behaviors in terms of the temperature of foods and drinks they consume may influence HSP-70 expression and, if HSP-70 expression contributes to energy balance, then this will confound matching protocols in clinical trials, such as treatment-matching, subject-matching, and data-matching protocols.

Evidence From the Effect of Dietary Temperature on Food and Liquid Intake

Although the current hypothesis is centered on the influence of dietary temperature on HSPs to cause changes in metabolic processes that favor energy storage, a potential confounding effect that may exist is the effect dietary temperature may have on eating behaviors. In an experiment conducted on rats, no interaction was reported between nurture temperature and meal temperature. The food temperature per se had no significant effect on food intake [55]. In contrast, food temperature had an impact on food intake in patients who were hospitalized. The percentage of hospitalized patients who rated the meal temperature as good was higher for those served with isothermal trolleys than those who were not. The amount of food consumed by patients served with isothermal trolleys was significantly greater than that consumed by patients served without the trolleys [56]. Similar results have been obtained in another hospital setting [57]. Furthermore, serving temperature may affect expected satiety and complementary food purchases. Consumers are more likely to choose complementary food items when they consume or intend to consume a food or beverage served cold rather than hot [58], and warm temperature attenuates the preference for savory meals [59]. The dietary temperature may additionally influence executive function and processes associated with obesity, whereas lower executive function acts as a risk factor for increases in specific eating behaviors that play a role in the development of weight management problems [60,61]. Therefore, the dietary temperature may have a complex interaction with total energy consumption, which deserves to be clinically investigated under controlled conditions.

The aforementioned literature justifies the need to conduct a well-controlled clinical trial to test whether higher dietary temperatures interfere with body and cellular energetic states and, thus, influence or confound the results of clinical trials that aim to compare or evaluate dietary interventions.

Methods

Overview

To the best of our knowledge, no studies are available regarding the possible contribution of dietary temperatures to the HSP response. We provide preliminary evidence supporting our hypothesis that higher dietary temperatures disproportionally induce activation of both intracellular and extracellular HSPs and that these HSPs influence energy balance and obesity. In this paper, we outline a protocol to test these hypotheses and elucidate the potential roles dietary temperature plays in obesity development.

A Proposal to Conduct an RCT

A 4-arm randomized design investigating diets served at different temperatures in 5 °C increments (with core body temperature as a reference) in healthy adults would be the first step to elucidate the potential mechanism linking higher meal temperature with energy contribution. The same protocol can be replicated in patients who are overweight and obese or in

XSL•FO
RenderX

people with T2DM. In addition, a crossover design can be performed with necessary modifications.

Participants: Inclusion and Exclusion Criteria

The participants will include 80 healthy (BMI 25-35 kg/m^2) men and women aged 19-65 years. Entry criteria will include people who are not currently dieting to lose weight and have had no weight loss or gain >2 kg over the past 3 months; not taking any medications (including antifever) that affect energy expenditure or eating; not using tobacco; not pregnant or lactating or planning to become pregnant in the next 12 months; and have no limitations to eating specific foods or to swallowing (eat and drink) a normally estimated range of meal temperatures (37-52 °C). The participants must not have major health problems; known cardiovascular (cardiac, peripheral vascular, and cerebrovascular), pulmonary (chronic obstructive pulmonary disease, interstitial lung disease, and cystic fibrosis), or metabolic (diabetes, thyroid disorders, and renal or liver disease) disease; and severe fever.

Procedures

The day before the experimental session, the participants will be instructed to avoid alcohol, caffeine, and strenuous exercise and to drink plenty of water for 24 hours. On the day of the experimental session, the participants will be asked to arrive at the laboratory adequately rested and will be provided with boluses of soups (each 100 ml) with a predefined temperature to be taken once (to overcome the problem of temperature dissipation).

The energy content of bolus diets (including the thermoneutral diet and temperature-graded bolus diets) will be matched to each of the participant's objectively calculated energy demands [62] and will be provided in the following manner: 20% energy for breakfast, 50% for lunch, and 30% for dinner. This procedure will facilitate the administration of boluses with graded temperatures (eg, +5 °C increments) with a fair precision from 37 °C to 52 °C, which is both ethical and within the optimal drinking temperature of 57.8 °C and <85 °C for the maximum temperature used to serve hot drinks such as coffee [63].

After assuring sufficient hydration (urine-specific gravity <1.025) [64], the participants will be instrumented in a thermoneutral room (approximately 25 °C) and then will be entered into a whole-body calorimeter regulated to 35 °C with approximately 20% relative humidity, where they will rest in an upright seated position for a 30-minute habituation period while steady-state measurements will be obtained.

The dietary temperature will be measured using a noncontact thermometer. All drinks and a standardized diet will be served at room temperature to maximize gastric emptying and fluid uptake while minimizing diuresis. It is expected that by using this metered intake to control for intake pacing, ingestion will be completed between 3 minutes and 5 minutes and will control for heat dissipation of foods and fluids as well. To avoid thermal injury while providing a satisfactory sensation to the participants, the optimum temperature for serving hot fluids and meals will be observed [63].

The drinks and meals will be consumed at a speed that is as rapid as the participants can comfortably manage, which is described elsewhere in detail (mean 11 seconds for 200 mL and 38 seconds for 500 mL) [65,66]. The intraesophageal and intragastric temperatures will be monitored using thermocouples, which is a widely used technique [67]. As currently there is no specific dynamic model for real-time monitoring or measuring of temperature changes of digested meals or drinks along the alimentary tract, inner food and drink temperature will be estimated using the inverse heat conduction problem methodology on surface temperature measurements obtained using thermography [68]. For practical and physiological purposes, considering the applied speed of ingestion, the magnitude of temperature changes along the alimentary tract could be considered as negligible [65-67,69,70].

Measures

All outcome measures will be measured at 0, 6, and 12 weeks. The participants will be asked to follow their assigned diet served at 37 °C, 42 °C, 47 °C, and 52 °C for 12 weeks.

Blood samples will be collected from each participant for analysis after 12-hour fasting, 3 times during the study (at the beginning and 6 and 12 weeks later).

Adipose tissue biopsies, protein isolation, and in vitro cell culture experiments will be performed as described elsewhere [33].

Cellular HSP-70 and HSP-90 levels will be measured to determine the thermic response to feeding, that is, evaluation of the causal relationship among higher dietary temperature, HSP-70/HSP-90 concentrations, and their time profile, as well as measures of obesity, aerobic fitness, resting metabolic rate, and diet-induced thermogenesis.

Food diaries will be analyzed using software to determine energy intake and macronutrient content.

An automated respirometer system plus a whole-body direct calorimeter, as the gold standard, will be used to measure energy expenditure and substrate utilization, aerobic fitness, resting metabolic rate, diet-induced thermogenesis, and markers of protein and fat catabolism to evaluate whether dietary temperature influences metabolism and surrogate end points of obesity in participants, such as weight and waist-hip ratio.

Duration of Study

The optimum length of the study will be 12 weeks, if feasible, and if not, at least 2 weeks would be necessary.

Assignment of Interventions

For treatment allocation, randomization (1:1:1:1) and blinding protocol will be used as described previously [71].

Proposed Outcome Measures

Primary Outcome Measures to Be Assessed

Subset A denotes the change in BMI, total body fat, body weight, percentage body fat, lean body mass, percentage lean body mass, waist circumference, and waist-hip ratio from baseline to 12 weeks (time frame: 0, 6, 12, and n weeks). The

XSL•FO
RenderX

measurements will be performed with light clothing before breakfast and preferably after voiding.

Subset B denotes changes in HSP-27, HSP-65, HSP-70, HSP-72, and HSP-90 (in plasma and total leukocytes) and anti–HSP-27, anti-HSP-65, anti-HSP-70, anti-HSP-72, and anti-HSP-90 antibodies from baseline to 12 weeks (or whatever time is feasible, time frame: 0, 6, 12, and n weeks).

Subset C denotes changes in motilin, fasting glucose, insulin, C-peptide, 2-hour glucose, and insulin plus homeostasis model assessment–estimated insulin resistance from baseline to 12 weeks (or whatever time is feasible, time frame: 0, 6, 12, and n weeks).

Secondary Outcome Measures to Be Assessed

Changes in total cholesterol, triglycerides, low-density lipoprotein, high-density lipoprotein, reactive oxygen species, reactive nitrogen species, and NF-κB from baseline to 12 weeks (or whatever time is feasible, time frame: 0, 6, 12, and n weeks) are to be assessed.

Other Outcome Measures to Be Assessed

Subset A denotes plasma levels of leptin and adiponectin from baseline to 12 weeks (or whatever time is feasible, time frame: 0, 6, 12, and n weeks).

Subset B denotes possible changes in appetite and food intake (using a 3-day dietary recall questionnaire). Immediately before and after each diet, participants will rate hunger, satiety, and prospective food consumption using 100-mm visual analog scales. Gastric motility will be measured using ultrasound imaging systems.

A Short Proposal to Conduct a Crossover Design

As there are between-individual responses to heat stress [72], there are also interindividual differences in the serum concentration of HSPs [73-75], which may confound statistical analyses when calculating interactions between frequency of drinking or eating hot foods and time elapsed after eating or drinking. To overcome issues with interindividual differences in its broad sense, a crossover design with necessary modifications can be performed. In this case, it will be necessary that participants can eat ad libitum.

A 2-week washout period and thermoneutral diet between conditions will be included, in which participants will eat boluses of soups served at approximately 37 °C. In this case, the order in which participants participate in each treatment will be randomized. The participants will be assigned 4 weeks of each treatment with a 2-week washout period between each of the 4 crossover treatments.

Before starting the second round of the trial, all 3 treatment groups will return to a thermoneutral bolus diet for another 5 weeks (5 weeks of active treatment, 2 weeks of washout period, and 5 weeks of crossover round).

Adipose tissue biopsies and plasma samples will be obtained at 2 time points: before and after dietary treatment diet.

Statistical Analyses

For statistical analysis, Bayesian adaptive approaches [76] will be applied whenever feasible because this approach is more likely to allocate participants to better-performing arms at each interim analysis.

In addition to standard analyses of RCTs, causal mediation analysis can be performed to determine how much of the weight change is mediated by the increase in HSP levels or appetite or both. Future trials should seek to identify alternative mechanisms with the aim of further refining the intervention.

This seminal clinical trial can provide preliminary data for causal mediation analysis to facilitate the exploration of the causal mechanisms underlying possible energy contributions through higher dietary temperatures. Proper methods will be used for this purpose [77,78].

Sample Size Calculation

As the choice of type I errors (α, false positive), type II errors (β, false negative), and effect size may be quite arbitrary [79], we suggest calculating the sample size or power using the *R* value (eHSP-70 to iHSP-70 ratio) for a pilot study (alternatively, owing to feasibility, a preliminary study may be conducted on mice or rats).

Furthermore, as providing a priori sample size calculation is misleading and the presentation of CIs—although serving the same purpose—is superior [80], it would be better to use the CI of the *R* value to calculate the sample size based on the feasibility of a priori assumptions about the study results and available resources. In addition, because foods and drinks may be served and consumed at even wider temperature ranges, it would be instrumental to calculate sample sizes based on wider *R* ranges (approximately 0.2-6).

According to Krause et al [30], assuming the ratio *R* = (eHSP-70) / (iHSP-70) = 1 for the controls (resting and unstimulated) and assuming a moderate-hot meal temperature may produce a shift in *R* to up to 5, which is paralleled by an increase in inflammatory markers and stimulation of cell proliferation, *R* values >5 can be considered as an exacerbated proinflammatory response. However, for a conservative calculation, we suggest using *R*=2. According to Hunter-Lavin et al [81], heat-shocked cells simultaneously measured HSP-70 at 37 °C (*R*=1.00), 39 °C (*R*=1.45), 42 °C (*R*=0.65), 43 °C (*R*=0.48), and 45 °C (*R*=1.97), this later temperature confirms a proinflammatory response.

Note that at 45 °C (*R*=1.97), there is a turning point compared with that at 43 °C. This means that if a study intends to investigate wider ranges of meal temperature, it is necessary to calculate an array of expected *R* values and then choose the maximum calculated sample size. For an *R* value between 0.22 and 1.1, a sample size of 9 participants is needed to achieve 80% power [1], whereas an *R* value between 1.8 and 6 would require 75 participants to achieve 90% power [2].

Changes in the calculation of the *R* value are suggested to be valid during heat exposure, as *R* values are associated with the heat exposure of peripheral blood mononuclear cells to different temperatures within a physiological range [30]. Precautions that

XSL•FO
RenderX

should be considered could include, but are not limited to, correction for noncompliance of the participants, adjustment for multiple comparisons, and innovative study design.

A total of 80 patients will be randomized equally (1:1:1:1) between the 3 active treatments and the thermoneutral group. Overall, 20 participants will be randomly allocated to the thermoneutral diet group (37 °C): 20 at 42 °C, 20 at 49 °C, and 20 at 54 °C. The primary analysis will be intention-to-treat for the whole study cohort.

It is possible that there are multiple roles of HSPs in body weight, weight regain, and composition, probably related to the exposure time during diet ingestion (and also dietary temperature acclimatization during short-term periods, midterm periods, and long-term periods and presence or absence as well as the degree of insulin resistance in people). Thus, conducting a clinical trial for 12 weeks would provide a sufficient time course to investigate this point.

Further Considerations and Opportunities

Due to HSPs' intertissue differences [30], it would be helpful to obtain samples of plasma, lymphocytes, central adipose tissue, and muscle (and liver tissue in case of animal study), if feasible, to attempt to find correlations between HSPs and other variables. This study will provide a great opportunity to administer an array of questionnaires to determine the quality of life, anxiety, depression, food frequency, physical activity, etc, and these data in combination with regular examinations will also help to decide whether and when this trial should be continued or stopped. As a preliminary study, it might be proposed to conduct an observational study to retrospectively investigate the mean differences in variables and odds ratios between people who report meals as cold and those who report consuming their meals while it is hot, in terms of serum baseline HSP levels. Subjective dietary temperatures should then be defined as objective temperatures with appropriate measures. This proposed trial can be replicated in healthy people, people with obesity, and people with T2DM (and in long-term patients vs newly diagnosed patients).

Further Technical Issues That Need to Be Addressed in the Pilot Clinical Trial

One might argue whether the study discriminates between other possible influences of meal temperature on energy balance mentioned in the paper (eg, effect on gastric emptying and diet-induced thermogenesis). Evidently, these issues should also be controlled. Participants can eat ad libitum during the 12 weeks of intervention and are fed only soups for 3 meals a day for 12 weeks and are supposed to stay in the laboratory during the entire experiment. This can confound the assessment of hunger or satiety obtained using the visual analog scale using different meal sizes. If participants receive standardized and isocaloric meals, it can mask a possible effect on appetite as well. A very important issue regarding meal temperature is the experienced pleasantness of the meal, which can influence food intake. This should be assessed as well. We have proposed an intention-to-treat analysis for the pilot study. Such a long intervention probably might result in a significant dropout rate, so it is questionable if sufficient participants will conclude the study.

Ethical Considerations

As this study involves human participants, the approval by Institutional Review Board (IRB) will need to be obtained before beginning any research activities. This will include an informed consent process, in which participants will be required to provide explicit informed consent for data collection, analysis, and reporting before the inclusion in the study. Such IRB approval will require privacy and confidentiality protection such as the deidentification of participant data, which would be appropriate for this trial. The compensation for participation in research will need to be considered by the specific IRB and research team.

Results

This trial protocol has not been initiated and funding has not been sought at the time of this publication.

Discussion

Principal Findings

Apart from the obvious need to improve weight loss or weight loss maintenance, elucidating the roles that HSP may play in the energy balance is important for future considerations in dietary assessment. The lack of control for dietary temperatures may have produced confounding effects in the data analysis of clinical trials of obesity and medical situations with obesity-related pathology. Dietary assessment tools are widely used in most nutritional and medical studies; therefore, it is critical to have accurate and validated tools. Several meta-analyses and systematic reviews have shown that dietary intake assessment tools have fundamental errors [82-84]; some researchers have proposed that their application in energy balance or obesity and body weight studies must be ceased [85]. It was recently proposed that self-reported energy intake should not be used for the study of energy balance in research on obesity because energy underreporting varies as a function of BMI, and interindividual variability in the underreporting of self-reported energy intake automatically attenuates diet-disease relationships [86]. Furthermore, there is a dispute regarding the validation of dietary assessment tools and the inaccuracy of energy intake measures [87-90]. If dietary temperatures prove to affect energy balance, then future attempts to correct for underreporting and misreporting of diet outcomes cannot avoid taking dietary temperature into account, regardless of whether these tools are kept or abandoned and new tools are developed.

We have presented our hypothesis that dietary temperatures influence energy balance, and we have followed this with a clinical trial that would address this question. The lack of literature regarding possible direct and independent effects of higher dietary temperatures on indexes of obesity warrants a well-designed clinical trial to shed light on the ambiguous role of dietary temperature on daily energy contribution. If meal or drink temperature proves to contribute to energy homeostasis, depending on its contribution and scale, future clinical trials should attempt to adjust this effect when analyzing data. In

XSL•FO
RenderX

addition, previous research and established relationships of disease states with dietary patterns, energy, and nutrient intake should be revisited.

This hypothetical proposal is important in several ways. Previous studies [69,70] have only examined the effect of water temperature on gastric emptying and thereby appetite and energy intake; however, they did not consider a potential and direct effect of higher meal or drink temperature through body thermodynamics and HSPs expression. Fujihira et al [69] were the first to investigate how different water temperatures impact gastric motility and energy intake. They showed that consuming 500 mL of water at 2 °C can suppress gastric contractions and ad libitum energy intake compared with consuming 500 mL of water at 37 °C and 60 °C. The subjective appetite perception of hunger in their study tended to be lower after consuming 500 mL of water at 2 °C than at 60 °C. They reported that reduced energy intake after consuming cold water (ie, at 2 °C) is accompanied by a change in gastric contractions. These findings suggest that water temperature may modulate gastric motility to influence energy intake. Indeed, the results of well-conducted experiments confirm that liquid and solid meals at 60 °C accelerated gastric emptying compared with those at 37 °C during the initial 30 minutes [66,70]. However, their findings can be simultaneously criticized, as they have not considered the potential biochemical effect of higher dietary temperatures on cell biology and body thermodynamics. For the first time, we argue that dietary temperature may directly influence energy balance through the induction of HSP-27, HSP-65, HSP-70, HSP-72, and HSP-90 expression.

Conclusions

Our hypothetical proposal potentially adds new knowledge to the existing literature that food temperature may directly contribute to energy balance and thereby influence weight management. Our proposal has profound and widespread implications. For instance, if dietary temperatures prove to affect energy balance, future clinical trials involving metabolic studies have to take dietary temperature into account. In addition, the results of many published metabolic clinical trials may need to be revisited. The results of this proposal will have deep implications for dietary recommendations, such as the recommended daily energy intake for different age groups and diet planning in different health and disease states. Efficacy studies of nutritional interventions will also need to consider this point. Furthermore, some cultures are accustomed to consuming hot meals and drinks. Comparative studies, particularly those dealing with weight or metabolism, may need to account for biases created by different dietary temperatures. Our hypothesis may also explain the discrepancies in different studies (that did not control for dietary temperature), despite similar methodologies.

The proposed trial does carry limitations. There is no specific dynamic model for real-time monitoring or measuring of temperature changes of digested meals or drinks along the alimentary tract; therefore, we will have to estimate the inner food and drink temperature using the inverse heat conduction problem methodology, which may influence the precision of the results.

Authors' Contributions

RR conceived the study and wrote the initial draft of the manuscript. KDF contributed to the revision of the paper and critically appraised the paper.

Abstract

Background: Mild cognitive impairment (MCI) and Alzheimer's disease (AD) might be more frequent in patients with inflammatory bowel disease (IBD), but the relationship between these 2 entities is yet to be entirely established. Certain blood biomarkers (eg, serum amyloid A [SAA] and serum homocysteine [Hcy], which increase in IBD and MCI; brain-derived neurotrophic factor [BDNF], which decreases in MCI and AD but is not clearly modified in IBD; and S100 calcium-binding protein B [S100B], which increases in the blood-brain barrier and neuronal lesions) might predict the stage of MCI or dementia or progression to a further state. The gut–brain axis (GBA) might be the key to the development of MCI in patients with IBD, along with systemic inflammation and the possible and unknown adverse effects of disease-modifying medication.

Objective: The aim of this study is to investigate whether GBA interactions play a role in MCI development in patients with IBD.

Methods: A case-control study will be conducted on at least 100 patients diagnosed with IBD, matched with 100 healthy individual controls. The matching will include sex, age, and education. Patients will be fully examined, and a full interview and a neurological and cognitive examination will be performed. The primary clinical outcomes will be cognitive test scores (Montreal Cognitive Assessment, Trail Making Test, Digit Symbol Substitution Test, forward and backward digit span testing). Depression, stress, and anxiety screening will also be performed. Blood samples from all participants will be collected, and aliquots will be immediately stored in a biobank. Primary laboratory outcomes will include serum levels of presumed cognitive dysfunction blood biomarkers SAA, Hcy, S100B, and BDNF. Follow-up will be performed at 12, 24, 36, and 48 months.

Results: Data collection started in December 2021 and is ongoing. So far, 53 patients with IBD have been recruited and 50 HC matched. Data collection should end in January 2030. Intermediary analysis will be performed in April 2024. We expect patients with IBD to have lower scores on cognitive testing and a positive correlation between disease length and cognitive impairment level. In addition, the levels of stress, anxiety, and depression should be higher in the IBD group. The serum levels of the 4 biomarkers could correlate or anticorrelate with cognitive scores and serve as predictive factors for MCI or dementia development. A higher level of education, a younger age, the absence of malabsorption, and good disease control might serve as protectors against MCI.

Conclusions: GBA interactions, along with systemic inflammation and the adverse effects of medication, might be a cause of MCI and AD development in patients with IBD. Serum biomarkers could prove cheap and useful predictors of MCI development.

Introduction

Background

Inflammatory bowel disease (IBD) is a group of chronic conditions characterized by intestinal inflammation. The 2 most common types of IBD are Crohn's disease (CD) and ulcerative colitis (UC) [1,2]. The exact mechanisms underlying the development of IBD are yet to be fully understood, but they are thought to be the result of a combination of genetic, environmental, and immunological factors. IBD is believed to be caused by an abnormal immune response that first appears in the gut, where the body's immune system mistakenly attacks the antigens of the healthy gut bacteria, leading to intestinal inflammation and damage to the intestinal barrier. Exposure to certain environmental triggers, such as a diet high in animal fats, smoking, and, most of all, bacterial or viral infections, may increase the risk of IBD. It is believed that the interplay between these factors leads to a self-perpetuating cycle of inflammation and tissue damage, which contributes to the chronic nature of IBD (a so-called vicious cycle). Systemic inflammation plays a role in IBD pathogenesis, which is proven by the beneficial effect of certain anti-inflammatory medications [3].

Clinical manifestations include common digestive symptoms, such as abdominal pain and cramping, diarrhea (which might be bloody), rectal bleeding, weight loss, fatigue, loss of appetite, anemia, nausea and vomiting, dehydration, and fever. In addition to these digestive symptoms, patients with IBD may also experience extraintestinal manifestations, such as joint pain, skin rashes, eye inflammation, and liver disease. The severity and frequency of symptoms can vary greatly between individuals and can also change over time in the same individual. CD carries a higher risk of extraintestinal manifestations, often believed to be caused by one of its pathogenic mechanisms or malabsorption [1,2].

Mild cognitive impairment (MCI) refers to a decline in cognitive abilities that is greater than that in normal aging but certainly not severe enough to interfere with daily life. MCI is often considered a transitional stage between normal aging and more severe forms of cognitive decline, such as dementia. MCI is most commonly characterized by memory problems, such as difficulty in recalling names and recent events, but it can also involve problems with other cognitive abilities, such as language, decision-making, and attention. The impairment of daily activities is a key criterion to diagnosing dementia and the difference between MCI and dementia [4]. Some of the known risk factors for MCI include age, family history, certain medical conditions, lifestyle factors (eg, smoking and excessive alcohol consumption), and certain medications [4]. There are some modern theories that imply inflammation as a mechanism underlying cognitive impairment [5-8]. A diagnosis is typically made based on a thorough medical and neurological evaluation, as well as a comprehensive assessment of the individual's cognitive abilities. This may involve a battery of tests, such as memory and language tests, as well as brain imaging studies. The most important thing to do when a cognitive impairment is suspected is follow-up over time, as early intervention might stop the progression of the disease [4]. MCI can sometimes progress to Alzheimer's disease (AD) or other types of dementia, depending on the cause, age, and other factors [9]. AD is a progressive brain disorder that affects memory, thinking, and behavior. It is the most common cause of dementia. The symptoms of AD usually start with mild memory loss but eventually progress to affect thinking, communication, and the ability to perform daily activities. As the disease progresses, patients may become increasingly dependent on others for their care [10]. Some studies have revealed a link between IBD and the development of AD [6,7,11,12]. Vascular dementia is a type of dementia that occurs due to problems in the blood supply to the brain. It is caused by damage to the blood vessels that deliver oxygen and nutrients to the brain, leading to brain injury and reduced brain function. It is often caused by conditions such as stroke, high blood pressure, and heart disease. Risk factors for vascular dementia include age, smoking, diabetes, and a family history of stroke or heart disease [13].

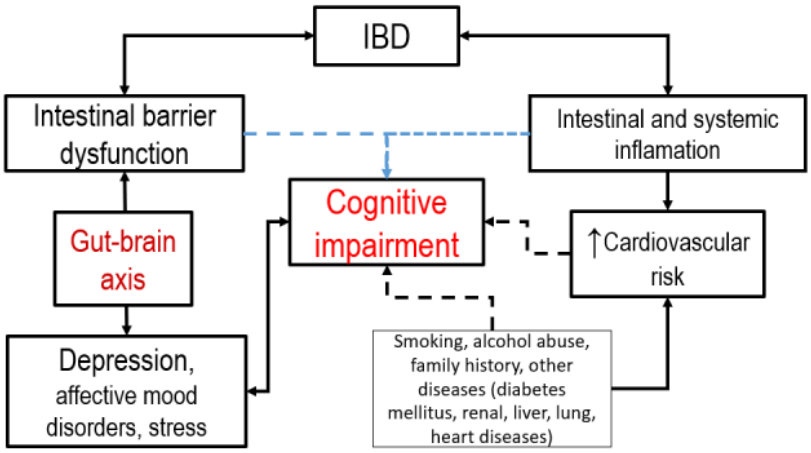
"Stress disorder" is a term used to describe a mental health condition that can develop in response to a traumatic or stressful event. Individuals may experience a range of symptoms, including intrusive thoughts or memories of the traumatic event; nightmares; and avoidance of people, places, or activities that are associated with the trauma. They may also experience physical symptoms, such as a racing heart, sweating, and muscle tension [14]. "Anxiety disorder" is a general term that refers to a group of mental health conditions characterized by excessive and persistent feelings of worry, fear, and unease [15]. Depression is a mental health condition characterized by persistent feelings of sadness, hopelessness, and a loss of interest in activities that were once enjoyable. It is a common and serious condition that can have a significant impact on an individual's daily life and overall well-being. In addition to feelings of sadness, depression can also cause a range of physical and emotional symptoms, including fatigue, changes in appetite and sleep patterns, difficulty in concentrating, and thoughts of self-harm or suicide. The exact cause of depression is not fully understood, but it is believed to be related to a combination of

XSL•FO
RenderX

genetic, biological, environmental, and psychological factors [16-18].

Homocysteine (Hcy) is an amino acid. Studies have shown that individuals with IBD have higher serum concentrations of Hcy compared to healthy controls (HC). The exact reason for this association is not fully understood, but it may be related to nutrient deficiencies caused by the inflammation and malabsorption in the gut that often occur in IBD. There is evidence to suggest that elevated levels of Hcy in the blood are associated with an increased risk of MCI and dementia. High Hcy levels have been linked to damage of the blood vessels in the brain, leading to decreased blood flow and oxidative stress, both of which can contribute to cognitive decline [19-23].

Serum amyloid A (SAA) is an acute-phase protein that is produced by the liver in response to inflammation. Amyloid proteins are abnormal fibrous proteins that can build up in tissues and organs, leading to the formation of amyloid plaques. In some cases, amyloid proteins can also enter the bloodstream and circulate in the body. Elevated levels of SAA can be an indicator of various diseases, such as AD, systemic amyloidosis, and hereditary transthyretin amyloidosis. Studies have shown that SAA can induce neuroinflammation and damage neurons in the brain, which may contribute to the development and progression of AD. In addition, SAA has been found to accumulate in the brain in the form of amyloid plaques, which are a hallmark feature of AD. There is limited research on the relationship between SAA levels and IBD. Some studies have suggested that individuals with IBD may have elevated levels of amyloid proteins in their bloodstream, possibly as a result of chronic inflammation in the gut [24-29].



Brain-derived neurotrophic factor (BDNF) is a type of protein that is important for the growth, maintenance, and survival of neurons in the central nervous system. BDNF plays a key role in processes such as neuroplasticity, learning, and memory formation. Low levels of BDNF have been associated with several neurological and psychiatric disorders, including depression and AD. BDNF plays a role in the inflammation associated with IBD. BDNF levels are modified in IBD, but there is little evidence of the direction [30-33].

S100 calcium-binding protein B (S100B) is a protein that is found in a variety of tissues, including the brain, where it has been implicated in several neurobiological processes, including synaptic plasticity, neurogenesis, and neuroinflammation. High serum S100B levels have been associated with a variety of neurological disorders, including traumatic brain injury, stroke, and neurodegenerative diseases. Studies have shown that S100B levels are elevated in the blood and intestinal tissue of patients with IBD, suggesting that the protein may play a role in the development and progression of the disease. In addition, high levels of S100B have been associated with increased inflammation and oxidative stress [34].

In conclusion, IBD is a combination of intestinal barrier dysfunction and intestinal and systemic inflammation. Due to intestinal barrier dysfunction, the intestinal microbiome is affected in the course of the disease or it is the cause of the disease (IBD). Several studies have shown the relationship between the gut–brain axis (GBA) and the development of depression, affective mood disorders, and stress, which might promote the development of cognitive impairment. Systemic inflammation is known to increase cardiovascular risk, which is a risk factor for cognitive impairment. Other risk factors, such as smoking, alcohol consumption, and other diseases, also promote the development of cognitive impairment. Some studies have suggested a link between IBD and cognitive disorders, while other studies have indicated a link between mood disorders and IBD, and still others have suggested a link between mood disorders and cognitive disorders. Therefore, this might be a vicious cycle.

In this study, blood biomarkers, such as SAA (an inflammatory biomarker, a precursor of beta-amyloid plaques in the brain), Hcy (a pro-inflammatory molecule increased in cognitive disorders), S100B (a neuronal structural protein increased in brain injury), and BDNF (decreased in cognitive disorders) were selected in order to validate the hypothesis that these biomarkers could be used as predictive factors for cognitive impairment associated with IBD. As a summary of the basic knowledge that led to the idea of this study, Figure 1 shows the possible implied mechanisms underlying the development of MCI in patients with chronic IBD.

Figure 1. Possible mechanisms underlying the development of cognitive impairment associated with IBD. IBD: inflammatory bowel disease.

XSL•FO
RenderX

Aim

The aim of this study is to investigate whether GBA interactions play a role in the development of MCI in patients diagnosed with IBD, mainly due to pathological changes at the intestinal level (destruction of the intestinal barrier and pathogenic species in the intestinal microbiome). Presumed cognitive dysfunction blood biomarkers (SAA, Hcy, S100B, BDNF) will be used as predictive factors for the development of MCI or dementia in the study groups. The primary and secondary objectives of the study can be reviewed in Table 1.

Table 1. Primary and secondary objectives.

Objective type	Description
Primary	• To describe the occurrence of MCI[a] in patients with MCI compared to HC[b] • To determine cognitive tests scores for the IBD[c] group compared to HC • To determine serum levels of SAA[d], Hcy[e], BDNF[f], and S100B[g] protein and their association with cognitive testing scores compared to HC • To determine whether there is any correlation between IBD duration, type, blood biomarkers and cognitive scores
Secondary	• To describe the progression of MCI during the follow-up period in both groups • To assess the occurrence of stress and anxiety disorders in the IBD group compared to HC • To assess the occurrence of depression in the IBD group compared to HC • To identify novel biological markers that can predict the stage of MCI or its progression in both groups • To quantify the quality of life of both groups • To identify risk factors for the development of MCI in both groups • To identify the comorbidities of participants in both groups • To quantify the clinical activity scores of the IBD group during patient interviews

[a]MCI: mild cognitive impairment.

[b]HC: healthy controls.

[c]IBD: inflammatory bowel disease.

[d]SAA: serum amyloid A.

[e]Hcy: homocysteine.

[f]BDNF: brain-derived neurotrophic factor.

[g]S100B: S100 calcium-binding protein B.

Methods

Study Design

The study will be a single-center, prospective, observational, analytic study with a group of at least 100 patients with a diagnosis of certainty of IBD and a group of at least 100 HC. The study is part of a PhD thesis, and funding was obtained from the parent university.

Sites, Population, and Case and Control Definitions

The study will take place in Cluj-Napoca, Romania, in the Clinical CF Hospital and the Regional Institute for Gastroenterology and Hepatology “Octavian Fodor.” An agreement was obtained from all the participant clinics.

Two separate groups consisting of at least 100 patients with IBD and at least 100 HC will be recruited. The study will be carried out from May 2021 to January 2030. The HC will be matched with the patients with IBD based on age, sex, and education.

Patients included in the case (IBD) group need to have a clear diagnosis of IBD. For this, a histopathological examination proof will be obtained from the databases of the participant centers or from the personal records of the patients (if the site does not have the original proof diagnosis).

The HC will be recruited from the day care hospital and ambulatory. Their diagnosis must have never been IBD, and they should be in good health at the moment of inclusion.

The inclusion criteria are listed in Table 2 and the exclusion criteria in Table 3.

XSL•FO
RenderX

Table 2. Inclusion criteria.

Study group	Inclusion criteria
IBD[a]	• Males and females aged over 18 years • Patients with a confirmed IBD diagnosis • Written informed consent obtained
HC[b]	• Males and females aged over 18 years • Good level of health • Written informed consent obtained

[a]IBD: inflammatory bowel disease.

[b]HC: healthy controls.

XSL•FO
RenderX

Table 3. Exclusion criteria.

Exclusion criteria	Details
Absolute exclusion criteria	
Prior stroke or myocardial infarction or cardiac arrest	Patients with known stroke and myocardial infarction are already known to have an accelerated cognitive decline rate due to a vascular mechanism. Postanoxic encephalitis after cardiac arrest carries an additional risk of cognitive decline.
Severe organ failure	This includes the presence of end-stage respiratory, liver, renal, and cardiac diseases.
Familial AD[a]	Patients with known familial AD develop the disease at an earlier age.
Concomitant past and current neurological disorders	These include epilepsy, encephalopathy due to any cause, history of severe head trauma, history of encephalitis, multiple sclerosis, Parkinson's disease, brain tumor, and dementia due to any cause.
Pregnancy	Pregnant women will not be included because they carry potentially other risks and might be stressed about their situation.
Prior psychiatric disorders and chronic use of neuroleptics and anticholinergic medication	These include all psychiatric pathologies, including depression, anxiety disorder, attention deficit hyperactivity disorder, autism spectrum disorders, posttraumatic stress disorder, schizophrenia, personality disorders, and alcohol and drug abuse. Also in this category is the use of neuroleptics, which are drugs that decrease cerebral function, although they might interfere with cognitive testing, depending on dose. Anticholinergic medication might slow cognitive functioning.
Unclear diagnosis	Patients with an unclear diagnosis will not be recruited as they might have a different pathology.
Involvement in clinical trials	Participation in clinical trials for medication might interfere with the study results because of the unknown side effects of the medication or other factors.
Current and past history of neoplasia	Patients with neoplasms already have a poor performance status, and this might negatively influence the results of this study. in addition, the medication might interfere with cognitive testing.
Use of vitamin B12 and B9 supplements	Vitamin B12 and B9 supplements might decrease serum levels of Hcy[b].
Short bowel syndrome	Intestinal resection carries the risk of malabsorption and might be a cause of cognitive impairment.
Diabetes mellitus	Diabetes mellitus carries an additional risk of MCI[c].
Hypothyroidism	Hypothyroidism leads to decreased brain performance.
Prior diagnosis of atrial fibrillation	Patients with known atrial fibrillation are at greater risk of cognitive dysfunction due to microembolic events.
Uncontrolled arterial hypertension	Patients with uncontrolled hypertension carry an additional risk of cognitive dysfunction.
Relative exclusion criteria	
Acute IBD[d] flares	Acute flares involve a burden of stress and anxiety, which might lead to false-positive results in cognitive testing. Patients will be informed of the possibility of inclusion, and if they agree, testing will be performed after the acute flare is over.
Age over 70 years	Patients aged over 70 years might have age-related cognitive impairment, which might interfere with the study results.

[a]AD: Alzheimer's disease.

[b]Hcy: homocysteine.

[c]MCI: mild cognitive impairment.

[d]IBD: inflammatory bowel disease.

Study Timeline

Patients will be recruited based on the inclusion and exclusion criteria. The recruitment moment will be called "baseline." Follow-up will be performed at 12, 24, and 36 months. A systematization of the procedures is presented in Table 4.

Procedures and Examinations

Clinical procedures and examinations will be performed in a silent room so there is no disturbance to both examiner and participant. Participants will receive information about each test that will be conducted. The scales and questionnaires used in the study are listed in Table 5.

XSL•FO
RenderX

Table 5. Scales used in the study.

Objective	Scales
Assessment of IBD[a] severity	HBI[b] for patients with CD[c] and SCCAI[d] for patients with UC[e]
Assessment of quality of life	Romanian WHOQOL-BREF[f] questionnaire
Assessment of depression, anxiety, and stress	Romanian DASS[g]-21
Cognitive assessment	Romanian MOCA[h] 7.1, TMT[i]-A and TMT-B, backward digit testing, forward digit testing, DSST[j]
Assessment of COVID-19	Short COVID-19 questionnaire
Assessment of ADL[k]	IADL[l] scale, Katz ADL scale

[a]IBD: inflammatory bowel disease.
[b]HBI: Harvey-Bradshaw Index.
[c]CD: Crohn's disease.
[d]SCCAI: Simple Clinical Colitis Activity Index.
[e]UC: ulcerative colitis.
[f]WHOQOL-BREF: World Health Organization Quality of Life Brief Version.
[g]DASS: Depression-Anxiety-Stress Scale.
[h]MOCA: Montreal Cognitive Assessment.
[i]TMT: Trail Making Test.
[j]DSST: Digit Symbol Substitution Test.
[k]ADL: activities of daily living.
[l]IADL: Instrumental Activities of Daily Living.

The Montreal Cognitive Assessment (MOCA) 7.1 scale includes the Trail Making Test (TMT), drawing, long-term memory testing, verbal fluency tests, short-term memory recall testing, calculus, and spatial and temporal orientation questions. The maximum score obtained is 30 points. The normal range is ≥26 points. An additional point is given to patients who have an education level of ≤12 years.

The memory impairment score (MIS) is derived from the MOCA scale. The maximum score is 15 points. It derives from the short-term memory recall test. Subjects have to recall 5 words to gain points. If they recall the words spontaneously, 3 points are awarded for each word. If any clue is provided, 2 points are awarded if the word is recalled. If variants are provided, 1 point is awarded if the word is recalled. No point is awarded if the word is not recalled.

The TMT involves the subject drawing a trail between 2 points, with the entire operation being timed. It has 2 different parts, TMT-A and TMT-B. TMT-A involves drawing a continuous line between numbers. TMT-B involves drawing a continuous line, alternating letters and numbers. An example of the test is provided before each part. TMT-A has a maximum time of 100 seconds, and 101 seconds means the subject has failed the test. TMT-B has a maximum time of 300 seconds, and 301 seconds means the subject has failed the test.

The Digit Symbol Substitution Test (DSST) involves the subject changing some numbers to symbols as specified in the legend of the test. A training zone is first created. If the training is completed, the subject is given 90 seconds to complete as many substitutions as possible. Correct and incorrect answers are counted.

In forward digit span testing (FDST) and backward digit span testing (BDST), the subject must recall the numbers provided by the examiner in forward order and then in backward order. FDST involves strings of numbers ranging from 2 to 8 numbers, and BDST involves strings of numbers ranging from 2 numbers to 7 numbers. Each string has 2 different variants, and the subject must make a maximum of 1 mistake in these variants, otherwise the test ends.

The Depression-Anxiety-Stress Scale (DASS) is a scale that includes 21 questions split into 3 categories (depression, stress, and anxiety), with 7 questions per category, the questions being interleaved. Each question has a score from 0 to 3, and the result is multiplied by 2.

The Harvey-Bradshaw Index (HBI) and the Simple Clinical Colitis Activity Index (SCCAI) are used for screening the subject. In this study, they are part of the inclusion criteria.

The quality-of-life instruments available in Romania are limited; therefore, the World Health Organization Quality of Life Brief Version (WHOQOL-BREF) will be used in order to determine the quality of life of our participants. The Instrumental Activities of Daily Living (IADL) is an 8-item scale that includes some instrumental daily activities, and it is a useful and essential tool for differentiating MCI from dementia. The Katzl ADL scale is a 6-item scale that includes casual daily activities and is also a useful and essential tool for differentiating MCI from dementia.

A blood sample will be obtained from each participant.

XSL•FO
RenderX

Outcomes

The first to be mentioned are demographic variables, which will be useful for stratifying our participants; the expected answers are presented in Table 6.

Table 6. Demographic variables.

Demographic characteristics	Expected answers
Education level	Absolute number of years
Current living environment	Rural, urban <10,000 inhabitants, urban 10,000-49,999 inhabitants, urban 50,000-99,999 inhabitants, urban >100,000 inhabitants
Marital status	Married, single, cohabitation, divorced, polygamy, widowed
Employment	Employed full-time, employed part-time, freelancer, retired, student, trainee
Toxic working environment	Yes, no, do not know
Night shifts	Yes, no
Financial status	Enough for a living and saving, enough for a living but not saving, not enough for a living
Monthly wage (average per family member)	<1500 lei (<USD 316.31), 1500-2500 lei (USD 316.31-527.18), 2500-3500 lei (USD 527.18-738.05), 3500-4500 lei (USD 738.05-948.93), >4500 lei (>USD 948.93)

The relationship status is important for affective mood but also for cognitive functioning; therefore, 3 questions will be answered by the participants, listed in Table 7.

Table 7. Current and past relationship data.

Question	Expected responses
Married before diagnosis of IBD[a]	Yes, no, not available
Relationship destabilization due to the disease	Yes, and it caused a broken relationship or divorce; yes, but it did not cause a broken relationship or divorce; no
Helped with the disease by the life partner	Yes, no, not available

[a]IBD: inflammatory bowel disease.

A short cognitive assessment will be performed in order to accommodate the participants in the subsequent questionnaires and tests. Questions are mentioned in Table 8.

Table 8. Short cognitive (long-term memory) and affective assessment.

Question	Expected responses
Trouble with memory in the past month	Yes, occasionally, no
Changes in personality	Yes, no
Difficulties in handling daily activities due to memory changes	Yes, no
Family history of dementia	Yes, AD[a]; yes, other dementia; no; do not know
Current president of Romania	Correct or incorrect answer
The year of the Great Union in Romania	Correct or incorrect answer
Naming a pencil	Correct or incorrect answer
Naming a medical coat	Correct or incorrect answer
Naming a clock	Correct or incorrect answer

[a]AD: Alzheimer's disease.

A short clinical examination will be performed. A full history of IBD will be taken. Variables obtained are mentioned in Table 9. The HBI and SCCAI will be the clinical disease activity scales used in the study, as mentioned in Table 10. Risk factor assessment will also be performed (Table 11).

XSL•FO
RenderX

Table 9. Physical examination and past medical history.

Variables	Expected responses
Physical examination	
Blood pressure	Value (mmHg)
Pulse	Absolute number (beats/minute)
Respiratory rate	Absolute number (respirations/minute)
Peripheric oxygenation percentage	Value (%)
Medication assessment	All concomitant medications used (international common names and dosing and posology)
IBD[a] history assessment	
Year of diagnosis	Absolute number
Montreal classification	A-L-B[b] for CD[c] patients, E-S[d] for UC[e] patients
Family history of IBD	Yes, no, do not know
Number of flares in the past 12 months	Absolute number
Number of flares since diagnosis	Absolute number
Number of hospitalizations for flares in the past 12 months	Absolute number
History of corticosteroid dependency	Yes, no
Duration of corticosteroid dependency (if the above answer is yes)	Absolute number (months)
Current medication	Name, dose, duration
Past medication	Name, dose, duration
Complications	Enumeration

[a]IBD: inflammatory bowel disease.

[b]A-L-B: onset (A), disease location (L), and disease behavior (B).

[c]CD: Crohn's disease.

[d]E-S: extent (E) and severity (S).

[e]UC: ulcerative colitis.

XSL•FO
RenderX

Table 10. Clinical disease activity score assessment.

Scales and items	Scoring (points in parentheses)
HBI[a] (0-4 points=remission; 5-7 points=mild disease; 8-16 points=moderate disease; >16 points=severe disease)	
General health	Very well (0), slightly below par (1), poor (2), very poor (3), terrible (4)
Abdominal pain	None (0), mild (1), moderate (2), severe (2)
Liquid or soft stools on the previous day	Absolute number (1 point for each)
Abdominal mass	None (0), dubious (1), definite (2), definite tender (3)
Complications	Arthralgia (1), uveitis (1), erythema nodosum (1), aphthous ulcer (1), pyoderma gangrenosum (1), anal fissure (1), new fistula (1), abscess (1)
SCCAI[b] (0-20 points; ≥5=active disease)	
Bowel frequency	0-3 stools (0), 4-6 stools (1), 7-9 (stools 2), >9 stools (3)
Bowel frequency (night)	0 stools (0), 1-3 stools (1), 4-6 stools (2)
Urgency defecation	No urgency (0), hurry (1), immediately (2), incontinence (3)
Blood in stool	No blood (0p, traces (1), occasionally frank (2), usually frank (3)
General health	Very well (0), slightly below par (1), poor (2), very poor (3), terrible (4)
Extracolonic manifestations	No feature (0), 1 feature (1), 2 features (2), 3 features (3), 4 features (4), 5 features (5)

[a]HBI: Harvey-Bradshaw Index.

[b]SCCAI: Simple Clinical Colitis Activity Index.

Table 11. Risk factor questionnaire.

Detailed risk factor questionnaire	Expected responses
Active smoker status	Yes, no, ex-smoker
Number of smoking years	Absolute number
Number of abstinence years	Absolute number
Daily number of cigarettes	Absolute number
Alcohol drinking rate	Daily, 3-5 times per week, 1-2 times per week, rarer, no drinking, other options (to be mentioned)
30 minutes of physical activity	Daily, 5 times per week, rarer, no physical activity, other frequency (to be mentioned)
Dietary trend	Nonspecific diet, vegetarian, vegan, flexitarian, colitis regimen, other (to be mentioned)
Number of sleeping hours per day (24 hours)	Absolute number
Daytime tiredness	Yes, no
Troubles with maintaining sleep	Yes, no
Troubles with falling asleep	Yes, no

A cognitive assessment must always be preceded by a screening of depression, anxiety, and stress because this may falsely create a diagnosis of cognitive dysfunction. Scales and their interpretations can be seen in Table 12.

XSL•FO
RenderX

Table 12. Depression, anxiety, and stress screening; COVID-19 impact; current quality of life; and ADL[a] assessment.

Scales and items	Expected responses
DASS[b]-21 scale (7 items each for depression, anxiety, and stress)	Depression (0-9, 10-13, 14-20, 21-27, ≥28 points), anxiety (0-7, 8-9, 10-14, 15-19, ≥20 points), stress (0-14, 15-18, 19-25, 26-33, ≥34 points)
COVID-19 impact questionnaire	
Vaccination status	Yes, no
COVID-19 vaccine (if the above answer is yes)	BNT162b2, NJ-78436735 (Ad26.COV2.S), AZD1222 (ChAdOx1), mRNA[c]-1273, other (mentioned in the questionnaire)
Number of doses	Absolute number
History of infection	Yes, no, do not know
WHOQOL-BREF[d]	Social relationships (4-20 points), environment (4-20 points), physical health (4-20 points), psychological (4-20 points)
ADL	
Katz ADL	0-6 points
IADL[e]	0-8 points

[a]ADL: activities of daily living.

[b]DASS: Depression Anxiety Stress Scale.

[c]mRNA: messenger ribonucleic acid.

[d]WHOQOL-BREF: World Health Organization Quality of Life Brief Version.

[e]IADL: Instrumental Activities of Daily Living

Cognitive assessment will include the baseline scales and follow-up at 12 months. The scoring is shown in Table 13.

XSL•FO

Table 13. Cognitive assessment scoring.

Timeline and scales	Scoring
Baseline	
MOCA[a]	0-30 points: executive function (0-5 points), naming (0-3 points), memory (0-5 points), attention (0-6 points), calculus (0-3 points), language (0-3 points), orientation (0-6 points), abstractization (0-2 points)
MIS[b]	0-15 points
BDST[c]	0-14 points
FDST[d]	0-16 points
TMT[e]-A	0-100 seconds (101 seconds means failed test)
TMT-B	0-300 seconds (301 seconds means failed test)
DSST[f]	Absolute number of correct answers (maximum 90 correct answers), absolute number of incorrect answers (maximum 90 incorrect answers)
12-month follow-up	
MOCA	0-30 points: executive function (0-5 points), naming (0-3 points), memory (0-5 points), attention (0-6 points), calculus (0-3 points), language (0-3 points), orientation (0-6 points), abstractization (0-2 points)
MIS	0-15 points
24-month follow-up	
MOCA	0-30 points: executive function (0-5 points), naming (0-3 points), memory (0-5 points), attention (0-6 points), calculus (0-3 points), language (0-3 points), orientation (0-6 points), abstractization (0-2 points)
MIS	0-15 points
36-month follow-up	
MOCA	0-30 points: executive function (0-5 points), naming (0-3 points), memory (0-5 points), attention (0-6 points), calculus (0-3 points), language (0-3 points), orientation (0-6 points), abstractization (0-2 points)
MIS	0-15 points
48-month follow-up	
MOCA	0-30 points: executive function (0-5 points), naming (0-3 points), memory (0-5 points), attention (0-6 points), calculus (0-3 points), language (0-3 points), orientation (0-6 points), abstractization (0-2 points)
MIS	0-15 points
BDST	0-14 points
FDST	0-16 points
TMT-A	0-100 seconds (101 seconds means failed test)
TMT-B	0-300 seconds (301 seconds means failed test)
DSST	Absolute number of correct answers (maximum 90 correct answers), absolute number of incorrect answers (maximum 90 incorrect answers)

[a]MOCA: Montreal Cognitive Assessment.

[b]MIS: memory impairment score.

[c]BDST: backward digit span testing.

[d]FDST: forward digit span testing.

[e]TMT: Trail Making Test.

[f]DSST: Digit Symbol Substitution Test.

Laboratory Procedures and Outcomes

We will obtain the serum from 5 mL of the blood sample of each participant and quantitatively measure serum SAA, Hcy, S100B, BDNF levels. The blood samples will be obtained at baseline. Other blood measurements will be performed at the hospital's laboratory as part of the visit, and values will be taken from the registry. All the necessary data that will be obtained from blood testing are mentioned in Table 14.

XSL•FO
RenderX

Table 14. Blood sample outcomes.

Markers	Measurement unit
Presumed cognitive biomarkers (serum levels)	
SAA[a]	mcg/mL
Hcy[b]	µmol/L
BDNF[c]	ng/mL
S100B[d]	mcg/mL
Common biomarkers (taken from the hospital registry from the baseline presentation period)	
C-reactive protein	mg/dL
Total hemoglobin	g/dL
Red blood cell count	number/mm^3
Fecal calprotectin	µg/mg
Triglycerides	mg/dL
Total cholesterol	mg/dL
Low-density lipoprotein (LDL) cholesterol	mg/dL
High-density lipoprotein (HDL) cholesterol	mg/dL
LDL/HDL ratio	fraction
Neutrophile-to-lymphocyte (NLR) ratio	fraction
Erythrocyte sedimentation rate	mm/hour
Mean corpuscular volume (MCV)	%
Basal blood glucose	mg/dL
Fibrinogen	mg/dL
Lactate dehydrogenase (LDH)	IU/L
Creatine kinase (CK)	U/L
CK-MB	% out of total CK

[a]SAA: serum amyloid A.

[b]Hcy: homocysteine.

[c]BDNF: brain-derived neurotrophic factor.

[d]S100B: S100 calcium-binding protein B.

Preparation of Serum Samples

The required materials are a serum collection vaccutainer, a fixed-angle centrifuge for 15 mL tubes, 1.5 mL protein low-binding tubes, 100-1000 µL tips, and a cryogenic box.

For serum preparation, after the blood is collected, the tube will be inverted gently, as indicated in the manufacturer's instructions (in general 5-6 times). The tube will be then left, as indicated in the manufacturer's instructions (in general 30 minutes), at room temperature to form a blood clot. Next, the tube will be centrifuged at 2000× *g* for 10 minutes at 4 °C, as indicated in the manufacturer's instructions, and 500 µL of serum will be aliquoted in 1.5 mL protein low binding tubes. The serum aliquots will be immediately frozen at –80 °C until use. No more than 2 freeze-thaw cycles will be allowed. The tube with the blood clot will be discarded in a biohazard waste container.

Absolute Quantification of Biomarkers

SAA, Hcy, S100B, and BDNF are biomarkers that will be quantified from the serum samples using standardized solid-phase sandwich enzyme-linked immunosorbent assay (ELISA) kits. Table 15 presents the kits that will be used and their related characteristics.

XSL•FO
RenderX

Table 15. ELISA[a] kits to be used for biomarker quantification.

Biomarker	ELISA kit	Serum volume required (µL)	Kit performance	Assay duration (hours)
SAA[b]	Abclonal catalog # RK04228 or similar	100	Range:0.156-10 ng/mL Sensitivity: <0.071 ng/mL Specificity: 50 ng/mL Intra-assay precision: CV[c]<10% Interassay precision: CV<12%	5.0
Hcy[d]	Assaygenie catalog # HU-FI04768 or similar	50	Range: 7.813-500 pmol/mL Sensitivity: <4.688 pmol/mL Specificity: 50 ng/mL Intra-assay precision: CV<8% Interassay precision: CV<10%	2.5
S100B[e]	Abclonal catalog # RK02234 or similar	100	Range: 46.9-3000 pg/ml Sensitivity: <23.5 pg/mL Specificity: 50 ng/mL Intra-assay precision: CV<10% Inter-assay precision: CV<15%	5.0
BDNF[f]	Abclonal catalog # RK00074 or similar	100	Range: 23.4-1500 pg/ml Sensitivity: <6.3 pg/mL Specificity: 50 ng/mL Intra-assay precision: CV<10% Interassay precision: CV<15%	5.0

[a]ELISA: enzyme-linked immunosorbent assay.

[b]SAA: serum amyloid A.

[c]CV: coefficient of variation.

[d]Hcy: homocysteine.

[e]S100B: S100 calcium-binding protein B.

[f]BDNF: brain-derived neurotrophic factor.

The required materials for this procedure are the serum aliquots, ice, a fixed-angle centrifuge for 2 mL tubes, 1.5 mL protein low-binding tubes, tips, pipettes, 15 or 50 mL tubes (depending on the ELISA kit instructions), a 96-well plate shaker (if mentioned by the ELISA kit manufacturer), a 96-well plate mixer with heating (if mentioned by the ELISA kit manufacturer), and a multiplate reader.

Serum aliquots will be thawed on ice and then mixed gently. Samples will be centrifuged at 13000× *g* for 2 minutes at 4°C to remove the cell debris. The volume indicated in the kit manufacturer's protocol will be taken. The instructions will be used for sample preparation and analysis. Measurements will be made in duplicate.

Calculation of Results

The optical density (OD) of each well will be read using a microplate reader set to 450 nm. The duplicate readings for each standard, control, and sample will be averaged, and the average 0 standard OD will be subtracted. A standard curve will be created by reducing the data using computer software capable of generating a 4-parameter logistic (4-PL) curve fit. Sample concentrations will be calculated from the equation. If samples have been diluted, the concentration read from the standard curve will be multiplied by the dilution factor.

Power Calculation, Statistical Model, and Data Analysis

Based on previous studies, the power of the study, with an α of .05 and a power of 80%, the required number of cases and controls is 52 and 26, respectively, for a mean difference in 2 points (SD 3.0) in MOCA scales.

Statistics will be computed using IBM SPSS software version 28.0.1 or newer. Descriptive analysis of the baseline characteristics of the overall population by gender, age, and education will be conducted. Continuous variables will be presented as the mean (SD) or the median (IQR), and countable data will be presented as numbers and percentages. Comparisons of groups will be conducted using the t-test or the Wilcoxon rank-sum test based on the type of distribution of data and the homogeneity of the variance. The chi-square test or the Fisher exact probability method will be used for counting data, as appropriate.

Multiple linear and logistical regression analyses will be performed to evaluate the association between outcomes and potential risk factors identified in the questionnaires. Participants lost to follow-up will be treated as right-censored data. The Pearson coefficient will be used to assess the correlation between cognitive scores and serum levels of the studied biomarkers. A

XSL•FO
RenderX

2-sided significance level of .05 will be used for all primary and secondary analyses unless stated otherwise.

Ethical Considerations

The protocol was approved by the Ethics Committees of the Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca (# 52/28.02.2022), the Regional Institute of Gastroenterology and Hepatology "Octavian Fodor" (# 10148/11.10.2022), and the Clinical CF Hospital (# 14/13.07.2022). It was registered with ClinicalTrials (identifier NCT05760729). The study will be conducted in accordance with the ethical principles outlined in the current version of the Declaration of Helsinki of 1975, revised in 2013, and all applicable local regulatory requirements.

All participants will be required to personally sign and date the latest approved version of the informed consent form (ICF) before any study specific procedures are performed. A written version of the participant information and informed consent will be presented to each participant, detailing no less than the exact nature of the study, what it will involve for the participant, the implications and constraints of the protocol, the known side effects and any risks involved in taking part, and the agreement to use the data for primary and secondary data analyses. It will be clearly stated that the participant is free to withdraw from the study at any time for any reason without prejudice to future care, without affecting their legal rights, and with no obligation to provide a reason for withdrawal.

All participants will be allowed as much time as needed to consider the information and an opportunity to question the investigator or other independent parties to decide whether they will participate in the study. Written informed consent will then be obtained by means of a participant-dated signature and a dated signature of the person who presented and obtained the informed consent. A copy of the signed informed consent will be provided to each participant. The original signed form will be retained at the study site.

There will be no participation fee nor any payment to any participant in the study.

Each participant will receive a unique number that will represent their unique ID in the study. Their blood sample will carry the same ID. The database will not include the name of the participants, as they will be deidentified, but their initials and national unique ID will be used to form a code (eg, John Doe with the unique ID 43 will have the code JD_43).

Results

The collection of study data started in December 2021, and it is currently ongoing. Since the start of the study, 53 patients with IBD have been recruited and 50 HC were matched until the moment of this paper being published. The blood samples collected were stored according to the laboratory procedures. Data collection should end in January 2030. Intermediary analysis will be performed in April 2024 after the first 50 patients recruited go through the 12-month follow-up visit. Recruitment will continue until the number of participants in the IBD and HC groups is met (n=100 for each group).

Discussion

Summary

The aim of the study is to evaluate whether there is a correlation between the level of the blood biomarkers studied (SAA, Hcy, S100B, and BDNF) and cognitive scores (MOCA, MIS, FDST, BDST, TMT-A, TMT-B, DSST) in a period of 12-48 months in patients with IBD compared to HC. Previous studies have shown that patients with IBD have lower cognitive scores compared to HC [3,5,8,9,11,12,35]. We expect similar results. Multiple biomarkers have been found modified in patients with MCI but also in patients with IBD; therefore, some reliable biomarkers have been selected for analysis [19-34]. A positive correlation between worse cognitive scores and elevated serum levels is expected to be found.

Perspectives and Clinical Implications

This study might serve as another "brick in the wall" for the question of whether the GBA is involved in the development of MCI. If the results show a correlation between the clinical onset and length of IBD and the risk of MCI development, we could rethink treatment strategies. Serum biomarkers could prove a useful tool for stratifying the risk of MCI development, as their levels can be determined for all patients and the costs are not high.

A possible link between IBD and MCI through the GBA should be further investigated at the molecular level in order to find the underlying pathogenic mechanism. According to the diagnosis criteria of AD, if we find a progression from MCI to AD in patients with IBD, perhaps a clinical study involving the detection of abnormal proteins in the cephalorahidian fluid obtained from a lumbar puncture could be performed in the future. In addition, we could expect some clinical trials involving prevention of the progression from MCI to AD if some more underlying pathogenic mechanisms are found. Furthermore, clinical trials studying the possible prophylactic treatments for the development of MCI must be performed in order to stop this invalidating disease from affecting the population.

Strengths and Limitations

One of the biggest limitations nowadays is the fear of the hospital, a so-called "syndrome" caused by the COVID-19 pandemic. However, this is overcome by the fact that many patients require medical prescriptions monthly or at 2-3-month intervals, so they have to visit the hospital. Language will be a barrier in this study because there are many cognitive tests and questionnaires that have never been validated clinically in Romania, so we have a narrow range to pick from. Neither telephonic nor video testing is available due to language issues. Finance is also a step-back in the development of this study, but it will not limit the results, because it is a prospective and screening study.

Risk of Bias

The risks of bias are negligible because the tests used have clear instructions and interpretations. However, there is a risk that the participants might grow impatient and not correctly complete the questionnaires or might rush them to finish them faster. To

XSL•FO
RenderX

reduce the risk of bias, the participants will be taken to a silent room and enough time will be provided for them to complete the questionnaires and tests in the best-possible correctly. In addition, clinical data will be obtained before laboratory biomarkers are dosed, so we will not know the results—whether they predict the development of MCI.

Risks and Side Effects

The risks associated with this study are the risks of normal blood collection, which is conducted anyway from time to time when patients visit the hospital for their regular blood analysis. In addition, almost all presentations at the hospital require blood sample collection; therefore, the study should not carry an additional risk. Other minor risks could be found in participants with stress or anxiety, and the fact that they will be interviewed for depression, anxiety, stress, and cognitive function might serve as an aggravating factor. Some patients might not take the tests seriously and might score worse on cognitive testing.

Unexpected Findings

The results may be contrary to the aim of the study. To the best of our knowledge, patients with IBD have a good level of education and this might lead to better cognitive functioning. In addition, patients with IBD are younger in age, and because education is better nowadays, cognitive tests could show better cognitive functioning among well-educated participants. Furthermore, maybe some treatments that are used to control IBD serve as protective factors against MCI, or maybe other medications might be a risk factor for the development of MCI.

Plan for Publication and Future Data Collection

The first phase of the protocol will include 50 patients with IBD and 50 HC, who will be evaluated for 12 months, and the results will be published. Furthermore, we will start applying for others grants in order to continue the clinical study. Details of the enrolled participants will be recorded in a database, and further studies will start based on the results of the first phase. Another study based on the COVID-19 questionnaire will be conducted with participants not included in this protocol (this study includes just partial results). Next, a third study on the quality of life and depression, anxiety, and stress screening will also be conducted with participants not included in this protocol. Finally, a fourth study including results from the first phase with participants not included in this protocol will be conducted.

Conclusion

The GBA might be the link between IBD and the development of MCI associated with systemic inflammation. Mood disorders can be a prodrome for the development of cognitive dysfunction. Serum biomarkers might serve as cheap predictive factors for the development of MCI. Therapies might require adjustments in order to prevent neurological complications of IBD.

Acknowledgments

We would like to thank all study participants, all clinicians who answered the call of participating in this study, hospital management, nurses, and all who have indirectly and directly facilitated this study. We would also like to thank the following contributors: Roxana Delia Zaharie, Stanciulescu Raluca, Mircea Vasile Milaciu, Lorena Ciumarnean.

This study was financed by the Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania (grant numbers 881/46/12 January 2022 and 772/37/11 January 2023). A total financing of around 4800 euros (USD 5025.34) was obtained at the moment of study publication.

Data Availability

Study data will be available upon reasonable request from the corresponding author. The data will not be published on a public platform for ethical reasons. The pseudonymization of the participants will be removed from the database if a request for access is received.

Authors' Contributions

OS contributed to the investigation, conceptualization, original draft preparation, funding acquisition, and visualization; VV, methodology, data curation, and resources; AS, funding acquisition, visualization, investigation, and resources; MI, software, resources, project administration, and formal analysis; and AIT, supervision, review and editing, validation, and project administration.

Conflicts of Interest

None declared.

(JMIR Res Protoc 2023;12:e47124) doi:10.2196/47124

In “A Text Messaging–Based Support Intervention to Enhance Pre-exposure Prophylaxis for HIV Prevention Adherence During Pregnancy and Breastfeeding: Protocol for a Randomized Controlled Trial” (JMIR Res Protoc 2023;12:e41170), the authors noted a typographical error in one of the senior author’s name.

In the originally published article, this author’s name was incorrectly spelled as:

Jilian Pintye

This has now been corrected to:

Jillian Pintye

The correction will appear in the online version of the paper on the JMIR Publications website on March 17, 2023, together with the publication of this correction notice. Since we have not made any changes to the main paper, we have not resubmitted the article.

Abstract

Background: Asthma is one of the most prevalent chronic diseases of childhood and disproportionately affects children with lower socioeconomic status. Controller medications such as inhaled corticosteroids significantly reduce asthma exacerbations and improve symptoms. However, a large proportion of children still have poor asthma control, in part owing to suboptimal adherence. Financial barriers contribute to hindering adherence, as do behavioral factors related to low income. For example, unmet social needs for food, lodging, and childcare may create stress and worry in parents, negatively influencing medication adherence. These needs are also cognitively taxing and force families to focus on immediate needs, leading to scarcity and heightening future discounting; thus, there is the tendency to attribute greater value to the present than to the future in making decisions.

XSL•FO
RenderX

Objective: In this project, we will investigate the relationship between unmet social needs, scarcity, and future discounting as well as their predictive power over time on medication adherence in children with asthma.

Methods: This 12-month prospective observational cohort study will recruit 200 families of children aged 2 to 17 years at the Asthma Clinic of the Centre Hospitalier Universitaire Sainte-Justine, a tertiary care pediatric hospital in Montreal, Canada. The primary outcome will be adherence to controller medication, measured using the proportion of prescribed days covered during follow-up. Exploratory outcomes will include health care use. The main independent variables will be unmet social needs, scarcity, and future discounting, measured using validated instruments. These variables will be measured at recruitment as well as at 6- and 12-month follow-ups. Covariates will include sociodemographics, disease and treatment characteristics, and parental stress. Primary analysis will compare adherence to controller medication, measured using the proportion of prescribed days covered, between families with versus those without unmet social needs during the study period using multivariate linear regression.

Results: The research activities of this study began in December 2021. Participant enrollment and data collection began in August 2022 and are expected to continue until September 2024.

Conclusions: This project will allow the documentation of the impact of unmet social needs, scarcity, and future discounting on adherence in children with asthma using robust metrics of adherence and validated measures of scarcity and future discounting. If the relationship between unmet social needs, behavioral factors, and adherence is supported by our findings, this will suggest the potential for novel targets for integrated social care interventions to improve adherence to controller medication and reduce risk across the life course for vulnerable children with asthma.

Introduction

Background

Asthma is one of the most prevalent chronic diseases of childhood, affecting 1 in 10 children and >3 million Canadians [1,2]. Asthma disproportionately affects children with lower socioeconomic status (SES) [3,4], who not only have a higher prevalence of asthma [5,6] but also have heavier symptom burdens, higher rates of emergency department (ED) visits [7-9], and more hospital admissions [2,4]. The higher burden of disease in these children has several overlapping causes including epigenetic changes related to stress during pregnancy [10], higher secondhand smoke exposure [9,11-13], and greater likelihood of living in environments where air quality is poor [8,14] and allergens are present [15]. Poorer housing quality is also associated with worse asthma control [13,16]. Moreover, families from lower SES have higher perceived barriers to care [17] and are more likely to have unmet care needs [18,19].

Controller medications such as inhaled corticosteroids significantly reduce asthma exacerbations while improving lung function and asthma symptom control [20-22]. Nonetheless, a large proportion of children have poor asthma control, in part owing to suboptimal adherence to inhaled corticosteroids, with objective adherence values ranging from 50% to 70% [23-26]. Previous reports [27-29] suggest that children with lower SES have lower adherence to controller medications, leading to worse asthma control and aggravating health inequities.

Adherence can be hindered by financial barriers that limit access to medication [8,19]. In addition, unmet social needs for food, lodging, and childcare may create stress and worry in parents, negatively influencing medication adherence [30]. Precarious employment, food insecurity, and unstable housing situations are also cognitively taxing and force families to focus on immediate needs [31,32].

Scarcity refers to a state in which one's cognitive resources such as attention and executive control are taxed by living with insufficient resources (money and time) [31]. Individuals may experience scarcity if they have high levels of stress at work, a relative who is acutely sick, or if they are in an unstable housing situation [32]. Although scarcity can affect anyone, those living in poverty may be particularly susceptible, given the financial constraints that require them to carefully balance immediate needs and upcoming expenses [31]. In pediatric asthma, the apparent unpredictable course of the disease is taxing for families. Psychological distress is frequently reported in qualitative studies of children with asthma and their parents [33], and caregiver life stress is associated with a heavier burden of asthma symptoms [34]. The relationship between stress and adherence in pediatric asthma has shown mixed results [35-37], suggesting that other variables such as scarcity may mediate the interaction.

In addition, poverty forces families to attend to immediate needs and makes it more challenging to think about, and invest in, the distant future. Future discounting represents the relative value one assigns to the future compared with the present [38,39]. Poverty is associated with higher levels of future discounting [40], which has been hypothesized to mediate the impact of lower SES on health outcomes [31,41,42]. Lower levels of future discounting (attributing a greater relative value to the future) are associated with several positive health behaviors, including influenza vaccination [43,44], physical activity [44,45], and abstinence from smoking [44,46-49]. In pediatrics, higher levels of future discounting correlate with lower

XSL•FO
RenderX

medication adherence in type 1 diabetes [50,51]. In asthma, as in other pediatric chronic diseases, parents are asked to administer medications to their children daily to prevent future exacerbations and negative health outcomes. Levels of future discounting correlate with adherence to controller medication in young adults with asthma [52], but whether the same is true in children is unknown. Future discounting may be especially important to study in pediatrics, as medication adherence is a shared responsibility between parents and children [53-59] that evolves with the child's age and developmental stage [53-60]. Children tend to be more present focused than parents [61], which may explain the decreasing levels of adherence to controller medication as the child or adolescent assumes greater responsibility for managing their asthma treatment [62].

In this project, we aim to investigate the relationship between unmet social needs, medication adherence, scarcity, and future discounting in pediatric asthma.

Scientific Objectives

The overall aims of this project are to determine whether scarcity and future discounting are associated with medication adherence in children with asthma and to explore their role in the relationship between unmet social needs and adherence. Using a prospective observational study, we will investigate three primary relationships:

1. The relationship between scarcity, future discounting, and adherence to asthma controller medication;
2. The association between unmet social needs, scarcity, and future discounting; and
3. The potentially mediating role of scarcity and future discounting on the relationship between unmet social needs and adherence to medication in children with asthma.

Our hypotheses related to each of these three primary relationships are the following:

1. We hypothesize that individuals experiencing scarcity and those with higher rates of future discounting will have lower adherence to asthma controller medication.
2. We hypothesize that unmet social needs will be related to scarcity and future discounting in the following ways:
   a. Parents reporting unmet social needs will be more likely to experience scarcity and have greater levels of future discounting;
   b. The number of unmet social needs will correlate with level of scarcity and future discounting; and
   c. Improvements in a family's unmet social needs during the study period will be associated with decreased scarcity and future discounting rates.
3. We expect that scarcity and future discounting will play a mediating role in the relationship between unmet social needs and adherence to medication, with higher levels of both scarcity and future discounting specifically amplifying the impact of unmet social needs on medication adherence.

We will also examine two exploratory aims:

1. Examine whether adherence to medication mediates the association between unmet social needs and asthma outcomes: asthma control, ED visits, and hospitalizations.
2. Document the progression of unmet social needs as the world moves to the next phase of the COVID-19 pandemic.

This project will help understand the relationship between cognitive factors, medication adherence, and unmet social needs, opening the door to developing targeted interventions to improve adherence to medication and, ultimately, children's health outcomes.

Methods

Study Design and Setting

This 12-month prospective observational cohort study will recruit 200 families at the Asthma Clinic of the Centre Hospitalier Universitaire Sainte-Justine, a tertiary care pediatric hospital in Montreal, Canada. The asthma clinic has a routine standardized collection of patient demographics (age and sex), disease (phenotype, control, and triggers), and treatment (dose, format, and frequency) characteristics. With patients' consent, clinical data can be linked with the *Registre de données sur les Medicaments* (reMed) database [63], which collects all data on medication dispensed by all pharmacies in the province of Québec.

Ethics Approval

The study was reviewed and approved by the Institutional Review Board of the Centre Hospitalier Universitaire Sainte-Justine Research Centre (protocol no: 2022-3888) and has been registered (ClinicalTrials.gov ID: NCT05278000).

Participants

Parents of children aged 2-17 years seen at the clinic with a diagnosis of asthma, made according to Canadian national guidelines [64], will be eligible for the study. This age range will help us explore whether the relationships identified vary by the age group of the child (preschool vs school-age vs adolescents).

The inclusion criteria will include (1) children with documented prescription for a controller medication at recruitment visit including at least one of the following: inhaled corticosteroids, long-acting beta-agonists, or leukotriene receptor antagonists and (2) consent to access the reMed database (see section *Study Design and Setting* above).

Participants will be excluded if (1) their child has another chronic pulmonary disease (eg, cystic fibrosis) and (2) parents have insufficient knowledge of French or English to complete the questionnaires.

Potential participants will be identified by a research assistant through prescreening of clinical patient lists. Specifically, the research assistant will prescreen patient lists for the following month and will confirm patient lists using physicians' daily appointment roster upon arrival at the clinic on each day of recruitment.

Recruitment

We will recruit 200 families, stratified to recruit 40 families geographically from each quintile of the Pampalon material deprivation index [65-67]. Refer to the *Power Calculation and*

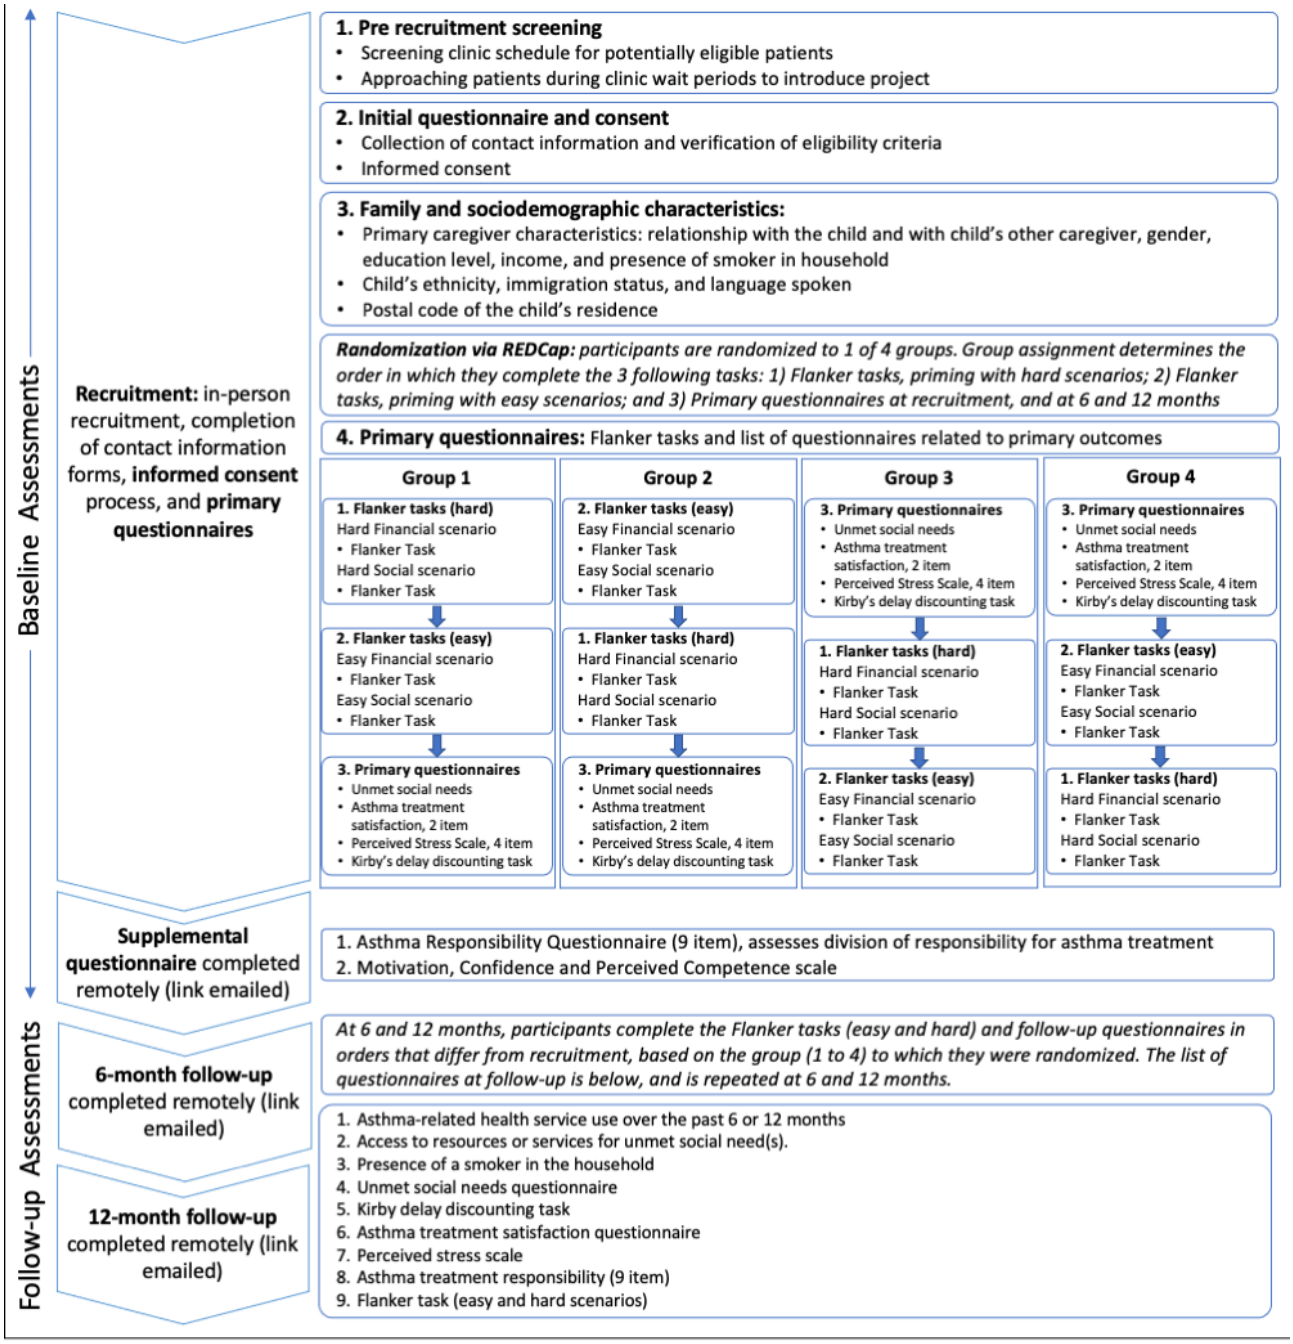
XSL•FO
RenderX

Feasibility section for the method of determining the sample size. The Pampalon material deprivation index, measured at the level of the dissemination area and associated with the postal code of the child's primary residence, is a composite of the (1) proportion of persons without a high school diploma, (2) employment:population ratio, and (3) average personal income obtained from the Canadian census [65,66].

Previous evidence suggests that adherence decreases with the age of the child, coinciding with responsibility for taking medication shifting from parents to their children as they age [53-59], whereas evidence for the impact of children's sex is mixed [56,57,62,68,69]. We will stratify our recruitment to ensure equal recruitment between age groups (2-7, 8-12, and 13-17 years), and all analyses will consider the child's age and sex [4].

Consent

Informed consent will be obtained from all participants in the asthma clinic, before enrollment, including consent for follow-up measures and access to clinical data in the reMed database. Consent forms and questionnaires will be administered in French and English according to each participant's preference.



Participants will be approached by a trained research assistant at the time of their clinic appointment. Given the patient flow and clinic organization, participants may be approached in the waiting room before their appointment, between parts of their appointment (ie, after seeing the nurse and before seeing their physician), or after having completed their appointment. The research assistant will approach the patients and describe the project and what their participation would require. Those who express interest in participating will accompany the research assistant to a private room where they will be given the opportunity to read the project consent form, with the research assistant available as needed to explain further or respond to questions. Participants who agree to participate will be asked to sign and date the consent form (either on paper or electronically using the REDCap [Research Electronic Data Capture; Vanderbilt University] database where the survey is hosted) as well as complete the consent form and questionnaire for inclusion in the reMed database, which is required for study participation (given that adherence to medication, obtained from this database, is the primary outcome). Participants will then complete the questionnaire on the REDCap database with guidance from the research assistant throughout.

Follow-up

Participants will be followed prospectively for 12 months after recruitment with measurements at baseline, 6 months, and 12 months (Figure 1). Using the REDCap database, they will be sent the follow-up questionnaires immediately following the baseline questionnaire and at the 6- and 12-month follow-ups. Refer to Figure 1 for the details of each measure.

XSL•FO
RenderX

Figure 1. Data collection and schedule of events. REDCap: Research Electronic Data Capture.

Outcome Measures

Details of each measure, including operational definitions and data collection methods, are described in the following sections (*Primary Outcome*, *Main Predictors*, *Other Measures and Covariates*, and *Follow-up Measures* sections) and detailed in Table 1.

XSL•FO

Table 1. Overview of measures, data sources, and timeline of measures.

Measure	Measurement details	Data source	Timeline		
			Recruitment	6-month follow-up	12-month follow-up
Primary outcome					
Adherence[a]*:* Proportion of prescribed days covered	Number of days for which the drug was dispensed by a pharmacy divided by the number of days for which it was prescribed [63,70]	Pharmacy claims data (*Registre de données sur les Médicaments*)	—[b]	—	X[c]
Main independent variables					
Unmet social needs	A series of validated questions assessing employment [71], housing stability and ability to pay for utilities, [72-75], financial resource strain [76-78], food security [79], transportation [75], childcare [80], and parent education and health literacy [80,81]	Questionnaire	X	X	X
Scarcity, via executive control—Eriksen flanker task	Speed of response and percentage accuracy [82-84], Δ accuracy between easy and hard condition	In-person computer-based task	X	X	X
Future discounting—Kirby delay discounting task	27-item questionnaire assessing temporal discounting	Questionnaire	X	X	X
Exploratory measures					
Capability	Perceived Competence Scale [85,86]	Questionnaire	X	—	—
Motivation	Treatment Self-Regulation Scale (adapted for adherence) [87]	Questionnaire	X	—	—
Perceived stress: perceived stress scale	4-item measure used to understand how respondents perceive stress and how their feelings are impacted by certain situations [88]	Questionnaire	X	X	X
Asthma severity: PPACI[d]	4-level PPACI assessed in the preceding 6-month period. On the basis of the number of doses per week of short-acting beta-agonists, use of oral corticosteroids within 14 days of a medical claim or hospitalization for asthma, any ED visit for asthma, and any hospitalization for asthma [89]	Medical chart	X	X	X
Access to resources	Whether families accessed resources to which they were referred (social worker at local community health center)	Questionnaire	—	X	X
Asthma treatment satisfaction	Single item inquiring who is primarily responsible for the child's asthma management and 1 question drawn from the Asthma Medication questionnaire [90] adapted to inquire specifically about management of one's child's asthma	Questionnaire	X	X	X
Asthma responsibility questionnaire	10-item measure examining the division of asthma management responsibilities between child and parent [91]	Questionnaire	X	—	X
Covariates					
Child's *age* and *sex*	N/A[e]	Medical chart	X	—	—
Child's *gender*	N/A	Questionnaire	X		
Caregiver's relationship with child	Two items interrogating relationship to the child and whether respondent is the child's legal guardian	Questionnaire	X	—	—
Caregiver's gender	N/A	Questionnaire	X	—	—
Caregiver's marital status and *living situation*	Single items assessing marital status and living situation as it relates to the child	Questionnaire	X	—	—
Postal code of the child's residence	N/A	Questionnaire	X	—	—

XSL•FO

Measure	Measurement details	Data source	Timeline		
			Recruitment	6-month follow-up	12-month follow-up
Caregiver's level of education	Elementary school or less, some high school, high school graduate, some college or technical school, college graduate, or completed a graduate degree	Questionnaire	X	—	—
Household income	One item question based on the Canadian income survey [92]	Questionnaire	X	—	—
Presence of a smoker or e-cigarette user in the house	2 question items investigating use of tobacco products or e-cigarettes in the last month [93]	Questionnaire	X	X	X
Responsibility for asthma management	"Who is responsible for asthma management?"	Questionnaire	X	—	—
Child's ethnicity, immigration status, and *language spoken at home*	Questions using categories from Canadian census [94]	Questionnaire	X	—	—
Class of controller medication received during study period	Inhaled corticosteroids and long-acting beta-agonists of leukotriene receptor antagonists	Medical chart	X	X	X

[a]The name of the variable in question has been italicized.

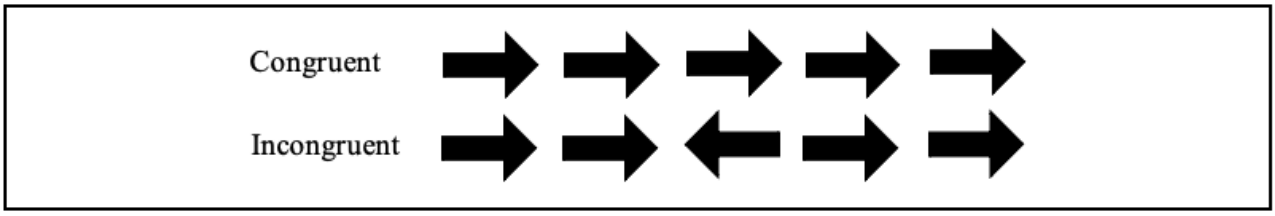
[b]Em dashes in the timeline signify that data for the associated variable will not be collected at the time point in question.

[c]X in the timeline indicate data collection for the associated variable at the time point (recruitment, 6-month follow-up, or 12-month follow-up) in question.

[d]PPACI: Pediatric Pharmacoepidemiology Asthma Control Index.

[e]N/A: not applicable.

Primary Outcome



Adherence to controller medication will be measured for the 12 months of follow-up on a scale of 0%-100% by the *proportion of prescribed days covered (PPDC)*, a validated index calculated as the number of days for which the drug was dispensed by a pharmacy divided by the number of days for which it was prescribed [63]. The PPDC accounts for varying durations of physician prescriptions [70] and leads to conservative estimates of adherence, as possession of medication is a prerequisite for adherence but does not confirm its use. The PPDC will be calculated using medical records (prescriptions made by the clinician) and the reMed database [24,63]. reMed collects drug claims for both privately and publicly insured children.

Main Predictors

Scarcity is a state in which individuals' cognitive resources (mental bandwidth) are occupied and taxed by preoccupations, including pressing financial concerns [31]. These worries consume mental bandwidth, leaving less of it available for other tasks. In this study, we will assess scarcity as per the original work in the field [95]. Briefly, participants will be exposed to hypothetical scenarios that are designed to elicit a scarcity mindset in those who are experiencing a state of scarcity. The scenarios bring to the fore participants' scarcity mindset by asking participants to imagine themselves in situations in which they would need to access scarce resources. Specifically, participants will be asked to imagine requiring an urgent car repair, costing either US $1500 in the more taxing, "hard" scenario or US $150 in the "easy" scenario. Similarly, participants will be asked to imagine that their child required either a hospitalization (hard scenario) or an ED visit (easy scenario) for their asthma. After listening to the scenarios, participants will complete the Eriksen flanker task, a widely used, standardized, and validated test of executive function assessing selective attention, information processing, and inhibitory function. The task requires participants to rapidly identify whether a series of arrows, colored boxes, or letters are congruent or incongruent (Figure 2). We will measure both the percentage accuracy and time to complete the task under each condition [31,82,95]. The outcome for each participant will be the difference in accuracy on the flanker test after the easy versus the hard scenarios.

XSL•FO
RenderX

Figure 2. Flanker task with arrows, illustrating congruent and incongruent series of arrows.

Future discounting will be assessed using Kirby delay discounting task, in which participants are asked to choose between a smaller, immediate financial reward or a larger, delayed reward. From the participant's answers to the 27 choices, a hyperbolic discount parameter (k) is calculated [96].

Unmet social needs will be assessed using validated measures of employment [71], housing stability, ability to pay for utilities [72-75], financial resource strain [76-78], food security [79], transportation [75], childcare [80], parent education, and health literacy [80,81]. We chose these needs as they had published and validated short question items assessing them, had either documented or plausible relationships with asthma, and could be amenable to intervention by social workers.

Families for whom unmet social needs have been identified will be asked whether they are interested in receiving support to address their needs. If they are interested, the study team will ensure referral to a social worker at a *centre locaux de services communautaires* (local community services centers), a service covered by the government's universal health insurance plan. With the participants' consent, their treating clinician will be informed of their unmet social needs and whether they were referred to a local community services center. Participants who agree to be referred to resources to address their unmet social needs at recruitment will be asked at 6 and 12 months if they accessed any resources to help them address their unmet needs and, if so, which ones. In our analysis, among participants with identified unmet social needs, we will explore whether the participants' desire for a referral for social services and, if applicable, access to those resources influenced the relationship between unmet social needs and adherence.

Other Measures and Covariates

Family and sociodemographic characteristics will include the child's age, sex, gender, ethnicity, and immigration status and parent participants' gender, race and ethnicity, level of education, and income. We will also inquire about the presence of a smoker in the household and the languages spoken at home.

Asthma and asthma treatment information will include controller medication type (inhaled corticosteroids, long-acting beta-agonists, or leukotriene receptor antagonists) and frequency (once vs twice daily) retrieved from medical records and asthma disease severity in the 6 months preceding recruitment using the 4-level Pediatric Pharmacoepidemiology Asthma Control Index (PPACI) using data from medical records. The PPACI categorizes asthma control based on the average number of doses per week of short-acting beta-agonists, any use of oral corticosteroids within 14 days of a medical claim or ED visit for asthma, and any hospitalization for asthma [89].

Perceived efficacy of medication will be assessed using a single item on a 5-point scale selected from the Patient Satisfaction with Asthma Medication questionnaire: "Would you recommend your child's asthma medication and its inhaler to someone else with asthma?" [90].

Perceived stress of respondents will be measured using the 4-item version of the Perceived Stress Scale, with each question rated on a 5-point scale [88,97]. The 4-item Perceived Stress Scale has a Cronbach α reliability coefficient of .72.

Capability and Motivation will be measured using a questionnaire based on the Capability, Opportunity, Motivation, and Behavior model [98]. This will serve to evaluate the mechanism by which scarcity and future discounting may influence medication adherence.

Capability will be measured using the 4-point Perceived Competence Scale, validated in adherence to medication as well as in the pediatric population [85,86]. These 4 items inquire specifically about the parent's perceived confidence and capability in ensuring that their child takes their asthma medication as prescribed.

Motivation will be assessed using selected items from the 15-item Treatment Self-Regulation Scale adapted for adherence [87]. The 2 selected items assess the perceived importance that their child takes their asthma medication as prescribed and their confidence in ensuring that they do so. Selected items, rather than the full scale, were chosen to limit participant burden.

Division of asthma treatment responsibility will be assessed using the 10-item Asthma Responsibility Questionnaire, which measures the division of asthma management responsibilities between child and parent [91]. It also measures the parent's degree of satisfaction with the amount of responsibility their child takes for their asthma.

Follow-up Measures

At 6 and 12 months, we will assess health service use, specifically asthma-related ED visits and hospitalizations, via parental reports as well as the patient's hospital file and provincial health insurance data. We will also measure access to resources to address unmet social needs for participants who agreed to be referred to a social worker at their local community services center using a single-item question for each identified unmet social need (eg, "Since you entered this study, have you been in contact with a social worker or someone from the local community services centre to help you access resources for [identified unmet social needs]?")

XSL•FO
RenderX

Study Procedures

Families will be made aware of the project via a posting in the clinic's regular electronic newsletter and posters in the clinic waiting room. Clinicians will be informed about the study through personalized emails from the study team. A research assistant will be present during each clinic day, prescreen clinic lists for eligible families, and approach primary caregivers for consent at the time of their clinic visit.

Study Assessments

The study flow, including the measurements at each time point, is shown in Figure 1. Measures will be completed on the web via the REDCap platform [99], except for the flanker task, which will be administered via the testable web-based platform.

Baseline

Potential participants will be approached by the research assistant during clinic hours, before their child's appointment with their treating physician. After ensuring that participants are eligible based on the inclusion and exclusion criteria, participants who consent to the study will be randomized to 1 of 4 groups, which determines the order in which they will complete the baseline questionnaire, the flanker task while primed with easy scenarios, and the flanker task while primed with hard scenarios. Details of the questionnaire sequences and randomization groups are shown in Figure 1. The participants will complete the baseline questionnaire on site guided by the research assistant. This includes the following measures (detailed in the *Primary Outcome*, *Main Predictors*, *Other Measures and Covariates*, and *Follow-up Measures* sections above): (1) scarcity assessment (flanker task)—2 rounds, once while primed with "hard" scenarios and once while primed with "easy" scenarios; (2) family and sociodemographic characteristics; (3) unmet social needs; (4) identification of person primarily responsible for the management of the child's asthma and satisfaction with asthma treatment; (5) Perceived Stress Scale; and (6) Kirby delay discounting task to assess future discounting.

To ascertain whether exposure to the scarcity-inducing scenarios and the subsequent completion of the flanker task impact self-reporting of unmet social needs, participants will be randomized to complete the flanker task either before or after having completed the other sections of the questionnaire. Similarly, to determine whether familiarity with the flanker test influences accuracy and speed rather than the type of scenario (easy vs hard), participants will be randomized to start with either the easy or the hard scenarios. A visual representation of the 4 permutations is presented in Figure 1.

Secondary Questionnaire

Immediately after the recruitment visit, participants will be emailed a secure link for a secondary questionnaire including (1) the Asthma Responsibility Questionnaire [91] and (2) questions drawn from the Perceived Competence Scale [85,86] and the Treatment Self-Regulation Scale (adapted for asthma treatment adherence) [87]. This division of the baseline and secondary questionnaire was chosen to limit participant burden and time required at the clinic on the day of recruitment.

Follow-up Questionnaires

Participants will be emailed 6 and 12 months after recruitment to complete the follow-up questionnaires, the contents of which are described in Table 1. Participants will be reminded and offered help to complete the questionnaire if not completed within a week via up to 2 email reminders and 1 phone call from the research assistant.

Participant Compensation

Participants will receive CAD $10 (US $7.50) in compensation for completion of the initial study questionnaire and CAD $10 (US $7.50) at the end of the study if all materials have been completed.

Statistical Analysis

Results will be reported following the recommendations of the Strengthening the Reporting of Observational Studies in Epidemiology Statement for cohort studies [100]. For *aim 1*, we will first perform descriptive statistics for our measures of executive function (accuracy and time to complete the Eriksen flanker task between easy and hard scenarios) at baseline, 6 months, and 12 months and model trajectories using mixed effects regression models. We will then quantify the relationship between both level of scarcity at baseline and trajectories with PPDC in the 12 months following the index visit. We will use unadjusted linear regression models, before adjusting for potential confounders, including sociodemographic factors (eg, child age and sex) and disease characteristics (eg, PPACI at baseline and class and dosing frequency of controller medication). We will perform collinearity diagnostics on potential confounders, and if significant correlation is identified, we will adjust our model accordingly. Exploratory analyses will use logistic and ordinal regression models and the same set of variables to examine any effect of scarcity on health service use (ED visit or hospitalization). We will use the same analysis plan to examine the relationship between future discounting (using Kirby's discount parameter) and PPDC.

For *aim 2*, we will first assess whether scarcity and future discounting scores at baseline differ between families with versus those without unmet social needs. In the subgroup with identified unmet social needs at any time during the study, we will use regression models with time-varying exposure to estimate the effect of referral to social services and access to services on the presence of unmet social needs (ie, determine if referral to social services led to improvement in unmet social needs). We will then use generalized estimating equations to estimate the effect of unmet social needs on cognitive capacity, executive control, and future discounting.

For *aim 3*, we will evaluate whether scarcity is a mediator of the relationship between unmet social needs and adherence with multiple regression models using a recognized approach [101]. We will use a similar analysis for future discounting.

For *aim 4*, we will use multivariable logistic regression models to examine the effect of unmet social needs on ED visits (any vs none) and hospitalizations (any vs none), testing whether there is an interaction between medication adherence and unmet social needs in this relationship (whether better adherence is

XSL•FO
RenderX

protective in children with unmet social needs). A similar approach will be used for asthma control using an ordinal regression model for the 4-point PPACI.

For *aim 5*, we will use descriptive statistics to document the prevalence of unmet social needs in our sample as well as within families and use logistic regression models to test whether referrals to social services modulate those trajectories.

Power Calculation and Feasibility

Previously published data using the asthma clinic database found a mean PPDC (our measure of adherence and primary outcome) of 68%, with an SD of 33% [24]. In previous studies, a 25% [102] or 1 SD difference [103] in adherence was associated with significant differences in the number of ED visits. As those studies used slightly different measures of adherence, we will be conservative and power our study to detect a 16% difference (half an SD) in PPDC between the participants above and below the median of scarcity and future discounting scores. Using 2-sample *t* tests (2-tailed), an α of .05, and a power of 0.8, this will require us to recruit 135 participants. Accounting for 30.4% (41/135) of missing data (covariates) and loss to follow-up, we will recruit 200 participants. The prevalence of unmet social needs in the clinical population is unavailable; however, in our patient population, 26.59% (335/1260) of children are from the lower quintile of the material deprivation index. In addition, recent Canadian data suggest a food insecurity prevalence of 29% among youth and young adults [104]. Assuming that 25% (50/200) of participants have at least one unmet social need, the proposed sample size will allow 85% power to detect a 16% difference (half an SD) in adherence between those with versus without unmet social needs.

On the basis of preliminary data from the asthma clinic, 87.68% (1139/1299) of patients who were prescribed daily controller medications consented to reMed. In another study (Poitras N et al, unpublished data, August 2023) from our clinic with a similar population and participant burden, 30% of eligible families consented to participate in the study. Using this ratio, we would need to approach approximately 670 families to obtain our desired sample size. There are at least three half-day clinics a week where recruitment could occur, with a minimum of 3 families per clinic. Using a conservative estimate, even if 29.9% (200/670) of families consent to participate, recruiting 200 participants will take 18 months.

Results

This study obtained funding in April 2021. The research activities of this study began in December 2021. Participant enrollment and data collection began in August 2022 and are expected to be completed in 24 months (August 2024). As of February 2023, 100 participants have been recruited and have completed all baseline data. Data analysis will begin once all participants have been recruited and follow-up measures (6-month and 12-month follow-up) are in progress. Primary results of the study are expected to be available in the first months of 2025.

Discussion

Principal Findings

This project will allow us to document the impact of unmet social needs, scarcity, and future discounting on adherence in a diverse population of children with asthma using robust documentation of adherence and validated measures of scarcity and future discounting. The study will also allow us to document ongoing changes in both unmet social needs and adherence to medication in children with asthma in the wake of the COVID-19 pandemic. This research will confirm the potential for scarcity and future discounting as novel targets for either new interventions or improving existing effective interventions to improve adherence to controller medication that may lead to reduced risk across the life course for vulnerable children with asthma. The development of an intervention and assessment of its effectiveness through a randomized trial will be the next stages of this line of research, with potential benefits at both the national and international levels (including in low- and middle-income countries) to ultimately help reduce the disease burden in this population.

Strengths

TTo the best of our knowledge, this study is the first to investigate the relationship between unmet social needs, scarcity, and future discounting in medication adherence. We will use objective measures of adherence, validated questionnaires, and psychometric testing to measure the main independent variables of interest.

We will recruit patients from a clinic with diverse population, representing a broad range of demographic characteristics, including SES and social situations, which we will be able to capture in detail with both our unmet social needs questionnaires and demographic questions. This will allow for important subgroup analyses by age, sex, race and ethnicity, and SES.

Finally, we are performing this study in Canada, where medical care insurance is universal and government-funded and where prescription medication insurance is also universal (either privately or publicly funded). As such, it will help better understand the factors influencing adherence in a setting where financial barriers to either care or prescription medication are lower, especially for low-income populations.

Limitations

Representativeness of the Population

Recruitment from a tertiary pediatric center clinic could, in theory, limit generalizability; however, the clinical population is quite diverse with regard to SES, race, and ethnicity [105]. Previous studies reported lower rates of controller medication prescription in patients with lower SES [106], leading to a potential selection bias. We will limit this bias through stratified recruitment by SES and an analysis of all eligible patients approached to ensure that a similar proportion of patients in each SES stratum were excluded owing to a lack of controller medication prescription.

XSL•FO
RenderX

Potential Biases

By collecting objective values of adherence using reMed, we will avoid self-reporting bias in adherence, which is our primary outcome. It is possible that objective adherence will be positively influenced by the mere involvement in the research study (Hawthorne effect). Would that occur, it would likely be of similar magnitude for all participants in the study and not substantially influence the associations found. We will also be able to estimate the size of this effect by comparing adherence in this study with previously reported historical data on adherence from other children followed in the clinic [105].

Social desirability may influence parents' report of confidence in managing their child's treatment or other elements on the questionnaire. We attempted to mitigate this potential bias through the selection of previously validated questionnaires as well as an emphasis on the nonjudgmental nature of the questionnaire and the confidentiality of the information they provide. Again, this potential bias would likely be present across our sample and therefore should not influence the relationship found in the study.

Conclusions

Documenting the impact of unmet social needs, scarcity, and future discounting on adherence in a diverse population of children with asthma will provide important data to allow for improved approaches to prescribing and monitoring asthma treatment adherence in children. Understanding and targeting elements especially prevalent in this vulnerable population also has the potential to lead to significant health care cost savings in addition to reducing health inequalities by improving outcomes for populations at highest risk. Finally, our methodological approach to examine scarcity and future discounting and their link to medication adherence has the potential to be applied to a wide range of other chronic diseases (diabetes, cystic fibrosis, heart disease, etc), potentially leading to improvements in health and quality of life for children and adults living with chronic diseases.

Abstract

Background: Since the COVID-19 pandemic began, there have been concerns that interruptions to the health care system may have led to changes in primary care, especially for care of chronic conditions such as diabetes and heart failure. Such changes may have longer term implications for population health.

Objective: This study aims to describe the impacts of the COVID-19 pandemic on indicators of primary care access, comprehensiveness, and appropriateness among adult patients, as well as on specific indictors of chronic conditions. Additionally, this study aims to determine whether any identified changes were associated with patient sociodemographic characteristics and multimorbidity.

Methods: This is a retrospective, single-arm, pre-post study using Canadian Primary Care Sentinel Surveillance Network (CPCSSN) data. CPCSSN is a research network supported by a primary care electronic medical record database, comprising over 1500 physicians and nearly 2 million patients. We are examining changes in care (eg, frequency of contacts, laboratory tests and investigations, referrals, medications prescribed, etc) among adults. We will also examine indicators specific to evidence-based recommendations for care in patients with diabetes and those with heart failure. We will compare rates of outcomes during key periods of the pandemic between March 13, 2020, and December 31, 2022, with equal time periods before the pandemic. Differences will be examined among specific subgroups of adults, including by decade of age, number of comorbidities, and socioeconomic status. Regression models appropriate to outcome distributions will be used to estimate changes, adjusting for potential confounders. This analysis is part of a mixed-methods study with a qualitative component investigating how patients with diabetes with or without concurrent heart failure perceived the impact of the pandemic on access to primary care and health care–related decisions. This study was approved by the Hamilton Integrated Research Ethics Board (14782-C).

Results: The start date of this study was October 5, 2022, and the prospective end date is January 31, 2024. As of May 2023, the study cohort (n=875,934) is defined, data cleaning is complete, and exploratory analyses have begun. Extended analyses using

XSL•FO
RenderX

2022 data are planned once the new data becomes available. We will disseminate results through peer-reviewed publications and academic conference, as well as creating evidence briefs, infographics, and a video for policy maker and patient audiences.

Conclusions: This study will investigate whether the COVID-19 pandemic has resulted in changes in the provision of primary care in Canada and whether these potential changes have led to gaps in care. This study will also identify patient-level characteristics associated with changes in care patterns across the COVID-19 pandemic. Indicators specific to chronic conditions, namely diabetes and heart failure, will also be explored to determine whether there were changes in care of these conditions.

Introduction

The presence of strong primary care systems has been shown to be associated with superior and more equitable health outcomes in the population [1-6]. Core elements of primary care that contribute to population health outcomes include access, continuity, comprehensiveness, coordination, person focus, and equity enhancement [7]. Chronic diseases are common and represent the leading causes of death worldwide [8]. The core elements of primary care make this setting ideal for managing chronic diseases [4,9], and family medicine and other primary care services provide the majority of care for chronic diseases across the lifespan [4,10]. With increasing age, there is an increasing prevalence of multiple chronic diseases [11], and these patients require careful management to reduce morbidity and mortality and improve quality of life [12]. Life-limiting chronic diseases such as chronic obstructive pulmonary disease, heart failure, and chronic kidney disease [13-15] affect millions of people in Canada and are mostly managed in primary care [16-19]. Other conditions that are risk factors for numerous cardiovascular and cerebrovascular diseases (eg, diabetes and hypertension) are associated with poor health outcomes, and these are also managed in primary care [20].

On March 11, 2020, the World Health Organization declared the circulating SARS-CoV-2 as a pandemic. The SARS-CoV-2 pandemic placed a substantial strain on health care services for care of both COVID-19 illness (the majority of which was provided in primary care without need for hospitalization) and non–COVID-19 illness [8,21]. The documented early impacts of the COVID-19 pandemic were reductions in the number of patients visiting primary care offices [22], dramatic increases in remote care especially for older patients [22,23], and new strategies to maintain care such as implementing wellness checks for high-risk patients [24,25].

Early in the pandemic, there were reductions in visits for chronic condition management [20,26,27], preventive screening and diagnostic testing [28,29], and changes in physician referral behaviors [30]. The limited availability of testing and coordination of prevention services was a concern among Canadian family physicians [31]. Professional organizations recommended continuation of in-person care during the pandemic for complex chronic conditions and when physical examination was required; however, many patients avoided seeking primary care, and clinics experienced decreased attendance relating to the care of serious conditions [32,33]. Although telemedicine strategies can be effective for some chronic disease monitoring, patients who experience lack of equity in access to health care are also likely to experience barriers to using technology [34-36].

The onset of the pandemic worsened existing challenges to the prospects of achieving and maintaining an adequate level of comprehensive primary care in Canada. Understanding the ways in which the core functions of primary care [37-39] were affected by the COVID-19 pandemic is essential for chronic condition management and for system assessment overall. Although there are reports that the volume of primary care in Canada has largely returned to prepandemic levels, it is not clear whether and for whom there is a need to “catch up” on care for chronic diseases. For practices with a tendency for overuse of testing and investigations, these may have declined to more appropriate levels during the pandemic, also highlighting the areas of practice improvement. The objectives of this study are to describe the impacts of COVID-19 on chronic disease care and to determine whether changes were associated with patients’ sociodemographic characteristics and multimorbidity.

Methods

Data Source

The Canadian Primary Care Sentinel Surveillance Network (CPCSSN [40]) is a multidisease electronic medical record (EMR) research and surveillance data repository that securely collects deidentified health information from EMRs of participating primary care clinicians (eg, family physicians and nurse practitioners) who are referred to as “sentinels.” CPCSSN currently brings together 13 primary care research networks for the purposes of research, disease surveillance, and quality improvement, with more networks due to join in the near future. Every 6 months, CPCSSN acquires deidentified patient-level clinical data from primary care EMR systems held by 1583 primary care providers across Canada, with approximately 200 patient encounters per month per physician [20]. CPCSSN acquires most of the data fields in Canadian primary care EMRs with the exceptions of portable document format such as imaging data and the narrative “Subjective, Objective,

XSL•FO
RenderX

Assessment, and Planning" notes. The acquired data are processed into a standard format and are made available for surveillance and research [41]. The relative frequency, longitudinal format, and comprehensiveness of CPCSSN data are ideal for the study of changes in practice, through time, in response to significant environmental imperatives, such as public health or research initiatives [41]. Numerous case definition validation studies have been completed [42-44], and the data have also been used to evaluate patterns and quality of health care [19,45].

Study Design

This protocol was designed using the RECORD (REporting of studies Conducted using Observational Routinely collected Data) statement [46]. We will conduct a retrospective closed cohort study with a single group using a pre-post design. We will examine prevention and management activities for exemplar conditions on the basis of having a validated CPCSSN case definition [47,48] (ie, diabetes and heart failure), having substantial prevalence in primary care, and either having high morbidity or being risk factors for morbidity if not well managed. Patient-level data extracted from the CPCSSN repository between 2018 and 2022 will be used to investigate changes in rates of presentation and clinical management of various chronic diseases before, and through the phases of, the pandemic.

Study Population

The study population is all patients who were 18 years and older in 2018, and some analyses will focus on subgroups of patients with specific chronic conditions. We will use the 2-year contact population as recommended previously for defining practice populations for primary care [49]. This method uses contacts within encounter, medication, and billing-related data tables, and has been used previously with CPCSSN data to produce national chronic disease estimates [50]. This method will be used in the period from March 13, 2018, to March 13 2020. We will use this population rather than the full CPCSSN patient population data (dating back more than 2 decades for some networks) to limit the size of the data set, while maintaining the patient population that is likely to have a relationship with a primary care practice during the study period. Although this approach may exclude patients who are younger, healthier, and less likely to seek primary care compared with patients with chronic conditions, we do not expect this to have a major impact on findings because this study focuses on the age group where chronic condition prevalence begins to increase and where screening guidelines apply (eg, diabetes). Therefore, this age group is more likely to see a primary care physician regularly.

People who died during the study period will be included up to the point of death using the death date if captured or the presence of a deceased status with date estimated from the most recent contact in CPCSSN data. Patients who were older than 105 years at the start of the COVID-19 pandemic will be excluded as a possible data error.

Variables of Interest

Primary Exposure

The primary exposure is the start of the pandemic in March 13, 2020. This date was selected as it marks the beginning of Canadian provincial governments responding to the formal declaration of the pandemic by the World Health Organization on March 11, 2020, by enforcing sweeping public health and safety measures. The prepandemic time frame used is defined as June 22, 2018, through March 12, 2020. The pandemic time frame used in this study runs from March 13, 2020, through December 31, 2022. In addition to comparison between these 2 periods, 30-day interval rates will also be calculated for selected outcomes and indicators where possible.

Outcome Definitions and Measures

Outcomes were informed by a large primary care trial on improving prevention and management of chronic conditions in primary care [51], a quality index created for primary care with items measurable in EMRs [52], and consideration of data capture across the networks of CPCSSN. We further conceptualized outcomes according to whether they represent aspects of access, comprehensiveness, or appropriateness (Table 1).

XSL•FO
RenderX

Table 1. Outcomes and outcome measures.

Population	Indicator	Related domain	Data source[a]
Number and types of encounters			Encounter, encounter diagnosis, and billing
All patients in our defined cohort	Overall number of all encounters	Access	
Patients with the CPCSSN[b] case definition of diabetes and HF[c]	Overall number and types of diabetes-related and HF-related investigations	Comprehensiveness	
Diagnoses addressed in encounters		Comprehensiveness and appropriateness	Encounter, encounter diagnosis, and billing
All patients	Number of different diagnoses addressed per patient per year		
Patients with ≥1 condition with the validated CPCSSN case definition	Number and proportion of chronic conditions (ie, CPCSSN case definitions) addressed by physician at least once a year		
Patients with the CPCSSN case definition of diabetes and HF	Overall number and types of diabetes-related and HF-related investigations		
Patients with the CPCSSN case definition of diabetes and HF	Proportion of patients with diabetes-related encounter and HF-related encounter every 6 and 12 months (as appropriate for condition)		
Services provided		Comprehensiveness	Billing, vaccine, and medication
Patients age ≥65 years	Number of patients receiving pneumococcal vaccine and influenza vaccine		
Patients with the CPCSSN case definition of diabetes and HF	Proportion of patients with influenza vaccination		
Procedures performed		Appropriateness	Billing
Patients with the CPCSSN case definition of diabetes	Proportion of patients with foot examinations in last 12 months		
Physical examinations		Appropriateness	Examinations
All patients in our defined cohort; all patients grouped by CPCSSN case definition	Proportion with BP[d] measured every 6 months or every 12 months (as appropriate for condition)		
Referrals made to specialists		Comprehensiveness	Referral
All patients in our defined cohort; all patients grouped by CPCSSN case definition	Overall number and types of referrals; proportion referred to cardiology, endocrinology (as appropriate for condition)		
Investigations performed		Appropriateness	Laboratory
All patients in our defined cohort	Number of vitamin D, CBC[e], eGFR[f], ACR[g], and liver function tests performed		
Patients with CKD[h]	Number with and frequency of eGFR and ACR tests		
Patients without diabetes	Number with HbA_{1c}[i], FBS[j] measured (screening)		
Patients taking or not taking statins	Number with and frequency of lipid panel/LDL[k]		

XSL•FO
RenderX

Population	Indicator	Related domain	Data source[a]
Patients taking or not taking levothyroxine	Number with and frequency of TSH[l] measured		
Patients with the CPCSSN case definition of diabetes	Proportion with HbA_{1c} measured every 6 months and every 12 months		
Monitoring results		Appropriateness	Examination
All patients in our defined cohort; all patients grouped by CPCSSN case definition and age	Proportion with BP ≤140/90 or ≤130/80 (as appropriate based on chronic conditions and age); proportion of patients in the following sBP[m] ranges: ≤130, 131-140, 141-150, 151-160, and >160		
Medications		Comprehensiveness and appropriateness	Medication and risk factor
Patients with the CPCSSN case definition of diabetes	Proportion of patients with and overall number and frequency of metformin prescriptions, insulin prescriptions, and other oral antidiabetic prescriptions[n]		
Patients with the CPCSSN case definition of HF	Proportion of patients with and overall number and frequency of β-blocker prescriptions, ARB[o] prescriptions, and ACE-I[p] prescriptions		
Patients who smoke	Number of patients with NRT[q] prescription		

[a]CPCSSN data table.

[b]CPCSSN: Canadian Primary Care Sentinel Surveillance Network.

[c]HF: heart failure.

[d]BP: blood pressure.

[e]CBC: complete blood count.

[f]eGFR: estimated glomerular filtration rate.

[g]ACR: albumin-to-creatinine ratio.

[h]CKD: chronic kidney disease.

[i]HbA_{1c}: hemoglobin A_{1c}.

[j]FBS: fasting blood sugar.

[k]LDL: low-density lipoprotein.

[l]TSH: thyroid-stimulating hormone.

[m]sBP: systolic blood pressure.

[n]Other oral antidiabetic medications include classes such as sodium-glucose cotransporter-2 inhibitors, sulfonylureas, meglitinides, dipeptidyl peptidase 4 inhibitors, etc.

[o]ARB: angiotensin receptor blocker.

[p]ACE-I: angiotensin-converting enzyme inhibitor.

[q]NRT: nicotine replacement therapy.

Access to the practice will be measured as the overall number of encounters.

Comprehensiveness refers to primary care addressing "all problems in the population (with short-term referral as needed), except those that are too unusual (generally a frequency of less than 1 or 2 per thousand in the population served) for the primary care practitioner or team to treat competently" [1]. As indicators of comprehensiveness, we will measure number of different diagnoses addressed per patient per year, proportion of patients' chronic conditions addressed at least once a year, number of pneumococcal vaccines and influenza vaccines in patients 65 years or older, and number of prescriptions for nicotine replacement therapy

Appropriateness will be examined in 2 ways: laboratory tests that are indicated for monitoring of chronic conditions but may be ordered more frequently than necessary (eg, hemoglobin A_{1c} in diabetics) and laboratory tests that are frequently ordered routinely (or for screening purposes) but may be overused in certain populations, including thyroid function tests, vitamin D, albumin-to-creatinine ratio, and lipid panel testing [53]. We hypothesize that some of these tests, while indicated at a base frequency, may be commonly overused; thus, their frequency may have declined during the pandemic.

XSL•FO
RenderX

Diabetes and heart failure are 2 chronic conditions where aspects of care can be reasonably evaluated in CPCSSN. We will describe care across the population in terms of frequency of contacts, laboratory tests and investigations, and medications prescribed that would suggest care that is in step with evidence-based recommendations [54]. For patients with diabetes, we will measure the percentage of patients with a diabetes-related encounter every 6 and 12 months; percent with a foot examination in the last 12 months; percent with a blood pressure measure and hemoglobin A_{1c} test every 6 and 12 months (and results); percent with influenza vaccination; overall number of diabetes-related investigations; percent referred to endocrinology; percent receiving, and number and frequency of metformin, insulin, and other antidiabetic prescriptions. For patients with heart failure, we will measure percentage of patients with heart failure–related encounters every 6 and 12 months; number of investigations (echocardiogram and blood tests); percent with a blood pressure measure every 6 and 12 months (and results); percent with influenza vaccination; percent receiving β-blocker, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers; and percent referred to cardiology and other specialists.

Statistical Analysis and Power

As of 2018, there were 1.13 million adult patients in the CPCSSN database, with 65% (734,500/1,130,000) having at least 1 chronic condition [55]. A sample size of 1276 paired (pre-post) individuals would be required to detect a change from 50% to 55% of patients experiencing an outcome, with a correlation between paired observations of 0.2 [56]. With a correlation between pairs of 0.1, the required sample size would be 1432. We expect to have adequate sample size to examine changes within specific conditions given the approximate prevalence of hypertension (22%), diabetes (10%), chronic obstructive pulmonary disease (4%), and heart failure (4%) among adults in CPCSSN data or other Canadian data [13,55].

Descriptive Analyses

To describe the cohort, continuous or count variables will be analyzed for their mean, median, SDs, and IQRs. For categorical variables, percentages will be calculated. We will present outcomes stratified by sex, age category (40-49, 50-59, 60-69, and ≥70 years), urban versus rural patient address, and neighborhood income quintile (1-2 [lower] vs 3-5 [higher]).

Analyses of Changes Over Time

We will present the proportions of patients experiencing the outcomes for each time period or mean changes for continuous variables and 95% CIs. Statistical significance of changes from pre to post time period will be assessed using the McNemar test for binary variables, the Wilcoxon signed rank test for original variables, and the paired *t* test for continuous variables. Regression models appropriate to outcome distributions will be used to control for potential confounders of age (<70 vs ≥70 years), sex, count of comorbidities (CPCSSN-validated conditions), neighborhood income quintile, and CPCSSN network (corresponding to location within Canada). Interactions will be examined in the descriptive analysis and will be considered for inclusion in models if they are found to be relevant. We will present adjusted estimates and 95% CIs for outcomes and parameter estimates for the independent variable and covariates. Analyses will be completed using SAS (version 9.4; SAS Institute, Inc).

Sensitivity Analysis

To examine whether results are biased because of the nonrepresentativeness of the CPCSSN population, we will conduct the analyses on a sample of patients that is representative of the Canadian population based on age, sex, neighborhood socioeconomic status, and rural or urban residence.

Ethics Approval

This study was approved by the Hamilton Integrated Research Ethics Board on April 11, 2022 (project number 14782-C). Because we will be using deidentified data, no consent is required. This study is also registered with ClinicalTrials.gov (NCT05813652).

Results

Study Timeline

The start date of this study was October 5, 2022, and the prospective end date is January 31, 2024. At the time of writing (May 2023), we have finished data cleaning and begun exploratory analyses. As there are known consistencies with CPCSSN data, having a longer exploratory analysis phase has allowed us to liaise with central CPCSSN data managers in order to prepare data for the main analyses. We have now also defined our study cohort: a total of 875,934 individuals between the ages of 18 and 105 years as of 2018 were included.

Future Analyses

We will attempt to extend our analyses to include the first half of 2022 when data become available if our timelines and resources allow. At the time of writing this protocol (May 2023), data were available up to December 2021. The additional 2022 data will allow us to investigate changes in primary care in the later portion of the COVID-19 pandemic, capturing the Omicron wave, and measure whether any changes identified in the earlier portion of the pandemic were sustained or returned to prepandemic patterns of care.

Dissemination

We plan to share knowledge products for patients and the public with the patient advisory committee being created as part of the David Braley Primary Care Research Collaborative at McMaster University, with whom several authors are affiliated. *For clinicians*, we will create evidence briefs to be shared with the national and provincial colleges of family physicians through social media and our CPCSSN practice-based research network linkages. *For researchers and policy and practice decision makers* (eg, College of Family Physicians of Canada), we will produce peer-reviewed publications and evidence briefs where we will contextualize the new knowledge against recent research relating to pandemic recovery in health care. The 1- to 2-page evidence briefs will be shared with knowledge users involved in the development and implementation of policies and resources

XSL•FO
RenderX

related to pandemic recovery. *For patients*, we will create infographics and a short video that will raise awareness of the issue of chronic condition care gaps and describe patients' perspectives. These will be circulated via social media and clinical organizations.

Discussion

Key Findings

The aim of this study is to help identify signals of change across several domains of primary care, including access, comprehensiveness, and appropriateness, that may have occurred in response to the COVID-19 pandemic. This will be done by investigating the overall number of primary care encounters during the pandemic compared with prepandemic, as well as potential changes in the number of diagnoses addressed during encounters, number of blood pressure measurements, number of vaccines provided, number of blood tests carried out, and so on. Potential changes in indicators specific to the management of chronic conditions will also be investigated, for example, frequency of HbA_{1c} testing for those with diabetes, number and frequency of visits for monitoring of heart failure, and number of prescriptions for diabetes or heart failure. Potential changes in any of these indicators may indicate that gaps in care are present that may benefit from targeted recovery measures.

However, these potential changes in primary care are not inherently negative. For example, many blood tests, examinations, and procedures are considered overused in certain populations and may be conducted more frequently than necessary [53,57,58]. If decreases in number or frequency of these overused tests are identified during the pandemic, this may be considered more appropriate use when compared to prepandemic levels. Furthermore, decreases in frequency of certain primary care interventions may not be clinically significant or necessarily lead to negative health outcomes. Therefore, it is important that each identified change be carefully considered in a broad clinical context before firm conclusions can be drawn.

Strengths and Limitations

The strengths of this study include the use of a large, multiprovince primary care EMR data source, developed to understand the epidemiology of chronic diseases and care in Canadian primary care. The data set is regularly updated and includes coded information on most aspects of primary care practice. The relative currency, longitudinal format, and comprehensiveness of CPCSSN data are ideal for the study of practice changes, through time, in response to significant environmental imperatives, such as the sweeping public health measures put in place during the pandemic [41]. Numerous case definition validation studies have been completed [42,43], and the data have also been used to evaluate patterns and quality of health care [19,45]. CPCSSN has undertaken extensive data cleaning algorithms to address data quality issues [41].

There are limitations in this study. EMR data are collected for clinical and administrative purposes and are not primarily collected for research, which may result in incomplete capture of information. Furthermore, participating sentinel clinics are overrepresented by academic practices [59], and by extension, we cannot be certain to what extent the patients in the CPCSSN data differ from other Canadian primary health care patients. There may be issues of nonparticipation bias and variation in data quality. This study will not provide information on people who are not attached to a primary care provider. As with primary care patients generally, older adults and female individuals are overrepresented in the CPCSSN database as compared with the national population; however, as this study is about changes in care patterns, this data set is representative of the population of interest [59]. Clinical context for some research based on secondary use of EMR data can be difficult to infer. Detailed information on family and living circumstances, ethnicity, language spoken, education, and socioeconomic status is rarely captured in EMRs, so it is more difficult to conduct equity analyses, relying instead on neighbor-level indicators.

Patient and Public Involvement

This research was initially designed and received funding without patient involvement. When the research team presented the data request to the CPCSSN data access committee (May 2022), a patient advisor on the committee provided input. The advisor noted that the proposal was broad in terms of the scope of chronic diseases to be investigated. In response, we refined our analysis plans to examine diabetes and heart failure in greater detail as exemplar diseases. The advisor also suggested that it would be important to consider the changes in the health care system and behaviors of the public over different phases of the pandemic, especially since the Omicron variant.

Conclusions

We anticipate that this study will provide evidence that will inform whether and in what aspects of primary care the COVID-19 pandemic is associated with interruptions that may require attention. It will also highlight gaps or provide reassurance with respect to chronic condition care for populations who were expected to be disproportionately affected by pandemic health care changes such as those who are older or of lower socioeconomic status.

Acknowledgments

The authors would like to sincerely thank Rachael Morkem, Stephanie Garies, Mike Cummings, Chad Herman, and the entire CPCSSN team for their generous help, guidance, and support with this study. This work was supported by the Canadian Institutes of Health Research (grant WI1-179885). The sponsor has no role in study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication.

Abstract

Background: There is increasing evidence that co-design can lead to more engaging, acceptable, relevant, feasible, and even effective interventions. However, no guidance is provided on the specific designs and associated methods or methodologies involved in the process. We propose the development of the Preferred Components for Co-design in Research (PRECISE) guideline to enhance the consistency, transparency, and quality of reporting co-design studies used to develop complex health interventions.

Objective: The aim is to develop the first iteration of the PRECISE guideline. The purpose of the PRECISE guideline is to improve the consistency, transparency, and quality of reporting on studies that use co-design to develop complex health interventions.

Methods: The aim will be achieved by addressing the following objectives: to review and synthesize the literature on the models, theories, and frameworks used in the co-design of complex health interventions to identify their common elements (components, values or principles, associated methods and methodologies, and outcomes); and by using the results of the scoping review, prioritize the co-design components, values or principles, associated methods and methodologies, and outcomes to be included in the PRECISE guideline.

Results: The project has been funded by the Canadian Institutes of Health Research.

Conclusions: The collective results of this project will lead to a ready-to-implement PRECISE guideline that outlines a minimum set of items to include when reporting the co-design of complex health interventions. The PRECISE guideline will improve the consistency, transparency, and quality of reports of studies. Additionally, it will include guidance on how to enact or enable the values or principles of co-design for meaningful and collaborative solutions (interventions). PRECISE might also be used by peer reviewers and editors to improve the review of manuscripts involving co-design. Ultimately, the PRECISE guideline will facilitate more efficient use of new results about complex health intervention development and bring better returns on research investments.

KEYWORDS

co-design; reporting; guidelines; complex health intervention; scoping review; consensus

Introduction

Health research can often be immaterial when it focuses on questions and outcomes that have limited relevance to the individuals who will ultimately use the research findings, such as patients and clinicians [1]. A scoping study conducted by Oliver and Gray [2] in 2006 found that out of 334 studies, only 9 compared the priorities of researchers with those of patients or clinicians in terms of research and outcomes for assessing treatment effects. If end users, including patients and clinicians, are excluded from the process of establishing research priorities, such as in the selection of research areas or intervention development, irrelevant health research results and interventions might be generated [3].

To address this issue, there has been a notable increase in patient and public involvement (PPI) in health research [4-11]. Acknowledging the significance of incorporating the viewpoints and firsthand knowledge of patients, families, clinicians, and policymakers, many funding agencies have made patient-oriented activities, also referred to as PPI, obligatory [12-14]. According to the Canadian Institutes of Health Research (CIHR), PPI refers to “a continuum of research, from initial studies in humans to comparative effectiveness and outcomes research, and the integration of this research into the health system and clinical practice” [15]. Thus, PPI involves actively involving patients, carers, and members of the public in various stages of research, such as setting priorities, designing studies, collecting and interpreting data, designing interventions, and disseminating findings [14,16,17]. This shift towards PPI signifies a paradigm shift in the research landscape, emphasizing the significance of collaborative and inclusive approaches to better address the needs and preferences of the communities being served [13,18,19]. Thus, researchers are challenged to “do... [PPI] right” [20].

To enact PPI, researchers have used various collaborative and participatory methods and designs [21]. One approach that has garnered significant attention and momentum is co-design, as a specific application and democratization of design that originated from the field of participatory design [22,23]. Co-design entails a process of collective creativity that spans the entire lifecycle of a design project [24]. This approach embraces creativity and flexibility to foster reflective feedback throughout the project [22]. Unlike the traditional expert-led approach, where interventions are designed “for” users, co-design emphasizes designing interventions “with” or “by”

users. Thus, co-design approaches aim to engage patients and other knowledge users in meaningful and reciprocal collaborations, fostering ownership, empowerment, and shared responsibility [25,26]. During co-design, active collaboration occurs among researchers, designers, developers, and users as experts in their experiences [27,28]. Co-design involves cooperatively exploring and communicating needs and devising solutions as a team [29,30]. Co-design aims for better design based on a richer, deeper understanding of what users know and experience [29]. Co-design in the domain of health services research, specifically in this case, involves multiple end-users, including researchers, designers, developers, and users, including health care workers and patients as experts who contribute their collective input for the purpose of developing a complex health intervention [24,27,29].

There is increasing evidence that co-design can lead to more engaging, acceptable, relevant, feasible, and even effective interventions [25,31]. A systematic review [8] reported examples of practice change from introducing co-designed outputs [31]. Changes included improved consistency in clinician assessment and identification of patient problems that were previously missed [32], revised clinical pathways [33], fewer hospital visits and admissions [32], and a reduction in the number of patients who failed to attend appointments [34]. Additional beneficial outcomes, such as patient satisfaction, were either demonstrated or perceived to be possible [35].

When practicing co-design, most researchers agree that co-design processes begin with understanding users' needs and behaviors and developing concepts that are tested and adapted in simple, fast, and low-cost ways [29,30]. For example, Boyd and colleagues [36] describe a 6-step process that includes engaging, planning, exploring, developing, deciding, and changing. However, there is considerable variation in how co-design is defined and practiced, ranging from feedback and consultation to user testing to web-based collaboration or user research and workshops [25]. Moreover, in practice, the terms co-design, cocreation, and coproduction are often used interchangeably and adopted and described inadequately, collectively termed "coapproaches" [23,31,37-39]. A recent overview of 23 reviews [25] concluded that, while co-design in health care appears to be widely used to develop complex health interventions, it is seldom described or evaluated in detail. The authors further concluded that realizing the potential of research-based co-design might require clearer and more consistent terminology and better reporting of the activities involved [25]. While some of the fundamentals of coapproaches have been described, for example, sharing power, including all perspectives and skills, respecting and valuing all knowledge, reciprocity, and building and maintaining relationships [40], there is limited consistency in understanding how to co-design complex health interventions and report them. Complex health interventions are defined as any effort, activity, or combination of program components that independently and interdependently improve health outcomes. Complex health interventions can be delivered in many settings, including health services, schools, local communities, or national populations. They can be delivered by a variety of individuals, including health care, social care, and public health practitioners, as well as professionals working outside of the health care sector, such as peers [41-43]. An example of a complex health intervention is a self-management program involving educational materials or resources and motivational enhancement delivered via weekly interactions with a peer. Complex health interventions do not include the development of medicines and any invasive interventions (eg, medical or surgical procedures).

In response to the reporting challenges specific to PPI in research, the Guidance for Reporting Involvement of Patients and the Public (GRIPP) [44] and GRIPP2 [45] were developed**.** The use of reporting guidelines can enhance transparency in the methodology presented in research reports and improve the adoption of research findings [45,46]. Reporting guidelines refer to a prescribed set of essential elements that should be included in co-design research reports [47]. These guidelines can be in the form of a checklist, flow diagram, or explicit text to assist authors in accurately reporting specific types of research [47]. The development of guidelines like these follows a well-defined methodology [47]. Hence, reporting checklists have dual applications: they can be used proactively to guide the research design, or retrospectively to evaluate the quality of reporting. Indeed, systematic reviewers have found the endorsement and implementation of guidelines by journals can improve reporting [46,48]. Ultimately, reporting guidelines contribute to the more effective use of new research findings and yield enhanced returns on research investments [46,48].

Despite the contribution of GRIPP2 [45], its guidance is generic and not focused on a particular approach or methodology—this leaves room to develop reporting guidance for particular approaches, including co-design approaches involving patients and other end-users to develop complex health interventions. Additionally, no guidance is provided on the specific designs and associated methods or methodologies involved in the process (eg, needs assessment via qualitative methods to clarify and address gaps in intervention preferences). Furthermore, GRIPP2 does not include guidance on the reporting of values or principles associated with meaningful co-design and how they are enacted or enabled. Thus, new guidelines are needed to promote consistent, transparent, and quality reporting of co-design studies to develop complex health intervention development.

We propose the development of the Preferred Components for Co-design in Research (PRECISE) guideline to enhance the consistency, transparency, and quality of reporting co-design studies used to develop complex health interventions. This aim will be realized by addressing the following objectives: to conduct a scoping review on the models, theories, and frameworks used to co-design complex health interventions to identify their common elements (components, values or principles, associated methods and methodologies, and outcomes); and to use these results to prioritize the co-design components, values or principles, associated methods and methodologies, and outcomes to be included in the PRECISE guideline using a modified Delphi process.

XSL•FO
RenderX

Methods

Study Design

The development of the PRECISE guideline will follow the methodological framework for developing reporting guidelines, as outlined by the Enhancing the Quality and Transparency of Health Research (EQUATOR) Network [49], and the Guidance for Developers of Health Research Reporting Guidelines [20].

Integrated Knowledge Translation Panel

An integrated knowledge translation (iKT) panel has been formed to codevelop the research protocol, including informing the search strategy, reviewing preliminary results, and planning knowledge dissemination strategies. The iKT panel includes patient partners, caregivers, health care administrators, and journal editors. The formation of the iKT panel aims to codevelop the research protocol, which includes ensuring patient-based data representation in journals, informing the search strategy, reviewing preliminary results, and planning knowledge dissemination strategies, all while fostering a brave space that promotes trust, inclusion, and respect among patient partners, caregivers, health care administrators, and journal editors involved in the process. We will use the reflective exercise titled "SPOREA Reflective EDI Exercise" to promote dialogue and understanding around equity, diversity, and inclusion (EDI) topics amongst all iKT panel members [50]. We will ensure that discussions are conducted in a manner that respects diverse perspectives and experiences. We will compensate patients for their time and expertise according to mutually agreed-upon guidelines, which will be informed by the SPOR Evidence Alliance's policies and procedures [51].

Phase 1: Scoping Review on Models, Theories, and Frameworks in the Co-Design of Complex Health Interventions

Study Design

The methodology for this scoping review was developed following the methodological frameworks of JBI [52] and Khalil and colleagues' [53] suggestions. The protocol for this scoping review was registered on the Open Science Framework Register on June 12, 2023 (osf.io/prd3t). The protocol was guided by and reported according to the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) [54]. The results of the review will be reported using the Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Reviews (PRISMA-ScR) checklist [55].

Stage 1: Developing a Search Strategy

An information specialist and health science librarian will create and draft the search strategy using OVID Medline in consultation with the research team. The Population, Concept, and Context framework will be used to guide the search strategy (population: model, theory, or frameworks; concept: co-design studies; context: complex health interventions). Literature search strategies using medical subject headings and text words related to co-design, cocreation, and coproduction and models, theories, and frameworks will be developed. This preliminary search strategy is based on the published search strategies of previous reviews [25,31]. The final search strategy will combine structure database-specific subject headings (as available) and keywords or synonyms. The final search strategy will also undergo peer review using the Peer Review of Electronic Search Strategies (PRESS) statement checklist [56].

The following databases will be searched: Medline, CINAHL, Embase, PsycINFO, ACM Digital Library, and Cochrane Central Register of Controlled Trials. Hand-searching of design-specific publications will also be performed (eg, *Design for Health*, *HERD: Health Environments Research & Design Journal*, and *Health Design*). To help capture any relevant literature, we will also search the reference lists of included studies and those of relevant systematic reviews. The searches will not be limited by study design or languages. The search will capture literature from 1972 to present, consistent with when the term co-design first originated [23,57]. We will also search the gray literature in specialized databases like OpenGrey, Grey Literature Report, and GreyNet International; platforms like arXiv, bioRxiv, and SSRN; and databases like ProQuest Dissertations and Theses. We will search for conference abstracts (full papers) in specialized co-design in health conference proceedings (ie, D4H Proceedings).

Stage 2: Evidence Screening and Selection

All primary studies that have applied a model, theory, or framework for the purpose of co-designing a complex health intervention will be eligible for inclusion. We define a model as the essential elements or variables of a phenomenon or a specific aspect of a phenomenon; a theory as "a set of analytical principles or statements designed to structure our observation, understanding, and explanation of the world;" and a framework as an explanation of a phenomenon by organizing it into a collection of descriptive categories and the relationships between them [58]. We focus on models, theories, and frameworks to identify key components, actions, and mechanisms.

All articles with primary study designs will be included (eg, experimental, quasi-experimental, observational, qualitative, mixed, and multiple methods). Systematic reviews, meta-analyses, editorials, commentaries, and nonspecific conference proceedings will be excluded to focus on including primary results and not preliminary findings or ongoing research; however, the reference lists of relevant reviews will be hand searched for relevant articles.

References for all included studies will be uploaded and managed through EndNote (Niles & Associates) [59] and duplicates will be removed before importing sources into Covidence (developed by an Australian not-for-profit company) [60]. To increase the reliability, a pilot test of the level 1 (title and abstract) screening form based on the criteria outlined above will be conducted on a random sample of approximately 50 papers by the entire team. The descriptions of the eligibility criteria will be revised if deemed necessary by the team or if a low agreement (ie, <70%) [61] is observed to improve the consistent application of the selection criteria**.** Our agreement will be defined by Cohen κ [62]. All screening (ie, levels 1 and 2, full-text) will occur in duplicate and independently. For level 1 screening, reviewers will screen the titles and abstracts for

XSL•FO
RenderX

inclusion using Covidence. For level 2, the full text of potentially relevant articles will then be collected and screened to determine final inclusion. A pilot test of the level 2 screening will also be performed on approximately 25% of the articles, similar to the process for level 1 screening. When necessary, another reviewer knowledgeable in the research area will be available to resolve conflicts. For studies that are excluded at level 2, the reason for exclusion will be recorded. Evidence screening will be managed using Covidence software [60]. Members of the research team, including members of the iKT panel, will conduct the screening.

Stage 3: Data Extraction

A standardized data extraction form will be developed by the research team, in consultation with the JBI manual data extraction suggestions [52] and the recommendations for the extraction, analysis, and presentation of results in scoping reviews [63]. Extracted data will include study characteristics (eg, year of publication and study design), participant population characteristics (eg, medical condition, age, race, sex, gender, and gender-related variables such as education and health literacy), types of health interventions (eg, in-person support program and apps), and details of the models, theories, frameworks (eg, name, reference, date of initial development, components, values or principles (and how they were enabled or enacted), associated methods and methodologies) that have been used in the co-design of complex health interventions. We will also collect data on how end users were engaged throughout the various stages of the co-design process and outcomes achieved as well as the results of the study. Additional categories will likely be identified through the completion of the search and through discussions with the research team.

To ensure all relevant results are extracted, 2 research assistants will conduct a pilot extraction by trialing the extraction template for 2 to 3 articles. All data will then be extracted in duplicate by 2 independent reviewers. Discrepancies in the extracted data will be discussed and resolved by the 2 reviewers. Quality or risk of bias will not be assessed, as this is not required in scoping reviews [55].

Stage 4: Data Analysis

The bibliographic data from this scoping review will be quantitatively summarized using numerical counts (eg, number of studies from Canada, the United States) and qualitatively using content analysis [64]. These data will be analyzed or coded manually. The data will be grouped by the main components of the model, theories, frameworks, values or principles (and how they were enacted), associated methods (eg, one-on-one interviews), and methodologies. We will also synthesize data on how end users were engaged throughout the various stages of the co-design process, the types of outcomes collected, as well as results. Depending on the included articles, subgroup analyses might be conducted by, for instance, complex health intervention type, sex, gender-related variables, as well as the other PROGRESS-Plus characteristics (eg, race, ethnicity, culture, language, education) [65]. If feasible, we will contact the study authors of the included studies to confirm that all the data collected were included in the article (eg, not excluded due to word count limitations of a journal).

Dissemination

The results of this scoping review will be used to inform the surveys for the Delphi discussions that will be implemented in phase 2, as well as the draft PRECISE guideline. Findings from the scoping review will help to identify which components, values or principles, associated methods and methodologies, and outcomes will be included in the guideline. Other outputs from the scoping review will include a peer-reviewed publication of the results, as well as a newsletter and webinar to promote engagement for phase 2.

Phase 2: Modified Delphi Process to Prioritize Items for the PRECISE Guideline

Study Design

As consensus-building processes are crucial in developing a reporting guideline as per the EQUATOR process [49], the prioritization of the PRECISE guideline items will occur using a modified Delphi process [47]. A modified Delphi process refers to a variation or adaptation of the traditional Delphi method. The Delphi method is a structured and iterative process used to gather insights and perspectives from a panel of experts to reach a consensus or make informed decisions [47,66]. The Delphi process involves repeated surveys to collect previously unknown information from a group of individuals with expertise in a particular area. Participants in a Delphi process are usually given a large number of items that need to be rated or ranked. Consistent with the methods used to develop other reporting guidelines [55], we will conduct this process over 3 rounds. The succeeding iterations of each round of the Delphi process are intended to decrease the number of items based on analyses of participant responses and denote the consensus of these experts.

Identification and Recruitment of Participants for the Modified Delphi Process and Web-Based Consensus Meeting

A multinational, multidisciplinary, and panel of experts specializing in co-design for the development of complex health interventions will be invited to engage in the modified Delphi process. This panel will consist of individuals from various geographical locations, diverse knowledge user types (including patients, caregivers, and members of the public), and a range of research backgrounds and personal characteristics such as sex, gender, and ethnicity. The experts within this panel will actively contribute their insights and recommendations, particularly emphasizing the involvement of specific patient and caregiver knowledge users.

Given the breadth and diversity of expertise and lived experience required for this study, we will use a purposive and snowball sampling strategy to achieve the recommended minimum sample size of 100-150, consistent with other reporting guideline initiatives [67].

Invitations will be extended to potential expert participants via email, accompanied by a comprehensive explanation of the initiative. To ensure inclusivity, individuals facing technological barriers will be offered assistance to facilitate their participation. This may involve conducting surveys over the phone or

XSL•FO
RenderX

providing participants with necessary devices such as tablets, along with any required training in using the technology.

Data Collection

The round 1 survey will be developed based on the findings of the scoping review. Findings from the scoping review will generate an initial list of PRECISE guideline items that will be reviewed by the researchers and iKT panel. The survey tool will ask participants to rank key concepts in terms of relevance, importance, and comment on the definition of the concept. Pilot testing will be conducted to ensure the content is clear and comprehensible, and necessary revisions will be made before distribution. Participants who complete the round 1 survey will be eligible to participate in the round 2 survey. Likewise, completion of the round 2 survey will determine eligibility for the round 3 survey. Participants in round 2 will be presented with the condensed list of concepts and asked to rank order from most to least important. As with round 1, experts will be asked to comment on the particular concepts listed and add any other categories not identified. This will be repeated for round 3.

During all rounds, participants will be asked to provide demographic and descriptive information, such as sex, gender identity, race, expert participant type, and career stage (if applicable). The web-based survey will be administered using Qualtrics software (Qualtrics XM) for all 3 rounds. This will last 4 weeks, and reminder emails will be sent every 7 days after the initial invitation to encourage participation. Each survey is estimated to take approximately 20 minutes to complete.

Participants will be requested to rate their agreement with the inclusion of each proposed guideline item using a 7-point Likert scale, ranging from “entirely disagree” to “entirely agree.” Surveys will be conducted exclusively in English. Furthermore, each survey item will include an optional text box for participants to provide comments, including suggestions for additions, deletions, aggregations, or refinements of items. This allows for the opportunity to modify and retain items based on participant feedback.

Upon joining the study, participants will be given an exclusive research code for identification purposes. A secure record containing the association between participants’ names and their respective research codes will be maintained on a protected network. Access to this record will be restricted solely to the research administrator responsible for supporting the study.

Analysis

Demographic and descriptive information provided by participants will be analyzed by calculating proportions expressed as percentages. This information will include factors such as sex, gender identity, race, knowledge user type, and career stage if applicable.

Throughout all 3 rounds of the survey, a consensus threshold of 80% agreement will be applied to each guideline item. This means that for an item to be considered as achieving consensus and being kept in the PRECISE guideline, at least 80% of participants must select values of 6 or 7 (mostly or entirely agree with its inclusion) on the Likert scale.

In cases where an item does not meet the 80% agreement threshold, it will be considered discrepant. To gain further insights, potential differences in item agreement will be investigated based on factors such as sex, gender, other aspects of diversity, and knowledge of user type. This analysis will be conducted using chi-square analysis.

Content analysis will be carried out for comments received during the survey [68]. These comments will be summarized and used to inform subsequent surveys. The content analysis process will involve the research team and the iKT panel. These results will be summarized and used to inform subsequent surveys. Furthermore, for the rounds 2 and 3 surveys, participants will be given their individual results as well as the overall group distribution, median, and interquartile range from the previous survey rounds (ie, rounds 1 and 2 surveys). These data will be summarized for transparency and to promote full consideration of discrepant items. In addition, as part of this exercise, in the rounds 2 and 3 surveys, we will ask participants to respond to the question, “After reviewing your survey results with respect to this item (ie, each discrepant item), please comment on why you rated this item the way you did.” Again, content analysis will be conducted on these comments to gain additional insights [68].

Consensus Meeting

After the completion of the 3 rounds of surveys, a web-based 2-day consensus meeting will be organized using Zoom. All expert participants who participated in rounds 1-3 will be invited to attend this meeting. The meeting will begin with a presentation of the summarized results from round 3, including any accompanying recommendations. We will report back demographic differences. Participants will have the opportunity to elaborate on their ratings of discrepant items.

During the consensus meeting, the researchers and iKT panel will draft the PRECISE guideline. This draft will be presented for discussion. Expert participants will collaborate to reach a consensus (ie, 80% agreement) to determine the items to be included in the final version of PRECISE, as well as determine their specific wording. The meeting will also explore the potential recommendation of a core set of items and the linkage of guideline items to checklist items. If appropriate and feasible, the weighting of items will be considered, and both short and long versions of PRECISE will be discussed.

Additionally, the consensus meeting will address how the PRECISE guideline and checklist can promote diverse perspectives and inclusive reporting. Dissemination strategies for the results will also be discussed during the meeting. Detailed records will be kept of all discussions related to the development of the PRECISE guideline and checklist, documenting the decisions made.

Following the consensus meeting, the guideline and checklist will be distributed to the expert participants for their review and to ensure that it accurately reflects the consensus decisions. The final PRECISE guideline and checklist will be tested with approximately 15 researchers or scientists, policymakers, and students by applying it to a study describing the co-design of a

XSL•FO
RenderX

complex health intervention, as done in the development of other guidelines [55].

Ethical Considerations

Research ethics board approval for this component of the study will be sought by the lead author's primary institution. PRECISE will seek to reflect not just the prioritized components and associated methods or methodologies of co-design, but also the values or principles that drive co-design and how they can be enacted or enabled.

Results

This guideline development is supported by the CIHR (Project Grant). This study will take place from April 2023 to March 2025.

Discussion

Expected Findings

This research will address the need for consistent reporting in the literature regarding the use of co-design in developing complex health interventions. The guidelines developed through this study will play a crucial role in facilitating future synthesis of studies in this field. The PRECISE guidelines will build on the GRIPP/GRIPP2 guidelines by emphasizing equal partnerships between researchers, practitioners, and knowledge users to generate shared knowledge and solutions. By following these guidelines, researchers can report on the authentic engagement of patients, carers, and other knowledge users, moving beyond thinly described coapproaches to describe methods and techniques that can move the field forward, and consequently lead to enhanced involvement and the promotion of inclusion of vulnerable populations to a greater extent in intervention design. The PRECISE guideline can improve the proliferation of the co-design method by providing researchers seeking grant funding a template to work from, improving reporting, and allowing for refinement of the method itself.

Strengths and Limitations

This research protocol has several notable strengths that contribute to its methodological soundness and comprehensiveness. One strength of the scoping review is the inclusion of gray literature, which helps mitigate publication bias and ensures a more comprehensive coverage of relevant information [69]. Similarly, we will use an iterative approach to ensure we capture all studies, using guidance from other published reviews and our iKT panel. Additionally, we will conduct a thorough search of reference lists in the included articles and have the search strategy peer-reviewed to further strengthen the quality and comprehensiveness of the search strategy, ensuring that it is thorough and effectively captures relevant literature. All searches will be performed by an information specialist experienced in scoping and systematic review methodologies including reviews on patient engagement. Due to resource limitations, we have made the decision to only include studies that are available in English as part of our inclusion criteria. However, we recognize that this approach may result in the exclusion of relevant studies published in languages other than English. Moreover, our protocol was developed with the EQUATOR guidelines in mind [49].

Future Directions

We will use a range of passive and active knowledge translation methods to disseminate our research findings. Traditional knowledge translation approaches will involve sharing our findings through local, national, and international meetings, as well as publishing in reputable peer-reviewed journals. Our project will yield open-access publications, including the scoping review itself, and the Delphi process, which will include the PRECISE guideline and checklist along with an explanation and elaboration (E and E) document, consistent with guidance provided by Moher et al [70]. We will widely share the PRECISE guideline and checklist within our networks. Input from our iKT panel and other knowledge users will inform our dissemination strategies and guide the planning of future research initiatives. The research team's strong connections to key journals in this space, such as *Health Expectations*, *Design for Health*, and the *International Journal of Integrated Care*, highlight our ability to disseminate our contributions to the advancement of co-design methodologies and practices.

Conclusions

The collective results of this project will lead to the development of a ready-to-implement PRECISE guideline that outlines a minimum set of items to include when reporting the co-design of complex health interventions. The PRECISE guideline will improve the consistency, transparency, and quality of reporting on studies by researchers and multiple knowledge users in policy and practice, including patients, that use co-design to develop complex health interventions. Additionally, it will include guidance on enacting or enabling the values or principles of co-design for meaningful and collaborative solutions (interventions). PRECISE might also be used by peer reviewers and editors to improve the review of manuscripts involving co-design. Ultimately, the PRECISE guideline will facilitate more efficient use of new results in complex health intervention development and bring better returns on research investments.

Abstract

Background: Older adults (people aged 65 years and older) face many difficult decisions. Patient decision aids (PtDAs) can help them and their families make informed value-congruent decisions. Some PtDAs have been developed for the home care context, but little is known about scaling them for use with older adults in a different culture.

Objective: This study aims to (1) assess the scalability of existing PtDAs for older adults in the home care context; (2) prioritize those that best match the decisional needs of older adults in home care; and (3) culturally adapt the prioritized PtDAs so they can be scaled successfully to the Quebec health care system.

Methods: This multimethod study includes 3 phases. All phases will be overseen by a steering committee of older adults, caregivers, health professionals, decision makers, community organization representatives, and researchers with the needed expertise. In phase 1, we will use the Innovation Scalability Self-administered Questionnaire, a validated scalability self-assessment tool, to assess the scalability of 33 PtDAs previously identified in a systematic review. Based on their scalability, their quality (based on the International Patient Decision Aids Standards), and the importance of the decision point, we will retain approximately a third of these. In phase 2, we will conduct a 2-round web-based Delphi to prioritize the PtDAs selected in phase 1. Using a snowball recruitment strategy, we aim to recruit 60 Delphi participants in the province of Quebec, including older adults, caregivers,

XSL•FO
RenderX

health professionals, decision makers involved in home care services, and PtDA experts. In the first round, we will ask participants to rate the importance of several PtDA decision points according to various criteria such as prevalence and difficulty on a 5-point Likert scale (1=not important to 5=very important). Approximately 6 of the highest-rated PtDAs will be retained for presentation in the second round, and we will select up to 3 PtDAs judged as having the highest priority for cultural adaptation. In phase 3, using the Chenel framework and user-centered design methods, we will update and adapt the PtDAs to the Quebec health care system and integrate these PtDAs into an interprofessional shared decision-making training program for home care teams. The adapted PtDAs will respect the International Patient Decision Aids Standards criteria.

Results: This study was funded in March 2022 by the Canadian Institutes of Health Research. Data collection for the web-based Delphi began in October 2023. Results are expected to be published in May 2024.

Conclusions: This project will provide relevant and culturally appropriate decision support tools for older adults making difficult decisions and their home care teams that will be ready for scaling across the province of Quebec.

Introduction

In Canada, the number of people aged 65 years or older has tripled over the past 40 years, and the current population is expected to grow by 68% by 2037 [1]. In the province of Quebec, Canada, people aged 65 years or older represent 21% of the population and should reach 26% by 2041 [2,3]. While 6.5% of all adults have received home care services in Quebec, this proportion rises to 28% among adults aged 75 years or older [4]. Thus, the demand for health and social services for older adults within the context of home care is likely to increase in the coming years. As older adults lose their autonomy and face increasing health problems, health decisions become more frequent as well as more difficult and decisions faced within the home care context present specific challenges [5].

Shared decision-making (SDM) is a collaborative process whereby clinical teams support individuals and their families to make informed health and social care decisions based on the best evidence and what matters most to them [6,7]. It fosters informed consent [8] and improves care experiences [9,10], health outcomes [10-12], clinical team well-being, and efficiency [13,14]. SDM also reduces the uptake of unproven treatments and, consequently, reduces health care waste [15]. It supports health equity, since the most vulnerable may benefit the most [16-18]. Finally, SDM has been adapted to and successfully tested in the home care context among interprofessional teams [19-21]. It was shown that home care interprofessional teams trained in SDM, along with older adults and their caregivers who had benefited from a decision aid, were more likely to share decisions together about housing transitions [19,20,22-24].

Patient decision aids (PtDAs) are tools that support people in defining the decision to be made, provide information regarding options and outcomes, and help clarify personal values and preferences [25]. They have been successfully used to bolster SDM [26] and to promote the involvement of family members in health decisions [19]. They have been shown to increase participants' knowledge, decrease their decisional conflict, and reduce the number of people who were passive or undecided in decision-making. They also improve patient - clinician communication and patient satisfaction with their decisions [16,18,27].

However, the uptake of SDM and PtDAs in Canada has been disappointing [15]. In a 2018 survey of 1591 Canadians, only 36% of older adults reported that they were always or often offered choices, and only 35% were always or often asked what was important to them. Among them, 8.9% reported receiving home care services, and results showed that they were the least engaged in decisions about their health [28]. In order to address this inequity in decision support, we conducted 2 pan-Canadian surveys and found that older adults in the home care context face numerous difficult decisions that fall under 3 main areas: housing and safety, managing health conditions, and end-of-life care [5,29]. In another survey, health care professionals reported that older adults and their family members needed more help in obtaining information about available options, dealing with peer pressure, and navigating the health care system [30].

We hypothesize that widespread uptake of PtDAs will be more likely if they are adapted to the context in which they will be used [31-33]. Most PtDAs are created to target 1 decision point, 1 defined population, and 1 context or health care system, but when they are scaled to further contexts, they rarely address the specificities of the stakeholders or health care systems into which they will be integrated. Rather than creating a new PtDA for each context, the adaptation of existing PtDAs has numerous benefits: it reduces the duplication of development efforts, optimizes the use of resources, improves relevance and applicability, and engages knowledge users in target locations [34].

Therefore, we propose the ENGAGE (Engagement of Older Adults Receiving Home Care Services and Their Caregivers in Health Decisions in Partnership With Clinical Teams) study: an integrated knowledge mobilization (iKM) scaling project whose aim is to assess the scalability of existing home care PtDAs, prioritize them in relation to the decisional needs of older adults in home care, and culturally adapt them so they can be scaled successfully to the Quebec health care system.

XSL•FO
RenderX

Methods

Overview of Study Design and Context

The ENGAGE study is a multimethod study with 3 phases: (1) a scalability assessment, (2) the prioritization of existing PtDAs, and (3) cultural adaptation of the most relevant PtDAs to the specificities of the stakeholders and the Quebec health care system. Each phase will use a distinct methodology to meet the objectives.

The ENGAGE study will be conducted within the Quebec health and social care system, 1 of 14 independent health and social care systems in Canada. Each of these systems (1 in each province or territory and 1 at the federal level) is responsible for coordinating, insuring, and managing care and services for the population. Within Quebec, health care services, including home care services, are provided by 18 regional authorities [15,35]. Since the province of Quebec has its own health care system and regulations, and its population is mostly French speaking, PtDAs need careful and culturally sensitive translation and need to be adapted to the Quebec situation, for example, include options available specifically in Quebec, to ensure their uptake by the population [36].

Throughout the project, we will use an iKM approach to strengthen our partnerships with knowledge users and other interested parties [37]. We will form a steering committee of 8-10 persons to oversee the operationalization of the project. The committee will involve older adults, caregivers, health professionals, decision makers in health organizations offering home care services, representatives of community organizations offering services to older adults and caregivers, and representatives of the provincial health ministry. The committee will also include researchers with the expertise needed to conduct the project, that is, experts in PtDAs, the interprofessional SDM approach, Delphi design, scaling, and research with older adults receiving home care services. We will recruit the committee through our networks in 2 regional health authorities (1 rural and 1 urban). We will organize at least 6 meetings over the course of the project to ensure the engagement of committee members in all phases of the project. We will also send quarterly newsletters to all knowledge users and partners to inform them of the project's progress. We will remain attentive to the needs of the knowledge users and will respect the constraints of the managers and workers in the clinical settings as well as the older adults and their families. We will also contribute to capacity building by including trainees in all phases of this project. Finally, considerations of sex, gender, equity, diversity, and inclusion will be considered at all stages of the project using the Canadian Institutes of Health Research (CIHR) guidelines [38,39].

To ensure accurate reporting of the iKM approach, we will report results using the Guidance for Reporting Involvement of Patients and the Public (GRIPP2) checklist [40]. We will also report on the adaptation of PtDAs according to the Guidance for Reporting Intervention Development Studies in Health Research (GUIDED) checklist [41].

Phase 1: Scalability Assessment of the Existing PtDAs

We recently completed a systematic review of PtDAs developed for home care [42]. For them to reach the largest proportion of people who can benefit from them, PtDAs for home care use must be analyzed for their scalability. Scalability is the ability of a health innovation that has demonstrated effectiveness under controlled conditions to be expanded in real-life circumstances to reach a larger proportion of the eligible population while still maintaining effectiveness [43]. Our team developed and tested the Innovation Scalability Self-administered Questionnaire (ISSaQ), a validated evaluation tool for assessing the scaling potential of health innovations that is designed to be used by teams planning to scale health and social services innovations [44,45]. ISSaQ is a list of 37 items covering 12 essential components of scalability, such as evidence on the effectiveness of the innovation, its characteristics, its acceptability, its adaptability, and the quantifiable costs and benefits of scaling (Multimedia Appendix 1, in French only). We will therefore use the ISSaQ to assess the scalability of each of the 33 PtDAs developed for home care that were identified in our systematic review [42].

First, we will retrieve all available information on each of the PtDAs included in our systematic review by searching for publications. A total of 2 team members will then independently extract the characteristics of the PtDAs (eg, type, purpose, decision point, target population) and complete the ISSaQ scalability assessment grid for all 33 PtDAs identified in the literature [42]. Any disagreements will be discussed with a third team member to reach a consensus. The results will be synthesized and discussed with the steering committee. Given the large number of PtDAs identified in the literature review (n=33), the steering committee will then select approximately one-third of the PtDAs based on the relevance of the decision point to home care for older adults in the experience of the steering committee, their scalability, and their quality according to the international criteria established by the International Patient Decision Aid Standards (IPDAS) Collaboration [46]. In order to reach a consensus on the final selection, steering committee members will vote according to all 3 criteria mentioned above, and PtDAs receiving the highest number of votes will be selected for the next phase.

Phase 2: Prioritization of PtDAs Selected in Phase 1

Study Design

We will conduct a web-based Delphi (e-Delphi) study to prioritize the PtDAs selected in phase 1 [47]. The RAND research organization at the University of California at Los Angeles (RAND/UCLA) appropriateness method will be used to judge the prioritization and relevance of the selected PtDAs (maximum of 10 PtDAs) [48]. The decision point criteria deemed necessary for prioritization will be determined by the steering committee. These criteria could include, for example, the prevalence of the decision addressed by the PtDAs, the level of difficulty of the decision, the date at which the evidence was updated, and its potential for scale-up. A questionnaire will then be developed that addresses the various decision point criteria identified as priorities.

XSL•FO
RenderX

Delphi Participants

Recruitment

We aim to recruit 60 participants in the province of Quebec for this phase of the study to ensure a minimum of 40 participants in both rounds of the e-Delphi study [49,50]. We will use a snowball recruitment strategy, a nonprobability sampling method whereby study participants are asked to recruit future participants from among their social networks [51]. We will recruit older adults, caregivers, health professionals, decision makers involved in home care services (eg, home care team managers, directors of community organizations, managers of health care organizations, and government deputy health ministers or advisers), researchers, and PtDA experts. We aim to recruit a minimum of 8 to 12 participants for each of these categories to ensure representativeness [49]. Inclusion criteria for older adults will be as follows: (1) aged 65 years or older; (2) has home care experience; (3) can participate in the specified timeframe; (4) can read and understand French; and (5) can give informed consent. Inclusion criteria for other categories of participants will be the same except for the following: (1) aged 18 years or older and (2) has home care experience as a caregiver, health professional, decision maker, or expert. We plan to recruit participants using the snowball method with the help of our steering committee members, partners, and knowledge users.

Older Adults and Caregivers

We will ask our partners about the possibility of recruiting potential candidates from their organizations. Our partners in relevant organizations will be invited to share the invitation email with their members and through their social media platforms. The clinical teams in home care working for 2 regional health and social service authorities (1 rural and 1 urban) will also be invited to share the invitation with the older adults and caregivers they meet during their home care appointments. If necessary, with the agreement of the potential participants, the names and telephone numbers of interested individuals may be shared with the research team so that a team member can contact them, explain the project further, and invite them to participate.

Health Care Professionals

Health care professionals will be recruited with the help of managers from the 2 regional health and social services authorities. We will ask them to distribute an invitation email to the health professionals in their organizations. If necessary, we will contact home care managers in other health authorities in the province of Quebec.

Decision Makers

We will solicit our partners who are already in decision-making roles to disseminate the invitation within their networks and help us identify other decision makers.

Other Experts

Finally, members of our research team and collaborating teams will circulate the invitation by email to their respective networks to help us identify potential PtDA experts who can manifest their interest by contacting the team members responsible for the study.

We will make sure all participants understand our research objectives as we prepare and oversee the information provided to them. With a concern for equity, we will also solicit older adults and family members in rural areas, whom we will reach in person if necessary.

Data Collection

The e-Delphi consensus study will be conducted over the web using the REDCap (Research Electronic Data Capture; Vanderbilt University) tools hosted at Université Laval [52,53]. Participants will read and sign a consent form in the REDCap platform before completing the questionnaire. We anticipate that 2 rounds will allow for an acceptable degree of agreement on the PtDAs to be prioritized. There will be an interval of approximately 3 weeks between the 2 questionnaires. Participants who do not have easy access to a computer will be invited to complete the questionnaire during an in-person meeting with a research assistant. For each round, participants will be asked to submit their completed questionnaire within 2 weeks. An email reminder will be sent 48 hours before the end of the 2-week period. In the first round, we will collect participants' sociodemographic information such as age, sex, gender, and education level. For each of the PtDAs selected in phase 1 (maximum of 10 PtDAs), we will present the main characteristics of the PtDAs (eg, decision point addressed, year, and country of development) and an image of each PtDA. Then we will ask participants to rate the PtDA according to the decision point criteria prioritized by the steering committee (eg, prevalence of the decision, level of difficulty of the decision, and potential for scale-up) included in the questionnaire on a 5-point Likert scale (1=not important to 5=very important). Participants will also be able to add free-text comments. We will calculate the overall scores and summarize free-text comments. Results will be synthesized and discussed with the steering committee. The highest-rated PtDAs will be retained for the next round (approximately 6 PtDAs).

In the second round, we will repeat the same procedure, but only the PtDAs prioritized in the first round will be presented (approximately 6 PtDAs). The results of the second round will be summarized and they will be presented and discussed with the steering committee. We will then select up to 3 PtDAs judged as having the highest priority for cultural adaptation (phase 3).

Data Analysis

Descriptive analyses of sociodemographic data will be conducted to profile the participants. Descriptive analyses will also be used to calculate the overall scores for each of the PtDAs after the 2 e-Delphi rounds. Regarding relevance and clarity, if the number of participants giving a score of 4 to 5 for each dimension divided by the total number of participants is greater than 0.80, this will be considered a good score. Regarding necessity, the formula $(Ne - N / 2) / (N / 2)$ will be applied, where Ne is the number of participants indicating an element as important and N is the total number of participants. This indicator varies between –1 and +1, with higher scores indicating

XSL•FO
RenderX

consensus. Results will be collated using SAS (version 9.0; SAS Institute Inc) to calculate the median score and percentage of agreement. We will summarize the open-ended comments using thematic analysis.

Phase 3: Adaptation of Prioritized PtDAs to the Specificities of the Stakeholders and Health Care Systems Into Which They Will Be Integrated

Chenel et al [54] propose a framework for cultural adaptation of PtDAs in 4 stages: exploration (ie, identification of content to be adapted), adaptation (ie, incorporation of modifications), pilot testing (ie, validation with knowledge users), and field testing (ie, validation in a real-world context). Informed by this framework, we propose to pilot the cultural adaptation of the selected PtDAs using user-centered design methods and to set up a process that will serve as a proof of concept for the adaptation of the PtDAs to Quebec.

Specifically, with the help of the steering committee and the extended knowledge user group involved in this project, we will translate the selected PtDAs into French and identify the content that needs to be adapted, such as evidence updates and local information on available options. The research team will then incorporate these changes into the new versions of the selected PtDAs. We will engage language editors or graphic design services as needed. We will then validate the new versions with the steering committee members and our extended knowledge user team, using a new collaborative web-based platform for designing printable and interactive PtDAs [55]. This user-tested platform (PADA) was developed by an international team and enables the collaborative design, revision, or adaptation of PtDAs for multiple needs and contexts. PADA also facilitates the collection and integration of knowledge users' feedback [56]. Agendas and minutes of each meeting will be produced to document the process of adapting the PtDAs to the Quebec cultural context. The final step will be to integrate the adapted PtDAs into an interprofessional SDM training program. Our team produced and contributed to the first interprofessional model of an SDM training program [57,58] and developed with knowledge users an interprofessional SDM training program for the use of a PtDA for housing transitions that was well received in home care settings [19-21,59]. We will develop a new generic version of this interprofessional SDM training program that can be used in conjunction with the selected PtDAs or any other PtDA.

Ethical Considerations

This project was approved by the ethics committee of the Centre intégré universitaire de santé et de services sociaux de la Capitale-Nationale (MP-13-2023-2848). All stages of this research project will be carried out in accordance with Canadian procedures for informed consent (Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans) [60]. These procedures include disclosure of benefits, risks, and drawbacks of participation, documentation of consent, patient or surrogate competency, plain language, the voluntary nature of the decision, consent for future use of data, confidentiality of data, and data management practices. All participants will give informed consent before participating in the study.

Results

This study was funded in March 2022 by the CIHR. This protocol was initially submitted before any participants were recruited. The steering committee was recruited in June 2023 and is ready to begin its work. The committee consists of 2 older adults or caregivers; 1 representative of an organization whose mission is to improve services for older adults; 2 health professionals who are also decision makers in 2 health organizations offering home care services in the province of Quebec; 1 representative of the provincial health ministry; 1 geriatric internist with expertise in research with older adults receiving home care services; 1 family physician with expertise in SDM, PtDAs, scalability assessment, and e-Delphi studies; and 1 junior researcher with expertise with SDM and PtDAs. The consensus meeting with the steering committee to select the PtDAs to be prioritized in the e-Delphi study was held in September 2023. Data collection for the e-Delphi study began in October 2023. Results are expected to be published in May 2024.

Discussion

This study will provide information about the scalability of PtDAs relevant to home care, a prioritized list of PtDAs for home care, and up to 3 PtDAs culturally adapted to the specificities of the Quebec health care system and stakeholders in the home care context. The study will provide a proof of concept of the process of adapting the PtDAs and integrating them into an interprofessional SDM training program for the home care sector so they can be scaled successfully in the Quebec health care system.

This study has several notable strengths. First, this project was developed as part of a collaboration with knowledge users that dates back to 2007, and its objectives were developed in response to their stated needs [19,20,28,59,61-63]. We have assembled an experienced interdisciplinary team with a long history of collaboration who possess expertise in developing and adapting PtDAs for the home care sector. In addition, the goals of this project are supported by earlier studies conducted by our team since 2007 showing that older adults have unmet needs for support in making shared informed decisions [5,19,20,28-30,59,61-63] and that the engagement of older adults and their families in health and social care decisions is encouraged by the use of PtDAs and training of clinical teams in SDM [19,20,64,65]. Since most PtDAs are in English and were developed in high-income countries, another strength of this study is that it will contribute to the literature on the cultural adaptation of PtDAs, not only for the Canadian context but for any context where languages and cultures differ within the same region or country.

The main limitation is that the PtDAs we will prioritize have been identified in a systematic review of published literature [42]. It is therefore possible that these PtDAs do not represent all the current or emerging difficult decisions faced by older adults, their families, and stakeholders. During the COVID-19 pandemic, different decisional needs emerged among older adults that affected their care, such as "should I delay my

XSL•FO
RenderX

surgery?" [66,67]. To address this limitation, if participants express a desire for new PtDAs that do not yet exist, we will use the generic Ottawa decision aid to create one that is culturally adapted to the Quebec context [68]. Finally, operational issues could include recruiting enough people for the e-Delphi study. If we are unsuccessful with our current methodology, we will ask the 32 home care teams who participated in our previous home care randomized trials to suggest additional potential members [19,21].

The ENGAGE project is a response to a declared urgent need by the Quebec government to address gaps in home care [69-72], including the need to support and empower older adults and their families in health-related decision-making. This project will provide relevant and culturally appropriate decision support tools for older adults making difficult decisions and their home care teams. The resulting tools will be ready for scaling across the province of Quebec.

Acknowledgments

Abstract

Background: The COVID-19 pandemic has had a profound impact on emergency department (ED) care in Canada and around the world. To prevent transmission of COVID-19, personal protective equipment (PPE) was required for all ED care providers in contact with suspected cases. With mass vaccination and improvements in several infection prevention components, our hypothesis is that the risks of transmission of COVID-19 will be significantly reduced and that current PPE use will have economic and ecological consequences that exceed its anticipated benefits. Evidence is needed to evaluate PPE use so that recommendations can ensure the clinical, economic, and environmental efficiency (ie, eco-efficiency) of its use.

Objective: To support the development of recommendations for the eco-efficient use of PPE, our research objectives are to (1) estimate the clinical effectiveness (reduced transmission, hospitalizations, mortality, and work absenteeism) of PPE against COVID-19 for health care workers; (2) estimate the financial cost of using PPE in the ED for the management of suspected or confirmed COVID-19 patients; and (3) estimate the ecological footprint of PPE use against COVID-19 in the ED.

XSL•FO
RenderX

Methods: We will conduct a mixed method study to evaluate the eco-efficiency of PPE use in the 5 EDs of the CHU de Québec-Université Laval (Québec, Canada). To achieve our goals, the project will include four phases: systematic review of the literature to assess the clinical effectiveness of PPE (objective 1; phase 1); cost estimation of PPE use in the ED using a time-driven activity-based costing method (objective 2; phase 2); ecological footprint estimation of PPE use using a life cycle assessment approach (objective 3; phase 3); and cost-consequence analysis and focus groups (integration of objectives 1 to 3; phase 4).

Results: The first 3 phases have started. The results of these phases will be available in 2023. Phase 4 will begin in 2023 and results will be available in 2024.

Conclusions: While the benefits of PPE use are likely to diminish as health care workers' immunity increases, it is important to assess its economic and ecological impacts to develop recommendations to guide its eco-efficient use.

Introduction

Background

The Impact of the Pandemic on Emergency Departments

The COVID-19 pandemic has had a profound effect on emergency care in Canada and around the world. Emergency departments (EDs) have been reconfigured to meet the new demands of the pandemic [1]. Some of the reconfigurations include increased capacity, physical divisions into identified risk zones, changes in care protocols, redefinition of staff tasks, and development of protective measures against COVID-19 nosocomial transmission [2,3].

Personal Protective Equipment

In order to prevent transmission at the peak of the pandemic, personal protective equipment (PPE) was required for all ED care providers (eg, physicians, nurses, and nursing assistants) in contact with patients with proven or suspected COVID-19. PPE encompasses all clothing and other equipment used to protect health care workers from injury or infection [4], and is considered the last step in the hierarchy of controls in infection prevention [5,6]. With respect to the COVID-19 pandemic, the term PPE refers primarily to two options (see Multimedia Appendices 1 and 2) [7]: (1) standard PPE, which includes procedural masks, isolation gowns, nonsterile gloves, and ocular protection; and (2) enhanced PPE which includes respirators (eg, N95), water-repellent gowns, long-cuff nitrile procedure gloves, and face shields. Since the beginning of the pandemic, the understanding of the COVID-19 modes of transmission and the most effective equipment to protect against it have greatly evolved. In many jurisdictions, enhanced PPE was initially reserved for aerosol-generating procedures (eg, endotracheal intubation), that is, aerosolized particles of <5 µm that can remain suspended in the air for extended periods of time and circulate over long distances on air currents [8]. In Canada, in 2021, the use of enhanced PPE with a respirator has gradually become the norm when caring for patients with confirmed or suspected COVID-19 cases, even in the absence of aerosol-generating procedures [9-11].

Conflicting Rules for PPE Use

The rules for PPE use in health care settings have fluctuated greatly and have been a source of uncertainty [8,12]. Often developed as a compromise between incomplete scientific evidence [7,8,13], uncertain PPE supplies [14-16], and staff concerns [12,17], these rules were sometimes so confusing for health care workers that their trust towards the infection control teams and managers was diminished [17]. Although the benefits of PPE for protecting health care workers against SARS-CoV-2 have been demonstrated [7,13,18], the level of evidence is relatively low and its use is more or less influenced by subjective preferences and personal values [19].

New Context, New Rules?

Although the achievement of a certain level of immunity in the population provides significant protection against severe or chronic symptoms of COVID-19 [20], important questions remain; what types of PPE will be needed to protect health care workers as SARS-CoV-2 becomes endemic and circulation in the community continues unabated? Somewhat less discussed since the beginning of the pandemic, the societal consequences of PPE use must also be considered. What will be the opportunity cost for public institutions to pursue the expanded use of PPE [21-23]? What is the ecological cost of continuing on this path [24-27]? More than ever, evidence is needed to evaluate PPE use and to provide recommendations that ensure the clinical, economical, and ecological efficiency of its use.

Hypothesis and Research Goal

With mass vaccination and improvements in several infection prevention components included in the hierarchy of controls, our hypothesis is that the risk of transmission of COVID-19 will be significantly reduced and that wearing fully enhanced PPE for every suspected COVID-19 patient will have economic and ecological consequences that exceed the anticipated benefits. To support the development of optimal rules for PPE use, our research objectives for this project are to (1) determine the clinical effectiveness (reduced transmission, hospitalization, mortality, and work absenteeism) of PPE to protect immune and nonimmune health care workers against COVID-19; (2)

XSL•FO
RenderX

estimate the financial cost of using PPE in the ED for the management of patients with suspected or confirmed COVID-19; and (3) estimate the ecological footprint of PPE use against COVID-19 in the ED.

Theoretical Framework

Our objectives address a transdisciplinary subject that goes beyond the boundaries of health research and consequently requires a conceptual framework that aggregates complementary theoretical approaches. We therefore propose an extended application of the value-based health care framework, which consists of orienting care practices, decisions, and policies to obtain the best health outcomes at the lowest cost. This model, developed by Porter [28-30] in the 2000s, is now widely used by various organizations [31-35] to improve health services. Optimizing the value of care can, among other things, be achieved by reducing its costs, which can be minimized by eliminating the inappropriate use of resources. The notion of value thus overlaps with the notion of eco-efficiency [36]. The Organization for Economic Cooperation and Development defines it as "a management philosophy that encourages business to seek environmental improvements that are accompanied by economic benefits" [37,38]. Eco-efficiency is closely tied to the appropriate use of resources extracted from the environment and the emissions generated throughout the life cycle in order to increase the economic value of what is ultimately produced. By revisiting these 2 concepts for our research framework, we will define eco-efficiency in health care as the maximization of the clinical benefits of a health care activity while minimizing its costs and its ecological footprint.

Methods

Setting

The project will evaluate the eco-efficiency of PPE use in the 5 EDs of the CHU de Québec-Université Laval (hereafter the CHU) in Québec City (Canada). The CHU is the largest academic hospital in Québec and 1 of the 3 largest in Canada. Its EDs record nearly 240,000 visits annually. They form the same clinical department, use the same protocols, and offer similar care paths. In terms of PPE, the donning and doffing protocols are identical. All CHU wards use disposable PPE. At the beginning of the pandemic, all CHU EDs cleaned and reused protection goggles and face shields. Similarly, one ED site used reusable gowns but has since switched to fully disposable PPE (Multimedia Appendix 3). The CHU's EDs are an ideal setting to conduct the proposed study because (1) several thousand units of PPE are used daily; (2) each of the 5 EDs has cold (non–COVID-19), warm (suspected COVID-19 cases), and hot (confirmed COVID-19 cases) areas; (3) there is a large diversity of patients, from children to elderly, and both medical and surgical cases; and (4) as opposed to high-risk units such as intensive care and COVID-19 units, where infected patients are grouped together and where the wearing of PPE appears more indicated, the majority of patients evaluated in the ED do not have COVID-19, even when the clinical picture is compatible. It is therefore in the ED that an evaluation of the eco-efficiency of PPE use can have the greatest impact on the recommendations for use in a low-risk clientele. Furthermore, since donning and doffing protocols do not differ significantly from one department to another and are very similar in all institutions in Quebec and across Canada, we will be able to infer some of our results from the entire hospital reality in Canada.

Study Design

We propose a mixed methods, multiphase study, merging approaches from epidemiology, biostatistics, industrial engineering, accounting, health economics, mathematics, psychology, and environmental engineering. To achieve our goals, the project will include four phases: systematic review of the literature to assess the clinical benefits of PPE (objective 1; phase 1); cost estimation of PPE use in the ED using a time-driven activity-based costing method (objective 2; phase 2); ecological footprint estimation of wearing PPE during the pandemic using a life cycle assessment approach (objective 3; phase 3); and cost-consequence analysis and focus groups (integration of objectives 1 to 3; phase 4).

For each of these phases, we will propose analyses distinguishing standard and enhanced PPE.

Phase 1: Systematic Review of the Literature (Objective 1)

Protocol and Registration

The protocol for this review is registered in the PROSPERO database of systematic reviews (CRD42022302598) and we will follow recommendations of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) guidelines for its reporting [39].

Research Question

What effect does wearing PPE have on health care workers' risk of becoming infected with SARS-CoV-2, being secondarily absent from work, admitted to the hospital or to the intensive care unit (ICU), or die? Table 1 shows the PICOS framework for the systematic review.

Table 1. PICOS (population, intervention, comparison, outcomes, and study design) framework for the systematic review.

Population	Health care workers
Intervention	Standard or enhanced personal protective equipment
Comparison	No or incomplete personal protective equipment
Outcomes	SARS-CoV-2 (COVID-19) infection, hospital admission, intensive care unit admission, mortality, and work absenteeism
Study design	Experimental or observational studies

XSL•FO
RenderX

Search Strategy

We will search for studies published since December 2019 (identification of SARS-CoV-2 in Wuhan) comparing health care workers' use of disposable or reusable, standard or enhanced PPE to no protection used or a different combination of PPE components. We will use Medline (Ovid), Embase, Cochrane Library, CINAHL, Epistemonikos, ClinicalTrials.gov, MedRxiv, and Web of Science search engines, without language restrictions. The search strategy was developed with the assistance of a qualified librarian and is available in the appendices (Multimedia Appendix 3). This strategy will be executed three times: (1) at the start of the systematic review (May 2022); (2) at the end of the prepublication data extraction (June 2023); and (3) before phase 4 (January 2024) to update the meta-analysis to adequately inform our focus groups.

Article Selection and Eligibility Criteria

Using the Covidence systematic review software (Veritas Health Innovation), 2 independent reviewers will select abstracts, read the articles, and determine their eligibility. All experimental or observational studies (cohort, case-control, or cross-sectional studies) comparing the use of PPE with the absence of PPE with regard to health care workers' risk of SARS-CoV-2 infection, hospitalization (ward or ICU), death, or absence from work, will be included in the review. Studies evaluating the effect of PPE when worn by nonhealth workers, narrative reviews, editorials, modeling studies without original clinical data, and practice guidelines will be excluded. Systematic reviews will also be excluded but will be consulted to identify original articles potentially missed by our search strategy. Bibliographies of selected articles will be reviewed in the same manner.

Data Extraction and Quality Assessment of Selected Studies

In total, 2 independent reviewers will collect data from the selected articles using a previously tested extraction grid. From each article, they will extract, when available, the following variables: authors; title; date and scientific journal of publication; country where the research was conducted; study design; population studied; sample size; age; gender; sex; vaccination or immune status; and comorbidities of the participants, study outcomes, and results. The quality of the selected studies will be assessed by 2 reviewers using the Cochrane Risk of Bias Tool for randomized studies [40] and ROBINS-I for observational studies [41].

Disagreements Among Reviewers

Disagreement between reviewers will be resolved through discussion and consensus. If a disagreement persists, a third reviewer will mediate to reach a final consensus.

Analysis and Synthesis of Results

The results will be presented in tabular and narrative form and will compare the benefits of standard or enhanced PPE to the absence of PPE use. Based on previous systematic reviews, we know that a random effects model meta-analysis is feasible and will then be conducted. According to the original data available, we will calculate estimates of relative risks (RR) or odds ratios (OR) on the risk of transmission of SARS-CoV-2 and of the other outcomes evaluated. The necessary numbers of PPE that must be used (number needed to treat) to prevent one SARS-CoV-2 transmission, admission, or death among staff will be calculated secondarily. Randomized studies will be analyzed separately from observational studies, as recommended by the Cochrane Handbook [42,43]. If studies are in sufficient numbers, we will conduct subgroup analyses by analyzing separately (1) the studies conducted in EDs; and (2) the studies conducted after the start of vaccination in the country where the research took place. Heterogeneity between studies will be assessed using the I^2, a statistic that estimates the percentage of variation in results between studies that are not explained by chance. Thus, an I^2 value between 0 and 40% will be considered to represent a low level of heterogeneity, while values between 30% and 60% represent a moderate level, between 50% and 90% a substantial level, and between 75% and 100% a considerable level [44]. The causes of heterogeneity will be examined by stratifying our outcome measures by (1) the country where the studies were conducted and (2) the clinical departments or units from which the data originated (eg, COVID-19 unit and ICU). We will also conduct a sensitivity analysis excluding studies with a high risk of bias. Finally, the quality of evidence for each outcome (high, moderate, low, and very low) will be assessed using the GRADE (Grading of Recommendations Assessment, Development, and Evaluation) approach [45].

Phase 2: Cost Estimation of PPE Use (Objective 2)

Concept

The cost of PPE use goes beyond the cost of purchasing its components. Wearing PPE means donning and doffing by care providers who, during this time, cannot engage in direct care, which is a cost to the health care system. Using PPE also incurs costs for material disposal (eg, garbage collection) and overhead (eg, supply management). Therefore, we will estimate the mean cost of wearing PPE in the CHU for contact with a possible case of COVID-19 using a time-driven activity-based costing method [46,47]. This method accounts for all expenditures incurred during direct patient care (eg, staff salaries and medical costs), consumables (eg, masks), and management costs (eg, disinfection service). It uses the duration of care processes to estimate the associated cost; the longer a process (eg, donning PPE) takes to be performed, the higher the cost. It provides a simpler, more accurate, and more reliable way of estimating the cost of health services than other methods frequently used in research or management, such as diagnosis-related group methods (DRG), the level of relative intensity of resource use (NIRRU) or the conventional activity-based costing method (ABC) [48-50]. Time-driven activity-based costing was previously used in many health care settings [48,51-56] and our team successfully adapted it for use in the ED [57-59]. For this project, we will apply this costing method to the care pathway of patients suspected with COVID-19 in the ED. We will analyze the processes involved in PPE use and disposal. The disposal component will include both trajectories of completely disposable PPE versus reusable gowns, as one of our sites used reusable gowns at the beginning of the pandemic. Cleaning of the reusable gowns was done by a subcontractor (Partagec), as

XSL•FO
RenderX

such, the cleaning cost will be estimated based on the weight of the gowns used as stipulated in the contract with Partagec.

Method Steps

Overview

Time-driven activity-based costing essentially requires two parameters: (1) the cost per minute for each human or material resource involved in care, and (2) the duration in minutes of each care process. To derive these, we will use data from the fiscal year beginning April 1, 2020, through March 31, 2021. We will estimate the average costs of standard and enhanced PPE using the following steps.

Process Maps

We will first map the ED care pathway of suspected COVID-19 cases. We will also map all specific processes performed in the wearing, disposal, recycling, and disinfection of PPE. This will primarily include (1) donning, (2) doffing, (3) disposal, and (4) collection and disinfection or cleaning of reusable components.

Time Measurements

We will estimate the mean time required to complete each mapped process through prospective field measurements at the ED using a time-motion study software (UmtPlus Max, Laubrass).

Resource Costs per Minute

We will calculate the cost per minute (CAD $ per minute; with an average currency exchange rate of CAD $1=US $0.8) of each human or material resource identified in the process maps by dividing its total annual cost for the year 2020-21 by the number of minutes in the same year that the resource was available for care or service. The following is an example from our previous work.

If applicable, a similar calculation will be performed for equipment by considering depreciation and maintenance expenses in the numerator and the number of minutes in service in 2020-21 in the denominator. The cost per minute of emergency physicians will be estimated by the same formula, but the total annual medical expenditures will be estimated using the average annual earnings of an emergency physician as obtained from the regulatory medical associations.

Consumable Costs

We will calculate from the CHU accounting records the average unit cost (CAD $/unit) of each component (gown, gloves, masks, and ocular protection) of PPE purchased by CHU in the financial year 2020-2021 and then break down the specific costs by supplier. The reusable equipment purchase cost will be amortized over the anticipated number of uses.

Overhead Expenses per Minute

Following a formula similar to item 3, we will calculate the cost per minute (CAD $ per minute) of overhead incurred by the CHU for PPE use (eg, rental or transportation of waste containers), by dividing the total overhead related to PPE use in the ED for the year 2020-21 by the number of minutes available for the care of the staff using PPE as part of their work.

Mean Process Costs

We will estimate the mean process costs for PPE by summing the costs of resources, consumables, and overhead according to the calculation presented in the following example based on previous work data and preliminary estimates. Similar calculations will be performed for all PPE-related processes (eg, doffing).

Further details on the method and its practical application can be found elsewhere [60,61].

Analyses

The preceding steps will estimate for each category of ED care providers (eg, nurses and physicians) the mean cost incurred during the pandemic for one standard and one enhanced PPE use, which includes donning, doffing, disposing, and disinfection or cleaning. A set of subanalyses will then estimate (1) the minimum and maximum costs of PPE use based on the minimum and maximum supplier unit costs of the PPE components purchased by the CHU in 2020-2021; (2) the weighted mean cost of PPE use based on the weight of participation of each category of providers in the care pathway, estimated using the mapping of a typical care pathway for COVID-19 in the ED (Multimedia Appendix 4); (3) The total cost of PPE use in the CHU EDs based on the number of suspected COVID-19 cases that consulted since the start of the pandemic, the weighted mean cost of using PPE, and the number of contacts with PPE per episode of care estimated with the mapping; and (4) mean costs based on component costs in the year prior to the pandemic (financial year 2019-2020) to estimate the effect of the shortage on equipment selling prices.

Phase 3: Ecological Footprint Estimation of PPE Use (Objective 3)

Concept

The ecological footprint of standard and enhanced PPE will be estimated through a life cycle assessment that will measure the pollutant load of all material and energy resources used (inputs) and residual materials generated (outputs) by their use (Multimedia Appendix 5 for a typical life cycle diagram). The analysis will assess the environmental impact of the consumables (eg, gloves) and processes (eg, disinfection of face shields) required for PPE use in CHU EDs from cradle to grave, that is, from their design and manufacturing to their final disposal. The life cycle assessment methodology, which is well established in the industrial field, has previously been used in the health field as well [62-64].

Methodology Phases

Overview

The life cycle assessment will follow the ISO-14040/ISO-14044 standards governed by the International Organization for Standardization [65-67]. These international standards are developed through consensus among experts from industry,

XSL•FO
RenderX

consumer associations, governments, nongovernmental organizations, and universities. The standards that will be used for this project provide a framework for an environmental management system, specifically the realization of a life cycle assessment. We will take the following steps.

Definition of the Objectives and Scope of the Study

The analysis will aim to assess the ecological footprint of one PPE used by a care provider in the ED for contact with a potential or confirmed COVID-19 case (functional unit). We will compare the ecological footprints of standard and enhanced PPE assuming an uneven level of protection that will be measured with the systematic review from the previous phase. Since supplies fluctuated over the course of the pandemic resulting in a very wide variety of equipment at the CHU, we will limit our analyses to those PPE components that were (1) the most frequently used, (2) the most and least costly, and (3) those whose supply contracts predict their predominant use for the foreseeable future.

Emissions and Extractions Inventory

Using the previously developed mappings, we will break down the donning and doffing process as well as the upstream (eg, production) and downstream (eg, disposal) processes to identify the use of consumable or reusable equipment and materials, and their disposition to waste or disinfection units. An inventory of activities and flow of materials, energy, and services will be conducted using data obtained from the CHU and PPE suppliers (eg, raw materials for PPE components and energy consumed at the production plant) and will be scaled to the functional unit level, that is, the use of a single PPE. This inventory will quantify the pollutants emitted and the resources extracted over the entire life cycle using a life cycle database (ecoinvent database, version 3.9.1; ecoinvent) adapted to Québec and data available in the life-cycle assessment literature.

Environmental Impact Analysis

Using the open access software OpenLCA, (version 1.11.0; GreenDelta) each previously collected inventory data on extractions and emissions from PPE use will be translated into potential impacts on environmental issues such as (1) climate change (in kg of CO_2 equivalent emitted), (2) human health (in disability-adjusted life years [DALYs]) [68], (3) resource use (in megajoules of energy—MJ), and (4) ecosystem quality (in PDF·m^2·year, the fraction of species potentially lost from a given area in a year). Conversion of PPE inventory data into impact units for each damage category will be done by the validated IMPACTWorld+ assessment method [67,69]. This method allows for a regionalized analysis by providing continent-specific impact data. An impact measure reflects a sequence of intermediate effects of a product (eg, PPE) production, use, and disposal that, by polluting water, air, soil, or food for example, ultimately affect the environment or human health.

Results Interpretation

The impact results will be interpreted in relation to the functional unit, that is, the use of a single PPE for contact with a suspected COVID-19 case by a care provider. The critical points, that is, the elements of PPE use that account for the greatest proportion of its impact, will be identified. Sensitivity analyses will be conducted to assess the possibility of bias due to incomplete or inaccurate inventory data. Where calculations are performed using proxies from inventory databases rather than original supplier data, we will reanalyze these uncertain variables by applying values for worst- and best-case scenarios.

Phase 4: Cost-Consequence Analysis and Focus Groups (Integration of Objectives 1 to 3)

Cost-Consequence Analysis

The results of the analyses of the previous 3 phases on benefits (OR, RR, and number needed to treat), costs, and ecological footprint will be scaled to a single PPE use for contact with a suspected or confirmed COVID-19 case by a care provider in the ED. They will also be secondarily extrapolated for the full duration of the pandemic from the number of suspected COVID-19 cases assessed in the CHU EDs during this period. Using data from the Institut national de santé publique du Québec on the hospitalization rate of COVID-19 cases in Quebec [70] and the cost of an average hospitalization at the CHU obtained by the Cost per Care Pathway and Service (CPSS) system [71], we will estimate the potentially avoided costs by preventing hospitalizations through PPE. We will do the same by estimating the avoided costs related to staff absenteeism using a human capital approach [72] on the basis of the care providers' salaries identified in phase 2. A cost-consequence analysis will then be carried out by presenting, in parallel, the benefits, costs, and environmental consequences with their 95% CIs in a simple and meaningful disaggregated format. A cost-consequence analysis is a type of economic evaluation that assesses a wide range of costs and consequences associated with an intervention. It can include all types of positive or negative effects of that intervention, including those that are health-related (eg, risk of transmission) and those that are not directly health-related (eg, environmental impact). By presenting the results separately in a nonaggregated manner, it allows stakeholders to determine for themselves the weight and value assigned to the costs and consequences presented for informed decision-making. We believe that cost-consequence analysis is most appropriate for our project because (1) the values and preferences of the stakeholders involved in PPE use are multiple and often divergent, making aggregative ratios or calculations inappropriate (eg the incremental cost-effectiveness ratio [ICER] assesses only one outcome or one benefit) and (2) the economic value of the benefits and consequences of PPE is not clearly elucidated, making cost-benefit analysis (ie, an analysis where all the consequences of intervention are converted into monetary value) problematic.

Focus Groups

The cost-consequence analysis will be presented and discussed in 4 focus groups [73] of 8 participants each [74], via 2 one-hour videoconferences for each group led by a facilitator and a note taker. A third videoconference will be held if not all topics have been covered in the first two. Individual interviews will be offered to participants who prefer this approach or who are unable to attend group meetings. The first group will bring together health care managers responsible for budgets; the second will bring together experts responsible for developing

XSL•FO
RenderX

recommendations on PPE use in hospitals; the third will gather the perceptions of health care providers, nursing assistants, respiratory therapists, and physicians; and the last group will survey the perspective of patients and citizens. Additional groups of participants will be recruited as needed until the data are saturated. A purposeful sampling strategy will be used to ensure representation of various levels of authority (departmental, regional, local), professions (eg, nurses), regions (urban, semiurban, and rural), and individual characteristics (gender, ethnicity, and age) [75]. Participants will be presented with all the results in a simple, adapted format, after consultation with experts in content (eg, economists and environmental engineers) and information formatting (eg, information designers and knowledge transfer experts). The discussions in each group will be semistructured. The primary objectives of the semistructured discussions will be to (1) analyze the perspective of each group on the study results and (2) identify the cost-consequence analysis results (benefits vs costs vs environmental impact) that participants believe should be prioritized for future recommendations regarding PPE use in the ED. The meetings will be recorded and fully transcribed (verbatim). In total, 2 independent reviewers will code the responses on NVivo 12 (Lumivero) to structure the data and bring out the main themes. Their disagreements will be reconciled by discussion or, if necessary, by the intervention of a third researcher. The analysis will take an inductive approach to capture the different perspectives on PPE use in the ED from the data collected and then develop a theoretical framework.

Ethical Considerations

This trial was approved by the CHU de Québec-Université Laval Research Ethics Board (#2022-6048).

Dissemination Plan

Our dissemination plan has an integrated approach by including co-researchers and knowledge users in strategic positions in our team, including a member of the Québec Nosocomial Infection Committee responsible for defining the rules for the use of PPE (YL) and at the CHU, the infection prevention and control program managers (AD and VD), the assistant director (AG) and the consultant (SC) responsible for sustainable development, the nursing (ST) and medical (IG) managers of the EDs, the clinical and organizational performance director (PL), and the patient experience and partnership expertise office manager (LB). In total, 3 clinicians (IG, EEB, and a collaborator Éric Notebaert) and 2 patient partners (EH and a collaborator Jean-Pierre Gendreau) also participated in our process. All these people have contributed to the development of the concept, will participate in its implementation, will be informed of the results, will interpret them from their perspectives, and will be able to quickly integrate them into their practices. Our dissemination strategy will also include (1) articles in general information newspapers to publicize our initiative; (2) a website to present our team, our results, and our future projects; (3) presentations for the general public in citizen forums or congresses; (4) at least 6 presentations in national (Association des médecins d'urgence du Québec, Association des médecins microbiologistes infectiologues du Québec, Canadian Association of Emergency Physicians, and Canadian Association for Health Services and Policy Research) and international (Society for Academic Emergency Medicine and Infectious Diseases Society of America) scientific conferences; (5) at least 4 publications in recognized peer-reviewed scientific journals; and (6) presentations to our partner organizations, including primarily the Québec Nosocomial Infection Committee, which we plan to meet at least 4 times during the course of the project to share our preliminary results and progress.

Results

Study Preparation

We have assembled a very strong research team composed of patients, clinicians, administrators, and researchers. In addition, 2 patient partners met with us regularly and provided helpful comments to make our research plan patient-centered. From previous studies, our team was able to perform life cycle assessment [76-80] and cost-effectiveness [60,61,81,82] measures. This previous work will help with the proposed study.

Phase 1

Our search strategy for the systematic review, launched on May 10, 2022, and updated on June 7, 2023, has generated a list of 26,591 articles, of which 10,209 duplicates were removed. As of July 9, 2023, a total of 15,539 studies have been screened. Of these, 192 abstracts were retained for full-text review and 74 studies were included.

Phase 2

Our team has made a first draft of the process map of the COVID-19 care pathway in the ED (Multimedia Appendix 6).

Process time measurements were performed in one of the CHU EDs for the donning and doffing of a PPE. Table 2 shows the mean time estimates for the different processes of PPE use. Our team is currently completing financial data collection on care providers' salaries, labor hours, PPE component costs, and overhead. Of these data, the mean total cost of the components for a single use of standard and enhanced PPE was estimated to be CAD $13.30 and CAD $21.50 (US $9.79 and US $15.83), respectively.

XSL•FO
RenderX

Table 2. Mean donning and doffing time (minutes) for PPE[a] based on field measurements.

Protective equipment	Donning		Doffing	
	n (%)	Mean (SD)	n (%)	Mean (SD)
Standard PPE[a]	63 (60)	1.28 (0.71)	65 (79)	1.10 (0.85)
Enhanced PPE	42 (40)	1.18 (0.43)	17 (21)	0.35 (0.37)
Any PPE	105 (100)	1.19 (0.45)	82 (100)	0.95 (0.84)

[a]PPE: personal protective equipment.

Phase 3

To date, we have begun an inventory of the materials used for each component using attenuated total reflectance-infrared spectroscopy. Additional analyses are performed to further validate the composition of the PPE components in terms of raw materials and the weight of each item. Once these data are obtained, the conversion of inventory into impact categories will be performed and analyzed.

Protocol Endorsement

Our protocol has been endorsed by organizations dedicated to achieving sustainable and eco-efficient health care (Association québécoises des médecins pour l'environnement, CHU de Québec-Université Laval, INSPQ, Ministère de la santé et des services sociaux du Québec, PULSAR). We also have support for our research initiative from an organization in sustainable development (Nature Québec), with life cycle assessment expertise (the International Reference Center for Life Cycle of Products, Processes and Services—CIRAIG) and with national responsibility for the use of PPE (Québec Nosocomial Infection Committee). This broad support demonstrates the importance of addressing the eco-efficiency of health care, particularly the issue of PPE use.

Research Agenda

We propose a 3-year research plan. After receiving funding on October 1, 2021, we have begun the administrative steps, mainly obtaining authorization from the ethics committee and intrainstitutional agreements for access to medico-administrative data. Phase 1 (systematic review) will run from May 2022 to September 2023 (16,401 abstracts screened) and will end with the submission of a paper for publication in December 2023. Phase 2 (cost estimation) and 3 (life cycle assessment) have begun in June 2022, and are expected to be completed in December 2023. Those 2 phases are performed concomitantly as they overlap in process mapping and medical-administrative data collection. Phase 4 will be conducted from January 2024 (preparation) to August 2024 end of focus group phase). Final publications and knowledge transfer activities will be completed in the last 6 months of 2024.

Discussion

Overview

PPE is the last step in the hierarchy of controls in infection prevention, but it has become an essential component of direct care for ED patients potentially infected with COVID-19. As new infection control measures have emerged, primarily from mass vaccination, some advocate for a more eco-efficient use of PPE, that is, one that provides the best possible protection with the least economic and ecological impact. The evidence generated by this study will support the infection control and prevention authorities in Canada and abroad by providing informed guidance for eco-efficient use of PPE in low-risk environments. They will also help us understand the perspective of different stakeholders on this sensitive and fundamental issue where material shortages, the risks to health care staff, the sustainability of the health system, and the protection of the environment are all intertwined.

Beyond this project on PPE, our multidisciplinary team of researchers from different backgrounds aims to initiate a profound change in managerial culture focused on sustainable health within our institutions, particularly in the ED. We propose an innovative conceptual framework, eco-efficiency in health, through which we wish to contribute to the best possible health outcomes in emergency care at the lowest cost and with the least environmental impact. Canada's health care system is among the least eco-efficient in the world, and its environmental impact paradoxically affects Canadians' health [83,84]. A paradigm shift is needed. Unfortunately, clinicians and managers have few tools to understand and act on their services' ecological footprint. Our work incorporating life cycle assessment will help them to (1) provide the best care with the least environmental impact, (2) set realistic targets for reducing their ecological footprint, and (3) optimize interventions to achieve this. Our proposed project on PPE is in fact only the first in a series of analyses of different emergency care activities with the ultimate goal of proposing a model for eco-efficient emergency services [85].

Challenges and Mitigation Strategies

Our project poses a few notable challenges. First, the systematic review will aim to estimate the benefits of using PPE as the risk of SARS-CoV-2 transmission decreases significantly as vaccination is accelerated. The relevance of the results of this phase will depend on the publication of articles that have evaluated the efficacy of PPE in a setting where the population and health care workers have been vaccinated. We have scheduled an update of our systematic review for September 2023, just before the start of our Phase 4 focus groups. Considering the wealth of scientific output on COVID-19 over the past years, we believe it unlikely that by this update, there will be no studies that have assessed the benefits of PPE since the beginning of vaccination. If not, we will use the results of our systematic review for nonimmune personnel and extrapolate the number needed to treat based on the observed rates of

XSL•FO
RenderX

vaccine protection in the population. Second, our study will be conducted in only one institution, the CHU. However, since supply purchases in Québec are carried out from the same supplier for a group of establishments (eg, eastern Québec), both the costs and the ecological footprint of PPE use in the ED should reflect the reality of all Québec establishments. Similarly, since most PPE suppliers export their products around the world, the results of our analyses will be useful for other health authorities outside Québec. Third, with respect to the life cycle assessment, suppliers of the PPE components studied may not disclose certain information related to the composition of their products and their factory production. In the absence of such data, we will make estimates and use equivalencies from the literature and available life cycle assessment inventory databases. We will disclose the details of these approximations and the uncertainty of the results to transparently inform the resulting organizational decisions.

Conclusions

The World Health Organization recently declared the end of the COVID-19 global health emergency, but acute and emergency care may maintain some habits and behaviors developed and implemented during this health crisis. The intensive use of PPE by care providers to protect patients and themselves from COVID-19 may be one of the pandemic care activities that will require further consideration. While the benefits of PPE use are likely to diminish as health care workers' immunity increases, it is important to assess its economic and ecological consequences so that new parameters and recommendations can be developed to guide its use and ensure eco-efficiency now and in the future.

Abstract

Background: Gay, bisexual, and other men who have sex with men (MSM), particularly Black or African American MSM (BMSM) and Hispanic or Latino MSM (HLMSM), continue to be disproportionately affected by the HIV epidemic in the United States. Previous HIV self-testing programs have yielded high testing rates, although these studies predominantly enrolled White, non-Hispanic MSM. Mobile health tools can support HIV prevention, testing, and treatment. This protocol details an implementation study of mailing free HIV self-tests (HIVSTs) nested within a randomized controlled trial designed to assess the benefit of a mobile phone app for increasing the uptake of HIV prevention and other social services.

Objective: This study was a comparative effectiveness trial of innovative recruitment and testing promotion strategies intended to effectively reach cisgender BMSM and HLMSM. We evaluated the use of a mobile app for increasing access to care.

Methods: Study development began with individual and group consultations that elicited feedback from 3 core groups: HIV care practitioners and researchers, HIV service organization leaders from study states, and BMSM and HLMSM living in the study states. Upon completion of the formative qualitative work, participants from 11 states, based on the observed areas of highest rate of new HIV diagnoses among Black and Hispanic MSM, were recruited through social networking websites and smartphone apps. After eligibility was verified, participants consented and were randomized to the intervention arm (access to the Know@Home mobile app) or the control arm (referral to web resources). We provided all participants with HIVSTs. The evaluation of the efficacy of a mobile phone app to support linkage to posttest prevention services that included sexually transmitted infection testing, pre-exposure prophylaxis initiation, antiretroviral treatment, and acquisition of condoms and compatible lubricants has been planned. Data on these outcomes were obtained from several sources, including HIVST-reporting surveys, the 4-month follow-up survey, laboratory analyses of dried blood spot cards returned by the participant, and data obtained from the state health department surveillance systems. Where possible, relevant subgroup analyses were performed.

XSL•FO
RenderX

Results: During the formative development phase, 9 consultations were conducted: 6 in-depth individual discussions and 3 group consultations. From February 2020 through February 2021, we enrolled 2093 MSM in the randomized controlled trial from 11 states, 1149 BMSM and 944 HLMSM.

Conclusions: This study was designed and implemented to evaluate the effectiveness of recruitment strategies to reach BMSM and HMSM and of a mobile app with regard to linkage to HIV prevention or treatment services. Data were also obtained to allow for the analyses of cost and cost-effectiveness related to study enrollment, HIV testing uptake, identification of previously undiagnosed HIV, sexually transmitted infection testing and treatment, and linkage to HIV prevention or treatment services.

KEYWORDS

HIV self-testing; HIV self-test; prevention; men who have sex with men; internet; mobile phone

Introduction

HIV testing is the cornerstone of HIV prevention and care and is the starting point for parallel HIV prevention and care continua [1-3]. The Centers for Disease Control and Prevention (CDC) recommends that gay, bisexual, and other men who have sex with men (MSM) test for HIV at least annually and more frequently (eg, at 3- to 6-month intervals) depending on their individual risk factors [4]. However, only about half of the MSM surveyed on the internet and who are not known to be living with HIV meet the minimal recommendation for annual screening [5]. Diagnosing HIV as early as possible, initiating treatment rapidly and effectively to achieve viral suppression, and preventing new HIV infections are the key pillars of the United States Department of Health and Human Services initiative, “Ending the HIV Epidemic in the US” [6]. Thus, interventions are needed for MSM in the United States to increase HIV testing frequency and, for those who are found to be living with HIV, to be promptly linked to HIV care.

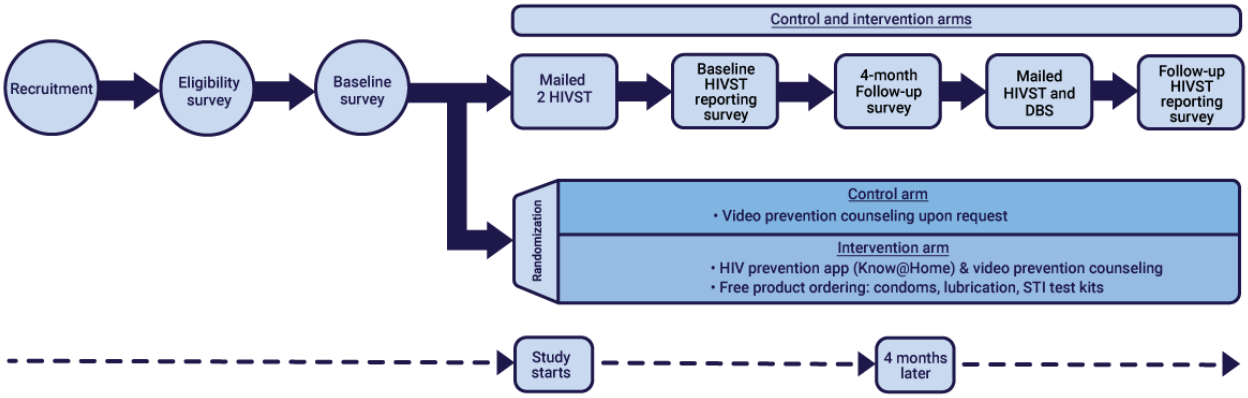
Considering the HIV prevention cascade, MSM who obtain a negative HIV test result also have indications for important follow-up prevention services, including sexually transmitted infection (STI) testing [7], provision of prevention commodities (eg, condoms and condom-compatible lubricants), and assessment for pre-exposure prophylaxis (PrEP) initiation [8]. Comprehensive prevention for men who obtain a negative HIV test result should include connecting them with appropriate service providers in the community, identifying sources of commodities if they cannot afford to buy them, and helping them receive other services. The Evaluation of Rapid HIV Self-testing Among MSM Project [9] demonstrated that providing internet-recruited MSM with HIV self-tests (HIVSTs), which could be replenished, resulted in more HIV testing and diagnoses during the study period compared with those who did not receive the HIVSTs. Although there was no statistically significant difference in linkage to care between the 2 arms, men in the HIV self-testing arm reported a lower linkage-to-care rate than those in the control arm. Furthermore, there were no reported differences in the number of sex partners or the number of anal sex partners without condoms among those who received HIVSTs [9]. However, this study had some limitations with external generalizability because Black or African American, non-Hispanic MSM (BMSM) were underenrolled (10%) relative to their representation in the US HIV epidemic (31%), as was the case for Hispanic or Latino MSM (HLMSM; 18% enrolled) relative to the 25% of HLMSM represented in the US HIV epidemic [9-11]. BMSM and HLMSM continue to be disproportionately affected by HIV compared with other groups and, in 2019, accounted for 38% and 35%, respectively, of new HIV diagnoses among MSM in the United States [12]. Research was needed to tailor HIVST delivery to these populations.

To address this gap, we developed a protocol for the Implementation of the Rapid HIV Self-testing Among MSM Project (iSTAMP), with the goal of demonstrating the costs and best practices for reaching BMSM and HLMSM on the internet and providing all participants with free HIVSTs. To ensure prompt linkage to additional HIV testing and care for those with a preliminary positive result and promote linkage to appropriate posttest sexual health care, we provided the intervention arm with a mobile phone app to facilitate linkage to services. We developed methods to enroll BMSM and HLMSM, provide them with HIVSTs, and evaluate the efficacy of a mobile phone app to support linkage to posttest prevention services, including STI testing, PrEP initiation, and acquisition of condoms and compatible lubricants. This paper describes the protocol and enrollment numbers for providing HIVSTs to BMSM and HLMSM enrolled in 11 select US states.

The purpose of this paper is to describe our study procedures and provide recommendations for reaching and distributing HIVSTs to MSM most disproportionately affected by HIV in the United States. In addition, although an HIVST is not designed to link the user to HIV testing and prevention services, we will evaluate the efficacy of a mobile app to increase the linkage to HIV and STI prevention services.

Methods

Overview



This study was a comparative effectiveness trial of 2093 cisgender MSM living across 11 states in the United States, including 1149 BMSM and 944 HLMSM. We selected these states based on race- and state-specific estimates of the MSM population size previously developed collaboratively by the CDC and Emory University [13]. We selected the 7 states with the highest populations of BMSM, and the 7 states with the

XSL•FO
RenderX

highest populations of HLMSM, because 3 states were included in both lists (Florida, Louisiana, and Mississippi), and 11 implementation states were included in our study (Alabama, California, Florida, Georgia, Louisiana, Mississippi, Nevada, New York, North Carolina, South Carolina, and Texas).

The study was conducted in 2 phases: phase 1 involved formative discussions with stakeholders to inform the implementation of phase 2. Phase 2 (Figure 1) was a randomized controlled trial, in which participants were recruited through websites and social networking apps. Enrolled participants were mailed 2 HIVSTs (Food and Drug Administration–approved OraQuick In-Home HIV Tests) after providing informed consent, completing a baseline survey, and providing valid contact information. Participants were followed up for 4 months with an additional study assessment at the end of the 4 months. Project staff members discussed the use of HIV surveillance data with the relevant state health departments for the evaluation of the comparative effectiveness of the intervention (access to the Know@Home mobile app) compared with the control (referral to web resources) condition with respect to the linkage of participants to appropriate treatment or preventive services. Phase 2 included obtaining costs for multiple cost-effectiveness analyses related to recruitment; HIV self-testing; and linkage to prevention, treatment, and care services. Recruitment was conducted from February 2020 through February 2021.

Figure 1. Flow and timeline for Implementation of Rapid HIV Self-testing Among MSM Project, a comparative effectiveness trial of Black or African American and Hispanic or Latino men who have sex with men in the United States (2020-2021). DBS: dried blood spot; HIVST: HIV self-test; STI: sexually transmitted infection.

Ethics Approval

This study was approved by the Emory Institutional Review Board (IRB00099710).

Formative Work

To inform the implementation trial recruitment strategy, study procedures, and linkage-to-care protocol, we conducted individual and group consultations to elicit feedback during the Know@Home study planning and app development phase. This formative work solicited feedback from three core groups: (1) HIV care practitioners and researchers, (2) HIV service organization leaders from study implementation states, and (3) BMSM and HLMSM who live within the implementation study states.

One-on-One Consultations With HIV Care Practitioners and Researchers

To gain insight into the nuances of HIV screening among BMSM and HLMSM, 6 HIV care physicians and researchers specializing in working with these populations were invited to participate in one-on-one discussions over video calls. Discussions centered around understanding their experiences of engaging BMSM and HLMSM in HIV research, what advertising venues they found effective for recruiting each population, recommendations for advertising imagery and written content, and approaches to garner trust and foster retention within the project. The notes taken during each discussion were compiled, reviewed by the study team, and assembled into overarching themes. These consultants primarily had experience working with BMSM and had less advice pertaining to HLMSM. There was consensus that dating and hookup apps were the most successful in recruiting BMSM and HLMSM and that images should reflect age, body type, and diversity of skin tone within these populations. Providers working in southern states noted that HIV stigma and distrust of health care and academic institutions were barriers to engaging BMSM in HIV research and prevention and care services. To build confidence, consultants recommended creating relationships with trusted community-based organizations (CBOs) and clinics embedded within these communities. Consultants recommended obtaining support from respected local and state CBOs and clinics to provide study credibility, help keep participants engaged in the duration of the project, and boost linkage-to-care efforts.

Group Consultation With HIV Service Organization Leaders

In an effort to help establish relationships with CBOs and ensure practical research deliverables, 5 directors of HIV service organizations were invited to participate in a consultation over a video call. These CBO directors specialized in providing HIV screening and linkage services for BMSM and HLMSM in Alabama, Florida, Mississippi, New York, and North Carolina. The discussions focused on the types of data that would support the creation and implementation of a web-based HIV self-testing program, strategies for reaching BMSM and HMSM, and considerations for scaling such a program to a local organizational level. The notes taken during the consultation

XSL•FO
RenderX

were reviewed by the study team, sorted thematically, and assembled into overarching themes. To help create an HIV self-testing program, the CBO directors highlighted their desire for metrics surrounding overall kit distribution, how many results were returned, and how many participants were successfully linked to care. In addition, all directors described the utility of a cost-effectiveness analysis to understand the expenses associated with such a self-testing program in relation to being able to link people who obtained a preliminary positive test result to HIV care. As many of the CBOs had existing laboratory partnerships, the consultants felt that if this program were brought to scale, they would be able to accommodate the processing of returned biospecimens for HIV testing (ie, dried blood spot [DBS] cards) and triple-site bacterial STI testing (ie, pharyngeal swabs, rectal swabs, and urine samples). All directors communicated that their implementation concerns were around staffing and funding, tracking HIVST kits, following up with clients who had a positive test result, and preventing some clients from acquiring more kits than necessary. Finally, CBO directors discussed how having a fully developed protocol for implementing an HIV self-testing program would help them bring a program to scale in their local service provision area.

Group Consultations With BMSM and HLMSM

The last element of the consultations sought to receive developmental input from BMSM and HLMSM regarding our recruitment materials, plans, and study procedures. To enlist BMSM and HLMSM, we asked our consultants (ie, HIV physicians, researchers, and CBO directors) in implementation study states to nominate community members who they felt were engaged with HIV and STI issues. Among the nominations offered, 3 HLMSM from California, Florida, and New York and 3 BMSM from California, Florida, and South Carolina participated. Two separate consultations were conducted via video calls—one with HLMSM and another with BMSM. During each consultation, a PowerPoint (Microsoft Corp) presentation was screen shared to elicit feedback on advertising imagery and content, possible recruitment venues, and strategies for disbursing incentives. The discussions also covered participant retention and study implementation design. Notes taken during each consultation were reviewed by the study team and assembled into a set of themes. Across both groups, community members advised using different dating or hookup apps for advertising in each state, based on their varying popularity, in addition to mainstream social media platforms. Retention issues that were cited included participants moving out of eligible study states during the follow-up period and the low monetary incentive for DBS sample collection. Their recommendations for implementation highlighted the importance of discreet shipment packaging, confidentiality of the result-reporting mechanism, linking those with a positive test result to locally trusted CBOs, and privacy of any study app notifications. Finally, the HLMSM group cautioned about the variability of Spanish dialects across the United States when attempting to offer Spanish-translated resources and materials.

During the 2 consultations with BMSM and HLMSM, feedback was obtained on draft advertisement images and taglines to be used for recruitment purposes. Consultants preferred joyous, light-hearted stock images of men to photos that conveyed solemnness. Consultants rated advertisements higher if they showcased everyday situations and “relatable” models that they felt were recognizable within their communities. Images that felt staged, unnatural, generic, or too commercial were ranked lower. Advertisements that portrayed physical affection and intimacy between men were also favored. Men who were shown hugging, kissing, or cuddling portrayed why HIV self-testing may be relevant to the target audience and related to healthy relationships or partner seeking. However, some images where men appeared too serious with their partners were thought to potentially depict intimate partner violence situations. In terms of race and ethnicity, participants gravitated to photos that included Black or African American and Hispanic or Latino men together and represented diverse skin tones. Finally, consultants endorsed tagline text that incorporated puns or turn of phrases such as “It Pays to Know” to more generic messaging such as “Find out your HIV status.”

Health Department Engagement

After the study states were selected, we contacted each state health department, beginning with HIV surveillance programs, and had multiple group webinars to share the proposed methods for the study and individual calls with some states to discuss the possibility of matching study participants to HIV surveillance records to ascertain the outcomes of testing.

Study Procedures

Eligibility

Study eligibility and exclusion criteria are listed in Textbox 1. We excluded people who were currently taking PrEP, as they would have been receiving regular HIV testing as part of their clinical care. Participants were required to own an Android or iOS smartphone because components of the trial were delivered via an Android or iOS smartphone app.

XSL•FO
RenderX

Textbox 1. Eligibility criteria for Implementation of Rapid HIV Self-testing Among MSM Project, a comparative effectiveness trial of Black or African American and Hispanic or Latino men who have sex with men in the United States (2020 to 2021).

- Eligibility criteria:
  - Black or African American race, or Hispanic or Latino ethnicity
  - Male sex at birth
  - Currently identifies as male
  - Reported anal sex with at least one man in the past 12 months
  - Aged ≥18 years
  - Has an Android or iOS smartphone
  - Currently resides in a study state (Alabama, California, Florida, Georgia, Louisiana, North Carolina, Nevada, New York, Mississippi, South Carolina, and Texas)
  - Willing to download the study mobile app
  - Willing to provide valid contact information
  - Successful completion of baseline survey
- Exclusionary criteria:
  - Currently participating in another HIV prevention research study or program
  - Had a bleeding disorder
  - Had previously participated in an HIV vaccine study
  - Currently taking pre-exposure prophylaxis for HIV prevention
  - Reported living with HIV
  - Has plans to move out of a study state during the 4-month study period

Recruitment, Screening, Consent, and Enrollment

Potential participants were reached through several web-based avenues, hereafter referred to as *recruitment sources*: (1) general, non–lesbian, gay, bisexual, transgender, and queer (LGBTQ)–oriented social networking websites that were not geared toward sex-seeking (eg, Facebook and Instagram); (2) LGBTQ-oriented websites (eg, Queerty or The Advocate); (3) LGBTQ-oriented mobile social networking apps or dating websites geared toward sex-seeking (eg, Jack'd and Adam4Adam); and (4) other (eg, unknown source, referral from participant, and referral from another research study). Advertisements were placed in these web-based venues and directed users to a web page containing basic study information. Interested individuals were required to complete the web-based consent form and screener, and those who were eligible were required to provide contact information. Those who were determined to be ineligible were asked if they could be contacted for future research. We did not indicate why participants were ineligible to prevent unintentional disclosure of the eligibility criteria or repeated attempts to enroll. All participants who completed the screener were directed to web-based resources for HIV prevention and sexual health. After verification and deduplication by study staff, eligible participants were electronically sent links to the main study informed consent form and the baseline survey. The baseline survey was estimated to be completed in approximately 20 minutes.

Completed baseline responses and participant information were reviewed and checked for duplication by the study team. Web-based screener and baseline survey responses were compared to ensure consistency (eg, date of birth, state of residence, and HIV status), and contact information and IP addresses were compared for duplication, as described elsewhere [14]. Participants were sent an SMS text message and were required to respond by verifying their contact mobile number.

After completing verification, participants were enrolled and assigned in a 1:1 ratio to the intervention or control arms using stratified randomization by race or ethnicity, state of residence, and recruitment source (general social media, LGBTQ-oriented websites, LGBTQ mobile apps or web-based dating platforms, and other), totaling 88 strata. Within the strata, participants were randomly assigned to the next treatment allocation from a randomly permuted block sequence (block sizes were 2 and 4).

Postenrollment Study Period

Participants in both the intervention and control arms were mailed 2 HIVSTs after completing the baseline survey. Participants were encouraged to use the second HIVST to either (1) test again if the first test did not work (eg, an invalid result or sample collection error) or (2) provide the HIVST to someone they thought may benefit from HIV testing (eg, friend or sex partner). After completing the 4-month follow-up survey, participants were mailed 1 additional HIVST along with the DBS self-collection kit. Participants were encouraged to use the HIVST because the results from laboratory tests conducted

XSL•FO
RenderX

on the DBS card could not be returned to participants. When participants used one or more of the study-provided HIVSTs, they were instructed to report each of their HIVST results and upload a photograph of each HIVST device via a secure web-based survey. Participants who gave HIVSTs to someone not enrolled in the study (referred to as *guests*) were advised to have the guest report their result and upload a photograph of their device via a web-based survey that did not collect any identifiable information. Guests were directed to a landing page with a consent form indicating that they were aged ≥18 years before completing an anonymous survey. At any point in the study, the participants and guests were allowed to stop participating.

Intervention

This study used the Know@Home app, which was built on the HealthMindr mobile health platform [15-17]. We made administrative changes to the functionality and content to match the study's design and updated public health messages. The locator tool was updated to national service locators, including HIV.gov and PrEP Locator [18]. Written feedback on content in the app was solicited from community advisory board members, and their input informed changes such as adding more exclamation points to help the messaging seem friendlier, adding information about undetectable=untransmittable, and streamlining the user experience by changing page order and functionality within the app. The app offers a variety of services related to post-HIV test sexual health care, including locators for PrEP services, STI testing, and postexposure prophylaxis services; tools to schedule periodic HIV testing and receive reminders to test; and PrEP and postexposure prophylaxis eligibility screening tools.

Incentives

Incentives in the form of e-gift cards were provided to participants for completing various study activities totaling up to US $70 over the 4-month study period. Participants received US $20 to complete the baseline survey, US $30 to complete the 4-month follow-up survey, US $10 to report their HIVST results in the baseline test results survey, and US $10 to complete and return their DBS card to Emory University. Participants could complete a web-based survey for the follow-up HIVST; however, they were not compensated for entering the follow-up HIVST result. Guests who used an HIVST provided by a study participant were not compensated for completing the anonymous web-based survey.

Commodity Ordering

Participants in the intervention arm had access to ordering free prevention commodities such as STI self-collection kits, condoms, and condom-compatible lubricants. The delivery of condoms and lubricants was fulfilled by Amazon Fulfillment Services. The delivery of STI self-collection kits was fulfilled by a Clinical Laboratory Improvement Amendments–accredited commercial laboratory. The STI self-collection kits included instructions and materials for participants to collect and return a urine sample, a rectal swab, a pharyngeal swab, a DBS sample, and a microtainer blood sample. The specimens were tested for urethral, rectal, and pharyngeal gonorrhea and chlamydia, and syphilis [19]. Specimens were returned by mail to the originating laboratory, where bacterial STI testing was performed using previously reported methods [20]. Negative STI results were provided to participants through a Health Insurance Portability and Accountability Act (HIPAA)–compliant patient portal, email, or SMS text messages; positive STI results were provided to participants by phone call and the HIPAA-compliant patient portal with referrals to local treatment locations.

Results Monitoring

For all study participants, the project staff monitored the HIVST-reporting survey data daily, Monday through Friday, and once on either Saturday or Sunday. The staff members sought to identify HIV test results that were (1) preliminary positive, (2) invalid, or (3) discrepant, meaning the result reported did not match the result image uploaded. When a preliminary positive result was provided, a staff member attempted to contact the participant to assess their emotional state, elicit existing systems of support, locate nearby HIV testing sites, and create a plan for the next steps. When the staff member identified an invalid result, they attempted to contact the participant about either receiving a replacement HIVST in the mail or providing HIV testing site referrals in their local area. After additional testing had been sought, the study staff member followed up with participants to document their corrected test result. If a discrepant result was identified, the study staff member attempted to contact the participant to verify the result entered in the test result survey, describe the source of the discrepancy, and review the test procedures, if needed. State guidelines for reporting an HIV test result to health departments were followed by study staff. As the guest test result survey (designed for individuals who were not enrolled in the study) did not collect identifiable information, the study staff member was unable to contact guests about their reported test results. Study contact information was listed on the guest test result survey, and guests had the option to schedule video counseling with trained study staff.

Linkage to Care

The study staff member attempted to contact all participants who reported a preliminary positive HIVST result, up to 10 times, by phone call, encrypted email, and SMS text message. Any unencrypted form of communication (ie, standard email or SMS text message) made no reference to HIV testing or their preliminary positive test result. If not successfully contacted by the third attempt, the study staff member sent a list of free or low-cost local HIV testing sites and care providers through an encrypted email. When the study staff member was able to speak to the participant over the phone, they confirmed that the participant was in a private location where they could talk about their result. If the participant was unable to discuss the results at that time, the study staff member asked for another time to call again. Once privacy had been established, the study staff member started by outlining the purpose of the interaction and then transitioned into inquiring about the participant's emotional state after receiving the preliminary positive result. The study staff member discussed the importance of having support from someone and addressed HIV disclosure strategies. The study staff member then discussed additional local HIV testing and

XSL•FO
RenderX

care options in the context of the participant's insurance status. Additional referrals offered were case management services, mental health support, HIV support groups, housing programs, food assistance, and transportation services. Agreed-upon referrals were sent via encrypted email that included information about the provider's website, their hours of operation, and a Google Maps link to the location. After successfully sending additional HIV testing referrals, subsequent contact attempts inquired if an appointment was made or attended, if the preliminary positive result was confirmed, and if the participant was able to initiate treatment. Additional care and support referrals were assessed at each follow-up contact attempt. Participants with a positive additional HIV test result and those who received an HIV diagnosis, had seen an HIV care provider, and received HIV medication were asked if they would like any additional follow-up from the study staff members. Participants were able to opt out of study linkage-to-care support contacts at any time.

Participants in the intervention arm also had the option of ordering STI self-collection kits that included instructions and materials for collecting and returning samples for gonorrhea, chlamydia, and syphilis testing. For any positive bacterial STI test results, the study staff member attempted to contact the participant up to 10 times, following the same procedures as the HIV test results. If after 3 attempts, the participant was not reachable, the participant was sent an encrypted email with a PDF document detailing the laboratory test results and information on several local free or low-cost STI treatment providers. Participants who had specific samples rejected by the laboratory owing to quality or sample collection issues were offered a replacement STI self-collection kit and a list of local STI testing services. Additional contact attempts by the study staff member assessed whether an appointment concerning the STI results had been made or attended and if any additional referrals were needed. Participants who had seen a care provider and received antibiotic treatment had no further contact from the study staff member.

Video Counseling

Remotely conducted video counseling services were made available to all iSTAMP participants and guests throughout the study. Staff members who provided video counseling were trained in the state health department HIV testing and counseling and were certified following their state guidelines. In addition, staff members were trained in motivational interviewing techniques for HIV risk behavioral change. Sessions were conducted using HIPAA-compliant Zoom Health with meeting passcodes, waiting room requirements, and end-to-end encryption.

Participants were able to schedule a video counseling session for any reason, but session types were advertised as (1) a pretest session where counselors explained how to collect samples and interpret the HIVST result, and for participants in the intervention arm, the STI collection procedures; (2) a facilitated HIV test session where the participant conducted the HIVST during the video call, discussed current HIV or STI prevention behaviors, interpreted results with the assistance of the video counselor, and then discussed next steps; and (3) a posttest session where participants, who have already completed their HIV self-testing or STI self-collection, discussed their results and received appropriate referrals for treatment or prevention services. Because participants were able to schedule a session at any time during the study without describing their needs beforehand, video counselors were trained to respond to any of these standard scenarios and had a detailed knowledge of study procedures to answer participation-related questions.

After their baseline HIVSTs had been shipped, participants received an email describing the video counseling service and a list of available appointment times for that week. A similar video counseling email was sent 4 months later when another HIVST and DBS card had been shipped to participants. Throughout the project, automated email reminders regarding study activities continued to advertise video counseling services. Participants were able to respond to any study-related communication (ie, phone call, SMS text message, or email) to request a video counseling session. Guaranteed video counselor availability was established during standard business hours, Monday through Friday from 9 AM to 6 PM in the eastern time zone. Participants were also able to schedule during evenings and weekends upon request. The study staff member followed telehealth procedures for client setup, provider setup, troubleshooting, and long-distance referrals described elsewhere [21]. To help demonstrate how to use various biological sample collection materials, the study staff members adhered to existing protocols [22].

Data Collection

Cost-effectiveness Data

A comprehensive cost analysis has been initiated to assess the cost of implementing recruitment strategies and the intervention. A microcosting approach was implemented, along with the standard literature practice of itemizing and assigning a dollar value to each component. Three cost-effectiveness analyses have been initiated from the health care payer perspective (the cost to the party implementing the program), which will include the different cost categories.

First, we obtained the costs incurred for the 3 web-based recruitment venue categories on the outcome of study enrollment (defined as the completion of the baseline survey and downloading of the study app). We collected data on the following cost categories: web-based banner advertisement placement and study staff time to (1) manage enrollment, (2) validate participant eligibility, and (3) monitor and evaluate enrollment data.

Second, we obtained cost data for the 3 venue categories on the outcome of HIVST results returned during the study period and the number of participants with a reactive result. We collected data on the costs of enrollment along with HIVST procurement and shipping, staff or personnel time to manage mailing or return of test kits, study staff time to manage monitoring and evaluation of HIV test result data, and study staff time to provide phone counseling to those who reported a preliminary positive HIV test result.

Finally, we obtained costs data for the intervention on linkage to 3 sexual health services (HIV care visit among those who

XSL•FO
RenderX

tested preliminary positive, PrEP discussion with a provider, and STI testing). We collected data on the costs incurred after the participants are provided with HIVSTs and randomly assigned them to 1 of the 2 study arms.

These analyses have included the cost of study staff time for processing orders, contacting participants, and app management or participant registration and are independent of the prerandomization cost-effectiveness analyses; no cost related to recruitment strategies were included.

Cost data were collected by extraction from accounting and budget records, external contracts, and study or personnel time required to manage the outlined tasks. Data were estimated using Clockify (COING Inc), a free software (both web- and mobile based) that allows personnel to track the time spent on daily tasks. To calculate personnel costs, we multiplied these hours by wage rates plus fringe. Only implementation costs (defined as the ongoing costs of delivering the intervention) were considered, and no costs associated with survey or app development, incentives, or research were included.

Survey Data

A web-based screening survey collected information to determine eligibility, including demographics, sexual behaviors, state of residence, HIV status, and contact information. Participants, if eligible, then completed a web-based baseline survey that collected information on additional demographic characteristics, sexual behaviors, HIV testing history, future preferences for PrEP use, HIV testing intentions, other health service history, internet and mobile app use, medical mistrust, and health literacy. Participants were prompted by email, SMS text message, or phone to take a web-based follow-up survey after 4 months, which covered the same domains as the baseline survey, with reporting limited to the postbaseline period. Additional topics in the follow-up survey included PrEP use, HIV treatment and care, and time and costs. Participants in the intervention arm answered additional questions in the follow-up survey regarding their experiences using the Know@Home mobile app, and individuals who used the video prevention counseling option were asked about their experiences using this service.

Separate test result–reporting surveys were distributed to participants after the baseline and 4-month follow-up surveys, referred to as the baseline test result–reporting survey and 4-month follow-up test result–reporting survey, respectively. The participant and guest surveys asked about their experience regarding (1) receiving HIVSTs, (2) experience using the rapid test, (3) the result of each HIVST, and (4) distributing HIVSTs.

As participants interacted with the Know@Home app, data about the features used, pages visited, functions used, and time spent were captured by the app and stored in the administrative portal.

Laboratory Data

Participants who consented to provide DBS samples for laboratory-based research were provided DBS self-collection kits after completing the 4-month survey. Using the instructions provided, participants prepared and mailed the DBS card for HIV diagnostic testing. Testing included an algorithm with antigen and antibody combination and HIV-1 and HIV-2 differentiation supplemental testing. The DBS samples served both as secondary testing that is more sensitive than the baseline rapid tests and to corroborate or identify new positive HIV results. As a supplemental assessment, participants who returned the DBS card and reported taking HIV medications (PrEP or antiretroviral medications) were sent a microtainer self-collection kit to mail the blood sample to the CDC. The purpose of the microtainer collection activity was to evaluate the feasibility and specimen integrity of self-collected microtainer samples from untrained participants in the United States. The samples were tested for HIV viral load and HIV medications (PrEP or antiretroviral medications).

Health Department Surveillance Data

The state departments of public health receive all reports of reactive HIV diagnostic tests, CD4 counts, and viral load tests performed on patients residing in their jurisdictions through systems such as the electronic HIV and AIDS Reporting System. The study staff member requested HIV surveillance data from state departments of public health following the end of a person's participation in the study. We requested that names and dates of birth of all participants be verified. The goal of this request was to identify participants who received a confirmed reactive HIV test result or entered HIV care for both participants who did or did not report a positive HIV test result during the study.

Other Data

Electronic case report forms (CRFs) were used to capture data for validation and enrollment, HIVST result follow-up communications, STI test result follow-up communications, referrals, and video counseling. For those who engaged in video counseling, data on the length and content of sessions were captured and stored in CRFs, excluding identifiable information.

Planned Analyses

Formative Work

In the first part of the study, we characterized the cultural appropriateness, possible web-based recruitment venues, barriers to engaging BMSM and HLMSM in HIV prevention including HIV testing promotion strategies, and additional considerations for the implementation and potential scale-up of mail-out HIVSTs, following conversations with key stakeholders.

In the second part of the study, we initiated several cost-effectiveness analyses and a comparative effectiveness evaluation of the intervention (Know@Home mobile app) on the linkage of participants to appropriate services (HIV treatment, PrEP, STI testing, additional prevention, and social services).

Cost and Cost-effectiveness Analyses

In primary analyses, we have initiated an evaluation of the cost and cost-effectiveness of the 2 LGBTQ-oriented recruitment platforms and the general, non–LGBTQ-oriented social networking websites for the following outcomes: (1) enrollment in the study defined as completion of the baseline survey, (2) HIVST results returned within 1 month of enrollment, and (3)

XSL•FO
RenderX

identification of established HIV infections (eg, new diagnoses). The secondary analyses consisted of the cost-effectiveness of the 2 randomized study arms for outcomes of linkage to HIV prevention or HIV care services: (1) HIV counseling and treatment for MSM with HIV, (2) PrEP counseling and uptake for MSM who obtained a negative HIV test result, and (3) STI testing and treatment for MSM. The time horizon used was the time from baseline to follow-up, and both costs and effects will be discounted at an annual rate of 3%. Analyses included the overall study population and were performed separately for the 2 MSM populations (BMSM and HLMSM) enrolled.

Standard methods [23,24] for economic analyses have been used for various HIV prevention interventions [24-26]. Cost and outcome data were entered into a standardized Excel spreadsheet with embedded formulas. The net cost of the recruitment strategies and intervention was calculated along with the incremental cost-effectiveness ratio (ICER) for the recruitment strategies compared with the reference (primary aim) or intervention arm compared with the control arm (secondary aim). For example, using ICER to compare the recruitment venues of LGBTQ-oriented mobile apps or web-based dating websites geared toward sex-seeking versus general, non–LGBTQ-oriented web-based websites not geared toward sex-seeking (the reference) on the outcome of enrollment were calculated as follows: $[(Cost_{\text{sex-seeking apps}} - Cost_{\text{reference}})] / [(Enrollment_{\text{sex-seeking apps}} - Enrollment_{\text{reference}})]$. This value yields the incremental cost per participant enrolled. Where no observed differences in the outcomes of interest by recruitment strategy (primary aim) or study arm (secondary aim) exist, then a cost minimization analysis is planned. One-way sensitivity analyses were planned for all input variables to determine the inputs for which the net costs and ICERs were the most sensitive. We explored the effects of realistic implementation scenarios, including health departments with or without the ability to outsource HIV testing, robust eHealth systems, and tech-savvy staff.

Usage of Test Kits and Counseling and Linkage to Care

Data on use of HIVSTs were collected in multiple surveys. Information on the use of HIVSTs was provided in test result–reporting surveys during the study, and all participants were also asked about their use of study-provided HIVSTs during the 4-month follow-up survey. The date and result of the most recent HIV test before enrollment in iSTAMP were collected at baseline. Participants were asked to report any additional HIV testing and result that occurred outside the study on their 4-month follow-up survey. For the outcome of HIVST use, we report descriptive statistics about the number of HIVSTs distributed or used during the study period, overall and stratified by race or ethnicity, HIV testing history at enrollment, and recruitment source.

We used data collected on CRFs to calculate the number and proportion of people who used the telehealth counseling provided through the study. We used data from counseling CRFs to describe the main reasons for seeking counseling and the types of services used.

Linkage to care is critical for people diagnosed with HIV. We documented the proportion of participants who tested positive for HIV that were linked to care and described the distribution of time from receiving a positive test result to linkage to care, as previously described [9]. We used 3 sources of data to describe linkage to care. First, we used the following data from the study surveys: participants who reported a positive test result were asked if they have seen an HIV care provider and the approximate date of their appointment with that provider. Second, we used notes from CRFs prepared by study staff who talked with participants and assisted with linking them to HIV care. Not all participants requested such assistance, so not every participant who received a positive result has a linkage or counseling CRF. Finally, we have worked with the 11 state health departments to create plans to match our participants to the state surveillance registries. This would allow us to assess the occurrence and timing of additional HIV testing and viral load evaluation and to determine the dates of these services as a marker of linkage to care. We have functioned as a testing provider and reported HIV diagnoses as required (some states require reporting of positive HIV self-test results). We provided feedback to testing providers about the linkage and care outcomes of people that the providers diagnose as a routine function of surveillance programs. Furthermore, we obtained informed consent from the participants to allow for such linkage.

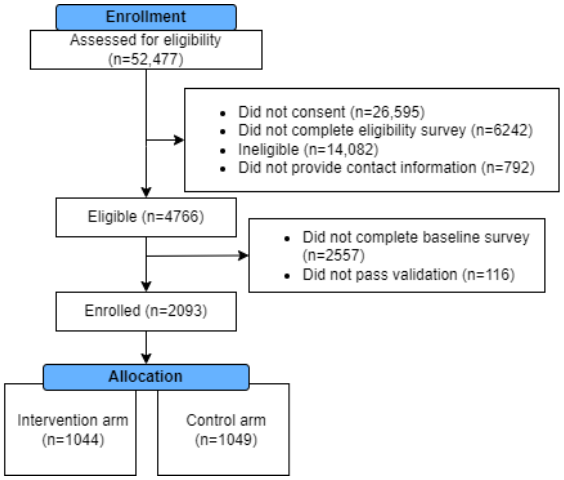
Receipt of Posttest Services by Allocation to App

HIV testing is the entry point for multiple care continua; for those who received a positive test result in this study, their linkage to care was assessed. We assessed the receipt of HIV and STI services during the follow-up period for those who received a negative result or who do not report HIV testing. We also determined whether randomization to the intervention arm (Know@Home app built on the HealthMindr platform [15,16]) was associated with a higher percentage for three outcomes measured at month 4: (1) testing for bacterial STIs in the previous 4 months; (2) receipt of condoms and condom-compatible lubricants in the prior 4 months; and (3) linkage to HIV (PrEP or antiretroviral therapy) services during the study follow-up period. We used an α value of .05 to designate statistically significant intervention effects. Given that we had prespecified 3 primary outcomes, adjustment for multiple comparisons was not necessary [27].

Results

Key Themes in Formative Work

Key themes in formative work among HIV providers and researchers (N=6) indicated that dating and hookup mobile apps have previously been successful in recruiting BMSM and HLMSM for research studies. In addition, HIV stigma and distrust of health care and academic institutions may act as barriers to engaging with these populations. Among HIV organization directors (n=5), primary themes included their desire for cost-effectiveness data for possible implementation of HIV self-testing services and concerns about staffing, funding, and linkage to care for clients who use an HIVST. Among the BMSM (n=3) and HLMSM (n=3) community members, the central findings consisted of their advertising



XSL•FO
RenderX

preferences for noncommercial images, diverse skin tones, and joyous and everyday scenes, accompanied by text that incorporated puns.

Progress to Date

iSTAMP began enrollment in February 2020 and concluded in February 2021, with participant follow-up data completed in September 2021. Of the individuals assessed for eligibility with screening questions, 9.08% (4765/52,481) were considered eligible to join (Figure 2). Of the MSM who consented, 43.92% (2093/4765) completed the baseline survey, passed the validation process, and were enrolled, of whom 45.10% (944/2093) were HLMSM and 54.90% (1149/2093) were BMSM. We randomly assigned 49.88% (1044/2093) participants to the intervention group and 50.12% (1049/2093) to the control group.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram for Implementation of Rapid HIV Self-testing Among MSM Project, a comparative effectiveness trial of Black or African American and Hispanic or Latino men who have sex with men in the United States (2020-2021).

To examine enrollment proportions relative to state demographic data, we compared participant enrollment numbers with the 2018 Census [10], which estimated the male population in each state, stratified by race or ethnicity (Table 1). Census data were categorized for comparison by including only those who selected single-race Black or African American, non-Hispanic, while iSTAMP allowed for participants included in the Black or African American, non-Hispanic strata to select multiple races.

Table 1. Enrolled study population compared with census-estimated population from 2018 by race or ethnicity for Implementation of Rapid HIV Self-testing Among MSM Project, a comparative effectiveness trial of Black or African American and Hispanic or Latino men who have sex with men in the United States (2020 to 2021).

State	Black NH[a] MSM[b] enrolled (n=1149), n (%)	Black NH men[c] in the state population (11 states; n=8,046,742), n (%)	Hispanic MSM enrolled (n=944), n (%)	Hispanic men in the state population (11 states; n=13,895,483), n (%)
Texas	205 (17.84)	1,220,831 (15.17)	253 (26.8)	3,842,932 (27.66)

Discussion

Public Health Need

Formative research synthesized concrete guidance from stakeholders and community members who informed the methods used to recruit and retain participants in this study. We were able to effectively engage BMSM and HLMSM in this project and share best practices related to recruiting this key population. BMSM and HLMSM are disproportionately affected by HIV [28], and to achieve health equity, it is necessary to develop methods to maximize the opportunities for these communities to access resources such as HIVST distribution. iSTAMP aimed to learn how to effectively reach BMSM and HLMSM and to implement a program for the distribution of free HIVSTs.

Barriers to HIV testing have been described for decades throughout the HIV epidemic in the United States. These include a lack of perception of risk, stigma associated with seeking testing, lack of convenient options for HIV testing, and fear of obtaining a positive test result. Stigma-related concerns may be heightened for BMSM and HLMSM who face intersectional stigmas around race and ethnicity, sexual or gender minority status, and HIV. It is crucial to develop a robust slate of option for HIV testing that will allow MSM at elevated risk for HIV to test as frequently as recommended by the CDC. One approach is by supplementing provider-based testing with HIV self-testing.

Key Innovations

Working closely with the states in which the study was conducted was an important aspect of our study. We conducted this study in states with large populations of BMSM, HLMSM, or both [13]. Involving the state health departments is crucial in planning implementation studies of interventions, because in the United States, with a few exceptions, the primary responsibility for providing prevention services and for following up with those living with HIV falls on state health departments. Thus, state health departments may eventually be implementers of the procedures developed and tested in this study. Including states in the planning phases increases the likelihood that programs can be rapidly and seamlessly implemented by health departments that choose to adopt them.

The cost-effectiveness analyses outlined in this protocol will provide necessary information for providers wishing to implement similar recruitment and testing promotion strategies to reach BMSM and HLMSM, among others. Data on both the cost and impact of such strategies can guide decision-making regarding the efficient allocation of limited resources to increase HIV testing among these populations. Although cost-effectiveness analyses are recognized as an important component of implementation science research, limited data on the cost-effectiveness of varied recruitment, HIV testing, and linkage strategies currently exist. Thus, iSTAMP will make an important contribution to HIV testing and prevention services.

Limitations

Our study had some limitations, including standard biases for randomized controlled trials. The study may be affected by selection bias in that the men who agreed to participate were not representative of all BMSM and HLMSM in the implementation states. Another potential limitation is the differential loss to follow-up between the intervention and control arms. This was mitigated through comprehensive efforts to retain participants in both arms by using multiple modes of contact (phone call, email, or SMS text message), compensating participants for their time to complete study activities, and by allowing all survey and study activities to be completed remotely. There is risk for misclassification bias because we rely, to a large extent, on participant-reported outcomes for the use of tests and linkage to follow-up services. We have taken steps to reduce this bias by allowing participants to complete surveys remotely, using survey tools that have been validated [9], and by measuring key outcomes from multiple sources of data (ie, surveys and communications with the staff). One factor that might influence the results is that this study was primarily conducted during the COVID-19 pandemic [29,30]. A study conducted in 2020 found that during the COVID-19 pandemic, MSM reported fewer sex partners and opportunities to have sex, as well as problems accessing HIV testing, which might have increased the use of HIVSTs [30]. However, because the study had been designed to be conducted entirely remotely, the procedures and protocols for the iSTAMP study did not meaningfully change due to the COVID-19 pandemic.

Public Health Implications

The distribution of HIVSTs is already moving into public health programs. It is critical that we identify and disseminate effective methods to reach BMSM and HLMSM through programs that strive toward health equity for these priority populations. A pilot project in which a community organization partnered with state and local health departments to fulfill orders for free HIVSTs showed that providing HIVST in a "direct-to-consumer" model is feasible and can reach populations with substantial HIV risk and those who have not recently tested for HIV [31]. In 2021, the CDC contracted with Insignia Federal Group, who partnered with Building Healthy Online Communities and Emory University to distribute 100,000 HIVSTs to those who requested an HIVST in the United States or Puerto Rico [32]. The marketing strategy was primarily driven by social media advertising and influencers to reach Black and Latino gay and bisexual cisgender men, transgender women, and Black cisgender women [32] and also included links to the HIVST ordering portal through the HIV testing locator of AIDSVu.org [11]. It is important that these programs continue to monitor the distribution of HIVSTs in the populations most affected by HIV. In the longer term, local or state health departments and CBOs that serve as major sources of public health guidance and provision of services could implement HIV self-testing programs that serve their local populations most affected by the HIV epidemic. The lessons learned in the iSTAMP study will be useful for the planning and budgeting of programs, for anticipating the need for telehealth counseling and linkage services, and for providing examples of program materials to help jump start national, state, or local programs.

Acknowledgments

This study was funded by the Centers for Disease Control and Prevention Cooperative Agreement #U01PS005181 to Emory University. The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the Centers for Disease Control and Prevention.

Data Availability

After the primary outcome analyses are completed, deidentified data sets can be made available upon written request to the investigator PSS. Interested parties should propose a specific analytic hypothesis. The data use agreement would be developed to ensure (1) data are used solely for research purposes without attempting to identify individual participants; (2) that there is a clear plan for maintaining the safety and security of data; and (3) commitment to the destruction or return of data after analysis.

Conflicts of Interest

None declared.

Abstract

Background: The rate of Type 2 diabetes mellitus (T2DM) among Mexican American individuals is 16.3%, about twice that of non-Hispanic White individuals. While a number of education approaches have been developed and shown to improve diabetes self-management behaviors and glycemic control for Spanish-speaking Latinx patients with T2DM, there is little research to guide health practitioners regarding which interventions to apply and when so that resources are used efficiently, and treatment outcomes are maximized.

Objective: This study aimed to describe an adaptive intervention that integrates community mental health workers, diabetes nurse educators, family members, and patients as partners in care while promoting diabetes self-management for Mexican American individuals with T2DM. The project incorporates four evidence-based, culturally tailored treatments to determine what sequence of intervention strategies work most efficiently and for whom. Given the increasing prevalence of T2DM, achieving better control of diabetes and lowering the associated medical complications experienced disproportionally by Mexican American individuals is a public health priority.

Methods: Funded by the National Institute of Nursing Research (National Institutes of Health grant R01 NR015809), this project used a sequential multiple assignment randomized trial and included 330 Spanish-speaking Latinx patients with T2DM. In the first phase of the study, subjects were randomly assigned to an evidence-based diabetes self-management educational program called Tomando Control delivered in a group format for 6, biweekly 1.5-hour sessions, led either by a community health worker or a diabetes nurse educator. In the second phase of the study, those subjects who did not improve their diabetes self-management behaviors were rerandomized to receive either an augmented version of Tomando Control or a multifamily group treatment focused on problem-solving. The primary outcome measure was the "Summary of Diabetes Self-Care Activities." Evaluations were made at baseline and at 3, 6, and 12 months.

Results: This study was funded in June 2016 for a period of 5 years. Institutional review board approval was obtained in November 2016. Between March 2017 and September 2020, a total of 330 patients were recruited from the outpatient primary care clinics of Olive View-UCLA Medical Center, with a brief hiatus between May 2020 and July 2020 due to COVID-19 restrictions. The study interventions were completed in December 2020. Data collection began in March 2017 and was completed in December 2021. Data analysis is expected to be completed in Spring 2023, and results will be published in Fall 2023.

XSL•FO
RenderX

Conclusions: The results of this trial should help practitioners in selecting the optimal approach for improving diabetes self-management in Spanish-speaking, Latinx patients with T2DM.

KEYWORDS

community health workers; diabetes education; Latinx; nurses; promotores; type 2 diabetes

Introduction

Background and Rationale

At 53 million people, the Latinx population is the largest minority group in the United States [1]. More than half of these are of Mexican origin, and this group has the lowest median age of any racial or ethnic group in the United States. Despite this, Latinx people living in the United States exhibit a disproportionate burden from type 2 diabetes mellitus (T2DM), with about double the prevalence among non-Hispanic White individuals [2]. A recent review of studies demonstrating an increased prevalence of diabetes and its complications among Latinx individuals compared with non-Hispanic White individuals suggested that low health literacy, lack of access to health care resources, and language barriers are among the main causes of T2DM ethnic disparities in the United States [3].

Over the past 20 years, several diabetes self-management education (DSME) approaches have been developed and shown to improve diabetes self-management behaviors and glycemic control as well as other health outcomes for Mexican American individuals with T2DM [4-9]. Numerous approaches have been developed, many of which share common elements including community involvement, face-to-face encounters, ongoing participation of a multidisciplinary treatment team, targeting the development of skills to promote behavior change, the provision of prompts and reminders, the use of a prior needs assessment to inform intervention design, and an explicit focus on social-contextual issues [10,11]. While each of these evidence-based DSME approaches has demonstrated advantages over usual practices in Mexican American communities, these interventions differ in their format (individual vs group), the type of provider used to deliver the DSME intervention (health professional vs lay community health worker or, in this study, *promotore*), and treatment target (patient vs patient and family). Such differences could be impactful both in terms of overall patient outcomes as well as economic feasibility for health care systems considering their implementation; however, there is little research to date to guide health practitioners regarding which interventions to apply and when in order to maximize treatment outcomes and resource efficiency.

An additional gap in the literature stems from the finding that fewer than 40% of subjects offered these treatments achieved levels of hemoglobin A1c (HbA1c) in accordance with the standards established by the American Diabetes Association [12]. Identifying nonresponding patients early in the treatment process and implementing more culturally appropriate, family-centered approaches could forestall long-term adverse consequences. The rationale of this study is to fill this gap of knowledge by comparing 4 different approaches to enhance diabetes self-management of Hispanic patients with T2DM.

Registered Nurses Versus Community Health Workers

Many educational and management strategies developed and implemented to address the specific needs of the Mexican American population were originally designed to involve registered nurses (RNs), certified diabetes educators, or dietitians as the primary patient educators [6,8,9]. The limited availability of such specialized providers in general, and bilingual or bicultural providers, in particular, prompted many interventions to use *promotores* to handle group educational and skill reinforcement sessions as adjuncts to the primary educators. In some programs, the role of the *promotore* was modified such that the *promotore* became the principal diabetes health educator, thus replacing highly educated personnel such as certified nurses for patient education and long-term case management [13-19].

The evidence regarding the efficacy of *promotore*-delivered interventions is mixed and incomplete. Some studies have found that interventions with community health workers do indeed have an impact when compared to usual clinical practice [8,9,16-18,20]. However, it has also been suggested that this may not be the case [19], and at least one study using focus groups with primarily Mexican American patients found that these patients strongly preferred trained health care professionals like nurses [12]. To date, there has been no study that has directly compared similar DSME interventions delivered by a community health worker (ie, a *promotore*) versus a health care professional such as a nurse.

Family Incorporation

Social support has been recognized as a crucial component of health and behavior change, and family members are the most significant source of that support [21]. Family behaviors and attitudes can support or challenge a patient's adaptation to illness and subsequently a patient's confidence, intent, and willingness to implement disease-management strategies [22], and a recent meta-analysis has suggested that addressing family functioning and problem-solving in addition to teaching diabetes self-management skills is critical to success [23]. Mexican American individuals with T2DM have cited attitudes, perceptions, and preferences of family members as significant barriers to making recommended changes in their diet and exercise patterns [24]. Interventions that target familial support to improve diabetes self-management have been effective within the Mexican American population [25]. Despite this evidence,

XSL•FO
RenderX

most of the abovementioned interventions designed and tested for Spanish-speaking Hispanic individuals only encourage the involvement of families in DSME interventions; none explicitly target the family or family behaviors.

To date, the literature offers only 2 examples of diabetes interventions that specifically target and address the Mexican American families' collective behaviors. The first was a demonstration project carried out in southern Arizona, which used *promotores* to deliver a 12-week program designed to build and reinforce family communication, collective esteem and efficacy, and family support for appropriate food choices and physical activity behaviors. A pre- versus postintervention comparison indicated a significant increase in diabetes knowledge, family efficacy to change food choices, and actual activity behaviors [9]. The other uncontrolled study enrolled 36 Latinx (predominantly Mexican American) families in rural North Carolina in a similar DSME curriculum but the groups were led by a nurse practitioner rather than a *promotore*. Patients showed significant improvement in diabetes knowledge, diabetes self-efficacy, and higher intake levels of healthy foods (ie, fruits and vegetables), and performance of blood glucose testing and foot inspections, while family members demonstrated improved diabetes knowledge and family support compared to baseline [26].

Group Versus Individual Sessions

The type and setting of these interventions may also be important, and one question that has received some attention is that of group versus individual sessions. One study that tested the "dosing" of an individual DSME found that 16 hours of education with an additional 6 hours of group support was as effective as 52 individual contact hours delivered over 12 months [6]. There are also 4 studies that have directly compared individual with group DSME; three of these led to the conclusion that group education appeared to have a greater impact on diabetes self-management and glycemic control than individual education at 6 and 9 months [27]. However, these were described as poor studies with small numbers and high dropout rates, and there was no significant difference between the interventions at 12 and 18 months. The fourth study did find that patients with T2DM of relatively long duration and HbA1c levels of 7% or higher had improved short-term HbA1c outcomes and a greater likelihood of achieving an HbA1c level below 7% if they were educated using the group approach versus the individual method; however, in this study, the total educator contact time was also greater for the group intervention (8 hours) than for the individual approach (3 hours) [28].

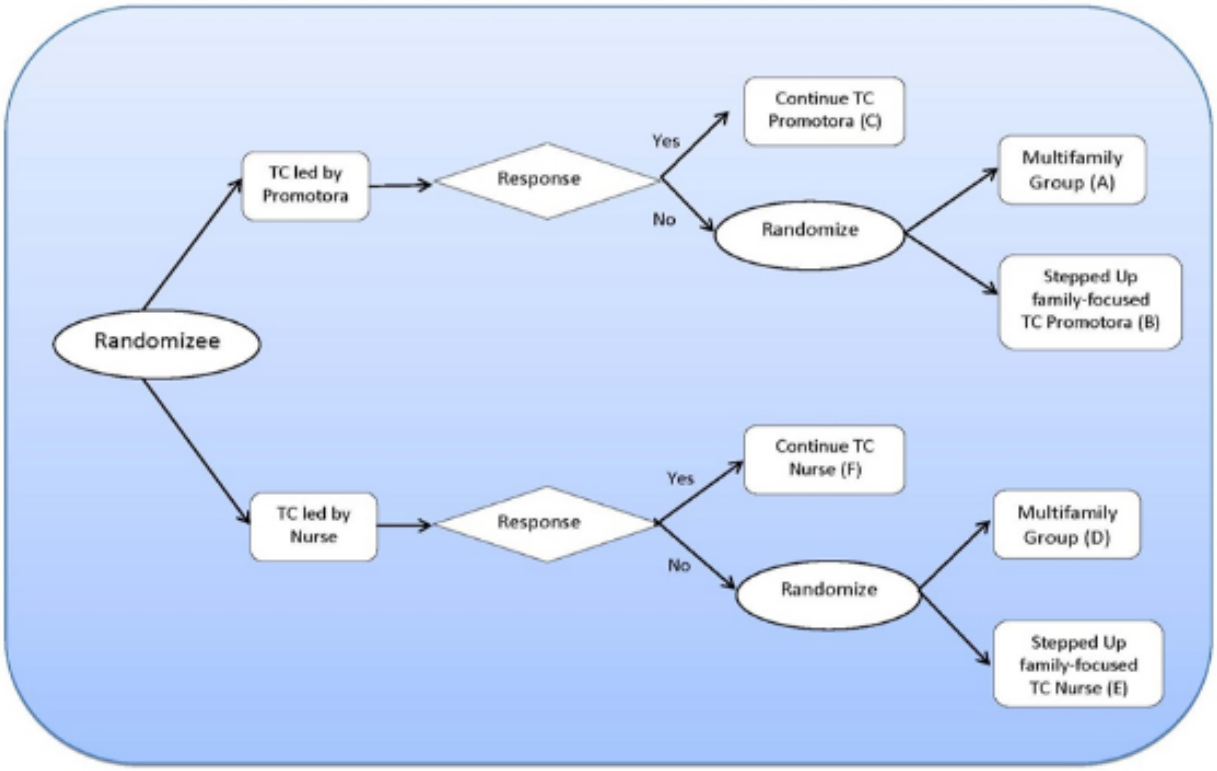
Some families may require extra efforts, such as home visits, telephone reminders, and cultural tailoring, to address the specific obstacles to attendance faced by families [9]. However, other families may need a far more intensive approach to encourage and sustain their participation in DSME, including multifamily groups (MFGs). Two lines of research support the value of MFGs for this purpose. First, randomized controlled studies of MFG in adolescents with type 1 diabetes have shown improvements in diabetes self-care, particularly in patients with poorer glycemic control at baseline [29,30]. Second, the MFG approach has been shown to improve self-management skills in a Mexican American population with chronic mental illness [31]. Given that this study was carried out with a hard-to-reach community of Spanish-speaking Mexican American individuals and that psychiatric symptoms (eg, depression, anxiety, and psychosis) have been identified as major impediments to use diabetes self-management practices [32-35], the results suggest that the MFG approach may be effective in this population.

Primary Objective

The overall objective of this project is to build the science of T2DM self-management for Latinx patients by constructing a family-centered adaptive intervention to help patients and their relatives enhance their diabetes knowledge and beliefs, increase the use of self-regulation behaviors, and foster social facilitation.

Hypothesis

There are 4 main hypotheses this study will test. First, subjects randomized to adaptive interventions that begin with nurse-led groups will show greater increases in diabetes self-management behaviors than those who begin with *promotore*-led groups. Second, among nonresponders to either of the first-line approaches, subjects randomized to a multifamily, problem-solving group will show greater improvements than those assigned to a single-family approach. Third, key relative's participation in treatments will lead to (1) increased patients' and relatives' diabetes knowledge; (2) increased diabetes self-efficacy; (3) increased collaborative goal setting by families with health care providers; (4) increased family support; and (5) increased T2DM self-management behaviors. Fourth, subjects who are older, female, less educated, and less acculturated have an alcohol use or psychiatric disorder or have a longer history and greater severity of T2DM will (1) be less likely to have family members participate in treatment and (2) use diabetes self-management skills less often.



Methods

Study Overview and Design

A sequential multiple assignment randomized trial study design evaluates 2 initial interventions for Hispanic adults with T2DM. Figure 1 indicates the study's procedural flow. First, after baseline assessment, subjects were randomly assigned to receive the *Tomando control* (TC) intervention led either by a community health worker or *promotore* (TC-*promotore*) or by a nurse (TC-nurse). Both of these consist of 6 biweekly 2.5-hour group sessions. After the first 3 intervention sessions (phase 1), preliminary response was measured. Early responders to each intervention continued their same assigned intervention for 3 more sessions. For nonresponders (defined below), participants were rerandomized (phase 2) to receive either an augmented, stepped-up intervention that makes additional efforts to engage family members in the DSME enterprise for 3 more sessions or an MFG intervention designed to individually tailor treatment to address the obstacles encountered in promoting diabetes self-management behaviors. The MFG intervention consisted of 6 additional group sessions.

XSL•FO

Figure 1. Smart design. TC: Tomando control.

Clinical Setting and Patient Population

The study was being conducted in the community served by Olive View-UCLA Medical Center, which is a teaching hospital affiliated with UCLA and part of the Los Angeles County Department of Health Services health care system. It is a safety net facility providing inpatient and outpatient services to the 4 million residents of the San Gabriel, San Fernando, and Antelope Valley regions of Los Angeles County. All patients at Olive View-UCLA Medical Center are under the care of a medical home, which includes full- and part-time staff composed of primary care physicians, residents, interns and medical students, nurses, and nursing assistants. The majority of patients are underinsured or uninsured. Approximately 60% (120,000/200,000) of patients speak Spanish as their primary language, and 60% (120,000/200,000) of patients are of Mexican descent. Among them, over 80% (96,000/200,000) of patients live with their families. The prevalence of T2DM is increased compared to the national average, with 50% (100,000/200,000) of the community affected.

Subject Eligibility and Recruitment Strategy

Inclusion criteria for study participants include the following: (1) aged at least 18 years, (2) being of Latinx origin speaking fluent Spanish, (3) self-report of type 2 diabetes, suboptimally controlled, defined as having HbA1c values of >7.0%, and (4) living with at least 1 adult family member who is willing to participate. Inclusion criteria of family members are as follows: (1) aged 18 years or older, (2) living in the same patient's residence, and (3) being of Latinx origin. Exclusion criteria include (1) type 1 diabetes, (2) pregnancy, and (3) significant cognitive impairment.

Participants were recruited from the outpatient primary care clinics of Olive View-UCLA Medical Center. Recruitment began by advertising the study using flyers in the primary care clinics. Interested individuals notified staff in the primary care clinic or the study coordinator. The study coordinator discussed the study and provided further information about the project. With the individual's permission, key relatives—significant others identified by the individual as among the most important people involved daily in his or her life—were contacted. Both the patient and the family member needed to provide informed consent for either to participate. Subject characteristics at baseline are depicted in Table 1.

XSL•FO

Characteristics and Training of DSME Leaders

The *promotores* were recruited from the workforce of Olive View-UCLA Medical Center (3 women and 1 man). They were of Hispanic origin and spoke fluent Spanish and English. The 3 RNs were employees at Olive View-UCLA Medical Center. All 3 spoke English and Spanish fluently. Two of the 3 RNs were of Hispanic origin. Both *promotores* and RNs were trained and certified in the Stanford Chronic Disease Self-Management program. This training included a 4-day onsite workshop in Palo Alto, California, followed by a cross-training webinar on diabetes self-management education and 2 sets of practice groups conducted at Olive View-UCLA Medical Center designed to ensure fidelity to the treatment model.

Initial Intervention: Tomando Control

The initial intervention, called "Taking Control of your Diabetes" or in Spanish "*Tomando Control de su diabetes*," consisted of 6 biweekly sessions lasting 2.5 hours each led either by 2 trained *promotores* (*promotore*-led group) or by RNs (RN-led group). Each session included 10-12 patients. Patients' families or friends were encouraged to attend sessions, which were held at Olive View-UCLA Medical Center. Each participant received a copy of the companion book, an audio relaxation tape, and an audio exercise tape with a booklet to supplement the material covered during the workshop sessions. The following topics were covered in sessions: (1) techniques to deal with the symptoms of diabetes and associated condition, (2) appropriate exercise, (3) healthy eating, (4) correct use of diabetes medications, and (5) working more effectively with health care providers in a collaborative partnership. Patients were expected to make weekly action plans, share experiences, and help each other solve problems they encountered in creating and carrying out their self-management strategies. The classes were highly participative and allowed participants to show mutual support and develop confidence in their abilities to manage their health. The program is based on the Stanford School of Medicine's Chronic Disease Management Program developed by Lorig et al [36] and culturally adapted by Mauldon et al [37]. Similar program content was delivered in each group, with the only difference being the type of trainer: *promotore* versus RN.

Early response status was determined after the third TC session (ie, 6 weeks after starting the intervention). An independent evaluator blind to study condition used the Summary of Diabetes Self-Care Activities (SDSCA) to assess diabetes self-management behavior. A subject was considered an early responder if he/she showed a gain of 50% over baseline on the SDSCA. Early responders continued to receive the TC intervention that they were originally assigned. Nonresponders, those subjects who did not show a gain of 50% over baseline, were rerandomized to receive either the stepped-up, family-focused TC approach or the MFG. The following sections describe these 2 interventions.

Second Intervention: Family-Focused TC Approach

For those subjects who were randomly assigned to receive the augmented TC, the TC clinician (either a *promotore* or nurse, depending on the original group assignment) conducted up to 3 home visits that were designed to explain the purpose of the TC intervention to a key relative so as to reengage the family member in the group process. Each visit was carefully scripted to address the family's role in helping the family member with

XSL•FO
RenderX

diabetes. The first home visit was focused on the family's reaction to having a loved one with diabetes and was designed to elicit how the family functioning had changed since the diagnosis was made. The second session aimed to help the family set realistic goals for participation in TC including the length of the groups and the expectations of the family in using the material covered in the group to effect behavior change. Logistical details (eg, which family member would accompany the patient to the group, how they would get to the group, and so on) were identified and obstacles to attendance were resolved. The third session solidified the gains made in the first 2 sessions as well as emphasized to the family that the *promotore* or nurse was available for crises or problem resolution if last-minute difficulties arose prior to the TC group. These engagement strategies have been very effective in increasing the participation of family members in group therapy [38].

Second Intervention: Multifamily Problem-Solving Group Approach

Overview

The other treatment assignment for nonresponders to TC was MFG. As described by McFarlane [39], standard MFG consists of 3 components: three initial "joining" sessions conducted with each of the families separately, a 1-day (6 hours) educational workshop, and ongoing MFG sessions. In the MFG used in this project, the joining sessions and educational workshop were performed as described in the MFG manual. However, the ongoing multifamily sessions in this project differed from standard MFG in which it was explicitly organized around the obstacles to diabetes self-management identified in family interviews. Each MFG session included structured activities that ensured participation by all families in each content area, gave information, carried out problem-solving exercises, and provided skills training focused on increasing individuals' diabetes self-management behaviors.

Joining Sessions

The 3 joining sessions offered each family an individualized approach designed to facilitate the process of engaging in treatment. The sessions were conducted by a bilingual, bicultural *promotore* or nurse, depending on the subject's initial group assignment. The sessions were designed to familiarize all members of the family with the therapists who conducted the ongoing MFG sessions and to educate them about the need for ongoing treatment. The sessions also helped the family identify and overcome the obstacles to successful diabetes self-management. All family members were given the opportunity to describe their understanding of their ill relative's problem and were also given factual information based on current knowledge about diabetes.

Educational Workshop

The educational workshop is a 6-hour program that provides information about the etiology, biology, genetics, symptoms, and treatment of T2DM. Much of this material will be covered in the TC groups; however, the educational workshop was made available to those MFG family members who did not attend the TC sessions. It was conducted by the MFG clinician along with one of the authors (AK). They used the Spanish translation of the standardized videotape and coping skills guidelines developed by the author. The material is presented in basic, elementary school level Spanish with little use of idioms or colloquialisms. Presentations were made both visually and orally, including the use of role plays to allow family members with poor reading skills to adequately assimilate the material.

Ongoing MFG Sessions

Following the joining sessions and educational workshop, each cohort of 5-6 families met twice monthly for 3 months (6 sessions total). All sessions were co-led by the clinicians who conducted the 3 joining sessions. The first MFG session was focused on teaching problem-solving skills. Participants learned the mechanics of the problem-solving method and how to apply it to various problem situations. The method involves 7 steps as follows: define the problem, set goals, generate alternatives, evaluate each, select one, implement it, and evaluate outcomes. The subsequent 5 sessions were structured in the usual MFG fashion. This included a brief sharing period followed by group discussion. The discussion consisted of the sharing of personal experiences, identification of a problem situation, and the use of the problem-solving method to address the situation within the context of general group support. The group ended with review of the gains made by group members that week.

Data Collection and Measures

Table 2 lists the measures to be used at each assessment point. Assessments were done at baseline and at 3, 6, and 12 months. In addition, the primary outcome variable (ie, diabetes self-management behaviors) was measured 6 weeks after the start of the first phase of the study to determine progress over time and the need for a change in treatment strategy. All measures were collected by a research assistant blind to the experimental conditions. Characteristics of the sample were measured at the initial visit including various demographic and clinical information.

The primary outcome is the difference in response scores of the SDSCA between the 4 groups at 3, 6, and 12 months after baseline [40]. The SDSCA is a well-validated instrument with excellent psychometric properties in several languages including Spanish [41,42]. It is the instrument most frequently used for assessing the acquisition of diabetes self-management behaviors [43]. The SDSCA is formatted to ask on how many of the previous 7 days the individual performed recommended self-management activities: eating healthy foods, following a diabetic diet, exercising, self-monitoring of glucose, and caring for one's feet. A weekly self-care score ranging from 0 to 7 is generated, with higher scores corresponding to greater number of days carrying out the recommended behaviors.

Several secondary outcomes were also measured in this study. Diabetes self-efficacy, defined as the confidence of a person with diabetes to manage diet, exercise, track blood glucose levels, and overall control their diabetes, was measured using the 8-item Stanford Self-Efficacy Scale. Scores range from 1 (no confidence) to 10 (total confidence). The internal reliability of the Spanish language version of this measure is 0.85 [44]. Diabetes knowledge was measured using the Spoken Knowledge in Low Literacy Patients with Diabetes scale, a 10-item scale

that assesses knowledge of glucose management, lifestyle modifications, recognition, and treatment of hyper- and hypoglycemia, and activities to prevent long-term consequences of the disease. Higher scores indicate better knowledge about diabetes, and the measure has been found to have excellent validity and reliability [45]. The patient's degree of family support was measured using the 17-item Diabetes Family Support Behavior Checklist, which uses a 5-point Likert scale to assess the patients' perceptions about their relatives' support in medication taking, glucose monitoring, exercise, and diet [46]. Cronbach αs have been reported between 0.64 and 0.71 in Hispanic subjects with diabetes [26,47]. Collaborative goal setting was measured with the Spanish version of the Patient Assessment of Chronic Illness Care [48], a 20-item survey for evaluating the quality and patient-centeredness of chronic illness care received by the patient according to the Chronic Care Model paradigm [49]. The Spanish language translation of this instrument has demonstrated high reliability, internal consistency, and test-retest reliability [50]. Treatment session attendance was assessed for both patients and their relatives, and the percentage of treatment sessions attended by the key relative was used to analyze relationships with other outcomes. Glycemic control, defined as HgA1c level, was tested using a Bayer A1C NOW kit (Bayer Healthcare) using finger stick blood taken by a phlebotomist. Levels greater than 7.0% are considered poor glycemic control, and levels greater than 10.0% are considered uncontrolled diabetes [51]. Height, weight, BMI, and blood pressure were measured using standard procedures.

Table 2. Study measures.

Variables	Measure	Content	Schedule[a]
Demographics	• UCLA Client Data Inventory • Cuellar acculturation scale • Structured Clinical Interview for DSM-IV (SCID-I)	Age, gender, marital status, work status, educational level, acculturation level, and medical/psychiatric disorders	T1
Diabetes self-management	• Revised Summary of Diabetes Self-Care Activities (SDSCA)	Assesses adherence to diet, exercise, self-monitoring, medications, and foot care	T1-T4 and week 6
Diabetes self-efficacy	• Stanford Self-Efficacy Scale	Measures confidence to self-manage diabetes	T1-T4
Diabetes knowledge	• Spoken Knowledge in Low Literacy Diabetes Patients (SKILLD)	Assesses knowledge of T2DM and its management	T1-T4
Family support	• Diabetes Family Support Behavior Checklist	Assesses family support for T2DM self-management	T1-T4
Collaborative goal setting	• Patient Assessment of Chronic Illness Care (PACIC)	Evaluates quality and patient centeredness of received treatment	T1-T4
Treatment attendance	• Treatment Attendance Log	The percentage of sessions attended by patient/relative	T3
T2DM control	• Bayer A1C NOW kit	Hemoglobin A1c level	T1-T4

[a]Data collection schedule: T1: baseline; T2: 3 months; T3: 6 months; T4: 12 months.

Statistical Analysis

Data analysis will be conducted by intent-to-treat with participants analyzed according to their randomized intervention regardless of attendance. Our primary analytical tool will be the generalized linear mixed model (GLMM) [52,53]. GLMMs accommodate multiple outcome types in a unified framework via an appropriate link function (identity link for continuous normally distributed measures; logistic link for binary measures); allow for both fixed and time-varying covariates; automatically handle missing data, producing unbiased parameter estimates provided observations are missing at random; and appropriately account for the correlations induced by repeated measurements within subjects. We will fit GLMMs with fixed effects for the intercept, time (baseline, 3, 6, and 12 months), group, and a group-by-time interaction term, where the definition of group depends on the hypothesis and an unstructured covariance matrix. Model diagnostics will be used to determine suitability of more parsimonious (eg, autoregressive) correlation structures and nonlinear (eg, quadratic) effects for time. A sample size of 330 patients will provide 90% power to detect a difference of 0.29 in the score of SDSCA between the study groups. Subgroup analysis will be performed to determine if some moderators differentially affect the outcome such as patients' age, gender, educational levels, duration of diabetes, and baseline HbA1c levels.

Ethics Approval

All participants signed an informed consent form. The trial protocol was reviewed and approved by the Institutional Review Board of the David Geffen School of Medicine at UCLA (#16-000434) and the Education and Research Institute of Olive View-UCLA Medical Center (#882988). Initial approvals were received in November 2016, and yearly renewal approvals were received throughout the course of the study. The 1-year follow-up assessments were completed in late 2021.

Results

This study was funded by the National Institute of Nursing Research in June 2016 for a period of 5 years. Institutional review board approval was obtained in November 2016. Between March 2017 and September 2020, a total of 330 patients were recruited from the outpatient primary care clinics of Olive View-UCLA Medical Center, with a brief hiatus between May 2020 and July 2020 due to COVID-19 restrictions. The study interventions were completed in December 2020. Data collection began in March 2017 and was completed in December 2021. Data analysis is expected to be completed in Spring 2023, and results will be published in Fall 2023.

Discussion

Principal Findings

This paper describes the protocol of a sequential multiple assignment randomized trial to better understand how various factors in the design and implementation of a DSME program can affect the outcomes of participants with T2DM.

The first question we address is whether RNs are more effective than *promotores* in leading DSME programs for Latinx patients with T2DM. This study represents a direct test of the hypothesis that Latinx subjects assigned to RN-led groups will perform more diabetes self-management behaviors than subjects assigned to *promotore*-led groups. The findings of this aspect of the study could have important economic implications, particularly if subjects in RN-led groups do not achieve better outcomes than subjects in *promotore*-led groups because of the greater cost and lower availability of RNs than those of *promotores*.

The design of this study will also further our understanding of the efficacy of interventions that use MFGs and how these are compared with interventions that focus on individual families. The reasons that patients may fail initial DSME interventions are numerous and varied, such that it may be difficult for any individual educator—professionally trained or otherwise—to be able to address all barriers that arise for a patient. The incorporation of multiple families with similar backgrounds in the same community provides the opportunity for participants to offer their combined, cumulative perspectives and experiences in order to problem solve and support their peers. This is important not only because of the increased likelihood of identifying reasonable solutions but also because it could help build a stronger sense of self-efficacy and agency among participants while also decreasing stigma, shame, and isolation. Furthermore, because sessions are intended to address behaviors and beliefs among the entire family, we hope to gain additional insight into how these dynamics influence outcomes for participants in this program.

This study will also measure various demographic variables including age, gender, marital status, working status, educational level, acculturation level, comorbid medical and psychiatric disorders, and severity of diabetes. These will also be analyzed to explore whether particular characteristics of the sample can serve as potential predictors of outcomes.

Comparison to Prior Work

There have been some studies that compared outcomes of patients with T2DM when counseled by RNs versus community health workers (the equivalent of *promotores*). The randomized trial by Babamoto et al directly compared the effectiveness of community health workers with case management and standard provider care in Latinx patients with T2DM for 6 months. In that study, patients in the community health worker group performed better than the other groups in several outcomes, namely higher retention rates, greater reduction in HbA1c concentrations, and medication adherence [16]. Kim et al compared outcomes in Korean Americans with T2DM, finding that patients counseled by community health workers had greater decreases in HbA1c concentrations than RN-counseled patients [54].

Several other studies using different methodological approaches have shown that interventions led by community health workers were cost effective and result in substantial reductions in diabetes complications. Ryabov et al estimated that interventions led by community health workers could result in an absolute reduction in projected probability of lifetime occurrence of nephropathy by 5.9%, neuropathy by 3.4%, retinopathy by 2.6%, and coronary artery disease by 3.8% [55]. Moreover, Brown et al suggested that *promotores* were most cost-effective among Latinx patients aged 50-65 years [56]. The benefits of community health workers extend to other ethnicities. For example, Huang et al found that home visits conducted by community health workers were highly cost-effective in a randomized study of 268 patients with T2DM in American Samoa [57]. We expect that our study will be particularly useful in building on this knowledge because the educational programming is standardized between both groups, with all participants receiving the same evidence-based intervention.

Strengths and Limitations

Strengths of this study include its randomized design and inclusion of enough patients to allow for adequate statistical power and subgroup analysis. This study uses the SDSCA, which is a well-validated instrument to assess diabetes self-management behavior. It is the most widely used self-report instrument for measuring diabetes self-management in US adults [41]. In an appraisal of 26 psychometric tools of diabetes education, Eigenmann et al identified the SDSCA as 1 of 3 tools that met all expected criteria for validity, reliability, relevance, feasibility and acceptability, and responsiveness to change [58].

One potential limitation of this study is that the investigators were aware of the patients' group assignment, and therefore bias in favor of any particular group cannot be excluded. However, every effort was made to ensure blinding. For instance, *promotores* and RNs were not aware of the purpose of the trial. An independent evaluator blind to study conditions was responsible for administering all study measures. A second limitation is the short duration of the trial (ie, 6 sessions over 3 months). However, many years of clinical experience and research data suggest that 6 intervention sessions are sufficient to result in clinically significant changes in diabetes self-management behavior [59].

Conclusions and Future Directions

The findings of this trial should contribute to our understanding of the roles of community health workers, RNs, and family members in this area and may have important economic implications. Future research will focus on understanding the factors that affect self-management for Latinx patients with T2DM and will provide valuable information toward constructing an adaptive intervention that will help to determine which treatment strategies work to improve diabetes self-management behaviors most efficiently and for whom. Given the ever-increasing prevalence of T2DM, achieving better control of diabetes and lowering the associated medical complications experienced disproportionally by Latinx patients is a public health priority for a group that has long been underserved by current research and practice.

Acknowledgments

This trial was entirely funded by the National Institute of Nursing Research (NIH grant R01NR015809).

Data Availability

Deidentified data will be made available to all appropriate requests from interested researchers at the time of results publication.

Abstract

Background: Firearm safety among individuals with Alzheimer disease and related dementias (ADRD) is an underdiscussed and underresearched concern in the United States, especially given the growing population of community-dwelling adults with ADRD. The “Safety in Dementia” (SiD) web-based decision aid was developed to support caregivers in addressing firearm access; the efficacy of SiD is unknown.

Objective: Through the SiD decision aid, the Safe at Home (S@H) study aims to support caregivers in making decisions about home safety that align with their goals and values, and behaviors regarding firearm access for persons with ADRD and firearm access.

Methods: The S@H study is a 2-armed randomized controlled trial to test the effect of the SiD decision aid on caregivers of community-dwelling adults with ADRD who have firearm access. S@H aims to recruit 500 ADRD caregivers (age ≥18 years, fluent in English or Spanish, and in the United States) through online or social media advertisements and through relevant organizations. Participants are randomized to view SiD or a control website at their own pace; all participants complete web-based questionnaires at baseline, 2 weeks, 2 months, and 6 months. The primary outcome is immediate preparation for decision-making; secondary outcomes include longitudinal decision outcomes and self-reported modifications to firearm access. The relative reach

XSL•FO
RenderX

and effectiveness of each recruitment method (online/social media and through relevant organizations) will be assessed by examining differences in caregiver participation, retention rates, and relative cost.

Results: The study enrollment began in May 2022. As of December 2022, a total of 117 participants had enrolled.

Conclusions: The S@H study is the first randomized trial of a firearm safety decision aid for ADRD caregivers. The results from this study will inform how best to support caregivers in decision-making regarding firearm safety. Further, results may guide approaches for recruiting caregivers and for dissemination of resources.

Introduction

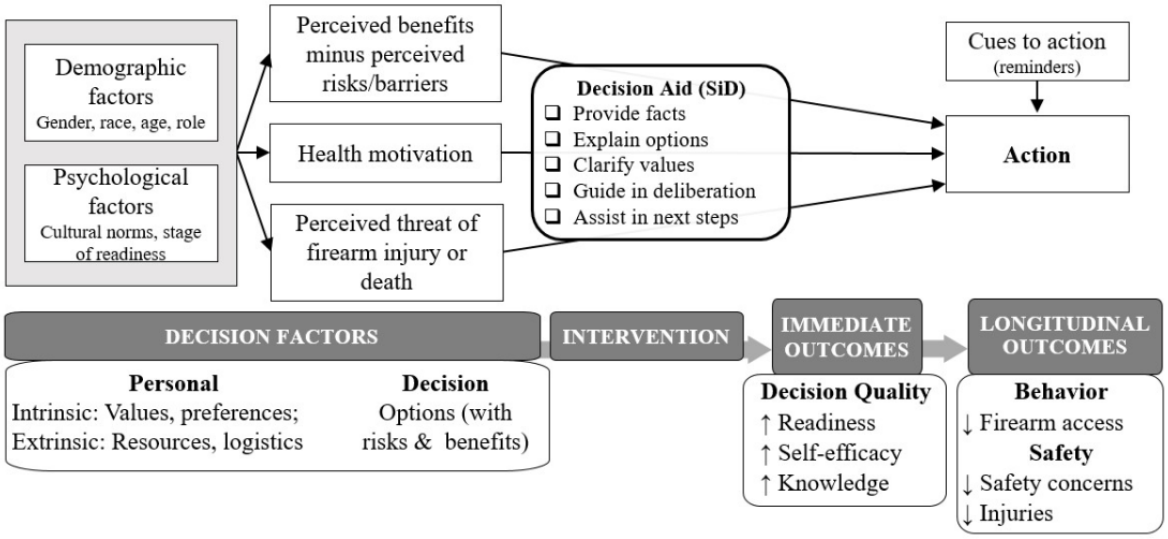
Background

Approximately 5.8 million Americans—roughly 10% of all adults aged 65 years or older, and 17% of Hispanic older adults [1]—live with Alzheimer disease and related dementias (ADRD) [2]. Almost three-quarters of people with ADRD live in the community [2] supported by an estimated 16 million informal caregivers (eg, spouses or other family members) [2]. Caregivers face myriad concerns and demands, including daily safety considerations, financial management, and long-term goals of care. There is an urgent need for effective, acceptable interventions to support informal caregivers in decision-making and behavior change to act on those decisions, especially regarding home safety. Ideally, the development and dissemination of such interventions—to the broad, diverse community of informal caregivers—could help reduce caregiving burden, delay nursing home placement, and support aging in place [3].

Many ADRD caregivers face difficult decisions about when and how to address the sensitive topic of in-home firearms. In the United States, an estimated 33%-60% of people with ADRD have a firearm in the home [4,5], and 38% of ADRD caregivers identify firearms as an issue to address [4]. Approximately one-third of older Americans (≥65 years) own a gun [6]; yet in a large sample of older firearm owners, only one-fifth reported having a plan for securing, removing, or transferring firearms if they could not handle them safely [7]. For firearm access, caregivers worry about how to take action, questions relate to legal and logistic uncertainties, and lack of guidance [8]. In a national survey of caregivers, although the majority supported ADRD-relevant firearm safety counseling by health care providers, only 5% had ever received it [9]. Caregivers must balance safety concerns (of both the person with ADRD and those around them) with considerations about the person with ADRD's response (eg, anger) and logistics (eg, cost of various options).

Providing resources to caregivers regarding firearm safety is of particular importance due to increased risk of suicide and risk related to behavior changes associated with ADRD. In the United States, 70% of older adult suicides involve a firearm, and suicide risk is elevated among individuals with ADRD, especially in early ADRD [10-12]. The rate of suicide among individuals in a prospective cohort study following individuals in the 12 months after dementia diagnosis was 26.42 per 100,000 person years, totaling 705 deaths by suicide of which 63.3% (nearly 450 deaths) were completed by firearm [13]. Dementia also raises concerns about the safety of others given the behavioral changes that commonly co-occur with ADRD, including confusion and emotional volatility. Violence toward others occurs annually in approximately 1% to 3% of older adults with ADRD [14]. Regarding firearm safety, even among older adults with prior training and safe handling skills, unintentional ("accidental") firearm injuries can also occur due to impairments in judgment, dexterity, and memory [9].

Web-based resources have the potential to reach a broad range of caregivers. More than 75% of American adults aged 30-64 years use at least one social media platform, most commonly Facebook and Instagram among middle-aged and older adults [15]. Web-based support groups are a leading source of health information for people living with or caring for loved ones with chronic disease [16,17]. The National Institute on Aging's (NIA) Informal Caregiving Panel and Alzheimer's Disease Research Summit recommended the development of technologies to integrate evidence-based treatments and support caregivers in the context of ADRDs [18-20]. Internet tools offer the promise of reaching diverse groups across broad geographic regions and allow individualized timing and pace of use [21]. eHealth interventions for informal ADRD caregivers show promise [22-24], are cost-efficient [25], and offer a way to sustain caregiver engagement over time [23]. The privacy afforded by eHealth, already cited as important by ADRD caregivers [23], may be particularly critical for the sensitive topic of firearms. ADRD caregivers may also prefer at-home internet resources or interventions because of limited ability or time to travel to an intervention site (eg, due to being with a home-bound person) [26].



Prior Work

To address caregiver needs related to firearm access, and guided by theory [27-29], our team previously developed the web-based Safety in Dementia (SiD) decision aid [30], which is available for public use at no cost [31]. This web-based tool adheres to the International Patient Decision Aid Standards [29] and recommendations for user-friendly web design for older adults [32-34]. SiD is based on behavior change and decision-making theories [27,28] (Figure 1) and includes content to help

XSL•FO
RenderX

caregivers understand options (with a balanced presentation of benefits and drawbacks) and then be motivated to take the action that works best for their situation. SiD provides parallel sections regarding driving safety and general home hazards to broaden reach and contextualize firearm safety, and the tool was designed in collaboration with partners from the firearms community. The SiD tool was translated into Spanish using a rigorous translation process including independent back-translation to English by certified translators with adjudication of any discrepancies [35,36]. The pilot trial of SiD, in a national convenience sample of caregivers of community-dwelling people with ADRD, found 44% of caregivers reported safety concerns regarding firearm access and approximately 30% were currently considering options for what to do about firearm access [37].

Figure 1. Theoretical framework of Safety in Dementia (SiD) immediate and long-term impact. Rectangles represent Health Belief Model. Ovals represent Ottawa Decision Support Framework and related measures.

Goal of this Study

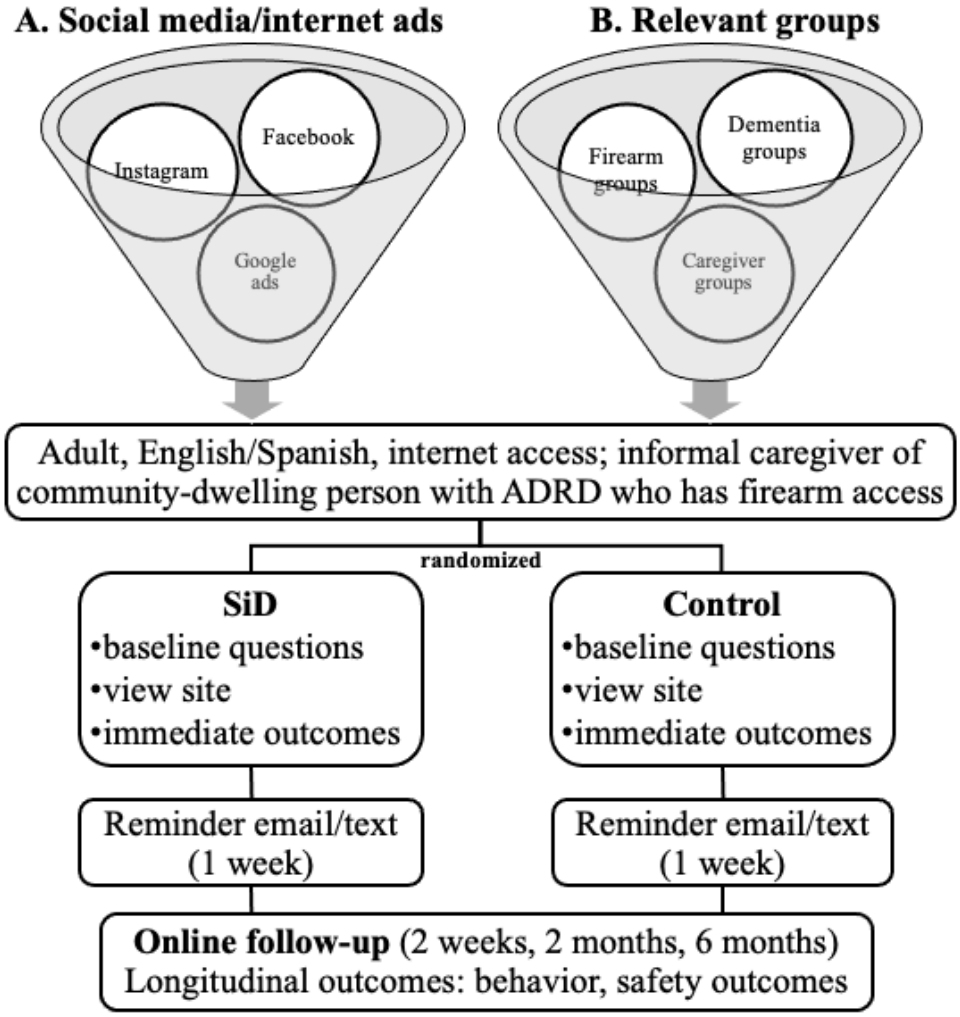
The primary goal of the S@H study is to assess the efficacy of the SiD decision aid on caregiver decision-making and behaviors regarding firearm access in the home of the person with ADRD. The study hypothesis is that the decision aid will increase the preparation for decision-making and the self-efficacy of informal caregivers to make and implement decisions that effectively address firearm access, thereby reducing firearm injury risk.

Methods

Study Design

The S@H study is a 2-armed randomized controlled trial. The study protocol follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) Guidelines [38]. The trial will be conducted and reported according to 2 checklists: the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth; Multimedia Appendix 1) [39] and the SUNDAE (Standards for Universal Reporting of Patient Decision Aid Evaluation; Multimedia Appendix 2) [40].

Theoretical Framework



The SiD decision aid and the S@H study are based on the Ottawa Decision Support Framework (Figure 1) [27], which incorporates concepts from psychology, social support, self-efficacy, and decision conflict. The framework suggests that decisional needs (eg, conflict/uncertainty, knowledge, and values) affect decision quality, with a decision being higher quality when it is informed by and reflective of the person's values. Decision aids can increase decision quality by addressing decisional needs, by identifying the decision, by providing a balanced explanation of the risks and benefits of options, by helping clarify personal values, and by activating the individual for decision-making [29,41]. Decision aids improve communication and knowledge and decrease decisional conflict and regret [42]. Application of the Health Belief Model [28] further expands this theoretical framework for how decision aids encourage action.

Eligibility

Participants must be adults aged 18 years or older, who live in the United States, are fluent in English or Spanish, and identify as informal caregivers for a community-dwelling person with ADRD who has firearm access. "Community-dwelling" is defined as a person with ADRD living in a private home and not in any type of caregiving facility (Figure 2). Participants must have internet access but do not need to live in the same home (or state) as the person with ADRD. Those in legal custody or institutionalized are not eligible to participate.

XSL•FO
RenderX

Figure 2. Study flow. ADRD: Alzheimer disease and related dementias; SiD: safety in dementia decision aid.

Recruitment

The S@H study aims to enroll 500 English- and Spanish-speaking caregivers through social media recruitment (including Facebook, Instagram, and Google ads) and relevant organizations in dementia/caregiver support, aging, and firearms. Social media postings are designed by the study team and then enhanced, implemented, and tracked by a digital marketing organization. Social media advertisement campaign parameters are set and modified to maximize reach and click-throughs, per standard web-based advertising practice; advertisements are iteratively adjusted for adequate gender and age diversity throughout the study.

Recruitment is also conducted via direct email through relevant organizations in dementia/caregiver support, aging, and firearm organizations, including web-based research databases like ResearchMatch and TrialMatch. Direct personal contact is made with relevant organizations by the study team and through the guidance and professional relationships of the Expert Advisory Panel. Study staff post advertisements directly (eg, in ResearchMatch) or send organizational representatives a toolkit with a sample text for inclusion in organization-generated newsletters, listservs, and flyers, on websites, and so on; sample social media content; and social shareables (images and informational graphics). The research team follows up 1 week after sending the media toolkit to inquire about the use of materials and to provide support as needed.

All advertisements contain similar messages and direct individuals to a landing webpage with a description of the study and identification of the lead organization (University of Colorado). The study has separate, identical landing web pages for each recruitment method and subgroup to allow tracking of overall analytics and participation by recruitment modality. There are 12 landing pages in total: 6 pages in English and 6 pages mirrored in Spanish. At each landing page, interested individuals can complete a brief web-based eligibility form. Those who choose to stop participation at any time or who are ineligible are provided with the hyperlink for the control (the NIA Home Safety Checklist for Alzheimer's Disease website, described below [43]).

Potential participants who are eligible based on the web-based form provide their contact information, and study staff then contact them by phone to validate identity (to reduce fraud or bot enrollment) and review eligibility and informed consent (Multimedia Appendix 3). For eligible, interested individuals, a study team member performs the randomization in REDCap (described below) [44,45] and emails or texts, depending upon preference indicated by the participant, the web-based survey link for the baseline assessment. Participants complete the

XSL•FO
RenderX

survey at a time and in a place of their choosing, on a computer or other web-enabled device, and at their own pace, allowing them to stop and come back to the survey.

Participants complete a set of web-based questionnaires before viewing the SiD decision aid or the control website (Figure 2, Table 1). After reviewing the website for as long as they want, participants complete a second set of web-based questionnaires with questions about the preparation for decision-making, self-efficacy, and knowledge (Table 1). One week after the baseline session, participants receive a text or email reminder (depending on their preference) with a hyperlink to the website to which they were randomized so they may visit it again if desired. Subsequent follow-up (at 2 weeks, 2 months, and 6 months) occurs via web-based surveys that are sent to participants. Participants receive incentives for each completed study survey (US $40 for baseline, US $60 for 2 weeks, and US $40 each for 2 and 6 months).

The study flow follows the SPIRIT template of recommended content for the schedule of enrollment, interventions, and assessments [38].

Randomization and Blinding

Enrolled participants are randomly assigned in equal numbers to the SiD intervention or control arm (Figure 2). Randomization is stratified between recruitment group A (social media or internet) and group B (relevant organizations). To reduce bias and aim for balance across arms, participants are randomized into blocks of undisclosed size. The team biostatistician conceals allocation using a centralized, computer-generated list in REDCap [46]. The study team's principal investigator and one of the biostatisticians are blinded; other members of the study team are unblinded. Participants are blinded to their study arm assignment.

Description of Intervention

In the intervention arm, participants are directed via hyperlink to the SiD decision aid. Participants may view the site in the format they prefer (eg phone, computer, and tablet) and are recommended to view the site for at least 5-10 minutes but may view it for as long as they want. Like other decision aids, SiD guides the participant through the decision process to promote person-centric consideration of values and preferences [47].

Description of Control

In the control arm, participants are directed via hyperlink to the NIA Home Safety Checklist for Alzheimer's Disease website [43]. Similar to the intervention arm, participants in the control arm may view the site in the format they prefer (eg, phone, computer, and tablet). The control (NIA website) represents typical care, as it is an easily accessible website that consistently appears in the top 5 results of a Google search for "home safety dementia" and provides basic education about home safety in the context of dementia [43]. The checklist provides limited guidance on firearms ("*Lock up or remove these potentially dangerous items from the home: ... Guns and other weapons, scissors, knives, power tools, and machinery*") [43] without information about specific locking or disposal options. Unlike the intervention, the NIA website does not guide the individual through the decision or promote person-centric consideration of values and preferences, making it an appropriate control [47].

Primary and Secondary Outcome Measures

Primary Outcome

The primary outcome is the effect of SiD on preparation for decision-making, a core element of the Ottawa Decision Support Framework [27] as a precursor to behavior change (Figure 2). A high-quality decision is defined as an informal caregiver making an informed decision consistent with their values [48,49]. The Preparation for Decision-Making Scale assesses the perception of how useful a decision aid is in preparing for subsequent decision-making. Scores range from 1 to 5, calculated from the average of 10 constructs (each ranging from 1: "strongly disagree" to 5: "strongly agree"). The scale has total test reliability of 0.944 [50].

A secondary immediate outcome is decision self-efficacy (self-confidence or belief in one's capability to make decisions), measured using the decision self-efficacy scale [51], as decision aids typically increase self-efficacy [52]. Transformed scores range from 0 (extremely low) to 100 (extremely high self-efficacy). In the SiD pilot trial, participants had a mean score of 77.6 (SD 17.2) after viewing the SiD firearm section [37] (Table 1).

Longitudinal Outcomes

Additional outcomes, also linked to our theoretical framework (Figure 1), are in Table 1. Firearm access (and actions to reduce access) for the person with ADRD is assessed with existing multipoint scales [52,53], with binary categorization (any access to ≥1 firearm versus no access to any firearms) and progression toward reduced access (eg, locking of additional firearm). This allows the identification of smaller, albeit important, changes. Firearm injury or near-injury in the person with ADRD or others in their home is assessed through questions about recent experiences (including incidents of threats with a firearm or "near-misses") and perceived risks. Caregiver burden is measured by the short-form (3-item) Zarit Burden Interview [24,54,55]. Benefits of caregiving are measured by the Positive Aspects of Caregiving Scale [56-58]; scores range from 0 to 36, calculated from the sum of 9 items (measured on a 5-point scale ranging from 0: "disagree a lot" to 4: "agree a lot"), with higher scores indicating positive experiences.

Other Covariates

Caregiver characteristics include basic demographic characteristics like participation language (English/Spanish) age, gender, race/ethnicity, living situation (marital status, income, and urban/rural), and education. The characteristics of a person with ADRD (as reported by the caregiver) include age, gender, race/ethnicity, and living situation (marital status, income, and urban/rural). Dementia severity and course over time will be measured using the validated caregiver-reported aging and dementia 8-item scale Dementia Screening and Revised Memory and Behavior Checklist. The characteristics of the caregiver relationship to person with ADRD include the type of relationship (eg, spouse and nonrelated friend) and living situation (together or apart; if apart, proximity).

Study measures pertaining to the stages and quality of decision-making are based on validated measures currently available in the literature. Validated measures in Spanish were available for more than half of the English measures. For measures which were not available in Spanish, translation followed a forward and back translation process used throughout the study, incorporating similar phrasing and structure of other validated measures when possible.

Additional Measures

The approximate cost per enrolled participant will be calculated based on advertising costs and fees, and staff time. Website analytics will also be analyzed for each recruitment group and subgroup randomized to SiD, measures will include average time spent on SiD (mean and SD, median, and IQR) and pages viewed.

Data Monitoring

The study team will work with a Data Safety Monitoring Board, along with the IRB and the NIA, to monitor participant safety, evaluate study progress, review procedures for maintaining the confidentiality of data, and ensure the quality of data collection,

XSL•FO
RenderX

management, and analyses. The following adverse and serious adverse events are monitored: any kind of negative interaction from intervention (eg, verbal disagreement or physical fight), increased stress due to actions taken to reduce firearm access for a person with dementia, physical injury sustained during actions to reduce firearm access for a person with dementia, suicide ideation or attempt in caregiver or individual with dementia, hospitalization due to emotional factors (stress, depression, suicidal, or homicidal ideation or intent), or hospitalization or surgery for a physical injury sustained during actions to reduce firearm access for a person with dementia. Each adverse event is graded by severity and relationship to intervention.

Data Collection

All participant-level data are collected and stored using self-reported, web-based questionnaires through REDCap [22,44,45]. Additional data are obtained through analytic reports provided by the digital marketing firm for each of the unique landing pages and web-based eligibility forms, while these sites will be identical, they will separate the trial participants by their origin of enrollment (group and subgroup). Website analytics will be analyzed at the level of groups or subgroups, as it will not be possible to identify individual participants from their website usage (eg, they do not login to a site or have other markers of identity). For social media and internet advertisements, ad impressions, click-throughs, and enrollment will be tracked and analyzed.

Statistical Analysis

Descriptive statistics will be computed for baseline caregiver characteristics (including key covariates, Table 1), reporting on differences between (1) intervention arm, (2) follow-up status, and (3) recruitment modality. To test the primary hypothesis that SiD increases immediate decision quality compared to control, we will test for a difference in the adjusted mean Preparation for Decision Making score at baseline after viewing SiD or control using multiple linear regression (MLR), with adjustment for baseline characteristics (eg, age, gender, caregiver burden, and severity of ADRD). Other components (decision quality, decision self-efficacy, and knowledge) will be analyzed similarly. To assess longitudinal end points, linear mixed models will replace multiple linear regression to assess changes in self-efficacy and knowledge over time by treatment arm, allowing an interaction of treatment arm and time [59,60]. Substantial efforts will be made to minimize missing data in data collection, and our models will adjust for covariates associated with drop-out to attenuate bias. If necessary, we will also use methods such as multiple imputation, pattern mixture models, or sensitivity analyses, following intent-to-treat principles [61].

To test the secondary hypothesis that SiD increases the odds that action is taken to reduce firearm access, a binomial-family logit-link generalized linear mixed models will be used with subject-specific random effects to account for correlations across measurements from the same individual and with fixed effects to adjust for baseline characteristics. The interaction between intervention and time will be tested to assess if the effect of SiD varies over time. We will use interaction terms to identify potential differential effects of treatment according to age, whether the caregiver lives with the person with ADRD (vs not), and recruitment group. Exploratory heterogeneity of treatment effect will also be conducted by caregiver gender, urban versus rural residence, and language (English vs Spanish). Additionally, we will examine longitudinal change in caregiver burden and reported safety concerns, and how these might affect treatment effects. Both multiplicity-adjusted and unadjusted *P* values will be presented for these comparisons.

We will use analytics from the eligibility screening websites to estimate the proportion of individuals who were eligible by recruitment modality, including separately by language, the proportion of eligible individuals who enrolled, and the rate of recruitment. The cost of recruitment per participant will be calculated based on advertising costs, fees paid to organizations, and estimates of study staff time [62,63]. Finally, among SiD participants, we will compare minutes on-site and trial retention at 6 months across recruitment modalities. Covariates will be included in multivariable models if they are associated with dropout, hypothesized a priori to be adjusted for, or if their inclusion improves the overall model's Akaike information criterion. If there is evidence that normality assumptions have been violated, appropriate transformations will be used, or the appropriate link function (eg, logit link for dichotomized measures).

Power

The target sample size for this study (n=500), which includes recruitment via social media (n=250) and relevant organizations (n=250), was powered conservatively for the primary outcome to allow comparisons by recruitment groups and other participant characteristics. In the pilot trial of 15 caregivers, the mean Preparation for Decision Making scores (using 9 constructs) was 3.9 (SD 0.7) after SiD versus 3.6 (SD 0.2) in the control group; this corresponds to a standardized effect size of 0.42 (3.9 vs 3.6 with a pooled SD of 0.7; d=0.3/0.7=0.42) [37,64]. Based on a *t* test, with the proposed sample size of 500 participants, the analysis will be able to detect a d=0.42 effect size with a very high power of >99% (α=.05) between SiD and control for the primary outcome (preparation for decision-making). Even if the effect is smaller (eg, d=0.30) and the sample size is 80% (400 in total), the power remains high at 84.9%. With a sample size of 500, there will be 125 in each of the final four analytic groups (stratified by recruitment group A vs B, SiD vs control). This sample will yield 80% power to detect any subgroup-specific standardized effect of d=0.36 or greater between SiD and control, including by recruitment group and other participant characteristics (using a *t* test and assuming sample sizes of 125 in each subgroup). Power calculations were computed using R version 4.0.2 (R Foundation for Statistical Computing) [65].

Ethics Approval

This study was approved by the Colorado Multiple Institutional Review Board (COMIRB) (21-4084). All study procedures and documents were reviewed and approved under Expedited Review, Category 7, by COMIRB. COMIRB approved a waiver of written documentation of informed consent and Health Insurance Portability and Accountability Act authorization. The

XSL•FO
RenderX

S@H trial is registered with ClinicalTrials.gov (ClinicalTrials.gov NCT05173922).

Results

This study was funded in December 2021. Data collection began in May 2022. As of December 2022, 117 participants have been enrolled in the study. This study will test the efficacy of the SiD web-based decision aid in decision-making among ADRD caregivers. Anticipated findings from this study include participant reports of increased preparation for decision-making and greater alignment of decision-making with their goals and values for all study participants; a higher degree of change is anticipated among participants randomized into the SiD decision aid arm. Further, this study anticipates effects on longitudinal decision outcomes including self-reported modifications that caregivers have made to firearm access for persons with ADRD. This study will also contribute to knowledge regarding effective tools for web-based recruitment methods, especially for ADRD caregivers.

Discussion

Principal Findings

This study aims to address the need for access to effective resources to support ADRD caregivers in decisions about firearm safety. Caregivers make important decisions regarding ADRD care, including home safety. Additional guidance—such as through SiD, if it is found effective—could help align decisions with caregiver goals and values, especially regarding difficult and under-discussed topics such as firearm injury prevention.

Strengths and Limitations

Collaborative, nonjudgmental approaches to firearm injury prevention show great promise. A major strength of the SiD decision aid and this study is that they were developed with ideas and recommendations of individuals from the firearms community, including range owners, retailers, and firearm instructors. Such early—and ongoing—stakeholder engagement will help optimize intervention acceptability and effectiveness [66]. Many firearm owners have strong beliefs in self-determination and individual liberty [67,68], which are reflected in many of the same philosophical tenets underpinning shared decision-making more broadly [69]. A culturally sensitive intervention may allow caregivers to more fully and autonomously explore options [70]. An intervention that is responsive to cultural factors and personal values may also have higher acceptability and uptake than historical approaches to promoting firearm safety, which are clinician-delivered and include “one size fits all” recommendations to all firearm users. SiD is the first such tailored intervention for firearm safety in ADRD.

The varied methods of recruitment of ADRD caregivers across the United States is another strength of this study. The prevalence of digital-only or digital/in-person hybrid trials has increased during COVID-19. However, the effectiveness and representativeness of digital recruitment remain under debate. In particular, for sensitive issues like ADRD and firearm safety, it is essential to rigorously evaluate the success and equity of novel recruitment methods. The final sample may not generalize to all ADRD caregivers, given the language restriction (English and Spanish) and the need for access to and ability to use web-based technology. Those who participate in a study may also be different from the general population of ADRD caregivers.

Future Directions

“Designing for dissemination” in interventions can promote real-world use [71]. The SiD decision aid and study design were guided by a desire to disseminate effective, acceptable interventions to support diverse caregivers, and reduce firearm injury among older adults. Translation into real-world application is central to the research design of the S@H study, which aims to evaluate tools and processes that are concurrently easy to implement and responsive to the needs of all involved [72], from caregivers who might use the tool, to older adults with ADRD themselves, to service providers who may recommend it to families, to firearm retailers and advocacy groups seeking to educate their communities [71,73]. Should the tool prove effective in the study, future work should examine its dissemination through formal and informal channels.

Conclusions

The S@H study is the first national randomized trial to evaluate a firearm safety resource for ADRD caregivers. This study will provide information on the efficacy of the SiD decision aid as well as insights on how to recruit caregivers in a national, web-based trial.

Acknowledgments

This study was funded by the National Institutes of Health/National Institute on Aging (R01AG076364). The funder had no role in the review or approval of the manuscript for publication. The contents of this work are the authors’ sole responsibility and do not necessarily represent the official views of the funder or author’s employers.

Data Availability

Requests for data from other researchers and the public will be considered, and data will be made available in accordance with local institution policies, Institutional Review Board (IRB) recommendations, local/state/federal laws and regulations, and considerations for publication. Any applicable data sharing will follow Health Insurance Portability and Accountability Act rules.

Protocol

A Peer-Led Digital Intervention to Reduce HIV Prevention and Care Disparities Among Young Brazilian Transgender Women (The BeT Study): Protocol for an Intervention Study

Abstract

Background: The HIV epidemic continues to disproportionately burden marginalized populations despite the availability of effective preventive and therapeutic interventions. Transgender women are severely affected by HIV worldwide including in Brazil and other low- and middle-income countries, with evidence of increasing new infections among young people. There is an urgent need for youth-specific HIV prevention and care interventions for young transgender women in Brazil.

Objective: This study aims to (1) address stigma in the Brazilian public health system and (2) reduce barriers to HIV care and prevention with systems navigation among young transgender women aged 18-24 years in Rio de Janeiro, Brazil.

Methods: The *Brilhar e Transcender* (BeT) study is a status-neutral, peer-led, single-arm digital intervention study enrolling 150 young transgender women in Rio de Janeiro, Brazil. The intervention was pilot tested and refined using data from a formative phase. The BeT intervention takes place over 3 months, is delivered remotely via mobile phone and in person by peers, and comprises three components: (1) BeT sessions, (2) digital interactions, and (3) automated messages. Eligibility criteria include identifying as transgender women, being aged 18-24 years, speaking in Portuguese, and living in the Rio de Janeiro metropolitan area in Brazil. The primary outcomes are HIV incidence, pre-exposure prophylaxis uptake, linkage to HIV care, and viral suppression. Primary outcomes were assessed at baseline and quarterly for 12 months. Participants respond to interviewer-based surveys and receive tests for HIV and sexually transmitted infections.

Results: The study has been approved by the Brazilian and the US local institutional review boards in accordance with all applicable regulations. Study recruitment began in February 2022 and was completed in early July 2022. Plans are to complete the follow-up assessment of study participants on July 2023, analyze the study data, and disseminate intervention results by December 2023.

Conclusions: Interventions to engage a new generation of transgender women in HIV prevention and care are needed to curb the epidemic. The BeT study will evaluate a digital peer-led intervention for young transgender women in Brazil, which builds on ways young people engage in systems and uses peer-led support to empower transgender youth in self-care and health promotion. A promising evaluation of the BeT intervention may lead to the availability of this rapidly scalable status-neutral HIV intervention that can be translated throughout Brazil and other low- and middle-income countries for young transgender women at high risk of or living with HIV.

youth; transgender women; Brazil; HIV prevention; HIV care; peer-led digital intervention

Introduction

Efforts to end the HIV epidemic by 2030 will not be possible without enhanced efforts to prevent new infections among youths and young adults [1]. Despite the availability of effective HIV care and prevention interventions, reductions in HIV prevalence have stalled, in part, owing to the lack of progress in reducing new infections among youths, especially those in low- and middle-income countries (LMICs) where most new infections are acquired. Innovations in HIV interventions have also failed to adequately reach marginalized populations most affected by HIV [2]. Transgender women are one of the most severely affected populations by HIV worldwide [3]. Brazil has a concentrated HIV epidemic with a 0.4% prevalence in the general population [4] with over 900,000 people living with HIV in the country [5] and the highest prevalence among transgender women who have sex with men [6,7]. Within the population of transgender women, young transgender women are at high risk for HIV and poor HIV care outcomes. The first respondent-driven sampling-based study of HIV risk and pre-exposure prophylaxis (PrEP) awareness among Brazilian transgender women identified that 24.2% of youths aged 18-24 years were living with HIV. Young transgender women also had lower knowledge of HIV prevention strategies (including PrEP) and higher HIV risk than their older peers, with 3 times as many unrecognized infections than adults [8]. These findings are worse than those reported in prior research, suggesting that 1 in 5 young transgender women were infected with HIV before having been aged 25 years [9,10].

Global data reflect a lack of incident infection decline among youths and point to a need for early intervention to curb risk among young transgender women [11]. In a study conducted from 2018 to 2020 using the Limiting Avidity assay as part of a recent infection testing algorithm, the annualized HIV incidence rate was 7% overall and 9% among transgender women [12]. In the largest PrEP demonstration study in Latin America, which enrolled a total of 9509 people, young and transgender participants had lower odds of long-term engagement in PrEP [13].

The Brazilian Public Health System (Sistema Único de Saúde) ensures universal and equitable provision of health care to the whole population; their approach toward the HIV epidemic was human rights–based and science-driven, integrating both prevention and treatment efforts into the Brazilian universal health care system and including a fundamental role of social movements advocacy. Brazilian regulations guide public health services to use social names (ie, names that transgender people use that are different from what is on their government-issued identification) and requested pronouns for them. Despite these protections, discrimination toward transgender people in the Brazilian Public Health System is well documented. For young transgender people, discrimination exacerbates common youth-related barriers to HIV prevention and care. Previous Brazilian research identified stigma as a critical roadblock to HIV prevention and care for transgender women [14,15]. Much like research from the United States, transgender women in our Brazilian study reported experiencing antitransgender stigma in the health care system [6,16-19], and most attributed their underuse of medical care to stigma [6,14]. Transgender people are known to postponing necessary care owing to experiences of and anticipation of discrimination [20,21]. Low health care usage may be the reason underlying very low awareness of PrEP in our US-based research with young transgender women [22]. Young transgender women face the challenge of addressing medical needs related to their gender identity, which compounds typical adolescent development [9,23-25]. For youths, health literacy, systems navigation, and low risk perception are barriers to HIV testing and linkage to HIV care [26-28].

The lack of interventions among young transgender women presents a troubling outlook to the HIV epidemic for young Brazilian transgender women. Overall, most interventions with transgender women focused on those already living with HIV [29]. The few primary prevention interventions are limited to pilot studies of small group sessions that combine didactic and participatory learning, with no information gathered on HIV incidence and risk behavior. Only one intervention has been developed and has shown efficacy for increasing HIV-related preventive behavior among young transgender women [30]. No known interventions have been developed to increase HIV care outcomes among young transgender women. Our data point to an urgent need for youth-specific HIV prevention and care interventions for young transgender women in Brazil. To address limitations in availability of HIV prevention and care interventions for young transgender women, we designed the *Brilhar e Transcender* (BeT [“shine and transcend” in English]) study, which combines a social marketing campaign to address antitransgender stigma in health services toward transgender women and an adapted evidence-based, HIV status–neutral intervention that uses peer-led digital and in-person systems navigation. Our primary aims are to (1) address stigma in the Brazilian public health system, (2) intervene to overcome youth challenges with health care systems navigation, and (3) implement our intervention among young transgender women aged 18-24 years in Rio de Janeiro, Brazil.

Methods

Study Design

The BeT study is one of 8 sponsored research projects chosen to be a part of a Eunice Kennedy Shriver National Institute of Child Health and Human Development–funded Prevention and Treatment through a Comprehensive Care Continuum for HIV-affected Adolescents in Resource Constrained Settings (PATC^{3}H) consortium [31], which conducts clinical research and evaluation of a variety of combination interventions to improve health outcomes among adolescents at risk for HIV

XSL•FO
RenderX

and youths living with HIV in resource-limited settings. The BeT study is the only PATC^{3}H project conducted in Latin America and among transgender youths and builds on decades of research and community engagement with transgender communities. The BeT study is a peer-led, digital-based intervention study aiming to enroll 150 young transgender women in Rio de Janeiro, Brazil.

Eligibility Criteria

Inclusion criteria are (1) having been assigned the male sex at birth and self-identifying as *travesti*, a transgender woman, or having a gender identity different from identities typically associated with the assigned sex at birth; (2) being aged between 18 and 24 years; (3) providing consent for study participation; (4) living in Rio de Janeiro or the greater metropolitan area; and (5) being sexually active. Additional criteria for HIV-negative individuals include (1) no current PrEP use, (2) PrEP indication per Brazilian standards of care, and (3) no PrEP contraindication. For participants living with HIV, additional inclusion criteria are (1) having a confirmed HIV diagnosis, (2) not currently using antiretroviral therapy (ART) or having a detectable viral load and treatment that is not linked to HIV care.

Exclusion criteria include participation in any HIV prevention or care intervention study in the last year, refusal to undergo HIV testing, or having any health condition that, in the opinion of the investigator, precludes participation in the study or may lead to harm to the participant.

Formative Phase

The study had a formative phase, which comprised developing and implementing an antistigma campaign, and adaptation and pilot testing of the system navigation intervention [32]. The campaign content included information on basic gender definitions (sex, gender identity, gender expression, and sexual orientation), regulations linked to gender and sexual orientation minorities, the medical transition process, overview of mental health and hormone therapy among transgender people, transphobia and violence against transgender people, and HIV among transgender women (Figure 1). The antistigma campaign, focused on health care settings, clinical providers, and support staff, took place at 4 health clinics serving transgender women in Rio de Janeiro, Brazil. We collected pre- and postcampaign qualitative and quantitative data with providers (N=10) to assess whether antitransgender stigma beliefs and attitudes changed among providers and support staff.

We also conducted formative qualitative interviews with 10 young transgender women (mean age 22.2 years) to inform the development of the pilot intervention. The BeT study uses an effective US Centers for Disease Control and Prevention intervention called *Anti-Retroviral Treatment and Access to Services* for system navigation and linkage [33,34]. Three components of the intervention required adaptation: (1) content of the Anti-Retroviral Treatment and Access to Services intervention session plan and asynchronous interactions with young transgender women, (2) adaptation to the cultural context of Brazil, and (3) the digital interface. Ten young transgender women were recruited through community outreach by our community engagement specialists (n=2) and through referrals from other studies at Fiocruz (n=8).

The BeT study pilot-assessed the intervention's preliminary efficacy among 20 participants. Results from the pilot intervention demonstrated preliminary efficacy for improving HIV prevention and care behaviors among young transgender women, as all HIV-negative participants were engaged in PrEP and all but one participant living with HIV became virally suppressed [32]. After the pilot phase, the team refined the intervention, which focused on streamlining the adapted intervention manual to improve peer navigator and participant accessibility. In addition, the team added additional medical monitoring to include important biomarkers of sexual health and HIV as part of the study protocol.

Study Procedures and Measures

Table 1 describes the study procedures. Potential participants are recruited by a community education team, through word of mouth, and via referrals from enrolled participants. Recruitment also occurs at the HIV prevention services based at our site and at an on-site mobile legal unit that offers weekly access to free legal services for transgender people.

Participants have 5 in-person encounters at the National Institute of Infectious Diseases Evandro Chagas, Fiocruz, including a screening and enrollment visit followed by 4 quarterly visits (at weeks 12, 24, 36, and 48). The BeT intervention takes place between the enrollment visit and the 12-week visit and is completed within that time frame. Trained staff conduct interviewer-administered surveys to participants at all study visits.

At baseline, all participants respond to a screening questionnaire and demographic information, after signing the written informed consent form. Baseline and quarterly survey content build upon questionnaires previously developed and tested with transgender women in Brazil and in the United States, as described in Table 2. During follow-up visits, we will collect information on study outcomes: HIV incidence, PrEP uptake and adherence among HIV-negative participants, and linkage to HIV care and viral load suppression among those living with HIV. In addition, we will also collect data on implementation science outcomes: (1) maintenance (pre- and poststudy) for study coordination, feasibility (poststudy) for peer health navigators, and feasibility, acceptability, and appropriateness (poststudy) for study participants.

The BeT Intervention

The 3-month BeT intervention comprises three components: (1) BeT sessions, (2) digital interactions, and (3) automatic messages (Figure 2). During the first BeT session, the participant works with a peer navigator to build a case management plan aimed at meeting HIV prevention and care goals, and getting other needs met to promote health and wellness (BeT plan). BeT sessions 1 and 3 are conducted in person at enrollment and week 12 visits, respectively. BeT session 2 is conducted remotely via a mobile phone. Participants select a preferred app (eg, WhatsApp or Facebook messenger) for communicating asynchronously with the peer navigator during BeT session 2. Asynchronous digital interactions with peer navigators occurs at least weekly for 3 months and can be more frequent based on participant needs. Digital interactions were not restricted to study participation or HIV prevention or care and can include social support, food basket provisions, and guidance on employment, self-care, and other supports. Finally, participants received weekly automatic messages with health information on HIV testing, prevention, and care.

Figure 2. Intervention components of the Brilhar e Transcender study.

Statistical Analysis

Statistical analysis will assess recruitment, baseline, and follow-up data and will describe the rapidity of enrollment of young transgender women, their demographic and risk characteristics, and participation as the percent intervention uptake (ie, the number of participants in the BeT intervention divided by the total number of individuals who were assessed for participation and were preliminarily eligible for the study). We will describe PrEP uptake and adherence and HIV care service linkage at intervention initiation and completion. For the primary endpoint, we will compare PrEP uptake and adherence and HIV care linkage between baseline and follow-up data (ie, before and after the intervention). Primary analyses will test the hypothesis that the odds of PrEP uptake and adherence and HIV care linkage will be higher post intervention relative to baseline data. We anticipate behavior change within 3 instead of 6 months because of our ability to more frequently interact with participants (3 months). In fact, we may achieve a greater dose response and intervention effect in a shorter amount of time because of the possibility for a higher number of encounters. At minimum, participants will engage with their digital navigator 4 to 5 times a week in the form of short digital encounters, and over the course of the intervention, participants will have 48 to 60 short digital encounters in total. We will use a pooled logistic model to estimate treatment effects on time to PrEP uptake and adherence and HIV care linkage.

We will also assess outcomes comparing data from the external comparison group to the BeT intervention group. First, we will conduct sensitivity analyses to compare the demographics of our intervention group to those of the external comparison group. In the analysis, we will focus on comparisons between the BeT intervention group and the external comparison group on measures of PrEP and ART adherence and viral suppression. Primary analyses will involve intention-to-treat analysis without considering adherence to the BeT intervention. This analysis will be a comparison of initiators of PrEP and ART, and we shall adjust for baseline confounders related to age or race. We have chosen to compare initiators of PrEP or ART and not assess PrEP uptake because a comparison of initiators parallels intention-to-treat analysis in which assignment and initiation of the treatment strategies occur together at baseline, regardless of whether individuals continue on the strategies after baseline [52]. We will combine outcome estimates with the cost estimates of the intervention component to calculate cost per participant and roughly estimate costs per HIV infection averted or poor health outcomes based on cohort data being collected in Brazil on HIV incidence and care outcomes.

Antistigma Campaign Evaluation

Data from the baseline and follow-up study surveys will be used to assess whether there were improvements among young transgender women in (1) feeling of safety in health clinics; (2) perceptions of provider, staff, and other patient attitudes toward transgender women; (3) anticipated stigma; (4) medical mistrust; (5) health care participation; and (6) avoidance of health care. We will use repeated measures ANOVA to compare changes in mean stigma scores over the course of time in participating in the intervention (ie, before and after the intervention). In intent-to-treat analyses, we will use generalized estimating equations (GEE) Poisson or negative binomial models with robust SEs to compute the ratio of the single arm intervention rates of change in the mean value of stigma over the study period. GEE methods produce estimates that account for within-subject correlation of stigma scores across time [53]. GEE methods will also be used to assess whether changes in stigma are associated with changes in PrEP uptake and adherence and HIV care linkage over time.

Sample Size and Power Calculation

We propose to enroll 150 participants and have estimated 80% power to detect effects for our primary outcomes using formulas for longitudinal study designs with attrition. These estimates account for an expected attrition of 15% of the sample by 12

XSL•FO
RenderX

months, as well as adjustment for time-dependent covariates in longitudinal analysis. We will also have 80% power to detect correlations of 0.23 of continuous baseline covariates with baseline responses and changes in study responses from baseline to 6 months.

In the analysis of changes, we will have 80% power in 2-sided tests with a type I error rate of 5% to detect changes from baseline to 12 months of 0.41 to 0.53 SDs in continuous responses, depending on within-subject correlation of the response, and increases of 10-15 percentage points in the frequency of binary responses, depending on baseline frequency as well as within-subject correlation. Thus, this study is powered to detect small to medium effect sizes that are consistent with or smaller than others reported in the literature.

Missing Data

Missing items at any visit should be minimal owing to the electronic data collection protocol described above. However, some loss to follow-up is inevitable. To assess sensitivity to dropout, multiple imputation will be used, under both the standard conditionally missing-at-random assumption, as well as plausible missing not-at-random scenarios. GEE methods can also be weighted to handle missing data.

Laboratory Assessments and Clinical Approach

HIV rapid tests will be performed at baseline for all participants and quarterly for HIV-negative participants. Participants reporting recent anal condomless sex (<30 days) with a negative HIV rapid test will be screened for acute HIV infection through HIV RNA viral load testing. The Limiting Antigen Avidity assay will be used to identify recent HIV seroconversions and may further support the calculation of HIV incidence by providing the timing of seroconversion [54]. Syphilis will be screened using treponemal testing, followed by venereal disease laboratory testing if the former test yields a positive result. Hepatitis B and C will be first screened using rapid tests followed by serology assessments, if needed. All participants will collect rectal swabs at baseline and the 48-week visit for the diagnosis of *Chlamydia trachomatis* and *Neisseria gonorrhea* infections. Sexually transmitted infections will be treated in accordance with Brazilian guidelines [55]. Participants who screened positive for hepatitis B and C will undergo complete the diagnosis algorithm (ie, hepatitis C viral load) [56] and will be referred to treatment. Participants with negative hepatitis B test results who have not been vaccinated will be referred for hepatitis B vaccination. PrEP adherence will be evaluated on the basis of tenofovir diphosphate concentrations in dried-blood spots.

Medical and psychiatric evaluation could occur as needed. Study referrals may include endocrinology, mental health evaluation, and proctology, among others. Participants may also access feminizing hormones on site.

Ethical Considerations

The BeT intervention study was reviewed and approved by the institutional review board of the National Institute of Infectious Diseases, Fiocruz (#CAAE 05018818.0.0000.5262) and the University of California, San Francisco Committee on Human Research (#18-26770) in accordance with all applicable regulations. All participants were asked to sign an informed consent form prior to any study procedure.

Results

Between the study pilot and the study intervention, the COVID-19 pandemic emerged, which caused a substantial impact on the implementation of the study. Study recruitment began in February 2022, initially slowly as Brazil was still facing high numbers of COVID-19 cases and deaths. Nevertheless, we were able to complete study enrollment by early July 2022. To achieve that, we combined prior experience of both the US and the Brazilian teams with transgender communities to new recruitment strategies. The team uses dynamic and multifaceted approaches to community engagement strategies to enhance existing strategies and implement new strategies using field and digital media initiatives for recruitment. The team also encouraged participants to bring other individuals and gave them gifts or reimbursement (eg, peer referrals).

Recruiting and retaining transgender women who are young, early in their gender development, marginalized, and less connected within community poses significant challenges to engagement in the intervention and retention. Therefore, the study team currently has a major focus on retention. Strong supervised peer navigation is important to reach, engage, and retain young transgender women. Regular and meaningful engagement with the community is essential to maintain these connections. Furthermore, we have been providing cell phone credits to the participants retained in the intervention. In addition, we also give participants small gifts, such as study bags, sponge bags, and daily planners, among others, if they achieve some goals (eg, attending study visits in the study window). In addition, we will also conduct raffles of electronic items (such as portable cell phone chargers and earphones) for participants completing the intervention and study visits. Peer navigators also maintain close connections with participants, supporting them in their in-person and remote interactions. Future perspectives are to complete follow-up with study participants by July 2023 and to analyze study data and disseminate intervention results December 2023.

Discussion

The BeT study is a pivotal study that will evaluate a digital peer-led intervention for young transgender women in a LMIC such as Brazil. We anticipate that the BeT intervention will successfully improve HIV prevention and care outcomes among young transgender women. A linkage to prevention intervention is particularly important once oral PrEP is a public health policy in Brazil. Oral PrEP requires strong care linkage, engagement, and retention to reap the prevention benefits. Although oral PrEP has been implemented since 2017 in Brazil, only a small percentage of PrEP users are transgender women [57]. Ancillary services and systems navigation to such services related to PrEP are essential supports to ensure success on PrEP. Among young cis women in Africa, PrEP uptake was facilitated when offered as part of an integrated sexual reproductive health service [58]. Based on the findings of the formative phase [32], BeT

XSL•FO
RenderX

intervention will be the first intervention tested to meet the needs of the transgender women population in LMICs and may be implemented in resource-constrained settings. We also expect stigma to be reduced over time as participants are engaged in a gender-affirming transgender-centered clinic where an antistigma campaign has been conducted.

The study has some limitations. First, the BeT intervention will not be tested in a randomized clinical trial. Owing to the heightened targeting of transgender people, randomizing BeT participants seemed unethical and impractical in our context. To address this issue, we will assess intervention effectiveness by monitoring changes in intervention outcomes before and after the intervention and comparing outcomes from our cohort to those in an external comparison group. Furthermore, our study will have a convenience sample and our results may not be applicable to all young transgender women. Our study also has some strengths. The study team has extensive experience in conducting transgender-related research. The Brazilian site has a successful history of engaging transgender women in relevant clinical studies owing to historical community engagement efforts that solidified the relationship with the local transgender population.

In the current local adverse political environment, where transphobia is rampant, the implementation of a transgender-specific study is an opportunity to engage a new generation of transgender women in health care. Moreover, peer-led support may empower transgender youth toward their self-care and health promotion. The BeT intervention may be rapidly brought to scale and translated to a relevant, replicable, sustainable, and evidence-based combination HIV prevention intervention for young transgender women in LMICs.

Acknowledgments

The members of the BeT team are as follows: Alexandra S. da Cruz, Ana Carolina Figueiredo, Carolina Ribeiro de Arsolino, Caroline de Souza Miguel, Claudia M. da Silva, Cristina M. Jalil, Cristiane Castro, Daniel Bezerra, Daniel Waite, Debora Santana, Eduardo Carvalheira, Edilene Bastos, Flavia Amancio, Flavia Lessa, Giovanna Costa, Jose Roberto Granjeiro, Karina M. de D. Henriques, Katia S. M. Derrico, Iasmim Garrido, Luana Marins, Luiz Ricardo S. Camacho, Marcella Feitosa, Marcos Davi, Mayara Secco, Natalia Ibiapino Proenca, Raquel M. de Souza, Renata Bastos, Rita de Cassia O. Cockrane, Robson Silva, Sandro Nazer, Tania Krstic, Thales Castro, Valeria Ribeiro, Wanderson Augusto, and Willian da Silva Santos.

This work was supported by the National Institute of Child Health and Human Development and the National Institutes of Health as the Prevention and Treatment through a Comprehensive Care Continuum for HIV-affected Adolescents in Resource Constrained Settings sponsor (grants UG3HD096914 and UH3HD096914). The sponsor had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Data Availability

We and our institutional review board have ethical concerns with releasing our study data publicly owing to the small numbers of transgender persons, the high likelihood that sharing the primary data may expose individual participants, and the possible harm that might befall participants if exposed.

Conflicts of Interest

None declared.

Abstract

Background: Underage drinking and related risky sexual behavior (RSB) are major public health concerns on United States college campuses. Although technology-delivered personalized feedback interventions (PFIs) are considered a best practice for individual-level campus alcohol prevention, there is room for improving the effectiveness of this approach with regard to alcohol-related RSB.

Objective: The aims of this study are to (1) evaluate the impact of a brief PFI that integrates content on alcohol use and RSB and is adapted to include a novel cross-tailored dynamic feedback (CDF) component for at-risk first-year college students and (2) identify implementation factors critical to the CDF's success to facilitate future scale-up in campus settings.

Methods: This study uses a hybrid type 1 effectiveness-implementation design and will be conducted in 3 phases. Phase 1 is a stakeholder-engaged PFI+CDF adaptation guided by focus groups and usability testing. In phase 2, 600 first-year college students who drink and are sexually active will be recruited from 2 sites (n=300 per site) to participate in a 4-group randomized controlled trial to examine the effectiveness of PFI+CDF in reducing alcohol-related RSB. Eligible participants will complete a baseline survey during the first week of the semester and follow-up surveys at 1, 2, 3, 6, and 13 months post baseline. Phase 3 is a qualitative evaluation with stakeholders to better understand relevant implementation factors.

Results: Recruitment and enrollment for phase 1 began in January 2022. Recruitment for phases 2 and 3 is planned for the summer of 2023 and 2024, respectively. Upon collection of data, the effectiveness of PFI+CDF will be examined, and factors critical to implementation will be evaluated.

Conclusions: This hybrid type 1 trial is designed to impact the field by testing an innovative adaptation that extends evidence-based alcohol programs to reduce alcohol-related RSB and provides insights related to implementation to bridge the gap between research and practice at the university level.

Trial Registration: ClinicalTrials.gov NCT05011903; https://clinicaltrials.gov/ct2/show/NCT05011903

Introduction

Overview

Despite declines over the past several decades, underage drinking and related harm continue to be major public health concerns on United States college campuses [1-3]. National data show two-thirds of college students are current drinkers, 1 in 3 reports past-month heavy-episodic drinking (more than 5 drinks in a row), and 1 in 10 reports high-intensity drinking (more than 10 drinks in a row) [1]. Greater college student alcohol consumption and heavy drinking on a given day are linked to increased sexual activity and risky sexual behavior (RSB; eg, unprotected sex and unplanned hookups) [4-9]. Alcohol-related RSB puts college students at risk for negative health outcomes (eg, sexually transmitted infections and unplanned pregnancies) and is a pathway to sexual victimization and escalated drinking [10-14]. Notably, alcohol use is implicated in approximately half of college student sexual assaults [14,15]. Given the high rates of alcohol misuse in college and the association between alcohol use and RSB, prevention efforts that reduce alcohol-related RSB have been identified as a priority area in the National Institute on Alcohol Abuse and Alcoholism (NIAAA) Strategic Plan 2017-2021 [3].

The first weeks of college are referred to as the red zone with escalations in heavy drinking [16-18] and sexual assault [19-23]. Changes in the salience of social and achievement goals and stressors during the transition to college impact alcohol use during this period [24]. Students who drink heavily prior to college are likely to escalate drinking [25], and nondrinkers or light drinkers may consume heavy amounts on occasion, increasing their risk of experiencing serious consequences [26,27]. This coincides with changes in students' sex-related cognitions and behaviors [8,28]. Thus, effective interventions for escalated alcohol use and RSB during this critical period of risk can result in high public health and clinical impacts [29].

Technology-Delivered Personalized Feedback Interventions

NIAAA's College Alcohol Intervention Matrix identifies technology-delivered personalized feedback interventions (PFIs) as a best practice for individual-level campus alcohol prevention [30]. PFIs typically involve a one-time, web-based assessment of an individual's alcohol use behaviors, followed by the provision of a tailored profile based on the assessment of the individual's drinking patterns and strategies to reduce harm [31-33]. The utilization of technology for assessment and feedback allows PFIs to retain key features of efficacious in-person brief motivational interventions without the high costs and need for trained personnel [34]. Many universities now opt for commercially developed PFIs for first-year students (eg, AlcoholEdu for College [35] and eCHECKUPTOGO [36]) [37-42].

Past work from the investigative team [32,43,44] highlights 2 important concerns with PFIs as widely implemented. First, a rather exclusive focus on the assessment and feedback of alcohol use means other health behaviors impacted by alcohol use, such as RSB, are rarely addressed [32]. To address this gap, a PFI with integrated alcohol and RSB content for sexually active, college-aged young adults who regularly drink was developed. The integrated PFI showed promise in reducing alcohol-related sexual outcomes [43]. Second, there is considerable heterogeneity in PFI effects across participants [45] and studies [44,46]. Further, PFIs tend to provide short-term intervention benefits but offer diminished protection to college students beyond 6 months [46,47]. The current intervention is designed to increase and extend the effects of the integrated alcohol and RSB PFI by incorporating repeated and dynamic assessment and feedback.

Extending PFIs With Cross-Tailored Dynamic Feedback

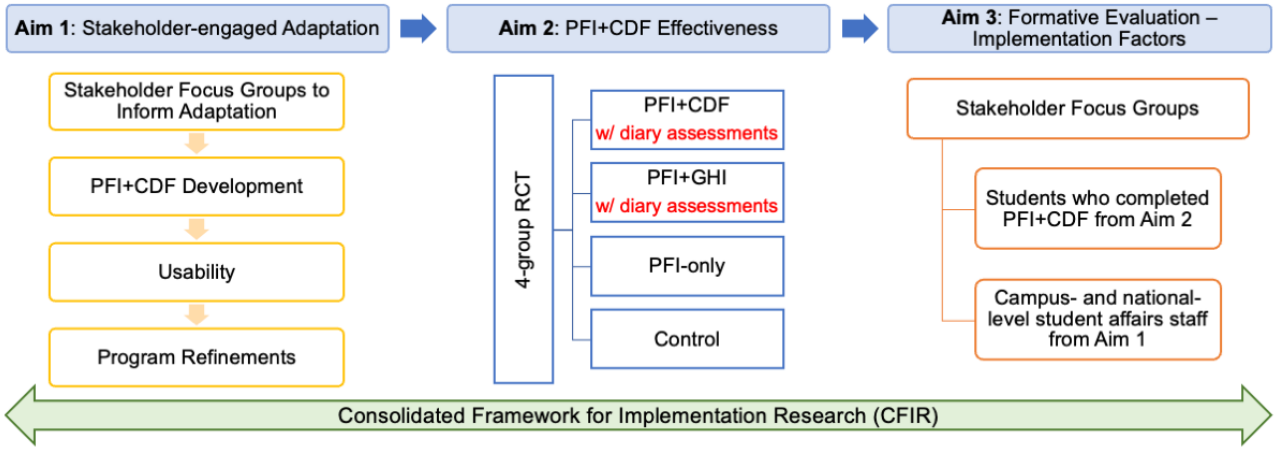
The prevailing approach to technology-delivered PFIs is to provide a single, point-in-time snapshot of one's behaviors and beliefs relative to others, analogous to a "between-person" comparison, which can create initial discrepancy and enhance motivation to change [48]. However, this feedback is limited to a one-time snapshot of individual differences in risk, does not capitalize on the beneficial effects of continued monitoring, and cannot capture dynamic changes in an individual's beliefs or behavior in response to feedback. The proposed PFI and cross-tailored dynamic feedback (CDF) adaptation (PFI+CDF) leverages semester-long diary assessments (once a day for 4 days a week over 12 weeks) to iteratively refine (ie, optimize) initial feedback. The addition of CDF has the potential to amplify the effects of PFIs through the provision of feedback linked to a user's personal, day-to-day trajectory of a target behavior. The integration of adaptive ("just-in-time") and dynamic feedback is designed to bolster and sustain the initial impact of the PFI by creating a unique form of self-monitoring of "within-person" trajectories. In this way, positive behavior change can be acknowledged, and the participant can be redirected when less desirable behaviors are reported. The CDF adaptation of a PFI is intended to develop discrepancy regarding alcohol-related RSB, alcohol use, and other RSB; enhance motivation to change; and boost self-efficacy in one's ability to change. To our knowledge, dynamic optimization of intervention content with rapid deployment and evaluation has never been attempted with alcohol-related RSB interventions.

Designing for Dissemination With an Effectiveness-Implementation Hybrid Design

Over the past 3 decades, researchers have made strides to enhance brief alcohol intervention implementation through a number of key adaptations (eg, extending to different subpopulations [44], altering delivery modality [49], adding

XSL•FO
RenderX

boosters [50-52], giving students a choice for intervention assignment [53], adding video content [54], and adding substance-free activities [55]). Despite these efforts, a significant proportion of college campuses do not implement evidence-based strategies [56-58]. Although PFIs are a popular choice among campuses that do implement such strategies, little is known regarding strategies they use to encourage stakeholder groups' participation or how PFIs complement other student health efforts.



Accordingly, the current intervention study is guided by a hybrid type 1 effectiveness-implementation design to examine PFI+CDF effectiveness and related implementation factors to improve and accelerate translation. Effectiveness-implementation hybrid designs offer a dual focus on both outcomes and process, which can serve to speed up the translation of an intervention if it is effective [59,60]. Process-oriented formative evaluations will be used with stakeholders at multiple levels prior to, during, and after program implementation to better understand implementation context, and barriers and facilitators to implementation [61-64]. It is critical to identify college-specific PFI implementation gaps at both the student level and systems level for the purpose of improving PFI+CDF's acceptance by students and achieving greater adoption on campuses. By engaging multilevel stakeholders at the outset, a "designing for dissemination" approach is followed, using feedback from members of the population of users and organizational adopters [65-68]. In this paper, we provide a description of the proposed hybrid type 1 effectiveness-implementation study protocol.

Methods

Study Design

Figure 1 provides an overview of the 3-phase, multisite hybrid type 1 effectiveness-implementation design to evaluate the effectiveness and understand the implementation of a novel PFI+CDF to reduce first-year college students' alcohol-related RSB. Phase 1 is a focus group-guided PFI+CDF adaptation and usability test. In phase 2, first-year college students who report past-month heavy-episodic drinking (more than 4 or 5 drinks for females or males within 2 hours) or drinking at least 3 times in the past month and who are sexually active without being in a monogamous relationship will be recruited from the University of Kentucky (UK) and the University of North Texas (UNT) to participate in a 4-group randomized controlled trial (RCT) to examine the effectiveness of PFI+CDF in reducing alcohol-related RSB. PFI+CDF will have 3 other comparison conditions: a PFI followed by the 12-week dynamic feedback on general health information (PFI+GHI), a PFI without any additional exposure to intervention (PFI), and assessment-only control (AOC). In phase 3, a qualitative evaluation will be conducted with multilevel stakeholders to better understand relevant implementation factors.

Figure 1. Overview of study design. CDF: cross-tailored dynamic feedback; GHI: generic health information; PFI: personalized feedback intervention; RCT: randomized controlled trial.

Phases 1 and 3 are guided by the Consolidated Framework for Implementation Research (CFIR), a comprehensive set of constructs describing factors influencing implementation across all stages of the implementation process [69,70]. CFIR is commonly used to guide formative investigations within the context of hybrid type 1 designs [61,64]. Constructs are grouped into 5 domains in the current intervention study: intervention characteristics (ie, characteristics of PFI+CDF), outer setting (ie, context surrounding student affairs), inner setting (ie, context within student affairs), individual characteristics (ie, students and student affairs staff), and process (ie, process for implementing PFI+CDF) [69].

Adaptation (Phase 1)

Overview

Phase 1 will focus on adapting the existing integrated PFI to the enhanced PFI+CDF with the following steps: (1) focus groups with multilevel stakeholders, including students and student affairs staff; (2) building the data capture and content platform; (3) usability testing; and (4) program refinements. These 4 key iterative steps of adaptation are crucial in the systematic modification of existing evidence-based interventions to improve their effects and potential for implementation [66]. Furthermore, they ensure that the adaptation of the integrated PFI to PFI+CDF is achieved with the principle of designing for dissemination in mind [65].

XSL•FO
RenderX

Focus Groups

We will conduct focus groups with stakeholders (ie, students and student affairs personnel) to solicit their perspectives on a prototype of the proposed PFI+CDF intervention. Focus group participants will be students and student affairs professionals (eg, individuals involved with implementation of prevention programming) at UK and UNT, as well as student affairs professionals at the national level, recruited at the annual meeting of NASPA-Student Affairs Administrators in Higher Education, the premier conference in this field [71]. Recruitment and facilitation of focus groups at NASPA will ensure a national perspective on the PFI+CDF intervention.

At UK and UNT, we anticipate a single focus group for staff and 3 focus groups for students, with 5-8 participants per group (32 participants per site, 64 participants total). At NASPA, we will aim for 4 focus groups with 5-8 participants per group, for a total of 32 participants. Development of the focus group interview guide will be informed by the CFIR interview guide tool [72] and will target constructs within the intervention characteristics domain of CFIR (eg, adaptability, complexity, design quality, and relative advantage), exploring barriers and facilitators to implementation at both the student level and systems level [69,73]. Groups will last 60-90 minutes and incentives will be US $50 and US $100 gift cards for students and student affairs staff, respectively.

We will conduct a systematic thematic analysis to identify relevant themes from the qualitative data collections [74]. Focus groups will be transcribed and analyzed using NVivo [75]. A designated subset of the research team will first work independently to identify recurrent themes and important statements specific to intervention content. They will then review the independent coding together, discuss the independent coding with the entire research team, and come to a consensus about the emerging themes. The themes will be compiled into summaries and circulated to the research team to guide discussion of intervention refinement.

Data Capture and Content Development

Overview

Findings from the multilevel stakeholder focus groups will inform the development of an updated version of an existing evidence-based integrated alcohol and RSB feedback profile (PFI) and the addition of CDF content, as well as an assessment and delivery platform necessary to populate and house the PFI and CDF content.

PFI and CDF Delivery Platform

The PFI and CDF content will be housed in a website application platform that offers flexibility in reach and accessibility but is optimized for viewing across device types (eg, computer, tablet, and phone). For example, links to PFI and CDF content can be sent to participants via multiple channels (eg, SMS text message and email) to access feedback. The assessment and content platform will be built as an integrated system, essential for scale-up for several reasons: (1) survey responses inform both the PFI and CDF content and are a necessary part of the system, (2) it allows for a built-in evaluation mechanism, and (3) it creates one overall system that is portable for hosting at other sites. The underlying programming will be conducted in HTML5 to ensure flexibility for future adaptations to other platforms. The web-based app will run on common web browsers on iOS and Android smartphones, tablets, and on iOS and Windows personal computers. A backend tracking program will record user progress.

Intervention Content: PFI

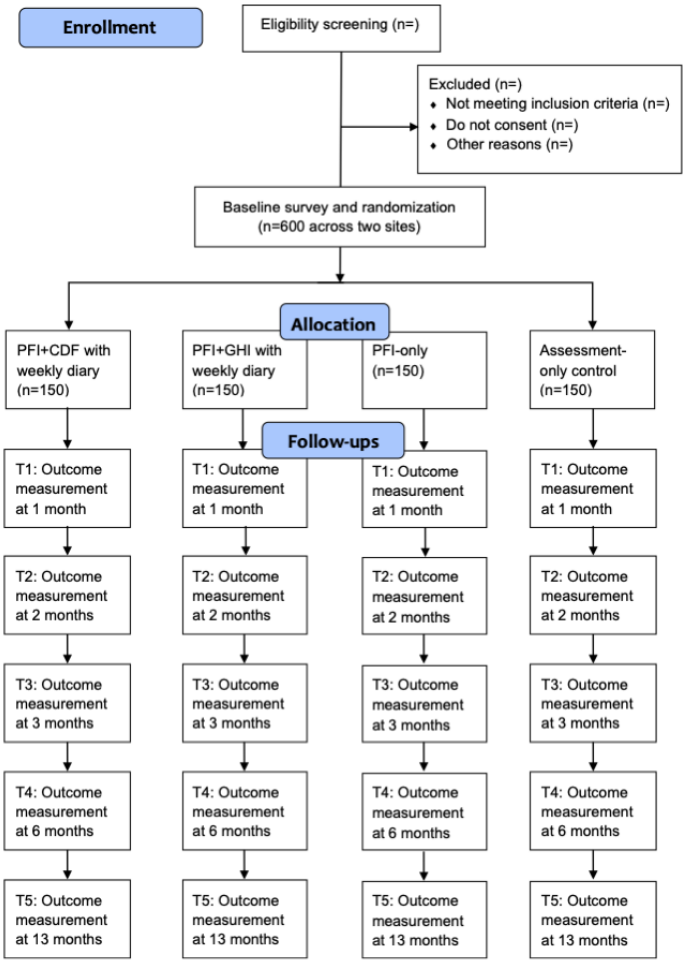
Consistent with prior work, PFI content will be generated from responses to a baseline assessment and offer participants integrated feedback on both alcohol use and RSB across the following content domains: a behavioral profile, normative comparisons, blood alcohol content, expectancies, perceived risk, likelihood of engaging in future risk behaviors, and protective behavioral strategies. In addition to integrated alcohol and RSB content, the PFI will include an option to view feedback on alcohol use behaviors only, as pilot data indicated separate alcohol-focused content was necessary to reduce alcohol use not specific to sexual behavior.

Intervention Content: CDF

CDF content will be generated from weekly diary-style surveys (Friday to Monday) in which students report their alcohol use and RSB, as well as their preferences when interacting with CDF content. Participants will receive dynamic feedback on their own behaviors for 12 weeks of the fall semester, allowing them to see their behaviors over time and receive feedback on their behavior changes (ie, “within-person” feedback). Although the overall system and specific design features will be created in consultation with students and technology developers, and subsequently refined following the usability testing, it is anticipated that the CDF content will include (1) a brief and updated behavior profile, (2) normative feedback on their current weekly drinking and related sexual behavior pattern, (3) positive reinforcement for improving behaviors within weekly and monthly time frames in figures, (4) brief updated intervention content topics (eg, individual-specific protective strategies that they can use in the following week) along with an option to see a full version, and (5) alerts for potential areas for improvement and referral information, if needed.

Usability Testing and Program Refinement

Usability testing will focus on (1) soliciting feedback on users’ experience with the enhanced PFI+CDF and (2) troubleshooting the CDF diary surveys and dynamic weekly feedback methodology. The usability test will be conducted with the methodology, assessments, and timing of the RCT procedures for the PFI+CDF group (see phase 2 description below), with the exception that the testing does not need to start at the beginning of the academic year or include follow-up surveys. Participants (n=100, 50 per site) will provide standard ratings of the acceptability [76] (eg, attractiveness, comprehension, relevance, and persuasive value) and usability [77] (eg, ease and efficiency of use) of the PFI+CDF intervention and respond to open-ended questions regarding most and least liked features. We will create a summary of participants’ impressions, commonly referenced problems, and acceptability and usability ratings, and use this information for one last round of program refinement, as recommended in systematic adaptation approaches.



XSL•FO
RenderX

Effectiveness Trial (Phase 2)

Overview of RCT Design

We will conduct a multisite, 4-group RCT to evaluate the intervention (Figure 2). Participants (N=600 total, 300 per site) will be randomized to 1 of 4 groups: (1) PFI+CDF with weekly diary surveys; (2) PFI+GHI (generic health information) with weekly diary surveys; (3) PFI-only, no weekly diary surveys; and (4) AOC, no weekly diary surveys. All participants will complete a baseline survey during the first week of the semester, be randomly assigned to 1 of the 4 groups, and complete follow-up surveys at 1, 2, 3, 6, and 13 months post baseline. The staggered design allows for comparison of the enhanced PFI+CDF relative to the PFI+GHI, which may be consistent with a "treatment-as-usual" comparison group (eg, of the universities that have adopted an evidence-guided alcohol intervention program for their campus, many currently deliver commercialized alcohol-focused PFIs to incoming first-year students) [35,36]. Providing weekly GHI in the comparison group allows for an equal number of "exposures" between PFI+CDF and PFI+GHI, analogous to an attention control group, offering a clearer understanding of the overall impact of the PFI+CDF adaptation. The inclusion of 2 PFI conditions, 1 with weekly diary assessments and 1 without, allows us to control potential assessment reactivity that might result from the diary-style assessment approach. This design is intended to allow a separation of the "true" intervention effect of the CDF above and beyond the effect of assessment reactivity. The PFI-only versus AOC group comparison will provide a test of the integrated PFI that has been adapted based on stakeholder feedback.

Figure 2. Randomized controlled trial workflow diagram. CDF: cross-tailored dynamic feedback; GHI: generic health information; PFI: personalized feedback intervention.

Recruitment

Contact information for a random sample of first-year college students between the ages of 18-20 years will be drawn from the registrar's office at each study site. Students will be sent a prenotification letter on the university letterhead describing the study and inviting their participation. The letter will inform them to check their email on the study start date for more details and be followed by an email that reiterates study details, invites their participation, and includes a web link and personal identification number to access a web-based consent form and screening survey. Other recruitment methods will supplement this recruitment from the registrar's office, including direct emails to interested students, advertisements in newspapers, on websites and social media, and postcards and fliers distributed at various on-campus locations. Eligibility criteria are shown in Textbox 1. Eligible students will be required to give informed consent before being directed to the baseline survey. Those who decline to consent and those who are not eligible will be directed out of the survey and removed from the participant list. Students

XSL•FO
RenderX

will receive email reminders over the course of the following week. We will oversample underrepresented groups (n=300, 50% non-White and n=300, 50% White students) and maintain an equal ratio of men and women at each site.

Textbox 1. Eligibility criteria for the randomized controlled trial.

Eligibility criteria

- First-year student
- 18-20 years of age
- Past 30-day heavy-episodic drinking (more than 4 or 5 drinks for females or males within 2 hours) or 3 or more drinking occasions within the past month
- Sexually active (oral, anal, or vaginal sex within past 12 months)
- Not in a monogamous relationship (single, not dating, or dating, not serious) or in a monogamous relationship (dating only 1 person) for less than 3 months or in a monogamous relationship but open to cheating
- Not pregnant or planning to become pregnant

Procedures

Following the baseline survey, participants randomized to 1 of the 3 PFI conditions will immediately be linked to their PFI, which will also be sent via email and SMS text message. A 2-week window is allotted at the beginning of the semester for participants to complete their baseline assessment and, if applicable, view their PFI content. Following that period, participants in the PFI+CDF and PFI+GHI will be sent prompts via email and SMS text message to complete diary surveys on Friday through Monday of each week. On Tuesdays, participants in the PFI+CDF group will receive a link to access their CDF corresponding to that week's behavior, via text and email, and those in the PFI+GHI group will receive a link to access health topics relevant to college students guided by the American College Health Association website (eg, nutrition, mono, exercise, and immunizations) [78]. These procedures will continue for a total of 12 weeks. All participants will be asked to complete web-based 1-, 2-, 3-, 6-, and 13-month follow-up assessments and receive up to US $100 (US $15 per survey, with an additional US $10 bonus for the 13-month follow-up). Participants in the diary conditions will receive an additional payment up to US $96 (US $2 per day×4 days×12 weeks=US $96).

Intervention Assessments and Other Measures

Table 1 shows a list of self-report measures, including primary and secondary outcomes, demographics, and covariates. Primary and secondary outcomes and content-specific measures will be assessed at baseline and in all follow-up surveys. Measures will be adapted for weekly diary assessments along with items related to daily drinking context, consistent with our prior work. We anticipate baseline and follow-up surveys to be approximately 20 minutes in length, and daily surveys will be 5 minutes in length. Participants will be made aware of the importance of the data, the confidential nature of their responses, and we will follow procedures to secure their privacy.

Table 1. Self-report measures.

Construct	Description
Primary outcomes	
Alcohol-related sexual behavior	Number of times that alcohol was consumed during or before sex, quantity of alcohol consumed before sex [79]
Alcohol-related consequences—sexual	Sexual consequence scale [80]
Secondary outcomes	
Alcohol use behavior	Daily drinking questionnaire [81], heavy-episodic drinking, and high-intensity drinking
Alcohol-related consequences—nonsexual	Young adult alcohol consequences questionnaire [82]
Sexual behavior	Frequency of sex (including oral, vaginal, or anal), number of casual sexual partners, and number of times that a condom was used during sex [79,83]
Demographics and covariates	
Background demographics	Birth sex, gender identity, sexual orientation, race and ethnicity, height and weight (for blood alcohol content calculation)
Alcohol use history	Lifetime alcohol use, age of drinking and intoxication onset, and family history
Sex history	Age of first sex and history of sexual behavior

In addition to self-report measures, participant behavior analytics will be captured to help ensure intervention fidelity and be included as covariates in analyses. Analytics include (1) whether or not participants accessed their PFI, CDF, or GHI; (2) the

XSL•FO
RenderX

number of times each PFI, CDF, or GHI was accessed; (3) time spent viewing each PFI, CDF, or GHI; and (4) time spent viewing each topic area within the PFI, CDF, or GHI. These data will be captured through tracking routines programmed on the website. We will examine the depth of college students' engagement with intervention content to assess the effects of program exposure (ie, dose) based on the level of access to content (eg, ranging from students who looked at PFIs and all weekly CDF and GHI content vs those who engaged in some or none of the content) and time spent on various intervention components. These data will provide intervention acceptability metrics and allow us to control each participant's exposure to the PFI, CDF, or GHI content in outcome analyses.

Sample Size Justification

Power analyses to detect intervention main effects were conducted using Optimal Design Plus Version 3.01 software and the "power determination approach." Based on past research, we assumed a standardized effect size of 0.3 (a small to medium effect size) from the repeated measures RCT with 5 follow-ups over 13 months. To examine the effect of the PFI+CDF and PFI interventions, compared to the control, a minimum of 452 participants are required for a power of 0.8 at an alpha level of .05. To examine the effect of the PFI+CDF intervention (vs PFI+GHI or PFI-only intervention), at least 350 participants are required. Based on this power analysis, there is sufficient power (≥0.89) to detect a small to medium effect size for the integrated interventions (PFI+CDF, PFI+GHI, and PFI only) versus control and sufficient power to detect the small effect of the PFI+CDF intervention compared to the PFI+GHI or PFI-only intervention over time. Although the overall effect size was conservatively assumed to fall between small and medium in size, due to the fine-grained assessment approach within the time period where most changes are likely to occur, followed by a long-term 13-month follow-up assessment, we anticipate that the proposed study is sufficiently powered.

Statistical Analysis

For study phase 2, we will use a multilevel model for the main outcome analysis where the participant is defined at the highest level of the model (level 2), and observations (level 1) are nested within the participant. We will assume that the observation-level (level 1) residual error term and participant-level (level 2) intercept coefficients (ie, random effects) are each normally distributed with mean zero and a variance that is estimated from the data, while intercept and slope coefficients are multivariate normally distributed with mean zero for each, and a covariance matrix that is estimated from the data. Intervention groups will be tested as a fixed effect. Given that many outcomes of our interest are count outcomes with excessive zeros, we will utilize appropriate models to accommodate a zero-inflated outcome distribution with overdispersion [44,84]. The 2 sites can be entered as a random effect (level 3) or a fixed effect in a 2-level model. We will include an interaction term to test whether PFI+CDF is similarly effective for men and women. The intercept and growth slopes will be appropriately specified to maximize information.

We will use a parallel process growth model to test the codevelopment of correlated processes (eg, alcohol use and RSB) and a parallel process growth mediation model. This allows for the examination of 2 potentially dependent reduction trajectories, which are altered by intervention. We expect that those who reduce alcohol misuse more rapidly in response to intervention will also exhibit a trajectory in which one's likelihood of engaging in RSB decreases, which can be tested by comparing a model where the 2 slope terms are correlated with a null model where its correlation is constrained to be zero. Intervention effects can be explicitly tested by adding intervention membership as an external covariate that changes these coupled processes. Intervention effect modifiers or moderators will be tested in a confirmatory (eg, sex) or exploratory investigations.

Implementation (Phase 3)

A qualitative postintervention assessment of intervention implementation will be conducted with multilevel stakeholders, including students and both campus- and national-level student affairs staff. The goals are to better understand (1) participating students' experiences with the intervention; (2) barriers and facilitators to implementation, guided by CFIR; (3) potential program sustainability; and (4) necessary modifications for other sites for scale-up.

Focus group participants will be a subset of students from the PFI+CDF arm of the RCT, as well as campus- and national-level stakeholders who also participated in preimplementation focus groups. Participants in the PFI+CDF condition will be asked if they are interested in participating in a follow-up study after the 13-month follow-up. We will randomly select up to 48 students who indicate interest in participating (n=24 per site) at varying levels of engagement with the intervention (as guided by program analytic measures) for a maximum of 3 focus groups per site (5-8 participants per group). Campus student affairs staff will be contacted via phone and email for staff focus groups (1 focus group per site for student affairs staff with 5-8 participants per group). At the national level, we will conduct 4 focus groups, with 5-8 participants per group, yielding a total of up to 32 participants. All focus groups will last 60-90 minutes with US $50 and US $100 gift card incentives for students and staff, respectively. The analytic plan for phase 3 qualitative data will mirror phase 1.

Ethics Approval

The study underwent review and approval by the UK Institutional Review Board (IRB #62769), which serves as the single IRB of record for this study. All participants will sign an approved consent form in accordance with the ethical standards of Helsinki.

Results

Recruitment and enrollment for phase 1 began in January 2022. The findings of phase 1 will inform the development and build of integrated PFI+CDF. It is anticipated that phase 2 will begin in August 2023, and phase 3 will begin in October 2024. Data will be shared in the NIAAA Data Archive twice a year (April 1 and October 1), starting from October 1, 2023. Findings will

XSL•FO
RenderX

be published in peer-reviewed journals and presented at international, national, or regional professional meetings and conferences.

Discussion

Overview

This project aims to fill a gap highlighted in the NIAAA Strategic Plan 2017-2021 [3] by advancing an intervention that integrates alcohol misuse and RSB. It also directly addresses the 2 primary areas of foci underlying a recent NIAAA workshop to advance the science on evidence-based brief interventions for young adult populations: (1) optimizing intervention design and (2) implementation and scale-up [85]. To the best of our knowledge, the use of dynamic feedback based on individual behavior trajectories to optimize PFI content with rapid and sustained deliveries and ongoing evaluations has never been attempted with this population and area of study. Understanding the impact of a dual-risk behavior PFI that incorporates novel, cross-tailored between- and within-person feedback profiles can help inform best practices for the delivery of prevention interventions relevant to college students. If successful, our approach could influence how PFIs are developed and delivered in other populations and settings for maximum benefit. In addition, employment of a hybrid type 1 effectiveness-implementation design for this population, behavior, and campus setting is also the first of its kind and is expected to yield broadly informative outcomes through its rigorous randomized trial design testing intervention effectiveness and multilevel stakeholder engagement pre- and postimplementation.

Limitations

There are several potential limitations that need to be acknowledged. First, the emphasis on first-year college students may be restrictive. We chose to focus on first-year students because they are at risk for alcohol use and RSB [16-26], but older students also experience alcohol-related harms. Many college campuses require students to complete a brief alcohol intervention at the start of college and often use existing commercialized PFIs, providing a built-in audience for the adapted PFI+CDF intervention [35,36]. We encourage future studies to explore PFI+CDF in other at-risk populations, such as older students and young adults not in college. Second, the PFI+CDF intervention approach is intensive and could lead to concerns about student engagement. However, our past work on integrated PFIs indicates that participants engaged with feedback content and viewed it multiple times [86]. We demonstrated that increased personalization leads to a stronger program effect, potentially mediated through increased attention to content [32]. By involving students in the design process in phase 1, we should enhance their interest [59,87,88]. Students also reported favorable reactions to the proposed study methods. Thus, we anticipate high levels of engagement, but will also examine program engagement in phase 2 analyses and phase 3 focus groups. Third, there are alternatives to a web-based app platform. Technology changes rapidly, with many other options for content delivery (eg, native mobile apps, smartwatches, social media). Our goal was to create a flexible system to deliver content in multiple ways (email and SMS text message), increasing the likelihood of engagement. Native mobile apps require more programming than web apps to operate across smartphone types and operating systems. Social media offers opportunities (eg, user-generated interaction and content) but also its own challenges (eg, spread of misinformation). Alternate delivery platforms will be explored during focus groups, and we anticipate the need for content to be portable to other platforms in future implementation.

Conclusions

This innovative, multisite hybrid effectiveness-implementation study will (1) evaluate the impact of a PFI that integrates content on alcohol use and RSB and is adapted to include an innovative CDF component for at-risk first-year college students and (2) identify implementation factors critical to its success to facilitate future scale-up in campus settings. The findings of this study will improve existing evidence-based alcohol programs and bridge the gap between research and practice at the university level.

Abstract

Background: A chronic condition, drug addiction, requires long-term multipronged health care and treatment services. Community-based approaches can offer the advantages of managing integrated care along the care continuum and improving clinical outcomes. However, scant rigorous research focuses on sustainable, community-based care and service delivery.

Objective: This protocol describes a study aiming to develop and test an intervention that features the alliance of community health workers and family members to provide integrated support and individualized services and treatment for people who use drugs (PWUD) in community settings.

Methods: Based on the National Institute on Drug Abuse's Seek-Test-Treat-Retain (STTR) framework, an intervention that provides training to community health workers will be developed and piloted before an intervention trial. Trained community health workers will conduct home visits and provide support for PWUD and their families. The intervention trial will be conducted in 3 regions in Vietnam, with 60 communities (named communes). These communes will be randomized to either an intervention or control condition. Intervention outcomes will be evaluated at baseline and at 3, 6, 9, and 12 months. The primary outcome measure is PWUD's STTR fulfillment, consisting of multiple individual fulfillment indicators across 5 domains: Seek, Test, Treat, Retain, and Health. The secondary outcomes of interest are the community health workers' service provision and family members' support. The primary analysis will follow an intention-to-treat approach. Generalized mixed-effects regression models will be used to compare changes in the outcome measures from baseline between intervention and control conditions.

Results: During the first year of the project, we conducted formative studies, including in-depth interviews and focus groups, to identify service barriers and intervention strategies. The intervention and assessment pilots are scheduled in 2023 before commencing the trial. Reports based on the baseline data will be distributed in early 2024. The intervention outcome results will be available within 6 months of the final data collection date, that is, the main study findings are expected to be available in early 2026.

Conclusions: This study will inform the establishment of community health workers and family members alliance, a locally available infrastructure, to support addiction services and care for PWUD. The methodology, findings, and lessons learned are expected to shed light on the addiction service continuum's implementation and demonstrate a community-based addiction service delivery model that can be transferable to other countries.

addiction service; community consortium; drug addiction; health care worker; health; family; Vietnam

Introduction

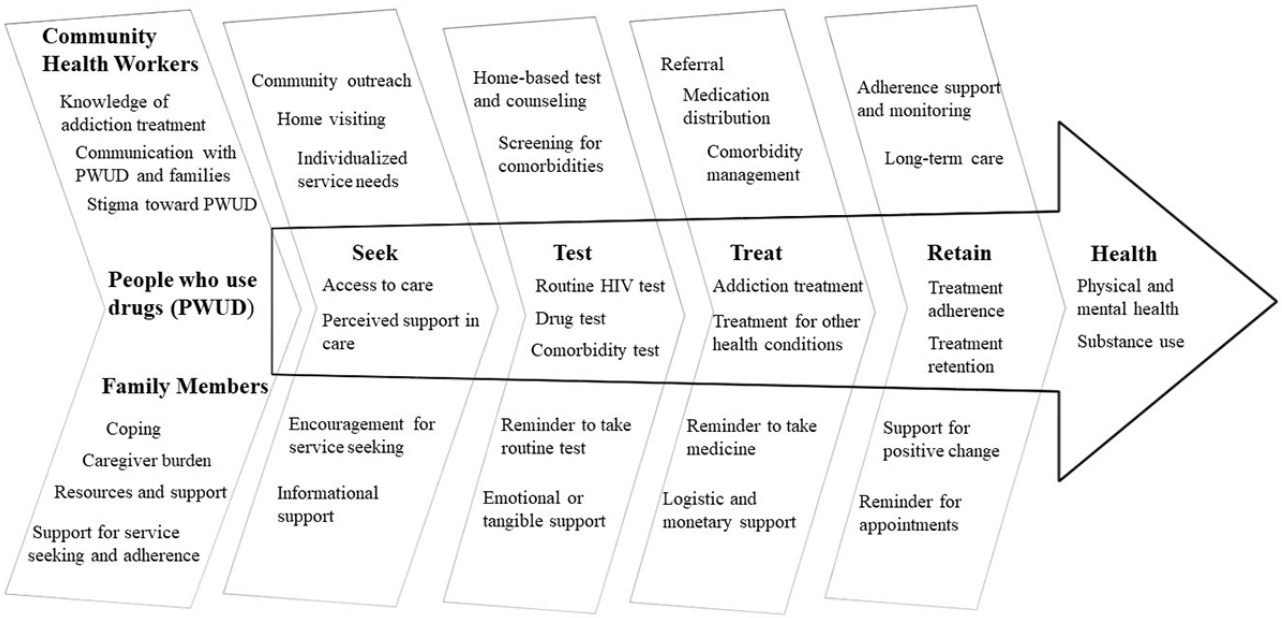
Drug addiction, such as opioid use disorder, is one of the most significant public health issues globally [1]. Medication-assisted therapies (MAT), including methadone and buprenorphine or naloxone, are in place to prevent opioid-related overdose and the spread of infectious diseases [2-5]. However, substantial barriers exist to the provision and use of MAT because of the shortage of addiction specialists to prescribe and monitor MAT, especially in remote areas [6,7]. For example, community MAT programs require community members' support and resources to train community health care workers [6,7].

Mobilization of community-based systems in the service delivery model has been advocated as a desirable strategy to reduce the current gap in MAT [8-12]. In addition, drug addiction, as a chronic condition, requires long-term multipronged health care [13,14]. Community-based approaches can offer the advantages of managing integrated care along the care continuum and improving clinical outcomes [15-18]. However, there is a lack of research focusing on the systematic implementation of MAT and its related service delivery in community care settings [18].

Commune Health Centers (CHCs) are grassroots health care facilities in rural Vietnam, where essential preventive care, initial diagnosis, and referral services can be accessed by residents [19]. Vietnam is one of the first countries to decentralize MAT delivery from centralized treatment sites to community settings [20,21]. However, its CHC-based MAT programs face challenges, such as community health workers (CHWs) lack of capacity in treatment services, misconceptions of harm reduction, and stigmatizing attitudes toward PWUD [22]. Hence, adherence to MAT has been suboptimal, and the patient dropout rates are alarmingly high [23,24].

In Vietnam, the family presents a critical source of support for people who use drugs (PWUD) [25-27]. Families are commonly the source of daily care and financial, emotional, tangible, and informational support for opioid users' care seeking. The support given by family members can significantly impact the health care use and outcomes of PWUD [28,29]. At the same time, close family members of PWUD often struggle with mental health issues, impaired social adjustment, poor work relations, decreased social participation, and increased intrafamily dysfunction [30,31]. These challenges have jeopardized the family's capacity to support PWUD in care seeking and adherence.

Current health care infrastructure and culture in Vietnam provide an opportunity to test a community-based service delivery model for addiction care and treatment. We plan to develop and test an intervention that features the alliance of community health workers and family members to provide integrated support and individualized treatment services for PWUD in community settings.



Methods

Theoretical Framework

The National Institute on Drug Abuse's Seek-Test-Treat-Retain (STTR) initiative provides a framework to guide the delivery of addiction services [32,33]. This approach requires reaching out to PWUD and understanding their health needs (Seek), engaging them in routine physical examinations and laboratory testing (Test), initiating MAT and treatment of comorbidities (Treat), and facilitating treatment adherence and long-term, uninterrupted care (Retain). Based on the theoretical framework, we plan to synergize the support from CHWs and family members as two of the most essential enabling factors to build a respectful, accepting, and supportive addiction care continuum for PWUD (Figure 1). Specifically, CHWs will be trained to provide individualized care with a nonstigmatizing attitude. In addition, family members will be mobilized to give continuous support to PWUD's service seeking and adherence. The coalition between CHWs and family members will provide a locally available infrastructure to support addiction treatment services, resulting in effective and sustainable outcomes.

XSL•FO

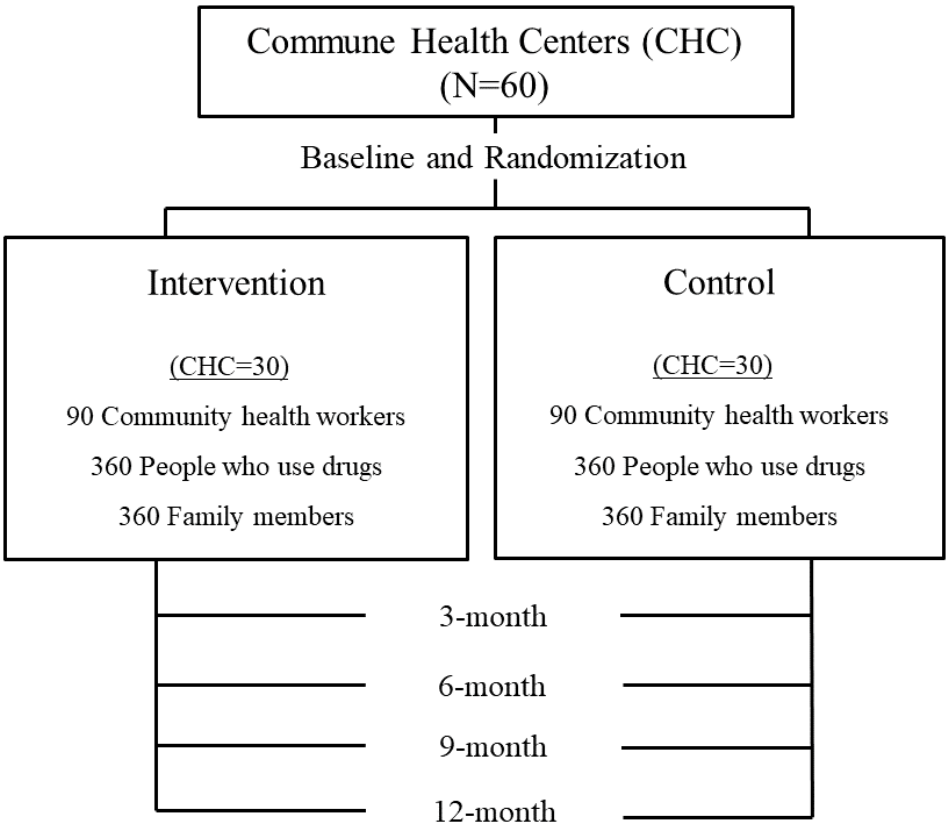
Figure 1. Theoretical Framework.

Intervention Development and Pilot

Formative studies, including focus groups and in-depth interviews, will inform intervention development and implementation plan. A total of 3 CHW focus groups and 3 focus groups with community representatives focus on identifying service gaps and effective local strategies to address the challenges. In-depth interviews with PWUD and family members will identify the needs in support, barriers, and facilitators to maintaining service engagement and retention. Following the formative studies, a multidisciplinary work group will be formed and go through 3 steps: (1) reviewing the problem and identifying intervention outcomes, (2) adapting evidence-based strategies to local infrastructure and culture, and (3) developing the intervention implementation and evaluation plan. A pilot version of the intervention program will be produced and followed by an intervention pilot study. The pilot will include a full implementation of intervention activities. In-depth interviews with participants and intervention team members will be conducted to refine the intervention. We will also finalize recruitment procedures and assessment batteries in this phase.



Cluster-Randomized Controlled Trial

Study Design

The intervention trial aims to test the efficacy of the intervention, primarily with PWUD outcomes, and secondly, at family members and CHW levels. We hypothesize that (1) the intervention will improve PWUD's service fulfillment along the addiction service continuum, as well as their health outcomes; (2) the intervention will enhance CHWs' provision of addiction-related service provision for PWUD and support of their family members; and (3) the intervention will improve family members' support for PWUD's engagement in the addiction continuum. The trial will be conducted in 3 regions in Vietnam. These regions represent geographical variations in the country. The trial will include 60 CHCs, randomized to either an intervention or control condition. We propose to enroll 720 PWUD and 720 family members (12 families per CHC) as well as 180 CHWs (3 per CHC). Intervention outcomes will be evaluated at baseline and every 3 months after that (Figure 2). We plan to select communes with the highest number of PWUD in each region to ensure adequate participants. The selected CHC in each region will be paired based on the number of PWUD. Within each pair, the CHC will be randomized after baseline.

XSL•FO
RenderX

Figure 2. Study design.

Eligibility and Recruitment

To recruit PWUD, we will post project recruitment flyers in major community activity sites, such as local commune culture centers, hospitals or pharmacies, and other places where local PWUD usually gather. PWUD interested in the study can contact our recruitment staff using the information printed on the flyers. Recruitment staff will meet with potential participants individually to screen for eligibility. Eligibility criteria include (1) age of 18 years and older, (2) having a history of drug use, (3) having disclosed the drug-using status to at least one of the family members and being willing to invite the family member to our study, and (4) currently residing in the selected communes. Written informed consent and consent to contacting a pointed family member will be obtained.

The consented PWUD will be asked to choose a family member in the order of closeness, usually starting from spouse, mother, father, sibling, to other relatives. The inclusion criteria for a family member are (1) age of 18 years and older, (2) being an immediate or extended family of the PWUD, and (3) knowing the PWUD's drug-using behavior. Our recruitment staff will work with the PWUD to arrange a private meeting with the nominated family member. If the nominated family member also has a history of drug use, he or she will be enrolled as a PWUD participant, and another family member will be recruited from the family. All family member participants will sign a written informed consent.

Eligibility criteria for CHWs include age of 18 years and older and being a CHW (including doctors, assistant doctors, and nurses) who regularly provides health services to community residents. Supporting staff, including cleaners, accountants, and security personnel, will be excluded. There are usually 3 to 5 eligible CHWs in each CHC, and they will be invited to participate in the study. Written informed consent will be obtained.

Intervention Implementation

Based on our literature review and intervention research experience, we plan to implement an intervention that combines CHWs' in-person group training sessions, online support groups, CHW-delivered home visits, and mobile phone text messages for PWUD and their family members. The group training sessions will be conducted with participating CHWs in the intervention arm. We anticipate conducting 2 group sessions, each lasting approximately 90 minutes. The training topics will concentrate on community-based addiction service delivery. After the initial group training sessions, online support groups will be formed to facilitate continued skill building, information sharing, networking, and problem-solving. As part of the intervention requirement, trained CHWs will work as a team to deliver individualized addiction services to PWUD and family members in the community. For each participating PWUD and their family, the trained CHW team will conduct home visits to identify PWUD's specific needs and gaps, offer referrals, and provide social and mental health support. During the home visits, activities will be conducted with family members to release the caregiver burden, enhance family support, and address other barriers. As a supplement to the home visits, mobile phone text messages will be delivered periodically from trained CHWs to PWUD participants for health promotion and

XSL•FO
RenderX

service engagement. The text messages will be adaptive to individual needs and preferences.

We will collect process evaluation data to monitor and improve intervention implementation, that is, evaluator observation, intervention activity tracking, and participant self-evaluation. For the in-person group sessions, facilitators will keep records of participants' attendance and activities conducted in each session. The investigators and field directors will observe training sessions and use a predesigned checklist to rate the adherence to session contents, time allocation, core elements, techniques, clarity, and responsiveness. For the online group discussion, the frequency and format will be tracked. Each group member's activity, including the initiation of threads, comments, and reactions, will be captured to determine the level of engagement. In addition, all CHWs in the intervention will be given a user-friendly service log to document their experiences and feedback on the program.

Data Collection

The intervention assessments will consist of self-report questionnaires and medical or service records. We will collect the information at baseline and at 3-, 6-, 9-, and 12-month follow-ups. CHWs will be surveyed using the Computer-Assisted Self-Interview method, as PWUD and family members will be assessed using the Computer-Assisted Personal Interview method. We will ask PWUD participants at each assessment to donate a urine sample to test. PWUD's service records will be chart reviewed, and their service encounters with providers, laboratory testing dates and results, and treatment status will be collected.

Outcome Measures

The primary outcome measure is the PWUD's STTR fulfillment score, which is a comprehensive score that integrates medical, behavioral, and psychosocial indicators to evaluate PWUD's health and service engagement profile. The score consists of multiple fulfillment indicators across 5 domains: Seek, Test, Treat, Retain, and Health. Most of the indicators were suggested by the STTR Data Collection and Harmonization Initiative [14,32] and adapted to the context of Vietnam. The secondary measures of interest include CHWs' service provision, support to PWUD and their family members, and family members' support of PWUD's service engagement. Other relevant indicators are listed in Figure 1. All the measures will be piloted before the trial.

Sample Size

The study will randomize 60 CHCs (clusters) to intervention and control conditions with a 1:1 ratio. The sample size calculation was based on the primary outcome measure. We propose enrolling 720 PWUD (360 per condition) to ensure we have 80% power at 5% significance level to detect a standardized effect size of 0.41 when comparing the mean change scores of the primary outcome between intervention and control conditions. The proposed sample size accounts for the commune-level clustering, repeated observations within PWUD, and an attrition rate up to 8% for PWUD.

Data Analysis

All participants will be analyzed on an intent-to-treat basis. Descriptive statistics, frequencies for demographic and baseline characteristics, and all the outcome measures will be summarized at baseline by intervention condition. For each study population, generalized linear mixed-effects regression models with appropriate link functions will be used to compare the changes in the primary outcome from baseline between intervention and control groups. Each regression model will include commune- and participant-level random effects to account for dependence within communes and repeated observations within participants. The main effects included in each model are intervention condition, visit, and a condition-by-visit interaction term. Intervention effects on the primary outcomes will be estimated using model contrasts. The preselected demographic and background characteristics (covariates) will be added to evaluate whether the intervention effects on primary outcomes remain significant. The same analytical approach will be applied to each STTR domain score and the secondary outcomes of interest. We also plan to conduct several exploratory data analyses to (1) examine the intervention effect on each STTR fulfillment indicator by subgroup, (2) explore the interrelationship among PWUD's STTR domains or indicators to identify service gap, and (3) explore the interconnectedness of intervention effects on CHW, PWUD, and family members.

Ethics Approval

The study protocol was reviewed and approved by the Institutional Review Board of the University of California, Los Angeles (UCLA IRB#20-001594-AM-0001) and the Institutional Review Board in Bio-Medical Research, National Institute of Hygiene & Epidemiology in Vietnam (NIHE IRB VN01057/IORG 0008555; No: NIHE IRB - 28/2022).

Results

The intervention and assessment instruments have been developed based on the findings from formative studies (in-depth interviews and focus groups). The pilot activities are scheduled for 2023 and followed by the main trial. For the assessment of trial outcomes, we are scheduled to collect data at baseline and at 3-, 6-, 9- and 12-month follow-ups. We will distribute reports based on the baseline data in early 2024. The intervention outcome results will be available within 6 months of the final data collection date, that is, the main study findings are expected to be available by early 2025.

Discussion

Expected Outcomes

We anticipate the intervention to be feasible and provide community stakeholders, health professionals, and policy makers with insights for the future establishment and implementation of a community-based addiction service continuum. Community-based service delivery model has been considered a desirable strategy, and the scale-up of accessible and community-led harm reduction services is a global priority [34]. The existing primary health care system in Vietnam provided

XSL•FO
RenderX

an opportunity and platform to test an intervention that features the alliance of CHWs and family members to provide a continuum of addiction services for PWUD. If tested effective, the delivery strategies in this study can potentially serve as an example to provide community-based addiction services in other countries. For example, the CHW training package can offer a transferable tool for training primary care providers in addiction disorders in a global context.

Compared to prior work on community-based service delivery models, this study focuses on community partnership rather than each target population, such as PWUD, family members, or CHWs, respectively. We anticipated that improving CHWs' capacity through intervention training will strengthen their support for PWUD and family members, which will in turn improve addiction service engagement and retention. With the capacity building in the community, we anticipate that the trained CHWs will focus on adapting services across the care continuum to reflect different conditions of individuals and families, potentially enhancing community service delivery with sustainable outcomes.

Another strength of this study is to pay special attention to the vulnerability of family members and the role of family support. We have learned from the existing literature and previous studies that family can be mobilized to become a locally available, trustful, and sustainable support system. We anticipate that our intervention effort will form a partnership between CHWs and family members. Our intervention aims to address the impact of addiction and stigma on families and the burden and challenges faced by family members. The study findings would contribute to the growing body of literature on the role of family support in community-based addiction services and care.

This study has some limitations. First, considering that we integrate various components (eg, in-person sessions, online groups, home visits, and text messages) in the intervention, we will not have the opportunity to assess the effect of each strategy. Second, the intervention program in this study is designed to use the capacity-building approach to train CHWs. The process of training health workers to improve their knowledge and skills to enhance care and services could be too complex to be identified. Third, although the intervention aims to mobilize community health workers and PWUD's family members to strengthen community partnerships to support addiction services, the study's outcome assessments and measures are mainly at the individual level.

Dissemination Plan

The dissemination of study findings will include articles in both Vietnamese and English journals, international conference presentations, and other scholarly channels. Also, we will disseminate study findings to stakeholders to support the development and implementation of health care policies in Vietnam. We will make the intervention training guides, tools, manuals, and materials available to other interested organizations and agencies.

Acknowledgments

This work was supported by the National Institute on Drug Abuse of the National Institutes of Health (NIH) under the award number R01DA050678 and the National Institute of Mental Health of NIH (award number P30MH058107). The content is solely the responsibility of the authors and does not necessarily represent the views of the NIH.

Data Availability

All data collected will be accessible by the study investigators, who have the right to analyze and publish data. After the publication of the primary findings, deidentified and individual-level data can be available upon reasonable requests by graduate students and research scholars. Data requests can be submitted to the investigators at both participating agencies in Vietnam and the United States.

Abstract

Background: Anxiety and depression are common in the perinatal period and negatively affect the health of the mother and baby. Our group has developed "Happy Mother-Healthy Baby" (HMHB), a cognitive behavioral therapy–based psychosocial intervention to address risk factors specific to anxiety during pregnancy in low- and middle-income countries (LMICs).

Objective: The purpose of this study is to examine biological mechanisms that may be linked to perinatal anxiety in conjunction with a randomized controlled trial of HMHB in Pakistan.

Methods: We are recruiting 120 pregnant women from the Holy Family Hospital, a public facility in Rawalpindi, Pakistan. Participants are assessed for at least mild anxiety symptoms using the Hospital Anxiety and Depression Scale (ie, a score ≥8 on the anxiety scale is necessary for inclusion in the anxiety groups and <8 for inclusion in the healthy control group). Women who meet the criteria for an anxiety group are randomized into either the HMHB intervention group or an enhanced usual care (EUC) control group. Participants receive HMHB or EUC throughout pregnancy and undergo blood draws at 4 time points (baseline, second trimester, third trimester, and 6 weeks post partum). We will assess peripheral cytokine concentrations using a multiplex assay and hormone concentrations using gas chromatography and mass spectrometry. The statistical analysis will use generalized linear models and mixed effects models to assess the relationships across time among anxiety, immune dysregulation, and hormone levels, and to assess whether these biological factors mediate the relationship between anxiety and birth and child development outcomes.

Results: Recruitment started on October 20, 2020, and data collection was completed on August 31, 2022. The start date for recruitment for this biological supplement study was delayed by approximately half a year due to the COVID-19 pandemic. The trial was registered at ClinicalTrials.gov (NCT03880032) on September 22, 2020. The last blood samples were shipped to the United States on September 24, 2022, where they will be processed for analysis.

Conclusions: This study is an important addition to the HMHB randomized controlled trial of an intervention for antenatal anxiety. The intervention itself makes use of nonspecialist providers and, if effective, will represent an important new tool for the treatment of antenatal anxiety in LMICs. Our biological substudy is one of the first attempts to link biological mechanisms

XSL•FO
RenderX

to antenatal anxiety in an LMIC in the context of a psychosocial intervention, and our findings have the potential to significantly advance our knowledge of the biological pathways of perinatal mental illness and treatment efficacy.

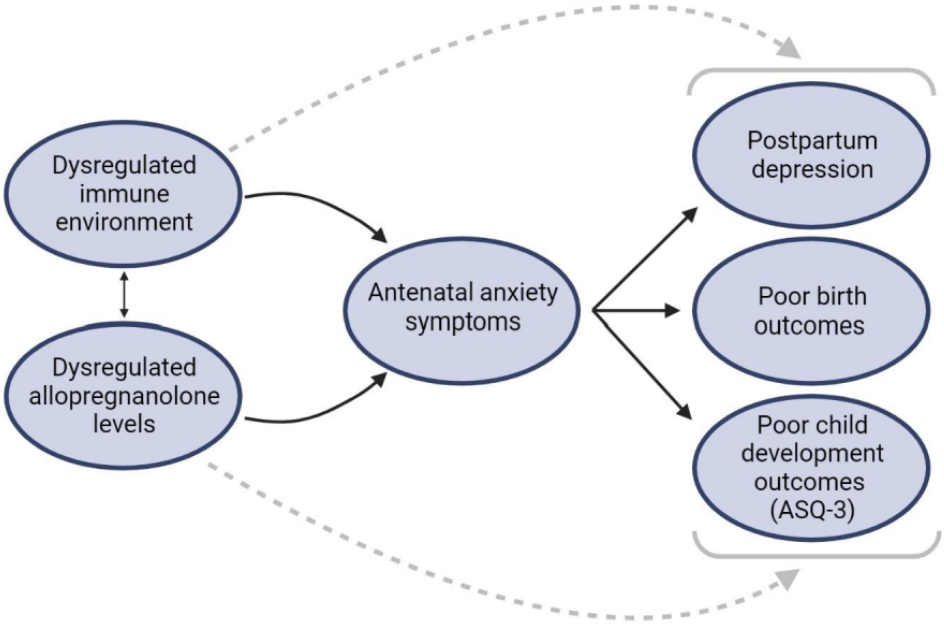
antenatal anxiety; perinatal anxiety; pregnancy; cognitive behavioral therapy; inflammation; allopregnanolone; Pakistan; randomized controlled trial

Introduction



Common perinatal mental disorders such as depression and anxiety occur frequently, are underdiagnosed, and negatively affect the health of both the mother and baby [1]. While the majority of epidemiological data is focused on perinatal depression, peripartum anxiety is equally prevalent, if not more so, yet remains largely understudied [2]. In Pakistan, for example, between one-third and one-half of pregnant women experience anxiety during pregnancy [3,4]. Despite the known morbidity associated with antenatal anxiety (ie, high risk of later anxiety or depression, risk of suicide [5-8], a range of poor birth outcomes [9-11], ill child health [12], and host of child development problems [13-17]), the biological underpinnings of antenatal anxiety remain unknown. In low- and middle-income countries (LMICs), the treatment gap for anxiety disorders exceeds 75%, largely due to the absence of specialists to provide evidence-based psychological interventions [18]. To address this gap, our group developed a cognitive behavioral therapy–based psychosocial intervention called "Happy Mother-Healthy Baby" (HMHB), delivered by nonspecialists and tailored to address risk factors specific to anxiety during pregnancy. HMHB is the subject of an ongoing randomized controlled trial in Rawalpindi District, Pakistan [19,20]. In conjunction with this larger study, our group has designed an observational study to examine biological factors that may be linked to perinatal anxiety, with a particular focus on immune dysregulation and sex hormones. Any such alterations can inform plausible mechanisms that can then be used in the development of other interventions, either psychosocial or biological (for example, anti-inflammatory nutritional approaches or exercise interventions).

The connection between anxiety and immune dysregulation outside of pregnancy is well-established [21,22], including studies showing heightened anxiety symptoms in women with inflammatory diseases such as colorectal cancer and irritable bowel syndrome [23-25]. There are several mechanisms by which increased inflammation could be related to fear and anxiety. For example, exposure to stressful stimuli has been shown to activate immune cells to release cytokines and other peripheral inflammatory markers [26-29]. This increased inflammation can be related to hypothalamic-pituitary-adrenal axis dysregulation and, in turn, to behavioral manifestations and clinical symptoms of anxiety [26-32]. Such changes may be especially important in pregnancy, as maternal immune activation has been implicated as a risk factor for child developmental outcomes such as altered neurobehavioral functioning [33,34]. Even a healthy pregnancy is a time of immune dysregulation [35-37]. Prior research has identified a distinct "cytokine fingerprint" in normal pregnancy—a pattern of relative changes in cytokine levels across time, despite individual differences in absolute levels—due in large part to hormonally driven decreases in both innate and adaptive immunity [37-40].

The neuroendocrine system is centrally related to the immune response in pregnancy. Progesterone (P4) and its metabolites, including allopregnanolone (ALLO), rise dramatically in healthy pregnancy [41], and there is bidirectional feedback between P4 metabolites and the immune system [42-46]. Higher levels of ALLO have been linked to decreased production of inflammatory mediators by microglia, reduced cytokine production by macrophages, and diminished lymphocyte proliferation [47]. Low levels of ALLO have also been linked to anxiety outside of pregnancy [48]. There is some evidence of a relationship between ALLO and psychiatric symptoms in the perinatal period as well [2,49-51]. A theoretical model outlining these possible connections is given in Figure 1.

XSL•FO
RenderX

Figure 1. Proposed theoretical model. In our study, we will measure the relationship between the dysregulated immune and endocrine environment, their influence on antenatal anxiety symptoms, and the direct and indirect influence on associated outcomes (postpartum depression, poor birth outcomes, and poor child development outcomes). ASQ-3: Ages and Stages Questionnaire.

The proposed study aims to investigate the biological mechanisms that underlie antenatal anxiety in women enrolled in the HMHB psychological intervention in Pakistan. This study sets out to answer the following research questions: (1) whether there is a pattern of immune dysregulation common to women with antenatal anxiety, (2) whether there is a relationship between ALLO and concurrent anxiety symptoms or future symptoms of postpartum depression, (3) whether immune dysregulation is related to dysregulation of ALLO, (4) whether these biological mechanisms are mediators of the association between antenatal anxiety and poor birth outcomes, and (5) if biological markers of anxiety are associated with infant neurodevelopment at 6 weeks of age as measured by the Ages and Stages Questionnaire (ASQ-3).

While the evidence concerning the role of such biological factors is increasing, no study has yet examined them in the context of a psychological intervention in pregnancy in an LMIC, where anxiety and depression rates are high and psychosocial intervention can make a meaningful difference [52]. This manuscript describes the design and implementation of one such study.

Methods

Study Design and Setting

Pregnant women are recruited from the Holy Family Hospital (HFH), a public facility in Rawalpindi, Pakistan.

Recruitment

The study is embedded in the main trial of the HMHB intervention, for which the recruitment of 1200 women started in April 2019 [20]. Recruitment for this supplemental biological study began in October 2020. Recruitment is carried out by a female assessment team based in the outpatient Gynecology and Obstetrics Department. The team describes the HMHB study to all pregnant women who fulfill the initial screening criteria (see next paragraph for details on level 1 screening) and their families visiting the department for their initial prenatal visit at or before 22 weeks' gestation (approximately 600 women monthly). For this biological supplement study, women are included if they are ≤12 weeks of gestation. All women eligible for the main study are offered the opportunity to participate in the supplemental study, and we anticipate enrollment of 120 participants over 18 months (30 from each arm of the main study and another 60 pregnant controls who are neither depressed nor anxious as assessed by the Hospital Anxiety and Depression Scale [HADS]); this rate of recruitment is slower than for the main study, due to the reluctance of many women to undergo blood draws, as well as stricter inclusion criteria related to gestational age and absence of anemia.

Screening Procedure and Eligibility Criteria

We use 3 levels of inclusion and exclusion screening criteria that occur at the same time at enrollment. For level 1 screening, we determine if the woman is at ≤12 weeks' gestation, ≥18 years old, resides ≤20 km from HFH, and understands Urdu. If they fulfill these criteria, women expressing initial interest are asked to provide informed consent for completing the next stage of screening. At level 2 screening, we determine from self-reports if women have (1) life-threatening health conditions, including suicidal ideation, (2) past or current serious learning disability, (3) past or current psychiatric disorder other than anxiety (eg, bipolar disorder or schizophrenia) or psychiatric treatment (eg, current use of anxiolytic drugs or other psychotropic drugs), (4) medical disorders or severe maternal morbidity that require current inpatient management, or (5) intensive care unit admission (for treatment, not solely for assessment). If not excluded on this basis, potential participants undergo level 3 screening, which includes assessment for the presence or absence of at least mild anxiety on the anxiety subscale of the HADS (ie, a score ≥8 is necessary for inclusion

XSL•FO
RenderX

in the anxiety groups and <8 on both the anxiety and depression subscales for the healthy controls). The HADS is a validated screening tool for depression and anxiety and has been used in research settings [53]. Women who score ≥8 on the HADS anxiety subscale move onto level 4 screening, which includes an interview with a qualified psychiatrist who conducts a Structured Clinical Interview for DSM V Diagnoses; women meeting criteria for a major depressive episode are excluded.

Randomization

Participants with anxiety are randomly assigned to a group using a pseudo-random number generator, which assigns a random sequence via permuted blocks of sizes 4, 8, 12, and 16. The list of assignments is printed out, and each step in the sequence is stored apart from the others in an opaque envelope; the envelopes are numbered sequentially with a 7-digit code. Participants are assigned to control or intervention according to the next available envelope after consent. All members of the on-site trial team, as well as the trial statistician, principal investigator, and coinvestigator leading the biological study, are blinded to the allocation.

Participant Groups

To enhance participation in the study and adherence to study protocols, all participants are reimbursed for transportation and for as many ultrasounds as are medically indicated at HFH during pregnancy.

Intervention Group

Women allocated to this group receive the HMHB intervention, a cognitive behavioral therapy–based treatment focused on anxiety and culturally adapted and tailored to a low-literacy population during the initial research phase [19,54]. Core principles include the mother's psychosocial well-being, preparation for birth, relationship skills, and psychosocial support [19]. HMHB includes 6 core weekly sessions and anywhere from 2 to 6 booster sessions, depending on the timing of enrollment and individual needs. The final core session is in the third trimester of pregnancy. HMHB is presented as a "mother-to-be" program (to combat the stigma associated with mental health issues), and family members are encouraged to participate in 3 sessions. The intervention is delivered by nonspecialist research therapists, who are university graduates with a master's degree in psychology but no experience delivering mental health care [55]. Prior to the start of the study, research therapists receive a 6-day classroom training, followed by field training and weekly group supervision. Competency is assessed by role plays during training and by direct observation of 15% of their sessions by independent assessors using the ENACT (Enhancing Assessment of Common Therapeutic Factors) rating scale for global training and supervision in mental health [56].

Enhanced Usual Care (EUC) Control Group

Women with anxiety allocated to the control condition are receiving EUC in the Obstetrics Department. The target number of visits is 8, as recommended by the World Health Organization (WHO) for a positive pregnancy experience [57]. Visits involve evaluating health status, discussing any concerns, and performing routine exams consistent with the stage of pregnancy.

Healthy Controls

The healthy control group consists of 60 women who have low or no anxiety or depressive symptoms (<8 on both the anxiety and depression subsections of the HADS). This will allow us to compare biological processes between women with anxiety (both those receiving the intervention and those in the EUC) and healthy controls.

Timing of and Measures for Data Collection

All participants in the main study with anxiety (either in the intervention group or receiving EUC) will undergo the same visits and psychological measures. The measures received by the healthy controls are indicated in the final column of Table 1. The timelines of visits and measures used are outlined in Table 1 and Figure 2, and details of these measures are described in the trial protocol paper for the main study [20].

Biological Sample Collection

Participants have their blood drawn (up to 20 ml) at 4 visits by a phlebotomist who was trained on the study protocol. Target times for sampling blood are at baseline (between 10 and 22 weeks' gestation), during the second trimester (between 22 and 26 weeks' gestation), during the third trimester (between 34 and 38 weeks' gestation), and between 4 and 8 weeks post partum. Each participant is scheduled as close as possible to the same time and during morning hours for all 4 blood draws (as blood is drawn in HFH between 8 AM and 1 PM), allowing us to account for diurnal variation in cytokine levels. Blood is centrifuged within 8 hours of collection using low-density gradient centrifugation via a Z326 High Performance Centrifuge. Plasma is immediately frozen in cryovials in a ThermoScientific Revco RLE Ultra-Low Lab Freezer at –80 °C and stored at the National Institute of Health Laboratory in Pakistan until it is shipped to Baltimore.

Shipping of Samples

Plasma samples (approximately 1280 cryovials) are being shipped from Pakistan to Baltimore, United States, in multiple shipments throughout the trial using courier services. Blood is kept frozen at a maximum temperature of –20 °C throughout shipment using standard cold packs, dry ice, or liquid nitrogen as required by local regulations and the standards of the courier services. All plasma samples are then stored at –80 °C in a ThermoScientific Revco RLE Ultra-Low Lab Freezer at Johns Hopkins to await analysis together at the end of the study to avoid batch effects.

Analysis of Biological Samples

Cytokine Analysis

Plasma cytokines will be measured using the Meso Scale Discovery (Gaithersburg, MD) Ultrasensitive Pro-inflammatory multiplex kit. The Meso Scale Discovery multispot array will be run according to the manufacturer's protocol. Calibration curves will be prepared. Plates will be read using the MS2400 imager. Samples for cases and controls will be assayed adjacently but in random order and replicated; the technician performing analyses will be unaware of the case status. To determine assay reliability, we will calculate the coefficient of variation for each woman's replicates when both have concentrations above the limit of detection [58].

Hormone Analysis

All hormone analyses will take place at the same time at the end of the study. Samples will be stored at –80 °C and run in 1 batch. Extraction, derivatization, and gas chromatography and mass spectrometry analyses of ALLO will be performed as previously described [59,60]. After the samples are extracted with ethyl acetate and lyophilized, the steroids of interest will be purified and separated by high-performance liquid chromatography. Tritiated neuroactive steroids will be added to monitor the high-performance liquid chromatography retention profile, while deuterated internal standards consisting of 2 pmol of deuterium-labeled neuroactive steroids will be

XSL•FO
RenderX

used to allow quantitation of the compound of interest and correct for procedural losses. Each steroid of interest will then be derivatized for gas chromatography and mass spectrometry [59,60]; mass spectrometry analysis will be performed in the standard electron impact mode for both ALLO and its isomers and P4 measurements. The quantity of each neuroactive steroid of interest will be calculated by dividing the area under the peak of the neuroactive steroid in the sample by the area under the peak of the deuterated internal standard.

Statistical Analysis

Aim 1: Immune Dysregulation and Anxiety

Models for Immune Marker Patterns

Initially, we will perform exploratory cross-sectional analyses at each time point, both for quality assurance and to attain a better understanding of the distributions of the outcome variables for use in subsequent analyses (eg, the need for any transformations), followed by the longitudinal analyses. Specifically, the distribution of cytokine values will be explored at each time point to assess the frequency of missingness (including the number of observations below the limit of detection) and summarized using descriptive statistics. Longitudinal models will be fit to the cytokine data to describe the average trajectory over the course of pregnancy. Generalized linear mixed-effects models (GLMMs) will be fit with random intercepts for women to account for within-woman correlation of the measurements over time. The basic model will include time, group (intervention, EUC, and healthy control), and their interaction, and will address whether cytokine trajectories differ between groups. This basic model will be extended to include a random slope for time if the exploratory analysis shows large variability in individual woman-specific cytokine trajectories over time. Additionally, nonindependent residual correlation structures will be explored to assess any leftover correlation after accounting for the random-effect structure. The main model will include log-transformed cytokine values; however, other distributions for the dependent variable will be used, such as multilevel Tobit models that account for the lower limit of detection for these measurements. GLMMs account for "missing at random" missingness, that is, women with missing data at some time points are not excluded, and missing cytokine values are assumed to depend on observed data: prior values and covariates in the model [61]. These models allow us to estimate each woman's trajectory as a deviation from the average trend using all their available data by borrowing information within and between women. However, in the case of substantial dropout, we will explore pattern mixture models where the "missing at random" assumption might not be adequate. These models allow us to estimate model coefficients for each pattern of drop-out or missing data and obtain overall estimates by averaging over the patterns [62]. Standard model checking will be performed, and the most parsimonious model will be selected based on the Bayesian information criterion.

Immune Dysregulation and Anxiety

To characterize the relationship between anxiety symptoms and peripheral markers of inflammation, we will assess the associations between cytokine levels as independent variables and the level of anxiety (as measured by the HADS-anxiety) as the dependent variable. The level of anxiety will be considered from the following perspectives: (1) dichotomous (HADS-anxiety score ≥8 or <8) and (2) continuous. In both analyses, we will compare women with anxiety against healthy controls to evaluate whether there is a positive association between cytokines and anxiety at different time points during pregnancy. In the exploratory analyses, we will also compare the distribution of demographic, medical, and pregnancy history characteristics across the 3 study groups to assess for potential confounding.

We will add anxiety measured as an independent variable to the model identified in the first set of analyses for cytokines as a dependent variable. The models will adjust for baseline symptom severity and other patient characteristics that are differentially distributed across the 3 study arms.

Aim 2: ALLO and Anxiety

To determine the relationship between levels of ALLO in pregnancy and anxiety symptoms, we will follow the same approach as for longitudinal modeling immune dysregulation, with ALLO levels as the independent variable and anxiety as the dependent variable. The model will include group and time as well as interactions of ALLO with group (to test whether the relationship between ALLO and anxiety differs by group) and ALLO with time (to test whether the relationship between ALLO and anxiety differs by time). The model will use concurrent values and lagged values for ALLO and anxiety to test whether the ALLO levels at prior time points are associated with the current value of anxiety scores.

Finally, because anxiety in pregnancy is a major risk factor for postpartum depression and our previous work has shown a relationship between ALLO in pregnancy and future postpartum depression [2,51], we will repeat all analyses using the development of postpartum depression as the dependent variable.

Aim 3: Immune Dysregulation and ALLO

We will evaluate the associations between ALLO levels and immune markers across time during pregnancy by disease group using exploratory analytic techniques, including visual displays to inform modeling. Using a similar GLMM framework, we will fit a separate model for each immune marker with ALLO levels as the independent variable, in addition to group, time, and other characteristics identified as potential confounders. Cytokine-specific models can be combined in 2 ways: (1) by creating a composite cytokine score for each woman, and (2) by fitting a multilevel model with crossed random effects that include random intercepts for women and immune markers to "borrow information" across multiple immune markers within the woman.

Aim 4: Mediation Analysis by Biological Measures

Estimated anxiety trajectories and ALLO levels (ie, random slope estimates from the GLMMs) will be used as candidate independent variables in generalized linear models (GLMs) for risk of pregnancy and birth outcomes: pre-eclampsia, gestational diabetes, preterm birth (PTB), small for gestational age (SGA),

XSL•FO
RenderX

and low birth weight (LBW). GLM with a Poisson distribution will be used to model risk for rare outcomes. The cross-validated area under the curve will be used to assess model discrimination and determine which model is the best fit for our data.

The next analysis will focus on the association of antenatal anxiety and birth outcomes, comparing anxious to nonanxious women. We will specifically assess mediation by biological factors in both cross-sectional and longitudinal analyses, partitioning the total effect of anxiety on birth outcomes as direct and indirect, through a change in cytokine and hormone levels.

Aim 5: Infant Neurodevelopment

The final analysis will examine the association between biological indicators of anxiety and infant neurodevelopment at 6 weeks post partum using the ASQ-3, comparing both groups of women with symptoms of anxiety (those who received the intervention and those who did not) to the healthy controls and controlling for ALLO and immune dysregulation. The same type of GLM described in the previous section will be used with appropriate distributions, such as Gaussian for continuous or normally distributed outcomes or Poisson for binary outcomes. We will also examine whether the severity of anxiety symptoms modifies the effect. Because the ASQ-3 can be used as both a dichotomous and continuous scale, we will examine it using both binary and continuous techniques.

Sample Size and Power

A sample size of 60 participants in each group, women with anxiety and healthy controls, will give us at least 80% power to detect a difference in the means of log-transformed cytokines across groups with an effect size of 0.3 to 0.5. This calculation assumes 4 repeated measurements with an exchangeable covariance structure, a correlation of 0.6, and an =.05. Sample size calculations were performed using the PASS Sample Size Software program (NCSS Statistical Software) [63]. Prior studies in our clinic in Baltimore have an attrition rate of up to 20%, but the attrition rate for this type of study in Pakistan is unknown.
